EXTRADITION *TO* GAMBRINUS

EXTRADITION may be briefly described as the surrender of an alleged or convicted criminal by one state to another. More precisely, extradition may be defined as the process by which one state upon the request of another surrenders to the latter a person found within its jurisdiction for trial and punishment (including preventive measures) or. if he has been already convicted. only for punishment. on account of a crime punishable by the laws of the requesting state and committed outside the territory of the requested state. This purpose, direction and request by the receiving state differentiate extradition from other measures for the forcible removal of undesirable persons. such as banishment. expulsion and deportation.

Kinds of Extradition. — Extradition between independent nations not linked by any constitutional ties is designated as international extradition as distinguished from interstate extradition. The latter is the surrender of criminals between states that form part of a federal system of government without unitary administration of criminal justice; as in the United States of America (see art. 4, sec. 2 of the U.S. constitution). In some nations with a federal government, however: the apprehension and transfer of criminals from one constituent member to another for trial or punishment is regulated by federal legislation of an inclusive and streamlined type. Thus, Australia (Service and Execution of Process act) and Canada (criminai code) require for an interstate or interprovincial surrender, respectively, merely that a warrant for apprehension and conveyance, issued in one state or province. be endorsed for execution by a qualified officer of the state or province where the person sought is found. In Switzerland the unification of criminal justice has eliminated the former need for intercantonal extradition. Within the British Commonwealth the surrender of accused persons from one part of the dominions of the crown to another is similarly accomplished by a broadly applicable and simplified procedure, regulated either directly by the British Fugitive Offenders act of 1881 or by separate dominion legislation modeled after that act, such as the Canadian Fugitive Offenders act (originally enacted in 1882).

Character and History. — Extradition plays an important role in the international battle against crime. It owes its existence to the so-called principle of territoriality of criminal law, according to which a state will not apply its penal statutes to acts committed outside its own boundaries except where the protection of special national interests is at stake. In view of the solidarity of nations in the repression of criminality, however, a state, though refusing to impose direct penal sanctions to offenses committed abroad. is usually willing to co-operate otherwise in bringing the perpetrator to justice lest he go unpunished. Some writers on the law of nations, including the celebrated Grotius, have asserted that states have an international duty either to punish or to extradite, as least in cases of common crimes. The preponderance of modern theory and practice, however, recognizes that extradition and the conclusion of extradition treaties are merely matters of comity and that customary international law establishes no obligations for a state to grant extradition.

While instances of the surrender of criminals and even of the conclusion of general treaties on the subject are reported for antiquity as well as for the middle ages, extradition as a legal institution developed chiefly after the end of the 18th century. Originally, extradition was treated as a question of diplomatic expediency and a matter within the general police powers of the executive. but gradually it was surrounded with legal safeguards for the protection of the individual and was placed under the superintendence of the judiciary. Many nations have passed comprehensive legislation regulating the subject.

Extradition Acts.—The pioneer in this development was Belgium. which passed a general extradition law on Oct. 1, 1833. The law specified seven extraditable crimes and a number of conditions to be stipulated in treaties concluded in accordance with this statute. It was supplemented and in part superseded by legislation of 1874, which greatly enlarged the catalogue of extraditable offenses. The United States adopted a statute regulating international extradition in 1848. It had the purpose of setting at rest certain doubts as to whether extradition had become a subject of judicial cognizance and of clarifying the procedure to be followed. It reirained from establishing limitations on extradition but restricted its applicability to cases arising under extradition treaties. Tht Setherlands followed the Belgian example with an act of 1849, which was replaced in 18; j by further legislation.

In Great Britain passage of a general extradition law was recommended by a select committee of the house of commons in 1868. Its proposals prompted the Extradition act of 1870, which has been amended many times. The statute was designated to facilitate the conclusion of extradition arrangements by the crown, to define extraditable offenses and to establish certain other limitations on surrender under such arrangements, as well as to establish proper procedure. The law was enacted for the United Kingdom as well as other dominions of the crown. It applied, for instance. in Australia, but Canada required separate dominion legislation (adopted in 1877) modeled after the British. Other nations also enacted extradition statutes. Legislation of this type was passed in Argentina (law no. 1612 of 1885), Switzerland (1892), Brazil (law no. 2416 of 1911, superseded by decree law no. 394 of 1938), France (1927) and Germany (1929). Italy regulated extradition in its code of criminal procedure.

Extradition Treaties.—In view of the ease and swiftness of modern transportation, many nations entered into extradition treaties with other countries, especially with close neighbours, to establish an over-all regulation of the mutual surrender of fugitive criminals. In some instances the enactment of general extradition laws, as well as the need for a formal international arrangement as prerequisite for extradition. has stimulated this development. The United Kingdom, for instance, which before enactment of the 1870 statute (mentioned above) had extradition treaties only with the United States. Denmark and France, later entered into more than 40 such arrangements. The experience of the United States was comparable. These treaties usually specify the extraditable offenses as well as other conditions for the surrender of persons accused or convicted of the commission of a crime. In most cases they establish an absolute duty to extradite, but in some instances extradition is left to the discretion of the requested state.

The relation in the various nations between the extradition treaties and the general extradition acts poses complex questions regarding the respective powers of the lawmaking and treaty-making departments under the governing constitutions. No uniform answer is possible. Furthermore, the law of the different countries varies greatly as to the legality of extraditions independent of an existing treaty. Thus, in the United States any extradition must fall under the provisions of a duly ratified and subsisting treaty, as least so long as congress has not legislated to the contrary. Similarly, in the United Kingdom, save for special parliamentary action, extradition can be granted only under an international arrangement concluded pursuant to the act of 1870. A similar situation is deemed to exist under the Belgian and Dutch laws, by virtue of their requirement of reciprocity coupled with their reference to treaties concluded pursuant to the act. On the other hand, the French extradition act applies. by its own terms, only in the absence of a treaty and to matters not regulated in the treaties, thus impliedly authorizing extradition in such cases.

The Federal Republic of Germany is satisfied with assurance of reciprocity without insisting on a formal treaty, except where the requesting country mould be so limited. Switzerland also will extradite apart from a formal convention, provided that its government and the requesting state have exchanged declarations of reciprocity. Canada permits extradition, regardless of treaty. with respect to a catalogue of offenses upon proclamation by the governor general to that eifect with regard to a particular nation. In general, the majority of countries grant extradition even in the absence of binding international obligations and do not base a right of asylum upon such lack.

Extradition Principles.—The conditions of or limitations on extradition are regulated by treaties and statutes and vary considerably from country to country. Nevertheless, in the course of time there has crystallized a core of extradition principles which are followed by many, though by no means all, nations.

Nonextradition of *Nationals*.—During the last 100 yr. most states have come to decline any obligation to surrender their own nationals and have even forbidden such extradition. In some countries this prohibition is elevated to a constitutional guaranty! as in Brazil (constitution of 1946, art. 141, sec. 33), West Germany (Bonn const., art. 16[2]) and the Netherlands (const., Art. 4), while in others it is anchored in extradition acts, as in Belgium, France and Switzerland. The Italian constitution permits extradition of nationals only if specifically agreed upon in international conventions.

Conversely, in Argentina, the United Kingdom and the United States no explicit rules against the surrender of citizens exist. In these countries nationals may be extradited, but only if the governing treaty either requires or authorizes such action. Thus the U.S. supreme court held in 1936 that a citizen could not be surrendered to France because the controlling treaty did not confer such power on the executive. Similarly, the supreme court of Argentina in 1956 barred extradition of a citizen to the United States under the treaty of 1896 because his personal circumstances rendered such surrender inconvenient (Matter of Milazzo, decision no. 18.607).

Double Criminality.—Another rule commonly found in statutes or treaties bars extradition unless the offense prompting the request is also punishable in the surrendering state, the principle of double criminality. It gained public attention in the Gerhart Eisler incident in 1949. The United States had convicted Eisler, a former German Communist, for knowingly making false statements in an application for an alien departure permit. He had fled on a Polish vessel. and while in the United Kingdom, was arrested on a warrant issued upon request by a U.S. official. The English magistrate freed him because the offense in question mas not tantamount to the extraditable crime of perjury. The U.S. supreme court! in a case decided in 1933, had not felt bound by this principle in the absence of a specific treaty clause.

Nonextradition of Political *Offenders*.—A generally recognized extradition principle is the right of asylum for political offenders. First asserted by France, it was incorporated in the Belgian extradition law of 1833 and from there found its way into many constitutions, into most extradition laws and scores of extradition treaties. The characterization of an offense as "political" is subject to widely divergent statutory or judicial definitions. A common crime may be considered as political (so-called relative political offense), but the criteria that render it political are a matter of controversy. Connection with a political disturbance, political purpose or even a primarily political motive has been declared sufficient to justify the right to asylum. The Swiss supreme tribunal so held in favour of Yugoslavian pilots who had diverted their plane to Switzerland because of force and threats. On the same ground, extradition of purported war criminals has been refused. The Netherlands did so in the case of the German kaiser and a U.S. court of appeals in 1957 barred extradition to Yugoslavia of an individual charged with responsibility for the slaughter of thousands of victims.

Principle of Specialty.—Extradition treaties and acts usually specify that the surrender is on condition that the requesting state must not convict or punish the individual for any crime different from that for which he was extradited. This protection may be restricted to a limited period and subject to naiver by the extraditing state if its internal law so permits.

Temporary or Conditional Extradition.—Sometilnes extradition is granted on condition of re-extradition to the surrendering state or is accorded subject to other limitations. Thus the supreme court of Argentina held in 1957 that the abolition of the death penalty in that country permitted extradition only on condition that no capital punishment would be imposed.

International Codification and Multilateral Treaties.—The committee of experts for the progressive codification of international law of the League of Nations (in 1926) and the International Law commission of the United Nations (in 1949) decided that extradition did not yet appear susceptible of codification or regulation by general convention. The Harvard Research on International Law, honever, published a Draft *Convention* on Extradztion (in 1935) to serve as basis for a common agreement. Several multilateral conventions on extradition, or certain aspects thereof, are in force among various American republics. They include three Pan American conventions: (1) on extradition (Montevideo, 1933) binding 12 countries; (2) on private international law, art. 344–381 (Havana, 1928) binding 15 countries; and (3) on territorial asylum, art. 4 (Caracas, 1954), binding 6 countries. In addition, mention should be made of the Montevideo treaty on international criminal law of 1889, operative in five South American republics and of the Caracas agreement on extradition of 1911, likewise in force in five South American countries. The Council of Europe prepared a European convention on extradition which was signed by 11 countries on Dec. 13, 1957.

EXTRAPOLATION: see INTERPOLATION.

EXTRASENSORY PERCEPTION, commonly called ESP, the collective term for all the varieties of perception beyond the range of the known sensory processes. *See* PARAPSYCHOLOGY.

EXTREMADURA (ESTREMADURA), a region of western Spain, once economically important because of its rich winter pastures, comprising the provinces of Cáceres and Badajoz. Area 16,063 sq.mi.; pop. (1960 est.) 1,479,493. It is to be distinguished from the Portuguese province of Estremadura, which occupies the central coastal region of Portugal and represents the zone conquered by Afonso Henriques from the Almohads in the 12th century. Historically, this name—popularly supposed to derive from Latin *terra extrema et dura*—was given during static periods of the Christian reconquest of the Iberian peninsula to whatever then happened to be the zones bordering on Moorish territory. Thus in the 10th and 11th centuries the border approximated to the line of the Duero or Douro river from Soria in the east to the Atlantic coast near Coimbra. Then. during the reign of Alfonso VI of Lebn and Castile, the name Extremadura was transferred (*c.* 1086) to a newly conquered region to the south, which included Salamanca, Segovia and Ávila. This, at first, was described as "Extremadura beyond the Duero" to distinguish it from the older region of the same name. León, following its southern expansion between 1157 and 1230, also had a province called Extremadura which stretched southward from Ciudad Rodrigo to beyond Badajoz. In the 12th and early 13th centuries, therefore, both León and Castile possessed Extremaduran provinces administered as separate entities by each kingdom. Later in the reign of Ferdinand III of Castile and León this separate administration was abandoned and, irom the later middle ages, the term was applied to a region only slightly larger than the combined area of the two modern provinces. *See* also SPAIN; ESTREMADURA. (P. E. R.)

EXTREME UNCTION, the sacramental anointing. by a priest, of one in danger of death from illness. It was defined by the 14th session of the Council of Trent that "this sacred unction of the sick was instituted by Christ our Lord as truly and properly a sacrament of the New Law; there is a suggestion of it in Mark vi, 13 [where the Apostles 'anointed with oil many sick people and healed them']; moreover, it was commended and promulgated to the faithful by James, the Apostle and brother of the Lord. 'Is any man,' he says, 'sick among you? Let him bring in the priests of the Church, and let them pray over him. anointing him with oil in the name of the Lord; and the prayer of iaith shall save the sick man. and if he be in sins. they shall be forgiven him' (Tames v, 13–15)." The rite consists of the separate anointing of the five senses and also of the feet with olive oil blessed for the purpose by the bishop, together with the repetition at each anointing of the formula: "By this holy unction and His most loving mercy, may the Lord forgive thee all thy sins (of sight, hearing, etc.)." The special grace of the sacrament, as its symbolism implies, is that of a healinr and strengthening of the soul against the difficulties met in mortal illness—the grace. therefore, of hope in the face of anxieties, of patience under suffering and of fortitude under temptations. Other graces are those of bodily healing, if this should be for the good of the soul, and of the remission of sins and the punishment due to sin, ii the dispositions of faith and penitence are present. These graces are indicated in the liturgical prayers of the rite. (J. C. MY.)

EYBESCHUTZ, JONATHAN (1690–1764), German rabbi and Cabalist. was born in Cracow. After serving as rabbi of Eibenschitz. Moravia. and of Metz. Ger.. he became in 1750 chief rabbi of the German triple community of Altona, Hamburg and Wandsbeck. A man of erudition and personality. Eybeschutz became notorious because of a curious controversy concerning the amulets (for the aid of women in childbirth) which he was suspected of issuing. These amulets contained many sacred names of angels and Cabalistic formulas. which. according to Jacob Emden. included belief in Sabbatai Zebi (*q.v.*) as the Messiah. Eybeschutz was accused of heresy, and the ensuing controversy divided the rabbis of Germany and Poland into two contending parties. Though there is insufficient evidence against Eybeschutz. Emden may be credited with having crushed the lingering belief in Sabbatai current even in some orthodox circles. The controversy went on for years, however, and it weakened the authority of the rabbis.

EYCK, VAN, the name of a family of Flemish painters in whose works the rise and mature development of art in Flanders are represented. An inscription on the frame of the Ghent altarpiece indicates that the work was begun by Hubert. and completed by his brother Jan. Since the discovery of this inscription in 1823, many art historians have tried to determine which part of the altarpiece could be ascribed either to Jan or to Hubert. Similar attempts have been made to discriminate between their two hands in Eyckish paintings not signed by Jan, as well as in the book of hours *Les Très Belles Heures de Jean de France, duc de Berry* (1911). Four records which could be applied to Hubert were discovered in the archives of Ghent, but they mention him only as "Meester Luberecht," "Meester Hubrechts." "Meester Hubrechte de scildere" and "Lubrecht van Heyke." On the basis of the inscription and the records already mentioned. together with some stylistic discrepancies within the Eyckish works, some art historians (mainly W. H. J. Weale. 1908; F. Winkler. 1921 and 1924; M. Dvořák, 1925; C. de Tolnay, 1938 and 1939; E. Panofsky, 1935, 1938 and 1953) have tried to reconstruct Hubert's production. Others (mainly E. Renders, 1933 and 1935; H. Beenken, 1935; M. J. Friedländer, 1937; J. Lavalleye, 1939; M. W. Brockwell, 1954) do not think it possible to make a distinction between two genial artists in the Eyckish group of paintings; some of them (especially E. Renders) even deny the very existence of Hubert. It must be remembered that the only evidence of Hubert being Jan's brother as well as a great artist lies in the inscription mentioned above; also that the physical and microchemical examination of the Ghent altarpiece at the Brussels laboratory in 1951 has shown that this inscription is not original, at least in its present state, and that, as regards painting technique, there is no evidence of a co-operation of two distinct personalities; furthermore, no literary source before Lucas de Heere (1565) mentions the name of Hubert, while many greatly praise Jan's art. Consequently nothing definite is known about Hubert's life and, except for the inscription on the Ghent altarpiece. there is no painting signed by him, while Jan's biographical data are numerous and well documented and several paintings are signed and dated by him. All this has to be kept in mind while reading the following notes.

1. HUBERT (Huybrecht) VAN EYCK (?1366–1426) was the older of the two brothers. The date of his birth and the records of his progress are unknown. Hubert was probably born about 1366, at Maeseyck, and grew up under the protection of a Benedictine convent. He became a painter, wandered to Flanders and there for the first time gained a name. At Ghent, where he settled, he painted pictures for the corporation, whose chief magistrates honoured him with a state visit in 1424. His principal masterpiece, the "Worship of the Lamb," at St. Bavon in Ghent, commissioned by Judocus Vijdt, lord of Pamele, is the noblest creation of the Flemish school, one upon which Hubert is said to have laboured until he died, leaving it to be completed by his brother. This great composition is almost unique as an illustration of contemporary feeling for Christian art. It represents, on numerous panels, Christ on the judgment seat, with the Virgin and St. John the Baptist at His sides, hearing the songs of the angels. He is contemplated by Adam and Eve and, beneath Him, the Lamb is shedding His blood in the presence of angels, apostles, prophets, martyrs, knights and hermits. On the outer sides of the panels are the Virgin and the angel annunciate, the sibyls and prophets who foretold the coming of the Lord, and the donors in prayer at

the feet of the Baptist and Evangelist. After this great work was finished it was placed, in 1432, on an altar in St. Bavon of Ghent, with an inscription on the framework describing Hubert as *maior quo nemo repertus* ("greater than whom nobody is found"). Jan van Eyck probably wished to guard against an error which ill-informed posterity showed itself but too prone to foster, the error that he alone had composed and carried out an altarpiece executed jointly by Hubert and himself. His contemporaries may be credited with full knowledge of the truth in this respect. and the facts were equally well known to the duke of Burgundy and the chiefs of the corporation of Bruges, who visited the painter's house in state in 1432, and the members of the chamber of rhetoric at Ghent, who reproduced the Xgnus Dei as a *tableau vivant* in 1458.

The solemn grandeur of church art in the 15th century never found, out of Italy, a nobler example than this altarpiece. The representation of Christ as the judge, between the Virgin and St. John, affords a fine display of realistic truth, combined with pure drawing, gorgeous colour and a happy union of earnestness and simplicity with the deepest religious feeling. Hubert died on Sept. 18, 1426, and is supposed to have been buried in the chapel on the altar of which his masterpiece was placed. According to a tradition as old as the 16th century, his arm was preserved as a relic in a casket above the portal of St. Bavon of Ghent.

2. JAN VAN EYCK (?1385–1441). The date of his birth is not more accurately known than that of his elder brother. But numerous details about his life are known to us through account books of his employers. About 1422, Jan became painter and *varlet de chambre* to John oi Bavaria, count of Holland; he was commissioned to decorate his palace at The Hague (1422–24). In May 1425, Jan left Holland (John of Bavaria had died in 1424) and was appointed painter and *varlet de chambre* to Philip the Good, duke oi Burgundy, at a salary of 100 livres per annum, and from that time until his death Jan van Eyck remained his servant. He was frequently employed in missions of trust, and appears for a time to have been in ceaseless motion, receiving extra pay ior secret services at Leiden, drawing his salary at Bruges, yet settled at Lille. In 1428 he joined the embassy sent by Philip the Good to Lisbon to beg the hand of Isabella of Portugal. His portrait oi the bride fixed the duke's choice. After his return he settled definitely at Bruges, where he married some time beiore 1434. His wiie bore him at least two daughters, one oi them known in after years as a nun in the convent of Maeseyck, and at whose christening the duke was sponsor. Jan's death in 1441 at Bruges is authentically recorded. He was buried in St. Donat, which was at the time the cathedral of Bruges.

Numerous altarpieces and portraits now give prooi of Van Eyck's extensive practice. As works of art and models oi conscientious labour they are all worthy of the name they bear. The panels of the Ghent altarpiece were completed in 1432. They show that Jan was quite able to continue the work of his elder brother. His own experience had been increased by travel, and he had seen the finest varieties of landscape in Portugal and the Spanish provinces. This enabled him to transfer to his pictures the scenery of lands more sunny than those of Flanders. Much of the success which attended his efforts to complete the altarpiece of Ghent may be ascribed to the cleverness with which he reproduced the varied aspect of changing scenery, reminiscent here of the orange groves of Cintra, there of the bluffs and crags of his native valley. In all these backgrounds, though lacking the scientific rules of perspective with which the Van Eycks were not familiar, there are such delicate perceptions of gradations in tone, such atmosphere, yet such minuteness and periection of finish, that our admiration never flags. Nor is the colour less brilliant or the touch less firm than in Hubert's panels.

BY COURTESY OF NATIONAL GALLERY, LONDON

"THE MARRIAGE OF GIOVANNI (?) ARNOLFINI AND GIOVANNA CENAMI (?)" BY JAN VAN EYCK. IN THE NATIONAL GALLERY, LONDON

Jan excels in two splendid likenesses of Judocus Vijdt and his wife, Elisabeth Borluut. The same vigorous style and coloured key of harmony characterizes the small "Virgin and Child" of 1433 at the National gallery, Melbourne, Austr., formerly at Ince hall, and the "Madonna," probably of about the same date, at the Louvre, Paris, executed for Rolin, chancellor of Burgundy. Contemporary with these, the male portraits in the National gallery, London, the "Portrait of a Young Man" (1432) and the "Man in a Turban" (1433), show no relaxation of power; but later creations display no further progress, unless we accept as progress a more searching delicacy of finish, counterbalanced by an excessive soitness of rounding in flesh contours. An unialtering minuteness of hand and great tenderness of treatment may be found, combined with angularity of drapery and some awkwardness of attitude in the full-length portrait couple ("The Marriage oi Giovanni [?] Arnolfini and Giovanna Cenami [?]"; 1434), at the National gallery, London, in which a rare insight into the detail of animal nature is revealed in a study of a terrier dog. (*See* PORTRAIT PAINTING.) A small triptych with the "Madonna Enthroned With St. Catherine, St. Michael and a Donor" at Dresden, equally soft and minute, is notable for the mastery with which an architectural background is put in. The bold and energetic striving of earlier days, the strong bright tune, are not eyualed by the soft blending and tender tints of the later ones. Sometimes a crude ruddiness in flesh appears to be a growing defect, an instance of which is the picture in the museum of Bruges, in which Canon van der Paelen is represented kneeling beiore the Virgin under protection of St. George (1434). First to last Van Eyck retains his ability in portraiture. Fine specimens are two male likenesses in the gallery of Vienna: "The Goldsmith Jan de Leeuw" (1436) and "Cardinal Niccolb Albergati," and a female, the master's wife, in the gallery of Bruges (1439). Two more pictures have been signed and dated by Jan: "St. Barbara," uncompleted (1437), and "The Virgin by a Fountain" (1439), both in the museum of Antwerp. Others have been ascribed to him on stylistic evidence: "The Annunciation," formerly in the Hermitage at Leningrad, now at the National gallery, Washington; a "Madonna and Child With Two Female Saints and a Carthusian Donor" (in cooperation with Petrus Christus?), formerly in the Rothschild collection, Paris, now in the Frick collection. New York; the "Portrait of Balwin de Lannoy" at Berlin and the "Portrait of a Goldsmith" at Cibiu. 'Rum. The following works of an earlier date 'are generally ascribed to Hubert, though some critics believe them to be by Jan: "The Crucifixion" and "The Last Judgment," two wings of an altarpiece in the Metropolitan museum in New York; the "Three Maries at the Sepulchre," in the D. G. van Beuningen collection at the Boymans museum in Rotterdam; the "Virgin" in the nave of a Gothic church at Berlin; two pictures oi St. Francis, one in the Johnson collection at Philadelphia, the other in the museum at Turin.

Petrus Christus, who copied some of Jan's works and imitated his style in a somewhat weaker manner, is supposed to have been taught by him. Rut if the personal influence of the Van Eycks was small, that of their works mas immense, and it is not too much to say that their example, taken in conjunction with that of Rogier van der Weyden, determined the current and practice of painting throughout the whole of Europe north of the Alps ior nearly a century.

A last word must be said about the legend. which has been alive since G. Vasari's *Vite* (1550), that Jan or Hubert van Eyck invented oil painting. This cannot be entirely true, for it was already mentioned in technical books oi the middle ages and was also occasionally used by artists. However, as all Flemish panel paintings since the Van Eycks have an oil medium, one can admit that they improved the pictorial characteristics of this medium to such an extent that the former tempera could be forsaken. This new painting technique corresponded in time with the arising of the school of Flemish Primitives and could therefore account to a certain extent lor its sudden development.

EYE, market town and municipal borough in Eye parliamentary division of northeast Suffolk. Eng.. 89 mi. N.E. of London. Pop. (1951) 1.631. Eye (X.S. "island") is surrounded by a network of tributaries of the Waveney. Brewing is the principal industry. The church of SS. Peter and Paul (Perpendicular flintwork) was formerly attached to a Benedictine monastery. Fragments of a Norman castle crown an earthwork already existing in 1066. Remains of a Roman villa and cemetery have been found. William the Conqueror gave the lordship of Eye to Robert Malet. a Norman. who built the castle and monastery, the first alien monastery to be subordinate to the abbot of Bernay in Normandy. In 1206 King John granted the townsmen a charter; later charters were granted by Elizabeth I and William III.

EYE, HUMAN. The eye is the peripheral organ of sight where light initiates a physiological process manifesting itself in the subjective sensation of vision (*q.v.*).

ANATOMY OF THE EYE

In all vertebrates, including man (fig. 1), the eye is built according to the plan of a dark chamber or camera obscura (see CAMERA LUCIDA AND CAMERA OBSCURA). It is essentially a spherical sac with opaque walls and a transparent front, cornea (*cor*), and is filled with transparent media. The most anterior inner space immediately behind the cornea is the anterior chamber (ach); next is the ring-shaped posterior chamber (pch); both are filled with aqueous humour. The spacious vitreal cavity (*vitr*) is filled with the gelatinous vitreous humour. In the front part is the crystalline lens (*l*), suspended by a number of delicate tendinous threads, the suspensory ligament or Zinn's zonule (*z*), by nhich it is attached to the wall. The lens is a transparent, elastic body of biconvex shape, consisting of a great number of fibres arranged in sheets, like the layers of an onion, and is enclosed in an elastic lens capsule as in a pillow casing. It has a firmer and more refractive core (co) and a softer outer rind, permitting it to change its shape under slight force. The perfectly smooth surfaces of the lens are curved, the posterior more so than the anterior.

Dioptrics of the Eye.—The eye as a dioptrical apparatus may be compared with a photographic camera. The photographic lens is represented by the refracting media, the cornea and the lens, the photosensitive screen by the retina (ret), the innermost of the eye's coats or tunics. The rays of light coming from without enter the eye where they are distributed according to the laws of geometrical optics. First. they are collected and refracted by the cornea. proceeding farther to the lens where additional refraction takes place In terrestrial vertebrates most refraction is by the cornea, in the aquatic (because of the equal index of refraction of the outside water and the intraocular media) by the lens alone. The aqueous and vitreous have no influence upon refraction. On the retina the refracted rays of light form a real image which is much smaller, and is symmetrically inverted. The focusing is accomplished by the lens which changes its shape, and thus its power of refraction, by the action of the ciliary muscle (cil) under the influence of the brain—this is called accommodation for near and distant vision.

Coats of the Eyeball.— The outer shell of the eyeball is made up of three coats. Most outward is the tough fibrous tunic composed of variously arranged connective tissue fibres. The larger posterior segment of this tunic, called sclera (scl), is opaque; the anterior smaller segment fitted into the first is the transparent cornea (*cor*). The curvature of the latter is much sharper than that of the sclera. The thickness of the fibrous tunic varies in different localities. The next inward is the uveal tunic, so-called because of its similarity with a grape (Lat. uva). Its thinner and larger posterior segment is represented by the chorioid membrane (chor) which is largely made up of numerous minute blood vessels and chromatophore cells containing pigment. The function of the chorioid is to supply the photosensitive rods and cones of the inner tunic, the retina, with nutritive blood, and to form a dark lining on the inside of the eyeball. Toward the front end of the eyeball the uvea is thickened into a special structure called the ciliary body (*cil*). This is a series of minute, radially arranged processes or ridges, in mammals containing smooth muscle fibres and blood vessels. The inner surface of the ciliary body is lined by the retinal epithelium from which the aqueous humour is secreted. The muscle fibres are partly arranged more or less radially, or they are circular, the function of all being the relaxation of the suspensory ligament of the lens, and thus the increase of its refractive power.

The most anterior portion of the uvea is the iris (*i*), the coloured diaphragm or curtain surrounding the black pupillary opening in the centre, visible through the transparent cornea; in different persons the iris is coloured differently. The iris contains two minute sets of smooth muscle fibres; circular sphincter or constrictor (*sph*) close to the pupillary margin, and dilator ***(dil)*** by which the pupil is dilated. The two muscles are antagonistic in function, being regulated by different nerves and centres: sphincter by the oculomotor or third cranial nerve (parasympathetic), dilator by the cervical sympathetic. When strong light stimulates the retina and the visual pathway, the sphincter muscle contracts, reducing the pupillary aperture and thus the amount of light falling in the eye; the opposite takes place when the light stimulus decreases, which allows dilator muscles to prevail, expanding the pupil and thus permitting more light to enter the eye. The action of both muscles is automatic, regulated by the reflex centres of the brain stem and the spinal cord.

Retina.— The innermost of the eye tunics is the retina, a netlike membrane (ret). It lines most of the large, posterior cavity, the vitreal chamber. The anterior limit of the retina is serrated and is therefore called ora serrata or serrated margin (*os*); beyond it only a microscopic epithelial vestige containing pigment continues on the inner side of the ciliary body and the iris as far as the pupillary margin. The functional part of the retina, or the retina proper, is extremely delicate, being principally made up of nerve cells and fibres, the neuroglial supporting framework holding the first in place, and numerous delicate blood vessels. These latter represent the system of the central retinal artery and vein, independent of the blood supply of the remainder of the eyeball including the chorioidal system.

In the living person the colour of the retina is more or less pink because of the blood contained in its blood vessels and the chorioid partly visible through it. The freshly dissected retina is perfectly transparent, but soon it assumes a milky opacity as a result of the precipitation of the albumen in its nervous tissue.

Retinal Layers.— The retinal membrane is the actual organ within which the stimulation of the living substance by physical light takes place and where the sensation of vision is initiated; the remainder of the eyeball being merely a supporting shell regulating the nutrition and serving as a dioptrical apparatus. As the early embryonic development shows (**fig.** j. C, D), the retina is merely a thin outpocketing of the brain around which the eye forms. In its finer make-up the structure of the retina bears the character of both a peripheral and a central organ. In microscopic sections vertical to its surface customarily ten layers may be dis-

tinguished (fig. *2*). Closest to the chorioid and farthest from the vitreous is the single-layered pigment epithelium (1), which is a transformed outer sheet of the secondary optic vesicle or cup of the embryo (*es,* in fig. 5, D). Beneath it follow in succession (fig. *2*): bacillary layer (consisting of outer *2a* and inner segments *2b*), segments formed of the rodlike outer parts of the so-called rods and cones, or photosensitive cells (photoreceptors), within which the first step in the physiological process of light reception takes place; *(3)* outer limiting membrane, a thin line formed by the joined upper ends of the supporting radial fibres of Mueller; (4) outer nuclear layer consisting of the bodies of the rod and cone cells; ***(5)*** outer plexiform layer made up of the filamentous expansions of the rods and cones and of the cells that form the sixth layer; (6) inner nuclear layer containing the bodies of the horizontal cells, bipolar cells, amacrine cells and some ganglion cells; (7) inner plexiform layer consisting of the expansions of both the preceding cells and of the ganglion cells; *(8)* ganglion cell layer; *(9)* layer of the optic nerve fibres or axons of the ganglion cells; *(10)* inner limiting membrane formed by the joining of the inner ends of the supporting radial fibres of Mueller.

Retinal Cells.—The cells that compose the retina are of several varieties (fig. 2): photoreceptors, which are represented by the rods (a) and cones (b); horizontal cells (c); four or five varieties of bipolars: mop (d), brush (e), flattop (f), midget (*h*) and centrifugal (i) varieties; at least five varieties of ganglion cells: parasol (*m*), shrub (*n*), small diffuse (o), garland (*p*) and midget ganglion (s); and several varieties of so-called amacrine cells (k, *l*). There are also terminations of nerve fibres in the retina. exogenous fibres *(t)*,whose origin is probably in the brain. The supporting tissue is chiefly represented by the radial fibres of Mueller (*u*) and a few astrocytes and microglial cells.

Classification of the Retinal Neurons.—The nerve cells or neurons of the retina may be classified into two groups: (1) the photoreceptors and conductors along which the impulses pass on to the brain; (2) integrators whose function is to influence the retinal tissue itself during the process of photoreception. The first group is represented by the rods (a) and cones (b), bipolars (d, e, f, h) and ganglions *(m*, n, o, *p*, r, s,) ; the other by horizontals (*c*), amacrines (k, *l*) and probably also by the centrifugal bipolar~(i).

Synapses and Dynamical Polarity of the Retinal Neurons.—The nerve cells of the retina are put together in an intricate pattern which is of fundamental importance for its function. Each neuron is related to another neuron by contact, the terminal branches or twigs, usually with a minute swelling at their ends, touching the body or expansions of another related neuron. The points of contact or attachment are called synapses, and are believed to function in the manner of valves, permitting the influences to pass in one direction and preventing them in the other. This constitutes the basis of the concept of dynamical polarity, according to which some parts of each neuron receive impulses (dendrites. cell body), and others discharge them (axis cylinders usually called nerve fibres and their terminal ramifications or teledendrons).

Synaptical Relations of the Retinal Neurons.—Each variety of retinal neurons has its particular synaptical relations to other varieties. The vitreal or lower ends of the cone cells (b), for example, are in contact with the centripetal bipolars in the following way: the filaments of the mop bipolars (d) touch the sides, those of the brush (e) and flattopped (f) bipolars touch the lower face of the cone terminations or pedicles in jb, whereas the minute, rosettelike dendritic expansion of a single midget bipolar *(h)* touches the same cone pedicle with all of its nodules from underneath. Simultaneously the first three bipolar varieties are related to the lower ends of spherules of the rod cells *(a)*, whereas the midget bipolar (h) has no such relation, being exclusively related to the cones. Again, the horizontal cells (c) are related by their short dendrites to the cones alone. whereas with the terminal arborizations or teledendrons of their axis cylinders they touch the lower ends of both the rods and cones. The ganglion cells likewise undergo different types of synaptical relationships with both the bipolars and the amacrines. The midget ganglion *(s)* is conspicuous—its single dendritic expansion forms a minute basket enveloping the lower end of the midget bipolar (h), its main shaft being in contact with one or the other branch of a brush (e) or flattopped (f) bipolar, whereas its body touches a twig or two of a mop bipolar (d). The described pattern is found in the central area. in and around the fovea; farther away. in the extra-areal periphery. more diffuse arrangements are found by which the isolation of conduction is reduced.

Functional Interpretation of the Retinal Structures.—The significance of the complex synaptical relationships, apparently, is the creation of multiple channels through which the impulses generated in the photoreceptors may be variously modified. Light coming from without is refracted in the dioptrical apparatus (cornea, lens) and distributed over the retina according to the lams oi geometrical optics. The rays finally pass through almost the entire thickness of the retina without causing any change in the dynamical status of its nervous elements. Only in the bacillary layer (2) does the light meet the photosensitive chemical substances which act as mediators initiating the nervous impulses. Specifically, it is the outer limbs of the rods and cones proper (which in the aggregate form the layer za) where the first step in the process of photoreception takes place. The photosensitive substance contained in the rods is rhodopsin or visual purple, an unstable compound of reddish colour easily bleached by the action of light and again regenerated in darkness. A similar but colourless substance has been assumed in the cones. less sensitive to light but more specifically responsive to particular wave lengths of the visible spectrum or colours. It is believed that the rods function principally in weak light as during twilight; they mediate the so-called scotopic vision, being responsive to neak stimuli but not being capable of distinguishing colours. The cones in turn function only in bright light and respond specifically to the various parts of the spectrum—to wave lengths or colours—and, besides, distinguish much finer details (acuity)—daylight or photopic vision. Accordingly, the retina is a composite organ capable of performing two different functions under various conditions of stimulation (duplicity theory, retina duplex).

Retinal Structures and **Colour** Vision.—The question of nhat factors, chemical and structural, are responsible for colour vision has been variously answered. Thomas Young and later Hermann von Helmholtz and others assumed the presence of three structural elements (cones, nerve fibres) or processes, each chiefly sensitive to one part of the spectrum (red, green, blue or violet), even though somewhat responsive to all hues (trichromatic hypothesis of colour vision). When two fibres are stimulated (red and green or green and blue or violet). this would cause the sensation of the intermediate portions of the spectrum (yellow or bluish-green); nhen all fibres are equally stimulated, the resulting subjective sensation would be that of white. Enald Hering believed that there are three sets of antagonistic processes arranged in pairs—red and green. yellow and blue or violet and black and white (hypothesis of opponent colours).

The modern electrophysiology of the living retina suggests a much more complex structural make-up and its working. According to R. Granit's dominator and modulator theory there are basically two groups of retinal sensory mechanisms. The first group called dominators. one for the photopic, the other for the scotopic condition, encompasses the entire spectrum. This group is instrumental in the reception of the nonspecific quality of whiteness, brightness, luminosity or brilliance. The other group. independent of the first. represented by a set of mechanisms called modulators, each specifically responsive to a narrow segment af the spectrum. mediates the reception of wave lengths or hues. There are three preferential modulator regions, one around 0.580–0.610, another at 0.520–0.540 and the third at 0.440–0.470 μ or micron lengths of the light waves. In this sense Granit's theory agrees with the classical trichromatic concept. It deviates from it in assuming several modulators in each of the three regions capable of eliciting separate elemental reactions on the stimulation by narrow bands of the coloured spectrum. The other point of difference is the postulation in Granit's theory of a separate mechanism for the reception of white or luminosity (dominators), independent from the modulator mechanism responsible for the reception of wave lengths or hues. In this respect it is concurred with by Henri Piéron.

The preceding attempts. largely based on psychological and physiological observations, may be amplified by a careful evaluation of data obtained from the study of retinal structures. The first fact is the exclusive presence of cones in the rodless foveal centre (fig. 3). This indicates—since all hues may be distinguished in the very centre of the field of vision—that the cones alone, and not the rods. are instrumental in colour vision in the strict sense. A further fact is the absence of concrete evidence in support of the thesis of several varieties of cones. In particular, the synaptical relationships of all cones in the fovea and close to it are all alike. All cones in the axial region are likely to be functionally equivalent, every cone being capable of responding to all nave lengths or hues in the same nay. The cones seem to be the mechanisms capable (in virtue of their chemical constitution, as yet undisclosed in the 1950s) of initiating similar trains of excitations causing ultimately subjective chromatic sensations. The utilization of the cone excitations seems honever, to be the incumbency of other retina! structures those related to the cones, in particular of the bipolars and ganglions (fig. 2). It is in these. apparently, that the principal function of processing the original cone excitations takes place whereby they are modificd in many ways: divided or selected, reinforced, combined, inhibited and so forth, as the case may be. The retina in this view, is an ingeniously organized sorting mechanism wherein the impulses generated in the photoreceptors are transformed, more so those of the cones than those of the rods, before being further transmitted to the centres of the brain for their final appraisal.

Regional Differentiation of the Retina and the Visual **Acuity.**—The structure of the retina, even though everywhere essentially the same. varies considerably in different localities. The most important is the region around the visual axis (*va* in fig. *1*). In fresh specimens this locality shows a yellow colouring—the yellow spot or *macula lutea*. Here the retina is much thicker because of the greater number of cells—central area. In its centre the central area is again much thinner, however, since most of the inner layers (*5–9*) are displaced here in a lateral direction to form an excabation—the central pit or fovea (*cf.* in fig. 1). Contrasting with this is the layer of photoreceptors which in the very centre. in the fovea, is exceptionally thick (fig. 3). This is caused by the lengthening of the cones proper which are here alone present—rodless area. This area measures approximately one-half millimetre across. There are no blood vessels here that might obstruct the free passage of light rays to the central cones—avascular central area. Conversely, the central cones are thinner in diameter than in any other region, being reduced in the very centre to one micron (one tnenty-file-thousandth part of an inch). This is the anatomical factor responsible for the fact that the highest visual acuity is in the centre of the field of vision. Viewed from the surface. the central cones show a solid mosaic of minute hexagonal fields corresponding to the individual cones, arranged in intercrossing rows. Not far from the central fovea is the optic papilla or disk (op in fig. 1), the locality where all axis cylinders of the ganglion cells, or optic nerve fibres, assemble before they leave the eyeball and form the optic nerve (on). Since there are no rods and cones here, the optic papilla is not sensitive to light—the blind spot in the field of vision. From the centre of the fovea nhere it is most refined. the structure of the retina gradually becomes cruder toward the periphery, especially close to the serrated margin (*os*). This agrees with the decrease of the acuity in the periphery of the field of vision. Other details. the connections of many more rods and cones with each bipolar cell and of many more bipolar cells with each ganglion cell than found in the central region of the retina, indicate a mechanism of convergence and summation by which the retinal periphery close to the *ora serrata* is made more sensitive to slight visual stimuli, especially those in motion, than the axial region.

Accessory Structures of the Eye.—The eyeball is lodged in the bony socket of the skull together with other parts pertaining to it: seven extrinsic muscles. blood vessels. nerves. lacrimal gland arid the orbital fat. From outside it is

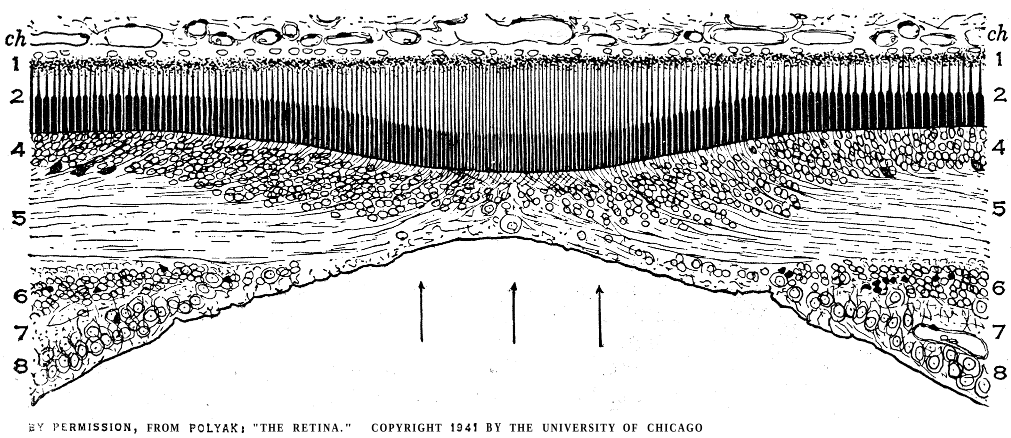

FIG. 3.—CROSSSECTION THROUGH THE DEEPEST PART OF THE HUMAN FOVEA SHOWING THE ATTENUATED, ELONGATED AND MORE NUMEROUS CONES IN THE CENTRE, INCREASING IN THICKNESS AND BECOMING LESS NUMEROUS TOWARD THE PERIPHERY

In the bacillary layer (2) a few rods are present at both ends. The inner layers *(5-9)* are practically absent in the foveal floor, permitting the rays of light, indicated by the arrows, to reach the photoreceptor layer (*2*) unhindered. The numbers of layers are the same as in fig. 2

protected by the fascia, mncous conjunctiva, skin, lashes and the brow. The tears secreted by the lacrimal gland moisten and wash the exposed parts, thus keeping the cornea clean and transparent. The surplus tears are carried through the two short lacrimal canals into the lacrimal sac, and from it through the nasal or nasolacrimal duct to the nasal cavity (fig. 4).

Ontogeny and Phylogeny of the Vertebrate Eye.—The primordia of the eyes appear in the human embryo at a very early stage *(A*, in fig. 5, stippled). At first they lie widely exposed on the surface of the body. As the neural tube closes, the primordia come to face inward (B). Next, by further expansion, they become primitive optic vesicles (C). Finally, by a process of invagination, double-walled secondary optic vesicles are formed (*D*). From the surrounding mesenchymal tissue other structures are formed in and around the vesicle: the vitreous and the outside coats of the eye, and from the adjacent part of the skin the crystalline lens.

There are reasons to think that the vertebrate eye also originated on the surface of the body, and that it was the most potent single factor in the rise and further evolution of the vertebrate phylum.

DISEASES OF THE EYE

Under this heading are included affections not only of the organ of vision itself but also of those parts connected with it which are necessary for its proper functioning.

It is customary to start with diseases of the conjunctiva. the transparent membrane which lines the posterior aspect of the eyelids and also covers the white of the eye. The exposed position of this membrane causes it to be more often affected than any other part of, or associated with, the eye.

It is necessary moreover to discuss the affections of the eyelids, since the eyelids both protect the eye and to a certain extent help to adjust the light to the retina, as in "screwing up the eyes," and also supply an oily secretion necessary for the well-being of the cornea.

Although each eye acts as a camera, under normal conditions only one image is seen. This is because the two eyes working together take almost the same picture from slightly different positions, exactly as in a stereoscopic camera. The images are fused and this forms the basis of stereoscopic vision. The perfect working of this mechanism depends in part on the delicate and accurate adjustment of movements of the eye muscles. If paralysis strikes one muscle, causing it to stop working, separate images are seen with the two eyes. These are no longer fused, and double vision results.

Finally it is necessary also to study the affections of the optic nerve and those parts of the brain concerned with the conduction and reception of the visual impulse. Apart from changes in the sight, these affections are often recognized by the alterations in the field of vision that they produce.

Diseases of the Conjunctiva.—Conjunctivitis.—The conjunctiva is a thin transparent sheet which lines the inner aspect of the eyelids and covers the white of the eye. Being thus exposed to dust, etc., the conjunctiva is very liable to inflammation. which may be of varying degrees of severity. This condition. known as conjunctivitis, is characterized by redness of the eye and discharge. The conjunctiva assumes a brick-red colour which must be distinguished from the rose-pink of deeper inflammations. Also the redness of conjunctivitis decreases in proportion to distance from the cornea while the deep redness forms a band encircling the cornea. The discharge, which is the characteristic symptom, may be mucoid or consist of mucus and pus or the eye may pour pus continually.

In practically all cases conjunctivitis affects both eyes. There is however a dangerous tendency to label all red eyes as having conjunctivitis. Where inflammation is confined to one eye a foreign body or some deeper inflammation is usually the cause. Many cases of conjunctivitis are so mild that they cause only the slightest inconvenience in an occasional feeling of heat and grittiness. The well-known "pink eye" is a form of conjunctivitis where the discharge is mucus mixed with pus. It is extremely contagious and may spread through homes and schools but eventually clears up without harming the eyes.

Purulent conjunctivitis, in which a continual stream of pus pours from the eyes. is much more severe and is most often, though not necessarily. caused by the gonococcus. The introduction of the sulfonamides and penicillin completely changed the outlook in this dreaded affection. Whereas at one time eyes were frequently lost through it, such a disaster now occurs only when treatment has been instituted too late.

Trachoma or *granular* conjunctivitis, although endemic in many countries, is but rarely seen in Great Britain or the U.S. in active form. It is characterized by granules or small elevations that stud the conjunctiva lining the lids and is chronic, taking a long time to cure and leaving sequelae of varying severity. It is produced by a filterable virus.

Pinguecula is a very common yellowish-white spot to one or other side of the cornea. It is of no significance and requires no treatment.

Pterygium is a triangular fold of conjunctiva which may gradually come down over the cornea. If it is advancing it requires surgery.

Diseases of the Cornea.—A corneal ulcer appears as a gray spot on the surface of the cornea. Such a spot, caused by the loss of some of the surface covering of the cornea, is distinguished from a scar by the fact that a drop of fluorescin will stain it green. The ulcer gives a good deal of pain. The essential treatment is to keep the eye covered by a pad and bandage and to enlarge the pupil with atropin. With treatment the ulcer usually heals, leaving, as a rule, a certain amount of opacity which may or may not be

serious. depending on its position and density. In rare cases, however, the ulcer spreads and may eventually cause a perforation of the cornea. The main types of corneal ulcer are described below.

Hypopyon ulcer is a severe affection in which the ulcer is accompanied by pus in the anterior chamber of the eye. The prognosis was much improved by the use of penicillin drops on the ulcer and one of the sulfonamide drugs taken by mouth.

A herpetic ulcer is characterized by little gray spots on the cornea. It often accoinpanies a cold or other respiratory affection.

A dendritic ulcer is so called because it branches like the branching of a tree. It also occurs in respiratory diseases.

Herpes ophthalmicus is an attack of shingles which affects the forehead and eye. It may be of varying severity and the eye may be almost unaffected or seriously damaged.

Neuroparalytic keratitis follows operations for the severe form of neuralgia known as tic douloureux, in which the cornea is rendered anaesthetic. As a result of this it may ulcerate and the eye be lost. The most effective treatment is to sew the eyelids together.

In *interstitial keratitis* the cornea assumes a ground glass appearance. There is no ulceration, and both eyes are usually affected. The disease takes about six to nine months to run its course and leaves a varying amount of opacity. It is most often caused by congenital syphilis.

Arcus senilis is a grayish ring or part of a ring near the periphery of the cornea. It occurs most frequently in the elderly but is often found before the age of 40 years. It is of no significance.

Corneal Grafting. — A very common result of affections of the cornea is to produce an opacity which reduces the vision according to its density and position. Thus it may hardly affect the sight or may make the patient to all intents and purposes blind. It is for the latter type of case that the operation of corneal grafting is done. A disk of the diseased opaque cornea is removed and then replaced by a transparent disk of the same shape taken from a cadaver eye or from the eye of another patient. that has had to be excised for a malignant new gron th.

Diseases of the Eyelids.— *Hordeolum* or *sty* is a small red swelling which forms at the base of an eyelash. It increases rapidly in size and forms a small abscess which discharges; and then heals. It is of no significance except for the disfigurement and the fact that there is the possibility of recurrence.

A *ckalazion,* popularly called a meibomian cyst, forms a rounded, usually painless swelling generally close to the line of the lashes. Again, it is of no importance and can be easily removed without leaving a visible scar.

In *blepharitis* whitish scales like dandruff collect round the roots of the lashes. These scales may be loose or somewhat adherent. When they are removed, the lid margin is found to be reddened but usually not ulcerated.

Diseases of the Iris and Ciliary Body.—The iris and ciliary body are structurally continuous and therefore both are usually affected at the same time. If the iris is mainly affected the disease is called iritis, if the ciliary body, cyclitis.

Iritis.—The movement of the iris on the front of the lens with dilatation and constriction of the pupil is much like that seen between joint surfaces. Indeed, iritis is often seen in joint disease and is caused by the same factors: septic foci, gonorrhoea. syphilis, tuberculosis, etc. It also results in adhesions between the margin of the pupil and the front of the lens.

Iritis causes a great deal of pain which is worst at night. The eye appears red, the redness differing from that seen in conjunctivitis in being rose pink and forming a band around the cornea. The pupil is small and irregular because of the adhesions to the lens. The eyeball is very tender to the touch. The essential treatment is to put atropin into the eye. This dilates the pupil and so breaks down the adhesions. Cortisone helped greatly in shortening the time taken for iritis to recover.

In cyclitis the essential sign is the formation of small gray spots behind the cornea. These cannot usually be seen by the naked eye and require some form of magnifying lens in order to make them visible.

Diseases of the Lens.—Cataract.—The lens, a bright crystalline body, forms the most obvious part when the eyeball is opened. It was this which caused the ancients to regard it and not the retina as the true seat of vision. In the past a cataract was thought to be an opacity which fell down like a cataract from above, between the iris and the lens. Now the term cataract is applied to any opacity of the lens. Cataract may roughly be classified as senile, congenital and secondary.

Senile cataract affects people over 50 years of age. Both eyes are always affected. Indeed, a cataract which remains confined to one eye is usually not a "good" cataract; and its removal, if this is at all advisable, is accompanied by many more risks than attend removal of the bilateral one. A cataract causes a varying amount of diminution of vision. A somewhat characteristic feature is that the patient sees better in the twilight than when the light is good. because the pupil is larger when the illumination is low and thus allows more light to enter the eye. A cataract causes the pupil to appear gray or white instead of black. It should be borne in mind, however, that in old people the pupil tends normally to be gray; and a great deal of unnecessary anxiety has been caused by such people being told they have a cataract when, in fact, no such thing has been present. Formerly a patient had to wait, often for years, until the cataract was ripe, before it could be operated on. Now no such waiting is necessary and the operation is done when the sight in the good eye no longer allows the patient to carry on his ordinary work. The ancients used to do the operation known as "couching." which is still performed in many parts of India. In this, the opaque lens is pushed back into the vitreous and out of the line of sight. The immediate effect of couching is often good but the eye is frequently lost later through inflammation. In normal practice the opaque lens is removed from the eye having the more serious condition. The prognosis here is by far the best, for in most cases good or useful vision is restored.

Congenital cataract is seen in babies. It usually affects both eyes and is of varying severity. If the loss of vision is great, the eyes are operated on but usually not before the age of one year. Latterly it was found that some cases of congenital cataract are the result of the mother's having had German measles in the early months of pregnancy.

Secondary cataract is the result of inflammation, increase of tension (glaucoma) or a new growth. It often affects one eye and removal of the cataract is not generally advisable.

Diseases of the Retina and Optic Nerve.—The retina is really a portion of the brain which grows out of the bony cranial cavity so that it may, literally, look upon the world. Its impressions are carried back to the remainder of the brain by the optic nerve with which it is continuous and which, therefore, is really not an ordinary nerve but a junction between one part of the brain and another.

With the ophthalmoscope minute changes can be observed in the retina and its vessels and in the termination of the optic nerve in the eye, known as the optic disk. A great deal of information may be obtained from an examination of the retina, especially about disease processes in the brain, kidneys and blood vessels of the body generally. Thus, one of the cardinal signs of tumour of the brain is that the optic disk becomes swollen, a condition known as papilloedema. In tabes, a form of creeping paralysis, and in general paralysis of the insane, the optic disk instead of being pink may be white or atrophic, as it is called. In certain severe forms of disease of the kidneys the first indication that anything is wrong may be found in the retina; haemorrhages and cloudy white spots may be seen with the ophthalmoscope. Where the general blood pressure is raised characteristic changes are seen in the retinal arteries which may later lead to haemorrhages and sharply circumscribed white patches. In diabetes also there are often changes in the eye such as cataract and retinal haemorrhages.

As might be expected, disease of the retina is accompanied by loss of vision. This is, however. of varying degree and is especially great when the macula or yellow spot. which is only the size of a pinhead, is affected. Sudden loss of vision occurs in the closure of the main artery or vein of the retina, in certain injuries of the optic nerve and retina, in some nervous diseases and in detachment of the retina. The loss of vision is greater when the central artery is closed than when the vein is. The latter may, however, be followed by a curious type of intractable glaucoma. In motor accidents it sometimes happens that when the injured person recovers consciousness he finds he cannot see with one or the other eye. Most often this is the result of injury to the optic nerve. Useful vision is only very rarely regained.

In detachment of the retina, fluid collects under the detached portion; this results in immediate loss of vision in the portion of the field subserved by the affected retina. Thus, if the detachment is below, the patient does not see the upper part of the object looked at; *e.g.*, a man may appear headless. Detachment of the retina is a very serious disease but the chances of recovery improved immeasurably after J. Gonin of Lausanne showed during the 1920s that in these cases there is a hole in the retina which must be closed for a cure to result. Before this discovery, detachment of the retina almost invariably led to blindness in the affected eye. By the 1950s the proportion of cures was variously given as from 40% to 80%.

In some cases detachment of the retina is caused by a malignant growth of the chorioid. Here the eye must be removed to effect a cure.

Glaucoma.—The word glaucoma is derived from the Greek word γλαύκωμα meaning sea-green; for, before the character of the disease was understood and adequate treatment became available, all cases of glaucoma resulted in blindness and the pupil took on a greenish hue. The term glaucoma is now applied to any condition where the tension of the eye is raised so that it becomes harder than normal. It is in most cases a very serious affection of the eye. Glaucoma may be acute or chronic.

In acute *glaucoma* the patient has an attack of severe pain in one of the eyes. The pain may radiate in many directions, so that he may complain of pain not in the eye but around it; may say he has a headache, or the pain may shoot down the nose or be attributed to toothache. The pain is usually so severe that the patient vomits. suggesting a bilious attack. The vision soon becomes very reduced and the eye stony hard. The eye assumes a dusky red colour and the cornea becomes steamy and the pupil dilated.

As treatment, oily drops consisting of 1% eserin are instilled repeatedly into the affected eye, and one drop is also put into the other eye because the anxiety may bring about an attack in this eye as well. The classical operation for acute glaucoma is a broad iridectomy in which a portion or sector of the iris is removed. This operation, devised by A. von Graefe in 1856, has since saved the sight of countless eyes.

Chronic glaucoma, on the other hand. is an insidious disease and may easily escape diagnosis in its early stages. Not infrequently it is found that the patient has had his glasses increased in strength at short intervals and that the underlying malady has been entirely overlooked. The patient may complain of gradual loss of vision, of transient attacks of misty vision or halos; *i.e.,* coloured rings around lights, which are very suggestive of glaucoma. The diagnosis is based upon the increase of tension which, however, may not be present continually, upon the loss of the inner portion of the field of vision and upon the fact that the entrance of the optic nerve into the eye is pushed back by the increase of tension to form a cavity, known as a cupped disk.

The treatment consists in the first instance of instilling pilocarpin or eserin which constricts the pupil. This may be continued so long as it controls the tension, the visual acuity and the field; but the majority of cases necessitate surgery sooner or later. In most cases a fistulizing operation is performed, by which a new drain is made in order that the intraocular fluid can escape to the outside of the eye and so reduce the tension. A careful watch must be kept on the other eye, as in nearly all cases the disease eventually affects both eyes Although, in general, glaucoma affects people over 40. it may occur in very young children. The result of tension in the baby's eye is quite different from that in the adult. For here the whole eye enlarges so that the parents often say that before they realized the seriousness of the disease they thought the child had large beautiful eyes. Indeed, the disease is known as buphthalmia or "ox eye."

Increase of tension in the eye may also be the result of certain other diseases of the eye. In cases of untreated iritis the pupil may become completely adherent to the lens, preventing the aqueous fluid from coming forward from the ciliary body where it is formed, through the pupil and then out of the eye by the canal of Schlemm. As a result of this the tension mounts. Increased tension may also accompany malignant growths inside the eye. This condition usually requires excision of the whole eye.

Injuries of the Eye.—The eye is protected by the bony orbit. the lids and the nose; further, its rounded form and socket of soft fat allow it to some extent to slip out of the way when hit. Yet injuries of the eye are very common; because of the eye's extreme sensitivity, traumata which would pass unnoticed elsewhere in the body here call for immediate attention.

Nonpenetrating Injuries.—An extremely common injury is a scratch or abrasion of the cornea. This may be very difficult to see; but it is very painful and is immediately shown up by a drop of fluorescin which stains the affected part green. Usually the abrasion heals quickly when treated with atropin ointment. After a blow to the eye, the anterior chamber may fill with blood. the iris may show a rent, the lens may be dislocated, the chorioid ruptured and the retina detached. If the blow is hard enough the whole globe may rupture.

Perforating injuries are always serious, not only so far as the affected eye is concerned but because they may also give rise to an inflammation of the fellow eye known as sympathetic ophthalmitis. If a piece of iris or ciliary body has prolapsed through the wound and non lies exposed, sympathetic ophthalmitis leads in most cases to blindness of both eyes. Sometimes the foreign body nhich caused the injury remains in the eye. If made of steel it can be removed by means of a giant magnet.

Burns ––Burns of the eye are usually produced by molten metal. steam, strong acids or caustics such as lime or alkalis. Burns from molten metal are usually rendered much less severe than mould be expected by the normal film of moisture on the front of the cornea.

Injuries Produced by Light.—Ultra-violet light causes intense pain in the eye which characteristically comes on about six to eight hours after the exposure. This is the cause of industrial photophthalmia in cinema workers. Snow blindness also is caused by ultra-violet light. Eclipse blindness is the result of heat rays producing a definite burn of the retina.

Affections of the **Pupil.**—Normally the pupils of the tno eyes are the same size. When a bright light is made to shine on one pupil, not only will it contract briskly but the pupil of the other eye will become small too. These changes are known as the direct and consensual reactions of the pupil. Any deviations from the normal may indicate not only serious trouble in the eye itself but also of the central nervous system. So, after severe head injuries, the direct reaction to light may be absent while the consensual remains. This indicates a severe lesion of the optic nerve.

The Argyll Robertson pupil is, typically. a small pupil which does not react to light directly or consensually, but becomes small when an object held close to the eye is looked at (reaction to convergence). It usually indicates tabes or other severe disease of the central nervous system.

The Field of Vision.—The vision of a normal person with one eye shut and looking straight ahead at a fixed point cannot go beyond a certain point upward. downward. inward and outward. The area that he can see is knonn as his field of vision. Usually the field is estimated nith an instrument called a perimeter and may give valuable information not only about diseases of the eye itself but also about the central nervous system. Thus, concentric diminution of the field is found in tabes, in general paralysis of the insane and in blindness caused by quinine. Loss of a portion of the inner or nasal field is found characteristically in glaucoma, whereas the temporal field is affected in pituitary tumour. When the visual tract is affected in front of the chiasma only one field is affected but lesions of the chiasma or of the visual fibres behind this affect the fields of both sides because they carry visual impressions from both eyes. Such bilateral loss is known as hemianopia. By a right homonymous hemianopia is meant the loss of the right halves of the visual fields; *i.e.*, the outer field of the right eye and the inner of the left. It is caused by a lesion of the left optic tract, optic radiations or visual cortex in the occipital lobe.

Strabismus or Squint.—In strabismus or squint the direction on which the affected eye looks bears an abnormal relation to the other. It is usually described as paralytic or nonparalytic.

In a paralytic squint one or other ocular muscle is paralyzed. Thus supposing that the muscle which normally makes the eye look outward is paralyzed. the unopposed muscle which makes the eye look inward will exert its pressure and an inward squint will result. Double vision is a distressing result of paralytic squint. There are a great many causes of such a squint; it may be an affection of the brain or of the nerves that supply the muscles or an affection of the muscle itself. *Nonparalytic squint* occurs as a rule in children about three years old; often after measles: scarlet fever, etc. They are usually highly strung and long sighted; but there is no disease of the eyes. Glasses are usually required and certain exercises to develop stereoscopic vision, known as trthoptic exercises, are useful in treatment of the squint. A certain number of cases require operation to put the eyes straight.

Nystagmus consists in rhythmic oscillation of the eyes typically not under control of the will. There are a number of types. *Infantile nystagmus* is found where a great defect of vision was present during the first weeks of life. *Miner's nystagmus* is common in miners working in poorly lighted mines. There is often an element of neurasthenia present in these cases. There is a nystagmus associated with disease of the inner ear (labyrinth), or central nervous system. Nystagmus may also be hereditary, physiological (as in looking out of a train) and. rarely, voluntary.

Intraocular **Tumours.**—Growths inside the eye are rare but, when they occur, are as a rule extremely malignant. They belong for the most part to the pigmented tumours (melanomata). Although the growth in the eye may be relatively small, it can produce secondary growths in all parts of the body. The only effective treatment is, as a rule, to remove the eye. The other great group of malignant growths in the eye occur in quite young children and are called glioma, or better, retinoblastoma. The pupils in these cases usually appear yellowish; hence the name amaurotic cat's eye. These tumours do not as a rule produce secondary growths but tend to spread back to the brain. In 25% of the cases both eyes are affected. Excision of the eye is the best treatment; but in rare cases where one eye has been removed it is justifiable to treat the remaining eye with radium.

EYE, SURGERY OF, comprises operations on any part of the eye. Modern developments in general and local anesthesia. drugs. instruments and techniques have made eye surgery a far safer and less painful procedure than it once was. and have prevented much blindness.

Eyelids.—Drooping. or ptosis, of the upper eyelids may be a hereditary defect or the result of an injury. Ptosis is corrected by shortening the levator muscle which raises the upper eyelid if it is not completely paralyzed. A piece of the levator muscle is removed and the remaining muscle is sutured farther downward under the skin of the eyelid. In paralytic ptosis a strip of skin. muscle or wire is used to form a sling from the upper eyelid to the frontalis muscle above the eyebrow. This permits the patient to open his eyelid by raising his eyebrow.

In mild cases of ectropion (outward turning of the eyelids). passing a cautery through the tarsus from the conjunctival surface brings the eyelid into position. In severe cases. the eyelid is shortened by removing skin and tarsus. In mild entropion (innard turning of tarsus and eyelid), a cautery applied through the skin may correct the condition. In severe cases more extensive surgery is required.

Tear Apparatus.— Tearing, usually caused by some obstruction to the tear duct and most commonly seen in infants in whom the lower end of the duct in the nose has failed to open, is often cured by passing a probe through the stricture. Pus in the lacrimal sac is drained by incising the local abscess. If the lower part of the duct is blocked the sac may be carried into the nose. producing a new drainage channel.

Eye Muscle.--The six external eye muscles (two oblique muscles and four straight or recti muscles) rotate the eye in various directions. Crossed eyes result from defective medial recti muscles. which draw the eyes nasally. When glasses and eye exercises fail to correct this condition: the medial recti muscles may be freed and reattached farther back on the eyeball; this operation is combined in some cases with shortening of the lateral recti muscles which pull the eyes outward.

In exotropia. also resulting from muscle defects that. in this case, pull the eyes outward. the majority of cases require freeing one or both lateral recti (fig. 1[A]) and reattaching these muscles

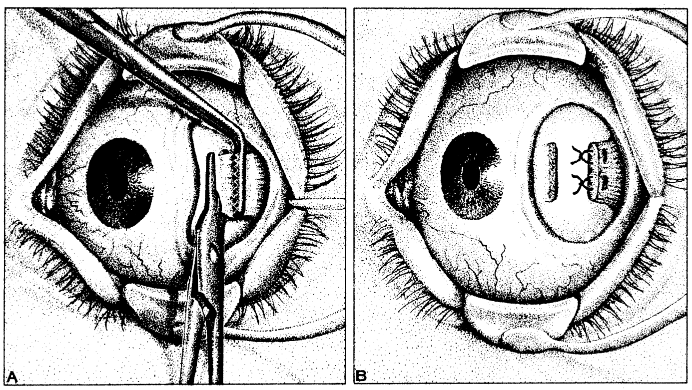

FIG. 1.—SURGERY TO CORRECT EXOTROPIA

(A) The muscle is severed from its normal insertion and (B) sutured farther back on the eyeball

farther back on the eyeball (fig. 1[B]). If the eyes are not straightened sufficiently, the medial recti muscles may be shortened.

Spasm of an inferior oblique muscle produces upward. inward turning of the eye, which is corrected by severing the muscle or by receding the muscle on the eyeball.

Cornea.— Scarring or clouding. whether caused by disease or injury. may involve all or part of the cornea. The opaque cornea may be merely tattooed (for cosmetic purposes). or partially or completely removed, replacing the opaque cornea n-ith a clear cornea from a donor's eye. This is accomplished by removing the opaque tissue with a tubular cutting instrument. the trephine (fig. 2[A]). A similar disc is cut from a transparent cornea of a donor's eye, transplanted to the patient's eye and sewn in place (fig, 2[B]).

Glaucoma.— This disease, a hardening of the eyeball, usually is caused by obstruction to the normal fluid outflow of the eye. Surgery becomes necessary when drugs iail to lower the eye pressure, and especially when the visual fields (side vision while looking straight ahead) contract. Operations creating artificial channels for the fluid outflow comprise iridencleiiis, in which a piece of the iris is drawn up into a wound made in the sclera; and iridocorneocclerectomy. wherein pieces of the sclera arc clipped away, allowing the fluids to escape under the conjunctiva.

In surgical treatment of congenital glaucoma. in which there is maldevelopment of the tissues in the angle between the cornea and iris, the tissues are cut with a knife to permit fluid outflow in

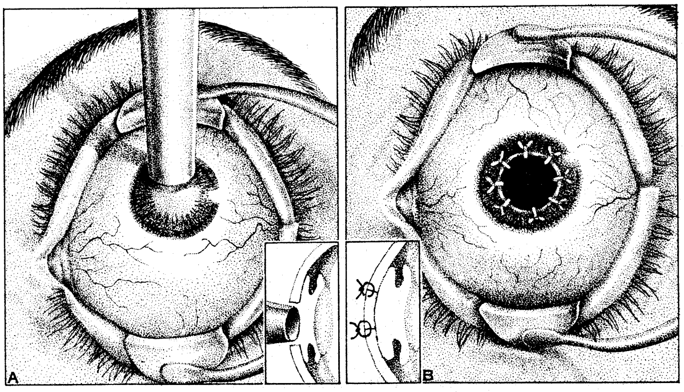

FIG. 2.— REMOVAL OF AN OPAQUE CORNEA

(A) A trephine cuts the opaque disc from the cornea. This disc is replaced by a similar disc of clear cornea from a donor's eye and (B) sutured in place

this area. When a decrease in the fluid production in glaucomatous eyes is necessary. parts of the ciliary body are destroyed chemically (cycloelectrolysis) or by heat (cyclodiathermy). (See also GLAUCOMA.)

Lens.—The lens is surgically removed when it has become opaque through disease or injury. An incision is made close to or in the cornea; the iris is cut and the lens grasped (fig. 3[A]) and gently pulled out of the wound. which then is closed with sutures (fig. 3[B]). In some case, an enzyme is injected to weaken the fibres which hold the lens in place. making removal by suction or by forceps easier.

Retina.—The retina (seeing membrane of the eye) may become partially or completely detached following injury or disease of the eye. Detachments are usually accompanied by tears. which must he carefully sealed off by applying diathermy punctures through the sclera over the tear; or by light coagulation. The eyeball is often shortened by folding or excising a strip of sclera. the fold being maintained by sutures.

Tumours.—Some small tumours on or within the eyeball may be excised or destroyed with radium or light rays. Diathermy applied to the sclera over a tumour has resulted in cures in some cases. Such tumours as glioma of infants and sarcoma of the choroid of adults usually necessitate removal of the eye.

(CD. BS.)

Artificial Eyes.—Artificial eyes are known to have been made in the 9th century B.C., when the Egyptians removed the eyes of the dead. poured wax or plaster into the orbits and inserted precious stones. In the 5th century B.C. Roman priests who practised surgery began to make artificial eyes for living patients. Glass eyes were first made in Venice in 1579, and important contributions to this art by French surgeons in the 17th and 19th centuries resulted in the artificial eye as it is known today. In the beginning of the 18th century the manufacture of glass eyes

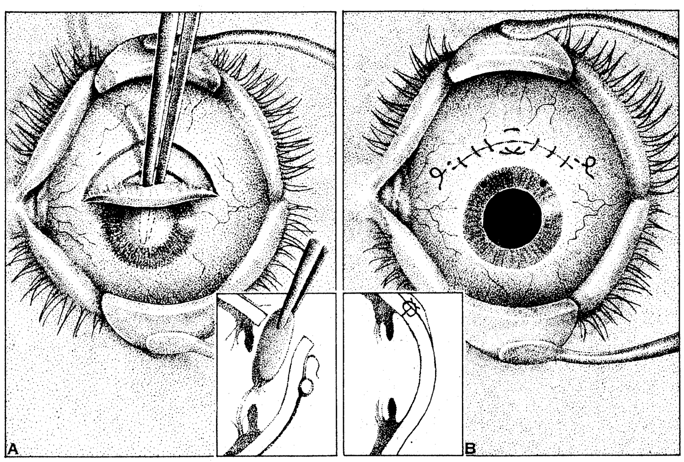

FIG. 3.— LENSURGERY

(A) The opaque lens is removed from the eyeball and (B) the wound closed with sutures was centred almost exclusively in Germany and Austria.

Originally, artificial eyes were made as oval shells. which were not only ill-fitting but also uncomfortable to wear. In 1898 an eye was developed that was in eifect a two-layered shell with space betneen the layers. Today the earlier type is used almost exclusively over deformed eyes or in evisceration cases, where the contents of the eye have been removed and the outer portion left intact. The tno-layered eye is used in cases of enucleation (removal of the entire eye).

Prior to 1939 artificial eyes were made from glass materials imported from Germany. Just before World War II. the *Reichsverband,* a government-controlled guild of eyemakers, established restrictions on shipments of glass and raised prices to a very high level. As a'result, U.S. manufacturers developed a glass comparable with the German product. In addition, a program sponsored by several commercial firms and the medical departments of the U.S. army and navy resulted in development of a plastic eye which would not break or crack.

After World War II several surgeons developed implants which could be inserted into the orbit after enucleation, imparting motility to the artificial eye through direct transmission, magnetic attraction or by leverage action The result is an artificial eye that moves to a degree in conjunction nith the good eye (S. W. R.)

EYEGLASSES, or spectacles, are optical devices intended to aid vision. Roger Bacon in 1268 recorded the earliest comment on the optical use of lenses, but magnifying glasses inserted in frames were used by the Chinese for reading as early as the 10th century. Marco Polo noted this custom also in the court of Kublai Khan (1270). Eyeglasses made their first European appearance in Italy, their introduction being attributed to Alessandro di Spina of Florence. The first portrait to show eyeglasses is that of Hugh of Provence by Tommaso da Modena, done at Treviso in 1352. Domenico Ghirlandajo in 1480 painted St. Jerome at a desk from nhich dangled eyeglasses, and from this detail St. Jerome became the patron saint of the spectacle makers' guild. At first only convex lenses were used for the aid of presbyopia (old-sight) and hyperopia (old-sight in young people). A concave lens for myopia is first evident in the portrait of Pope Leo X, painted by Raphael in 1517.

Originally lenses mere made of transparent quartz and beryl (of nhich aquamarine is a variety), but increased demand led to the adoption of optical glass, for which Venice and then Nurnberg were the chief centres. The availability of glass lenses not only aided ocular efficiency but led to the invention of the microscope (1590) and of the telescope (1608). In 1784 Benjamin Franklin invented bifocals, dividing his lenses for distant and near vision, the split parts being held together by the frame. Cement bifocals were invented in 1884. and the fused and one-piece types follow-ed in 1908 and 1910, respectively. Trifocals and new designs in bifocals nere later introduced. including the Franklin bifocal revived in one-piece form, to satisfy more adequately diverse optical problems and occupational needs When the corrections for the tno eyes vary significantly, there occurs in the reading field a disturbing prismatic efiect that can be nullified by a compensating prism in the bifocal area or by dissimilar bifocal segments.

In 1827 Sir George Airy, a British astronomer, made the first attempt to correct astigmatism (his own) by a suitable cylindrical lens. Astigmatism was considered a curiosity until its prevalence was firmly established by F. C. Donders, whose classic work (1864) created scientific clinical refraction and stimulated further improvement in both the subjective and objective determination of the glasses needed. Donders also popularized the adding of prisms to facilitate the muscular adjustments in binocular vision.

In 1804 William Wollaston of London found that the peripheral aberrations noted in "flat" lenses mere almost entirely eliminated when the corrections nere ground in appropriate convexo-concave forms. The virtues of these meniscus lenses were extended later to cylindrical corrections by incorporating the cylinder in a toric curve. Since the previously standardized toric surface proved inadequate when the spherical component was strongly plus, an extra series of "corrected curve" lenses was introduced in 1930. The proper toric form increases the effective field of view, but occasionally a person who requires a weak minus correction notes disturbing reflections. particularly in artificial light.

The varieties of fine optical glass essential for high-grade ophthalmic lenses resulted from a century of costly research. Ernst Abbe and Otto Schott in 188; demonstrated that the incorporation of sundry new elements into the glass melt led to many desirable variations in refractive index and dispersive power. Optical glass for ophthalmic lenses is first rolled into plate glass form. The bulk of spectacle lenses are made from clear crown glass of refractive index 1.523. However, in high myopic corrections a cosmetic improvement is effected if the lenses are made of dense flint glass (refractive index 1.69) and coated with a film of magnesium fluoride to nullify the surface reflections Flint glass or barium cronn. which has less dispersive power, is used in fused bifocals (see GLASS). The power of a lens was expressed by its focal length in inches until Monoyer of France introduced in 1872 the diopter unit. A lens of one diopter (1 D.) brings parallel rays to a focus at one metre; as the dioptric power increases, the principal focal length decreases proportionately. Prisms were measured originally by their refractive angle in degrees, but this was changed to the prism-diopter at the suggestion of Charles F. Prentice of New York (1890). A prism that causes a deflection of one centimetre at a distance of one metre is one prism-diopter ($1^{\triangle}$).

Visual discomfort and fatigue are commonly associated with errors of refraction or of oculomotor balance. Occasionally the disturbance is caused by inequality of the retinal images (aniseikonia), which is remediable by lenses that equalize the retinal image without altering the effective optical power.

Decreasing use of shading headgear promoted the popularity of sunglasses. Any sunglass that transmits more than 30% of light does not adequately prevent dazzling. Constant wearing of slightly tinted glasses is not desirable, since they tend to affect adversely normal adaptation, night vision and indoor working acuity.

Spectacle frames and the shape of lenses vary with fashion. George Washington more quadrilateral lenses in steel spectacles nith long jointed temples. After rimless spectacles were devised in 1840, this inconspicuous style was the vogue until supplanted by plastic frames The monocle is an irrational affectation.

About one-third of schoolchildren require eyeglasses for efficient far and near vision. Regular screening tests hence are desirable. (J. E. Ls.)

Contact Lenses. — Contact lenses are lenses worn on the eyeball. They can be made to correct all visual conditions correctible by regular eyeglasses. The first contact lenses to be used as refractive devices were made by A. E. Fick in 1887. The early lenses were made of glass, but after 1938 plastic, usually methylmethacrylate, was used. From 1938 to 1950 most lenses were made by taking impressions of the eye and forming the lens on this mold. Such lenses covered most of the eye, and a fluid was used under them. After 1950 smaller lenses were used which cover only the cornea (front surface of the eye) and float on a layer of tears It is not necessary to make an impression of the eye, as the curvature of the cornea can be measured by optical instruments. Such lenses. only 7 to 11 mm. in diameter and 0.1 to 1 mm. in thickness, usually can be worn all day without removal. Contact lenses are invisible, and they give a wider field of vision than eyeglasses do. Since they are not easily broken they can be worn while participating in active sports. Further, some visual conditions which cannot be corrected by regular glasses can be corrected by contact lenses. Contact lenses can be coloured for use as sun lenses; they also have been used by actors to change the colour of the eyes. In 1958 bifocal contact lenses were developed.

Contact lenses cost more than regular eyeglasses do, and many persons experience difficulty in learning to wear them.

EYEISH. A North American Indian tribe of the Caddo confederacy, the Eyeish, also called the Aas, Aays, Aes, Aix, Haish, Yayecha, and other names, lived on the Eyeish or Ayish creek, between the Neches and Sabine rivers in northeastern Texas.

By the beginning of the 20th century the tribe was virtually extinct. Twenty families of the "Ays" were reported in 1779 and 300 "Ahijitos" in 1785. There were only 20 living members of the tribe in 1805. according to John Sibley, but in 1828 160 families living between the Colorado and Brazos rivers were reported (Sociedad Mexicana de Geografia y Estadistica. *Boletin,* 1870).

History. — Luis Moscoso de Alvarado succeeded Ferdinando de Soto after the Spanish explorer's death in 1542, and in that pear Moscoso and his men visited the Eyeish.

Late in the 17th century the French explored the tribe's country, associates of René Robert Cavelier, sieur de la Salle, noting the tribe in 1686–87.

In 1716 Spaniards founded the Franciscan mission of Nuestra Señora de los Dolores de los Ais near the Sabine river. The mission was abandoned three years later and the Indians destroyed its property. Re-established in 1721, it was again abandoned in 1773.

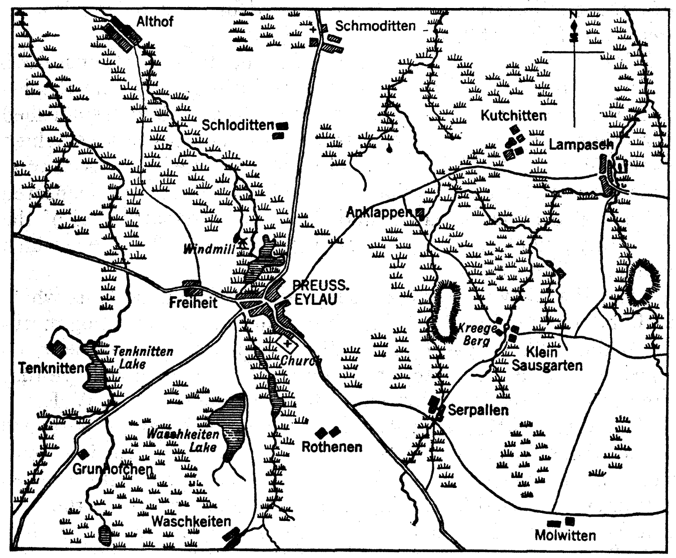
The Eyeish tribe. near both French and Spanish posts, suffered from the new diseases brought by the white people. The Eyeish who survived the ravages of war and disease during the 19th century were settled with other Caddoans on the Wichita reservation in Oklahoma.

EYEMOUTH, a small burgh of Berwickshire, Scot. Pop. (1951) 2.269. It is situated at the mouth of the Eye, $7\frac{1}{2}$ mi. N.N.W. of Berwick-upon-Tweed. The main occupation is seine-net fishing. with some boat-building and allied trades. Eyemouth was known as a port as early as the reign of Alexander II (1214–49); the harbour was enlarged in 1887. The rugged coast with its numerous ravines and caves was formerly infested with smugglers. St. Abb's Head is 3 mi. to the northwest.

EYLAU (BAGRATIONOVSK) a town of the Kalinin *oblast,* Russian Soviet Federated Socialist Republic, U.S.S.R., formerly in east Prussia, Ger., on the Pasmar, 23 mi. S. by E. of Kaliningrad (Konigsberg) by rail on the Pillau-Prostken line. It has an Evangelical church, teachers' seminary, hospital, foundries and sawmills. Eylau was founded in 1336 by Arnolf von Eilenstein, a knight of the Teutonic Order. It was the scene of a battle between the army of Napoleon and the Russians and Prussians commanded by Gen. Levin Bennigsen, fought on Feb. 8, 1807.

The battle was preceded by a severe general engagement on the 7th. The head of Napoleon's column advancing from the southwest, found itself opposed at the outlet of the Griinhofchen defile by a strong Russian rearguard which held the (frozen) lakes on either side of the Eylau road. The French turned both wings of the enemy, and Bagration, who commanded the Russian rearguard, retired through Eylau to the main army, which was now arrayed for battle east of Eylau. Barclay de Tolly made a strenuous resistance in Eylau itself, and in the churchyard, and these localities changed hands several times before remaining finally in possession of the French. It is very doubtful whether Napoleon actually ordered this attack upon Eylau, and it is suggested that the French soldiers were encouraged to a premature assault by the hope of obtaining quarters in the village. There is, however, no reason to suppose that this attack was prejudicial to Napoleon's chance of success, for his own army was intended to pin the enemy in front, while the outlying "masses of manoeuvre" closed upon his flanks and rear (*see* NAPOLEONIC CAMPAIGNS). In this case the vigour of the "general advanced guard" was superfluous, for Bennigsen stood to fight of his own free-will.

The foremost line of the French bivouacs extended from Rothenen to Freiheit, but a large proportion of the army spent the night in quarters farther back. The Russian army on the other hand spent the night bivouacked in order of battle. The cold was extreme, and food was scarce in both armies. The ground was covered at the time of battle with deep snow, and all the lakes and marshes were frozen, so that troops of all arms could pass everywhere, so far as the snow permitted. Two of Napoleon's corps (Davout and Ney) were still absent, and Ney did not receive his orders until the morning of the 8th. His task was to descend upon the Russian right, and also to prevent a Prussian corps under Lestocq from coming on to the battlefield. Davout's corps advancing from the south-east on Mollwitten was destined for the attack of Bennigsen's left wing. In the meantime Napoleon made preparations for the frontal attack. His infantry extended from the windmill, through Eylau, to Rothenen, and the artillery was deployed along the whole front; behind each infantry corps and on the wings stood the cavalry. The Guard was in second line south



MAP OF EYLAU AND SURROUNDING COUNTRY IN GERMANY

The scene of battle between the French army under Napoleon, who, advancing from the southwest, met the Russians and Prussians at Grunhbfchen. The action began at 8 A.M. on Feb. 8, 1807, and ended at nightfall with the retreat of the Russian and Prussian armies

of Eylau, and an army reserve stood near the Waschkeiten lake. Bennigsen's army was drawn up in line from Schloditten to Klein Sausgarten, the front likewise covered by guns, in which arm he was numerically much superior—having some zoo. A detachment occupied Serpallen.

The battle opened in a dense snowstorm. About 8 A.M. Bennigsen's guns opened fire on Eylau, and after a fierce but undecided artillery fight the French delivered an infantry attack from Eylau. This was repulsed with heavy losses, and the Russians advanced towards the windmill in force. Thereupon Napoleon ordered his centre, the VII. Corps of Augereau. to move forward from the church against the Russian front, the division of St. Hilaire on Augereau's right participating in the attack. If we conceive of this first stage of the battle as the action of the "general advance guard," Augereau must be held to have overdone his part. The VII. Corps advanced in dense masses, but in the fierce snowstorm lost its direction. St. Hilaire attacked directly and unsupported; Augereau's corps was still less fortunate. Crossing obliquely the front of the Russian line, as if making for Schloditten, it came under a *feu d'enfer* and was practically annihilated. In the confusion the Russian cavalry charged with the utmost fury downhill and with the wind behind them. Three thousand men only out of about fourteen thousand appeared at the evening parade of the corps. The marshal and every senior officer were amongst the killed and wounded. The Russian counterstroke penetrated into Eylau itself and Napoleon himself was in serious danger. His staff was seized with panic for his safety, and sent for the horses, but Napoleon himself, with the utmost coolness, judged the pace of the Russian advance and ordered up a battalion of the Guard at the exact moment required. In the streets of Eylau the Guard had the Russians at their mercy, and few escaped. Still the situation for the French was desperate and the battle had to be maintained at all costs. Napoleon now sent forward the cavalry along the whole line. In the centre the charge was led by Murat and Bessières, and the Russian horsemen were swept off the field. The Cuirassiers under D'Hautpoult charged through the Russian guns, broke through the first line of infantry and then through the second, penetrating to the woods of Anklappen.

The shock of a second wave of cavalry broke the lines again, and though in the final retirement the exhausted troopers lost terribly, they had achieved their object. The wreck of Augereau's and other divisions had been reformed, the Guard brought up into first line, and, above all, Davout's leading troops had occupied Serpallen. Thence, with his left in touch with Napoleon's right (St. Hilaire), and his right extending gradually towards Klein Sausgarten, Davout pressed steadily upon the Russian left, rolling it up before him, until his right had reached Kutschitten and his centre Anklappen. By that time the troops under Napoleon's immediate command, pivoting their left on Eylau church, had wheeled gradually inward until the general line extended from the church to Kutschitten. The Russian army was being driven westward, when the advance of Lestocq gave them fresh steadiness. The Prussian corps had been fighting a continuous flank-guard action against Marshal Ney to the north-west of Althof, and Lestocq had finally succeeded in disengaging his main body, Ney being held up at Althof by a small rearguard, while the Prussians, gathering as they went the fugitives of the Russian army, hastened to oppose Davout. The impetus of these fresh troops led by Lestocq and his stafi-officer Scharnhorst was such as to check even the famous divisions of Davout's corps which had won the battle of Auerstadt single-handed. The French were now gradually forced back until their right was again at Sausgarten and their centre on the Kreege Berg.

Both sides were now utterly exhausted, for the Prussians also had been marching and fighting all day against Ney. The battle died away at nightfall, Ney's corps being unable effectively to intervene owing to the steadiness of the Prussian detachment left to oppose him, and the extreme difficulty of the roads. A severe conflict between the Russian extreme right and Ney's corps which at last appeared on the field at Schloditten ended the battle. Bennigsen retreated during the night through Schmoditten, Lestocq through Kutschitten — unpursued. The numbers engaged in the first stage of the battle may be taken as—Napoleon, 50,000, Bennigsen, 67,000, to which later were added on the one side Ney and Davout, 29.000. on the other Lestocq, 7,000. The losses were roughly 15,000 men to the French, 18,000 to the Allies, or 21 and 27% respectively of the troops actually engaged.

EYRA, a name applied to the red colour phase of the jaguarondi (*q.v.*) (*Felis yaguarondi*). For a long time it was thought that these were different species, and much confusion arose. The colour varies from reddish yellow to chestnut, in contrast to the grizzled appearance of the norm-a1 variety. It occurs from Paraguay to southern Texas. (J. E. Hl.)

REDRAWN FROM A PHOTOGRAPH, NEW YORK ZOOLOGICAL SOCIETY

EYRA OR JAGUARONDI (FELIS YAGUARONDI)

EYRE, EDWARD JOHN (1815–1901), British explorer and colonial governor. remembered especially for his suppression of a Negro uprising in Jamaica (1865). was born at Hornsea, Yorkshire. on Aug. 5. 1815. He emigrated to New South Wales in 1832 and farmed sheep. becoming a pioneer "overlander" driving stock from Sydney to South Australia. He explored the central deserts of South Australia, where Lake Eyre bears his name; his most famous voyage was in 1840–41, when almost alone he made an expedition round the Great Australian Bight which proved the possibility of land communication between South and Western Australia. As early as 1836 Eyre was appointed a magistrate and protector of ahorigines. with whom he got on particularly good terms. He returned to England in 1845 and was appointed in 1846 lieutenant governor of New Zealand, where he served under Sir George Grey. After governing St. Vincent and the Leeward Islands in turn, he was appointed acting governor of Jamaica in 1861 and governor in 1864. In Oct. 1865 he suppressed a Negro uprising there with an efficient severity which earned him the warm gratitude of the local Europeans, but raised a storm in England: there were over 400 executions, and it was claimed that some of them had been illegal. The Whig government, after an inquiry, both thanked Eyre for putting the uprising down and blamed him for taking excessive reprisals; in July 1866 he was recalled. Several unofficial' attempts to try him failed, and he was acquitted in a civil case brought against him by a Jamaican. Eyre was finally granted the usual colonial governor's pension in 1874. He died near Tavistock on Nov. 30, 1901. (M. R. D. F.)

EYSTEIN (EYSTEIN ERLENDSSON) (d. 1188). one of the foremost ecclesiastical leaders of medieval Norway, came of an aristocratic family of Trondheim. On the death of Jon Birgisson, first archbishop of Nidaros, in 1157, King Ingi the Hunchback nominated Eystein to succeed him. Eystein received the pallium from Pope Alexander III four years later and returned to Norway in 1161. By that time King Ingi was dead and Norway was divided in a struggle for succession between Haakon II Broad-Shoulders and Erling, who claimed the throne for his infant son Magnus. Haakon was defeated and killed in 1162. The archbishop was meanwhile consolidating the position of the church. The cathedral of Nidaros, in which he took a special interest, was being built and there was need to increase the ecclesiastical revenues. Eystein reformed the system under which ecclesiastical dues were paid, demanding pure silver instead of debased coinage. and was thus led to hard bargaining with Erling. Each side gave the other generous concessions: though Eystein was the more astute. The power of the church was increased and the position of the infant king, whose claims to the throne were questionable. was temporarily secured. It was agreed that Magnus should receive the sanction of the church, and in 1163, at the age of seven, he was crowned. as Magnus V, by the archbishop in the presence of the papal legate Stephanus of Orvieto. This was the first time the ceremony of coronation had been performed in Norway.

Eystein stood for the universal power of the church and in some ways resembled Thomas Becket. His policy came clearly to light in his dealing with Iceland (part of his province), where he tried unsuccessfully to compel chieftains to hand over churches they owned.

When the upstart Sverre from the Faeroes, asserting claims to the throne, had driven Magnus from Norway (1180), Eystein who had sponsored the latter's cause. fled to England and formally excommunicated Sverre. He returned to Norway, however, in 1183 and made peace with Sverre.

Eystein was also remembered as the author of a lawbook, now lost. called *Guldfjaer* ("Golden-Quill") perhaps because of its illuminations; and of part, at least, of a work on the passion and miracles of St. Olaf.

EYTH, MAX VON (1836–1906), German engineer, inventor and pioneer in the mechanization of agriculture. who founded the Deutsche Landwirtschafts-Gesellschaft (German Agricultural society) in 1884, was born on May 6, 1836, at Kirchheim unter Teck, Württemberg, and graduated in engineering at the Stuttgart polytechnic. His interest in the gas engine developed by E. Lenoir took him to Paris; and later, in England, he joined Sir John Fowler! the pioneer of steam traction engines. As a representative of Fowler's Steam-Plough works he spent some time in Egypt, the United States! India, Trinidad and most countries of Europe, where his expert knowledge of machinery and his enthusiasm did a great deal to introduce steam power and machinery for plowing, irrigation, earth moving and towing canal boats.

Eyth also wrote a play and a number of novels inspired by his experiences as an engineer and traveler, as well as some indifferent poetry. In his novel *Der Kampf um die Cheopspyramide* (2 vol., 1902), as also in *Der Schneider von Ulm* (2 vol., 1906). a story of early aviation, Eythe reveals an unusually balanced view for his period of the importance of machinery and technological achievements as opposed to that of the human element. His journals, *Wanderbuch eines Ingenieurs* (6 vol.), cover the years 1871–84. He died at Ulm on Aug. 25, 1906.

See T. Ebner, *Max Eyth, der Dichter und Ingenieur* (1906). (Er. H.)

EZEKIEL the prophet has recorded, or left us to infer, a few facts about himself. He had been a priest in Jerusalem, most likely a member of the clan of Zadok; while still young he was carried away to Babylonia in the First Captivity, 597 B.C.; his call to prophesy came in 593; after that, he lived in a house of his own, with his wife (xxiv. 18), among the Jewish exiles at Tel Abîb on the Grand canal ("the river Chebar" iii. 15), somewhere in the neighbourhood of Babylon or Kippur. His fellow-exiles evidently treated him with respect, and waited upon his words (viii. 1, xiv. 1, xxxiii. 31 f.); judging from xxix. 17, 571 B.C., his ministry lasted 22 years. Some notion of the man may be gathered from his book. He possessed in a high degree the prophetic temperament, a sensitiveness to the reality of the invisible world, which made him respond at once to the touch of the Divine hand (i. 3, viii. 1, etc.), a capacity for absorbed meditation, often passing into the state of trance. While in this condition he saw the moving throne (i.), performed a mimic siege of Jerusalem (iv.), felt himself transported from Babylonia to Jerusalem and back (viii.–xi.), saw the valley full of bones (xxxvii. 1–14), and the great temple of the future (xl. ff.). Often he made use of symbolic actions to enforce his message. At times these acts were performed in the presence of spectators; *e.g.*, xii. 3–16, xxiv. 15–24, xxxvii. 16–20; but some of them must have taken place in vision, while the trance lay on him; *e.g.*, iii. 1–3. Such, at any rate, seems the best account to give of the weird symbolism of ch. iv. and v. 1–4. He was subject to periods of speechlessness, iii. 25f., xxiv. 27; but when the impulse seized him, he would burst into poetry: xv. 1–5; xvii. 1–10; xix.; xxi. 14–22; xxvi. (in part); xxvii. (in part); xxxi. 2–9; xxxii. 2–16. These fine oracles stand out vividly from the monotonous background of his prose.

The Teaching of Ezekiel.—(A.) His conception of God is marked by a deep sense of awe: the holiness and sovereignty of Jahveh were impressed upon the prophet in the vision which constituted his call (ch. i.). Jahveh will brook no rival, and therefore will punish Israel for its disloyalty and the heathen for their false notions of His divinity and power; His motive, whether in punishment or mercy, is to bring about the recognition of His sole Godhead: "and they, or ye, shall know that I am Jahveh" sounds like a refrain throughout the book. Ezekiel thinks in symbols; the ultimate, according to his view, finds expression in the concrete. (B.) Far away in Babylonia, his attention was riveted upon the course of events at home. He denounces Israel's practical heathenism; he insists on the speedy overthrow of the Jewish state, in just requital for centuries of ill-doing (i.–xxiv.). That pessimism in reviewing Israel's past, which became characteristic of later writers, is strongly marked in Ezekiel. He rarely betrays any sympathy with his countrymen (except ix. 8, xi. 13). His hopes were fixed upon the exiles; they were not indeed wholly loyal, yet the future of the true faith lay with them. The message is stern and uncompromising; it was no time for half-measures; Israel's religion was at stake; that it survived at all was largely due to Ezekiel. (C.) As with Israel, so with the nations round, both the petty States that were nearest (xxv.), and the greater powers of Tyre (xxvi.–xxviii.) and Egypt (xxix.–xxxii., xxxv.): they deserve nothing but the severest judgment, and Nebuchadrezzar is to be the scourge (xxvi., xxx.). Curiously enough, Babylon itself comes in for no denunciation, probably because the prophet, in his bitterness against his own people, regarded the instrument of retribution as on the side of God. Ezekiel holds out no hope for the heathen. (D.) When the news reached Babylonia that Jerusalem had fallen ([586 B.C.] xxxiii. 21 f.), Ezekiel's tone changed. His prophecies of punishment had been fulfilled; he could now look forward to the restoration of the exiles. If he had previously argued the freedom and responsibility of the individual (xviii.), it was not with the aim of encouraging an individualistic type of religion, but of building up a community out of converted individuals. That is the ideal which henceforth occupies his mind: a new Israel, risen as it were from the dead, living in a land transformed, with Jahveh's sanctuary in the midst of them for evermore (xxxvi., xxxvii.). Yet there remains one more act in the Divine plan; the invasion and defeat of all the forces of heathenism, the acknowledgment of Jahveh by all, the final act of history (xxxviii., xxxix.). This apocalyptic conception had an immense influence upon subsequent thought. (E.) But Ezekiel was the most practical of dreamers. In the last section of the book, xl.–xlviii., he describes his vision of the restored temple, the centre of the new community, built on an imposing scale like one of the Babylonian sanctuaries (xl.–xlii.). The glory of Jahveh hallows it once more (xliii. 1–5); every source of defilement is removed; the only priests who minister there are to be the sons of Zadok (xliv. 15 ff.); and from the temple itself flows a mystic stream, cleansing, healing and beneficent (xlvii. 1–12).

Text and Authorship.—The textual criticism of Ezekiel was put upon a new footing by Cornill in 1888; and since that time progress has been made in the scientific use of the Greek and other versions for the correction of the Hebrew text, which is one of the most corrupt and obscure in the Old Testament. At present attention is being devoted to the higher criticism of the book, its literary structure, the origin of its ideas, the history and psychology which it contains. The book gives the impression of being arranged on a systematic plan, with four divisions, i.–xxiv., xxv.–xxxii., xxxiii.–xxxix., xl.–xlviii., in chronological order. Exact dates occur 13 times, but the sequence, though observed in the main, is broken on three occasions, xxvi. 1, xxix 17, xxxii. 1; the plan, therefore, is not so perfect as it looks On closer inspection, the four chief divisions turn out to be collections of oracles often independent of each other in time and contents; moreover, the date at the head of a section does not always hold good till the next date is given; for example, ch. vii, which stands under the year 593 (i. 1 f.), seems to belong to 586 B.C., and xl.–xlviii., headed 573 B.C., is mostly composed of far later material. In fact the impression of unity and chronological arrangement gives way under examination; the general plan may have been laid down by the prophet, but other hands have enlarged it. Editors must be held responsible for some, at least, of the headings, and for the double texts which are met with now and then, *e.g.*, ch. i. repeated partly in x., xxxiii. in iii., vii. 5–9=2–4, x. 19=xi. 22 f.

The element of conventionality and repetition which enters largely into the prose of Ezekiel may be in some measure due to scribes, who felt no scruple in glossing the text or altering it to suit their taste. A good instance of their methods is seen in ch. xxvii.; the splendid dirge over Tyre has been cut in two by the insertion of a prose passage, vv. 11–25*a*, which ruins the unity of the poem. Evidently Ezekiel's writings were studied with keen interest, as we may gather from the final section, xl.–xlviii. The first three chapters, with the additions of xliii. 1–12, xliv. 9–25, 28–30, xlvii. 1–12, are probably the work of the prophet; all that remains in xliii.–xlviii. is made up of fragments, which here and there reveal the technique of the priestly school. They are experiments in legislation. Most of them were never carried out, *e.g.*, the re-distribution of the land, xlvii. 13–xlviii. 35; some were modified later, *e.g.*, the two days of atonement, xlv. 18–20; in fact, what we come upon here is an early stage of the movement which in the end produced the Priestly Code. The task of reconstruction which Ezekiel had begun was carried on for years in priestly circles, and their tentative regulations were attached to his book, a natural place for them to find a lodging. Historically these enactments stand midway between Deuteronomy and P. Another law-book with which Ezekiel has relations is Lev. xvii.–xxvi., the law of holiness, as it is called; and in this case the relationship is so close that it points to a common time of origin and the same circle of ideas and interests.

The affinity between Ezekiel and Jeremiah is also remarkable. Thus both prophets insist, often in similar language, upon the overthrow of Jerusalem and the temple (*e.g.*, Jer. vii., xxvii.; Ezek. iv. f., vii., xix.–xxiv.); both give up the people of Judah in despair, and fix their hopes upon the exiles (Jer. xxiv., xxix. 10 ff.; Ezek. xi. 16–21, xxxvi. 24 ff.); both proclaim the responsibility of the individual (Jer. xxxi. 29 f.; Ezek. xviii.). They are equally certain that the dispersed will be gathered and return to their native land (Jer. xxiii. 3, xxix. 14, xxxi. 8 ff.; Ezek. xi, 17, xx. 34, 41 f.), and that a second David will come to rule over a united nation (Jer. xxiii. 5 f., xxxiii. 14–16; Ezek. xxxiv. 23 f., xxxvii. 24 f.); and while Jeremiah has not the priestly temper of Ezekiel, yet he too looks forward to the continuance of the Levitical ministry (Jer xxxiii. 18, 21 f.; Ezek. xliv. 15 ff.). Nevertheless. in spite of all these points of contact with other writings, Ezekiel has an impressive character of its own among the great books of prophecy; none exercised more influence upon subsequent thought and practice, and none perhaps baffles our understanding more.

A different conception from that outlined above has been worked out by Holscher (1924). Ezekiel. he maintains. was the prophet of doom and of nothing else; he saw but two visions: the one induced him to prophesy the fall of Jerusalem, the other revealed the idolatry in the temple, and roused his fury against the city and its allies, Tyre and Egypt. Ezekiel's own oracles are few, and invariably poetical in form; all else in the book is the work of a redactor, or of several redactors, who lived just before the time of Xehemiah (*c.* 444–430 B.C.). This view of the book does account for the difference, noticed by every reader, between the monotony of the prose and the passion of the lyrics; but the effect of Holscher's criticism is to empty the prophecies of all serious meaning, and it is applied on *à priori* principles in a ruthless way which excites distrust.

EZION-GEBER, seaport of Solomon and the later kings of Judah, now Tell al Kheleifeh 3 mi. N.W. of Aqaba, at the extreme northern end of the Gulf of Aqaba. The boundary between Israel and Jordan crosses the site. About 2 mi. S.E. of Kheleifeh are the remains of Roman Aelana (biblical Elath; now probably buried under the sand). In the Bible Ezion-geber is mentioned beside Elath or in its immediate vicinity (Deut. ii. 8: I Kings ix. 26). The site of Ezion-geber was independently found by Fritz Frank and Nelson Glueck, who excavated it for three seasons (1938–40). Glueck proved that the site had been occupied by a fortified settlement surrounded by strong walls from the 10th to the 4th century B.C. It was almost certainly founded about 950 B.C. by Solomon. who used it both as a port for his trade with Ophir (Somaliland) and as a copper refinery. Large-scale refinery installations show its industrial importance.

See Nelson Glueck, *The Other Side of the Jordan* (1940), *Rivers in the Desert* (1959). (W. F. A.)

EZRA (Greek ESDRAS), a Babylonian Jew, in the 4th or 5th century B C .led a caravan of Jews to Palestine. where he promoted the establishment of an exclusive. legalistic type of religion that became dominant in later Judaism. The history of his reforms is given in the Old Testament books of Ezra and Nehemiah and in I Esdras (see also EZRA AND NEHEMIAH, BOOKS OF; ESDRAS, FIRST BOOK OF).

Ezra is called a priest (Ezra vii, 11–12), and Josephus, in the *Antiquities,* following I Esd. ix, 40, calls him chief priest, reflecting the tradition that supplied Ezra with a genealogy linking him to the pre-exilic high priests, back to Aaron (Ezra vii, 1–5). He is also called a scribe (Ezra vii, 11–12), which may mean that he was an official secretary of Jenish affairs in the Persian court; but, because of Ezra's concern for the Law. the title is usually understood in the later sense of one who is especially concerned with the preservation and propagation of Jewish religious law. It is said (Ezra vii, 7–8) that he began his aork in the seventh year of King Artaxerxes, but since the Bible does not specify which Artaxerxes, the date of Ezra's journey to Judea is uncertain. Either 458 B.C. or 398 B.C is defensible (see EZRA AND NEHEMIAH. BOOKS OF).

The Ezra story is now included in the Chronicler's history of Israel (Chronicles-Ezra-Nehemiah), where a considerable part of the Ezra narrative has been transposed to the Book of Nehemiah as the result of a copyist's mistake. Because the Ezra story shows some of the distinctive language and ideas of the Chronicler, there are some, notably C. C. Torrey, who mistrust its historicity and even doubt the existence of Ezra, regarding him as a fictional creation of the Chronicler, as the personification of the Chronicler's interests or as a symbol embodying legalistic, priestly Judaism. There is, however, an increasing tendency to regard the Ezra story as essentially historical.

On his arrival at Jerusalem Ezra read the Law to the people and instructed them in its meaning. When he had won its acceptance by the community he accomplished important reforms in accordance with it (Ezra x. 3). Chief among these was the purging of the community of all non-Jewish elements by prohibition of mixed marriages and the banishment of all persons who were even partially of non-Jewish stock.

Nehemiah rather than Ezra was lauded in early lists of Jewish worthies (Ecclus. xlix. 13 and II Macc. i and ii), but as Jewish religion developed along the exclusive, legalistic lines favoured in Ezra's reforms. Ezra's stature increased mightily until he was regarded as a second Moses who restored the Jewish Law, the founder of modern Judaism.

Rowley, "The Chronological Order of Ezra and Nehemiah," *The Servant of the Lord,* pp. 131–159 (1952) ; C. C. Torrey, *Ezra Studies* (1910). (RD. A. B.)

EZRA, THIRD BOOK OF, is one of the two apocryphal Ezra books of the Bible. The title III Esdras is used for the so-called Greek Ezra (I Esdras) in Latin Bibles since Jerome. in the English Great Bible (1539) and in the Anglican Book of Common Prayer, art. vi. See ESDRAS. FIRST BOOK OF.

EZRA, FOURTH BOOK OF, commonly known as the Ezra Apocalypse, is one of the two apocryphal Ezra books of the Bible. It is appended to the Vulgate Bible as IV Esdras. In the English Bible it is the second of the apocryphal books and is numbered II Esdras. See ESDRAS. SECOND BOOK OF.

EZRA AND NEHEMIAH, BOOKS OF, two books of the Old Testament. ranking among the Hagiographa, or Writings. Along with the Books of Chronicles, Ezra and Nehemiah once formed a history of Israel from Adam to the 4th century B.C.. written about 350 B.C. by an anonymous "Chronicler." Its purpose seems to have been to trace the origin of the temple and to show the antiquity and authenticity of its cultus and of the formal, legalistic type of religion that dominated later Judaism. Most of this history is written in the distinctive language and style of the Chronicler. and it is permeated with his religious ideas. Later Jewish scholars severed the Books of Chronicles, which mere largely dependent upon earlier biblical books. from the postexilic history of the Persian period which did not duplicate material already in the Bible. The unique material was then called "Ezra," and talmudic tradition regarded the reformer Ezra as its author. At least as late as Melito of Sardes (A.D. 170) Ezra-Yehemiah formed one book called Ezra. In the Codex Vaticanus of the Greek Bible and in I Esdras the narrative proceeds directly from Ezra into the Book of Nehemiah without indicating a break (see ESDRAS. FIRST BOOK OF). Division into two books is first mentioned by Origen (3rd century A.D.), and the actual separation is encountered first in the Vulgate version, where the Book of Nehemiah appears as II Esdras. A separate Book of Nehemiah was not found in the Hebrew Bible until the Bomberg edition (A.D. 1525). (For a table outlining the Ezra literature, see ESDRAS, SECOND BOOK OF.)

Scholars have differed considerably in their opinions regarding the character of the books of Ezra and Nehemiah and their historical value. Some (*e.g.,* C. C. Torrey) have regarded the Chronicler as a novelist who freely composed his story for apologetic purposes, with little or no use of documentary sources. Such records as are quoted are believed to be forgeries, and the Chronicler's work is regarded as fiction with no value as history. Others consider the Chronicler to have been an editor rather than an author. His use of earlier biblical writings can be demonstrated in the Books of Chronicles, and works no longer preserved are cited in Ezra-Nehemiah (*e.g.,* Neh. vii, 5; xii, 23). It may be assumed. where the Chronicler's sources have disappeared, that he used the same editorial techniques of copying and rewriting, omission and supplementation, that can be observed where his biblical sources are still available to serve as a check. Undisputed is his use of the personal memoir of Nehemiah as a source (see below). Less clear is the nature of his Ezra source, since the Chronicler's own characteristics are most conspicuous in the Ezra story. The Chronicler's liking for lists, clearly indicated also in the Books of Chronicles, is demonstrated also in Ezra-Nehemiah. He presents not only inventories of animals and gifts to the temple but also genealogies, lists of leaders in civil projects. census reports and lists of temple ministrants.: designated by class. The lists are often such as may have been preserved as temple records.

Among the Chronicler's sources in Ezra is a collection of what purport to be official documents issued during the reigns of several Persian kings, written in Aramaic, one of the official languages of the Persian empire (Ezra iv. 7–vi, 18). These documents, reflecting the continual harassment of the Jews who were attempting to restore their city, have been called the Chronicler's forgeries, but they are probably an earlier assemblage of records which the Chronicler used to account for the delay in rebuilding the temple (Ezra iv, 23–24). He misunderstood his source. in part, for Ezra iv. 11–16 is concerned with the building of the city wall rather than the temple. The royal commission granted to Ezra (Ezra vii, 12–26) is also written in the Aramaic language.

The text of Ezra-Nehemiah is not in its original order. Its faulty Persian chronology may have been correct in the Chronicler's Aramaic source, but because he was more concerned with the history of the temple than with accurate chronology. the Chronicler arbitrarily shifted the text of Ezra iv. 6–23 (Artaxerxes) from its original place after Ezra v, 1–vi. 18 (Darius. who was in fact a predecessor of Artaxerxes) to its present location. This permitted his narrative to flow without interruption from the completion of the temple and its dedication (Ezra vi. 15–18) to the reinstitution of cultic services, as preliminary to the story of Ezra (Ezra vii, 1–x, 44). A later editor transposed three chapters of the Ezra story (Neh. vii. 73b–x. 39) from its position after Ezra viii, 36 to its present place in the Book of Nehemiah. Such dislocation may have been due to faulty transmission of the text by a copyist confused by the close resemblance of Ezra ii. 68–iii, 1 to Neh. vii. 70–viii. la. The correct original order is still maintained in I Esdras and in Josephus' narrative. The original order of the Ezra story was thus Ezra vii–viii. Neh. viii–x; Ezra ix–x. At an early date a pagan story was interpolated into the Book of Ezra to show how Zerubbabel won the right to rebuild Jerusalem. It is preserved in I Esd. iii, 1–v, 6 and in Josephus' *Antiquities* but not in the Hebrew Bible.

Book of Ezra. — Evidence for the original union of the Book of Ezra with the Books of Chronicles is found in the duplication of II Chron. xxxvi. 22–23 at the beginning of the hook (Ezra i. 1–3a). In the I Esdras translation of the Book of Ezra the duplicated material begins with II Chron. xxxv. 1. The Book of Ezra has two parts: (1) postexilic history prior to Ezra (Ezra i–vi), consisting largely of the Aramaic documents (see above) ; and (2) the Ezra story (vii–x). of which part has been transposed to the Book of Nehemiah (Neh. vii. 73b–x).

The former part includes an account of the decree of Cyrus and the return of Jews from Babylonia to Judea during his reign (Ezra i–ii) and the record of Jewish attempts to rebuild Jerusalem and its temple despite the opposition of neighbouring peoples and Persian officials (Ezra iii–vi). The story of Ezra the "priest" and "scribe" (Ezra vii. 11–12) records Ezra's journey to Palestine in the time of Artaxerxes with a royal commission to institute Jewish law there (Ezra vii–viii); the account of the reading of the Law in Jerusalem and its acceptance by the people. who then pledge to support the temple (now found in Keh. vii. 73b–x. 39) ; and the purging of the Jewish community of all non-Hebrew persons after the Jews promised to keep separate from the "people of the land" (Ezra ix–x).

Because of the difficulty of identifying the Artaxerxes of Ezra vii, 7. the date of Ezra is not fixed. The Bible places him in Jerusalem before Nehemiah, presumably under Artaxerxes I (458 B.C.; this Artaxerxes reigned 464–423 B.C.). Since Nehemiah, when he arrived in Jerusalem in 445 B.C. (Neh. ii, 1). found no evidence of Ezra or his reforms but rather a social. economic and religious situation as bad as or even worse than that which Ezra encountered, and since neither Ezra nor Nehemiah mentions the other, it is unlikely that they were contemporaries in Jerusalem. The references that seem to indicate that they were (Neh. viii, 9; xii, 36) are later additions to the text Ezra probably came to Palestine in 398 B.C. under Artaxerxes II (reigned 404 to 358 B.C). By arbitrarily emending Ezra vii. 7 to the 37th rather than the 7th year. some would place the arrival of Ezra in Jerusalem in 428 B.C., while Nehemiah was absent from Jerusalen~.

Since the Chronicler's language. style and ideas are encountered through the Ezra story, a genuine Ezra narrative, apart from the Chronicler's contribution, cannot be isolated. Some have regarded the portion of narrative written in the first person (Ezra vii, 27–28; viii, 1–34: cf. ix. 1–15) as an autobiographical nucleus; but others have called it a literary device of no significance, and there remains great diversity among scholars as to the extent of the genuine Ezra story. Judged by substance rather than style. the Ezra narrative seems to include Ezra vii. 11–x. 44 and Keh. vii. 73b -ix. 5.

Book of Nehemiah. — The only undisputed source for Jewish history between 520 and 175 B.C. is Nehemiah's memoir (Neh. i, 1–vii. 73a; xi. 1–2; xii. 27–43; xiii. 4–31). written not long after 432 B.C. (*cf.* Neh. v. 14: Artaxerxes I ascended the throne in 464). It is an accurate historical record preserved by the Chronicler with but little reworking or interpolation. As a memorial record it was perhaps intended to be placed before God in the temple nhere it would stir remembrance of Nehemiah's good works and assure a "name" for him who was probably a eunuch and who could not obtain it through descendants (Isa. lvi. 3–5). It is likely that the Nehemiah memoir circulated separately as late as about 180 B.C. (Ecclus. xlix. 13) and when II Macc. ii, 13 was written. probably between 100 B.C. and A.D. 70. Although I Esdras contains Neh. vii. 73–viii. 12 (I Esd. ix. 37–55) it does not have the Nehemiah story, and Josephus. who depends upon I Esdras. presents the Nehemiah memoir in a form somewhat different from that in the Bible. He gives the substance of Keh. i–vi; alludes to Neh. vii. 4 and. with no reference to Neh. ix–x. proceeds directly to Keh. xi, 1; xii, 27; and xiii. 10 ff.

The Book of Nehemiah includes (1) an account of how Nehemiah. a royal official in Susa. learned of the distress of Jerusalen~ and obtained a royal commission to rebuild the city (Neh. i, 1–ii. 10): 12) a record of the rebuilding of the wall of Jerusalem despite opposition by Samaritans. Ammonites and Arabs (Neh. ii. 11–iv. 23: vi. 1. 15; vii. 1) and of attempts to entrap and assassinate Nehemiah (Neh. vi. 1–14. 17–19); (3) a description of the repopulation of Jerusalem (Neh. vii. 2–73a; xi, 1–24) and the dedication of the city wall (Neh. xii. 27–43); (4) an account of the social and religious reforms instituted by Nehemiah. including the prohibition of usury leading to the enslavement of Hebrews (Neh. v. 1–13). the reinstitution and organization of temple services that had been neglected (Neh. vii. 1; xii. 44–47; xiii. 4–14. 30–31). Sabbath reforms (Neh. xiii. 15–22) and the purging of Jerusalem of all non-Hebrew persons (Neh. xiii. 1–3. 23–30). In Neh. v, 14–19 Nehemiah asserts the policies of his administration which reflected his generosity and self-sacrifice.

After 12 years as administrator in Jerusalem (Neh. v, 14). Nehemiah returned to his king in the 32nd year of Artaxerxes I (433–432 B.C.; Neh. xiii. 6). According to Neh. xiii. 6–7 something later induced him to return to Jerusalem for an indeterminate period. The reforms described in Neh. xiii are presumably those of his second administration. C. C. Torrey believed that Nehemiah's work was concluded with the completion of the city walls and that Neh. xiii is the Chronicler's fiction, utterly worthless as history. While Neh. xiii, 1–3 is certainly the Chronicler's work and his hand is observable elsewhere in Neh. xiii. which is concerned with such subjects as greatly appealed to the Chronicler. the vivid forcefulness of the chapter is in keeping with the activity of Nehemiah recorded in his memoir and it is probable that the kernel of Neh. xiii. 4–31 is part of Nehemiah's memoir—a description of his solving of problems that had arisen during his absence from Jerusalem.

EZZELINO DA ROMANO (1194–1259). Ghibelline lord of Verona. Vicenza and Padua. was born on April 25. 1194. of a German family from Franconia that had been enfeoffed by the emperor Conrad II early in the 11th century with lands in northeastern Italy including the castle of Romano near Vicenza. A ruthless leader, feared and hated for his coldly deliberate cruelty, Ezzelino was prominent for nearly 40 years in the wars and factions of his native region and was also the first Italian despot to seize and hold authority successfully for any length of time (from 1236 to 1259).

His career began in 1226 when he became Ghibelline *podestà* of Verona. but four years later he lost the city. The fight went on uncertainly for several years until in 1236–37, acting in the name and with the help of the emperor Frederick II (*q.v.*), Ezzelino resumed control of Verona and took Vicenza and Padua as well. In Nov. 1237 he fought on the imperial side at Cortenuova; in 1238 he married Frederick's natural daughter, Selvaggia; and in 1230 he was appointed imperial vicar of the march of Treviso. Ezzelino thus built up his despotism less from within than by alliance with the emperor against their common enemies; and it was this more than loyalty that bound him to the Hohenstaufen dynasty. With little care for formal offices like that of *podestà*, Ezzelino sought and won actual power and independence, so that when Frederick II died in 1250 his position was not immediately affected. In spite of his ferocity, however, his rule was under constant challenge from hostile neighbours and the papacy. In 1254 he was excommunicated, and shortly after a crusade was proclaimed against him. Then. in 1259. he quarreled with the other Ghibelline leaders. Oberto Pelavicino and Buoso da Dovara. He was wounded and captured in battle at Cassano on Sept 27, 1259. and died four days later, refusing both medical aid and peace with the church He left no issue.

Ezzelino was commemorated as a tyrant in Dante's *Inferno* and in a tragic drama. the *Ecerinis,* written in the Latin manner by the early Paduan humanist Albertino Mussato.

EZZO (EHRENFRIED) (*c.* 954–1024), count palatine in Lorraine. was the son of a certain Hermann (d. c. 1000). also a count palatine in Lorraine who had possessions in the neighbourhood of Bonn. Having married Matilda (d. 1025), a daughter of the emperor Otto II, Ezzo came to the front during the reign of his brother-in-law. the emperor Otto III (983–1002); his power mas increased owing to the liberal grant of lands in Thuringia and Franconia which he received with his wife, and some time later his position as count palatine was recognized as a hereditary dignity. Otto's successor. the emperor Henry II. was less friendly toward the powerful count palatine, though there was no serious trouble between them until 1011; but some disturbances in Lorraine quickly compelled the emperor to come to terms. and the assistance of Ezzo was purchased by a gift of lands. Henceforward the relations between Henry and his vassal appear to have been satisfactory. Ezzo died at Saalfeld on March 21, 1024. He left three sons, among them being Hermann, archbishop of Cologne from 1036 to 1056, and Otto, who was for a short time duke of Suabia; and seven daughters, six of whom became abbesses.

F THIS letter corresponds to the sixth letter of the Greek, Etruscan, and Latin alphabets. known to the Greeks as digamma. The sound represented by the letter in Greek was a labial semivowel similar to English *w*. This sound had disappeared early from the Ionic and Attic Greek dialects, so that the Ionic alphabet, which eventually came into general use in Greece, contained no digamma. It was retained, however, for some time in many local dialects and alphabets, including that from which the Etruscan (and through it the Latin alphabet) was derived.

The form of the letter in Greek was Ϝ, F, or Ϲ, none of which forms occur in the Semitic alphabets. Its origin in the Greek alphabet has been a matter of dispute, some maintaining

CLASSICAL LATIN AND ONWARDS		F

THE DEVELOPMENT OF THE LETTER "F" FROM THE PHOENICIAN THROUGH THE CLASSICAL LATIN TO THE PRESENT FORM

that it descends from Semitic *vau* Y, others. far less convincingly, maintaining that it was merely differentiated from the preceding letter Ǝ by the omission of a horizontal stroke. In either case it is probable that the Greeks were not the innovators. since a form of the letter (ꟻ) occurs in the Lydian alphabet. The letter nas probably contained in an Asianic alphabet from which the Greek, Lydian and Etruscan were derived.

In some very early Latin inscriptions F was used in combination with h to represent the unvoiced labial spirant (English *f*), as in the word FREFEAKED "he made." The h was soon dropped, and the sound represented by the letter F alone. It was not required in Latin to represent the bilabial semivowel (w), for the Latins had taken the letter V to represent both this sound and the corresponding vowel (*u*). F has represented the unvoiced labial spirant ever since.

In the Faliscan alphabet the letter had the curious form ↑, and in Latin there was a form I' corresponding to the form II of the preceding letter. Latin cursive of the 5th century A.D. employed a lengthened form F, and the letter was generally extended below the line in uncial writing. F.

In Irish writing of the 7th century the form was F, and the Carolingian with further rounding of the top ʃ. From this developed the modern minuscule *f*. *See* also ALPHABET.

In music, F is the name of the sixth note of the musical alphabet, otherwise the fourth note of the scale of C. It also gives its name to the bass clef. whose distinguishing sign denotes the F line. Further, it serves as an abbreviation for *forte* (f) and *fortissimo* (*ff*).

In chemistry, F is the symbol for fluorine.

For a discussion of phonetic correspondences involving the letter f in Indo-European languages, *see* GERMANIC LANGUAGES. (J. W. P.)

FA, the name given in French and Italian nomenclature to the fourth note of the natural scale of C., *i.e.*, F. In the tonic-sol-fa system and others, employing what is called a "movable Do" or tonic it is given to the fourth note of any major scale.

FABBRONI, ANGELO (1732–1803), Italian biographer, was born at Marradi in Tuscany on Sept. 25, 1732, and died at Pisa on Sept. 22, 1803. His principal work is *Vitae Italorum doctrina excellentium qui saeculis XVII et XVIII floruerunt,* 20 vol. (1778–99, 1804–05).

The last two volumes, published posthumously. contain a life of the author.

FABER, a family of German lead-pencil manufacturers. The business was founded in 1761 by Kaspar Faber (d. 1784) near Nuremberg and remained in the Faber family until 1903. The founder's great-grandson Johann Lothar von Faber (1817–1896) established branches of the company in New York city, Paris, London and Berlin. and agencies elsewhere in Europe. Johann contracted for exclusive control of all graphite from the east Siberian mines. He also branched out into the manufacture of water colours and oil paints, inks, slates and slate pencils and drawing instruments. His factory became a model of efficiency for German and Austrian manufacturers. The German emperor gave him a patent of nobility and appointed him councilor of state.

Eberhard Faber (1822–1879), another great-grandson of the founder, in 1848 went to the United States and in 1849 established a business in his oun name and built the first U.S. pencil factory in 1861. (J. R. LT.)

FABER, FREDERICK WILLIAM (1814–1863), British hymn-writer and theologian, was born on June 28, 1814 at Calverley, Yorkshire. Educated at Harrow and at Balliol college, Oxford, he was elected fellow of University college in 1837. Meanwhile he had given up Calvinistic views, and had become an enthusiastic follower of John Henry Newman. In 1843, he became rector of Elton in Huntingdonshire, but after a prolonged mental struggle joined the Roman Catholic communion in Nov. 1845. He founded a religious community at Birmingham, called Wilfridians, which was ultimately merged in the oratory of St. Philip Neri, with Newman as Superior. In 1849 a branch of the oratory was established in London, first in King William street, and afterwards at Brompton, over which Faber presided till his death on Sept. 26, 1863. It is mainly as a hymn-writer that Faber is remembered. His other works include *Lives of Modern Saints* (1847 *sq.*); *The Blessed Sacrament* (1855); *The Creator and the Creature* (1858); *Growth of Holiness* (1854); *Spiritual Conference..* (1859); *The Foot of the Cross* (8 vols., 1853–60); and *Notes on Doctrinal Subjects*, 2 vols. (1866).

See J. E. Bowden, *Life and Letters of Fr. Faber* (2nd ed. 1888), and *A Brief Sketch of the Early Life of the late F. W. Faber, D.D.*, by his brother the Rev. F. A. Faber (1869).

FABER, FABRI or **FABRY** (surnamed STAPULENSIS), **JACOBUS** [Jacques Lefèvre d'Étaples] (c. 1455–1536), a pioneer of the Protestant movement in France, was born of humble parents at Étaples, Pas de Calais. He had already been ordained priest when he entered the university of Paris, where Hermonymus of Sparta was his master in Greek. He visited Italy before 1486, for he heard the lectures of Argyropulus, who died in that year; he formed a friendship with Paulus Aemilius of Verona. In 1492 he again travelled in Italy, studying in Florence, Rome and Venice, making himself familiar with the writings of Aristotle, though greatly influenced by the Platonic philosophy. Returning to Paris, he became professor in the college of Cardinal Lemoine. Among his famous pupils were F. W. Vatable and Farel; his connection with the latter drew him to the Calvinistic side of the movement of reform. At this time he began the publication, with critical apparatus, of Boëtius *(De Arithmetica)*, and Aristotle's *Physics* (1492), *Ethics* (1497), *Metaphysics* (1501) and *Politics* (1506). In 1507 he settled in the Benedictine Abbey of St. Germain des Prés, near Paris, where his former pupil, William Briçonnet, later cardinal bishop of Meaux, was abbot. He now began his Biblical studies, the first-fruit of which was his *Quintuplex Psalterium: Gallicum, Romanum, Hebraicum, Vetus, Conciliatum* (1509); the *Conciliatum* was his own version. This was followed by *S. Pauli Epistolae xiv. ex vulgata editione, adjecta intelligentia ex Graeco cum commentariis* (1512), a work of great independence and judgment. His *De Maria Magdalena et triduo Christi disceptatio* (1517) provoked violent controversy and was condemned by the Sorbonne (1521). At Briçonnet's invitation he went in 1520 to Meaux, and in 1523 published his French version of the New Testament. From this, in the same year, he extracted the versions of the Gospels and Epistles "à l'usage du diocèse de Meaux." Faber was protected by Francis I. and the princess Margaret, but Francis being in captivity after the battle of Pavia (Feb. 25, 1525), he was condemned and his works suppressed by commission of the parliament. With the other Meaux preachers he fled to Strasbourg, but, as soon as Francis returned, he with others, was recalled. Faber now became tutor to one of the king's sons. He issued *Le Psautier de David* (1525), and was appointed royal librarian at Blois (1526); his version of the Pentateuch appeared two years later. His complete version of the Bible (1530), on the basis of Jerome, took the same place as his version of the New Testament. Margaret (now queen of Navarre) led him to take refuge (1531) at Nérac from persecution. He is said to have been visited (1533) by Calvin on his flight from France. He died at Nérac in 1536.

See C. H. Graf, *Essai sur la vie et les écrits* (1842); G. Bonet-Maury, in A. Herzog-Hauck's *Realencyklopadie* (1898).

FABER (or LEFÈVRE), **JOHANN** (1478–1541), German theologian, styled from the title of one of his works "Malleus Haereticorum," son of one Heigerlin, a smith *(faber)*, was born at Leutkirch, Suabia, in 1478. He studied theology and canon law at Tübingen and at Freiburg im Breisgau, and became vicar of Lindau and Leutkirch and shortly afterwards canon of Basel. In 1518 Hugo von Landenberg, bishop of Constance, made him one of his vicars-general, and Leo X. appointed him papal protonotary. He was an advocate of reforms, in sympathy with Erasmus, and corresponded (1519–20) with Zwingli. While he defended Luther against Eck, he was as little inclined to adopt the position of Luther as of Carlstadt. His journey to Rome in the autumn of 1521 had the result of estranging him from the views of the Protestant leaders. He published *Opus adversus nova quaedam dogmata Lutheri* (1522), appeared as a disputant against Zwingli at Zürich (1523), and then put forth his *Malleus in haeresin Lutheranam* (1524). In 1526 he became court preacher to the emperor Ferdinand, and in 1527–28 was sent by him as envoy to Spain and England. He approved the death by burning of Balthasar Hubmeier, the Baptist, at Vienna on March 10, 1528. In 1531 he was consecrated bishop of Vienna, and combined with this (till 1538) the administration of the diocese of Neustadt. He died at Vienna on May 21, 1541. His works were collected in three volumes, 1537, 1539 and 1541.

See C. E. Kettner, *Diss. de J. Fabri Vita Scriptisque* (1737) Wagenmann and Egli in Herzog-Hauck's *Realencyklopädie* (1898).

FABERGÉ, PETER CARL (KARL GUSTAVOVICH FABERGÉ) (1846–1920), Russian goldsmith whose work, comparable to that of Benvenuti Cellini. ranks with the finest of all ages. Fabergé was born of Huguenot descent at St. Petersburg in 1846 and was educated in Dresden, Italy. France and England. Inheriting his father's establishment in 1870, he made a bold change from the exclusive design and manufacture of jewelry to the creation of objects of fantasy.

The workshop soon became famous for exquisite masterpieces: flowers. figure groups. animals and the celebrated imperial Easter eggs, which became the delight of Russian and other royalty throughout Europe and Asia. Alexander III commissioned the first of the eggs for his tsarina in 1884. The Fabergé studios in St. Petersburg and Moscow employed artists and skilled craftsmen who achieved wonders of imaginative. elfin delicacy until the revolution of 1917 ended the world of Fabergé. He died in exile in 1920. (M. C. Rs.)

FABERT, ABRAHAM DE (1599–1660), marshal of France, was the son of Abraham Fabert, seigneur de Moulins (d. 1638), a famous printer who rendered great services, civil and military, to Henry IV. At the age of 14 he entered the *Gardes françaises*, and from 1618 was almost constantly in service. He was a brilliant engineer, and at the siege of Stenay he introduced new methods of siegecraft which anticipated in a measure the great improvements of Vauban. In 1658 Fabert was made a marshal of France, being the first commoner to attain that rank. He died at Sedan on May 17, 1660.

See *Histoire du maréchal de Fabert* (1697); P. Barre, *Vie de Fabert* (1752); A. Feillet, *Le Premier Maréchal de France plébéien* (1869); Bourelly, *Le Maréchal Fabert* (1880).

FABIAN (FABIANUS), **SAINT** (d. 250), pope and martyr, was chosen pope in Jan. 236. He was martyred during the persecution under Decius on Jan. 20, 250, and was buried in the catacomb of Calixtus. He is said to have baptized the emperor Philip and his son, to have improved the organization of the church in Rome, to have appointed officials to register the deeds of the martyrs. and to have founded several churches in France.

FABIAN SOCIETY, a socialist society founded in 1883–84 by a small group in London who aimed at "reconstructing society in accordance with the highest moral possibilities." The name is derived from the Roman general Fabius Cunctator, whose elusive tactics in avoiding pitched battles secured his ultimate victory over stronger forces. The early members included George Bernard Shaw. Sidney Webb, Annie Besant (*qq.v.*), Edward Pease and Graham Wallas. Shaw and Webb, joined later by Webb's wife Beatrice, were the outstanding leaders for many years. In 1889, the society published *Fabian Essays in Socialism*, edited by Shaw; and since then it has sold in large numbers. It was reinforced in 1952 by *New Fabian Essays*, edited by R. H. S. Crossman. The

Fabians preferred John Stuart Mill and Stanley Jevons to Karl Marx; they put their faith in evolutionary socialism rather than revolution; and they considered that the utilitarian aim of the greatest happiness of the greatest number could be secured only by extensive action by the state in the economic field. They regarded the state, as a social machine to be captured and used for the promotion of social welfare, not as an instrument of class domination to be overthrown. At first, the Fabians attempted to permeate the Liberal and Conservative parties with socialist ideas, but later they helped to organize the separate Labour representation committee, which became the Labour party in 1906. The society is affiliated with the Labour party.

The rules of the society state that it consists of socialists: "It therefore aims at the establishment of a society in which equality of opportunity will be assured and the economic power and privileges of individuals and classes abolished through the collective ownership and democratic control of the economic resources of the community. It seeks to secure these ends by the methods of political democracy." However, all publications appear under the names of the individual authors who are alone responsible for the views expressed. and the rules require that research carried out by the society shall be free and objective. The society has thus attracted the intelligentsia of the Labour movement and provided it with the opportunity for expression and criticism.

The national membership reached a peak in 1946 with 5,089 members. Thereafter it declined sharply until 1956, but after that it rose gently again. The importance of the society has always been much greater than its size might suggest. Generally, nearly half the number of Labour members of parliament in the house of commons and a majority of the party leaders are Fabians; and in addition to the national society there are more than 80 local Fabian societies.

The principal activities of the society consist in the furtherance of socialism and the education of the public on socialist lines by means of meetings, lectures, discussion groups, conferences and summer schools; carrying out research into political, economic and social problems; and publishing books, pamphlets and periodicals. In 1931, the New Fabian Research bureau was established as an independent body. The bureau and the society amalgamated in 1938 to form a new and revitalized Fabian society. Since then research has formed an important part of the society's work, and many research pamphlets have been published.

In the first 20 or 30 years of its existence, much of the attention of the society was devoted to general arguments against capitalism and in favour of socialism. The tone was severely rational, practical and empirical. During this early period the society also stressed the importance of local government as a means of promoting collective ownership. The horizons have gradually widened, and Fabians have become as much interested in the social services as in the nationalization of industry. In 1940, the colonial bureau was established and thereafter produced a continuous stream of Fabian discussion and writing on colonial questions. The Fabian International bureau was started in 1941, as an integral part of the society, to cater to the growing concern of Fabians with foreign policy and the great issues of war and peace.

Many practical reforms can be traced in part to the work of Fabians: but much of the impact of Fabianism has been through the gradual permeation of Fabian ideas among teachers, civil servants, politicians, trade union officials and others in influential positions. The work of the society tended to become more specialized in dealing with such subjects as economic planning, social security, consumers' councils, leasehold enfranchisement, monetary policy and housing; but leaders of the society also encouraged it to deal with the problems of man in society in order to discover how iar people aspire toward equality, a classless society and a widely dispersed power of self-government. In approaching this problem, emphasis was less on doctrine than on sociological and psychological investigation.

FABIOLA (? –*c.* 399 A.D.), Christian noblewoman of Rome, credited with founding the first public hospital in western Europe, n-as a member of the great Fabian family. After her conversion to Christianity she worked closely with Jerome, like other women of her class who had accepted the new religion. Her immense wealth and energy she dedicated to the church with the intention of atoning for transgression against a church law in marrying a second time while her first husband, whom she had divorced, was alive. On the death of her second husband she began her career of charity. She not only founded the first general public hospital in the western part of the Roman empire, but, acting as physician and nurse, cared for the sick herself. According to Jerome no patient was so sick that she refused to nurse him. With Pammachius she also founded a hospice for pilgrims at Ostia and gave generously to other religious foundations throughout Italy and the Mediterranean islands. A woman of learning who knew Hebrew and Greek as well as Latin, she studied the Scriptures under the guidance of Jerome whom she followed to Bethlehem. There at her request, he wrote a treatise on the priesthood of Aaron and the priestly dress. Jerome's treatise on the 42 stopping places of the Israelites in the wilderness was also written for her, though she did not live to see it finished. When disturbances in the eastern empire made a sojourn there precarious Fabiola returned to Rome and died in her native city about 399 A.D. The Romans, remembering the solicitude she had displayed for them, attended her funeral in great numbers as a mark of the veneration in which they held her.

FABIUS, the name of a number of Roman soldiers and statesmen. The Fabian gens was one of the oldest and most distinguished patrician families of Rome. Its members claimed descent from Hercules and a daughter of the Arcadian Evander. From the earliest times it played a prominent part in Roman history, and was one of the two gentes exclusively charged with the management of the most ancient festival in Rome—the Lupercalia (Ovid, *Fasti,* ii, 375). The chief family names of the Fabian gens or clan, in republican times, were Vibulanus, Ambustus, Maximus, Buteo, Pictor, Dorso, Labeo; with surnames Verrucosus, Rullianus, Gurges Aemilianus, Allobrogicus (all of the Maximus branch). The most important members of the family are the following:—

1. MARCUS FABIUS AMBUSTUS, *pontifex maximus* in the year of the capture of Rome by the Gauls (390 B.C.). His three sons, sent as ambassadors to the Gauls when they were besieging Clusium, subsequently took part in hostilities (Livy v, 35). The Gauls thereupon demanded their surrender, on the ground that they had violated the law of nations; the Romans, by way of reply, elected them consular tribunes in the following year. The result was the march of the Gauls upon Rome, the battle of the Allia, and the capture of the city (Livy vi, 1).

2. Q. FABIUS MAXIMUS, surnamed Rullianus or Rullus, master of the horse in the second Samnite War to L. Papirius Cursor, by whom he was degraded for having fought the Samnites contrary to orders (Livy viii, 30), in spite of the fact that he gained a victory. In 31j B.C., when dictator, he was defeated by the Samnites at Lautulae (Livy ix, 23). In 310 he defeated the Etruscans at the Vadimonian Lake. In 295, consul for the fifth time, he defeated, at the great battle of Sentinum, the combined forces of the Etrurians, Umbrians, Samnites and Gauls (see ROME: History, II "The Republic"). As censor (304) he limited the freedmen to the four city tribes.

3. QUINTUS FABIUS MAXIMUS, surnamed *Cunctator* ("the delayer," from his cautious tactics in the war against Hannibal), grandson of the preceding. He served his first consulship in Liguria (233 B.C.), was censor (230) and consul for the second time (228). In 218 he was sent to Carthage to demand satisfaction for the attack on Saguntum (Livy xxi, 18). According to the well-known story, he held up a fold of his toga and offered the

Carthaginians the choice between peace and war. When they declared themselves indifferent, he let fall his toga with the words, "Then take war." After the disasters of the Trebia and Lake Trasimenus, Fabius was named dictator (Livy calls him prodictator, since he was nominated, not by the consul, but by the people) in 217, and began his tactics of "masterly inactivity." Manoeuvring among the hills, where Hannibal's cavalry was useless, he cut off his supplies, harassed him incessantly and did everything except fight. His steady adherence to his plan caused dissatisfaction at Rome and in his own camp. Minucius Rufus. his master of the horse, during the absence of Fabius at Rome. made a successful attack upon the enemy. The people then divided the command between Minucius and Fabius (Livy xxii, 1 j. 24; Polybius iii, 88). Minucius was led into an ambuscade by Hannibal, and his army was saved only by the opportune arrival of Fabius. Minucius confessed his mistake and henceforth submitted to the orders of Fabius (Livy xxiii. 32). At the end of the legal time of six months Fabius resigned the dictatorship. and the result of the abandonment of Fabian tactics was the disaster of Cannae (216). In 21 j and 214 (as consul for the third and fourth times) he was in charge of the operations against Hannibal together with Claudius Marcellus (Livy xxiii, 39). He laid siege to Capua, which had gone over to Hannibal after Cannae, and captured the important position of Casilinum; in his fifth consulship (209) he retook Tarentum. which had been occupied by Hannibal for three years (Livy xxvii, 15; Polybius xiii, 4; Plutarch, *Fabizis).* He died in 203. Fabius was a strenuous opponent of the new aggressive policy, and did all he could to prevent the invasion of Africa by Scipio. In his later years he became morose, and showed jealousy of rising young men, especially Scipio *(Life* by Plutarch; Livy xx–xxx; Polybius iii, 87–106).

4. Q. FABIUS VIBULANUS, with his brothers Caeso and Marcus, filled the consulship for seven years in succession (485–479 B.c.). In the last year there was a reaction against the family, in consequence of Caeso's espousing the cause of the plebeians. Thereupon the Fabii emigrated from Rome under the leadership of Caeso, and settled on the banks of the Cremera, a feu' miles above Rome. For two years they defended the city against the Veientes, until at last they were surprised and cut off. The only survivor of the gens was Quintus, the son of Marcus, who apparently took no part in the battle. This Quintus was consul in 467, 465 and 459, and a member of the second decemvirate in 450, on the fall of which he went into voluntary exile (Livy ii, 42, 48–50, iii, 1, 9, 41, 58, vi, 1; Dion Halic. viii, 82–86, ix, 14–22; Ovid, *Fasti*, ii, 195).

The Fabian name is met with as late as the 2nd century A.D. A complete list of the Fabii will be iound in de Vit's *Onomasticon;* see also W. N. du Kieu, *Disputatio* de *Gente Fabia* (1856), containing an account of 57 members of the iamily.

FABLE. With certain restrictions, the necessity of which will be shown in the course ot the article, we may accept the definition of "fable" which Dr. Johnson proposes in his *Life of Gay:* "A *fable* or *apologue* seems to be, in its genuine state, a narrative in which beings irrational, and sometimes inanimate *(arbores loquuntur, non tantum ferae)*, are, for the purpose of moral instruction, feigned to act and speak with human interests and passions." The description of Jean de la Fontaine, the greatest of fabulists, is a poetic rendering of Johnson's definition:

> Fables in sooth are not what they appear;
> Our moralists are mice, and such small deer.
> We yawn at sermons, but we gladly turn
> To moral tales, and so amused we learn.

The fable is distinguished from the myth which grow and is not made, the spontaneous and unconscious product of primitive fancy as it plays round some phenomenon of natural or historical fact. The literary myth, such as, for instance, the legend of Pandora in Hesiod or the tale of Er in the *Republic* of Plato, is really an allegory, and differs from the fable in so far as it is self-interpreting; the story and the moral are intermingled throughout. Between the parable and the fable there is no clear line of demarcation. The soundest distinction is drawn by Neander. In the fable human passions and actions are attributed to beasts; in the parable the lower creation is employed only to illustrate the higher life and never transgresses the laws of its kind. There is an affinity between the fable and the proverb. A proverb is often a condensed or fossilized fable, and not a few fables are amplified or elaborated proverbs.

With the fable, as we know it, the moral is indispensable. As La Fontaine puts it, an apologue is composed of two parts, body and soul. The body is the story, the soul the morality. But in the primitive beast-fable, which is the direct progenitor of the Aesopian fable, the story is told simply for its own sake, and is as innocent of any moral as the fairy tales of "Little Red Riding-Hood" and "Jack and the Beanstalk." Thus, in a legend of the Flathead Indians, the Little Wolf found in cloud-land his grandsires the Spiders with their grizzled hair and long crooked tails, and they spun balls of thread to let him down to earth; when he came down and found his wife, the Speckled Duck, whom the Old Wolf had taken from him, she fled in confusion, and this is why she lives and dives alone to this very day. Such animal myths are as common in the new world as in the old, and abound from Finland and Kamchatka to the Hottentots and Australasians.

From these beast-fables of savages must be derived, through some common store of primitive moralizing, the fables of Greece and India. In the form in which we have them the Greek fables are the older: there is a fable of true type in Hesiod. In the latter part of the 5th century B.C. they became connected with the name of Aesop (*q.v.*). The first collection we hear of was made about 300 B.C. These Greek fables are best represented by the verse collection of Babrius (*q.v.*) made about AD. 200. An inferior version is found in the Latin of Phaedrus (early part of the 1st century). Phaedrus and a third ancient fabulist Avianus (4th century) were textbooks in medieval schools and were constantly imitated and expanded. The oldest Indian collection, the *Panchatantra*, goes back to Buddhist sources of the 4th century or earlier. The *Httopadesa* is a medieval form of the same work, the fables being strung together on a thread of narrative. As *Kalilah* and *Dimnah* or *Fables of* **Bidpni** *(Pilpay)* the Indian fables passed through Old Persian and Arabic into Latin, and joined the stream flouing from the Latin fabulists. thus fertilizing the rising vernacular literatures with a variety of *motifs* which could be used either for entertainment or edification. One of the most successful medieval collections is that of Odo of Cheriton. a Kentish preacher of the 12th century, who published separately the fables he had used in his sermons.

Modern Literature. — As the supremacy of Latin declined, the fable took a new life in the modern languages. Not only were there numerous adaptations of Aesop, known as Ysopets, but Marie de France in the 13th century composed many original fables, some rivalling La Fontaine's in simplicity and gracefulness. Later, also, fables were not wanting, though not numerous, in the English tongue. Geoffrey Chaucer has given us one, in his Nonne Preestes Tale, which is an expansion of the fable *Don Coc et don Werpil* of Marie de France; another is Lydgate's tale of The Churl and the Bird.

Several of Odo's tales, like Chaucer's story, can be ultimately traced to the History of Reynard the Fox. This great beast-epic is known to us in three forms, Latin, French and German, each with independent episodes, but all woven upon a common basis, and it probably took shape in Picardy in the 10th or 11th century. The Latin form is probably the earliest, and next the German versions. The French poem of more than 30,000 lines, the *Roman du Rénard,* belongs probably to the 13th century. In 1498 appeared *Reynke de Voss,* almost a literal version in Low Saxon of the older Flemish poem, *Reinaert de Vos.* Hence the well-known version of Goethe into modern German hexameters was taken. We have here no short and unconnected stories. Materials, partly borrowed from older apologues, but in a much greater proportion new, are worked up into one long and systematic tale. The moral, so prominent in the fable proper, shrinks so far into the background that the epic might be considered a work of pure fiction, an animal romance recounting a contest maintained successfully, by selfish craft and audacity, against enemies of all sorts, in a half-barbarous and ill-organized society.

France alone in modern times has attained any pre-eminence in the fable, and this distinction is almost entirely owing to one author. Marie de France in the 13th century, Gilles Corrozet, Guillaume Haudent and Guillaume Gueroult in the 16th, are now studied mainly as the precursors of La Fontaine, from whom he may have borrowed a stray hint or the outline of a story. The unique character of his work has given a new word to the French language: other writers of fables are called *fabulistes,* La Fontaine is named *le fablier.* He is a true poet; his verse is exquisitely modulated; his love of nature often reminds us of Virgil, as do his tenderness and pathos (*see,* for instance, "The Two Pigeons and Death and the Woodcutter"). He is full of sly fun and delicate humour; like Horace he satirizes without wounding, and "plays around the heart." Lastly, he is a keen observer of men. The nhole society of the 17th century, its greatness and its foibles, its luxury and its squalor, from *Le grand monarque* to the poor *manant,* from his majesty the lion to the courtier of an ape, is painted to the life. To borrow his own phrase, La Fontaine's fables are "une ample comédie à cent actes divers." Rousseau did his best to discredit the *Fables* as immoral and corruptors of youth, but in spite of *Émile* they are studied in every French school and are more familiar to most Frenchmen than their breviary. Among the French successors of La Fontaine the most distinguished is Jean Pierre de Florian: among foreigners who have worked in his vein are the Spaniard Tomás de Yriarte, the Russian Ivan Andreevich Krylov, and the Italian Pignotti. John Gay's *Fifty-one Fables in Verse* (1727) has much of the charm of La Fontaine. John Dryden's *Fables* (1699) are adaptations of Chaucer's and Boccaccio's tales and Ovid's *Metamorphoses* and are fables only in name.

The fables of Gotthold Lessing represent the reaction against the French school of fabulists. "With La Fontaine himself," says Lessing, "I have no quarrel, but against the imitators of La Fontaine I enter my protest." His attention was first called to the fable by Christian Gellert's popular work published in 1746 Gellert's fables were closely modelled after La Fontaine's, and were a vehicle for lively railings against women, and hits at contemporary follies. Lessing's early essays were in the same style, but his subsequent study of the history and theory of the fable led him to discard his former model as a perversion of later times, and the "Fabeln," published in 1759, are the outcome of his riper views. Lessing's fables, like all that he wrote, display his vigorous common sense, but he has little of La Fontaine's sly humour and lightness of touch. On the other hand, he has the rare power of looking at both sides of a moral problem; he holds a brief for the stupid and the feeble, the ass and the lamb; and in spite of his formal protest against poetical ornament, there is in not a few of his fables a vein of true poetry, as in the Sheep (ii, 13) and Jupiter and the Sheep (ii, 18). But the monograph which introduced the *Fabeln* is of more importance than the fables themselves. According to Lessing the ideal fable is that of Aesop. All the elaborations and refinements of later authors, from Phaedrus to La Fontaine, are perversions of this original. The fable is essentially a moral precept illustrated by a single example, and it is the lesson thus enforced which gives to the fable its unity and makes it a work of art.

FABLIAU. The entertaining tales in eight-syllable rhymed verse which form a marked section of French mediaeval literature are called *fabliaux,* the word being derived by M. Littré from *fablel,* a diminutive of *fable.* It is a mistake to suppose, as is frequently done, that every legend of the middle ages is a fabliau. In a poem of the 12th century a clear distinction is drawn between songs of chivalry, mar or love, and *fabliaux,* which are recitals of laughter. A fabliau always related an event; it was usually brief, containing not more than 400 lines; it was neither sentimental. religious nor supernatural, but comic and gay. About 150 fabliaux have come down to us more or less intact; a vast number have doubtless disappeared. As early as the 8th century fabliaux must have existed, since the faithful are forbidden to take pleasure in these *fabulas inanes* by the *Paenitentiale* of Egbert. But the earliest surviving fabliau is that of *Richeut,* which dates from 1159. This is a rough and powerful study of the coarse life of the day, with little plot, but engaged with a realistic picture of manners. Such poems, but of a more strictly narrative nature, continued to be produced, mainly in the north and northeast of France, until the middle of the 14th century. It does not seem probable that any ancient or exotic influences were brought to bear upon the French jongleurs, who simply invented or adapted stories of that universal kind which springs unsown from every untilled field of human society. More remarkable than the narratives themselves is the spirit in which they are told. This is full of the national humour and the national irony, the true *esprit gaulois.* A very large section of these popular poems deals satirically with the pretensions of the clergy. There are also tales whose purpose is rather voluptuous than witty, and whose aim is to excuse libertinage and render marriage ridiculous. Among these are prominent *Court Mantel* and *Le Dit de Berenger.* Yet another class repeated, with a strain of irony or oddity, such familiar classical stories as those of Narcissus, and Pyramus and Thisbe.

The object of the writers was the immediate amusement of their audience; by reference to familiar things, they hoped to arouse a quick and genuine merriment. Hence in the fabliaux we get closer than elsewhere to the living diction of mediaeval France. Such scholars as Gaston Paris and Paul Meyer have praised, in the general laxity of style and garrulity of the middle ages, the terseness of the jongleurs; in the period of false ornament, their fidelity to nature; in a time of general vagueness, the sharp and picturesque outlines of their art. One feature of the fabliaux, however, cannot be praised and yet must not be overlooked. In no other section of the world's literature is the scorn and hatred of women so prominent. It is difficult to account for the antifeminine rage which pervades the fabliaux, and takes hideous shapes in such examples as *Le Valet aux deux femmes, Le Pêcheur de Pont-sur-Seine* and *Chicheface et Bigorne.* Probably this was a violent reaction against the extravagant cult of woman as expressed in the contemporary *lais* as well as in the legends of saints. We must remember, too, that those who listened were not nobles or clerks, they were the common people. The fabliaux were *fabellae ignobilium,* little stories told to amuse persons of low degree, who were irritated by the moral pretensions of their superiors.

The names of about 20 of the authors of fabliaux have been preserved, although in most cases nothing is known of their personal history. The most famous is the man uhose name, or more probably pseudonym, was Rutebeuf. He wrote *Frère Denyse* and *Le Sacristain,* while to him is attributed the *Dit d'Aristote,* in the course of which Aristotle gives good advice to Alexander. Fabliaux, however, form but a small part of the work of Rutebeuf, who aas a satirical poet of wide accomplishment and varied energy. Henri d'Andeli was an ecclesiastic, attached, it is supposed, to the cathedral of Rouen. Jean de Condé, who flourished in the court of Hainaut from 1310 to 1340, and who is the latest of the genuine writers of fabliaux, lived in comfort and security, but most of the professional jongleurs seem to have spent their years in a Bohemian existence, wandering among the clergy and the merchant class, alternately begging for money and food and reciting their mocking verses.

BIBLIOGRAPHY.—The principal authorities for the fabliaux are Anatole de Montaiglon and Gaston Raynaud, who published the text, in 6 vols., between 1872 and 1890. This edition supplemented the labours of Méon (1808–23) and Jubinal (1839–42). The works of Henri d'Andeli were edited by A. Heron in 1880, and those of Rutebeuf by Lion Clédat in 1891. *See* also the editions of separate fabliaux by Gaston Paris, Paul Meyer, C. D. Ebeling, August Schéler and other modern scholars. Joseph Bedier's *Les Fabliaux* (1925) is a useful summary of critical opinion on the entire subject.

FABRE, FERDINAND (1827–1898), French novelist who may be said to have founded the French regional novel with his studies of country life that seem to spring from the very soil of the Cévennes, was born at Bédarieux, Hérault, June 9, 1827. Brought up by his uncle, a country cure, he was sent to the seminary of Saint-Pons but, having no vocation, he began to write poems and went to Paris, where his *Feuilles de lierre* (1853) attracted attention. Illness sent him back to the country, where he wrote *Les Courbezon* (1862), describing the life of a country priest in the Cevennes. Of a score of similar novels—including *Julien Savignac* and *Mdlle de Malavielle* (1563) ; *Le Chevrier* and *Scènes de la vie rustique* (1868) ; *Barnabé* (1874) ; *Mon oncle Célestin* (1881) ; and *Lucifer* (1884)—the masterpiece is *L'Abbé Tigrane* (1873), which tells the story of an ambitious priest. who intrigues his way to a cardinalate, with such dispassionate realism that it mas attacked both by the church and by anticlericals. Fabre was appointed keeper of the Bibliothèque Mazarine in 1883 and died in Paris. Feb. 11, 1898. (R. DL.)

FABRE, JEAN HENRI (1823–1915), French entomologist who performed early research into animal behaviour, was born at St. Léons in Aveyron on Dec. 21, 1823. He taught successively at Carpentras, at the college of Ajaccio. Corsica, and in 1552 at the *lycée* of Avignon. Meanwhile he had taken his doctor's degree in Paris, devoting himself to the study of the life history, habits and instincts of insects, his sole occupation after his retirement to Serignan in 1871.

All his work was based on direct observation. Although the ways of all insects interested him, his attention was given chiefly to the Hymenoptera, Coleoptera and Orthoptera, as well as to spiders. Of the first: the wasps, with their skill in stinging their prey in the region of the nervous ganglia so as to paralyze it and preserve it living as food for their young, seemed to Fabre to show an intelligence irreconcilable with the theory of fixed habits. Other researches led him to oppose the theory of evolution. His observations and deductions concerning the relation between the animal and the human mind, and between entomology and agriculture, are detailed in *Annales des sciences naturelles* (1855–58) and in the 10 volumes of *Souvenirs entomologiques* (1879–1907; Eng. trans. by De bfattos. 1912 *et seq.*), which was crowned by the Institute of France. He was a member of many academies and scientific societies.

Fabre died at Sérignan, Provence, on Oct. 11, 1915.

FABRE D'ÉGLANTINE, PHILIPPE FRANÇOIS NAZAIRE (1750–1794). French dramatist and a prominent figure in the Revolution, mas born at Carcassonne in July 1750, the son of a draper. He added to his surname Fabre the appellation "d'Églantine," claiming without justification that he had won a golden eglantine in a literary competition organized by the academy of floral games at Toulouse. After publishing a poem, *L'Étude de la nature* (1783), dedicated to Buffon, he wrote a large number of comedies, the most celebrated being *Le Philinte de Molière* (1790), a self-styled sequel to Molière's *Le Misanthrope*, showing Philinte as a politically dangerous aristocrat and Alceste as a virtuous republican. Fabre's best-known work is the famous song, "Il pleut, il pleut, bergère." He was an energetic revolutionary, a close associate of Danton and Camille Desmoulins, a deputy in the National Convention and a member of the committee of public safety. He voted for the execution of Louis XVI, supporting his opinion with quotations from Rousseau. In spite of his meagre astronomical competence, he was *rapporteur* of the committee which drew up the republican calendar and was personally responsible for some of the nomenclature. Arrested on a charge of forgery in connection with the Compagnie des Indes, he was sentenced to death and guillotined on April 6, 1794. Opinion about his innocence has remained divided) but modern judgment denies it.

BIBLIOGRAPHY.—His *Oeuvres [dramatiques] choisies* mere edited by C. Nodier and P. Lepeintre (1824). His *Oeuvres politiques* were edited by C. Vellay (1914). *See* also C. FABRIANO, GENTILE DA: *see* GENTILE DA FABRIANO.

FABRIANO, a town and episcopal see of the bfarche, Italy, province of Ancona, from which it is 44 mi. S.W. by rail, 1,066 ft. above sea level. Pop. (1951) 12,409. It has been noted from 1276 for its paper mills. A number of the churches, several of which are of the 13th century, contain works by Allegretto Nuzi (1308–85) and other local masters. His pupil Gentile da Fabriano (1370–1427) was a painter of greater skill.

The medieval Palazzo del Podestà (13th century) is picturesque, and there are other interesting buildings. The municipal picture gallery also contains an interesting collection of pictures. The Archivio Comunale contains documents on watermarked paper of local manufacture going back to 1293–94. Cement, pottery and vats are also made. A branch railway leads from Fabriano to Urbino (*q.v.*).

FABRICIUS, GAIUS LUSCINUS (*i.e.*, "the one-eyed"), Roman general, mas the first member of the Fabrician gens who settled in Rome. He migrated to Rome from Aletrium (Livy ix, 43). In 285 he was one of the ambassadors sent to the Tarentines to dissuade them from making war on the Romans. In 282 B.C. (when consul) he defeated the Bruttians and Lucanians, who had besieged Thurii (Livy. *Epit.* 12). After the defeat of the Romans by Pyrrhus at Heraclea in 280, Fabricius was sent to treat for the ransom and exchange of the prisoners. All attempts to bribe him were unsuccessful, and Pyrrhus is said to have been so impressed that he released the prisoners without ransom (Plutarch, *Pyrrhus*, 18).

In 278 Fabricius was elected consul for the second time and was successful in negotiating terms of peace with Pyrrhus. Fabricius afterward gained a series of victories over the Samnites, the Lucanians and the Bruttians, and on his return to Rome received a triumph. He died poor, and provision had to be made for his daughter out of the funds of the state (Val. Max. iv, 4. 10).

FABRICIUS, JOHANN ALBERT (1668–1736). German classical scholar and bibliographer, was born at Leipzig. His father. Werner Fabricius, director of music in the church of St. Paul at Leipzig. was the author of several works, the most important being *Deliciae Harmonicae* (1656). Johann Albert studied under J. G. Herrichen and afterward at Quedlinburg under Samuel Schmid. At Leipzig he published anonymously (1688) his first work. *Scriptorum recentiorum decas*, an attack on ten writers of the day. His *Decas Decadum, sive plagiariorum et pseudonymorum centuria* (1689) is the only one of his works to which he signs the name Faber.

In 1693 Fabricius settled at Hamburg as librarian to J. F. Mayer. In 1696 he accompanied his patron to Sweden; and in 1699 succeeded Vincent Placcius in the chair of rhetoric and ethics, a post which he held till his death.

Fabricius is credited with 128 books. but very many of them were only books which he had edited. One of the most famed and laborious of these is the *Bibliotheca Latina* (1697, republished in an improved and amended form by J. A. Ernesti, 1773). The divisions of the compilation are, first, the writers to the age of Tiberius; second, thence to that of the Antonines; and third, to the decay of the language; a fourth gives fragments from old authors and chapters on early Christian literature. A supplementary work was *Bibliotheca Latina mediae et infimae Aetatis* (1734–36; supplementary volume by C. Schottgen, 1746. edited by Mansi, 1754). His *chef d'oeuvre*, however, is the *Bibliotheca Graeca* (1705–28, revised and continued by G. C. Harles, 1790–1812), a work which has justly been denominated *maximus antiquae eruditionis thesaurus*. Its divisions are marked off by Homer, Plato, Christ, Constantine, and the capture of Constantinople (1453), while a sixth section is devoted to canon law, jurisprudence and medicine.

Of his remaining works we may mention *Bibliotheca Antiquaria*, an account of the writers whose works illustrated Hebrew, Greek, Roman and Christian antiquities (1713); *Centifolium Lutheranum*, a Lutheran bibliography (1728); *Bibliotheca Ecclesiastica* (1718). His *Codex Apocryphus* (1703) is still considered indispensable as an authority on apocryphal Christian literature.

The details of the life of Fabricius are to be found in *De Vita et Scriptis J. A. Fabricii Commentarius* (1737), by his son-in-law, H. S. Reimarus, the well-known editor of Dio Cassius; *see* also C. F. Bahr in Ersch and Gruber's *Allgemeine Encyklopadie*, and J. E. Sandys, *Hist.* Class *Schol.*, iii (1908).

FABRICIUS, JOHANN CHRISTIAN (1745–1808). Danish entomologist and economist, whose scientific reputation rested upon the system of classification which he founded upon the structure of the organs of the mouth instead of the wings. He was born at Tondern, Jan. 7, 1745. He studied at Altona and Copenhagen and at Uppsala under Linnaeus. In 1769 he lectured on political economy and in 1775 was appointed professor of natural history, economy and finance at Kiel.

Fabricius died March 3, 1808. It is as an entomologist that his memory survives.

FABRICIUS AB AQUAPENDENTE, HIERONYMUS (GERONIMO or GIROLAMO FABRIZIO or FABRICI) (1537–1619), Italian anatomist and embryologist, one of the founders of modern embryology, studied at Padua, where he succeeded his master, Gabriel Fallopius, as teacher of anatomy and surgery, on the latter's death in 1562. Fabricius' studies of the effect of ligatures and the valves in the veins influenced the discoveries of his famous pupil, William Harvey. Fabricius was greatest as a teacher; he failed to follow his own discoveries to their logical conclusion. He died at Padua on May 21, 1619.

Fabricius' collected works were published at Leipzig in 1687 as *Opera omnia Anatomica et Physiologica*, but the Leyden edition, published by Xlbinus in 1738, is more complete.

FABRITIUS, CAREL (1624?–1654), Dutch painter whose few surviving works reveal an artist of great power. The date and place of his birth are unknown. From a description of Delft dated 1667, stating that he was killed in an explosion at Delft on Oct. 12, 1654, at about 30 years of age, it is inferred that he was born about 1624. He was a pupil of Rembrandt and appears as a serious and cultivated artist in the conversation on art of Rembrandt's pupils as reported by S. D. van Hoogstraten. In 16jo he married Agathe van Pruyssen, a widow in Delft, and in 1652 he entered the painters' guild in that city.

He was a master of the first rank, an independent spirit who did not lose his own individuality while studying under the great Rembrandt. He seems to have first established a reputation in painting mural decorations with views of architecture in perspective. But of these works nothing remains.

The earliest extant work is the hali-length portrait of Abraham de Notte in the Rijks museum at Amsterdam. Dated 1640, it is the work of a mature artist. A portrait of a man in the museum at Rotterdam was attributed to Rembrandt until the signature of Fabritius was discovered. The National gallery, London, has a splendid hali-length portrait of a soldier. In the same collection is the picture of "A Musical Instrument Dealer With a View of Delft." The museum at Schwerin contains "The Sentinel," dated 1654, and the Ferdinandeum at Innsbruck the picture of "Tobias and His Wife." In the Mauritshuis at The Hague is the famous "Goldfinch," signed and dated 1654. In distinction to Rembrandt, whose figures emerge modeled by the action of light from a dark background, the figures of Fabritius are silhouetted against a light background, a scheme which was adopted and developed by Fabritius' pupil, Jan van Delft Vermeer.

FABRIZI, NICOLA (1804–1885), Italian patriot, was born at Modena on April 4, 1804 He took part in the Modena insurrection of 1831, and attempted to succour Ancona, but was arrested at sea and taken to Toulon, whence he proceeded to Marseilles. Afterward he organized with Mazzini the ill-fated Savoy expedition. Taking refuge in Spain, he fought against the Carlists, and was decorated for valour on the battlefield (July 18, 1837) At the end of the Carlist war he established a centre of conspiracy at Malta, endeavoured to dissuade Mazzini from the Bandiera enterprise, but aided Crispi in organizing the Sicilian revolution of 1848. He took part in the defense of Venice and of San Pancrazio. Upon the fall of Rome he returned to Malta, accumulating arms and stores, which he conveyed to Sicily, after having, in 1859, worked with Crispi to prepare the Sicilian revolution of 1860. While Garibaldi was sailing from Genoa toward Marsala, Fabrizi landed at Pizzolo, and after severe fighting joined Garibaldi at Palermo. Under the Garibaldian dictatorship he was appointed governor of Messina and minister of war. Returning to Malta aiter the Neapolitan plebiscite, which he had vainly endeavoured to postpone, he was recalled to aid Cialdini in suppressing brigandage. While on his way to Sicily in 1862, to induce Garibaldi to give up the Aspromonte enterprise, he was arrested at Naples by Lamarmora. During the war of 1866 he became Garibaldi's chief of staff, and in 1867 fought at Mentana. In parliament he endeavoured to promote agreement between the chiefs of the left, and from 1878 onward worked to secure the return of Crispi to power, but died on March 31, 1885, two years before the realization of his object. His life was characterized by ardent patriotism and unimpeachable integrity. (H. W. S.)

FABYAN, ROBERT (d. 1513). English chronicler, belonged to an Essex family, members of which had been connected with trade in London. He married Elizabeth Pake, by whom he had a large family. He was a member of the Drapers' company, and served as sheriff in 1493–94. In 1496 he was one of those appointed to make representations to the king on the new impositions on English cloth in Flanders. Next year he was one of the aldermen employed in keeping watch at the time of the Cornish rebellion. He resigned his aldermanry in 1502, and spent his latter years on his estate in Essex. He died on Feb. 28, 1513.

Fabyan's Chronicle was first published by Richard Pynson in 1516 as *The New Chronicles of England and of France*. In this edition it ends with the reign of Richard III, and this probably represents the work as Fabyan left it, though with the omission of an autobiographical note and some religious verses, which are first found in the second edition, printed by John Rastell in 1j33 with continuations down to 1509 A third edition appeared in 1542, and a fourth in 1559 with additions to that year. The only modern edition is that of Sir Henry Ellis, 1811. There is evidence that Fabyan had continued his Chronicle to 1511, but no trace of the manuscript can be found.

Fabyan's own merits are little more than those of an industrious compiler, who strung together the accounts of his different authorities without any critical capacity. Nevertheless he deserves the praise which he has received as all early worker, and for having made public information which through Hall and Holinshed has become the common property of later historians, and has only recently been otherwise accessible. John Bale alleges that the first edition was burned by order of Cardinal Wolsey because it reflected on the wealth of the clergy; this probably refers to his version of the Lollards bill of 1410, which Fabyan extracted from one of the London Chronicles.

FACCIOLATI, JACOPO (1682–1769), Italian philologist, was born at Torriglia, near Padua, on Jan. 4, 1682. As professor of logic and regent of the schools, Facciolati was for 45 years the outstanding teacher of the seminary of Padua. He died at Padua on August 26, 1769.

His magnum opus is the *Totius Latinitatis Lexicon* (4 vol., 1771; rev. ed. by De Vit, 1858–87). In the compilation of this work the chief burden seems to have been borne by Facciolati's pupil Egidio Forcellini. It has been said that the whole body of Latinity, if it were to perish, might be restored from this lexicon. In 1808 a volume containing nine of Facciolati's *Epistles* was issued at Padua.

FACE, a term anatomically denoting the front part of the head, which, in the higher animals with backbones (vertebrates), houses the sense organs oi vision and smell as well as the mouth and jaws.

During evolution from prehuman, apelike forms to modern man (Homo *sapiens*), the iace became smaller in relation to the over-all size of the head. While brain and brain case (cranium) nearly doubled in volume, the jaws became shorter and the teeth simpler in form and smaller in size. In consequence the face receded beneath the forehead. Thus modern man exhibits an essentially vertical profile, in marked contrast to the protruding snout or facial muzzle of the gorilla, the chimpanzee and, to a lesser extent, such extinct forms of early man as Java and Peking man. The recession of the tooth-bearing portion of the jaws beneath the forehead left two distinctively human features: a prominent, projecting nose and a clearly defined chin.

The reduction in size of the face is usually attributed to the development of intelligence, which made possible the making and use of tools and weapons that, in turn. eliminated any advantage from the possession of large, tusklike teeth; and also to the acquiring of erect posture. which favoured forms with smaller, less protruding faces, since in these forms the head is more easily balanced on the vertical spine.

The facial features characteristic of the major physical groupings of mankind (Caucasoid, Mongoloid: Segroid) resulted from the same evolutionary processes responsible for creating racial differences generally within the species.

Typically. the Caucasoid face is long. with width ranging from narrow to medium broad; the nose is prominent. the bridge high; the lips are thin; facial hair in the male is abundant; and the contour of the profile ranges from straight to convex. The Mongoloid face tends to be moderately long and very broad, with prominent cheekbones and a wide jaw; the nose is moderately wide. the bridge low; the inner corner of the eye is covered by a skin fold (epicanthus); facial hair is sparse; the contour of the prohle tends to be flat and straight. The Segroid face tends to be short and narrow; the nose broad, the bridge low; the lips are thick; facial hair is sparse; and the jaws protrude, creating a forward-slanting profile.

Facial traits are not exclusive to any one grouping; for example, some Caucasians have wider noses than some Negroes. In evolutionary advancement, each major grouping possesses "primitive" as well as "advanced" traits. Thus the protruding jaws of the Negro are a "primitive" trait, the thick everted lips an "advanced" trait.

In individual development, face and brain case follow difierent patterns of growth. The brain and brain case attain 90% of adult size by the age of six years, while the face grows more slowly in concurrence with the enlargement of the nasal passages and the eruption of both sets of teeth. Viewed in profile. the face at birth is less than one-fifth the size of the brain case; by adulthood it has increased to nearly one-half. Facial dimensions increase most in depth. next in height (length) and least in width. The more sturdy appearance of the male face, as compared with the delicate features of the female face, is produced by the greater development of facial musculature and the enlargement of the facial sinuses in adolescence.

A research technique widely adopted after 1931, consisting of the use of serial X-ray pictures of the living subject, permits a more exact investigation of facial growth changes than was possible with caliper measurements. With this technique, measurements of different facial dimensions can be taken directly from the X-ray film and compared at several stages of development. Data bearing on facial growth in man have been gathered also through investigations of bone growth in animals. In such studies normal growth may be interfered with surgically, or dyes may be injected to stain the living bone to show areas and extent of growth. See also PHYSIOGNOMY; SKULL; RACES OF MANKIND.

(M. J. BR.)

FACILITATION, a term used in neurology to designate the favourable influence exerted over a conduction path by the passage of an impulse having an identical end effect with the impulse favoured. This facilitation of one nerve impulse by another may be successive or simultaneous. Activation of any reflex path leaves that path in a more favourable "set" for subsequent repetitions of the same response. Subliminal stimuli, simultaneously applied, may facilitate one another sufficiently to produce an overt response if these impulses are allied in a final common path. Facilitation probably occurs at the synapse. The facilitating influence exercised by one impulse on another is generally known as bahnung.

See C. S. Sherrington, *Integrative Action* of *the Nervous System.*

FACSIMILE TRANSMISSION, the electrical transmission of pictures, maps and other printed matter. dates from the work of Alexander Bain, who outlined the principles in a British patent in 1843. Arthur Korn in Germany and Edouard Belin in France were outstanding European contributors, while in the Cnited States major advances were made by Maurice Artzt. Austin G. Cooley, John V. L. Hogan, Pierre Mertz, Raleigh J. Wise, Charles J. Young and many others.

Many different equipment designs have been proposed, but practically all are based on the scanning of the original copy, one elemental area at a time, and representing the shade or tone of each area by a specified amount of electric current; this current then is used at the receiver to reproduce an image of the elemental area in the proper relative position and the correct shade of gray. The original is scanned by optical means, but recording may be accomplished by exposure of light-sensitive film, by electrothermal methods, by electrolytic action or through the use of carbon paper.

Fig. 1 is a block diagram of a telephotograph system typical of those used for transmission of news photographs. The original photograph is placed on the sending picture drum and unexposed photographic film on the receiving drum. Both drums are rotated at a very constant speed controlled by oscillators. and their rotation is synchronized or phased; that is, the edges of the film pass the recording position at the same time the edges of the original photo pass the scanning position. The lens and aperture combined with the rotational and axial movement of the sending drum dissect the picture into small elemental areas which are scanned one at a time. The photo tube converts the varying amounts of reflected light into corresponding electrical signals which are sent to the receiving station and there converted by the recording lamp, aperture and lens into a spot of light of proper intensity. Thus the film on

FIG. 2.— FACSIMILE SCANNER OF THE ROTARY-MIRROR TYPE

noise to reduce distortion in the signal. For transmission over radio circuits, frequency-modulation (FM) techniques are used (see RADIO).

A significant advance in transmitting photographs and detailed graphic data was achieved by employing Polaroid film, which can be developed without the use of darkroom equipment. The scanning method is shown in fig. 2. A fluorescent lamp illuminates the original picture, and the lens and mirror focus an image of the original on the aperture plate. As the mirror rotates, one elemental area after another of one scanning line is presented to the aperture and then to the photo tube. When one complete line has been scanned, the next face of the mirror is in position to start scanning the next line, the original copy having advanced by the height of a line. The same technique can be used for facsimile recording.

Another form of continuous scanner is shown in fig. 3. This is an exploded view and actually the image of the original; the coarse spiral, slit and fine spiral are as close as practical. An image of the original is focused (fig. 3[A]) on a scanning plane where the intersections of the transparent slit and five transparent turns of the fine spiral form five apertures as shown in fig. 3(B).

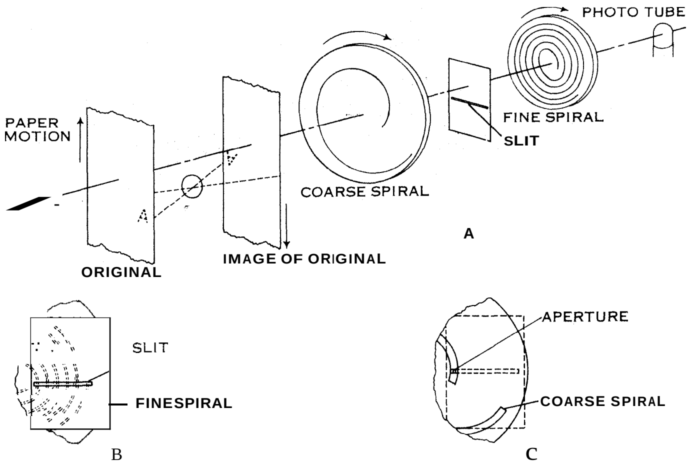

FIG. 3.— CONTINUOUS-FEED SCANNER SHOWING (A) EXPLODED VIEW; (B) DETAIL OF SLIT AND FINE SPIRAL WITH COARSE SPIRAL REMOVED; (C) DETAIL OF APERTURE FORMED BY INTERSECTION OF COARSE SPIRAL AND SLIT

However, the coarse scanning disk, containing one transparent spiral, is actually in front of the scanning plane, as shown in fig. 3(C), and the image reaches only one of the five apertures. The use of the fine spiral instead of a single-turn spiral improves scanning detail and minimizes a defect known as "jitter" which tends to make straight lines appear jagged.

In addition to photographic facsimile recorders, there is a large group of direct recorders, so named because a visible copy is produced during the recording process without need for subsequent photographic developing. Electrothermal. electrolytic or pigment transfer methods are usually used. The electrothermal process consists in the burning away of a white surface of a special recording paper. exposing a black subsurface. as current is passed through the paper. This type of facsimile recorder is used for transmission of telegrams, railroad ticket reservations and weather charts.

Electrolytic recorders depend upon chemical change as current is passed through an electrolyte impregnated in the recording paper. This change may utilize the metal of the electrode or may use chemicals entirely within the electrolyte. A helix wire wrapped around a drum in front of the paper and a straightedge behind the paper provide a traveling intersection of electrodes as the drum revolves. This type of recorder is often used as a monitor, enabling newspaper editors at their desks to view photos that are being received simultaneously in the darkrooms and to make a rapid selection of pictures to use in a newspaper edition.

Carbon paper recorders may be thought of as utilizing pigment transfer. Until the middle 1940s such recorders were extremely difficult to adjust and recording speed was slow. However. an improved system was developed using three recording heads mounted on a continuous belt. Carbon paper and ordinary paper feed from rolls. and marking takes place when the recording stylus applies pressure to the carbon paper.

Facsimile machines have been made which transmit a letter-size page in a fraction of a second. The operating speed for most facsimile equipment, however, is limited by the electrical characteristics of the circuit used for transmission. In most cases this is equivalent in signal-carrying capacity to a voice circuit but is specially designed to transmit a signal with minimum distortion. A typical picture machine operating over such a circuit might have the following characteristics: 96 scanning lines per inch, a rectangular elemental scanning area $\frac{1}{96} \times \frac{1}{138}$ in., 90 scanning lines per minute, copy size $8\frac{1}{2} \times 7$ in., transmission time about $7\frac{1}{2}$ min. (H. F. B.)

FACTOR, strictly "one who makes"; thus, in ordinary parlance, anything which goes to the composition of anything else is termed one of its "factors," and in mathematics the term is used of those quantities which, when multiplied together, produce a given product.

In a special sense, however—and that to which this article is devoted—"factor" is the name given to a mercantile agent (of the class known as "general agents") employed to buy or sell goods for a commission. When employed to sell the possession of the goods is entrusted to him by his principal, and when employed to buy it is his duty to obtain possession of the goods and to consign them to his principal. In this he differs from a broker (*q.v.*), who has not such possession, and it is this distinguishing characteristic which gave rise in England to the series of statutes known as the Factors Acts. By these acts, consolidated and extended by the act of 1889. third parties buying or taking pledges from factors are protected as if the factor were in reality owner; but these enactments have in no way affected the contractual relations between the factor and his employer, and it will be convenient to define them before discussing the position of third parties as affected by the act.

Factor and Principal

A factor may be appointed or he may be dismissed in the same way as any other agent. He may be employed for a single transaction or to transact all his principal's business of a certain class during a limited period or till such time as his authority may be determined. It does not matter that a factor carries on a separate business on his own account. either of. the same kind as that in which he is employed as factor, or of some other kind. A factor's duty is to sell or buy. as directed; to carry out with care, skill and good faith any instructions he may receive; to receive or make payment; to keep accounts and to render them to his principal regularly, or when requested to do so, and to hand over to his principal the balance standing to his principal's credit, without any deduction save for commission and expenses. A factor is bound to account for any moneys he receives for his principal, and if between receiving it and paying it over, the money is lost (as for instance if the factor deposited it with a banker who became insolvent), the loss must be borne by the factor. All express instructions he must carry out to the full. and generally speaking literally, provided they do not involve fraud or illegality, but under circumstances of emergency he may deviate from his instructions (as for instance when goods are perishing) and if in so doing he exercises reasonable and proper skill and care he will not be liable for any loss there may ensue. Where he is not given any express instructions, or on any point not covered by these, he must act bona fide and to the best of his skill and judgment. and he is bound to follow the usual practice of his particular business and any usages of the trade which may exist, if not inconsistent with his instructions or his position as factor, or unless. to a man of ordinary prudence, it would be manifestly disadvantageous to his employer's interests to do so. Many usages of businesses in which factors are employed have been proved in court, and may now be regarded as legally established. For instance, he may, unless otherwise directed. sell in his own name, and (apart from any express limit) at such price as to the best of his judgment he thinks proper, give warranties as to goods sold by him, sell by sample (in most businesses), give such credit as is usual in his business. receive payment in cash or as customary, and give receipts in full discharge, sell by indorsement of bills of lading, and insure the goods. He is not bound to insure goods unless to do so is according to the course of business with his principal. If he does effect an insurance he must see that all necessary risks are covered, satisfy himself as to the solvency of the underwriters. and disclose to them all material facts relating to the risk to be undertaken by them. It is his duty to clear the goods at the customs. take charge of them and keep them as safely as reasonable care and diligence will permit: give such notices to his principal and others as may be required, and in particular give punctual notice to his principal of all matters by which the rights or interests of the principal may be affected, as for instance the insolvency of a customer, or failure to effect an insurance. and if necessary take legal proceedings for the protection of the goods. On the other hand, he has not authority to delegate his employment, unless by usage of the trade or by express permission, or to barter, or to accept or negotiate bills of exchange except by authority of his principal and as between himsclf and his principal he has no right to pledge the goods, although as between the principal and the pledgee, an unauthorized pledge made by the factor may by virtue of the Factors Act 1889 be binding upon the principal. In the same way a factor has of course no right as between himself and his principal to sell goods in contravention of his principal's instructions, although as between his principal and the purchaser the sale may be binding upon the principal, It is, moreover. inconsistent with the factor's employment as agent that he should buy or sell on his own account from or to his principal.

On the due performance of his duties the factor is entitled to his commission, which is usually a percentage on the value of the goods sold or bought by him on account of his principal, regulated in amount by the usages of each business or by express agreement. Failing that, or any usage in the trade, the factor is entitled to a "reasonable" sum as commission. Sometimes the factor makes himsclf personally responsible for the solvency of the persons with whom he deals. in order that his principal may avoid the risk entailed by the usual trade credit. In such a case the factor is said to be employed on *del credere* terms, and is entitled to a higher rate of commission, usually $2\frac{1}{2}\%$ extra. Such an arrangement is not a contract of guarantee within the Statute of Frauds, and therefore need not he in writing. Besides his remuneration, the factor is entitled to be reimbursed by his principal for any expenses, and to be indemnified against any liabilities which he may have properly incurred in the execution of his principal's instructions. He cannot as a rule recover for any expenditure which is not expressly or impliedly covered by his instructions but he may do so in case of emergency if it is reasonable and in his employer's interests. For the purpose of enforcing his rights a factor has, without legal proceedings, two remedies. First, by virtue of his general *lien* (*q.v.*) he may hold any of his principal's goods which come lawfully to his hands in the course of his agency as security for the payment to him of any commission, out-of-pocket expenses, or even general balance of account in his favour, and in virtue of his particular lien he may hold any particular chattel in respect of which he has incurred expense. He may not sell the goods unless they have been entrusted to him for sale. in which case he may sell and claim a lien on the price. He can pledge the goods to the extent of his lien but no further. and exercise a lien on the money so raised. and by virtue of the Factors Acts the principal will not be able to recover the goods from the pawnbroker except by discharging the advance made by him The lien is lost if the goods are improperly sold or pledged, or the possession of them is parted with, or the factor takes security from his principal for the debt, or enters into any special arrangement with him, such as to give him credit Secondly, when by contracting in his own name he has rendered himself personally liable to pay for goods he has bought for his principal, and where he has consigned goods to his principal but not been paid, he may *"stop in transit"* subject to the same rules of law as an ordinary vendor; that is to say. he must exercise his right before the transit ends; and his right may be defeated by his principal transferring the document of title to the goods to some third person, who takes it in good faith and for valuable consideration (Factors Act 1839, and Sale of Goods Act 1893, s. 47). If the factor does not carry out his principal's instructions, or carries them out so negligently or unskilfully that his principal gets no benefit thereby, the factor loses his commission and his right to reimbursement and indemnity. If by such failure or negligence the principal suffers any loss, the latter may recover it as damages So too if the factor fails to render proper accounts his principal may by proper legal proceedings obtain an account and payment of what is found due; and threatened breaches of duty may be summarily stopped by an injunction. "An action will of course lie against a *del credere* agent for the price of goods sold to a purchaser who has failed to make payment." Criminal acts by the factor in relation to his principal's goods are dealt with by ss. 20 and 22 of the Larceny Act 1916.

PRINCIPAL AND THIRD PARTY

The rights of a third party as regards the power of a factor to bind his principal have been well-established at common law and amplified in the provisions of a special act.

(*a*) *At Common Law.*—The actual authority of a factor is defined by the same limits as his duty. the nature of which has been described; *i.e.*, firstly. by his principal's express instructions; secondly. by the rules of law and usages of trade. in view of which those instructions were expressed But his power to bind his principal as regards third parties is often wider than his actual authority; for it would not be reasonable that third parties should be prejudiced by secret instructions. given in derogation of the authority ordinarily conferred by the custom of trade; and, as regards them, the factor is said to have *"apparent"* or *"ostensible"* authority, or to be *held out* as having authority to do what is customary, even though he may in fact have been expressly forbidden so to do by his principal. But this rule is subject to the proviso that if the third party have notice of the factor's actual instructions, the "apparent" authority will not be greater than the actual. "The general principle of law." said Lord Blackburn in the case of *Cole* v. *North-Western Bank*, 1875, *LR.* 10, C.P.363, "is that when the true owner has clothed any one with apparent authority to act as his agent. he is bound to those who deal with the agent on the assumption that he really is an agent with that authority, to the same extent as if the apparent authority were real " Cnder such circumstances the principal is for reasons of common fairness precluded. or, in legal phraseology, *estopped,* from denying his agent's authority. On the same principle of estoppel. but not by reason of any trade usages, a course of dealing which has been followed between a factor and a third party with the assent of the principal will give the factor apparent authority to continue dealing on the same terms even after the principal's assent has been withdrawn; provided that the third party has no notice of the withdraual.

Such apparent authority binds the principal both as to acts done in excess of the actual authority and also when the actual authority has entirely ceased For instance, A. B receives goods from C D with instructions not to sell below 1s per lb ; A B sells at 10½d the market price; the buyer is entitled to the goods at 10½d because A B had apparent authority, although he exceeded his actual authority. On the same principle the buyer would get a good title by buying from A. B. goods entrusted to him by C D. even though at the time of the sale C. D had revoked A. B.'s authority and instructed him not to sell at all. In either case the factor is held out as having authority to sell, and the principal cannot afterwards turn round and say that his factor had no such authority. As in the course of his business the factor must necessarily make representations preliminary to the contracts into which he enters, so the principal will be bound by any such representations as may be within the factor's actual or apparent authority to the same degree as by the factor's contracts.

(b) Under the Factors Act, 1889.—The main object of the Factors Acts, in so far as they relate to transactions carried out by factors, has been to add to the number of cases in which third parties honestly buying or lending money on the security of goods may get a good title from persons in whose possession the goods are nith the consent, actual or apparent, of the real owners, thus calling in aid the principle of French law that "*possession vaut titre*" as against the doctrine of the English common law that "*nemo dat quod non habet.*" As regards sales by factors and the title which purchasers thereby acquire against the principal, the Factors Acts are mainly declaratory of the common law as stated above, but with this difference, that whereas at common law it was always an open question of fact to be determined by the court whether the principal had in truth held out his agent as having authority to effect the sale, the effect of the Factors Acts is that the principal is *deemed* to have authorized the agent by the fact of entrusting him with the goods. Under the act of 1889 it can be put even higher, and the agent is deemed to have authority by the mere fact of having the goods in his possession with the owner's consent, although there is no evidence of the owner having actually 'entrusted' them to him; the owner's 'consent' being presumed in the absence of evidence to the contrary (*Oppenheimer* v. *Attenboroztgh,* 1908, 1 K.B. 221, C.A ; *Oppenhcimer* v. *Frazer and Wyatt,* 1907, 2 K.B. 50, C.A.) The chief change, however, in the law relating specially to factors has been to put pledges by factors on the same footing as sales, so as to bind a principal to third parties by his factor's pledge as by his factor's sale. The Factors Act 1889 in part re-enacts and in part extends the provisions of the earlier acts of 1823, 1825, 1842 and 1877. Its most important provisions concerning sales, pledges and other dispositions by factors are as follows:—

Section II., s.s. 1. Where a mercantile agent is, with the consent of the owner, in possession of goods or of the documents or title to goods, any sale, pledge or other disposition of the goods made by him when acting in the ordinary course of business of a mercantile agent shall, subject to the provisions of this act, be as valid as if he mere expressly authorized by the owner of the goods to make the same; provided that the person taking under the disposition acts in good faith, and has not at the time of the disposition notice that the person making the disposition has not authority to make the same.

2. Where a mercantile agent has, with the consent of the owner, been in possession of goods or of the documents of title to goods, any sale, pledge or other disposition which would have been valid if the consent had continued shall be valid notwithstanding the determination of the consent; provided that the person taking under the disposition has not at the time thereof notice that the consent has been determined.

With regard to these provisions the following points should be noticed: (i.) the term 'notice' is stated by Chalmers (*Sale* of *Goods Act,* 10th ed. p. 166) to mean probably 'actual though not formal notice: that is to say, either knowledge of the facts or a suspicion of something wrong, combined with a wilful disregard of the means of knowledge.' The onus of proving good faith and want of notice is on the purchaser of the goods. (ii.) The 'consent' of the owner to the factor's possession of the goods is to be presumed in the absence of evidence to the contrary (s. 2, s.s. 4 of the Factors Act 1889). (iii.) Although the Factors Act may operate to make an unauthorized sale or pledge by a factor good as between principal and third party, nothing in the act makes such a sale or pledge good as between principal and factor, or operates to exempt the factor from civil or criminal liability (s. 12. s.s. 1 of the Factors Act 1889). (iv.) In order that s. 2, s.s. 1 and 2 of the Factors Act 1889 (quoted above) may apply, and a sale pledge or other disposition by the factor be good as between principal and third party, it is necessary that the goods should have been in the possession of the factor *in his capacity as such,* and not in some other capacity. If, for instance, a factor also carries on business as a warehouseman, and goods are entrusted to him not in his capacity as factor, but in his capacity as warehouseman, and solely to be warehoused, any disposition of the goods by him will not be covered by the Factors Act.

Enforcement of Contracts.—I. Where a factor makes a contract in the name of his principal and himself signs as agent only, he drops out as soon as the contract is made, and the principal and third party alone can sue or be sued upon it. As factors usually contract in their own name this is not a common case. It is characteristic of brokers rather than of factors.

2. Where a factor makes a contract for the principal without disclosing his principal's name, the third party may, on discovering the principal, elect whether he will treat the factor or his principal as the party to the contract; provided that if the factor contract expressly as factor, so as to exclude the idea that he is personally responsible, he will not be liable. The principal may sue upon the contract, so also may the factor, unless the principal first intervene.

3. Where a factor makes a contract in his own name without disclosing the existence of his principal, the third party may, on discovering the existence of the principal, elect whether he will sue the factor or the principal. Either principal or factor may sue the third party upon the contract. But if the factor has been permitted by the principal to hold himself out as the principal, and the person dealing with the factor has believed that the factor was the principal and has acted on that belief before ascertaining his mistake, then in an action by the principal the third party may set up any defences he would have had against the factor if the factor had brought the action on his own account as principal.

4. Where a factor has a lien upon the goods and their proceeds for advances made to the principal it will be no defence to an action by him for the third party to plead that he has paid the principal, unless the factor by his conduct led the third party to believe that he agreed to a settlement being made with his principal.

5. The factor who acts for a foreign principal will always be personally liable unless it is clear that the third party has agreed to look only to the principal, and equally the factor may always sue on the contract.

6. If a factor contract by deed under seal, or draws, accepts, or indorses a bill of exchange or promissory note, he alone can sue or be sued upon the contract. (L. Sc.)

United States.—In only a few particulars does the American law differ from the English as set forth above, notably in regard to the Factors Act 1889. A number of U.S. States—chiefly on the seaboard—passed Factors Acts, and those Acts are hardly so far-reaching in their effects as the English, so that in general it is not law in the United States that a factor can effectively pledge his principal's goods — beyond the extent of his own interest by virtue of advances made to his principal — to secure his own debts. There is, however, an important qualification of the rule, derived from the widespread adoption of the uniform commercial Acts. Under the Sales Act and in certain States, without that Act, the factor (or any other person to whom an owner has entrusted a bill of lading running to order, and properly endorsed) can effectively pledge or sell the document, and so the goods represented by the document, although he does so in breach of duty; and under the Federal Bills of Lading Act the rule holds as well for all order bills of lading arising out of inter-State shipments. Moreover, under the Warehouse Receipts Act widely adopted in the United States, the same holds as to goods covered by warehouse receipts running to order. This is not true of documents which lack the word "order" or "negotiable," nor as to transactions involving goods in specie; but since most (not all) such attempted pledges involve such order documents: the old rule has been very substantially impaired.

The factor appears in the United States chiefly under the commercial designation "commission man"; goods sent to a factor, large or small, are commonly said to be shipped "on consignment," as distinguished from shipment pursuant to a contract for sale. In the main, such a commission man is a feature of a central market, to which sellers, especially of raw materials, are shipping: so especially agricultural produce such as fruits and vegetables, or cotton, coffee, live stock, etc. Factorage here serves as an alternative to the middle man who goes about among growers buying up their produce in advance. Both ways of dealing presuppose a seller who is relatively weak financially; hence the importance of factors' advances to their principals, and of factors' liens.

It should be noted that wherever the factor attains great financial power — as, in the United States, particularly in some phases of importing and in the merchandising of textiles — he tends to develop into a peculiar and specialized type of commercial (and even investment) banker, whose loans are limited to the one specific field in which he is skilled; whose earnings include commissions on his own selling of the merchandise delivered to him as security; and whose banking assets are not recruited by deposits, so as to subject him to state control. Along another line the factor, being located in a central market and becoming skilled in its operations, tends to branch out into independent trading — as do similarly situated brokers. Hence at times a conflict of interest between himself and his principals, as to whose goods shall get sold on a falling or fluctuating market; hence also some of those financial involvements which raise the question of how far the factor has power to pledge away his principal's goods; hence, finally, occasional legislation aimed at control of the commission man's business in the interest of his principals. (K. N. L.)

FACTORING: *see* BROKER.

FACTORS OF PRODUCTION. An economy's factors of production represent all those economic resources, both human and other, which if properly utilized will bring about a flow or output of goods and services. The availability of the factors of production is thus a necessary condition for production; without such factors: production could not take place at all.

However, not all the "inputs" that must be applied as the condition of there being an output are to be regarded as factors in the economic sense. Some of these inputs, in a normal situation, are "free": the organizing unit — the firm, or perhaps the economy — does not have to make any allo ance or take account of any cost for securing such inputs. Although atmospheric air, for example, or a substitute for it, must be at hand to enable production to go on, it is not counted among the factors since it is available in most circumstances in practically unlimited quantities. But if it is to be piped into a deep mine, or under water, it would then have to be treated like the other "economic resources." Incidentally, from the standpoint of the whole economy, a cost is involved in using a resource if as a result of this particular use the production of something else which depends upon the same kind of resource is hampered. Thus, if the input is scarce in relation to the need for it, it is regarded as a factor of production. The needed inputs may be scarce, and so constitute productive factors, either because they represent something which cannot be produced, like land (in the strictly economic sense), or because although their supply could be enlarged. like factories. to do so would be costly in terms of resources.

The productive factors are commonly classified into three groups: land, labour and capital. The first represents resources whose supply is low in relation to demand and cannot be increased as the result of production. The income derived from the o nership of this factor is known as economic rent. The factor of labour represents all those productive resources that can be applied only at the cost of human effort. The wage or salary is the form of payment for the use of this factor. And the effort which the economist regards as qualifying may be either manual or mental, although in earlier periods, and apparently under the Soviets, manual labour alone was considered a productive factor. The final category, capital, is a more complex one. In the simplest sense, it refers to all the "produced" instruments of production — the factories, their equipment, their stocks of raw materials and finished goods, houses, trade facilities, and so on. The owners of capital receive their income in various possible forms; profits and interest are the usual ones. w

It is generally assumed that the level of an economy's output depends directly and indeed simply, upon the amount of its productive factors in use. It is also supposed that in some degree one kind of factor can be substituted for another in production. The study of the level of factor employment, of the specific direction of their employment and of the rewards received for their use constitutes the greater part of economics. ***See*** also ECONOMIC PRODUCTIVITY. (L. Ts.)

FACTORY DESIGN: *see* INDUSTRIAL ARCHITECTURE.

FACTORY INSPECTION. The purpose of factory inspection as stated in most U.S. state laws is to ensure compliance with the applicable regulatory requirements for minimum standards of safety, health and welfare for employees. Although the inspection is carried out by factory inspectors. it usually applies to many places of employment other than factories, such as building sites and mercantile establishments.

Factory inspection in the United States is difficult to describe satisfactorily because of the many agencies having jurisdiction, the poorly defined limits of authority and the diversity of the regulatory requirements among the various agencies. This stems from the fact that the original 13 states formed a national government by assigning to it only the authorities and functions they considered vitally necessary to the successful functioning of the confederation as a whole. All powers not specifically so assigned were reserved to the respective states. The subsequent trend, however, was to strengthen and extend the federal authority at the expense of that of the states.

The constitutions of the respective states (with some exceptions which apply to a number of the older and more powerful cities such as Baltimore, Boston and New York) are sovereign over cities within their borders. A city may, and often does, act to control factories within its borders in advance of state action. But when the state legislates to cover the same field, as for example to control steam-power boiler construction and operation, such legislation automatically transcends the city authority unless the state legislation specifically exempts the city involved.

The definition of factory varies widely among the states, a fact which introduces its own element of confusion. Also, in many states entire types of industry are exempt from inspection as, for example, the lumbering industry in many of the southern states and the mining industry in certain western states.

Little control is ever exerted over farming — even farms or establishments whose employed personnel is large. Canneries are covered in some states but not in others. Some states exclude from their minimum safety and health requirements all establishments employing fewer than a fixed minimum number of persons, most frequently five.

While some of the states inspect all steam-power boiler and pressure vessels within all factories in the state, most of the large cities inspect all boilers in the city, and the state inspects those outside such cities. Some states accept the inspection of the insurance underwriters who carry the insurance against explosion. On the other hand, some of the states do not inspect boilers at all, nor do they seek to control their safety in any way. Almost all jurisdictions which make boiler inspections either apply or follow closely the provisions of the power boiler code of the American Society of Mechanical Engineers.

Elevator inspection is for the most part carried on by specialized personnel of either city or state regulatory bodies.

Few states seek to control the design and construction of factory buildings, though a few, notably New York, New Jersey and Pznnsylvania, require that plans be approved as to the conditions of safety and health for the employees and require their inspectors to resurvey them as needed to check on alterations and additions.

U.S. Federal Inspection.—Federal control is exercised over interstate commerce, the operation of vessels on navigable waters, the safety and health of stevedoring, the processing of imported products (such as wool, hair and hides) insofar as may be necessary to give protection against infectious diseases (such as anthrax), and over the slaughtering industry, insofar as it is necessary to ensure the wholesomeness of meat products. The control of child labour also is primarily a federal function.

Interstate commerce has included commercial transportation across state lines since the adoption of the federal constitution. Consequently, federal control was exerted successively over railroads, bus and truck haulage and air transport.

The passage of the Public Contracts (Walsh-Healey) act in 1936 extended federal inspection still further. It required that goods manufactured to fill contracts for the federal government be produced under safe and healthful working conditions. Enforcement of this act was combined with that of the Wage-Hour act, which specified minimum wage rates to be paid to workers engaged in the production of goods to be shipped across state lines. However, since the Public Contracts act also specified that compliance with the safety and health requirements of the respective states should be *prima facie* compliance with the requirements of the act, it meant that in the administration of this law the federal government was enforcing state standards on safety and health and did not apply standards of its own except in states lacking such standards as, for example, Louisiana, Maine or Mississippi. States deemed to have inspection personnel and procedures adequate for the purpose were requested to act as agents of the federal government in enforcing the Public Contracts act. By the 1950s, nearly half the states had accepted this arrangement by written agreements. Since during World War II, practically all of the productive industry of the United States was wholly or largely on federal contracts, federal inspection was almost universal in theory. In practice, federal inspection forces were far from adequate, and matters of safety and health of workers in factories built for the federal government or under federal control were handled by special forces, chiefly the services of supply of the United States army.

U.S. State Inspection.—The extent of state inspection has varied from practically nothing in the less industrialized states to extensive inspection systems in such states as California, Illinois, Ohio, Pennsylvania and New York. At mid-20th century the latter state maintained a force of about 300 inspectors who regularly visited about 200,000 work places: factories, mercantile establishments, construction operations and homes where factory work was carried on. They also were inspecting places of public assembly, particularly in regard to safety to life from fire. The factory inspections cover primarily safety and health, minimum wages, hours and child labour.

While New York at mid-century maintained the most detailed inspection and enforcement of its safety requirements, certain other states, notably Wisconsin and Oregon, were regarded by many authorities as having more progressive systems. They enforced what they regarded as essential, but put major emphasis on the education of employer and employee alike to appreciate the value of performance in accordance with good working standards and to comply voluntarily. A few states, notably Ohio, maintained one set of inspectors to enforce the laws and the codes thereunder and another force to render a consulting and advisory service on safety and health to such employers as felt a need for their services. These state authorities, recognizing that these consultants would be welcomed only if competent, set a reasonably high standard for them. They did not set the requirements as high for the enforcement group. The result was that the advisory group came to render a valuable safety service to the firms who were already at least moderately progressive as to safety and were, therefore, less in need of help than the firms which had to be forced into compliance. These firms were served by a less competent group.

The competence of the state inspection forces varied widely at mid-century. A number of the states had their inspectors under merit service on at least a reasonably good basis. The majority did not; hence, with each change in the political control of the state government, there was a complete or partial overturn of the personnel and often a major change of policy. This condition, however, was slowly but steadily improving because of two factors: first, the federal influence; second, the broadening realization by both employers and organized labour that the inspection service is important and that, given competent personnel and good administration, it can be a major factor in preventing work injuries and in fostering sound and constructive employer-employee relationships. The federal influence was being exerted through example (its inspection and professional forces all on merit service), through the administration of the Public Contracts act, but chiefly through safety courses which the bureau of labour standards set up for state factory inspectors. The bureau also established an advisory service for the states on safety code development.

(Ro. P. Be.)

Great Britain.—There is a uniform system of factory inspection throughout the country administered by the factory inspectorate of the ministry of labour and national service independent of political changes. Its duties consist broadly of the enforcement of the Factory and Workshop acts, the Truck acts (in factories and workshops) and acts dealing with poisons used in industry. Trades in which special or unusually high hazards exist are designated dangerous and receive extra attention.

Although concerned primarily with the enforcement of the statutory requirements regarding safety, inspectors have duties also in the inspection of sanitary and certain welfare arrangements, and in ensuring that conditions of employment, including hours of work and shift systems, particularly with regard to women and young persons, are properly observed. While enforcement of regulations is strict, emphasis is placed on positive measures of encouragement, and safety committees of employers and employees have been set up in many works. The competence of the inspectors is so well established that when they do find it necessary to prosecute, the courts almost always support them. (V. Cs.)

(Ro. P. Be.)

FACTORY PRODUCTION, HISTORY OF. The industrial factory first became dominant during the 19th century in Europe, North America and Australia and was making deep inroads into Asia by 1900. While it displaced various domestic types of production, in which work was done with simple equipment in the home or adjacent shed, it also incorporated certain well-established nondomestic forms of production.

From ancient times workers were gathered into central workshops. even though the equipment and processes were like those used in home or shed. Some of these workshops were set up by governments to produce large quantities of necessities for the armed forces; *e.g.,* local potteries, ordnance shops and textile plants for Roman legions stationed in Gaul. Others made luxury articles, such as fine silk fabrics, Gobelin tapestries or Sevres china for a royal court. But the more significant central workshops were those into which many an early modern merchant or manufacturer gathered his workers instead of putting out his material to be processed by them, perhaps with their own implements, in their homes. The "putting-out" system had the merit of enabling the entrepreneur to employ many urban and scattered rural workers, including women and children, without having to sink capital in working quarters or equipment. But its demerits were serious: much time was wasted putting out and collecting the material; standards of work were not easily maintained, much less raised; the worker could not always be relied on to finish his task on time: and the risk of embezzlement of material was very real.

These defects could be eliminated by gathering workers into a central workshop. In addition, division of labour could be intensified and new patterns, processes, or products introduced. The obstacles were also great. The employer would need to invest much capital in buildings, equipment and possibly houses; the total cost of rent, repairs, foremen's wages and other overhead or operating expenses might run high; and workers were unwilling to leave home or let their dependents do so. Yet the net balance of advantages had become so marked by 1750 that centralized production was gaining ground at the expense of the putting-out system.

By that time the invention'of new machines was gathering pace, especially in the metalware industries. In 1700 Christopher Polhem, a Swedish manufacturer, had 100 men, each trained for a special task, working in his factory with water-powered machines to cut bars, slit nail rods, roll metal into sheets and make cogwheels, pots, pans and plowshares.

In 1762 Matthew Boulton built a factory near Birmingham, Eng., with two waterwheels to turn rollers, grinding or polishing machines and lathes used by his 600 employees for producing buckles, buttons and other small metal articles. In 1775, taking James Watt into partnership, he began making the patented improved parts Watt had invented for steam engines (1769), then those which enabled the engine to turn wheels, thus offering factory operators a new source of power.

The textile industry opened factories gradually. The fulling of woolens and silk throwing had gone into mills before 1300, and dyeing and finishing were central workshop processes. But spinning and weaving remained strongholds of domestic industry. Between 1764 and 1779 three famous British inventions—Hargreaves' jenny, Arkwright's frame and Crompton's mule—expanded enormously the output of yarn per spinner and reduced the labour cost by at least nine-tenths. The jenny could be worked by hand in the home, but since the other two machines needed much power and floor space, spinning mills sprang up in Lancashire, Yorkshire, Lanarkshire and other textile counties, and yarn making became a factory process within about a generation.

Other textile processes and other industries moved into the factory later and more slowly. Though a power loom was invented in 1784, it was not satisfactory for weaving cottons until about 1825–30, worsteds until 1840 and woolens until at least 1850. By the latter date the factory was well on its way both in conquering former domestic occupations and in converting central workshops into factories. It was dominating the production of paper, books, glass, pottery, metalware, engines and machines. After 1850 it absorbed much of the production of clothing and shoes; the cutting of wood into furniture and building material; and such food industries as canning, butter making and, after 1900, baking. The factory was also the home of most new products, such as bicycles, automobiles, electrical appliances, chemicals and rubber goods.

The spread of factory production methods beyond Great Britain was most marked in Belgium, the United States, France and Germany. British laws forbidding the export, save under licence, of machines (until 1843) and the emigration of skilled artisans (until 1825) could not be rigorously enforced. Machines or models might be shipped in falsely labeled packing cases, and plans could go out in emigrants' heads. Artisans slipped out furtively or told port inspectors that they were farmers or labourers. Hence we find William Cockerill (*q.v*), a Lancashire mechanic, living in Sweden and Russia before he landed in Belgium (1798), there to make spinning frames, engines, rolling mills and other British machines as they came along. Samuel Slater (*q.v.*), who built, equipped and operated a spinning mill at Pawtucket, R.I. (1790–91), was the most publicized of many British technicians who reached the United States between 1783 and 1812, either by invitation or on their own initiative, to establish, manage or work in factories which spun yarn, printed calicoes, finished woolens, made paper or constructed machines. France, Germany, Italy, Russia, Canada, Asia and Australia all drew on British skill and equipment for initiating factory production.

The United States made outstanding adaptations and innovations to factory processes. Scarcity of labour, especially skilled, provoked an effort to design labour-saving, highly specialized machines. Factories so equipped for manufacturing guns, clocks, harvesters, doors, window frames and the like were by 1850 far ahead of anything known in Europe. They constituted a distinctively American factory system, and their descendants were the mass-production plants, equipped with one-purpose automatic machines, conveyer devices and the assembly-line technique. (See also INDUSTRIAL REVOLUTION.)

The Capital Supply.—The first problem confronting the factory industrialist was the raising of sufficient capital for buildings and equipment. The amount might be small, and often entire spinning mills cost less than the average of $6,000-$7,000 needed to equip a single North American factory worker in the 1930s; but many plants cost $50,000, and some at least twice that amount. While landlords helped sometimes by building and leasing mills and some merchants put considerable sums into factories, the main effort was made by the industrialist. He emptied his own pockets, raided the family purse, sought partners with cash, borrowed wherever he could, austerely rationed his personal spending and plowed much of his profits back into the firm.

This private financing was only slowly supplemented by public investment when, in the last third of the 19th century, the formation of limited-liability joint-stock companies became legally easy and investment bankers, especially in Germany and the United States, began to underwrite the issue of corporate stocks and bonds.

Labour Supply.—The second problem was the recruiting of a labour force. In the beginning this was difficult when domestic workers refused to leave home or when water-driven mills had to be located in remote, sparsely peopled spots. For a time some British spinning mills drew on supplies of pauper children from southern England; a mill at Lowell, Mass., induced farmers' daughters to come and work there in order to earn money for their trousseaus; but these temporary labour supplies soon dried up as steam-driven factories were planted in towns and as labour began to flow in of its own accord from nearby communities, from rural areas to urban, from Ireland to England and Scotland, from eastern Germany to western and from Europe to North America.

Factory working conditions quickly attracted public attention. The working day of 12 or more hours, child labour, physical strain, unhealthful environment, occupational diseases or accidents, personal cruelty and low wages had been common, though unnoticed, features of the domestic system, and the discipline of regular hours had been imposed in central workshops. Now they became mobilized, generalized and accentuated in a visible mass. New occupational risks emerged when operatives tended fast-moving machines. Long hours for six days a week were worked throughout the year once illumination by gaslight became possible.

State regulation, at first primarily on humanitarian grounds, therefore began with the first British Factory act (1802). Step by step, its range widened and its enforcement was improved in Britain, then in other countries. By 1914 it dealt with the minimum working age. maximum hours, the working environment, wages and insurance against sickness or unemployment. Alongside this growth of factory acts went the voluntary efforts of workers to improve their lot as wage earners by organizing trade unions and as wage spenders through consumers' co-operative societies. Those efforts began to achieve a measure of success after 1850.

The wider effects of the development of the factory are part of the general shaping of modern capitalistic industrialized society. The factory extended, but did not create, the proletariat, since many domestic workers were already propertyless wage earners. It tended to attract industry and population to regions favourably located in terms of access to fuel. raw materials or markets, thus causing heavy regional concentration in "black countries" and the rise of industrial towns, with all the consequent problems of housing, public health, local government and political controversies based in part on class conflict.

While the factory destroyed the value of some ancient skills, it created many ne skilled jobs.

Finally, in the controversies which swarmed around the social and economic problems created by the factory, sight was often lost of the fact that factory methods brought a greatly enhanced productivity of human labour as hours were reduced, working conditions improved and participation by children eliminated. Such rising productivity made it possible to feed, clothe and house populations that were expanding at a rate previously unknown.

FACULAE: see SUN.

FADING is the variation of the signal intensity received at a given location from a radio transmitting station as a result of changes in the transmission path.

FAED, THOMAS (1826–1900), British painter, born in Kirkcudbrightshire, studied at the school of design, Edinburgh, was a member of the Royal Scottish academy and became a member of the Royal Academy in 1864.

Three of his pictures, "The Silken Gown," "Faults on Both Sides" and "The Highland Mother," are in the National Gallery of British Art (Tate gallery), London.

See William D. McKay, *The Scottish School of Painting* (1906).

FAENZA, a city and episcopal see of Emilia-Romagna, Italy (anc. Faventia), province of Ravenna, 31 mi. S.W. from the town of Ravenna by rail, 110 ft. above sea level. It is 31 mi. S.E. of Bologna by rail, on the line from Bologna to Rimini, and it is the junction of a line to Florence through the Apennines. Pop. (1951) 25,041. The town still preserves traces of the Roman rectangular plan and is surrounded by walls which date from 1456. The cathedral of S. Pietro stands in the centre of the town. It was begun in 1474 by Giuliano da Maiano; the façade is, however, incomplete. In the interior is the beautiful early Renaissance tomb of S. Savinus, with reliefs showing scenes from his life, by Benedetto da Maiano. Opposite the cathedral is a fountain with bronze ornamentation (1621).

The municipal buildings have been restored; the picturesque arcades of the Palazzo del Comune date from the 15th century and those of the Palazzo del Podestà from the 18th. The municipal art gallery contains fine specimens of majolica, a variety of which. faience, takes its name from the town. It was largely manufactured in the 15th and 16th centuries, and the industry was revived in modern times. (See POTTERY AND PORCELAIN.) There is an international museum of ceramics there with specimens of every date and country.

The name Faventia is clearly Roman. The town lay on the Via Aemilia; there Papirius Carbo and C. Norbanus were defeated by Q. Caecilius Metellus Pius in 82 B.C. Pliny speaks of the whiteness of its linen, and the productiveness of its vines is mentioned. In 740 it was taken by Liutprand. Desiderius gave it to the church with the duchy of Ferrara. It was a free city at the beginning of the 12th century and at first took the imperial side, but in 1240 it stood a long siege from Frederick II and was taken only after eight months. In 1313 the Manfredi made themselves masters of the place and remained in power until 1501, when the town was taken by Caesar Borgia.

FAEROE ISLANDS (also written FAROE or THE FAEROES, Danish FAEROERNE, Faeroese FOROYAR), a group of islands in the North Atlantic ocean forming a self-governing community within the kingdom of Denmark. They are situated between Iceland and the Shetland Islands, about 200 mi. S.W. of the latter. between latitude 62° 24' and 61° 26' N. and longitude 6° 15' and 7° 41' W. The total area of the group is 540 sq.mi., and there are 18 inhabited islands.

The principal islands are Streymoy, Eysturoy, Vagar, Suduroy, Sandoy and Bordoy (Danish forms: Stromo, Ostero. Vaago, Sudero, Sando and Bordo). Pop. (1955) 32,456. Capital, Thorshavn, on Streymoy; pop. 6,067.

Physical Features. — The islands were formed by submarine outpourings of basalt in Tertiary times, with thin, intercalated, reddish tuff. The layers of basalt are from 30 ft. to 100 ft. thick, those of tuff about 3 ft. thick. Upon the basalt rests the so-called coal formation, 35 ft.–50 ft. thick; the lower part is mainly fire clays and sandstone, and the upper part is weathered clay with thin layers of shale and brown coal. The latter occurs especially on Suduroy. Above this, over most of the surface, lie beds of dolerite. 15 ft.–20 ft. thick. All these beds of basalt, tuff and dolerite lie practically horizontally. During the glacial period the whole surface up to 1,500 ft. was covered by ice sheets, and the relief is mainly the result of the action of ice upon the horizontal beds.

The rocky ground of the islands is covered by a thin layer of moraine or peat soil, the latter being used for heating. The islands are high and rugged, with perpendicular cliffs and flat summits separated by narrow ravines. The coasts are deeply indented, and a series of fiords runs northwest-southeast. The narrow passages between the islands are made dangerous by very strong tidal currents. The greatest height is Slattaretindur (2,894 ft.) in Eysturoy. There are several lakes in which trout is abundant; the largest is Lake Sorvagur in Vagar, which discharges into the sea by a sheer fall of 108 ft.

The climate is oceanic, with mild but stormy winters and cool summers. Rainfall is heavy (59 in. a year), the maximum occurring in autumn and winter. There are 275 rainy days a year. The sky is generally overcast, and fogs are frequent. There are seldom long periods of frost, and the harbours are rarely icebound. At midsummer the sun is above the horizon for about 19¾ hours.

There are no indigenous land mammals. Rats and mice have come with ships, and the polar hare is imported. Toads and reptiles are also missing. Numerous sea birds, including the auk, puffin and eider duck, nest in the cliffs. Because of the strong westerly winds and frequent gales the islands are naturally treeless, but hardy conifers, maple and mountain ash have been planted.

History. — The oldest map mentioning the Faeroe Islands by name is the Hereford map (1280), where they are called Farei, perhaps a Celtic word akin to *fearand* ("area"), perhaps a Scandinavian word akin to faar ("sheep"). It seems probable that Irish hermits lived in the islands in the 7th and 8th centuries, but the population is descended from 9th-century Norse settlers. Olaf I Tryggvesson, king of Norway, introduced Christianity about 1000 and gave the islands to the Faeroese Sigmund Bresterson, but he was killed, as the islanders clung to their independence. In 1035, however, the islands became a Norwegian feoff and were associated with Denmark in the 14th century, when Norway and Denmark were united. In 1814, when Norway was separated from Denmark, the Danish king retained the islands. The name of Magnus Heineson, a native of Streymoy, who cleared the seas of English adventurers in the 16th century, is still celebrated in many songs and stories. So also is the period of Sigmund Bresterson, in the *Faereyinga Saga* and in popular songs and legends. This early native literature became the starting point of modern Faeroese nationalism. The folklorist Ulricus Hammershaimb formed in the 19th century a written Faeroese language, and in the 20th century Joannes Patursson made his farm an intellectual and national centre. In 1906 he formed the Sjalvstyrisflokkur. or Home Rule party. After 1912 the use of Faeroese in schools and churches was to some extent authorized. In 1938 the local language became the single teaching language, if the teacher wished it. The Sambandsparti was formed to maintain ties with Denmark, in opposition to the Sjalvstyrisflokkur. There was also a Social Democratic party.

The old Faeroese *lagting* (a combined jury and parliament), abolished during the absolutism, was restored in 1852 as an *amtsraud* (county council).

When the Germans invaded Denmark in 1940, Great Britain took over control of the islands until Sept. 1945. Thirty-nine fishing vessels were sunk and 131 fishermen and seamen lost their lives.

After the war Denmark proposed to give the islands a greater measure of self-government. but at a plebiscite in 1946 only 5,490 voted for the government proposal as against 5,656 for an independent republic, which was demanded by the new Home Rule party. the Folkaflokkurin. Election for the *lagting* displayed. in the same year, an opposite result, leaving the Folkaflokkurin as a minority (5.383 votes as against 7,470 votes to the other parties). In 1947 negotiations were renewed in Copenhagen, and as a result the islands were given self-government, their own flag and their own unit of currency, the krona (1 krona= 1 Danish krone).

A decline in the prices of fish products in 1952 caused economic troubles; the Sjovinnu bank suspended its payments, and the Danish government had to make loans and subscribe new shares in the bank in order to overcome the crisis.

Social Conditions and Administration. — The Faeroe islanders constitute a separate nationality and have preserved numerous ancient manners and customs. Faeroese is the main teaching language. Besides elementary schools there are five secondary schools, including a grammar school in Thorshavn. There are also a navigation school. technical schools and a high school. Most islanders are Lutherans, belonging to the Danish national church. The population rose from 5,200 in 1801 to 15,230 in 1901 and later more than doubled.

The Faeroe Islands form a self-governing community within the kingdom of Denmark. Matters of self-government are: electoral rules, municipal institutions, sanitation. schools. social services, trade laws and taxation. Self-government is exercised through the *landsstyre* (executive) and the *lagting* (parliament). All men and women over 21 may vote. The Danish government is represented by *rigsombudsmanden*. The islands elect two representatives to the Danish parliament *(folketing)*.

Agriculture and Industries. — The ground around the farms is used for hay, potatoes, turnips and barley crops, but less than 4% of the total area is under cultivation. Vegetables are grown, berry fruits flourish and even the strawberry ripens late in the summer. The uncultivated area offers good pasture, where sheep graze in summer and winter. The wool is exported or used by a small home industry in spinning and knitting. Two modern textile mills have been built. There are cows, but they give little milk because of their coarse feed. The puffin is caught for food, and the feathers of the eider duck are collected. About 300,000 sea birds are caught annually. Fishing. however, has become the main trade of the islands. The cod fishery is especially important, dried and frozen fish being exported in large quantities. The swim bladders are made into gelatin and the cod liver into liver oil. Salted herrings are also exported. The whaling industry became important toward the close of the 19th century.

About 40% of the population is engaged in fishing and less than 10% in agriculture; about 80% is dependent on fishing.

Exports from the Faeroe Islands, 1952

(In 000 kronar)

Item	Denmark	U.K.	Spain	Italy	Other countries	Total
Fresh and frozen fish	198	5,720	—	—	—	5,918

Total	10,995	6,948	30,531	8,454	13,033	69,961

The number of registered Faeroese ships in 1952 was 231, amounting to 33,281 registered tons. The islands have regular communication by ship with Denmark (Copenhagen), Scotland and Iceland.

During and after World War II Faeroese roads were improved, and in 1952 the islands had 462 cars and trucks. Hydroelectric power stations were constructed after the war.

FAESI, ROBERT (1883–). Swiss poet, dramatist, story writer and literary critic, was born at Zurich on April 10, 1883. and became professor of German literature at the university of that town. His tragedies *Odysseus und Nausikaa* (1911) and *Opferspiel* (1925) and the comedy of *Die Fassade* (1918) attained a high level of excellence. His chief poems are *Aus der Brandung* (1917; an outcome of World War I) and *Der Brennende Busch* (1926).

The *Zürcher Idylle* (1908) and the *Konig von Ste. Pelagie* (1924) are attractive short stories.

Other works included studies of Carl Spitteler (1915), Rainer Maria Rilke (1919) and C. F. Meyer (1925), a volume entitled *Gestalten und Wandlungen schweizerischer Dichtung* (1922), *Der Magier* (1938) and *Ungereimte Welt gereimt* (1946).

FÁFNIR is the name of the dragon in the Norse version of Nibelung legend. Fafnir turned into a dragon after killing his father, Hreidmar, and after seizing the Nibelungs' hoard of gold. He lay on this until the hero Siegfried (*q.v.*) slew him, so that gold came to be called "the dragon's bed!' by Norse poets. *See* also NIBELUNGENLIED. (G. T.-P.)

FAGACEAE, the beech family, contains more than 800 species, including giant trees and prostrate shrubs. They are broad-leafed plants with deciduous or evergreen, alternate, simple leaves which are lobed, toothed or entire. The wind-pollinated flowers are inconspicuous, borne singly or in groups, the male usually in catkins. the female in small clusters.

The fruit is a nut borne singly in a cup as in the oak (an acorn) or several in burlike bracts as in the chestnut and beech.

(C. H. MR.)

FAGGING, in the English public schools, is the compulsory performance by junior boys of prescribed menial services for senior boys. The etymology of the word is obscure, but it is clearly connected with "fag" for weariness, hence drudgery. Like many other public school features popularly supposed to be of immemorial antiquity, fagging is in fact of quite late development. The custom developed rapidly after about 1785 and was in general recognized by the school authorities, and sometimes regulated by them. Probably, as A. F. Leach suggests, its growth was occasioned by the development of organized games and the introduction of extra meals.

By the mid-19th century fagging was customary in most of the great public schools. An illustration of how fagging worked at Rugby is to be found in T. Hughes' *Tom Brown's School Days* (1857). For details of its operation in the public schools generally, the best source is the report of the Clarendon commission (1864), where the returns to the commissioners' queries no. 29 and 30 and the (indexed) minutes of evidence and recommendations give full particulars of the heavy tax upon young boys' time involved by fagging, and lurid (perhaps not altogether reliable) details of the alleged "oppressive, degrading and brutal" abuses of the system. By the second half of the 20th century fagging had either been abolished or reformed beyond recognition.

(W. E. T.)

FAGUET, EMILE (1847–1916), French critic and man of letters, was born at La Roche sur Yon. He mas educated at the École normale in Paris; after teaching for some time in La Rochelle and Bordeaux he went to Paris. After acting as assistant professor of poetry in the university he became professor in 1897. He was elected to the Academy in 1900 and received the ribbon of the Legion of Honour in the next year. He acted as dramatic critic to the *Soleil;* from 1892 he was literary critic to the *Revue bleue* and in 1896 took the place of M. Jules Lemaitre on the *Journal des débats.* Among his works are monographs on *Flaubert* (1899), *Andre' Chénier* (1902), *Zola* (1903), *Balzac* (1913), *Mgr. Dupanloup* (1914); an admirably concise *Histoire de la Littérature française depuis le XVII^e^ siècle jusqu'à nos jours;* series of literary studies on the 17th, 18th and 19th centuries: *Questions politiques* (1899); *Propos littéraires* (3 series, 1902–05); *Le Libéralisme* (1902); *L'Anticléricalisme* (1906); *Le Paceficisme* (1908); and several works on Rousseau (between 1910 and 1912). He died in Paris on June 7, 1916.

FAHRENHEIT, GABRIEL DANIEL (1686–1736), German physicist who made important improvements in the construction of thermometers and introduced the thermometric scale known by his name (*see* THERMOMETRY). He was born at Danzig on May 14, 1686. For the most part he lived in England and Holland, devoting himself to the study of physics and making a living, apparently, by the manufacture of meteorological instruments. He also invented an improved form of hygrometer, a description of which, together with accounts of various observations and experiments made by him, was published in the *Philosophical Transactions* (1724). He died in Holland on Sept. 16, 1736.

FA-HSIEN (fl. A.D. 399–414), Chinese Buddhist monk and traveler in central Asia, India and Ceylon, whose record of his journeys and studies is valuable evidence for the history of Buddhism and its strength in central Asia and northern India before its eclipse by Islam and the resurgence of Hinduism. Born at Shansi during the 4th century A.D. Fa-hsien set out from China, traveled westward through Turkistan and, about A.D. 402, crossed the Hindu Kush into India. There, in the then central Buddhist realm, he stayed for ten years, visiting Afghanistan and the Ganges valley, conversing with Buddhist monks and scholars and copying Buddhist texts. From India he sailed to Ceylon, where he continued transcribing sacred texts that were unknown in China. About A.D. 414 he returned via Java to Nanking where he translated these texts (listed in P. C. Bagchi, *Le Canon bouddhique en Chine,* 1927) from Sanskrit into Chinese.

Translations of his narrative include S. Beal, *Travels of Fah-Hian and Sung-Yun* (1869); J. Legge, *Fa-hsien, a Record of Buddhistic Kingdoms* (1886); H. A. Giles, *The Travels of Fa-hsien* (399–414 A.D.) (1923). (R. L. HL.)

FAIDHERBE, LOUIS LEON CÉSAR (1818–1889), French general and colonial administrator, was born on June 3, 1818, at Lille. He received his military education at the École Polytechnique and at Metz and entered the engineers in 1840. From 1844 to 1847 he served in Algeria, then two years in the West Indies, and again in Algeria, taking part in many expeditions against the Arabs. In 18jz he was transferred to Senegal as sub-director of engineers and in 1854 became governor of the colony. He held this post with one brief interval until July 1865. The work he accomplished in West Africa constitutes his most enduring monument. At that time France possessed in Senegal little else than the town of St. Louis and a strip of coast. Faidherbe dreamed of creating a French African empire stretching from Senegal to the Red sea. By boldly advancing the French outposts on the upper Senegal he stemmed the Moslem advance on the middle Niger; and by an advantageous treaty with Omar al-Hadji, the ruler of these countries, in 1860 he brought the French possessions into touch with the Niger. He also conquered the country lying between the Senegal and Gambia. When he resigned his post the foundation of the French dominion in West Africa had been laid. In 1863 he became general of brigade.

From 1867 to 1870 he commanded the subdivision of Bona in Algeria; he was commanding the Constantine division at the commencement of the Franco-German War. Promoted to general of division in Nov. 1870, he was appointed (Dec. 3) commander-in-chief of the army of the north. The struggle between the I German army and that commanded by Faidherbe, in which were included the hard-fought battles of Pont Noyelles, Bapaume and St. Quentin, was perhaps the most honourable to the French army in the whole of the war. Elected to the national assembly for the *département* of the Nord, he resigned his seat in consequence of its reactionary proceedings. Faidherbe was made chancellor of the order of the Legion of Honour. In 1872 he went on a scientific mission to upper Egypt, where he studied the monuments and inscriptions. He was elected a senator in 1879. He died on Sept. 29, 1889, and received a public funeral. Statues and monuments to his memory were erected at Lille, Bapaume, St. Quentin and St. Louis, Senegal. His works include *Collection des inscriptions numidiques* (1870); *Epigraphie phénicienne* (1873); *Essai sur la langue poul* (1875); *Le Ze'naga des tribus sénégalaises* (1877); *Campagne de l'armée du Nord* (1871); *Le Soudan Français* (1884); *Le Sénégal* (1889).

See Brunel, *Le Général Faidherbe* (2 vol, *1892);* Riethy, *Histoire populaire du général Faidherbe* (1901); and Froelicher, *Trois Colonisateurs: Bugeaud, Faidherbe, Galliéni* (1903).

FAIENCE, a term applied generally to all kinds of glazed pottery, but properly the French word for the *porzellana di Faenza,* a fine kind of glazed and painted earthenware made in Faenza, Italy. *See* POTTERY AND PORCELAIN.

FAIN, AGATHON JEAN FRANÇOIS (1778–1837), French historian, was secretary and archivist to the *cabinet particulier* of Napoleon I from 1806 to 1815. He was born at Paris on Jan. 11, 1778. At the time of his appointment to the emperor's cabinet he had been working since 1795 in various state archives. Napoleon created him a baron in 1809 and in 1813 made him his private secretary. This office, lost at the first Bourbon restoration, was resumed during the Hundred Days. after which Fain retired into private life. He was recalled in 1830 by Louis Philippe, who appointed him first secretary of the cabinet and, on occasion, administrator of the civil list. He was also, from 1834 until his death at Paris on Sept. 16. 1837, the deputy for Montargis, Loiret.

Fain employed his years of retirement in publishing his reminiscences of Napoleon's reign. These works have remained important sources for the history of the first empire in France; the most notable are *Manuscrit de* 1814, *contenant l'histoire des six derniers mois du règne de Napoléon* (1823); *Manuscrit de* 1813, *contenant le précis des événements de cette année pour servir à l'histoire de l'empereur Napoléon,* 2 vol. (1824); *Manuscrit de* 1812, 2 vol. (1827); and *Manuscrit de l'an 111* (1794–1795) (1828). Fain's *Mémoires* were published posthumously in 1908.

FAIR: *see* EXHIBITIONS AND TRADE FAIRS.

FAIRBAIRN, ANDREW MARTIN (1838–1912), British Congregational theologian, an advocate of theological liberalism, was born at Inverkeithing, Fife, on Nov. 4, 1838. He was educated at Edinburgh and Berlin and at the Evangelical Union Theological academy in Glasgow; entering the Congregational ministry, he held pastorates at Bathgate, West Lothian and Aberdeen. From 1877 to 1886 he was principal of Airedale college, Bradford, a post which he gave up to become the first principal of Mansfield college, Oxford. In 1883 he was chairman of the Congregational Union of England and Wales. He resigned his position at Mansfield college in 1909 and died in London, Feb. 9, 1912.

Among his more important works are *Studies in the Philosophy of Religion and History* (1876), *Philosophy of the Christian Re-*

ligion (1902) and *Studies in Religion and Theology* (1909).

See W. B. Selbie, *Life of Andrew Martin Fairbairn* (1914).

FAIRBAIRN, SIR WILLIAM, BART. (1789–1874), British engineer who in 1845 collaborated with Robert Stephenson in the design of the famous early railway bridges over the Menai strait and the River Conway, and who made the tests that led to the adoption of the tubular design, was born at Kelso, Roxburghshire, on Feb. 19. 1789. Although for a time he ran a yard to build iron ships in Millwall, London, most of his working life was spent in Manchester, with James Lillie as partner from 1817 to 1832, thereafter on his own.

In 1844 Fairbairn introduced the Lancashire boiler with twin flues. He pioneered the use of wrought iron as a material for the hulls of ships and for bridges, and introduced it in preference to cast iron for mill shafting and for beams for buildings. From 1834 Fairbairn scientifically investigated the strength of iron, the relative merits of hot and cold blast, and how to abate smoke; with Eaton Hodgkinson he studied the strength of iron beams and columns. For Lord Kelvin he determined (1851) the melting points of many substances under great pressure. He conducted or guided experimental work for several government committees and was consulted on many and varied works both in Great Britain and abroad.

Fairbairn was president of the Institution of Mechanical Engineers in 1854, and of the British association in 1861. He received a gold medal from the Royal society in 1860 and was made a baronet in 1869. He died at Moor Park, Surrey, on Aug. 18, 1874. His youngest brother, Sir Peter (1799–1861), founded in Leeds an establishment to make textile machinery and machine tools: and was knighted in 1858.

See *The Life of Sir William Fairbairn,* partly written *by* himself, edited and completed by William Pole (1877). (S. B. HN.)

FAIRBANKS, CHARLES WARREN (1852–1918), U.S. politician, vice-president under Theodore Roosevelt (1905–09), was born in Unionville Center, Ohio, on May 11, 1852. He graduated from Ohio Wesleyan university, Delaware, in 1872, studied law in Cleveland and began practice in Indianapolis, Ind. He was the chief power in the Republican party in that state from 1896 until his death. He was temporary chairman and keynote speaker of the convention which nominated William McKinley, and was U.S. senator from Indiana: 1897–1905. A conservative and representing a doubtful state! he was the political choice as running mate to Theodore Roosevelt in 1904. In 1912 Fairbanks supported William Howard Taft instead of Roosevelt. He was again his party's nominee for vice-president on the unsuccessful ticket of 1916 headed by Charles Evans Hughes.

Fairbanks died June 4, 1918.

FAIRBANKS, DOUGLAS (1883–1939), motion-picture actor and producer, best known for his portrayals of ebullient and athletic heroes. was born in Denver, Colo., May 23, 1883. After college study he began a stage career. eventually becoming a leading man in New York (1906). Within a few years he turned to motion pictures: and in 1917 was head of his own producing company. Among his many popularly successful pictures were *Tlze Mark of Zorro* (1920), *The Three Musketeers* (1921), *Robin Hood* (1922), *The Black Pirate* (1926) and *The Iron Mask* (1929). He was married to Mary Pickford (*q.v.*) in 1920 and divorced by her in 1935. With Miss Pickford, Charlie Chaplin and others, he was a founder of the United Artists corporation. Fairbanks died in Santa Monica. Calif.. Dec. 12, 1939.

His son, DOUGLAS (ELTON) FAIRBANKS (1909–), also was a film star, served with distinction in World War II and later became a television producer in England. (M. S. BY.)

FAIRBANKS, ERASTUS (1792–1864), U.S. manufacturer, was born in Brimfield, Mass., on Oct. 28, 1792. In 1824 he formed a partnership with his brother Thaddeus for the manufacture of stoves and plows. Erastus was a member of the state legislature in 1836–38, and governor of Vermont in 1852–53 and 1860–61. His son HORACE FAIRBANKS (1820–88) became president of E. and T. Fairbanks and Co. in 1874, and was governor of Vermont from 1876 to 1878.

His brother THADDEUS FAIRBANKS (1796–1886), inventor, was born at Brimfield on Jan'. 17, 1796. He designed the models from which he and his brother manufactured stoves and plows at St. Johnsbury, Vt. In 1826 he patented a cast-iron plow which was extensively used. In 1831 he invented the famous compound-lever platform scale, which marked a great advance in the construction of machines for weighing heavy objects. He died at St. Johnsbury on April 12, 1886.

FAIRBANKS, the principal city of the interior of Alaska, U.S., is a mining and transportation centre located 250 mi. up the Tanana river from its confluence with the Yukon. A gold strike in 1902 brought stampeders to the vicinity; in 1906 the population may temporarily have reached 8,000. That year gold production surpassed $9,000,000. Expensive dredges soon became necessary to reach the gold-bearing gravels; a number were still operating in the second half of the 20th century.

The Richardson highway from Fairbanks to the coast at Valdez was completed in 1923. In the same year the Alaska railroad was completed from Anchorage. In the 1920s Fairbanks became a centre for Alaska's famed "bush pilots." During World War II construction of the Alaska highway linked Fairbanks with the major North American highways. Ladd and Eielson air force bases were built nearby.

The meeting of the mining frontier and the air age at Fairbanks is symbolized by sturdy log cabins nestling beside multistory steel buildings. The University of Alaska is noted both for its mining course and for its advanced geophysical institute. For comparative population figures *see* table in ALASKA: *Population.* (J. E. CL.)

FAIRCHILD, DAVID GRANDISON (1869–1954), U.S. agricultural explorer who supervised the introduction of many useful plants into the United States, was born on April 17, 1869, at Lansing, Mich. In 1888 he graduated from Kansas State college, Manhattan, and, after some graduate work at the University of Iowa, Iowa City, and Rutgers, New Brunswick. N.J.. he joined the section of plant pathology of the United States department of agriculture in Washington, D.C., in 1889. From 1893 to 1896 he studied in Italy, Germany and Java. He helped W. T. Swingle organize the section of plant introduction (then the section of foreign seed and plant introduction) of the department of agriculture in 1897–98. Fairchild served the section as agricultural explorer (1898–1903), as administrator in charge (1903–28) and, after retirement, as collaborator (1928–54). During his administration many thousands of kinds of plants were introduced into the country. In 1905 he married Marian, daughter of Alexander Graham Bell. Fairchild was the author of several books, including *Exploring for Plants* (1930), an account of the Allison Vincent Armour expeditions for the United States department of agriculture; the autobiographical *The World Was My Garden* (1938); and *The World Grows Round My Door* (1947), story of the Kampong, Fairchild's home in Coconut Grove, Fla. The Fairchild Tropical garden at Coconut Grove was named in his honour. Fairchild died in Coconut Grove on Aug. 6, 1954. (J. W. TT.)

FAIRFAX, EDWARD (*c.* 1575–1635), English poet. translator of Tasso and refiner of couplet verse, was born at Leeds, Yorkshire, *c.* 1575. His *Godfrey of Bulloigne or the Recoverie of Jerusalem* (1600), a translation of Tasso's *Gerusalemme Liberata,* achieved great fame, and was praised by John Dryden: "For *Spenser* and *Fairfax* both . . . saw much farther into the Beauties of our Numbers, than those who immediately followed them."

Although translating stanza by stanza. Fairfax freely altered poetic detail. His terminal couplets are often sonorous departures from the Italian, and from these especially Edmund Waller "deriv'd the Harmony of his Numbers."

For in the secret of her troubled thought,
A doubtful combat, love and honour fought;
(*Godfrey,* vi, 70)

is a typically well-balanced couplet which Waller copied in *Instructions to a Painter* (1666). Fairfax also influenced Milton, whose tonal harmony he often anticipated:

And counsellors of her old love, she made
Those vallies dumb, that silence and that shade.
(*Godfrey,* vi, 103)

Among Fairfax' other works were 12 eclogues, of which only 2 and most of a third have been found. The finest, "Hermes and Lycaon," is an apocalyptic singing match between worldly and spiritual lovers, and was published, with a curious account of the bewitching of the poet's daughters, in the Philobiblon society's *Miscellanies* (1858–59). Another eclogue appeared in *The Muses' Library* (1737). The complete manuscript of the eclogues still survived in 1789 and may exist unnoticed. Fairfax died in Jan. 1635. (C. G. B.)

FAIRFAX OF CAMERON, FERDINANDO FAIRFAX, 2ND BARON (1584–1648), English parliamentary general, was born on March 29, 1584, son of Thomas Fairfax of Denton (1560–1640; created Baron Fairfax of Cameron, 1627). He was M.P. for Boroughbridge during the six parliaments which met between 1614 and 1629 and also during the Short Parliament of 1640. In May 1640 he succeeded his father as Baron Fairfax, but being a Scottish peer he sat in the English house of commons as one of the representatives of Yorkshire during the Long Parliament from 1640 until his death; he took the side of the parliament, but held moderate views and desired to maintain the peace. In the first Scottish War Fairfax had commanded a regiment in the king's army; on the outbreak of the Great Rebellion in 1642 he was made commander of the parliamentary forces in Yorkshire, with Newcastle as his opponent. Hostilities began after the repudiation of a treaty of neutrality entered into by Fairfax with the royalists. At first he met with no success. He was driven from York, where he was besieging the royalists, to Selby; then in 1643 to Leeds; and after beating off an attack at that place he was totally defeated at Adwalton moor (June 30). He escaped to Hull, which he defended against the duke of Newcastle (Sept. 2–Oct. 11), and by means of a brilliant sally caused the siege to be raised. Fairfax was victorious at Selby (April 11, 1644), and joining the Scots besieged York, after which he was present at Marston moor. In July he was made governor of York, in December he took the town of Pontefract, but failed to secure the castle. He resigned his command on the passing of the Self-Denying ordinance, but remained a member of the committee for the government of Yorkshire. He died from an accident on March 14, 1648, and was buried at Bolton Percy. He was twice married, and by his first wife, Mary, daughter of Edmund Sheffield, 3rd Lord Sheffield (afterward 1st earl of Mulgrave), he had six daughters and two sons, Thomas, who succeeded him as 3rd baron, and Charles, a colonel of horse, who was killed at Marston moor.

FAIRFAX OF CAMERON, THOMAS FAIRFAX, 3RD BARON (1612–1671), parliamentary general and commander in chief during the English Civil War, the eldest son of the 2nd baron, was born at Denton, near Otley, Yorkshire, on Jan. 17, 1612. He studied at St. John's college, Cambridge (1626–29), and then served as a volunteer with the English army in the Low Countries under Lord Vere, whose daughter Anne he married in 1637. He was knighted in 1640.

The Fairfaxes, father and son, though they served in the royal army during the first Scottish War, sided with the Long Parliament in its quarrel with Charles I. When Charles endeavoured to raise a guard for his own person at York, intending it to form the nucleus of an army, Fairfax presented a petition asking him to discontinue the raising of troops. This was at a meeting of the freeholders and farmers of Yorkshire convened by the king on Heworth moor near York (June 1642). When war broke out, Lord Fairfax was appointed general of the parliamentary forces in the north, and his son, Sir Thomas, was made lieutenant-general of horse under him. Both father and son distinguished themselves in the campaigns in Yorkshire (*see* CIVIL WAR, ENGLISH). Sometimes severely defeated, more often successful and always energetic, prudent and resourceful, they maintained the struggle until the crisis of 1644, when York was held by the marquess of Newcastle against the combined forces of the English parliamentarians and the Scots, and Prince Rupert hastened with all available forces to its relief. The battle of Marston moor (*q.v.*) mas decisive of the struggle in the north. The younger Fairfax bore himself nith the greatest gallantry in the battle and, though severely wounded, managed to join Cromwell and the victorious cavalry on the other wing. One of his brothers, Col. Charles Fairfax, was killed in the action.

After the passing of the Self-denying ordinance Thomas Fairfax was selected to succeed Essex, as lord general, with Oliver Cromwell as his lieutenant-general and cavalry commander; and after a short preliminary campaign the "New Model" army justified its existence, and "the rebels' new brutish general," as the king called him, his capacity as commander in chief in the decisive victory of Naseby (*q.v.*). The king fled to Wales. Fairfax besieged Leicester and was successful at Taunton, Bridgwater and Bristol. Oxford surrendered in 1646, and it is characteristic of the man that the general's first act was to set a strong guard on the Bodleian library.

In Jan. 1647 Charles was delivered up by the Scots to the commissioners of parliament. Fairfax met the king beyond Nottingham and accompanied him during the journey to Holmby, treating him with the utmost consideration. In the confused negotiations between the various parties which followed, Fairfax was placed in the unpleasant position of intermediary between his own officers and parliament. He was more at home in the field than at the head of a political committee and, finding events too strong for him, he sought in vain to resign his commission as commander in chief. He remained the titular chief of the army party. and with the greater part of its objects he was in complete, sometimes most active, sympathy. Shortly before the outbreak of the second Civil War, Fairfax succeeded his father in the barony and in the office of governor of Hull. In the field against the English royalists in 1648 his operations culminated in the successful siege of Colchester, after the surrender of which place he approved the execution of the royalist leaders Sir Charles Lucas and Sir George Lisle, holding that these officers had broken their parole. At the same time Cromwell's great victory of Preston crushed the Scots, and the independents became practically all-powerful.

Milton, in a sonnet written during the siege of Colchester, called upon the lord general to settle the kingdom, but the crisis was now at hand. Fairfax approved, if he did not take an active part in, Pride's Purge (Dec. 6, 1648), but on the question of the fate of Charles he opposed the army officers. He presided over the judges who were to try the king at the preliminary sitting. Then, convinced that the king's death was intended, he refused to act. In calling over the court, when the crier pronounced the name of Fairfax, Lady Fairfax, from the gallery, cried out "that the Lord Fairfax was not there in person, that he would never sit among them, and that they did him wrong to name him as a commissioner." His last service as commander in chief was the suppression of the Leveller mutiny at Burford in May 1649. He had been reappointed lord general, but the council of state resolved to send an army against the Scots in 1650. Fairfax resigned his commission. Cromwell was appointed his successor. Fairfax received a pension of £5,000 a year, and lived in retirement at his Yorkshire home of Nunappleton till after the death of the Protector.

The troubles of the later Commonwealth recalled him to political activity, when Monk invited his co-operation against Lambert's army. When, in Dec. 1659, he appeared at the head of a body of Yorkshire gentlemen, 1,200 horse quitted Lambert's colours and joined him. That day secured the restoration of the monarchy. Fairfax was elected member for Yorkshire in the "free" parliament and led the commission appointed by the house of commons to wait upon Charles II at The Hague and urge his speedy return.

The remaining 11 years of the life of Lord Fairfax were spent in retirement at his seat in Yorkshire. He died at Nunappleton on Nov. 12, 1671, and was buried at Bilborough, near York. As a soldier he was exact and methodical in planning, in the heat of battle "so highly transported that scarce any one durst speak a word to him" (Bulstrode Whitelocke), chivalrous and punctilious in his dealings with his own men and the enemy. Honour and conscientiousness were equally the characteristics of his private and public character. But both in war and peace he was overshadowed by his associate Cromwell.

Lord Fairfax translated some of the psalms, and wrote poems on solitude, the Christian warfare, the shortness of life, etc. During the last year or two of his life he wrote two Memorials which have been published—one on the northern actions in which he was engaged in 1642–44, and the other on some events in his tenure of the chief command. At York and at Oxford he endeavoured to save the libraries from pillage, and he enriched the Bodleian with some valuable manuscripts. His only daughter, Mary Fairfax, was married to George Villiers, the profligate duke of Buckingham of Charles II's court.

BIBLIOGRAPHY.—*Fairfax* Correspondence, 4 vol., 2 vol. ed. by G. W. Johnson (1848) and 2 vol. under the title Memorials of the Civil *War* ed. by R. Bell (1849); M. A. Gibb, The Lord General, a Life of Thomas *Fairfax* (Oxford, 1940) ; S. R. Gardiner, History of the Great Civil War (1893).

His descendant Thomas, 6th baron (1692–1782), inherited from his mother. the heiress of Thomas, 2nd Baron Culpepper, large estates in Virginia, U.S., and having sold Denton hall and his Yorkshire estates he retired there about 1746, dying a bachelor. He was a friend of George Washington's. Thomas found his cousin William Fairfax settled in Virginia and made him his agent; and Bryan (1737–1802), the son of William Fairfax, eventually inherited the title, becoming 8th baron in 1793. His claim was admitted by the house of lords in 1800. But it was practically dropped by the U.S. family, until, shortly before the coronation of Edward VII, the successor in title was discovered in Albert Kirby Fairfax (1870–1939), a descendant of the 8th baron, who was a U.S. citizen. In Nov. 1908 Albert's claim to the title as 12th baron was confirmed by the house of lords.

FAIRFIELD, a town of Fairfield county, Conn., U.S., on Long Island sound, adjoining Bridgeport on the southwest. (For comparative population figures *see* table in CONNECTICUT: *Population.*)

Although known as a summer resort, industries include the manufacture of batteries, chemicals, drugs, roller bearings and automobile accessories. Fairfield university, officially Fairfield University of St. Robert Bellarmine (Roman Catholic), a college of liberal arts for men, was founded there in 1942.

The town was settled in 1639 by Roger Ludlow, who in 1637 had been one of a band which defeated the Pequot Indians in the vicinity. During the colonial period it was a place of importance, but later it was overshadowed by Bridgeport. On July 8, 1779, Fairfield was burned by the British and Hessians under Gov. William Tryon.

FAIRHAVEN, a town of Bristol county, Mass., U.S., on Buzzards bay, across the Acushnet river from New Bedford. (For comparative population figures *see* table in MASSACHUSETTS: Population.) The town is a summer resort and a residential suburb of New Bedford and has factories which manufacture tacks, machinery and commercial fishing equipment. Whaling, the principal industry in mid-19th century, was replaced by shellfishing, deep-sea fishing and the building of fishing vessels. Fairhaven was the home port of Captain Joshua Slocum, the first man to sail alone around the world (1895–98).

First settled in 1670, Fairhaven was separated from New Bedford and incorporated as a town in 1812. In 1778, British forces dismantled the small fort and set fire to the town, but were driven off by militia under Maj. Israel Fearing. The fort was rebuilt at once and renamed Ft. Phoenix. In the War of 1812, it was a strong defense point on the New England coast. (CA. M. C.)

FAIR ISLE, a rugged island between the Orkney and Shetland Islands northeast of the Scottish mainland in Zetland county. It is composed of Old Red Sandstone and its highest point, Ward hill, reaches 400 ft. It has two lighthouses. Fewer than 100 crofters live on Fair Isle, many of whom still knit the multicoloured woollen garments which made the island famous. To ornithologists Fair Isle rivals Heligoland in its importance as a bird-migration station, and since 1949 it has belonged to the Fair Isle Observatory trust.

Pop. (1951) 73; area 3 sq.mi.

FAIR LAWN, a borough of Bergen county, N.J., U.S., 10 mi. from the George Washington bridge to New York city. The borough is separated from Paterson, N.J., by the Passaic river. The population was 36,421 in 1960. (For comparative population figures *see* table in NEW JERSEY: Population.)

A carefully planned community, the borough was incorporated in 1924, and in 1948 a council-manager form of government was established.

In 1929 a model garden apartment community named Radburn was built under the auspices of the Rockefeller foundation. This community served as an example of desirable apartment planning; its pattern was adopted in modified form in many places. An industrial park covering 175 ac. is another example of community planning. The park contains several light industries whose buildings have been integrated into the community without depressing property values. Local manufactures include airplane parts, dyes and concrete products. (S. HE.)

FAIRMONT, a city of northern West Virginia, U.S., 65 airline miles south of Pittsburgh, Pa., at the confluence of West Fork and Tygart Valley rivers, the head of navigation of the Monongahela river; seat of Marion county. (For comparative population figures *see* table in WEST VIRGINIA: Population.) First settled after the American Revolution, it was incorporated in 1820 as Middletown, and renamed Fairmont in 1843. After the arrival of the Baltimore and Ohio railroad in 1852 it became an important political, mercantile and bituminous coal-mining centre. At nearby Monongah a coal mine explosion took 359 lives in 1907. Since 1919 Fairmont has had a unique four-man bipartisan commission government. Fairmont State college was founded in 1867 as a state supported college. Industrial products include glass containers, aluminum sheets, fluorescent lamps, paper boxes, mining machinery and coke. (GE. W. SM.)

FAIR OAKS, a station on a branch (formerly famous as the York river railway) of the Southern railway, 6 mi. E. of Richmond, Virginia, U.S. It is noted as the site of one of the battles of the Civil War (*q.v.*), fought on May 31 and June 1, 1862, between the Union (Army of the Potomac) under Gen. G. B. McClellan and the Confederate forces (Army of Northern Virginia) commanded by Gen. J. E. Johnston. The attack of the Confederates was made at a moment when the river Chickahominy divided the federal army into two unequal parts—two corps on the south bank, three on the north—and was, moreover, swollen to such a degree as to endanger the bridges. Gen. Johnston stationed part of his troops along the river to prevent the Federals sending aid to the smaller force south of it, upon which the Confederate attack, commanded by Gen. Longstreet, was directed. Many accidents, due to the inexperience of the staff officers and to the difficulty of the ground, hindered the development of Longstreet's attack, but the Federals were gradually driven back with a loss of ten guns, though at the last moment reinforcements managed to cross the river and re-establish the line of defense. At the close of the day Johnston was severely wounded, and Gen. G. W. Smith succeeded to the command. The battle was renewed on June 1 but not fought out. At the close of the action Gen. R. E. Lee took over the command of the Confederates, which he held till the final surrender in April 1865. So far as the victory lay with either side, it was with the Union army, for the Confederates failed to achieve their purpose of destroying the almost isolated left wing of McClellan's army, and after the battle they withdrew into the lines of Richmond. The Union losses were 5,031 in killed, wounded and missing; those of the Confederates were 6,134. The battle is alternatively known as the battle of Seven Pines.

FAIR TRADE LAWS, a term applied to laws that allow manufacturers of branded, trade-marked goods, or, in some instances, distributors of such products, to fix the actual or minimum resale prices of these branded goods by resellers. Such price controls are more widely effective in retail sales to consumers than at other levels of marketing. Only a few types of goods have come under such controls, the leading examples being drugs and pharmaceuticals, books. photographic supplies, liquors, miscellaneous household appliances and various specialty goods.

By the 1960s "fair trade laws" had been enacted at various times in 45 states of the United States. The laws are rooted in a long, controversial history that began in the 1880s and has been paralleled by similar developments in other parts of the world, especially in the highly industrialized western countries.

The designation "fair trade law" became widespread in the United States following the adoption of the California Fair Trade law in 1931, and its amendment in 1933. The label probably was inherited from the American Fair Trade league, an association of manufacturers of branded goods organized in 1913, which attempted for some 20 years to obtain federal legislation sanctioning resale price maintenance contracts between manufacturers and their distributors. Prior to 1931 in the United States, and in other countries historically and currently, the recognized name for this important problem area was "resale price maintenance."

The Sherman Antitrust act of 1890 in the United States, with its prohibition of monopolies, early gave resale price maintenance a peculiar status. The U.S. courts, especially the supreme court, erected barriers to effective enforcement by prohibiting or casting doubts upon the means of enforcement. In other countries, and especially in Great Britain, resale price maintenance came into wide use, enforced by trade associations and groups of trade associations. Before enactment of the 1931 California Fair Trade law, resale price maintenance in interstate commerce in the United States was limited to the mere suggestion of prices to dealers without effective power of enforcement or to sale through bona fide agents and on consignment. The crux of the whole matter from the point of view of those wishing such controls was inability to enforce prices on unwilling independent dealers who chose to sell below the suggested prices of manufacturers. Under these conditions, the controls covered only a small proportion of total consumers' goods.

In 1933 California amended its 1931 statute to make the contractual prices agreed upon between a manufacturer and contracting dealers binding upon all resellers. This so-called "nonsigners' clause" with its coercive authority over unwilling dealers gave the fair trade movement enormous momentum. Although resale price maintenance historically is not a depression phenomenon, its legislative sanction was influenced very greatly by the depressed markets of the 1930s. In a few years following the 1931 and 1933 California acts, identical or similar statutes were enacted by 44 other states. In the meantime, the legal doubts and barriers were removed or relieved by a favourable 1936 review by the U.S. supreme court in Old *Dearborn Distributing Co.* v. *Seagram Distillers Corp.,* 229 U.S. 183 and passage of the Miller-Tydings act in 1937, which removed the barriers in interstate commerce between states with fair trade laws.

Thus, when World War II began, resale price maintenance had become widely accepted legally in the United States, as it had also in several other countries. The coercive pouer of the nonsigners' clause, in fact, gave manufacturers more specific authority over pricing in the U.S. marketing channels than was true in most other parts of the world, but, as it turned out, this was only a temporary peak in the United States. In the postwar years the entire issue was reopened in the United States and elsewhere.

In 1951, the U.S. supreme court raised serious doubts concerning the nonsigners' clause in *Schwegmann Bros.* v. *Culvert Distillers Corp.,* 341 U.S. 384. In 1952 congress passed the McGuire act in order to reestablish the position of the nonsigners' clause, and it was upheld by the U.S. supreme court in 1953. However, in subsequent years the fair trade laws of the states ran into increasing difficulties in state supreme courts. By the end of 1959, fair trade was without firm legal sanction or was in serious legal jeopardy in 20 states (including Vermont, Texas and Missouri, where such laws had never been enacted) and the District of Columbia.

During the postwar years, resale price maintenance as a business practice and organized movement weakened even more perceptibly in some other countries. It was prohibited in both Canada and Sweden and serious doubts about it existed in France. Developments in Great Britain were most interesting in light of the long British record of collective enforcement going back to 1890 and the relatively favourable reports on the subject by governmental committees in 1920 and in 1930. During the earlier period, British courts and governmental committees interpreted the right of contract broadly to permit manufacturers to make resale price maintenance agreements among themselves and with their distributors, provided undue restraint of trade was not shown. In the absence of outright prohibitions of collusive agreements or cartels, as in the United States, collective enforcement became widespread. In 1949, a third governmental committee, following an extended investigation and much more comprehensive treatment than in the earlier reports, recommended strongly against collective sanctions and enforcement. It also took a strong position in favour of the right of independent enforcement by individual producers.

In 1956 the Restrictive Trade Practices act prohibited the enforcement of resale prices by the collective withholding of supplies and related arrangements; it also strengthened the position of the individual supplier by giving him a right of recourse to the courts in enforcement against dealers who were not parties to the agreement. A review of law, regulation and practice throughout the leading nations of the world in 1960 disclosed that the issues and forces involved under "fair trade" and "resale price maintenances" were far from being resolved.

Actually, it seems unlikely that a stable equilibrium or solution can be achieved either in law or in business practice. The initial movement beginning in the 1880s reflected the impact of successful brand promotion by manufacturers upon relations in the distributive trades and the division of the market among competing brands. The very success of manufacturer brand promotion made for more active competition among retailers. The modern U.S. drug store, for example, with its shelves loaded with national brands is in much keener, more direct competition with other similar stores than was true of the former "chemists" and "apothecaries" who did their own mixing and labeling. Resale price maintenance by manufacturers might have become fairly widespread and effective, however, if retailing had remained in the hands of armies of unorganized small, local independent dealers. Large-scale retailing, together with the growth of strong dealer organizations, sets up strong conflicting interests within retailing and in the marketing channels. In most fields in highly industrialized countries. the marketing channels are both complex and highly overlapping. Consequently the establishment and enforcement of a single price or even of a minimum price by manufacturers is a complicated and burdensome business in the absence of collective enforcement efforts, limitation of numbers of enterprises or governmental intervention. In a few instances. as in the sale of alcoholic beverages in some jurisdictions, resale price maintenance has become mandatory and is enforced by governmental agencies. The long-run rationale of "fair trade" or resale price maintenance points either away from the unique traditional antitrust approach in the United States or toward governmental regulation. The conflicting interests of consumers, retailers, wholesalers and producers are so diverse and well organized as to allow no point of stable equilibrium in the absence of private or public limitations on free access to the market. Effective resale price controls act as magnets to attract excessive capital and manpower into distributive activities. Hence such a program is not workable in the long run without means of restricting numbers of enterprises.

Unfortunately, in the play of the competing forces and pressures on markets, occasional important injuries to individual enterprises or classes of enterprises occur. Thus, manufacturers of well known advertised brands may be injured if their products are featured as "leaders" or "loss leaders" or are used as "bait," insofar as distributors may be able to push the sale of other brands in higher regard with them. Small independent specialty dealers are unable to use "leaders" and "loss leaders" as effectively as are department stores and supermarkets. Sellers and the consuming public both are injured by deceptive price practices. It is generally agreed among impartial observers that resale price maintenance or "fair trade" is not a true solution to problems arising out of trade conflicts or unfair and deceptive practices. It is held that active enforcement of antitrust legislation and of laws curbing unfair and deceptive methods of competition provide adequate safeguards for all concerned — manufacturers, retail and wholesale distributors and consumer-buyers.

FAIRŪZĀBĀDĪ (Abū-ṭ-Ṭāhir ibn Ibrahim Majd ud-Dīn ul-Fairūzābādī) (1329–1414), Arabian lexicographer, was born at Kārazīn near Shiraz. His student days were spent in Shiraz, Wāsit, Baghdad and Damascus. He taught for ten years in Jerusalem, and afterwards travelled in western Asia and Egypt. In 1368 he settled in Mecca, where he remained for 15 years. He next visited India and spent some time in Delhi, then remained in Mecca another ten years. The following three years were spent in Baghdad, in Shiraz (where he was received by Timur), and in Ta'iz. In 1395 he was appointed chief cadi (qadi) of Yemen, married a daughter of the sultan, and died at Zabid in 1414. During this last period of his life he converted his house at Mecca into a school of Mālikite law and established three teachers in it. He wrote a huge lexicographical work of 60 or 100 volumes uniting the dictionaries of Ibn Sida, a Spanish philologist (d. 1066), and of Sajānī (d. 1252). A digest of or an extract from this last work is his famous dictionary *al-Qāmūs* ("the Ocean"), which has been published in Egypt, Constantinople and India, has been translated into Turkish and Persian, and has itself been the basis of several later dictionaries.

FAIRY, the common term for a supposed race of supernatural beings who magically intermeddle in human affairs. (Fr. *fée*, faerie; Prov. *fada;* Sp. *hada;* Ital. fata; med. Lat. *fatare,* to enchant, from Lat. jatum, fate, destiny.) They are not the immediate product of one country or of one time; they have a pedigree. But mixture and connection of races have so changed the original folk-product that it is difficult to separate the different strains that have gone to the moulding of the result.

It is not in literature that the early forms of the fairy belief must be sought. Many of Homer's heroes have fairy lemans, called nymphs, but the fairy leman is familiar to the unpoetical Eskimo, and to the Red Indians, with their bird-bride and beaver-bride (see A. Lang's *Custom and Myth,* "The Story of Cupid and Psyche"). The Gandharvas of Sanskrit poetry are also fairies.

One of the most interesting facts about fairies is the wide distribution and long persistence of the belief in them. They are the chief factor in surviving Irish superstition. Here they dwell in the "raths," old earth-forts. They are an organized people, and their life corresponds to human life in all particulars, They carry off children and are generally the causes of all mysterious phenomena. Whirls of dust are caused by the fairy marching army, as by the beings called Kutchi in the Dieri tribe of Australia. The fairy changeling belief also exists in some districts of Argyll. In Ireland and the west Highlands neolithic arrowheads and flint chips are still fairy weapons. They are dipped in water, which is given to ailing cattle and human beings as a sovereign remedy for diseases. In the Highlands there is much more interest in second sight than in fairies, while in Ireland the reverse is the case The best book on Celtic fairy lore is still that of the minister of Aberfoyle, the Rev. Mr. Kirk (ob. 1692). His work on *The* Secret Comnzonwealth *of* Elves, Fauns, *and* Fairies, left in ms. and incomplete (the remainder is in the Laing mss., Edinburgh University library), uas published (100 copies) in 1815 by Sir Walter Scott, and in the *Bibliothèque* de Carabas (Lang) there is a French translation. There is a theory that the fairies survive in legend from prehistoric memories of a pigmy people dwelling in the subterranean earth houses, but the contents of these do not indicate an age prior to the close of the Roman occupation of Britain; nor are pigmy bones common in neolithic sepulchres. The "people of peace" (*Daoine Shie*) of Ireland and Scotland are usually of ordinary stature, only varying from mankind by their proceedings. (*See* J. Curtin, *Irish Folk-tales.*)

The belief in a species of lady fairies, deathly to their human lovers, was found by R. L. Stevenson to be as common in Samoa (see *Island Nights' Entertainments*) as on the banks of Loch Awe. The Greek sirens of Homer are a form of these fairies, as the Nereids, Oreads and Naiads are fairies of wells, mountains and the sea. The fairy women who come to the births of children and foretell their fortunes (Fata, Moerae, ancient Egyptian Hathors, *Fées,* Dominae Fatales), with their spindles, are refractions of the human "spae-women" (in the Scots term) who derive omens of the child's future from various signs. These women. represented in the spiritual world by *Fata,* bequeath to us the French *fée*, in the sense of fairy. Perrault uses *fée* for anything that has magical quality.

The nearest analogy to the shape which fairy belief takes in Scotland and Ireland—the "pixies" of southwestern England—is in *Jān* or *Jinnis* of the Arabs, Moors and people of Palestine. In stories which have passed through a literary medium, like *The Arabian Nights*, the *geni* or *Jān* do not so much resemble our fairies as they do in the popular superstitions of the East, orally collected. They chiefly differ from our fairies in their greater tendency to wear animal forms; though when they choose to appear in human shape they are not to be distinguished from mortals. Like the fairies everywhere they have amours with mortals. The herb rue is potent against them, as in British folklore. They, like the British brownies (a kind of domesticated fairy), are the causes of strange disappearances of things. To preserve houses from their influences rue is kept, and the name of Allah is constantly invoked.

They often bear animal names. Euphemistically they are addressed as *mubārakin*, "blessed ones." As our fairies give gold which changes into withered leaves, the *Jān* give onion peels which turn into gold. Like our fairies the Jan can apply an ointment. kohl, to human eyes, after which the person so favoured can see Jan, which are invisible to other mortals, and can see treasure wherever it may be concealed. (See Folk-lore *of* the Holy Land, by J. E. Hanauer, 1907.)

The enjoyment of love between a fairy and a mortal is generally qualified by some restriction or compact, the breaking of which is the cause of calamity to the lover and all his race, as in the notable tale of Melusine (*q.v.*, and see the chapter De *lamiis* et *nocturnis larvis* in *Otia Imperialia,* written early in the 13th century, by Gervaise of Tilbury). At the birth of Ogier le Danois six fairies attend, five of whom give good gifts, which the sixth overrides with a restriction. There is little in these fairies of romance to distinguish them from human beings, except their supernatural knowledge and power. To this class belong the fairies of Boiardo, Ariosto and Spenser.

There is no good modern book on the fairy belief in general. Keightley's *Fairy Mythology* is interesting; Rhys's *Celtic Mythology* is copious about Welsh fairies, practically identical with those of Ireland and Scotland. The works of Mr. Jeremiah Curtin and Dr. Douglas Hyde are useful for Ireland, for Scotland, Kirk's *Secret Commonwealth* has already been quoted. Scott's dissertation on fairies in *The Border Minstrelsy* is rich in lore, though Scott had not the benefit of recent researches. There is a full description of French fairies of the 15th century in the evidence of Jeanne d'Arc at her trial (1431) in Quicherat's *Procès de Jeanne d'Arc,* vol. i pp. 67, 68, 187, 209, 212; vol. ii pp. 390, 404, 450. In another vein is Sir A. Conan Doyle's *The Coming of the Fairies* (1922).

FAIRY RING, the popular name of the darker green circles occurring on lawns or meadows, in folklore supposed to mark the spots where fairies danced at midmght. They are the result of the growth in the soil of the mycelium (spawn) of certain fungi. The mycelium arises from a spore and radiates from the centre outward at an approximately equal rate, the resulting circle increasing in diameter annually. Fruiting bodies arise at the periphery of the ring. The darker colour is produced by a stimulation of the vegetation due to the increase of available nitrogen brought about both by the action of the fungus on the organic matter in the soil and by the decay of the old mycelium. Rings up to 65 m. (71.1 yd.) in diameter have been recorded.

JOHN H. GERARD

FAIRY RING MUSHROOMS (MARASMIUS OREADES)

FAISAL IBN HUSAIN (1885–1933), king of Iraq, was born at Taif, third son of Sherif Husain, a descendant of Fatima, only surviving child of the Prophet, through Hasan, her eldest son by marriage with 'Ali ibn Abi Talib, fourth amir al-Mu'-minin. After the custom of his house, Faisal was sent when only seven davs old to Rahab palace, the country seat of the al-'Aun family, in the territory of his clan, Beni 'Abadiyah and their confederates the 'Ataibah. There he remained until he was seven. In 1893, when Husain was ordered to Constantinople, Faisal accompanied him and was educated privately in that city. In 1905 he married his cousin. He returned to the Hejaz in 1909, when his father was appointed sherif.

In 1913 Faisal became deputy for Jidda and proceeded to identify himself with the Arab national movement. He commanded his father's forces in Asir in 1914 and was at Mecca on the outbreak of World War I. He was posted with the Turkish governor of Syria in 1915, but escaped to the Hejaz early in the folloaing year and there played a leading part in the Arab revolt, commanding the Arab forces with General Allenby's army until the capture of Aleppo in Oct. 1918. His influence with the tribes did much to keep Husain's tribal levies in the field. As commander in chief of the Arab army under the Allied commander in chief he then undertook the administration of the newly constituted Syrian state and, after attending the peace conference in Paris, returned to Syria in April 1919.

In September he again visited Europe and remained until Feb. 1920; in the following month he was proclaimed king of Syria, but being unable to come to terms with the French mandatory power he left Damascus in July 1920. After spending the winter in England he proceeded to Iraq as candidate for the throne in June 1921 and was elected king by a plebiscite in which he received 96% of the votes cast. He died suddenly at Berne on Sept. 8, 1933, after another visit to London.

For the events of his reign see IRAQ.

See P. W. Ireland, *Iraq: a Study in Political Development* (1937); George Antonius, *The Arab Awakening (1938).*

FAITH is an attitude of mind which, though not confined to religious experience, can best be examined by setting out from its manifestations within that sphere of experience. There we find in clearest form illustrations of the several shades of meaning which the word "faith" has borne. A classic definition is that presented in the Epistle to the Hebrews, xi, 1: "faith is the substance of things hoped for, the evidence of things not seen" (King James or Authorized version). In the Revised version the word for "evidence" is rendered as "proving," and for "substance" are offered the alternative translations "assurance" and "the giving substance to." In the Revised Standard version, "evidence" becomes "conviction," and "substance" is translated "assurance." Assurance, certitude or convincedness, and giving substance to what we do not perceive and as to which we, therefore, only entertain an idea or a supposition, may at first seem somewhat disparate meanings for one word; but the connection between them is revealed by a common signification of the word "realize." We speak of realizing what some event is when we discern its import, and when what was, so to say, "nothing to us" is found to be something with which we have to reckon or which can influence our thought and action. Personal certitude or conviction as to what as yet is not matter of scientific knowledge or proven with logical certainty is of the essence of faith; and action upon it may lead on to discovery of the actuality of the object; *i.e.,* to substantiation of the hoped for or the unseen. In the case of faith in God, whom "no man hath seen at any time," such certitude cannot issue in sight or sensibly verified knowledge; though it may develop into "proving" in the sense of establishing reasoned and reasonable belief, such as fact and experience corroborate. But in other spheres faith often issues in knowledge, such as can be characterized as seeing or perceiving what, without such exercise of faith, would have remained unseen or unknown. Thus the faith of Columbus ('realized" America for the European; and an idea of Stephenson's led to the actual locomotive engine. In neither case did faith create the reality, but in both it substantiated the unseen, and brought men into actual touch with what had been but conceived or supposed. Thus faith begins in creating or fashioning an idea; and it may issue in finding a real counterpart to the idea. There is, however, no necessity that it shall so issue; and frequently it does not: no one. *e.g.,* has realized the idea of a machine capable of perpetual motion, though many have experimented with the notion. The description of faith cited above from Heb. xi, 1 is only lacking in psychological completeness. in that it contemplates successful ventures alone, and is silent as to such as may fail. Otherwise it is of more general and exhaustive a nature than is any other conception met with in the New Testament. For instance, St. Paul considers the efficacy of faith only insofar as it is faith in Christ or in God; one of his central doctrines is that we are justified by God through faith in Christ. On the other hand the writer of Hebrews includes, among his illustrations of the faithful life, the case of Rahab who was one of "them that believed not" in the God of Israel; and the object of faith, with him, includes the whole region of the unseen, whatever it may contain. His teaching is aptly expressed in the lines of Hartley Coleridge: faith

> . . . is an affirmation and an act
> That binds eternal truth to present fact.

The long list of instances of the faithful given in Heb. xi is made up of prophets, kings, etc., who achieved the heroic life and victories of various kinds, in virtue of their souls being possessed by faith; their faith was verified by their lives. They are all concrete embodiments of the principle "nothing venture, nothing have." And that principle is not only the essence of religious faith; it underlies the acquisition of all human knowledge, such as, for the conduct of life, is most worth having. Thus the "father of the faithful" who obeyed his inward summons and went forward "not knowing whither" is an allegory of the intellectual progress of mankind. Man did not begin with scientific knowledge or knowing, but with learning through doing. He learned by failure as well as by success, and in either case he ventured before he came to have. The uniformity of nature, *e.g.,* was not written so legibly on natural phenomena that, in the time of man's primitiveness, he who ran could read it off. On the other hand, if it had not been tentatively assumed, here a little and there a little. it could never have got "substance" for man's knowledge or relevance to his life; had it not been trusted while as yet unverified, no evidence of its actuality could have emerged. And the most recent advance in logic consists in making clearer than ever before that this principle of uniformity, underlying all our inductive science, is, and must ever remain, a postulate incapable of logical proof. Thus faith, in its primary sense, is not a word to be confined to the vocabulary of theology. Philosophy, or theory of knowledge, requires it and so does science, if it would understand its own logical structure and the presuppositions on which it rests. Probability is not only "the guide of life"; it is also of the very texture of all ('knowledge" as to the actual world as distinguished from pure mathematics or truth as to the relations between ideas; and probability in the last resort, *i.e.,* in the case of the fundamental postulates underlying induction, is not a matter of numerical calculability or of formal logic, but of human hope, sanguine expectation, faith in the unseen. Instead of being logically certified it is but pragmatically "verified." The old hard and fast line between knowledge and belief or faith has disappeared. The very rationality of the world, which science would read and expound, is at bottom an idea of faith. Reason, if it include the discovery of true premises as well as the logical deduction of consequences from premises that may be either true or false, contains faith as well as logical linkage of sense data. Besides the primary meaning that has been set forth "faith" has borne others. Sometimes the word has been used as a synonym for "belief" or intellectual assent. But whereas belief is more or less constrained by fact already known, and which convinces us independently of any striving on our part, "faith" is generally used to emphasize the active or volitional element of experience, involved in venture reaching beyond the already known. Faith, again, is to be distinguished from credulity, with which it is apt to be confounded. The open mind and docility, personified in the New Testament as "the little child," are requisite for reception of truth; but there is no beatitude on credulousness. If faith, or the working to a lead or suggestion that experience suggests but does not warrant, is to issue in reasonable belief, credulity must be restrained by resort to the method of doubt, which is equally essential for acquisition of knowledge. And faith proper is doubt-sifted credulity. It proves all things before holding fast to them as true, and pursues no apparently open road after it has been shown to be closed; whereas credulity is interested belief, such as is often resorted to in order to escape the discomfort of uncertitude. Faith or belief worth calling belief must often "be purchased with the sweat of the brow." Another meaning of "faith" current in theological literature as well as in common speech, is that of trust. This resembles faith, as above described, and differs from belief in involving will and feeling: but it is rather an attitude issuing out of, and presupposing, the faith which creates its idea and then establishes belief in its actuality. Before we can trust in God, we must believe that He is; and that belief is acquired by a venture of faith. Lastly, it is unnecessary to narrow down faith to moral postulation, or to the attitude of valuation, exclusively. Religious faith was forthcoming before advanced morality appeared; moreover, it is not concerned with what ought to be real or realized, but with what is realizable. Theology founded on faith is dogma concerning ultimate reality, not pictorial recipes for pious conduct. When religious faith is conceived as but a particular case of the faith that is involved in all knowledge and reason, science and faith can be seen to be complementary, not mutually exclusive; they can lodge, without need of reconciliation, in brotherly relation within one mind, provided the mind is content with reasonableness, where logical rationality is unattainable.

(F. R. T.)

FAITHFULL, EMILY (1835–1895), English reformer, who took great interest in the problems of working women, was born at Headley rectory, Surrey, in 1835. She set up a printing establishment for women in London (1860) and soon afterward was appointed printer and publisher to Queen Victoria. Her The Victoria Magazine (est. 1863) advocated the claims of women to remunerative employment. She published a novel, Change *Upon* Change (1868), and lectured widely and successfully both in England and the U.S.

She died in Manchester, May 31, 1895.

FAITH HEALING, a form of "mind cure," characterized by the doctrine that pain and disease really exist, but may be neutralized and dispelled by faith in divine power; Christian Science (*q.v.*) holds that pain is an illusion and seeks to cure the patient by instilling into him this belief. In the Christian church the tradition of faith healing dates from the earliest days of Christianity; upon the miracles of the New Testament follow cases of healing, first by the Apostles, then by their successors. After the 3rd century it became transformed into trust in relics, though faith cures still occur sporadically in later times. With the Reformation faith healing proper reappears among the Moravians and Waldenses, who, like the Peculiar People of the 19th and 20th centuries, put their trust in prayer and anointing with oil. In the 16th century faith cures were recorded of Luther and other reformers, in the next century of the Baptists, Quakers and other Puritan sects, and in the 18th century the faith healing of the Methodists in this country was paralleled by pietism in Germany. In the 19th century Prince Hohenlohe-Waldenburg-Schillingsfurst, canon of Grosswardein, was a famous healer on the continent; the Mormons and Irvingites were prominent among English-speaking peoples; in the last quarter of the 19th century faith healing became popular in London, and Bethshan homes were opened in 1881, and since then it has found many adherents in England.

Under faith healing in a wider sense may be included: (1) the cures in the temples of Aesculapius and other deities in the ancient world; (2) the practice of touching for the king's evil, in vogue from the 11th to the 18th century; (3) the cures of Valentine Greatrakes, the "stroker" (1629–83); and (4) the miracles of Lourdes and other resorts of pilgrims, including St. Winifred's well in Flintshire, Trêves with its holy coat, the grave of the Jansenist F. de Paris in the 18th century, the little town of Kevelaer from 1641 onward, the tombs of St. Louis, Francis of Assisi, Catherine of Siena and others.

An animistic theory of disease was held by several European faith healers. Used in this sense, faith healing is indistinguishable from much of savage leechcraft, which seeks to cure disease by expelling the evil spirit in some portion of the body. Although it is usually present, faith in the medicine man is not essential for the efficacy of the method. The same may be said of the lineal descendant of savage medicine—the magical leechcraft of European folklore; cures for toothache, warts, etc., act in spite of the disbelief of the sufferer; how far incredulity on the part of the healer would result in failure is an open question.

From the psychological point of view all kinds of mind cure depend on suggestion (*q.v.*). In faith healing proper powerful direct suggestions are used, while the religious atmosphere and the autosuggestions of the patient co-operate, especially where the cures take place during a period of religious revival when large assemblies and strong emotions are found.

FAITHORNE, WILLIAM (*c.* 1616–1691), English engraver and portrait draftsman noted for his fine line engraving, was born in London. He was a pupil of the painter Robert Peake, Sr., and the engraver John Payne. During the Great Rebellion he was captured, imprisoned and exiled. In Paris he became the protégé of the print collector Michel de Marolles and may have worked in the studio of Philippe de Champaigne. He returned to London in 1650 to become a print seller, printer and engraver. In 1662 he published The Art *of* Graving *and Etching.* His early engraving style is derived from Claude Mellan; his middle period combines Mellan's line technique with delicate point work, and it was in this middle period that Faithorne raised English line engraving to a level on which it competed with the best French work. In 1658 Faithorne published his maps of London and he made also maps of Virginia and Maryland. Examples of his portrait drawings are in the Ashmolean museum, the Bodleian library and the British museum. He died on May 13, 1691, in London.

One of his sons, WILLIAM (1656–1710), became a mezzotint engraver.

See Louis Alexander Fagan, *A Descriptive Catalogue of the Engraved Works of William Faithorne* (1888). (C. H. C. B.; H. Es.)

FAIZABAD, a town of Afghanistan, capital of the province of Badakshan, situated on the Kokcha river. In 1821 it was destroyed by Murad Beg of Kunduz, and the inhabitants removed to Kunduz. But after Badakshan was annexed by Abdur Rahman, the town recovered its former importance, and became a considerable place of trade.

The chief cantonment for eastern Afghanistan and the Pamir region, it is protected by a fort built in 1904.

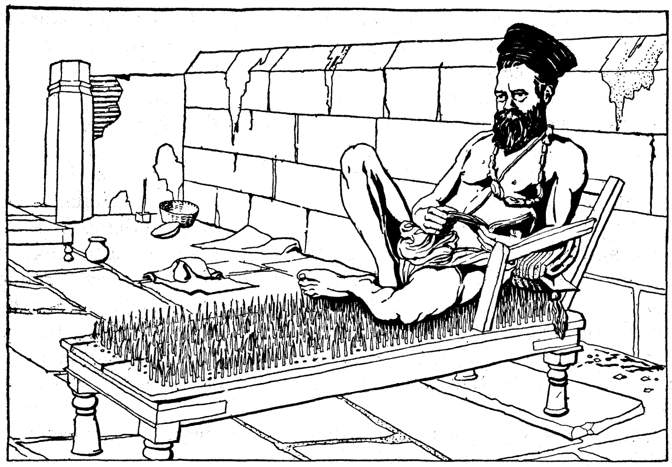
FAJANS, KASIMIR (1887–), Polish physical chemist, discovered (1913), simultaneously with Frederick Soddy, the displacement rule governing radioactive transformations resulting from alpha- and beta-ray emissions. He was born in Warsaw on May 27, 1887. After studying at Leipzig, Heidelberg (Ph.D. 1909), Ziirich and Manchester, he joined the faculty of the Technische Hochschule at Karlsruhe (1911–17). He rose from associate professor to director of the Institute of Physical Chemistry at Munich (1917–35). From 1936 Fajans served as professor at the University of Michigan, Ann Arbor. He became a naturalized U.S. citizen in 1942. Thermochemistry, theory of chemical forces, photochemistry and light absorption are areas in which he became an authority. With O. H. Gohring, he discovered uranium X_2. Author of *Radioactivity* and *Refractometry in Physical Methods of Organic Chemistry* with N. Bauch (1945), he was coeditor of *Zeitschrift für Kristallographie* (1924–29) and associate editor of *Journal of Physical and Colloid Chemistry* (1949).

His honours included the Victor Meyer prize (Heidelberg, 1909) and the Liège medal (1948). (V. Bw.)

FAJARDO, a town on the eastern coast of Puerto Rico. Pop. (1960) 12,424. The port of Fajardo has freight and passenger services to the off-lying islands of Vieques and Culebra. Water transportation is also available for the Virgin Islands of St. Thomas and St. Croix. A modern highway connects the town with San Juan, the island capital. Fajardo is the centre of one of the largest sugar corporations on the island. To the south of the toun is the U.S. naval air base Roosevelt Roads. (T. G. Ms)

FAKHR AL-DIN: *see* RAZI, AL-.

FAKIR, a generic term, synonymous with dervish (q v.), for a religious mendicant. A Mohammedan word, it has come to be applied also to Hindus. replacing *bhikshu* and older words. Fakirs are common to all the creeds of India, and in theory mostly belong to a religious order. But as a Moslem order does not usually profess celibacy and the Hindu and other orders do not always enforce it. the orders tend to form castes on the ordinary pattern. Where strict monasticism has been maintained, the influence of the orders has been on the whole good. But when discipline has been relaxed. many evils have ensued. Mendicancy has often become a pretext for extortion and occult poners a cloak for impudent swindling, sometimes assisted by murder. While many fakirs practise austerities of the severest kinds, others peregrinate the country with performing animals, selling love philtres, profess to transmute silver coin or other metals into gold and batten on



BY COURTESY OF THE BOARD OF FOREIGN MISSIONS

A NOMAD FAKIR OF INDIA READING HIS PRAYERS ON A BED OF NAILS

This class of fakir has little in common with the religious order of the same name, except a claim to sanctity. The beggars that compose it wander about the country, living on alms and subjecting themselves to unbelievable tortures

the credulity of the people. The chief Hindu orders are the Saniasis, Gosains, Jogis (who in theory profess yoga). bairagis. the Sikh Udasis, Nirmalas, Akalis, the Mohammedan Chishtis, Qadiris, Suharwardis, Naqshbandis, who owe much to Sufiism (*q.v.*); and minor fraternities. Several orders have militant branches.

FALAISE, a town of northwestern France, capital of an arrondissement in the *département* of Calvados, on the right bank of the Ante, 19 mi. S.E. of Caen by road. Pop. (1954) 5,289. The castle, now partly in ruins, was formerly the seat of the dukes of Normandy and the birthplace of William the Conqueror. It stands on a high crag overlooking the town, and consists of a square mass defended by towers and flanked by a small donjon and a lofty tower added by the English in the 15th century; the rest of the castle dates chiefly from the 12th century. Near the castle, in the Place de la Trinité, is an equestrian statue in bronze of William the Conqueror, to whom the town owed its prosperity. From 1417, when the town succumbed to Henry V of England, till 1450, when it was retaken by the French, Falaise was in the hands of the English. Falaise has populous suburbs, one of which, Guibray, is celebrated for its annual fair for horses, cattle and wool, which has been held in August since the 11th century. The town is the seat of a subprefecture and has tribunals of first instance and commerce, a chamber of arts and manufacture and a board of trade arbitrators. Tanning (from at least the 11th century) and some cotton manufactures are carried on.

FALASHAS, or "JEWS OF ABYSSINIA," a tribe of Hamitic stock, akin to Galla, who profess the Jewish religion and claim to be descended from the ten tribes banished from the Holy Land. Another tradition assigns them, as ancestor, Menelek, Solomon's alleged son by the queen of Sheba. It is uncertain when they became Jews: one account suggests in Solomon's time; another, at the Babylonian captivity; a third, during the 1st century of the Christian era. One of the earlier dates is in all probability correct since the Falashas know nothing of either the Babylonian or Jerusalem Talmud, make no use of phylacteries (*tefillin*) and observe neither the feast of Purim nor the dedication of the temple. They possess—not in Hebrew, of which they are altogether ignorant, but in Ethiopic (or Geez)—the canonical and apocryphal books of the Old Testament; a volume of extracts from the Pentateuch, with comments given to Moses by God on Mount Sinai; the Te-e-sa-sa Sanbat, or laws of the Sabbath; the Ardit, a book of secrets revealed to 12 saints, which is used as a charm against disease; lives of Abraham, Moses, etc.; and a translation of Josephus called Sana Aihud. A copy of the Orit, or Mosaic law, is kept in the holy of holies in every synagogue. Every newly built house is considered uninhabitable till the blood of a sheep or fowl has been spilt in it; a woman guilty of a breach of chastity has to undergo purification by leaping into a flaming fire; the Sabbath has been deified, and, as the goddess Sanbat, receives adoration and sacrifice and is said to have 10,000 times 10,000 angels to wait on her commands.

Under the monastic system, founded it is said in the 4th century A.D. by Aba Zebra, a pious man who retired from the world and lived in the cave of Hoharewa, in the province of Armatshoho, the monks must prepare all their food with their own hands, and no lay person, male or female, may enter their houses. Priests are allowed to marry once only, and no one is admitted into the order who has eaten bread with a Christian, or is the son or grandson of a man thus contaminated. Belief in the evil eye or shadow is universal, and spirit raisers, soothsayers and rain doctors are in repute. Education is in the hands of the monks and priests, and is confined to boys. Fasts, obligatory on all above seven years of age, are held on every Monday and Thursday, on every new moon and at the Passover (April 21 or 22). The annual festivals are the Passover, the harvest feast, the Baala Mazalat or feast of tabernacles (during which, however, no booths are built), the day of covenant or assembly and Abraham's day. It is believed that after death the soul remains in a place of darkness till the third day, when the first sacrifice for the dead is offered; prayers are read in the synagogue for the repose of the departed, and for seven days a formal lament takes place every morning in his house. No coffins are used, and a stone vault is built over the corpse so that it may not come into direct contact with the earth.

The Falashas live for the most part in villages of their own, or, if settled in a Christian or Mohammedan town, occupy a separate quarter. Their own kings, they pretend, were descended from David, but in 1800 the royal race became extinct, and they then became subject to the Abyssinian kingdom of Tigré. They do not mix with the Abyssinians. and never marry women of alien religions. They are even forbidden to enter the houses of Christians, and from such a pollution have to be purified before entering their own houses. Polygamy is not practised; early marriages are rare and their morals are generally better than those of their Christian masters. They have no liking for trade, but are skilled in agriculture, in the manufacture of pottery, ironware and cloth and are good masons.

FALCÃO, CRISTÓVÃO (c. 1515–c. 1553), Portuguese poet whose most famous eclogue has achieved added interest by a dispute about its authorship. was born at Portalegre in the province of Alentejo, of a noble but impoverished family. The details of his life are uncertain but he is said to have fallen in love with a young heiress, Maria Brandão, to have married her, and to have been separated from her by hostile parents. Because of this he was imprisoned for about five years, but was later restored to royal favour and employed on a diplomatic mission in Rome. His love story is told in the Carta de *um preso* and the charming eclogue *Crisfal.* Falcão's poems have resemblances to those of Bernardim Ribeiro to whom some critics have ascribed Crisfal.

FALCK, ANTON REINHARD (1777–1843), Dutch statesman, was born at Utrecht on March 19, 1777. He studied at the University of Leyden, entered the diplomatic service and became ambassador at Madrid. Under King Louis Napoleon he was secretary-general for foreign affairs, but resigned office on the annexation of the Batavian republic to France. He took part in the revolt of 1813 and in the organization of the new kingdom of the Netherlands. He was minister of education and of the colonies under William I, until the king tired of his counsels and sent him as ambassador to London.

The disturbances of 1830 convinced him of the necessity of the separation of Belgium from Holland. He consequently resigned his post and lived in close retirement until 1839, when he became the first Dutch minister at the Belgian court. He died at Brussels on March 16. 1843. Besiaes some historical works he left Brieven van *A.* R. Falck, *1795–1843* (2nd ed., 1861) and *Ambtsbrieven* van *A.* R. Falck (1878). His memoirs were edited by Colenbrander in 1913.

FALCÓN, a state in northwestern Venezuela, on the Caribbean bordering the Gulf of Venezuela. Area 9,575 sq.mi.; pop. (1950) a58,759. It consists of coastal lowlands and spurs which are outliers of the Andes. The state has a tropical wet and dry climate but because of the strong influence of the trade winds it is the dry period that dominates. Much of the land is quite useless for farming but the rearing of goats is important. Petroleum has been exploited on a large scale in the state but its importance stems from pipelines, refineries, storage facilities and loading terminals rather than production. There are some small oil-bearing formations in the barren north near the Caribbean, but the Falcón area is a declining one and has never produced more than a fraction of the total Venezuelan oil output. There are salt works at Mitare and fishing is carried on along the coast, mainly along the Paraguana peninsula (*q.v.*). In the interior, particularly in the area around Churuguara, sugar, coffee, cacao and other tropical crops are grown, and cattle are raised. Coro, the state capital (pop. 29,341), is the leading commercial and distributing centre. The chief ports are La Vela. Puerto Cumarebo and Tucacas. (L. WE.)

FALCON, the name applied to the long-winged birds of prey which take their quarry as they move. As in all the group of diurnal birds of prey, the female is larger than the male. As type of the family Falconidae may be taken the peregrine falcon (Falco *p.* peregrinus) and the scarcely separable duck hawk (F. *p.* anatum) of North America and F. *p. macropus* of Australia. The peregrine falcon inhabits practically every part of the world, about 16 races being recognized. For its size, it is perhaps the most powerful bird of prey that flies, and its courage is as great as its power. Famous in the days of hawking (see FALCONRY), the plumage of this bird is blackish-blue above and white with a more or less deep cream-coloured tinge below, barred, except on the chin and throat, with black. It nests on cliffs and trees, laying four or five eggs mottled with reddish-brown.

The gyrfalcon (F. *rusticolus*) is larger and inhabits the Scandinavian mountains. The Iceland falcon (F. r. islandus) is paler. The black gyrfalcon (F. r. obsoletus), with a pale phase, occurs in northeastern North America; the Asiatic gyrfalcon (F. r. *uralensis*) in northern Siberia to the Bering coast of Alaska.

The "desert" falcons differ from the preceding in that they retain the longitudinal barring on the breast throughout life, instead of changing it after the first molt to transverse bars. They include in the old world the lanner (F. *biarmicus*), the saker (F. cherrug) and the luggar or laggar (F. jugger) of India; in the new, the prairie falcon (F. mexzcanus) of the western plains of North America.

The hobby falcons are characterized by their bold upstanding position and long wings. The beautiful little English hobby (F. *subbuteo*) lives mainly on insects and is a summer visitor to most parts of Europe. About 30 other species of true falcons are found throughout the world, one in the genus leracidea of Australia, all others in the genus Falco, divided into ten subgenera, sometimes raised to generic rank. These all constitute the subfamily Falconinae. The pygmy falcons, 5 genera and 17 species, including the smallest raptorial birds of prey, no larger than a robin or sparrow, constitute the near-related subfamily Polihieracinae. (See MERLIN; KESTREL.)

A falcon is also a primitive light gun. 2½-in. bore, weighing about 6 cwt., and firing a 2-lb. shot. It takes its name from the bird of prey in accordance with an old fashion.

FALCONE, ANIELLO (1600–1665), Italian battle painter, was born in Naples. He studied under Ribera (Lo Spagnoletto), was influenced by Domenichino and later by the Dutch school. He decorated the cupola of a chapel in San Paolo del Padri Teatini at Naples. He painted a "Flight Into Egypt" in the sacristy of Naples cathedral (signed and dated 1641); and the frescoes in the sacristy of Gesu Nuovo, also at Naples. He was famous as a battle painter. two of his battle pieces being in the Naples museum and in the Prado, Madrid. His many pupils included Salvatore Rosa. Some engraved plates have been attributed to Falcone without sufficient evidence.

FALCONER, HUGH (1808–1865), British paleontologist and botanist, was born at Forres on Feb. 29, 1808. He studied at Aberdeen and at Edinburgh, where he took his M.D. in 1829. Proceeding to Calcutta in 1830 as assistant surgeon on the Bengal establishment of the East India company, he soon published his description of the fossil bones from Ava in the possession of the Asiatic Society of Bengal. In 1831 he was appointed superintendent of the botanic garden of Saharanpur. In 1834 he published a geological description of the Siwalik hills and subsequently brought to light a subtropical fossil fauna of unexampled extent and richness, including remains of Mastodon, the colossal ruminant Sivatherium and the enormous tortoise Colossochelys atlas. It was on his recommendation in 1834 that tea was introduced into India.

When illness required him to return to England, in 1842, he began his Fauna Antigua Sivalensis, of which part i was issued in 1846 and 107 plates during the years 1846–49. He was elected fellow of the Royal society in 1845. and in 1847 was appointed superintendent of the Calcutta botanical garden, and professor of botany in the medical college. In 1850 he published an important report on the teak forests of Tenasserim, and through his recommendation the cultivation of the cinchona bark was introduced into India. From 1855 he spent the remainder of his life in examining fossil species in England and on the continent corresponding to those found in India notably the species of mastodon, elephant and rhinoceros; he also described some new Mammalia from the Purbeck strata. and he reported on the bone caves of Sicily, Gibraltar. Gower and Brixham. He died on Jan. 31, 1865.

FALCONER, WILLIAM (1732–1769) British poet, sailor and lexicographer whose poem *The Shipwreck* achieved nide popularity, nas born in Edinburgh, Feb. 8, 1732. A poor barber's son he went to sea in 1746 His survival. at 18, of the nreck of the "Britannia" off Cape Colonna inspired *The Shipwreck* (1762: revised 1764 and 1769), a long, conventional poem. giving nonetheless a sailor's firsthand account of a storm at sea. On the advice of the duke of York, to whom he dedicated the poem. Falconer then joined the navy and sailed on the "Royal George," becoming the purser of the "Glory" in 1763. He continued to write attacking John Wilkes and Charles Churchill in *The Demagogue* (1765), and published his useful *Universal Dictionary of the Marine* in 1769. He had meannhile rejected an offer of partnership by the publisher John Murray in favour of the pursership of the frigate "Aurora," bound for India. She sailed on Sept. 20, 1769, reached the Cape of Good Hope on Dec. 27 and was never heard of again.

FALCONET, ETIENNE MAURICE (1716–1791), French sculptor, the chief exponent of "Pompadour" artifice, yet capable of the sublime, as in his statue of Peter the Great, was born in Paris on Dec. 1, 1716. He was first apprenticed to a carpenter and later became a pupil of J. B. Lemoyne. In 1744 he was elected to the Academy of Fine Arts upon presentation of his statue of Milo of Crotona (Louvre). He was nominated director of sculpture at the Sèvres factory in 1757 through Madame de Pompadour's influence. He supplied numerous models to be executed in Sèvres biscuitware (*e.g.,* "Pendule des Trois Grâces," Wallace collection, London), which gave a character of delicate, mannered grace to a whole phase of his work. From 1766 until 1778 he was in Russia, summoned by Catherine the Great, and sculptured the impressive equestrian statue of Peter the Great at St. Petersburg. He died in Paris on Jan. 24, 1791.

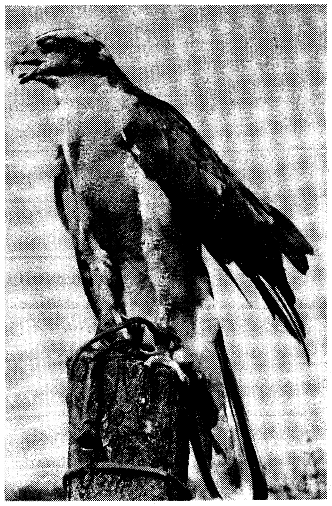
His writings were collected under the title of *Oeuvres Littéraires* (6 vol., 1781–82; 3 vol., 1787). A series of letters he exchanged with Diderot concerning the statue of Marcus Aurelius on the capitol in Rome was published in 1958. (P. LN)

FALCONIDAE: see FALCON; CARACARA.

FALCONRY. The art of employing falcons and hawks in the chase, often termed hawking (Fr. *fauconnerie,* from late Lat. *falco,* falcon). Falconry was a favourite recreation of the aristocracy during the middle ages, followed, as it seems, more as a sport than as a means of getting game for the table. The antiquity of falconry is very great. It appears to have been known in China some 2,000 years B.C. In Japan it appears to have been known at least 600 years B.C., and probably at an equally early date in India, Arabia, Iran and Syria. Sir A. H. Layard says that on a bas-relief found in the ruins of Khorsabad "there appeared to be a falconer bearing a hawk on his wrist" from which it would appear to have been knonn there some 700 years B.C. In all the above mentioned countries of Asia it is practised at the present day.

Persian and Arabic manuscripts attribute the origin of falconry to a pre-historic Persian king; certain it is that the Moguls gave a great impetus to hawking in India. From ancient carvings and drawings it seems to have been known in Egypt many ages ago. The older writers on falconry, English and Continental, often mention Barbary and Tunisian falcons. It is still practised in Egypt. The oldest records of falconry in Europe are in the writings of Pliny, Aristotle and Martial. It was probably introduced into England from the Continent about A.D. 860. and from that time down to the middle of the 17th century, falconry was followed with an ardour that perhaps no other English sport has ever evoked. Stringent laws and enactments were passed from time to time in its interest. About the middle of the 17th century its popularity began to decline in England, to revive somewhat at the Restoration; it never however recovered its former favour, a variety of causes operating against it, such as the enclosure of waste lands and the introduction of fire-arms into the sporting field. Yet it has never been even temporarily extinct, and it is practised at the present day. Falconry has made small progress as a sport in the United States, due largely to adverse legislation in many states on the use of hanks to kill game.

ERIC HOSKING
HOODED PEREGRINE FALCON (FALCO PEREGRINUS PEREGRINUS)



KARL H. MASLOWSKI
GOSHAWK (ACCIPITER GENTILIS) SHOWN WITH JESSES AND BELLS

In Europe the "quarry" at which hawks are flown consists of grouse (confined to the British Isles), black-game, pheasants, partridges, quails, landrails, ducks, teal, woodcocks, snipe, herons, rooks, crows, gulls, magpies, jays, blackbirds, thrushes, larks, hares and rabbits; in former days geese, cranes, kites, ravens and bustards were also flown at. Old German works make much mention of the use of the Iceland falcon for taking the great bustard, a flight scarcely alluded to by English writers. In Asia the list of "quarry" is longer, and in addition to all the foregoing, or their Asiatic representatives, various kinds of bustards, sand grouse, storks, ibises, spoonbills, jungle fowl, kites, vultures and gazelles are captured by trained hawks. In Mongolia and Chinese Tartary, and among the nomad tribes of central Asia the sport still flourishes; and a species of eagle known locally as the "berkute" is trained in those regions to take large game, such as antelopes and wolves. In Africa gazelles are taken and also partridges and wild fowl. The hawks used in England are the Greenland, Iceland and Norway falcons, the peregrine falcon, the hobby, the merlin, the goshawk and the European sparrow hawk. In former days the saker, the lanner and the Barbary or Tunisian falcon were also employed. The most efficient in the field are the American duck hawk, prairie falcon, goshawk and Cooper's hawk, and the European peregrine falcon and the goshawk. In all species of hawk the female is larger and more powerful than the male.

Hawks are divided by falconers all over the world into four classes. The first class comprises "falcons," *i.e.,* "long winged hawks," or "hawks of the lure." The falcons include, in order of size, the jer-falcons, native to Greenland, Iceland and Norway; the American prairie falcon and the duck hawk or peregrine, with its many closely related species throughout the world; the pigeon hawk, hobby and merlin and, finally, the European kestrel and the American sparrow hawk, both of which are too small for use in practical falconry. The second class, that of the *accipiter* or short-winged hawks or "hawks of the fist," includes the European and American goshawk, the American Cooper's hawk, the European and Asiatic sparrow hawk and the somewhat similar American sharp-shinned hawk. Both the falcons and short-winged hanks are primarily bird-hunting Raptores although the larger representatives of both types occasionally kill hares, rabbits or even larger animals, and the smaller species, particularly the American sparrow hawk, feed extensively on mice and insects.

The third category of hawks comprises the broad-winged or *buteo* hawks, the "buzzard" hawks of Europe and the rough-legged, red-tailed, red-shouldered and broad-winged American hawks. They are rodent-hunting hawks, slower and less aggressive than the falcons and short-winged hawks, much inferior to them for falconry, although the powerful red-tailed hawk has been trained to perform well against pheasants and rabbits. Eagles, likewise used for the chase, are closely related to the *buteo* hawks, and share their preference for animal prey. A fourth class of hawk, the ground-skimming, mouse-hunting harriers, which includes the American marsh hawk, is unsatisfactory for falconry. All birds of prey, including even the owls, can be trained to the basic task of falconry, nhich is to kill quarry and remain upon it until the falconer picks the hawk up, or calls it to his fist. While Chinese golden eagles are reported to kill foxes and carry them to their handlers, no hawk or owl can be trained to retrieve the kill. Its dominant instinct is to attack, kill and devour, and this can only be modified by training to the extent of permitting man to guide the timing of the attack, and prevent the hawk from flying off uith its quarry, or escaping if it fails to kill.

Capture of Hawks.—In certain parts of the continent and in the bazaars of North Africa, the near east and Asia, captive hawks are sometimes available for purchase at auction and otherwise. Damascus for centuries has been a market for trained hawks, brought in by the Arabs from the Syrian desert. However, in most parts of the world, the falconer must procure his own hawks by trapping wild adults, or taking nestlings before they learn to fly. The instinct of hawks is to nest in remote, inaccessible places, in caves on the sheer face of cliffs, or in high trees. There are few regions near human settlements where hawks are abundant. The capture of fledglings thus presents difficulties, increased by the fact that only during a few brief weeks in early summer can young hawks be found. The co-operation of watchful rural lads in locating hawk nests and the skilful use of ladders, ropes or climbing irons are required. The trapping of adult wild hawks provides an interesting feature of falconry. It can be practised in most parts of the northern hemisphere at all seasons, but most productively in the great southward migratory flight of the hawks in early autumn. **A** variety of traps has been developed through the centuries, the main objective being dependable operation, without injury to the hawk, since even a few lost or broken feathers seriously handicap a trained hawk in the field.

The Plains Indians, in quest of eagle plumes for decoration, devised an effective method of trapping birds of prey. Driving an eagle away from a bird or animal on which it fed, the Indian concealed himself in a hole or blind close by, or even within the carcass of a large animal. Upon the eagle's return to the kill, he seized it by the legs, and quickly rendered it helpless to attack him with its talons. Modifications of this "hand trap" have been successfully employed in the capture of large and small hawks, using as bait a tethered live pigeon, whose flutterings will attract a hawk from an incredible distance. Nets in many forms are used to capture hawks. The Dho-Gaza trap of India is a net of fine thread stretched between two vertical poles, with bait birds in a cage at the bottom of the net. A hawk diving down for the kill strikes the invisible net and falls with it to the ground, wrapped in its meshes. An American trap, used on falcons with good results, is a rectangular frame of lath, covered with netting. **A** bait bird is tied to a stake inside the trap. The hawk can reach its prey only through a tunnel-like entrance at each end, on the ground, and usually is unable to find its way out of the device uhen it seeks to fly away.

Most useful of all hawk traps, but difficult of operation, is the bow-net trap, employed for centuries by the famous falconers of Belgium and the Netherlands. A semicircular bow net on a wooden frame of about 6 ft. diameter is lightly pegged to the ground at its circular edge, and centred upon an axis along its diameter. When a hawk, attracted by a tethered pigeon nearby, makes the kill, the trapper, nho remains in a blind at a distance, drags the pigeon by a long wire or cord to a point along the edge of the net where the trapper's pull upon a second cord throws the net over the hawk while it is occupied in holding and depluming the pigeon. A modern, automatic variation of this trap employs springs or elastic cords which throw the net over the hawk when, in attacking a bait bird, it trips a trigger which releases the springs.

In India, short-winged hawks are trapped with small horsehair nooses fastened at the sides of a dome-shaped cage containing a live grouse or pheasant. A similar method in the United States employs steel spring or jump traps with padded jaws, placed above and around the cage. The pole-trap, most effective for owls and broad-winged hawks, is simply a steel trap placed at the top of a high pole in a field or clearing. No bait is required, as these birds by habit perch on poles and dead trees to wait for rodent quarry to appear in the surrounding grass or cover. The steel trap is fastened to the pole by a long cord, so that the trapped hawk can settle, uninjured, to the ground. While the principal modes of hawk trapping have been described here, it is worth pointing out that hawks have been captured by an almost infinite variety of other devices. The great difficulty in trapping birds of prey arises from the fact that they are by nature extremely shy and wary. They eat ravenously when hungry, perhaps only once or twice in a day, but at all other times they are indifferent to the most enticing prey. The trapper, therefore, should resign himself to the frustration of watching scores of hawks pass over his traps unheeding for every one which may be spurred by hunger to attack the bait. The scarcity of hawks in most areas during the greater part of the year, the obstacles which make a capture a rare event and the swiftness with which a migrant hawk passes through the falconer's trapping territory emphasize the desirability of types of traps which are ready for action at all times, are simple and certain of operation and cannot injure the captive hawk in its frenzied struggles to escape.

Training.—It is through the appetite principally that hawks are tamed; but to fit them for use in the field, much patience, gentleness and care are necessary. Slovenly taming necessitates starving, and low condition and weakness are the result. The aim of the falconer should be to have his hawk always keen, and the appetite, when it is brought into the field, should be such as would induce the bird in a state of nature to put forth its full powers to obtain its food, with, as near as possible, a corresponding bodily condition.

The process of training an adult wild falcon deserves description. When first taken, a rufter or easy-fitting hood should be put on her head, and she must be furnished with jesses, swivel, leash and bell; jesses are strips of light leather for the legs. A thick glove or rather gauntlet should be worn on the left hand. (Eastern falconers always carry a hawk on the right.) She must be carried on the fist for several hours at a time, and late into the night, at intervals being gently stroked with a bird's wing or feather. At night she should be tied to a perch in a room with the windows darkened, so that no light can enter in the morning. The perch should be a padded one placed across the room about $4\frac{1}{2}$ ft. from the ground with a canvas screen underneath. She will be easily induced to feed, in most cases, by drawing a piece of beefsteak over her feet, brushing her legs at the time with a feather, and now and then, as she snaps at it, slipping a morsel into her mouth. Care must be taken to use a low whistle as she is in the act of swallowing; she will very soon learn to associate this sound with feeding, and it will be found that directly she hears it, she will gripe with her talons and bend down to feel for her food. When the falconer perceives this and other signs of her "coming to," that she no longer starts at the voice or touch, and steps quietly up from the perch when the hand is placed under her feet, it will be time to change her rufter hood for the ordinary hood. This latter should be an easy fitting one, in which the braces draw closely and yet easily, and without jerking. An old one previously worn is to be recommended. The hawk should be taken into an absolutely dark room, and the change should be made if possible in total darkness. After this she must be brought to feed with her hood off; at first she must be fed in a darkened room, more light being admitted as she is able to bear it. The first day, the hank having seized the food and begun to pull at it freely, the hood may be gently slipped off, and after she has eaten a moderate quantity, it must be replaced as slowly and gently as possible, and she should be allowed to finish her meal through the hood Next day the hood may be twice removed, and so on; day by day the practice should be continued, more light being gradually admitted, until the hawk will feed freely in broad daylight, and allow the hood to be taken off and replaced without opposition. She must now be accustomed to see strangers, dogs, horses, etc., and to feed in their presence. A good plan is to take her into the streets of a town at night, at first where the artificial light is not strong, unhooding and hooding her from time to time, but not letting her get frightened. Up to this time she should be fed on lean beefsteak with no casting, but as soon as she is tolerably tame and submits well to the hood, she must occasionally be fed with pigeons and other birds. This should be done not later than 3 or 4 P.M., and when she is placed on her perch for the night in the dark room, she must be unhooded and left so, of course, being carefully tied up. The falconer should leave her unhooded until such time as she has "cast."

She must now be taught to recognize the voice—the shout that is used to call her in the field—and to jump to the fist for food, the voice being used every time she is fed. When she comes freely to the fist she must be made acquainted with the lure. Kneeling down with the hawk on his fist, and gently unhooding her, the falconer casts out the lure, which may be either a dead pigeon, or an artificial lure garnished with beefsteak tied to a string, to a distance of a few feet in front of her. When she jumps down to it, she should be allowed to feed a little upon it—the voice being used—while occasionally receiving morsels from the falconer's hand; and before her meal is finished she must be taken up on to the hand, being induced to forsake the lure for the hand by offering her a piece of meat. This treatment will help to check her inclination hereafter to carry her quarry. This lesson is to be continued till the falcon feeds boldly on the lure on the ground in the falconer's presence—till she will allow him to walk round her while she is feeding. All this time she will have been held by the leash only, but in the next step a strong, but light creance—a line attached to the swivel—must be made fast to the leash, and an assistant holding the hawk should unhood her, as the falconer, standing at a little distance from her, calls her by shouting and casting out the lure.

Day by day the distance will be increased, until the hawk will come 30, 60, 100 yd. and so on without hesitation: then she may be trusted to fly to the lure at liberty and by degrees from any distance, say 200 yards. This accomplished she should learn to stoop at the lure. Instead of allowing the hank to seize upon it as she comes up the falconer will snatch the lure away and let her pass by, and immediately put it out that she may readily seize it when she turns round to look for it. This should be done at hrst only once, and then progressively, until she will stoop backwards and forwards at the lure as often as desired. Next she should be entered to her quarry.

Eyasses, hawks which have been taken as fledglings on the nest, must be put into a sheltered place, such as an outhouse or shed The basket or hamper should be filled with straw. A hamper is best, with the lid so placed as to form a platform upon nhich the young hawks can come out to feed. This should be fastened to a beam or prop a few feet from the ground. The young hawks must be plentifully fed on the best fresh food obtainable—such as good lean beef and fresh killed birds and rabbits The food should be securely tied in separate portions to a board, or better to wooden blocks, one for each hawk. At this stage the young hawk should be interfered with as little as possible. The falconer should place the food down for them and then retire as quickly as possible. The wilder and more independent they become during the period of "hack" the better. As they grow older they will come out and perch about the roof of their shed, by degrees extending their flights to neighbouring buildings or trees, never failing to come back at feeding time to the place where they are fed. Soon they will be continually on the wing, soaring up and playing with one another, and later the falconer will observe them chasing other birds, such as pigeons or rooks, which may be passing by. As soon as a young hawk fails to return to the hack for its meal a note should be made of its absence, and it should at once be caught in a bow net or snare the first time it comes back, or it may absent itself for good. It must be borne in mind that the longer hawks can be left out "at hack" the better they are likely to be in the field—those hawks being always the best which have preyed a few times for themselves when "at hack." There is, of course, a great risk of losing hawks altogether when they begin to prey for themselves, but this is a matter for the falconer's judgment. As soon as the eyas knows the lure sufficiently well to come to it sharp and straight from a distance, she must be taught to "wait on." This is effected by letting the hawk loose, choosing the most open space available. It will be found that she will circle round the falconer looking expectantly for the lure—perhaps mount a little in the air, and advantage must be taken of a favourable moment when the hawk is at a little height, her head being turned inwards towards the falconer, to loose a pigeon with shortened wings which she can easily catch. When the hawk has taken two or three pigeons in this way, and mounts into the air immediately in expectation, in short, begins to "wait on," she should be given no more pigeons, but be tried at game as soon as possible. The young hawk must be given every possible advantage when first flown at wild quarry. The training of the great northern falcons, as well as that of merlins and hobbies, is conducted much on the above principles, but the jer-falcons will seldom "wait on" well, and merlins will not do so at all.

The training of short-winged hawks is a simpler but longer process, as they require long walks on the fist to accustom them to handling. They must be provided with jesses, swivel, leash and bell. European sparrow hawks can, however, scarcely carry a bell big enough to be of any service. The hood is seldom used for short-winged hawks—never in the field. They must be made as tame as possible by carriage on the fist and the society of man, and taught to come to the fist freely when required—at first to jump to it in a room, and then out of doors. When the goshawk comes freely and without hesitation from short distances, she should be called from longer distances from the hand of an assistant, but not oftener than twice in each meal, until she will come several hundred yards, on each occasion being well rewarded with some favourite food such as fresh killed birds. When she does this freely, and endures the presence of strangers, dogs, etc., a few bagged rabbits may be given to her, and she will be ready to take the field. Some accustom the goshawk to the use of the lure, for the purpose of recovering her if she refuses to come to the fist in the field, when she has taken stand in a tree after being baulked of her quarry, but this is not a good practice. For various reasons goshawks in England cannot be brought to the perfection to which they are brought in the east. In India, for instance. there is a far greater variety of quarry suited to them, and wild birds are much more approachable; moreover, there are advantages for training which do not exist in England. Unmolested, the eastern falconer carries his hawk by day and night in the crowded bazaars, till the bird becomes perfectly indifferent to men, horses, and vehicles.

Methods of Hawking.—Falcons or long-winged hawks are either "flown out of the hood" (*i.e.*, unhooded and slipped when the quarry is in sight), or they are made to "wait on" till game is flushed. Herons, rooks, magpies and crows are always taken by the former method. Passage hawks are generally employed for flying at these birds, though good eyasses are occasionally equal to the work. Though he has no chance in competing against a falcon in straightforward flight, the heron has large concave wings, and a proportionately light body, and he can rise with astonishing rapidity, more perpendicularly or, in other words, in smaller rings than the falcon can and with less effort. As soon as he sees the approach of the falcon, he makes for the upper regions. The falcon then commences to climb to get above him, but in a very different style. She makes wider circles or rings, travelling at a higher rate of speed, due to her strength, weight and power of flying, till she rises above the heron. Then she makes her attack by stooping with great force at the quarry, sometimes falling so far below him that she cannot shoot up to a sufficient pitch for the next stoop, and has to make another ring to regain her lost command over the heron, which is ever rising, and so on —the "field" meanwhile galloping in the direction the flight is taking, till the falcon seizes the heron aloft, "binds" to him, and both come to the ground together.

For game hawking eyasses are generally used, though undoubtedly passage or wild caught hawks are to be preferred. The best

HAWKS AND FALCONS

1. Immature eyas tiercel, used for game hawking. An eyas is a hawk which has been trained from the nest. The male of any hawk, being a third smaller than the female, is called *tiercel.* 2. A cast (male and female) of merlins, on a lark which they have killed. Merlins are flown only at larks. 3. An adult eyas tiercel. A hawk is considered adult after the first moulting, when the marking of the plumage becomes horizontal instead of perpendicular. Tiercels are best used for partridges, magpies and gulls. Only the largest can kill grouse. 4. A female goshawk, flown at hares, rabbits or pheasants, shown sitting by a rabbit she has just caught. 5. Hocded falcons on the cadge, a wooden frame on which hawks are transported to and from the field. Their vision is cut off by leather hoods to ensure their sitting still. 6. Jack merlin, or male. The female is called the merlin. 7. An eyas peregrine tiercel (see fig. 3). This bird killed 504 head of game, principally partridge and grouse, in eight years. 8. Haggard peregrine falcon, the bird most successfully used in falconry. *Haggard* signifies a hawk caught wild in adult plumage. 9. A gerfalcon of the Greenland variety, the largest of the falcons. Modern falconers have not been successful in training this bird, having found it difficult to keep it in health and condition

game hawks are passage hawks, but there are difficulties attending their use. It may perhaps be fairly said that passage hawks can be trained to "wait on" in grand style, but until they have got through their first season, they are more liable to be lost than eyasses. The advantages attending the use of eyasses may be summed up as follows: they are easier to obtain. to train and to keep; they moult more regularly than passage hanks, and if lost in the field they will often return home by themselves, or remain in the country where they are accustomed to being flown. Experience and, we must add, some good fortune also are requisite to make eyasses good for "waiting on" at game. Slight mistakes on the part of the falconer, false points from dogs, or bad luck in serving, will cause a young hawk to acquire bad habits, such as sitting down on the ground, taking stand in a tree, raking out wide, skimming the ground, or lazily flying round at an insufficient altitude. A good game hawk in proper flying order mounts rapidly to a high pitch until she appears no larger than a swallow in the sky, keeping well over the falconer and dogs, and ready to stoop when the quarry is sprung. Hanks that have been successfully trained and judiciously worked become wonderfully clever, and soon learn to regulate their flight by the movements of their master. Eyasses were not held in esteem by the old falconers, and it is evident from their writings that these hawks have been much better understood and managed in modern times than in the middle ages. It is probable that the old falconers procured the aild-caught hawks with greater facility than at the present day. There was a hawk mart held at Valkenswaard in the Netherlands, where hawks were sold after the annual catch during the autumn migration. It was visited by falconers from all over Europe, large sums often being paid at auction for particularly choice birds.

Many European falconers in modern times have owned eyasses which have killed grouse, ducks and other quarry in a style almost equalling that of passage hawks. Moors, downs, open country where the hedges are low and weak are best suited to game hawking. Pointers or setters may be used to find the game, or the hawk may be loosed on reaching the ground where game is knonn to lie, and suffered, if an experienced one, to "wait on" till it is flushed. However, the best plan with most hawks, young ones especially, is to use a dog, and to "cast off" the hawk when the dog points, and to flush the birds as soon as the hawk has reached her pitch. The hawk should be well over the birds, and if possible a little up-wind of them when they rise, she will then be better placed for a down-wind stoop, as the game will not dare to fly up-wind under the hawk. The hawk will then turn over, and, flying headlong downwards with incredible speed, will, with the gathered impetus of her fall from the sky, rapidly overtake the bird she has from the first moment selected as her victim. As she reaches it, she strikes it a heavy blow with the hind talon of her foot, and the bird falls to the ground, often stone-dead, leaving a cloud of feathers in its track, or, just as she rushes up to it, the quarry may evade the stroke by a clever shift, and hurl itself into the nearest cover before the hawk has recovered from her stoop. The falconer will then come up as quickly as possible to "serve" the hawk by putting the bird out again while she "waits on" overhead. If this be successful. she is nearly certain to kill at the second attempt. Falcons, being larger and stronger, are to be preferred for grouse and tiercels for partridges. Woodcock afford capital sport where the country is sufficiently open; it will generally be found that after the first stoop at a woodcock, the cock will try to escape by taking the air, and will show a very fine flight. When beaten in the air it will try to get back to covert again, but when once a hawk has outflonn a woodcock, he is pretty sure to kill it. Snipe may be killed with first-class tiercels in favourable localities. Wild duck and teal are only to be flown at when they can be found in small pools or brooks at a distance from large sheets of water—where the fowl can be suddenly flushed by men or dogs, while the falcon is flying at her pitch overhead. For duck falcons should be used; tiercels will kill teal well. The merlin is used for flying at larks, and there does not seem to be any other use to which this pretty little falcon may fairly be put. It is very active, but far from being, as some authors have stated, the swiftest of all hawks. The peregrine has been known to attain a level speed of 70 m.p.h, and a diving velocity above 100 m p h. The hobby is swifter than the merlin, but cannot be said to be efficient in the field.

The three great northern falcons are not easy to procure in proper condition for training. They are difficult to break to the hood and to manage in the field. They can be flown, like the peregrine, at herons and rooks, and in former days were used for kites and hares. Their style of flight is magnificent: they are swifter than the peregrine, and are deadly "footers." They seem, however, to lack someuhat of the spirit and dash of the peregrine.

The distinctive hunting habits of each of the various types of hawks determine the way in which it must be handled for falconry in the field. In their uild state, the long-winged hawks, or falcons, are birds of the high and open sky, accustomed to take their prey from above, after a circling climb of pursuit or a headlong dive, often from a great height. The short-winged hawks, on the contrary, are silent assassins of the forest, which make a swift, short darting attack at low level, weaving among branches and tree trunks uith incredible dexterity. They kill by overtaking their prey in the air or on the ground, grasping it nith the needle-sharp talons of both feet. The broad-winged or *buteo* hawks, in turn, are rodent hunters, which locate their quarry by soaring flight, or from perches on posts or treetops, and glide down to seize it by surprise.

The true falcons are trained by man to follow their natural instinct by circling or "waiting on" high above the beaters, or flying from the falconer's fist when game is flushed to rise above it during what may be a high, prolonged chase of many miles before the falcon can make its spectacular diving kill. The short-winged hawks, and also the *buteos* and eagles are usually carried on the falconer's fist until the quarry is actually sighted near enough at hand to be overtaken in a short dash, much as though the falconer were using the hawk as a shotgun. Thus, while falcons are best adapted to hunting over open, unfenced country, where their long, free flights can be followed on horseback, short-winged hanks are more useful against birds found in wooded areas or heavy cover, with the falconer afoot, and the broad-aings are chiefly effective against animals and birds on the ground. in fields, swamps and meadows which are their natural hunting territory. In India falconry has always been a flourishing art. Indian falconers far surpass Iranians and Arabs. Eyasses are not used, and the system of flying "at hack" is unknown. Hanks are caught on the passage, manned and trained to the lure in a wonderfully short time, but very seldom is a falconer to be found who can maintain hanks in good flying condition. In the Punjab, sakers are the falcons chiefly used; haggard and young passage hawks are flown at hares and hubara. Successful falconers get these sakers into good wind by daily exercise at the lure giving them about 25 stoops in the morning, and about the same number in the evening They are then kept fit by daily stooping to the lure. Arabian falconers omit this exercise altogether, and keep their hawks in such poor condition that they are unable to kill hubara on the wing. Their hawks follow the quarry in the open desert, and when it settles, kill after a rough and tumble on the ground.

Hawks from which work in the field is expected should be kept in the highest health, and they must be carefully fed; no bad or tainted meat must be given to them Peregrines and the great northern falcons are best kept on lean beefsteak with a frequent change in the shape of fresh killed pigeons and other birds Freshly killed rabbits are a change to a lighter diet. The smaller falcons require small birds to keep them in health. For goshawks a coarser diet, such as rats or rabbits, suffices. The smaller short-winged hanks, like small falcons, require birds. All haaks need to be given castings. Hawks will exist, and often appear to thrive, on good food nithout castings, but the seeds of future injury to their health are being sonn. If it is more convenient to feed the hawks on beefsteak, they should frequently be given the wings, heads and necks of game and poultry, with the blood carefully removed. In addition to the castings which they swallow, tearing the pinion joint of a uing is good exercise for them, and biting the bones keeps their beaks in good trim. Most hawks, peregrines especially, require a bath. The end of a cask sawn to give a depth of about 6 in. makes a good bath, which should be permitted at least twice a week.

The best way, where practicable, of keeping hawks, is to tether them to blocks on the lawn. Goshawks are generally placed on bow perches, which ought not to be more than 8 or 9 in. high at the centre of the arc. It will be several months before passage or wild-caught falcons can be kept out of doors; they must be fastened to a perch in a darkened room, hooded, and, by degrees, as they get tamer, they may be put out on the lawn. In England (especially in the south) peregrines, the northern falcons and goshawks may be kept out of doors all day and night in a sheltered situation. An eastern aspect is best—all birds enjoy the morning sun and it is beneficial to them. The more hawks confined to blocks out of doors see of persons, dogs, horses, etc., moving about, the better.

Contrary to the prevailing notion, hawks that have been well handled show a good deal of attachment to their owners. It is true that by hunger they are in great measure tamed and controlled, and the same may be said of many undomesticated and many domesticated animals. Instinct prompts all wild creatures when away from man's control to return to their former shyness, but hawks certainly retain their tameness for a long time, and their memory is remarkably retentive. It is useless to bring a hawk into the field unless she has a keen appetite; if she has not, she will neither hunt effectually nor follow her master. Even wild-caught falcons, however, may sometimes become so attached to their owner that, when sitting on their blocks with food in their crops, they will, on seeing him, "bate" hard to get to reach him, till he either allows them to jump up to his hand, or withdraws from their sight. Goshawks too evince great attachment to their owner. Another error is that hawks are lazy birds, requiring hunger to stir them to action. The reverse is the truth; they are birds of very active habits and exceedingly restless. The wild falcon requires an immense amount of exercise to enable her to exert her speed and power of flight; instinct prompts her to spend hours daily on the wing, soaring and playing about in the air in all weathers, often chasing birds merely for play. When full gorged she takes a siesta; but unless she fills her crop late in the evening she is soon on the move again. Goshawks and sparrow hawks, too, habitually soar in the air at about 9 or 10 A.M., and remain aloft a considerable time, but these birds are not so active as the falcons. The falconer, therefore, should endeavour to give his hawks as much flying as possible, and he should avoid the mistake of keeping too many hawks.

The larger hawks may be kept in health and working order for many years. The writer has known peregrines, shaheens and goshawks to reach ages of 15 and 20 years. Goshawks, however, never fly well after four or five seasons, when they will no longer take difficult quarry; they may be used for rabbits as long as they live. Shaheens have been seen in the east at an advanced age, killing wild fowl beautifully. The shaheen is a falcon of the peregrine type, but smaller, which does not travel, like the peregrine, all over the world. It appears that the jerfalcons also may be worked to an advanced age. Old Symon Latham tells of these birds—"I myself have known one of them an excellent hearnor (killer of herons) and to continue her goodnesse very neere twentie yeeres, or full out the time."

(E. D.-Ra.; G. Dk.)

Modern Falconry.—With the advent of the shotgun and after the enclosure of the open lands and numerous social upheavals in the older countries, the sport of falconry nearly died out. A revival of interest occurred after World War II, however, and in the United States alone there were more than 1.500 enthusiasts after mid-century who were either full or part-time falconers or who were interested in the art and literature of falconry.

Falconry survived in Europe largely through the enthusiasm of members of hawking clubs in various countries. In Great Britain the Falconers' society of England was founded about 1770 but ceased in 1838 with the death of the then manager, Lord Berners. Because of the scarcity of herons (a main quarry of the club's peregrines in East Anglia) and also partly because of the plowing up of the heath land over which the falconers rode, the centre of English falconry moved to the Netherlands and in 1839 the Loo Hawking club, an Anglo-Dutch society under the patronage of King William II of the Netherlands, was formed; in the first eight years of its existence 1,500 herons were taken by its hawks. In 1853 the royal patronage was withdrawn and the Loo club came to an end. For the next ten years falconry was kept alive in England by a few amateurs and their professional falconers. Then, in 1864, the Old Hawking club of England was founded, mainly to hawk rooks on the Wiltshire downs. It was wound up in 1926 and the British Falconers' club was founded in 1927.

In the second half of the 20th century the British Falconers' club had a membership of about 150 but only half of these were resident in the United Kingdom, of whom only about 30 kept and flew hawks. The virtual disappearance of the rabbit due to myxomatosis and the placing of many of the traditional quarries on the protected list both had a profound effect on the sport after World War II. All British birds of prey, except the sparrow hawk, became protected by law and a licence was required from the home office before an intending falconer could take a young hawk for falconry.

Falconry clubs exist in other European countries. The French Club de Champagne went out of existence in 1870 but French falconers are organized in the Association Nationale des Fauconniers et Autoursiers Français. In Germany, the Deutscher Falkenorden was founded in 1923 and is a thriving club. Austria has its club, and Italy the Circolo dei Falconieri d'Italia.

Falconry is still practised by the Arabs in Cyrenaica, and oil-rich sheiks in Saudi Arabia and the Persian gulf still train their *saker* falcons to hunt bustard. In Indian and Pakistan Punjab and in the Northwest Frontier region of Pakistan falconers fly their falcons at duck and their goshawks at partridge. Much-prized Indian hawk bells are made at Lahore and Amritsar. A few falconers survive in Japan, flying their Japanese hawk eagles at hares and their goshawks at pheasants.

Hecht, 1954); E. B. Mitchell, *The Art and Practice of Hawking* (1900); M. H. Woodford, *A Manual of Falconry* (1960).

FALERII: *see* Civita Castellana.

FALERIO (mod. ***Falerone***), an ancient town of Picenum, Italy, about 10 mi. S.E. of Urbs Salvia, which, from the remains of its buildings, appears to have been of some importance. It was probably founded as a colony by Augustus after his victory at Actium.

Considerable remains of a theatre in concrete faced with brickwork, erected, according to an inscription, in 43 B.C., and 161 ft. in diameter, were excavated in 1838 and are still visible; an amphitheatre, less well preserved, also exists, the arena of which measures about 180 by 150 ft.

Between the two is a water reservoir (called Bagno della Regina) connected with remains of baths.

FALGUIÈRE, JEAN ALEXANDRE JOSEPH (1831–1900), French sculptor, whose most significant works were his naturalistic female nudes, was born at Toulouse on Sept. 7, 1831. He won the Prix de Rome in 1859 and became a member of the Institute in 1882. His "Victor of the Cock-Fight" (1864) and "Tarcisus the Christian Boy-Martyr" (1867) are in the Luxembourg. Falguière's more important monuments are those to Admiral Courbet (1890) at Abbeville and the famous "Joan of Arc." His "Triumph of the Republic" (1881–86), a vast quadriga for the Arc de Triomphe, Paris, was perhaps more amazingly full of life than others of his works, all of which revealed this quality of vitality in superlative degree.

To these works should be added his monument to "General de La Fayette" (in Washington), and his statues of "Lamartine" (1876) and "St. Vincent de Paul" (1879). His "Balzac" was executed for the Société des Gens de Lettres on the rejection of that by Rodin. "Diana" and "Woman and Peacock" are examples of his sensual treatment of the human form which aroused accusations of vulgarity from his contemporaries. He died in Paris on April 19, 1900. Falguière was a painter as well as a sculptor, but somewhat inferior in merit.

FALIERI, MARINO (1279–1355), doge of Venice, belonged to one of the oldest and most illustrious Venetian families and had served the republic with distinction in various capacities. In 1346 he commanded the Venetian land forces at the siege of Zara, where he was attacked by the Hungarians under King Louis the Great and totally defeated them; this victory led to the surrender of the city. In Sept. 1354, while absent on a mission to Pope Innocent IV at Avignon, Falieri was elected doge, an honour which apparently he had not sought. His reign began, as it was to end, in disaster, for very soon after his election the Venetian fleet was completely destroyed by the Genoese off the island of Sapienza, while plague and a declining commerce aggravated the situation. Falieri fretted under the constitutional restrictions of the ducal power, and the discontent of the arsenal hands at their treatment by the nobles offered him his opportunity. In concert with a sea-captain named Bertuccio Ixarella (who had received a blow from the noble Giovanni Dandolo), Filippo Calendario, a stonemason, and others, a plot was laid to murder the chief patricians on April 15 and proclaim Falieri prince of Venice. The Council of Ten arrested the ringleaders; several of the conspirators were condemned to death and others to various terms of imprisonment. The doge was himself arrested; at the trial he confessed everything, and was condemned and executed on April 17, 1355.

See Horatio Brown, *Studies in Venetian History* (1907, with bibliography).

FALISCI, a tribe of Sabine origin or connections, but speaking a dialect closely akin to Latin, who inhabited the town of Falerii as well as a considerable tract of the surrounding country, probably as far south as Capena. But at the beginning of the historical period (*i.e.*, from the beginning of the 5th century B.C.), and no doubt earlier, the dominant element in the town was Etruscan; and all through the wars of the following centuries the town was counted a member, and sometimes a leading member, of the Etruscan league (*cf.* Livy iv. 23, v. 17, vii. 17).

The Faliscans show many traces of their Italic origin, above all in their language, which is preserved in some 36 short inscriptions, dating from the 3rd and 2nd centuries B.C., written from right to left in a peculiar alphabet denved from the Etruscan, with some traces of the influence of the Latin alphabet.

The phonetic characteristics of the Faliscan dialect are:—

1. The retention of medial *f* which in Latin became b;

2. The representation of an initial Ind.-Eur. gh by *f* (*foied,* contrast Latin *hodie)*;

3. The palatalization of *d*+consonant *i* into some sound denoted merely by *i*—the central sound of *foied,* from *fo-died;*

4. The loss of final *s,* at all events before certain following sounds (*cra* beside Latin *crds).*

Other characteristics, appearing elsewhere, are:

5. The retention of the velars (Fal. *cuando* = Latin *quando;* contrast Umbrian *pan(n)u*);

6. The assimilation of some final consonants to the initial letter of the next word.

It seems probable that the dialect lasted on, though being gradually permeated with Latin, till at least 150 B.C.

The remains found in the graves, which belong mainly to the period of Etruscan domination, give ample evidence of material prosperity and refinement. The earlier strata have yielded more primitive remains from the Italic epoch. A large number of inscriptions consisting mainly of proper names may be regarded as Etruscan rather than Faliscan.

See W. Deecke, *Die Falisker;* E. Bormann, *in C.I.L.* xi. pp. 465 ff.; and R. S. Conway, *Italic Dialects.*

FALK, ADALBERT (1827–1900), German politician, was born at Matschkau, Silesia, on Aug. 10, 1827. In 1847 he entered the Prussian state service. and in 1853 became public prosecutor at Lyck. From 1872 to 1879 he was minister of education, and in connection with Bismarck's policy of the *Kultur-kampf* he was responsible for the famous May Laws against the Catholics *(see* GERMANY: *The German Empire).* He retained his seat in the reichstag till 1882, when he was made president of the supreme court of justice at Hamm. He died on July 7, 1900.

See H. R. Fischer, *Adalbert Falk* (1901).

FALK, JOHANN DANIEL (1768–1826), German author and philanthropist, was born at Danzig on Oct. 28, 1768. In 1813 he established a philanthropic society (Gesellschaft der Freunde in der Not), one of the earliest of its kind, and about the same time founded an institute for the care and education of neglected and orphan children, which, in 1829, was taken over by the state and still exists as the Falksches Institut. Falk lived at Weimar, and enjoyed the intimate friendship of Goethe; his account of their intercourse was posthumously published under the title *Goethe aus näherein persönlichen Umgange dargestellt* (1832) (English trans. by S. Austin). Falk died on Feb. 14, 1826.

Falk's *Satirische Werke* appeared in 7 vols. (1817 and 1826); his *Auserlesene Schriften (3* vols., 1819). See *Johannes Falk: Erinnerungsblatter aus Briefen und Tagebuchern* edited by his daughter, (1868); Heinzelmann, *Johannes Falk und die Gesellschaft der Freunde in der Not* (1879); S. Schultze, *Falk und Goethe* (1900).

FALK, MAX (1828–1908), Hungarian editor and statesman, was born at Budapest, Oct. 7, 1828. While he was still a young man, he edited in succession three small newspapers. In 1861 he was imprisoned for his part in the Hungarian nationalist movement, but was released in 1867 to become' the teacher of the Empress Elizabeth. In 1868 Falk assumed the editorship of the *Pester Lloyd,* a position he held until 1906. He was elected to the Hungarian parliament in 1869 and joined the liberal faction led by Francis Deak and the elder Count Julius Andrassy. He was the author of a biography of Count Istvan Széchenyi and of a book of reminiscences about the Empress Elizabeth. He died in Budapest, Sept. 10, 1908.

FALKE, GUSTAVE (1853–1916), German lyric poet and novelist, was born in Lubeck, Jan. 11, 1853. After finishing his studies at the Lubeck Catharineum, he became a bookseller. a position he gave up in 1878 when he was made professor of music at Hamburg. In 1903 the Hamburg government gave him a yearly subsidy of 3,000 marks so that he was able to devote the remainder of his life to writing. Falke wrote mainly of homely things such as the country about Hamburg and the simple pleasures of domestic life. In his early years his work was much influenced by that of the poet, Detlev von Liliencron. His poems include *Mynkeer der Tod* (1892), *Frohe Fracht* (1907), an epic poem, *Hohe Sommertage* (1902), and numerous others. His best-known novel is *Der Mann im Nebel* (1899) He died in Hamburg, Feb. 8, 1916.

FALKE, JOHANN FRIEDRICH GOTTLIEB (1823–1876), German historian, was born at Ratzeburg on April 10, 1823. In 1856 he was appointed secretary of the German museum at Nuremberg, and in 1859 keeper of the manuscripts. With the aid of the manuscript collections in the museum he studied economic history, and, with Johann H. Müller, established an historical journal, *Zeitschrift* fur *deutsche Kulturgeschichte* (4 vols., Kuremberg, 1856–59). To this journal he contributed a history of German taxation and commerce. In 1862 he became secretary and, later, keeper of the state archives at Dresden. His works include: *Geschichte des deutschen Handels* (2 vols., 1859–60); *Die Hansa als deutsche See- und Handels-macht* (1862), and *Geschichte des deutscken Zollwesens* (1869). He died at Dresden on March 2, 1876.

FALKENHAYN, ERICH VON (1861–1922), Prussian general, was born on Nov. 11, 1861 at Burg Belchau (Thorn). He took part in the China expedition of 1900 and remained in China with a brigade of occupation until 1903. In 1907 he was appointed chief of staff of the XVI, and in 1912 of the IV army corps. In 1911 he was appointed commander of the 4th guards (infantry) regiment. In 1913 he was made general. and from July 7, 1913, to Jan. 20, 1915, was Prussian war minister. He succeeded General von Moltke on Nov. 3, 1914, as chief of the general staff of the army Although Falkenhayn did not accept the principle that a decision could be obtained in the east, the abandonment of the plan for a break-through on the Albert-Arras front, and the increasing evidence of shortage of material and weakening efficiency on the Russian side made him regard a very heavy blow on the Russian front as necessary and desirable. Eight divisions were brought from the Western front, and Mackensen was made chief of this army (XI), which succeeded in breaking through the Russian lines (Gorlice–Tarnow) on May 2–3, 1915 (*see* WORLD WAR I).

Falkenhayn later helped to plan the summer offensive of 1915 against Russia. At the end of 1915 he became convinced of the necessity of opening a road to Turkey for the transit of munitions and expert personnel, and organized the operations by which. with the co-operation of the Bulgarian army, Serbia was overrun in the winter of 1915–16. At the end of Dec. 191j, Falkenhayn sent the Kaiser a memorandum setting forth his reasons for advocating an attack on Verdun, and he was severely blamed when the attack eventually failed. (*See* also VERDUN, BATTLES OF.)

In July 1916, Falkenhayn, submitting to public opinion, proposed that Field Marshal von Hindenburg should be made supreme commander from Pripet to the Dniester, and a few days later he offered him the command of the whole eastern front from the Baltic to the Carpathians. The desire for the creation of a general supreme command was rapidly growing even in Austria, and on Sept. 16. 1916 the *Oberste Kriegsleitung* was signed by German and Austrian plenipotentiaries; under this agreement the German Kaiser became responsible for the higher leading of operations in general.

This agreement was signed on the part of the Germans by Hindenburg, who had succeeded Falkenhayn as new chief of the general staff on Aug. 29, 1916, the immediate cause of Falkenhayn's dismissal being the Rumanian declaration of war (Aug. 27, 1916). Falkenhayn was then assigned the leadership of the IX army against Rumania and commanded in the fighting at Hermannstadt and on the Targu Jin.

In 1917 he took command of the so-called Asiatic corps, for operations in the Caucasus, and in 1918 and 1919 was at the head of the X army in Lithuania.

He wrote an interesting account of the German conduct of the war during its first two years, entitled *Die oberste Heeresleitzrng in ihren wichtigsten Entschliessungen 1914–16* (1919), and *Der Feldzug der IX Armee gegen die Rumänen und Russen 1916–17*, 2 vol. (1921). He died on April 8, 1922, at the castle of Lindstet, near Wildpark.

See A. Alberte, *General Falkenhayn, die Beziehungen zwischen den Generalstabschefs des Dreibundr* (1924).

FALKIRK, a large and parliamentary burgh of Stirlingshire, Scot., 11 mi. S.E. of Stirling by road and about midway betneen Edinburgh and Glasgow. Pop. (1961) 38,043. Falkirk stands on high ground overlooking the fertile Carse of Falkirk. The Forth and Clyde canal passes through the north of the burgh and the Antonine wall runs through the southern end. The suburb of Camelon is the site of successive Roman forts. Grangemouth (*q.v.*), the port, lies 3 mi. N.E. The Gaelic name, Eaglais Bhreac (1166), the Latin Varia Capella (1166) and the English Faw Kirk (1298) all mean "speckled (or many-colouredj church." The place is mentioned by Simeon of Durham (early 12th century) as Egglesbreth.

The first church was built by Malcolm Canmore, but the present church is of the early 19th century. The town became a burgh of barony in 1600 and of regality in 1646 under the important Livingston family who had held the estate of Callendar (with its *caput* immediately southeast of Falkirk) since the mid-14th century. They were forfeited after the rebellion of 1715 and the regality was canceled.

Control of the town fell eventually into the hands of the stentmasters (a body of men elected by the trades to levy a "stent" to be spent for the common good). who governed its finances until 1857. Falkirk is now under the control of a council with provost and bailies, and combines with Stirling and Grangemouth to return one member to parliament.

The long-important trysts or sales of cattle and sheep, known as the Great Mercat, were transferred to Falkirk from Crieff in about 1750, but only local markets are now held. The district is rich in coal. and fire clay is mined, though iron is no longer worked. Falkirk is the chief seat of the light-casting trade in Scotland; other industries include aluminum rolling. precast concrete, chemicals and hosiery manufacture, and brewing and bookbinding are also carried on.

Carron, 2 mi. N.N.W., is well known for the ironworks established in 1759 by John Roebuck for whom John Smeaton and James Watt (*qq.v.*) worked. (X.)

Battles of **Falkirk.**—These were two engagements, one fought in 1298, the other in 1746. The battle of July 22, 1298. was fought between the forces of Edward I of England and those of the Scottish national party under the command of Sir William Wallace. The Scots had taken up a strong position on a hillside south of the town with an impassable marsh to their front, and were formed in four "schiltrouns" or dense circles of spearmen, with archers between the schiltrouns and a small body of mounted men in reserve.

The English first line, under the earl marshal and the earls of Hereford and Lincoln, tried the morass in vain and then rode round its western side. The second line. commanded by the warlike bishop of Durham, Antony Bek, rounded the marsh to the east and then halted to await the arrival of the third line under the king. The bishop's undisciplined and impatient followers, telling him to go back to his Mass and leave warfare to soldiers, charged the nearest schiltroun. The first line under the earls attacked on the other side but Wallace's "forest of spearmen" resolutely repulsed all attacks with heavy loss. The Scottish cavalry fled without striking a blow, except for a few leaders such as Sir John de Graham and Sir John Stewart who remained to die with the archers and spearmen.

Seeing that his cavalry could make no headway, Edward brought up his Welsh archers, who from a safe distance wrought such havoc among the schiltrouns with arrows and stones that the mounted troops were at last able to break the weakened and disorganized Scottish ranks and complete their destruction. It was the first victory of the longbow in a major battle.

At the second battle of Falkirk, fought on Jan. 17, 1746, the Jacobites, under Prince Charles Edward. defeated the government troops under Gen. Henry Hawley. Hawley had formed the opinion that a Highland army could not withstand a charge of cavalry and allowed them to occupy the high ground to the west of Falkirk. The dragoons, attacking uphill against driving rain. broke under the controlled and heavy fire of the Highland right under Lord George Murray. Most of the infantry became involved in the rout and Hawley fell back to Edinburgh with heavy losses in men, guns and stores. (R. L. HR.)

FALKLAND, LUCIUS CARY, 2nd VISCOUNT (*c.* 1610–1643), son of Sir Henry Cary. afterward 1st Viscount Falkland (d. 1633), lord deputy of Ireland from 1622 to 1629, was born either in 1609 or 1610. and was educated at Trinity college, Dublin. In 1625 he inherited from his grandfather the manors of Great Tew and Burford in Oxfordshire; he married Lettice. daughter of Sir Richard Morrison. In 1633 he succeeded his father as Viscount Falkland.

He assembled round him at Great Tew many learned men. He was the friend of Hales and Chiilingworth, was celebrated by Jonson, Suckling, Cowley and Waller in verse. and in prose by Clarendon, who is eloquent in describing the virtues and genius of the "incomparable" Falkland, and draws a delightful picture of his society and hospitality.

Falkland served on the king's side as a volunteer under Essex in the campaign of 1639 against the Scots. In 1640 he was returned for Newport in the Isle of Wight to the Short and Long Parliaments, and took an active part on the side of the opposition. He spoke against the exaction of shipmoney on Dec. 7, 1640, denouncing the servile conduct of Lord Keeper Finch and the judges.

Falkland supported the prosecution of Strafford and he voted for the third reading of the attainder. On the church question he deprecated clerical encroachment in secular matters; on the other hand, though he denied that episcopacy existed *iure divino,* he was opposed to its abolition, fearing the establishment of the Presbyterian system. which in Scotland had proved equally tyrannical. In fact Falkland sought compromise, but a bill simply excluding the clergy from secular offices failed, and on May 27, 1641, the Root and Branch bill, for the total abolition of episcopacy, was introduced in the house of commons. This measure Falkland opposed, as well as the second bill for excluding the bishops, introduced on Oct. 21. In the discussion on the Grand Remonstrance he took the part of the bishops and the Arminians. He was now definitely ranged against the policy of the parliament, and on Jan. 1, 1642. was persuaded by Hyde to accept the secretaryship of state, though he had little influence in the king's councils.

He signed the protestation against making war at York on June 1j, 1642. On Sept. j he carried Charles's overtures for peace to the parliament, when he informed the leaders of the opposition that the king consented to a thorough reformation of religion. The secret correspondence connected with the Waller plot passed through his hands. He was present with the king at Edge Hill and at the siege of Gloucester. By this time the hopelessness of the situation had completely overwhelmed him, and he welcomed death on the battlefield as an escape from the catastrophe which he foresaw but saw no means of avoiding. Riding alone at a gap in a hedge commanded by the enemy's fire in the battle of Iiewbury (Sept. 20. 1643), he was immediately killed. He was succeeded in the title by his eldest son, Lucius, 3rd Viscount Falkland, his male descent becoming extinct in the person of Anthony, jth viscount, in 1694. when the viscounty passed to Lucius Henry (1687–1730), a descendant of the first viscount.

Falkland wrote a *Discourse of Infallibility* (1646); *A Letter . . . 30 Sept. 1642 Concerning the Late Conflict Before Worcester* (1642); and *Poems* (ed. by A. B. Grosart, 1871, in Fuller's Worthies Library) in which he shows himself a follower of Ben Jonson.

See Lady M. T. Lewis, "Life of Falkland," in *Lives of the Friends . . . of Lord Chancellor Clarendon,* vol. i, p. 3 (1852); J. A. R. Marriott. *Life and Times of Lucius Cary, Viscount Falkland* (1907).

FALKLAND, a royal burgh and civil parish of Fifeshire, Scot., at the northern base of the hill of East Lomond (1,471 ft.), 21 mi. N. of Edinburgh as the crow flies and 16 mi. S.E. of Perth by road. Pop. (1961) 1,032. The little town, with its cobbled streets and many old houses, has been connected with Scottish kings since the 12th century. The castle was replaced by Falkland palace which, from the 16th century, became a favourite seat of the Scottish court. It was finished in 1j40 by James V who died there in 1542. Its east wing was partly destroyed by fire in 1654 while Cromwell's forces were in occupation; only the foundations remain of the north wing; the south wing was rebuilt by the 3rd marquess of Bute. who acquired the property in 1887. The gardens have been restored to their original royal plan and at Falkland is the only royal tennis court left in Scotland.

In 1952 the National Trust for Scotland became deputy keeper of the palace.

Falkland became a royal burgh in 1458 and its charter was renewed in 1595. It gives the title of viscount to the Devon family of Cary (granted in 1620). Richard Cameron (*q.v.*) the Covenanter was born at Falkland *c.* 1648 and his thatched house still stands. The chief industries are linen and linoleum.

FALKLAND ISLANDS AND BRITISH ANTARCTIC TERRITORY. The Falkland Islands, a group of islands in the South Atlantic ocean. belonging to Great Britain, lie between latitudes 51° S. and 53° S. and longitudes 57° W. and 62" W., and about 250 mi. E. of the nearest point on the South American mainland. The two principal islands. East Falkland and West Falkland. are separated by the Falkland sound. a narrow strait running northeast to southwest and nowhere more than 25 mi. across. Round them lie about 200 smaller islands. of which about a dozen are inhabited. The total area is 4.618 sq.mi. Pop. (1953) 2,230. Capital. Stanley. *(See* below, *Falkland Islands Dependencies and British Antarctic Territory.)*

Physical Features.—The coast line is deeply indented and affords many secure and sheltered anchorages. In dull weather, which predominates, the general appearance of the islands is uninviting, but under bright sun the scenery takes on colour and beauty. East Falkland is almost bisected by the Choiseul and Brenton sounds. Its hilly northern part is traversed by the Wickham heights, a rugged range running from east to west with its highest point at Mt. Usborne (2,245 ft.). The remainder of the island is mainly low and undulating ground covered with coarse grasses, with small streams feeding the valleys but also with extensive bog and shallow tarns and much stony outcrop. Seen from the air, its appearance is bleak and inhospitable. At the northern extremity are two fine inlets. Berkeley sound and Port William. The early seat of government, Port Louis, lay at the head of the former but it was moved in about 1844 to its present site at Stanley, a landlocked harbour within Port William.

West Falkland enjoys a gentler climate. Its hillier part lies to the east of the island where the Hornby hills, running parallel to the Falkland sound, reach their highest at Mt. Adam (2.290 ft.).

The small town of Stanley is built along the southern slope of Port William inlet, overlooking the harbour, and on a fine day presents an attractive picture with its cluster of clapboard houses with their painted roofs and their porches gay with flowers. It is dominated at one end by the red brick Anglican cathedral and at the other by Government house.

With the exception of Lafonia (the southern part of East Falkland). which is Permocarboniferous. the islands consist of the older Paleozoic rocks, Lower Devonian or Upper Silurian, slightly metamorphosed and a good deal crumpled and distorted. In the low grounds are clay. slate and soft sandstone and on the ridges hard sandstone passing into white quartzite. There are no minerals of value. Many valleys in the islands are characterized by the presence of "stone runs" of varying length which upon examination are revealed as extensive accumulations of quartzite boulders. from 2 ft. to 20 ft. long and half as wide and with a depth corresponding to the quartzite ridges of the hills above. These blocks or boulders, angular in form and resting irregularly. though close packed, one upon another. give an unmistakable impression of a river of stone flowing down toward the sea.

The Falkland Islands correspond in latitude in the southern hemisphere with London in the northern, and the temperature is equable with an annual mean of 43° F. The climate is not unlike that of the Outer Hebrides though somewhat colder. Its most trying feature is a persistent wind that blows at an average strength of 15 knots throughout the year and often with great force. The average annual rainfall (27 in.) is rather more than that of London. but the hours of sunshine. though fitful, are much the same. The strong winds and tempestuous seas have accounted for more than 130 wrecks around the islands and the hazards of navigation have been enhanced by the lack of beacons. There is only one lighthouse, at Cape Pembroke. but automatic lights have been placed at a number of danger points.

There is no evidence of human occupation before the establishment of the first settlement at Port Louis, in 1764, by L. A. de Bougainville. The land fauna is scanty. A small wolf or wild dog—the *loup-renard* of De Bougainville—is extinct, having last been seen in 1875. There are introduced hares and rabbits and, on two of the islands. Patagonian foxes, which have become a menace to young lambs. The herds of cattle that ran wild after the departure of the first settlers and bred prolifically have almost died out. and sheep. which were first raised on East Falkland in 1835, provide the sole economy of the islands. The whole colony is divided into sheep farms varying in size from 3.600 ac. to 400,000 ac. These carry a total in excess of 600.000 head with an average production of about 5,000,000 lb. of wool annually. The mortality. especially among lambs. is very high. Hair seal (sea lion and elephant seal) abound but attempts to exploit them commercially in the 20th century have failed. The southern fur seal, which was almost exterminated by wholesale killing in the 19th century. is re-establishing itself as the result of close protection. There are a few species of land birds. some of which, including the white-rumped sandpiper of North America, the Paraguayan snipe and the military starling, are migratory. There is a great wealth of sea birds and the islands possess large colonies of penguins. petrels and albatross. The only insect pest is the bluebottle.

As the islands are connected with subantarctic South America by an elevated submarine plateau, the island flora much resembles that found on the mainland except that the trees, of which there are such dense forests in southern Patagonia, are wholly absent. Attempts at tree planting have not met with success. The greater part of the land is formed of peat which is in some places of considerable age and depth and, at the bottom of the beds, dense and bituminous. It differs in character from the peat of northern Europe. for the lower plants enter but little into its composition and it is formed almost entirely of the roots and stems of *Empetrum nigrum* variety *rubrum,* a kind of crowberry bearing the local name of diddle-dee; of *Myrtus nummularia,* a small creeping myrtle known as teaberry; and of sedges and sedgelike plants. It is in general use as fuel. Two vegetable products. balsam bog *(Azorella caespitosa)* and tussock grass *(Poa flabellata),* have long been objects of interest. The first is a boulder-shaped, bright green mass which when dead becomes gray and stony in appearance. When cut open it reveals an infinity of minute leaf buds and stems from which, at intervals, exudes an aromatic resin. The second is not unlike an African sword grass but has broader leaves and grows in tufts that rise about six to ten feet high. The leaves are cut and fed to dairy cattle and horses and, having a high protein content, make admirable fodder. With the introduction of sheep, which eat the heart of the plant, the tussock grass was threatened with extinction on the main islands. Where it survives it is fenced in. On many of the smaller islands, where it is prolific. cattle and horses are put out to winter and. as they feed only on the leaves, do the plant no harm.

History. — The Falklands were discovered by the English navigator John Davis (Davys) in the "Desire" in 1592 and two years later Sir Richard Hawkins sailed along their northern shore. In 1598 Sebald van Weerdt appears to have visited some of the northern islands of the group (probably the Jasons). which were for long named the Sebaldine Islands. The Falklands derive their present name from Capt. John Strong, who, in 1690, sailed down the sound separating the eastern and western islands and called them after Lucius Carey, Viscount Falkland, then treasurer of the navy. Their existence had long been known to French mariners sailing out of St. Malo for the Rio de la Plata who called them Les Îles Malouines, which the Spaniards on the mainland converted to Las Islas Malvinas.

Recorded history begins with the establishment by De Bougainville of a party of settlers on East Falkland in 1764. In the following year Capt. John Byron, who had been sent out on a survey expedition, claimed the islands for Great Britain and left a small party at Port Egmont on Saunders Island. In 1766 the French settlement was withdrawn under pressure from Spain, which later (17'70) ejected the British party — an action that brought the two countries to the brink of war. Port Egmont was restored to Britain in 1771 but voluntarily abandoned three years later. In 1829 the Republic of Buenos Aires, which claimed to have inherited the rights of Spain, sent Louis Vernet to develop a colony in its name; he made some progress but in 1831 was rash enough to seize three U.S. sealing vessels and this brought down a U.S. corvette, the "Lexington," which "laid waste the Settlement and proclaimed the islands free of all governance." In 1833 Great Britain, which had never renounced its claims to sovereignty, resumed official occupation. The colony was under the charge of successive naval officers engaged on hydrographic work until 1841 when a civil administration was set up at Port Louis and continued from that time. In 1914 the adjacent waters were the scene of the battle of the Falkland Islands (*q.v.*), and during World War II Stanley was an important naval base and radiotelegraphy station.

Claims are outstanding by Argentina to the Falkland Islands and their dependencies and to the antarctic continental shelf opposite Argentina, and by Chile to territories lying between longitudes 53° W. and 90° W., including the South Shetlands. The claims of the two countries overlap and are contested by Great Britain. Bases were set up by both claimants in the territories claimed. Great Britain sought the arbitration of the International Court of Justice, but the court refused arbitration in March 1947 because Argentina and Chile had rejected its competence to adjudicate. A truce between the three countries, agreeing not to move warships south of 60° S. latitude, was renewed from time to time, and the 12-nation agreement of Dec. 1959 on the peaceful use of the antarctic continent, involving a moratorium on territorial claims, served to relax tension.

Administration and Population. — The administration follows the normal crown colony pattern under a governor who is appointed by the crown and is himself advised by an executive council of four official and three unofficial members. The lawmaking body is the legislative council comprising five official and six unofficial members, of whom four are popularly elected. There is thus an unofficialmajority. There is no public debt and the colony is self-supporting. The revenue is derived mainly from income tax and from duty levied on imports of malt, wine, spirits and tobacco and upon the exports of hides and skins, tallow and wool. In the case of wool the duty is assessed on the average price for the season's clip. The islands have no other resources and apart from meat, fish and vegetables are dependent on external supply. The biggest single landowner is the Falkland Islands company. which obtained a royal charter in 1851. This company is responsible for the shipment and delivery to the London market of the annual wool clip. It acts as general agent for the farms and owns a large retail store and workshops at Stanley.

About half the population live in Stanley and the remainder on the farms. Most are of British descent but there are some Scandinavian strains. Family allowances are paid by the government, provided there are two or more children, and there is a contributory old-age pension scheme for male workers. Education is the responsibility of the government, which maintains two schools in Stanley where attendance is obligatory between the ages of 5 and 14 and voluntary up to 16 years. There is a flourishing boarding school at Darwin on East Falkland and a smaller school on West Falkland. Elsewhere on the farms education is largely dependent on traveling teachers. There is a well-equipped hospital and dental surgery and, in addition, medical officers are stationed on East and West Falkland. The colony has an efficient mdiotelegraphy station, which is its link with the outside world, and a substation at Fox Bay on West Falkland. All farms and outlying islands are provided with two-way radiotelephone sets that keep them in daily touch with Stanley. Physical communications with the mainland and with the farms are maintained by the company's steamer, supplemented in the latter case by privately owned cutters, by a small government motor vessel and by an internal air service operating float planes. This air service, with the number of natural harbours available and the close proximity of the farms to them, provides the ideal medium. It is extremely popular and along with the provision of radiotelephone sets has revolutionized life in the islands.

Falkland Islands Dependencies and British Antarctic Territory. — By an order in council effective from March 3, 1962, the separate colony of British Antarctic Territory was established, comprising part of the former territory of the Falkland Islands dependencies. The dependencies now consist of the islands lying between longitudes 20° W. and 50° W. and latitudes 50" S. and 60° S., and those between longitudes 50° W. and 80" W. and latitudes 58° S. and 60° S. These are principally South Georgia and the South Sandwich group.

British Antarctic Territory comprises all land and islands between longitudes 20° W. and 80° W. and south of latitude 60° S.: namely the South Orkney and South Shetland island groups, and the wedge-shaped sector of the antarctic continent from Palmer peninsula (including Graham Coast) to the south pole. It is administered by the Falkland Islands' governor acting as high commissioner.

The above territories, until 1962 all part of the Falkland Islands dependencies, were annexed to the British crown in 1908. The area of the dependencies is 1.570 sq.mi., and their population about 1,300 in summer and 100 in winter. The area of British Antarctic Territory is about 475,000 sq.mi., and its population 150 in summer and 90 in winter. South Georgia is the site of an important land-based whaling industry. A chain of meteorological and scientific bases is maintained on British Antarctic Territory, stretching from Signy Island in the South Orkneys to Stonington Island off the west coast of Palmer peninsula, and manned by the British Antarctic survey (formerly the Falkland Islands Dependencies survey). This organization has been responsible for the topographical and geological survey of the greater part of British Antarctica. A meteorological office at Stanley receives reports from the bases and issues a daily weather forecast of which wide use is made. A scientific bureau in London serves as a clearinghouse for the distribution of this material and the publication of reports. Revenue is derived mainly from income tax, customs duties and an export tax on whale oil, and is supplemented by a substantial grant from the U.K. Most of the revenue is spent on the maintenance of the scientific bases.

While the bases, generally, are icebound throughout the winter months. South Georgia remains open. The South Sandwich group and Deception Island in the South Shetlands are volcanic and there are hot springs at the latter. The scenery in Antarctica as a whole is magnificent on a fine day in the summer, and this is especially true of South Georgia.

The island is closely associated with the memory of the explorer Sir Ernest Shackleton, who is buried there, and of his heroic journey during 1915–16.

South Georgia and the South Sandwich Islands were discovered in 1775 by Capt. James Cook, the navigator, who took possession for the crown. His reports of the abundance of whales and seals in those waters led to the discovery of the antarctic continent by the whalers and sealers who followed in his wake, for some of the shipowners were interested in discovery for its own sake and encouraged their captains to push even farther afield. Outstanding among the latter were George Powell (South Orkneys. 1821–22). William Smith (South Shetlands, 1819), James Weddell, Edward Bransfield (antarctic mainland. 1820) and John Biscoe (Graham Land. 1832); these in turn led to the expeditions of A. de Gerlache (Belgian), Otto Nordenskjöld (Swedish), W. S. Bruce. (Scottish); J. B. Charcot (French), Shackleton (British) and W. Filchner (German), the continuing work of the Discovery committee and the British Graham Land expedition, and so to the establishment of the Falkland Islands Dependencies survey in 1943.

FALKLAND ISLANDS, BATTLE OF. One of the principal actions of World War I, known as the battle of the Falklands, was fought on Dec. 8, 1914, to the southeastward of the Falkland Islands, between a British squadron under Vice-Adm. Sir Doveton Sturdee and a German squadron under Vice-Adm. Graf von Spee. This battle was a counterstroke to the battle of Coronel (*q.v.*). With the utmost secrecy the two battle cruisers "Invincible" and "Inflexible" had been detached from the grand fleet in the North sea and sent, with all dispatch, to reinforce the British squadron in the South Atlantic. Admiral Sturdee's orders, on leaving England in the "Invincible," were to "Seek out and destroy the enemy." The following table shows the details of the rival forces:

Armament and Speed of Rival Forces

Type of ship	Name	Guns	Nominal speed
British			
Battle cruisers .	"Invincible"	8 12-in.	26 knots
	"Inflexible"	8 12-in.	26 ,,
Armoured cruisers	"Carnarvon"	4 7.j-in., 6 6-in.	22 ,,
	'all"	14 6-in.	23.5 ,,
	"Rent"	14 6-in.	23.5 ,,
Light cruisers .	"Glasgow"	2 6-in., 10 4-in.	25 ,,
	"Bristol"	2 6-in., 10 4-in.	24 ,,
Armed merchant cruiser . .	"Rfacedonia"	...	
German			
Armoured cruisers	"Scharnhorst"	8 8.2-in. 6 5.9-in.	23 knots
	"Gneisenau"	8 8.2-in. 6 5.9-in.	23 ,,
Light cruisers .	"Leipzig"	10 4.1-in.	23 ,,
	"Nürnberg"	10 4.1-in.	23.5 ,,
	"Dresden"	10 4.1-in.	24 ,,
Supply ships .	"Seydlitz"	...	
	"Baden"	...	
	"Santa Isabel"	...	

Fleet at Port William.—After the defeat of Admiral Cradock's squadron at Coronel, the old battleship "Canopus" had returned to the Falklands and was berthed on the mud in Port Stanley, the inner harbour. Her light guns had been erected on shore and the entrance to the harbour mined with electric mines constructed out of old oil drums. A signal station had been erected and the local volunteers organized as a defense force. Thus being sturdily prepared for eventualities, the little colony had waited.

On his arrival at Port William on Dec. 7, Admiral Sturdee ordered the "Macedonia" to patrol outside the harbour; the "Inflexible" and "Kent" to be ready for 14 knots at half an hour's notice and the other ships of his squadron to keep steam for 12 knots at two hours' notice. Only three colliers were available, so all ships could not coal at once. By 6 A.M. on Dec. 8. the "Carnarvon" and "Glasgow" had finished coaling. The "Invincible" and "Inflexible" then began. The "Bristol" had her fires out to remedy defects and the "Cornwall" had one engine opened up at six hours' notice; the "Glasgow" was also repairing machinery and could not be ready for two hours. Such was the situation when, at 7.50 A.M.. the observation post on Sapper's hill reported two strange ships in sight. At 7.56 A.M. the "Glasgow" fired a gun to draw attention to a signal flying in the "Canopus," making known this report.

German Squadron in Sight.—A scene of activity ensued; colliers were cast off and preparations made for leaving harbour. The "Kent," having just taken over guard duty, was ordered to weigh and observe the enemy. The general signal to weigh was made at 8.14 A.M.; at 8.30 "action" was sounded off and all ships were striving to raise steam at the earliest possible moment.

The two ships which had been sighted were the "Gneisenau" and "Nürnberg," which Spee had sent on ahead to reconnoitre; they were not visible from the "Canopus" but, with the aid of an extemporized observation hut which had been established on the hill, she opened fire on them at 9.15 A.M. with her 12 in. guns. The range, however, was too great and the shots fell short; nevertheless, the firing made the two German ships turn away to the southeast.

Von Spee, in the "Scharnhorst" was some 15 miles distant from the harbour, but the clouds of smoke visible over the intervening land made him suspicious. The "Gneisenau" was near enough to make out the masts and funnels of six ships in the harbour, and, worse still, some observers thought they could distinguish the tripod masts of battle-cruisers. The report from the "Gneisenau" confirmed von Spee in his misgivings and he immediately ordered the advanced ships not to accept action. This order was followed by a general signal to his squadron to raise steam in all boilers and steer east.

Von Spee's Intentions. — It is impossible to be sure with what intention Admiral von Spee made for the Falkland Islands. By one account he expected to find there a British squadron weaker than his own; he hoped to draw them to sea, destroy them, and then occupy the Islands. Some colour is lent to this by the report of British officers at the observation post on shore that they could distinguish, through telescopes, men on board the "Gneisenau" dressed and equipped ready for landing. Von Spee was certainly unaware that the Admiralty had despatched two battle-cruisers to these waters. Their arrival just in time was a stroke of luck which the latter fully dcservcd; but Admiral Sturdee was momentarily at a distinct disadvantage owing to his ships being at anchor with colliers alongside.

Von Spee's position if the British squadron brought him to action in the open was hopeless; but if the Germans had pressed home an attack at the entrance to the harbour, the prospects would have been far from pleasant for the British forces within.

Pursuit of the German Squadron. — By 10.15 A.M. all ships, excepting the "Bristol," had steam up, and 1j minutes later they had cleared the harbour; the enemy was hull-down to the south-east, some 12 or 13 miles distant; so Admiral Sturdee made the signal for "general chase," an order for each ship to steam at her utmost speed in pursuit. The sea was calm, the sky clear, and a light north-westerly breeze was blowing. At 10 50 A M. it became evident that the British ships were gaining and Sturdee ordered the "Glasgow" to keep three miles ahead, and the "Inflexible" to keep on the port quarter, of the "Invincible." This annulled the "general chase." By 11 A.M. the German ships were clearly visible and the battle-cruisers reduced speed to 24 knots. The "Carnarvon" and "Cornwall" were now lagging behind, their best speed being 20 knots and 22 knots respectively, and, to avoid his ships becoming too widely scattered, Sturdee reduced the speed of the squadron to 19 knots and ordered the crews to be piped to dinner. The German squadron was then doing little more than 1j knots.

Meanwhile, the German auxiliaries had been sighted from the Islands, and the "Bristol," which by extraordinary exertions had managed to raise steam and was just leaving harbour, was ordered to take "Macedonia" under her orders and "destroy the transports." Unfortunately, it was not known then that these ships were colliers.

At 12.20 P.M. Sturdee decided to press the chase and speed was increased to 22 knots; by 12.50 P.M. the British battle-cruisers were steaming 25 knots and were rapidly overhauling the enemy. At 12.55 P.M. fire was opened by the "Inflexible" on the "Leipzig" at a range of 16,000 yards. To save his light cruisers, von Spee ordered them to scatter and make for the South American coast; they turned away to the southward at about 1.20 P M. Such a contingency had been provided for, and, without further orders, the British cruisers turned off in pursuit.

The Battle-Cruiser Action. — As his light cruisers left him, von Spee turned to the eastward to accept action; and Sturdee's battle-cruisers turned into line ahead on a nearly parallel course to the enemy. Fire was now opened on both sides, but the range —about 14,000yd.—was too great, and the shots from the German ships fell short. The range closed to 12,500yd. and about 1.45 P.M. "Invincible" was hit; whereupon Sturdee turned away to open the range and obtain full advantage from his heavier armament. His object was to annihilate the enemy, but in doing so to receive as little damage as possible. By 2 P.M. the range had increased to 16,000 yd. and firing ceased for a time.

In order to renew the action, the British battle-cruisers altered course to starboard, and gradually reduced the range to 15,000 yd. Fire was then reopened and von Spee again accepted action, manoeuvring his ships to reduce the range sufficiently for his secondary armament to be brought into action. Sturdee allowed the range to fall to about 12,500 yd. and then, as the Germans began to fire with their 5.9-in. guns, he sheered off again. With his superior speed Sturdee was able to keep the range as he wished and the British guns now began to inflict severe damage on the enemy ships.

By 3 10 P M. the Germans showed signs of damage; the "Scharnhorst" being on fire. The smother of smoke made spotting the fall of shot a matter of some difficulty, so, at 3 1j P M., Sturdee turned the battle-cruisers round to port; von Spee replied by also turning his ships, and the action now ran to the south-westward.

End of the **"Scharnhorst."**—By 4 P.M. the "Scharnhorst" was suffering terribly; she was on fire from stem to stern; her superstructure was in ruins and she had a heavy list to port, but she continued to lire gamely with her remaining guns. Her end came at 4.17 P.M., when she turned completely over and sank with flag flying. No one was saved.

The "Gneisenau" Sunk. — After the "Scharnhorst" sank, both battle-cruisers engaged the "Gneisenau," and, to prevent being blinded by smoke, steered on independent courses. The "Carnarvon" had now been able to close sufficiently to open fire, and the doomed German cruiser became a target for a concentrated fire from three directions. Her fire slackened; she was on fire fore and aft and her speed rapidly dropped. Her one remaining gun continued to fire at intervals; but at 5.40 P.M. her splendid fight against hopeless odds was at an end and she heeled slowly over and sank at about 6 P.M. The British ships closed, lowered their boats and succeeded in rescuing 187 survivors from the icy water.

The Light Cruisers. — When the German light cruisers broke away, they had about 11 miles' start on their pursuers. The British ships had nominally no superiority in speed, but, owing to their recent continuous cruising, the boilers in the German ships were in no condition to withstand severe pressure. At first the enemy kept together. The "Glasgow" was the fastest of the pursuers and soon forged ahead of her consorts, the "Kent" and "Cornwall," and, having crossed ahead of them, she headed for the "Dresden," the fastest of the pursued. It was, however, soon evident that the only chance of bringing the enemy to action before the light failed. waa to attack the rearmost ship, in the hopes that this would bring the others back to her assistance.

"Glasgow" and **"Cornwall"** versus **"Leipzig."**—At 2.53 P.M. the "Glasgow" opened fire on the "Leipzig" and by 4.15 P.M. the "Cornwall" had closed the range sufficiently to bring her guns into action. The "Leipzig" suffered considerably under the cross-fire from the two British cruisers; her speed too was falling so rapidly that her attackers were in the fortunate position of being able to keep the range as they desired. By 7 P.M. the "Leipzig's" stern was enveloped in flames and she was in sorry plight, but she made no sign of surrender. At about 8.10 P.M. she made signals of distress and the British ships closed and lowered boats to rescue survivors. At 9.23 P.M. there was an explosion and the "Leipzig" disappeared.

"Kent" versus **"Nürnberg."**—The "Kent" meanwhile had been pursuing the "Niirnberg" and, by extraordinary efforts on the part of her engine-room department, succeeded in exceeding her designed speed. At 5 P.M. the "Niirnberg" opened fire, but the 6-in. guns of the "Kent" were not yet within range. The weather was becoming thick, owing to a fine drizzle having set in, when fortune favoured the pursuer; the "Nürnberg's" boiler tubes gave out and her speed sank rapidly, which enabled the "Kent" to close to effective range. By 6.25 P.M. the "Niirnberg" was a blazing wreck and about 7.30 P.M. she turned over and sank. The boats from the "Kent" searched the sea until g P.M. but rescued only seven survivors.

German Colliers Destroyed. — Meanwhile two of the German colliers had been overhauled by the "Bristol" and "Macedonia." They were captured at about 4 P.M. The signalled order to the "Bristol" to "destroy the transports" was literally obeyed in spite of these ships not being transports, but ships full of valuable coal. The "Dresden" escaped and was not hunted down and destroyed until March 14, 1915.

Casualties. — The following table shows the casualties of the British and German forces.

Ship	Hits Received	Casualties	Rounds fired
British:			
"Invincible" . . .	22	0 k., 1 w.	573 12-in.
"Inflexible" . . .	3	1 k., 2 w.	661 12-in.
"Glasgow" . . .	2	1 k., 4 w.	316 6-in.
"Cornwall" . . .	18	0 k., 0 w.	1,000 6-in.
"Kent"	36	4 k., 12 w.	646 6-in.
"Carnarvon" . .	0	0 k., 0 w.	...
German:

*k=killed, w=wounded. (J. E. T. H.)

FALKNER, WILLIAM: *see* FAULKNER, WILLIAM.

FALL, ALBERT BACON (1861–1944), U.S. politician, was born on Nov. 26, 1861, at Frankfort, Ky. He served in the U.S. senate from 1912 to 1921, when he became secretary of the interior. Following a senate investigation of his action in leasing to private oil interests certain tracts in the Teapot Dome reserve in Wyoming and other reserves in California, Fall was convicted of accepting a $100.000 bribe and served a year and a day in prison. Fall died in El Paso, Tex., Nov. 30, 1944.

FALLA, MANUEL DE (1876–1946), the most distinguished Spanish composer of the early 20th century. was born at Cádiz on Nov. 23, 1876. and took piano lessons from his mother, aho encouraged his early musical ambitions. Later he went to Madrid to continue his piano studies and to study composition with Felipe Pedrell, who inspired him with his own enthusiasm for 16th-century Spanish church music, folk music and native opera. He had already written two *zarzuelas* (the distinctively Spanish type of operetta), though without recognition.

In 1905 Falla won two prizes, one for piano playing, which led to his teaching the piano in Madrid for two years, and the other for a national opera aith *La vida breve,* which despite lyrical passages influenced by the works of Jules Massenet evoked a truly Andalusian background. Disappointingly. it was not performed until 1913. In 1907 Falla moved to Paris, where he associated with Claude Debussy (who had an intuitive sympathy for Andalusian music), Paul Dukas and Maurice Ravel (whose orchestration influenced his own), and there he published his first piano pieces and songs.

At the outbreak of World War I he returned to Madrid, where the success of *La vida breve* led to his being invited to write the music for a ballet, *El amor brujo* (Madrid, 1915), which aroused enthusiasm only after the original chamber scoring had been expanded. The work is remarkable for its distillation of Andalusian folk music, though. as in all his works, save occasionally for the purposes of allusion, there is no actual quotation of folk melodies. Falla, followed this with a mime version of a folk tale, *El corregidor y la molinera* (Madrid, 1917), which had an immediate success and attracted the attention of Diaghilev, who persuaded him to reshape and rescore it for a ballet by Leonide Massine; under the title *El sombrero de tres picos* (*The Three-Cornered Hut;* London, 1919) its vitality and wit scored a triumph. *Nqches en los jardines de España (Nights in the Gardens of Spain),* a suite of three impressions for piano and orchestra (the piano being treated not as a concerto instrument but as *primus inter pares)* (Madrid, 1916), was a poetic evocation in the most subtle instrumental colouring of Andalusian atmosphere, though by suggestion rather than by illustration. All these works established Falla internationally as the leading Spanish composer.

Having always been interested in *cante jondo,* the traditional folk song of southern Spain, the flavour of which he had captured in *La vida breve,* Falla retired to Granada, where in 1922 he organized a *cante jondo* festival and composed a puppet opera, *El retablo de Maese Pedro* (*Master Peter's Puppet Show),* based on an episode in *Don Quixote.* Like the subsequent *Harpsichord Concerto* (1926), containing echoes of a Corpus Christi procession and of Domenico Scarlatti, the *Retablo* shows Falla in a new idiom, much influenced by Igor Stravinsky; his style was now neoclassical instead of romantic. It was nonetheless quintessentially Spanish, but Castilian rather than Andalusian.

After 1926 he wrote little, living in semiretirement first in Mallorca and, from 1939, in Argentina, where he worked fitfully on a cantata, *L'Atlántida,* which was, however, left unfinished at his death and was completed by his pupil Ernesto Halffter. Contemplative and scholarly by nature and a perfectionist in his ideas, Falla sought to lead Spanish' music out of facile and false "Hispanicisms," and in his own work achieved a fusion of poetry, asceticism and ardour that represents the spirit of Spain at its purest. He died at Alta Gracia, Arg., on Nov. 14, 1946.

FALLACY, the term given generally to any mistaken statement used in argument; in logic, technically, any violation of the conditions of valid inference (Lat. *jallax,* "deceptive"). An argument may be fallacious in matter *(i e.,* misstatement of facts), in wording (*i.e.,* wrong use of words) or in the process of inference. Fallacies have, therefore, been classified as material, verbal and logical (or formal). The two latter kinds are often included under the general description logical and in scholastic phraseology, following Aristotle, are called fallacies *in dictione* or *in voce,* as opposed to material fallacies *in re* or *extra dictionem.*

Material.— The classification widely adopted by modern logicians and based on that of Aristotle's *Organon (Sophistici elenchi*) is as follows. (1) *Fallacy of accident; i.e.,* confusing what is accidental with what is essential. (2) *Secundum quid; i.e.,* arguing erroneously from a general rule to a particular case, without proper regard to special circumstances which vitiate the application of the general rule: *e.g.,* if manhood suffrage be the law, arguing that a criminal or a lunatic must, therefore, have a vote; or the converse fallacy of arguing from a special case to a general rule. (3) *Irrelevant conclusion,* or *ignoratio elenchi,* wherein, instead of proving the fact in dispute, the arguer seeks to gain his point by diverting attention to some extraneous fact (as in the legal story of "No case. Abuse the plaintiff's attorney"). Under this head come the so-called *argumentum (a) ad hominem, (b) ad populum,* (*c*) *ad baculum, (d) ad verecundiam,* common in platform oratory, in which the speaker obscures the real issue by appealing to his audience on the grounds of *(a)* purely personal considerations, *(b)* popular sentiment, *(c)* fear, (d) conventional propriety. This fallacy has been illustrated by ethical or theological arguments wherein the fear of punishment is subtly substituted for abstract right as the sanction of moral obligation. (4) *Petitio principii* (begging the question) or *circulus in probando* (arguing in a circle), which consists in demonstrating a conclusion by means of premisses which presuppose that conclusion. Jeremy Bentham points out that this fallacy may lurk in a single word, especially in an epithet; *e.g.,* if a measure were condemned simply on the ground that it is alleged to be "un-English." (5) *Fallacy of the consequent,* arguing from *a* consequent to its condition; *e g,* if a man is a drunkard he becomes destitute; therefore, if he is destitute, he is a drunkard. (6) *Fallacy of false cause,* or *non sequitur* ("it does not follow"), bases a conclusion on an insufficient or erroneous reason. This is often confused with (7) *Post hoc ergo propter hoc* ("after this, therefore. because of this"), wherein one thing is incorrectly assumed as the *cause* of another, as when the ancients attributed a public calamity to a meteorological phenomenon. (8) *Fallacy of many questions* (*plurium interrogationum*), wherein several questions are improperly grouped in the form of one, and a direct categorical answer is demanded; *e.g.,* if a prosecuting counsel asked the prisoner, "What time was it uhen you met this man?" with the intention of eliciting the tacit admission that such a meeting had taken place.

Verbal.— These fallacies are those in which a false conclusion is obtained by improper or ambiguous use of words. They are generally classified as follows. (1) *Equivocation* consists in employing the same word in two or more senses; *e.g.,* in a syllogism, the middle term being used in one sense in the major and another in the minor premiss, so that in fact there are four not three terms ("All fair things are honourable; This woman is fair; therefore this woman is honourable," the second "fair" being in reference to complexion). (2) *Amphibology* is the result of ambiguity of grammatical structure; *e.g.*, of the position of the adverb "only" in careless writings ("He only said that," in which sentence, as experience shows, the adverb has been intended to qualify any one of the other three words). (3) *Composition,* a species of (1) which results from the confused use of collective terms ("The angles of a triangle are less than two right angles" might refer to the angles separately or added together). (4) *Division,* the converse of the preceding, which consists in employing the middle term distributively in the minor and collectively in the major premiss. (5) *Accent,* which occurs only in speaking and consists of emphasizing the wrong word in a sentence ("He is a fairly good pianist," according to the emphasis on the words, may imply praise of a beginner's progress, or an expert's depreciation of a popular hero, or it may imply that the person in question is a deplorable violinist). (6) *Figure of speech,* misinterpretation of a form of expression or an inflection; *e.g.,* taking "desirable" to mean what can be desired (instead of what ought to be desired) because "visible" means what can be seen.

Logical.—The purely logical or formal fallacies consist in the violation of the formal rules of the syllogism (*q.v.*). They are: (1) fallacy of four terms (*quaternio terminorum*); (2) of undistributed middle; (3) of illicit process of the major or the minor term; (4) of negative premises.

Of other classifications of fallacies in general the most famous are those of Francis Bacon and J. S. Mill. Bacon (*Novum organum,* Aph. i, 33, 38 *et seq.*) divided fallacies into four *idola* (idols; *i.e.,* false appearances), which summarize the various kinds of mistakes to which the human intellect is prone (*see* BACON, FRANCIS). With these should be compared the *offendicula* of Roger Bacon, explained in the *Opus maius,* pt. i. Mill discussed the subject in book v of his *Logic,* and Jeremy Bentham's *Book of Fallacies* (1824) contains valuable remarks.

See A. Sidgwick, *Fallacies* (London, 1883); H. W. B. Joseph, *An Introduction to Logic,* 2nd ed. (Oxford, 1916).

FALLIÈRES, CLÉMENT ARMAND (1841–1931), president of the French republic, was born on Nov. 6. 1841 at Mezin, Lot-et-Garonne, where his father was clerk of the peace. He studied law and became an advocate at Nérac, beginning his public career there as municipal councillor (1868), afterward mayor (1871), and as councillor general of the department of Lot-et-Garonne (1871). He lost his position in May 1873 upon the fall of Thiers, but in Feb. 1876 was elected deputy for Nérac. In the chamber he sat with the Republican left, signed the protestation of May 18, 1877, and was re-elected in October by his constituency. He held at first a minor part (1880–81) in the Jules Ferry ministry, was then minister of the interior (1882–83) and for a month (Feb. 1883) premier. His ministry had to face the question of the expulsion of the pretenders to the throne of France, because of the proclamation by Prince Jérome Napoleon (Jan. 1883), and Fallieres, who was ill at the time, resigned when the senate rejected his project. He became minister of public instruction (Nov. 1883–March 1885), then minister of the interior in the M. Rouvier cabinet in May 1887, and exchanged his portfolio in December for that of justice. He returned to the ministry of the interior in Feb. 1889, and was minister of justice from 1890 to 1892. In June 1890 his department (Lot-et-Garonne) elected him to the senate by 417 votes to 23. In March 1899 he was elected president of the senate, and retained that position until Jan. 1906, when he was chosen by a union of the groups of the left in both chambers as candidate for the presidency of the republic. He was elected on the first ballot by 449 votes against 371 for his opponent, Paul Doumer. He held office until Jan. 7, 1913, when he was succeeded by R. Poincaré. He died June 22, 1931. For the events of his presidency *see* FRANCE: *History.*

FALLING STARS: *see* **METEOR.**

FALL LINE, in U.S. geology, a line marking the junction between the hard rocks of the Appalachians and the softer deposits of the coastal plain. The Pre-Cambrian and metamorphic rocks of the mountain mass form a continuous ledge parallel to the east coast, where they form a series of "falls" and rapids in the river courses all along this line. The relief of the land below the falls is very slight, and this low, level country, the tidewater region of Virginia, for example, rarely rises to a height of 200 ft., so that the rivers are navigable up to the falls, while the falls themselves are a valuable source of power. A line of cities may be traced upon the map whose position will thus be readily understood in relation to the economic importance of the fall line. They are Trenton on the Delaware, Philadelphia on the Schuylkill, Georgetown on the Potomac, Richmond on the James and Augusta on the Savannah. It will be understood that the softer and more recent rocks of the coastal plane have been more easily washed away, while the harder rocks of the mountains, because of differential denudation, are left standing high above them, and that the trend of the edge of this great lenticular mass of ancient rock is roughly parallel to that of the Appalachian system.

FALLMERAYER, JAKOB PHILIPP (1790–1861), German traveler and Byzantinist, who propounded the theory that the inhabitants of Greece are descended not from the ancient Greeks but from the Slavs and Albanians who later overran the country (*see* GREECE: *Postclassical and Medieval History*), was born of a peasant family at Tschötsch (now Scesse), near Bressanone, in the Tirol. He studied theology and classics at Salzburg. law at Landshut and modern Greek. Turkish and Persian while on garrison duty during the latter part of his five years' military service (1813–18). During 1818–1830 he taught at Augsburg and at Landshut. and in 1827 he made his name with his first book, *Geschichte des Kaiserthums von Trapezunt.* After producing the first volume of *Geschichte drr Halbinsel Morea* (1830; 2nd vol.. 1836) in which he enunciated his ethnological theories, he set out on a series of lengthy journeys which took him all over Greece and the Levant, as well as round Europe. He acted as foreign correspondent for an Augsburg newspaper, and published a number of political. historical and critical pieces. In 1848 he became professor of history at Munich. but had to resign in the following year when as a member of the national congress he accompanied the rump parliament to Stuttgart. The amnesty of 18jo permitted him to return to Munich, where he died on April 26. 1861.

Fallmerayer was one of the first to discuss the ethnological problems of the Byzantine empire, which are difficult to solve as the racial terminology of most Byzantine writers is far from precise. His extreme position on the Greek question, which caused much controversy among scholars, is now generally discarded, but the subject is still a living issue.

BIBLIOGRAPHY.—*Gesammelte Werke von J. P. Fallmerayer,* ed. by G. M. Thomas, 3 vol. (1861), contains political, critical and travel works only. Some of his historical works are collected under the title *Byzanz und das Abendland* (1943). *See* also the full list of his writings in H. Seidler, J. P. *Fallmerayers geistige Entwicklung* (1947). For criticism of his ethnological views *see* H. O. Eberl, J. *P. Fallmerayers Schriften in ihrer Bedeutung für die historische Erkenntnis des gräkoslavischen Kulturkreise* (1930).

FALLOPIUS, GABRIEL (GABRIELLO FALLOPIO or FALLOPIA) (1523–1562), Italian anatomist, was born at Modena, where he became a canon of the cathedral. He studied medicine at Ferrara and became teacher of anatomy in that city and later at Pisa and Padua, where he worked with Andreas Vesalius (*q.v.*). He died on Oct. 9, 1562.

Fallopius discovered or described the chorda tympani. the sphenoid sinus, the opening of the uterine tubes of the human female into the abdominal cavity, the trigeminal, auditory and glossopharyngeal nerves. He named the ovarian tubes. the vagina. the placenta, the muscles of the forehead, occiput and tongue. He boldly attacked the teaching of Galen. Only one treatise by Fallopius appeared during his lifetime, the *Observationes anatomicae* (Venice, 1561).

FALL-OUT. The phenomenon of deposition of radioactive materials on the earth from the atmosphere is known as radioactive fall-out or more commonly fall-out. Strictly speaking, fall-out refers only to deposition during nonprecipitant weather. with such terms as rain-out and snow-out used to describe the deposition during precipitant weather. However, in the broader sense and when discussing long-time effects, fall-out can include deposition during all types of weather.

This radioactivity in the atmosphere may arise from (1) natural causes; (2) atomic bomb or thermonuclear bomb explosions; and (3) induced radioactivities and fission products from atomic reactor operations.

Most of the natural radioactivity in the atmosphere is a result of cosmic rays and the gaseous diffusion of radon and thoron from natural uranium and thorium found in the earth's crust. The local concentrations of these gases in the atmosphere depend to a great extent on the concentrations of uranium and thorium in the earth, as well as on meteorological conditions. Cosmic rays produce, among other isotopes, radioactive forms of carbon and hydrogen. Radioactive carbon has a sufficiently long half-life to be useful in the dating of archeological objects. This interesting technique arises from the fact that the isotope is absorbed into a plant only during its growth and remains there after the death of the plant, slowly dissipating in the course of time. Knowledge of the initial amount. present amount and the half-life of the isotope leads to the age of the object. Radioactive hydrogen is similarly used, but for the dating of much more recent objects.

Concerning the explosion of nuclear bombs which release radioactivity, there are three separate types of fall-out: local. tropospheric and stratospheric. The local fall-out is due to the deposition of the larger radioactive particles near the site of the explosion. This is quite intense but relatively short-lived. Tropospheric fall-out occurs when the finer particles become trapped in the troposphere and are deposited at a later time and over a larger area—both factors being determined by the local meteorological conditions. In general tropospheric fall-out occurs in the month following the explosion. and takes place in the general latitude of the explosion site. Stratospheric fall-out. due to extremely fine particles in the stratosphere. may continue years after the explosion and the distribution is nearly world-wide. Generally only very large bombs (*i.e.*, thermonuclear) produce stratospheric fall-out. While many different radioisotopes are formed during a nuclear explosion, only the long-lived isotopes are concerned in stratospheric fall-out. Particularly involved are cesium-137 and strontium-go which have 27 and 28 year half-lives. The latter presents the greater hazard to humans since it is chemically similar to calcium and. in calcium deficient areas, it may replace the calcium in certain foods and ultimately become deposited in the body. The radioactive material in the stratosphere ultimately mixes with the troposphere where it then deposits out on to the earth through electrical attraction, gravity or by attachment to larger particles such as water droplets. Since the latter is the largest effect it is obvious that the rate of fall-out will be larger during precipitant conditions where the droplets are not only coming down, but scrubbing the atmosphere at the same time.

The final sources of the radioactivity which might be dispersed in the atmosphere are emanations from reactor operations. The normal radioactive products associated nith reactors can be quite successfully controlled and contained; however, should a reactor accidentally explode, the net result would be little different from that of a small nuclear bomb explosion and would produce large local fall-out but mould not penetrate the stratosphere.

Concerning the levels of radioactivity. it has been estimated that by the end of the 1950s, the world-wide stratospheric and tropospheric fall-out from nuclear bomb tests, reactors and other man-made radioactivity was very small—about $\frac{1}{100}$ of the radioactivity resulting from natural causes.

FALLOUX, FRÉDÉRIC ALFRED PIERRE, COMTE DE (1811–1886), French politician and author, was born at Angers on May 11. 1811. His father had been ennobled by Charles X, and Falloux began his career as a legitimist and clerical journalist under the influence of Rfme. Swetchine. In 1846 he entered the legislature as deputy for Maine-et-Loire, and with many other ultra-Catholics he gave real or pretended support t~ the revolution of 1848. Louis Napoleon made him minister of education in 1849, but disagreements with the president led to his resignation within a year. He had nevertheless secured the passage of the Loi *Falloux* (March 1j, 1850) for the organization of primary and secondary education. This law provided that the clergy and members of ecclesiastical orders, male and female, might exercise the profession of teaching without producing any further qualification. This exemption was extended even to priests who taught in secondary schools. where a university degree was exacted from lay teachers. The primary schools were put under the management of the curés. Falloux was elected to the French academy in 1856. His failure to secure re-election to the legislature in 1866, 1869. 1870 and 1871 was a result of the opposition of the stricter legitimists, who viewed with suspicion his attempts to reconcile the Orléans princes with Henri, comte de Chambord. In spite of his failure to enter the national assembly his influence was very great. and was increased by the intimacy of his personal relations with Thiers. But in 1872 he offended both sections of the monarchical party at a conference arranged in the hope of effecting a fusion between the partisans of the comte de Chambord and of the Orléans princes, divided on the vexed question of the flag. He suggested that the comte de Chambord might recede from his position with dignity at the desire of the national assembly, and he insinuated the possibility of a transitional stage with the duc d'Aumale as president of the republic. His disgrace with the Catholic party was so complete that he was excommunicated by the bishop of Angers in 1876.

Falloux died on Jan. 16, 1886.

Of his numerous works the best known are his *Histoire de Louis XVI* (1840); *Histoire de Saint Pie* (1845); *De la contre-révolution* (1876); and the posthumous *Mémoires d'un royaliste,* 2 vol. (1888).

FALLOW. Fallow is land normally under cultivation that is allowed to be idle for a season (sometimes longer) with or without cultivation. In dry-land areas the term applies specifically to land that is clean cultivated for a season to store water or release plant food for a crop the next year. Fallowing is a standard practice in many dry-land areas where the annual rainfall is not sufficient to produce paying crops regularly unless supplemented by stored moisture. Where the surface litter is plowed under it is called "black fallow" or "bare fallow" and where crop residues are left on the surface it may be called "trashy fallow."

In humid or subhumid areas fallow may be land lying idle without cultivation, but more often it is land plowed during the summer to destroy needs or to improve the next year's crop prospects. Although true fallow is land without a crop, there are modified forms such as "green manure fallow" where a growing crop, usually a legume, is turned under; "bastard fallow" where a fall-planted crop is pastured off or harvested in an immature state in the spring and the land then cultivated; and "green fallow," a term used in some countries to indicate an intertilled crop such as turnips or potatoes. Fallow is not properly used to describe land cultivated for only part of a season after a mature crop has been harvested.

FALLOW DEER (*Dama dama*), a medium-sized representative of the family Cervidae, characterized by its palmated antlers, rather long tail (black above and white below) and a coat spotted with white in summer but uniformly coloured in winter. The shoulder height is about three feet. The species is semidomesticated in British parks and occurs wild in western Asia, north Africa, south Europe and Sardinia. In prehistoric times it occurred throughout northern and central Europe. Bucks and does live apart except during the pairing season, and the doe produces one or two and sometimes three fawns at a birth. The Persian fallow deer (*D. mesopotamica*) is larger and has a brighter

EUROPEAN FALLOW DEER (DAMA DAMA)

coat differing in some details of colouring. An allied genus, the gigantic fossil deer commonly known as the Irish elk (*Megaceros giganteus*), had horns of the fallow-deer type This deer inhabited Ireland Great Britain, central and northern Europe and western Asia in Pleistocene and prehistoric times, and stood 6 ft. high at the shoulder The antlers were greatly palmated and of enormous size, fine specimens measuring 11 ft. betueen the tips. See also DEER.

FALL RIVER, a city of Bristol county in southeastern Massachusetts, U.S , on the east shore of Mount Hope bay at the mouth of the Taunton river, about 50 mi S. of Boston. Atop a sharply rising granite ledge, the city faces west overlooking its large harbour. Pop (1960) city, 99,942; standard metropolitan statistical area (Fall River city and Somerset, Swansea and Westport tonns in Bristol county, Tiverton town in Neuport county. Rhode Island), 138,156. (For comparative population figures see table in MASSACHUSETTS : *Population*)

French and English legends on monuments and French language newspapers testify to the considerable number of residents who are of French-Canadian origin.

'(Freeman's Purchase," or Freetown, including the present city of Fall river, was bought from the Indians by a group of settlers who came from Plymouth in 1656 In 1803 "Fallriver" was incorporated as a separate toun. The name was changed to Troy a year later, but in 1834 it was changed back to Fall River, after the Quequechan (or Fall) river which flows through the city from the Watuppa lakes about 200 ft. above the city, and 2 mi. E. It was incorporated as a city in 1854.

Until the American Revolution, agricultural interests predominated, but the city developed some industry thereafter and by 1871 had established itself as the cotton textile centre of the nation. Despite a disastrous fire in 1843 Fall River's natural advantages — water power, a mild moist climate and a good sea harbour — provided a basis for continuing booms in the cotton industry, and attracted new residents throughout the 19th century. The population grew from 14,026 in 1860 to 104,863 in 1900.

Although the Fall River cotton millworkers lost two of three important strikes in 1870 and 1875, textile craft unions nevertheless obtained recognition. Cotton workers predominated in the United Textile Workers of America, formed in 1901, and Fall River was its backbone. One of the first big walkouts after the union's organization occurred in Fall River in 1904, when about 27.000 workers stayed out for six months in protest against a general wage cut. The outcome was important because Fall River wage rates generally governed the rest of the industry. The strike ended by state intervention, and the workers accepted a unique sliding scale arrangement which actually meant a reduction. The industry, and the city as a whole, were seriously affected by the depression of 1920–21, competition of southern cotton mills and the hnancial crash of 1929. The apparel and textile industries, however, continued in the second half of the 20th century to be the largest source of employment; the manufacture of rubber products is the next industry of importance.

Fall River was the scene of the celebrated unsolved mystery in which Lizzie Andrew Borden (1860–1927) was acquitted of the ax-murder of her wealthy father and step-mother Aug. 4, 1892.

(L. G. BA)

FALMOUTH, a seaport, holiday resort and municipal borough in the Falmouth and Camborne parliamentary division of Cornwall, Eng., 36 mi. E.N.E. of Land's End and 11 mi. S. of Truro by road. Pop. (1951) 16,975. Area 2.9 sq.mi. Falmouth stands on the uest shore of Carrick roads, the largest of the estuaries which open on the south coast of Cornuall. Several rivers empty into the estuary, opening it to inland navigation by river steamer; the largest is the Fal, at the head of the estuary on the east shore; the Penryn river and creek join Falmouth with Penryn on the west, and the picturesque inlet of the Percuil (Porthcuel) river opens out from St. Mawes, near the entrance opposite Falmouth. Carrick roads forms one of the best refuges for shipping on the south coast, being accessible at all times by the largest vessels. The shores are beautifully nooded and slope sharply up to about 250 ft The entrance from Falmouth bay on the channel is about 1 mi. across betneen St. Anthony's point, with its lighthouse, and Zone point, on the east, and Pendennis point, the promontory of Falmouth, on the west. Pendennis and St. Mawes castles are Tudor fortresses; the former is celebrated for its gallant defense in the Civil War, when Cornwall was a centre of the royalist cause, another memorial being the Restoration church of King Charles the Martyr, built about 1662. Standing on a peninsula, Falmouth faces the water on both sides, and the old part of the town, with narrow streets, overlooks the inner harbour, while the newer residential area with the hotels faces the bay. There is an extensive marine drive, a concert hall, three sheltered beaches and approximately 100 ac. of public walks and pleasure grounds. Among the chief buildings are the town hall and municipal buildings. Because of its especially line yachting harbour, the Royal Cornwall Yacht club has its headquarters in Falmouth; the principal prize in the annual regatta, held in August, is a cup usually given by the prince of Wales as duke of Cornwall.

Falmouth (*Falemuth* in 1235) as a haven, port and mail-packet station, has had a place in the maritime history of Cornwall from early times. The site of the town, formerly known as Smithick and Pennycomequick, formed part of the manor of Arwenack held by the Killigrew family, the last of whom died in the 18th century. Arwenack house still stands. In 1652 the Commonwealth parliament granted a market to Smithick. This market was confirmed to Sir Peter Killigrew in 1660, together with two fairs and a ferry, which still runs. between Smithick and Flushing, on the opposite shore of Penryn creek. By the charter of incorporation granted in the following year the name was changed to Falmouth. In 1664 an act creating the borough a separate ecclesiastical parish empowered the mayor and aldermen to assess all buildings within the town for the support of the rector, but this rector's rate later occasioned some ill feeling and by act of parliament (1896) it was taken over by the corporation and finally abolished. By the Redistribution act, 188j, 'the number of members returned to parliament by the united boroughs of Penryn and Falmouth was reduced from two to one. The municipal borough is under a mayor, four aldermen and 12 councillors, and has a separate commission of the peace.

With its sandy beaches and equable climate, Falmouth is a favoured holiday town all the year round. Engineering and ship repairing are undertaken, and there are oyster fisheries in Falmouth harbour and Helford river. The ever-increasing importance of the town as a ship-repairing centre was being met in 1956 by increased wharfage and the extension of dry-dock facilities to accommodate the world's largest oil tankers and other ships. The area of the tidal harbour within the docks is about 42 ac.

Across the bay to the east is the Roseland peninsula with the parishes of St. Anthony in Roseland and St. Just in Roseland. The church of St. Anthony has a Norman doorway, that of St. Just is Perpendicular and stands by a creek of Carrick roads with an exceptionally beautiful wooded churchyard sloping down toward the water. Both villages are well known for their beauty. In 1956 part of the Trelissick estate on the estuary of the Fal was made over to the National Trust. It includes Trelissick house, which existed as a farm in the reign of Elizabeth I.

FALSE IMPRISONMENT is the total restraint upon the liberty of another person for however short a time without legal justification. Imprisonment may be justified either at common law or under statute, but justification for interference with 'the liberty of the subject must be strictly proved. (See also ARREST; HABEAS CORPUS.)

FALSE PRETENCE: see FRAUD.

FALSETTO, a forced form of sound production employed to obtain notes above the natural range of the voice. The notes of this register are of poor and peculiar quality owing to the vocal cords being only partially set in vibration.

FALSTAFF, SIR JOHN: see OLDCASTLE, SIR JOHN; FASTOLF, SIR JOHN.

FALTICENI, a town in the region of Suceava, Rumania, on a tributary of the Sereth, on the fall line between the Transylvanian Alps and the Bessarabian plain. The population in 1956 was 13,085. A branch railway runs for 15 mi. to join the main line between Czernowitz (Cernauti) and Galatz

(Galati). The Suceava department (named after Suceava or Suciava, its former capital) is densely forested; its considerable timber trade centres in Falticeni. It has a summer fair.

FALUN, a town of Sweden, capital of the district (*län*) of Kopparberg, 153 mi. N.W. of Stockholm by rail. Pop. (1950) 14,741. It is situated in difficult country near the northern shore of Lake Runn. Its famous copper mines have been worked since the 13th century. Their produce gradually decreased after the 17th century, and is now unimportant, but various secondary products are still obtained. The mines belong to the Kopparberg Mining company, the oldest industrial corporation in Sweden, established before 1347. It has various industrial interests besides copper mining. Falun has railway rolling-stock factories and there are museums of mineralogy and geology and a school of mining.

FAMA, in classical mythology, the personification of rumour (Gr. Φήμη, Ὄσσα). The Homeric equivalent Ossa (Iliad, ii, 93) is represented as the messenger of Zeus. who spreads reports with the rapidity of a conflagration. Homer does not personify Pheme, which is merely a presage drawn from human utterances, whereas Ossa (until later times) is associated with the idea of divine origin. A more definite character is given to Pheme by Hesiod (*Works* and Days, 764), who calls her a goddess; in Sophocles (Oed. Tyr., 158) she is the daughter of Hope. According to Aeschines the orator (c. Timarch., 128, de falsa leg. 145) and Pausanias (i, 17, I) there was a temple of Pheme at Athens, but apart from this, she is a figure of mythical and poetical imagination rather than cult.

In Rome, Fama is purely a poetical figure (*e.g.,* Virgil, Aen., iv, 173). The Φήμη καὶ κληδὼν of Plutarch (*Camillus,* 30. de fert. Roman., 319 A) is simply Aius *Locutius,* misunderstood, *cp.* Livy, v, 50, 5.

FAMAGUSTA, a town and harbour on the east coast of Cyprus (Gr. Ammochostos). 2½ mi. S. of the ruins of Salamis (*q.v.*). When Salamis (Roman Constantia) was destroyed by the Arabs in A.D. 647, its Christian inhabitants settled at the neighbouring Arsinoe (Ammochostos "choked with sand") which had been built by Ptolemy Philadelphus in 274 B.C., and now became the seat of the orthodox archbishopric.

Famagusta received many refugees at the fall of Acre in 1291; was annexed by the Genoese in 1376; reunited to the throne of Cyprus in 1464; and surrendered to the Turks in 1571 after a year's siege. The fortifications, remodelled by the Venetians after 1489, the castle, the grand Gothic cathedral of St. Nicolas (now the mosque St. Sophia), the Palazzo del Proveditore and the remains of many churches testify to the mediaeval splendour of Famagusta. Acts ii and v of Shakespeare's Othello pass there, and the "Moor's tower" is still shown. Much was done to develop the natural harbour, which is connected by railway with Nicosia (*q.v.*).

Population (1946 census) 16,194. Most of the Christians have migrated to the near-by suburb of Varosha.

FAMILIARITY, in psychology, is defined as a feeling upon which recognition follows so immediately that its complex nature is hidden. This recognition is based upon subliminal association and there is consequently no need for the presence of mental images.

Familiarity is therefore a developed "new" process of the mind, resulting from a fusion or combination of mental processes no longer individually felt. See ASSOCIATION. MENTAL.

FAMILISTS, a term of English origin (later adopted in other languages) to denote the members of the "Family of Love." founded by Hendrik Niclaes who died probably in 1580. His calling was that of a merchant, in which he and his son Franz prospered, ultimately becoming wealthy. Not till 1540 did he appear in the character of one divinely endowed with "the spirit of the true love of Jesus Christ." For 20 years (1540–60) Emden was the headquarters at once of his merchandise and of his propaganda, but he travelled in both interests to various countries, visiting England in 1552 or 1553. Niclaes claimed to hold an impartial attitude towards all existing religious parties, and his mysticism. derived from David Joris, was undogmatic. Yet he admitted his followers by the rite of adult baptism, and set up a hierarchy among them on the Roman model (see his *Evangelium* Regni, in English A *Joyfull Message* of the **Kingdom,** 1574?; reprinted, 1652).

His pantheism had an antinomian drift; for himself and his officials he claimed impeccability; but whatever truth there may be in the charge that among his followers were those who interpreted "love" as licence, no such charge can be sustained against the morals of Niclaes and the other leaders of the sect. The society spread in the eastern counties, in spite of repressive measures; it revived under the Commonwealth, and lingered into the early years of the 18th century.

The leading idea of the society's "service of love" was a reliance on sympathy and tenderness for the moral and spiritual edification of its members. Thus, in an age of strife and polemics, it seemed to afford a refuge for quiet, gentle spirits and meditative temperaments.

See W. T. Whitley, article "Enthusiasts, Religious" in Hastings, *Encyclopaedia of Religion* and *Ethics;* F. Loofs, article "Familisten" in Herzog-Hauck, *Realencyklopaedie;* F. Nippold, "H. Niclaes und das Haus der Liebe" in *Zeitschrift* fur *die hist. Theol. (1862).*

FAMILY. Viewed abstractly, the most familiar of social institutions seems the most stable, enduring and universal. It appears to have arisen earlier in human prehistory and occurred more ubiquitously than church or state or any of the other persistent forms of relationship by which men organize their activities. Viewed individually and concretely, however, each family is endangered by multiple threats of dissolution at every phase along its typical cycle of existence. The dependence of human beings almost exclusively upon their families for the satisfaction of certain of their most important wants makes the continued working of this institution a perennial concern.

For the sake of analysis, many anthropologists assert that the family functions to satisfy certain universal needs nhich persist among all men in all times The forms of relationship assumed by actual families, however. are not given in nature; they arise as artifacts of human ingenuity. Thus, patterns of family life are extremely variable.

In any particular time and place, the favoured form of the institution is believed by such theorists to be that which has proven most workable in meeting the universal needs under the existing specific conditions. And in the career of any single family, its unique variation upon the traditional design of its society is the adaptation it has made to the conditions and crises confronting it. Moreover, if the imputed underlying needs are granted to change, then still further diversity and uncertainty of outcomes must be expected. The kinds of classifications and generalizations and predictions which can be made about the family, therefore, must always remain somewhat loose and controversial.

Many late 19th-century scholars sought to establish an evolutionary sequence in the development of the forms of the family. The most advanced outcome of human progress was taken to be the form reached in western Europe during that period — a form much altered in the half-century since. Notable controversies arose over the inferred origin of the family — from a promiscuous horde, a polygamous patriarchy, a matriarchy or a nuclear family of father, mother and children, with variations added.

Although continuing among a few specialists, these controversies began to die down unresolved uith World War I, along with theological interest in primitive origins and popular faith in the idea of progress. Investigations among living primitive peoples, moreover, had brought to light the immense range of variation existing in familial forms. The distribution of these customs around the globe could be accounted for better by specific histories of cultural invention and diffusion than by some supposedly biological process.

Celibacy, contraception, infidelity. illegitimacy, incest, infanticide and neglect and desertion are found among all peoples, as are also kinship systems, marriage, adoption, incest tabus and rules of morality. Only a wide range of capacities can be regarded as innate and universal, capacities which make any concrete form of family behaviour possible for each individual.

Despite the occurrence of what looks like the nuclear human family among primates and some lower species, it is now recognized that there is no instinctual basis universally compelling human beings to form families or to rear their young. The long period of dependency of the human infant is now regarded as a necessary condition of its uniquely extreme malleability. The characteristic patterns of behaviour it acquires are learned rather than instinctual; their identity depends upon the local version of human culture to which it is exposed. That each society appears to have instituted some kind of family to care for and instruct its young has never insured that this will be done without exception. Each society has devised distinctive myths to explain the origins and uphold the duties of families, but this does not permit the reading of some innate purpose into sexual complementariness and infant helplessness.

Classifications of Forms of Family Organization. — Certain analytical terms derived from ethnological studies are useful in classifying existent forms of family organization and in sketching a broad historical movement away from joint families and extended kin groups (combining several generations and degrees of relationship) toward the nuclear form as the most characteristic of mobile, industrial communities and societies.

Consanguineal families have been more prominent in the past and in peasant countries. Here the family is defined primarily in terms of blood relationship and descent, with family functions concentrated in the unit so constituted. Ralph Linton speaks of the consanguineal family as consisting of parents, children and grandchildren, surrounded by a fringe of spouses. He contrasts it with the conjugal family, consisting of husband, wife and their offspring, surrounded by a fringe of loosely attached and intermittently operative relatives. The nuclear family structure which can be detected underlying all other forms is identical with the conjugal family as to form, but this analytical observation is not to be confused with the matter of social recognition and emphasis; until recently consanguineal obligations have generally received prominence and precedence over conjugal. Another way of clarifying the distinction is from the standpoint of an individual adult: he normally belongs to two families, his family of orientation (parents, siblings, relatives) and his family of procreation (spouse and children). Universal tabus upon incest have persisted to prevent any accepted merger of consanguineal and conjugal types of families in any known society. The ruling Pharaohs of ancient Egypt were expected to marry their sisters to conserve the royal lineage, but the practice was forbidden to commoners, so this does not constitute a valid exception.

The conjugal family is knit primarily by the marriage bond rather than by descent, but conjugal family practices tend to show some impress of the pattern of descent. If descent — of name and relationship, but usually including appended attributes, such as ownership and residence — is traced through the father, the family is called patrilineal; if through the mother, which is less common, matrilineal; if through both, which is common in western countries but less common elsewhere, bilineal. Least meaningful for English-speaking societies is the corresponding distinction into patrilocal and matrilocal, according to whether the custom is for the wife to live with her husband's family or, less commonly, the husband to live with his wife's. This distinction is very meaningful for those societies where a family's occupation is agriculture and its settled residence is the land it farms, although migratory grazing and hunting tribes often exhibit the pattern when they travel in groups. It is significant that among peoples like the Eskimo, who migrate continually in minimal family units, the conjugal form almost necessarily predominates because of the dispersion of the food supply. Economic advantage, whether conceived in terms of industrial plenty or agrarian scarcity, appears to be a major influence affecting the forms of descent in families and a powerful sanction in enforcing authority.

Distinctions like patriarchal and matriarchal continue to have meaning in all societies, with fathers far more commonly ruling their families. In English-speaking countries. however, paternal authority tends to decline wherever the father's occupation removes him from his home and wife and children much of the time, or where their employment away from their home reduces their dependency upon him. Frequent and substantial changes of job and residence likewise reduce the control which can be exerted by relatives, while industrial changes which reward skill and learning rather than property ownership reduce the economic advantages of loyalty to the consanguineal family. Thus, with the spread of industrialization and urbanization, the further attrition of consanguineal family types can be predicted. From the scientific standpoint, this trend can be adjudged neither progress nor retrogression, but numerous partisans uphold each view.

Between World War I and World War II, previous emphases by scholars upon biological and historical origins were replaced by attention to the dependence of the forms of institutions upon the functions they are intended to perform. This latter outlook led increasingly toward psychological and sociological interpretations of change in family forms. The transfer of production from homes to industrial and commercial institutions was pointed out as reducing the economic functions of the family to serving only as a consuming unit. The reduced differentiation of men's work from women's work in the home tended to transform marriage from interdependence into companionship, especially among urban couples above the lowest income levels. Children ceased to be valued as economic assets in a family enterprise and became in a sense wanted "items of consumption," with each family deciding how many it could afford. Maintenance of health, protection from enemies, education of the young, religious and recreational functions likewise were transferred in large part to specialized institutions.

Family **Stability.**—Despite certain retransfers and the emergence of various new functions, as in hygiene and recreation, the net effect of these changes has been generally appraised as reducing the importance of families to their members, thereby posing an additional threat to family stability. On the other hand, certain traditional functions have remained the recognized responsibility and offering of families; indeed, comparison might indicate that families show more attention than in the past to the giving and receiving of affection, the care and enjoyment of children. Such transformations as these can no longer be usefully conceived as the natural unfolding of an independent entity; instead, the family is now seen as both a reaction to and an influence upon other institutions of the whole society.

Thus the family is studied and served professionally from the standpoint of each of its functions — as a biological unit (demography, medicine), as a producing and consuming unit (home economics), as a unit of social organization (sociology, law), as a personality-forming agency (psychology, social work), as a culture-transmitting agency (education) and as a centre for the formation of values and identities (recreation, religion).

The popular and conservative outlook tends to construe certain forms of family life in each culture and subculture as sacred, given, ideal and not subject to purposeful modification .or legitimate deviation therefrom. While all societies exhibit actual deviations in behaviour from the ideal forms upheld in their recognized moralities, all known societies employ a variety of means to stabilize and enforce conformity to the forms they honour. Indeed, a large share of what is known as morality in every society is devoted to specifying the proper behaviour of family members toward each other.

The sociologist Charles Horton Cooley stated the influential proposition that moralization of communities at large, and ultimately of world society, consists of extending to secondary groups the relations characteristic of primary (face-to-face) groups. In view of the frequency of hatred and violence within families. his notion that family relations may be extended to less personal group relationships was probably more realistic than he supposed. Like Cooley, virtually all religions tend to conceive the proper relationships of mankind in family terms. Because of the interdependence of institutions, the growth of love within families and of brotherhood among nations is now thought more likely to proceed in step than apart.

The devices which have traditionally been employed to strengthen observance of family rules and enforce moral obligations include ritual advertisement of changes in family status; ascription of sacramental significance to wedding and name-giving ceremonies; cultivation of fears of supernatural sanctions; ridicule and ostracism of violators: withdrawal of economic support or co-operation; and, of course, the sanctions of law, courts and the state. Only recently in western European countries have there been tendencies to construe marriage as simply a matter-of-fact civil contract. Despite widespread decline of these religious and moral fortifications of marriage and the family, many spokesmen maintain strong misgivings as to whether families can remain sufficiently united without them to perform the functions for which the family is still deemed indispensable.

Commitment to certain moral norms ultimately furnishes the structure of any society, without which its members cannot organize and successfully conduct their various interdependent activities. Yet moral commitment based solely upon individual self-interest is a contradiction in terms. This modern dilemma is causing both social scientists and philosophers to scrutinize deeply the conditions upon which marriage and parenthood may be freely contracted yet may effectively commit the partners to the discharge of their family obligations.

In the representative conjugal family, it is the quality of the marriage between husband and wife which principally guarantees successful performance by the family of its functions. On this account, although marriage and the family are quite distinguishable, they are almost merged as concepts in popular thought among English-speaking people. Apart from the death or physical or mental breakdown of members, the major threat to any family is dissolution of the marriage which launched it. Correspondingly, the frequency of divorce is widely taken as the most significant index of family instability. Yet many unseparated families are quite unsuccessful in rendering to members the satisfactions they expect. Professional scholars are therefore engaged in research to find more precise and valid indexes of family success than the raw divorce rate: measures of welfare; happiness, solidarity, adjustment, development and competence.

Modern societies tend to require every person to achieve independence from his parents at adulthood. Asserting emancipation from parents often generates a stormy period of reorganization of family relationships during adolescence. which may overlap with the period of courtship. mate selection and marriage. Marriage in a society holding to the conjugal type of family ordinarily marks the transition of a person's primary loyalty from his family of orientation to his family of procreation. To the extent that he does not so transfer his loyalty, he endangers the stability of his marriage. Such readjustments require insight, skills and resources for handling problematic life situations. An important recent development which may contribute to increased family success is the belief that these insights, skills and resources may be improved through training and professional assistance. It may be debated whether in eras of large, consanguineal-type families and closely knit neighbourhoods such preparation for marriage and parenthood nas more available or less needed; in either event. consciousness of the value of adequate preparation has been growing. It is giving rise to a diffuse movement for family-life education in schools and colleges. Family failures in recent decades account for a vast array of remedial agencies, both public and private, in all the English-speaking countries. Some of the remedial agencies are likeaise turning their interest toward measures to prevent breakdowns, through programs of education, recreation and community planning.

Where the consanguineal family system predominates, mate selection is usually not left to the two individuals who marry, but is arranged by parents, brokers or community functionaries. It is paradoxical that as successful marriage becomes more basic to stability of the family, it is less and less entrusted to experienced persons to arrange. Contemporary insistence by young people upon making free choice of mates introduces new hazards of unwise selection, especially as the average age at marriage has tended to drop. The uncertainties of making a wise choice have given rise to an impressive growth of both magical and scientific devices for predicting success in marriage before it is contracted. The scientific procedures are still in their infancy, though the magical procedures are very old (see MARRIAGE).

The scientific method may have raised unjustified hopes that it could allay some of the perennial risks inherent in launching and conducting a family. There is, however, logically no direct appeal which can be made to science. as to religion, to strengthen the bond of marriage. On the other hand, it may be justifiable at least to hope that research and experiment mill progressively become able to state the conditions under which an optimum outcome is attainable. A description of these conditions may resemble no existing form of family life. Since the scientific approach is to evaluate such forms comparatively and experimentally, they would probably be conceived as tested organizational procedures rather than as sacred dogmas. Equipped nith such a basis for predicting and controlling outcomes, however. human beings might as readily employ it in venturing upon new explorations as in eliminating the hazards to family solidarity. Were all the striving to stabilize this errant institution ever to succeed. human life would lose its familiar likeness to a game of chance and skill. Only a glance at a daily newspaper is required to confirm the observation that not all persons place the same value upon successful marriage and stable families.

Values. — At the risk of oversimplification, changes in the family may be further analyzed in terms of a contrast between two general sets of values, familism and the pursuit of individual happiness. Some influential scholars, pointing to the trend from the large, patriarchal, consanguineal type of family to the small, equalitarian, conjugal type, ascribe this development to wider acceptance of the values of freedom, equality, participation in decision-making and the development of personality. At the same time, spokesmen who deplore this change are inclined to blame it upon the weakening of certain traditional values: obedience to legitimate authority, loyalty to parents and kin, respect for ancestors and the past and the virtues of the large-sized family. Despite their important disagreements, it may be noted that partisans of each type of family assume that the values they hold will influence further developments. Moreover. each party claims that its favoured form of organization is more conducive to the optimal development of children—whose rearing both groups agree upon as the principal end served by families. It is quite conceivable that the family as an institution could be dispensed with altogether and society would survive, since theoretically all family functions could be transferred to other institutions. But no influential theorists at present would hold with Plato that, for the best development of the children who are to become the guardians of society, they should be taken at birth from their parents and reared expertly by the state. A few tendencies in this direction in the early Soviet Cnion were soon reversed.

It is upon general commitment to the value of some kind of family, despite differences as to exact kind, that continuation of the institution depends. Thus it becomes useful to specify more closely the values sought in family life, and to regard these as diverse, variable. problematic. It is not valid to dispute one type of family over another simply in terms of their relative efficiency in satisfying imputed fixed needs. The functionalist approach uhich characterized professional thinking during the period between World Wars I and II is making way for a more procedural analysis of family functioning. The latter approach stresses periodic appraisal of the forms and functioning of family life in relation to specified, desired outcomes, these in turn being concrete versions of general values. Thus nepotism and the inheritance of wealth are family practices highly honoured according to certain traditional family values; but where emphasis is upon equality of opportunity for the children of all families, they are viewed as unethical advantages. The sovereignty of parents over children, as against public intervention, is a dispute over values. expressed in the contrasting practices of child labour and compulsory education. The privacy of the home may be regarded as sacred in one country but an invitation to conspiracy against the state in another. Financial responsibility for aged parents has become controversial.

To the extent that the forms and functions of family life come to be devised and deliberately revised according to conscious value judgments, the character of family living is seen as the product of specific social policies. In the modern world this definition has been given to many social institutions, and the family is apparently not to be excepted.

Public Programs. — Even an outcome ostensibly so much a matter of biology, of hope and fate, as the number of children a family will have is now increasingly thought of as subject to influence by the population policy of governments. Thus through several decades countries such as Sweden and France attempted to encourage the birth rate through such devices as child welfare programs and family allowances. Other governments give tax exemptions for dependents as an indirect form of assistance to families who raise children. Conversely, some countries which deemed themselves overpopulated ventured to conduct broad programs for discouraging birth rates.

Policies are in process of formulation in all modern countries affecting other major aspects of family life — health, standard of living, legal obligation and personal development. These programs go considerably beyond mere remedial measures designed to correct cases of deviation from norms; they include definition of new norms as goals of concerted social effort, and thus constitute positive planning as distinguished from either therapy or philanthropy.

Since their outcome prior to trial is uncertain. programs of reconstruction often arouse anxiety. The security of a dynamic society, however, appears to rest more in becoming able to make reliable predictions of outcomes than in attempting to restore a state of affairs in which change would cease. 'The growth of population, invention, mobility, knowledge and diversity of outlook make it improbable that any *status quo* ante could be restored and maintained. Yet, among the many instabilities of contemporary life, people may turn hopefully to their homes for the security they miss outside. Some theorists go on from this observation to declare that only well-prepared families can successfully foster the kind of balanced and competent personality which in turn can weather the strains of urban, industrial existence. If their belief is correct, then public policy may become still further oriented to facilitating the optimal personality development of children and the mental health of families. Such an orientation of policy was the theme of the Midcentury White House Conference on Children and Youth, held in 1950. Similar trends in policy-making have been observed outside the U.S.

Influence of the Family on Individual Personality. — Psydhiatrists, contemplating the incidence of personality instability and breakdown, have turned intent scrutiny upon the family experiences of individuals from infancy onward. Until the post-World War II period, however, this scrutiny proceeded largely upon the assumption of some natural pattern of development. Distortions of this pattern, which could be diagnosed and dealt with remedially, were taken as the origins of maladjustment. Since then the view that personality development within the family is a continuous process of construction or fabrication of some complex identity as an expression of the family's values has gained renewed recognition. This perspective implies a heightened degree of responsibility of the family for the kind of child personality it turns out as its product.

In the English-speaking countries, particularly, this outlook gained wide acceptance and led to formation of child study groups, courses for prospective parents, media for dispensing expert knowledge, child development research and professional counselling. At their outset, these activities involved mothers almost exclusively, but a trend toward participation by fathers gradually developed. Self-conscious improvement of competence as parents by these means is related to a general social movement toward professionalization in industrial countries. In countries of high birth rates and low standards of living, however, the main aim in child rearing remains physical survival.

The popularity of existentialist philosophies in the years after World War II may be traced largely to the sense of personal isolation and loneliness which became common with the decline of family and neighbourhood solidarity. Psychoanalytic thought has likewise concentrated upon the effects of isolation and the processes of identification of children with their parents. Immense quantities of popular literature are devoted to the hazards and tragedies which befall the pursuit of romantic love in mobile, competitive settings. Much professional thought goes into attempts to intensify the sense of intimacy and trust in quasi-family groups. Whether this strenuous intellectual ferment a-ill produce a fresh synthesis or will eventually turn back toward restoration of classical family life will probably depend upon whether it can find new supports for individual identity.

The traditional family conferred upon each member an unquestioned sense of identity and even the illusion of being part of an immortal chain. It did this through associating him in a virtually permanent way with a definite physical place — an abode if not a piece of land, with a trade or enterprise which descended by inheritance and domestic instruction through successive generations and with a closely associated body of kin (as in the "place-work-people" formula of the early French sociologist. Pierre Guillaume Frédéric Le Play). So much was personal identity established by these three modes of placement in the social order that most surnames are derived from these sources. Only individuals of the most talented or heroic distinction ever achieved surnames based upon personal traits.

The small, modern family of industrial countries, however, has neither fixed place of abode, family transmission of occupation nor more than a tenuous connection with kindred. A steadily growing practice among persons in professional ranks may therefore be prophetic. The changing of names by individuals to foster or to distinguish their public careers is a phenomenon which could spread to other strata. Some women in business and the professions keep their maiden names after marriage — though their children continue to take the father's name, at least until they choose their own professional names. If the changing of names at adolescence or at entry into a professional career were to increase, and the chosen identity could be satisfactorily established. then it could be asserted that the identity-conferring function of the family had been transferred to the career as a social institution. This possibility accords with a tendency in sociological circles to redefine marriage as a mutually contingent pair of careers; in this light, the ancient division of labour between man and wife, which has everywhere given function and solidarity to the family, receives a new definition.

On the other hand, the immense increase of leisure in the industrial countries has worked a curious reversal upon the earlier separation of work from residence. Though many mothers hold jobs which absent them more and more from their families, the reduction of hours of work has made it possible for fathers to spend more time with their families than was formerly the case. The possibility of using this leisure in forms of recreation conducive to optimal personal development is being grasped and employed by increasing numbers of families and family agencies.

Utilization of the opportunities presented may suffice not only to correct the previously disproportionate influence of the mother in rearing children, but may accentuate optimal child development as a principal value and goal of family functioning. As parenthood has become more voluntary, children are coming to be wanted more consciously as expressions of the creative and affection-giving potentialities of their parents. This trend may help to account for the decline of such institutions as orphanages. Among industrial countries the demand for children for adoption outruns the supply of children made available by illegitimacy, desertion or death of the parents. Demand has significantly become greatest for infants, rather than for children of working age, as used to be true for children taken from orphanages. Some observers professed to see the emergence of a child-centred family and ultimately of a child-centred society.

Future. — Despite the hazards imposed by mobility and migration, the breakup of traditional supports and controls. the perils in readjusting authority and dependency roles, the greater ease of divorce and remarriage, there are probably as many grounds for hope as for anxiety regarding the future of the family. No doubt the outlines of the conjugal form will persist indefinitely, but the family is likely to be conceived increasingly as constituted by interpersonal values, to which concrete forms function instrumentally. Family policy for the future. both public and private, may thus come to crystallize around a dynamic conception of personality development, dramatized by identities self-chosen at adolescence. As ever, the principal function of the family will remain the rearing of children, but for their own sake. Assuming an increasing sense of competence through scientific research and experiment, the people of industrial countries may view the developing drama of family life with mounting enjoyment rather than anxiety or dread.

FAMINE. The story of famine goes far back in history. The Bible relates how a young Jewish administrator named Joseph advised the Pharaohs on famine relief measures in ancient Egypt. Thereafter a long list of famines links up with famines of the 20th century.

B.C. 436	Famine at Rome, when thousands of starving people threw themselves into the Tiber.
A.D. 42	Great famine in Egypt.
879	Universal famine.
1005	Famine in England.
1016	Famine throughout Europe.
1064–72	Seven years' famine in Egypt.
1148–59	Eleven years' famine in India.
1162	Universal famine.
1344–45	Great famine in India, when the Mogul emperor was unable to obtain the necessities for his household.
1396–1407	The Durga Devi famine in India, lasting 12 years.
1586	Famine in England giving rise to Poor Law system.
1661	Famine in India. No rain fell for two years.
1769–70	Great famine in Bengal; a third of the population (10,000,000 persons) perished.
1783	The Chalisa famine in India extending from eastern edge of the Benares province to Lahore and Jammu.
1790–92	The Doji Bara, or skull famine, in India, so called because the dead were too numerous to be buried. Relief works first opened during this famine in Madras.
1838	Intense famine in North-Western Provinces (Uttar Pradesh), India; 800,000 perished.
1846–47	Famine in Ireland, resulting from the failure of the potato crop. Parliamentary grants up to £10,000,000.
1861	Famine in northwest India.
1866	Famine in Bengal and Orissa; 1,000,000 perished.
1869	Intense famine in Rajputana; 1,500,000 perished.
1874	Famine in Behar, India. Government relief in excess of the needs of the people.
1876–78	Famine in Bombay, Madras and Mysore; 5,000,000 perished. Relief insufficient.
1877–78	Famine in north China; 9,500,000 said to have perished.
1887–89	Famine in China.
1891–92	Famine in Russia.
1897	Famine in India. Government policy successful. Mansion house fund £550,000.
1899–1901	Famine in India; 1,000,000 perished. The government spent £10,000,000 on relief, and at one time there were 4,500,000 people on the relief works.
1905	Famine in Russia.
1916	Famine in China.
1921	Famine in Russia.
1932–33	Famine in Russia.
1943	Famine in Bengal; about 1,500,000 perished.

In the decade 1940–50, there was famine in the ghettos of Warsaw, in prison camps in central Europe, in the Setherlands. Greece and in besieged Leningrad. A major famine occurred in Bengal. In the far east, many in the Japanese prison camps lived under famine conditions and also some of the peoples of the Netherlands East Indies during the Japanese occupation. Only a blind optimist can think this tale complete. Half the population of the world consists of peasants struggling to produce food against the uncertainties of primitive agriculture. In the industrial cities, the social and economic factors that poise the delicate balance between the outflow of manufactured goods and services to the countryside in return for a supply of food are uncertain and readily upset. Then hunger and perhaps famine must follow.

Causes of Famine.—The primary causes of famine are four:

1. *Widespread* Failure of Crops Because of Lack of *Water.*—Vast numbers of people in tropical and subtropical countries have died in famines arising from drought. Irrigation schemes have enabled man to preserve and, in a relatively small way, to control the rain after it has fallen. Millions of acres of land are now partially independent of direct rainfalls. Yet there were no signs at mid-20th century that science would soon be able to insure a regular rainfall over all the cultivated areas of the world, and so danger of famine from this cause will continue to arise.

2. War and Civil Disturbance.—Europe, North America and most other temperate regions enjoy such a regular rainfall that natural famines caused by catastrophic failures of the crops from lack of water are rare. European famines have been characteristically man-made. War is a potent cause. Armies fighting over a countryside may cause famine by destruction and, more especially, by requisition or looting of crops. In this way, many famines arose, especially in the religious wars of the 16th and 17th centuries. In the 20th century, fighting in Europe has seldom been so widespread or prolonged as to cause major destruction of the crops except in relatively local areas, nor did the armies. in the west at least. generally live off the land.

Famine conditions have arisen in the great industrial cities more frequently than in the countrysides. The disruption of large transport systems and of the economic structure of society necessary for the feeding of urban populations has in many cases led to famine (*e.g.*, in Vienna in 1919). Finally, in some cases famine conditions have been deliberately produced for the purpose of exterminating large masses of people. This happened in the ghettos of Warsaw in 1942 and in the nazi concentration camps.

3. Destruction of Crops by Diseases and Pests.—The great Irish famine of the 19th century was caused by the destruction of the potato crops by the blight, a fungus infection. In these famines 2,000,000 to 3,000,000 persons died, and large numbers emigrated. Wherever one single crop dominates agriculture there is always a risk that the crop may perish from a plant disease. In those large areas of the world subject to plagues of locusts, safety from famine can only be purchased by constant vigilance.

4. Great *Natural Disturbances.*—Earthquakes and floods are a constant threat in many parts of the world. Great destruction of crops, food stores and communications may result.

Famine Relief.—A sound agriculture with the best possible use of available water supplies is the best provision against famines in the tropics. Political and economic stability will usually prevent famine in temperate regions. A reasonable agricultural surplus to carry over from the last harvest is essential. This necessitates adequate storage accommodation.

Successive Indian governments acquired much experience in the handling of famines. Nearly all famines are relatively local and the main problem is the bringing of food from neighbouring areas. Transport is a key to the problem. The building of the Indian railways in the middle of the 19th century thus led indirectly to a great saving of life. A principle of British famine administration in India was that gratuitous relief should not be given. If money could be got into the famine area, then food would follow automatically through the normal trade channels. The organization of large emergency public works was the means adopted to overcome the shortage of money. Elaborate plans were drawn up in all areas where famine was possible and works opened as soon as signs of scarcity arose. There are criticisms in detail of this method (for instance manual labour increases food requirements), but on the whole the measures prevented major disasters.

Almost every year famine conditions arise in India, but only rarely do people die of starvation. In Bengal in 1943 at least

1,500,000 people died when relief measures were not introduced until several weeks after famine had begun. Adequate information about the scarcity in the villages was not available in Calcutta until too late.

The United Nations Relief and Rehabilitation administration (USRRX) took effective relief measures against famine in Europe following World War II. As early as Nov. 1943, representatives of 44 nations met in Washington. D.C., at the invitation of Pres. Franklin D. Roosevelt. The countries that had not been invaded agreed to contribute 2% of their income to the resources of the administration. UNRRA poured vital supplies into Albania, Austria, Byelorussia, China, Czechoslovakia, Ethiopia, Greece. Italy, Poland, the Ukraine and Yugoslavia. Limited aid was also given to six other countries. Goods included locomotives, trucks and freight cars for the transport of food to centres of population, farm animals, tractors and plows and seed grains necessary for the restarting of agriculture, besides fully equipped hospitals and medical supplies. The most vital and immediate part of UNRRA's work was, however, the provision of food of every kind. The result was that at least three famines that might have involved 15,000,000 people in Europe were prevented; misery, hardship and underfeeding among many more millions were alleviated. The general assembly of the UN has given the Food and Agriculture organization the responsibility of keeping watch on threatening famine and reporting without delay.

Effects of Famine. — If a group of persons are forced to live on a limited diet yielding only about 1,600 calories daily (equivalent to about one pound of cereals), at first they will lose weight rapidly. After a few meeks this process will slow down and after two to three months. when about 25% of their initial weight has been lost. they will be in equilibrium again and may continue to exist for many months on such a diet Provided medical and good sanitary services are available. the death rate should be little above normal. If the calorie content of the diet is lowered still further, neight losses will increase rapidly, deaths from starvation will soon occur and become increasingly numerous. For women, children and persons of small build, slightly lower food intakes could be tolerated If hard labour is forced upon the group, then deterioration will be more rapid and equilibrium cannot be reached. Some persons resist famine better than others. But deaths become frequent in any group in which, on an average, the weight has fallen more than 25% of the weight in health. The body is able to make remarkable adjustments to conserve energy. The reduction in weight reduces the active tissues. nhich use energy, and there is also a decreased rate of utilization of energy (metabolism) in the tissues which remain. There is in addition a great economy of movement. A marked lethargy prevents any unnecessary muscular effort. Psychologically the mind is dominated by a desire for food. Other emotions are dulled and there is a mental apathy, but the intellect can function normally if necessary. Moral standards fall and this may be aggravated by social circumstances. Murder and cannibalism have frequently been reported in famines.

Dropsy is often found in famine victims and in severe starvation there is a constant and very distressing diarrhea which is often the immediate cause of death. The pulse rate is slowed, the blood pressure falls and the heart is atrophied. This atrophy may be irreversible and resist all rehabilitation. Vitamin deficiencies are not common in simple starvation. Anemia is usual, but seldom severe. Amenorrhea usually soon sets in, and in both sexes the libido is markedly reduced. (See EDEMA.)

Epidemics of infectious diseases such as cholera, malaria, louse-born typhus, influenza and tuberculosis add greatly to the death toll in famines.

A very important aspect of famine in a peasant community has been the disruption of family and village life. Whole villages may migrate and wander in search of food. Children may be separated forever from their parents, hordes of such children may roam the countryside capable of any crime in their search for food.

FAN, in its usually restricted sense denotes a light instrument held in the hand and used for raising a current of air to cool the face. Among the ancients the fan was also known as a winnower, as a bellows for fire and as a fly whisk. Modern usage also applies the word to an instrument for winnowing grain (winnowing fan) and to various appliances in systems of ventilation. (See FAN [MECHANICAL].)

In the more familiar sense the forms of the fan may be divided into two main groups — the screen fan and the folding fan. In general the former consists of a handle to which is attached a rigid mount; except feather fans, which may be included in this class, the usual mount is made of straw, cane, silk, parchment, etc., and is square, circular, pear or leaf-shaped. In some cases the mount is placed at one side, producing a flaglike form, such as the Venetian type of the 16th century, which was also known to the Copts of the early Christian era. The so-called cockade fan, which, as its name implies, has a circular pleated mount that may be folded flat, also belongs to this group. Types of the screen fan are to be found throughout the world in all periods, among both primitive and highly civilized peoples. The folding fan, although the better-known form, has a more circumscribed history. It is said to have been invented in Japan about A.D. 670. It was introduced into China in the 10th century and thence into Europe in the late 15th or early 16th century, probably at the time when the Portuguese under Vasco da Gama established themselves as the supreme trading power in the East. The folding fan is composed of sticks and a mount. The sticks are a number of blades, the one at each end being a guard; they may be ivory, mother-of-pearl or various woods, pierced, carved and often ornamented with inlay and gilding; all are fastened at the handle end by a pin or rivet. The mount (or leaf), is pleated and stretched over the blades at the top, it may be made of paper, parchment, silk, lace and "chicken-skin" (an especially prepared kidskin) or other materials, and is usually decorated with painting. A variant of the folding fan, popular in France in the 18th century, is the cabriolet, which will be described later. The distinguishing feature of the *brisé* fan is that it has no mount but is composed of a number of blades fastened at the handle end by a rivet and radiating toward the top where they are connected by a ribbon; the delicately carved ivory fans of China are exquisite examples of this type.

China. — The fan of the Far East is the most ancient known to us and is a separate chapter in the history of the instrument. Some authorities testify that in China fans have been known since about 3000 B.C. The earliest form was of dyed pheasant or peacock feathers mounted on a handle. Cockade fans and large ceremonial screens are also of ancient origin while the small handscreens of various shapes, made of palm, bamboo and silk stretched on a frame, have been in use from ancient to modern times. Ivory fans seem to have come into being shortly after the folding fan was introduced into China. The Imperial ivory works within the palace at Pekin were founded in the 17th century and became the centre of the best productions. The delicacy of carving in ivory *brisé* fans can hardly be overestimated. Sometimes the decoration is made up of pierced, flat, open work, sometimes of elaborately carved figure or floral subjects with a background formed by ribbing of exquisite quality. Tortoise-shell was used in a similar way, also sandalwood and mother-of-pearl. Filigree fans of silver or silver gilt frequently inlaid with enamel form another variation. A class of Chinese folding fan often seen is the mandarin fan with sticks of carved ivory and the leaf painted with

FANS OF THE 18TH CENTURL

1. Cabriolet fan, with three strips of painted skin, sticks and guards of painted ivory. This type of folding fan was in vogue about 1755 when the cabriolet, a light two-wheeled carriage, which is often represented in the scenes or engraved on the fan leaves, became popular in France
2. Mask fan, popular in Spain during the second quarter of the 18th century. The leaf is of paper
3. Fan of painted skin with ivory sticks and guards, used in France during the third quarter of the 18th century
4. Vernis-Martin fan. This variety is one of the rarest and most sought after by collectors. Ine name is derived from tne transrucent varnisn accidentally discovered by the brothers Martin, French coach painters, while they were attempting to imitate Japanese lacquer. The painting on the fan reproduced is attributed to Boucher
5. Elaborate French fan of the 18th century. On the parchment leaf are painted the figures of Louis XVI., Marie Antoinette, the princess royal and the dauphin. This fan, a product of the period when the most extravagant and luxurlous ornament was in vogue, has sticks and guerds made of carved and gilded mother-of-pearl

FANS OF THE SIXTEENTH, EIGHTEENTH AND NINETEENTH CENTURIES

1. Itaiian fan, early 19th century. Leaf of skin painted in ***gouache*** with view of the Colosseum; sticks and guards of pierced mother-of-pearl. 2. Ivory brisé fan with painted medallion in style of Cosway. English, late 18th century. 3. Fan with mount of painted skin, sticks and guards of carved and painted ivory. English, middle of the 18th century. 4. French fan, mount of Argentan lace, sticks and guards of carved ivory. Third quarter of the 18th century. 5. Carved ivory brisé fan. Chinese, 18th century. 6. Late 16th century Itaiian fan with mount of parchment cut out in a geometric design. The sticks are of ivory

innumerable minute figures with ivory heads and silk costumes applied. Almost every city or district in China has its characteristic fan distinguishable by its colour and ornament and made to suit every class from mandarin to peasant.

Japan. — In Japan also the use of the fan is very closely linked with the life and customs of the people. In Rhead's *History of the Fan* the author says that it is regarded as an emblem of life, widening and expanding as the sticks radiate from the rivet. It plays a part in almost every aspect of their existence: it is presented to the youth on the attainment of his majority; it is used by jugglers in feats of skill; the condemned man marches to the scaffold fan in hand. The earliest examples were made of palm leaves or feathers while the rigid screen fans were introduced from China in the 6th century A.D. Large screens were used tor religious and civil ceremonial and as war standards. Most interesting of all the rigid fans is the Gumbai Uchuia, a type of battle fan of iron first kno n in the 11th century. It is, however, the folding fan, invented by the Japanese in the 7th century, that has played such an important role in their history and art. There are innumerable variations of its form each designed for a particular use and possessing individual characteristics. The Akomé Ogi is the earliest form of court fan having come into use in the 7th century; it is composed of 38 blades fastened with a rivet. formed of a bird or butterfly, and ornamented at the corners with artificial flowers and 12 long streamers of coloured silks; it was the type used by court ladies until 1868. The Gun Sen is the folding battle fan with sticks of wrought iron and the mount of thick paper painted with the sun, moon or star in red or gold on a black or coloured ground; its initial purpose in battle was as a signal. The Mai-Ogi or dancing fan dates from the 17th century; it has 10 sticks and a mount of thick paper usually decorated with a family crest. The Rikin-Ogi or tea fan, used in tea ceremonies celebrated in each province on the first day of every month, has only three sticks and the paper mount is simply decorated, the fan itself being used for handing around little cakes, fanning being prohibited during this dignified ceremony. Many early fans were designed with the infinite artistry of the great painters of Japan but these are rarely seen to-day. Those most often found in collections are the modern brisd of ivory or tortoise-shell decorated with lacquer and inlay and often made for exportation to Europe. *(See* DRESS: *Far Eastern.)*

Ancient. — In the cultures of ancient Egypt, Assyria and India, the fan achieved considerable importance both as a civil and religious emblem. Especially in Egypt fans played an important part in royal ceremony; the office of fan-bearer to the king was a highly prized honour; their fans, made of feathers arranged in a half-circle and mounted on long handles, may be seen in Egyptian wall paintings and reliefs. Two actual examples now in the museum at Cairo, were found in the tomb of Tut-ankh-amen (14th century B.C.); the gold mounts with embossed and incised decorations were fitted with brown and white ostrich plumes and the handles were made in one case of gold and in the other of ebony overlaid with gold and lapis-lazuli In India both the fan and umbrella were held in reverence; the punkah or large screen fans are still hung in rooms and manipulated by servants detailed for the purpose. In Greece peacock feather hand fans were known about 500 B C. and may be seen in contemporary vase paintings while the rigid palm leaf shaped fan is frequently depicted in the terracotta figurines from Tanagra. As for ancient Italy, an Etruscan cinerary urn in the hfetropolitan hfuseum of Art shows the deceased in the customary reclining posture holding in her hand a feather fan; and in Rome tablet fans of precious woods or finely cut ivory were carried by the exquisites on the Via Sacra for their ladies, while another type was always part of the bridal outfit of a Roman woman.

Mediaeval. — In the Middle Ages the Christian Church perceived the usefulness of the fan in religious ceremonials The *flabellum*, as it was called, a disc sometimes of silver or silver gilt mounted on a long handle, was held by deacons and used to drive away flies and insects from the sacramental vessels. Accounts of the *flabellum* occur repeatedly in the old inventories of church and abbey property but except for two, whose use was probably secular. no fans of the period exist to-day. With the exception of the large feather fan carried in state processions for the pope, the fan is no longer used in the Western Church, but it still appears in the rites of the Eastern Church. The two famous specimens mentioned above, of the mediaeval period, are of the cockade type with mount of vellum and handle of carved bone. One of these dating from the 11th century from the abbey church of Tournus is now in the National museum at Florence while the other, said to be the oldest existing Christian fan and identified with Theodolinda, queen of the Lombards, is now preserved as a sacred relic in the cathedral of Monza near hfilan, where superstition has invested it with magic powers.

Modern European. — The vogue of the folding fan in Europe dates from its introduction through Portuguese trade connections with India and the Far East in the 16th century. Although it may have been known earlier, the impetus supplied by oriental importations produced a new era in its evolution. In popularity it soon supplanted the feather fan mounted on a carved ivory handle and the Venetian flag-like instrument. The type of folding fan found in late 16th century portraits is about a quarter circle in shape with sticks of ivory and a mount composed of alternate strips of vellum and mica, or of vellum cut out in a geometrical pattern of circles and lozenges similar to the designs of reticello lace of the period. Of this kind, called *découpé* from the perforated vellum mount, there is a beautiful example in the Cluny museum and one almost identical in a private collection in New York. It was at this time that the vogue for fans, already general in Italy and Spain, spread to France and England. Although not then confined to the use of ladies, special conventions were developed and gestures in handling them grew into code signals of amorous import.

In the 17th century Paris became the centre for the manufacture of fans. Louis XIV. issued edicts at various times for the regulation of the industry and in 1678 the Fanmakers' Guild was formed. The revocation of the Edict of Nantes (1685) drove many fanmakers to England and Holland. In consequence a fan trade was established in England where, after the formation of the Fanmakers' Company (1709), the importation of foreign fans, especially from India and China, was for a time prohibited. During this period the shape of the fan gradually grew to a full semi-circle with sticks of ivory or mother-of-pearl pierced or carved. The mounts of paper, vellum, parchment and specially prepared kidskin were painted or engraved, often from designs of such artists as Lebrun, Romanelli, Abraham Bosse and Callot.

It was, however, in the 18th century that the most extravagant and luxurious ornament was expended upon the decoration of the fan. The delicately carved sticks of ivory and mother-of-pearl, sometimes the product of Chinese workmen in Europe, were further enriched with incrustations of gold, silver, enamel and jewels. The mounts were made not only of skin but of silk, lace and paper perforated in imitation of lace, while the suave and gracious designs with which they were painted followed the fashion set by the chief artists and decorators of the day. As it was an age of considerable decorative invention, it is not surprising that new forms of the folding fan should appear. One of the rarest and most sought after by collectors is the so-called Vernis Martin. In form this type of fan is an ivory *brisé*, the blades of which are painted in thin oils and then varnished. It is from the particular translucent varnish that the name is derived, for in attempting to imitate Japanese lacquer, the brothers Martin, coach painters by trade, accidentally developed a method suitable for this decoration. Vernis Martin fans are smaller in size than the usual type of the period and because of their interest to collectors many imitations have been made. About the middle of the reign of Louis XV. another type of folding fan, the cabriolet, became the vogue. This was a reflection of the immense popularity achieved by a light two-wheeled carriage introduced to Paris by Josiah Child in 1755. For such fans, the mount instead of being one broad strip, was composed of two or sometimes three narrow strips with an intervening space between them. The strips were then painted or engraved with small scenes which usually included representations of people driving about in the fantastically popular carriage itself.

Toward the end of the reign of Louis XV. the fan industry suffered from a vogue for cheap printed fans. The sticks were thin and often undecorated, the printed paper mounts frequently depicted incidents and personages connected with contemporary political events. Some of the most interesting of these fans commemorate the balloon ascensions of 1784 and 1785 and the meeting of the Estates General in 1789. Other more pretentious fans of the period were much ornamented with spangles and tinsel, often with cheap effect. In England at this time there developed a particular type of ivory *brisé* fan—the ivory pierced and decorated with medallions painted in miniature in the style of Cosway or Angelica Kaufman.

During the period of the First Empire fans retrieved very little of their past elegance. They were small, delicate instruments often with mounts of spangled gauze and sticks of pierced ivory. The lorgnette fan, a variant of the cockade form, was made of pierced horn or ivory and had a little glass inserted at the rivet. As the century advanced the romantic and antiquarian tastes of the Victorian era were reflected in the style and decoration of fans There was much lifeless imitation of the Louis XV. types, and there were many large fans with mounts of lace or, frequently, paper with coloured lithographic prints of romantic scenes. The sticks of mother-of-pearl were pierced and gilded and, except in rare cases, were coarse in both design and execution. The invention of Alphonse Baude in 1859 for carving sticks by machinery reveals the lack of taste and discriminating quality of the time, for no mechanical contrivance can duplicate the verve of hand-carving. Somewhat later, however, certain fan-makers attempted to revive the old distinction of design and workmanship. Exhibitions were held in Paris and at South Kensington (1870) and painters of repute made designs for fan mounts, among whom may be cited Gavarni, Diaz, Couture, Solde, Jacquemart and Charles Conder (1868–1909).

FAN (MECHANICAL), a device for moving air or other gases or vapours. (For the light hand instrument, *see* FAN.) Mechanical fans are used in systems for ventilating, heating and air conditioning buildings; for cooling and drying different materials and products; for cooling internal-combustion engines; for dust exhaust; for conveying light materials; and for induced and forced draft for steam boilers. In a fan the change in fluid density is so small that the gas is regarded as incompressible. A fan develops a relatively low pressure difference, of the order of a few inches of water to less than one pound per square inch. As a contrast, in an air or gas compressor the density change is appreciable; the pressure developed by the compressor is measured in pounds per square inch instead of inches of water.

Sometimes various qualifying terms are applied to a fan. In a so-called exhaust fan, piping may be connected only to the inlet of the fan, and the fan discharges directly into the atmosphere. In a blower fan, piping may be connected only to the outlet of the fan, and the fan inlet is open directly to the atmosphere. A desk fan is a relatively small portable unit used to circulate air within the room in which it operates; fans also may be fixed to a wall or a ceiling to circulate air in a room.

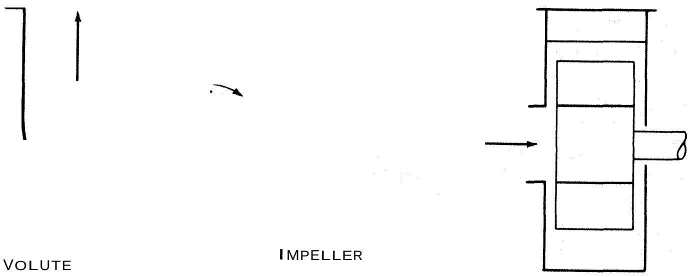

FIG. 1.—SCHEMATIC DIAGRAMS OF CENTRIFUGAL FAN (*see* TEXT FOR FURTHER EXPLANATION)

Fans are frequently classified according to the motion of the fluid through the rotating member; this rotating member may be called an impeller, rotor or a runner. Fig. 1 illustrates a centrifugal fan. Air is led through the inlet pipe to the centre or eye of the impeller. The impeller throws the fluid into the volute or spiral casing or scroll, where it is led to the discharge piping. If the flow through the impeller is primarily in a radial direction, the impeller could be classed as a radial-flow runner.

Fig. 2 illustrates an axial-flow fan, with the runner and guide vanes in a cylindrical casing or housing. The air passes through the runner essentially without changing its distance from the axis of rotation. In a centrifugal fan, air moves from one inner radius to another outer radius; there is a centrifugal force effect which increases the air pressure. In an axial-flow fan, however, this centrifugal force effect is not present. In a mixed-flow runner, the air flows through the runner partly in an axial direction and partly in a radial direction. Fig. 2 shows an axial-flow fan with fixed inlet guide vanes and fixed exit guide vanes; these vanes are sometimes called stator vanes. Guide vanes serve to modify performance and improve efficiency. The phrase "vane-axial" is sometimes used to designate a fan with a runner and a set of inlet or exit guide vanes in a cylindrical casing; the term "tube-axial." to designate a fan which has only a runner in a cylindrical casing and no guide vanes. A propeller type of fan is one with a propeller or disk within a mounting plate or ring.

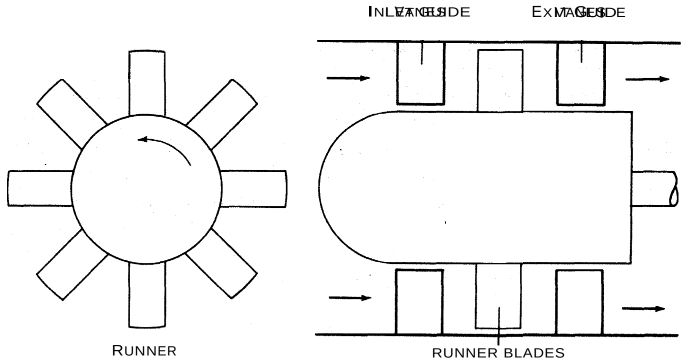

FIG. 2.—SCHEMATIC DIAGRAMS OF AN AXIAL-FLOW FAN

The fan housing or casing may be constructed of sheet metal or cast metals with or without protective coatings, as rubber, lead or enamel. Fan wheels may be constructed of sheet metal or cast metals. The sheet metal may be steel or an aluminum alloy. In centrifugal fans the number of blades may range from 5 to 66; in axial-flow fans, from 3 to 26. A fan runner may be driven by a high-speed electric motor, an internal-combustion engine, a steam turbine or a gas turbine. Belt drives and direct connections between driver and fan wheel are used.

Various factors or parameters are used in correlating data on performance and design. One useful factor is the specific speed N_s which is defined as

$$N_s = \frac{N\sqrt{C.F.M.}}{H^{\frac{3}{4}}}$$

where N is the angular speed of the runner in revolutions per minute, C.F.M. is the flow through the fan in cubic feet per minute and H is the fan head in feet of the fluid flowing. For narrow straight-blade centrifugal fans, N_s varies from about 140 to goo; for curved-blade centrifugal fans, from about 1,000 to 3,000; and for axial-flow fans, from about 4.000 to 8,000. Generally speaking, an axial-flow fan is suitable for a relatively large rate of flow with a relatively small pressure boost and a centrifugal fan for a small rate of flow and a large pressure boost. In some cases it is desired to obtain a relatively high pressure boost with a relatively large capacity. Two or more axial-flow fans can be staged. When staged, several fans are essentially connected in series, so that the same capacity goes through each fan, but each fan adds to the pressure boost.

The capacities of fans may range from 100 to 500,000 cu.ft. per minute. That of small kitchen fans may range from 300 to 800 and the capacities of attic window fans from 3.000 to 8,000. Exhaust fans for use in a central system may have capacities ranging from 2.000 to 100,000.

In selecting a fan it is frequently necessary to consider performance characteristics. It is customary to test a fan at constant speed of the runner. Measurements are made of the head or pressure rise across the runner, the capacity or volume rate of flow through the fan and the power input to the runner. Fig. 3 illustrates a plot of head versus capacity and a plot of power versus capacity. The head characteristic is important in matching a fan to a system, in order to maintain the proper flow through the system. The power characteristic is important in deciding the size of the motor or engine needed to drive the fan. Different fans have different performance characteristics. By examining the performance characteristics one can match a fan to a particular system over a range of flow rates.

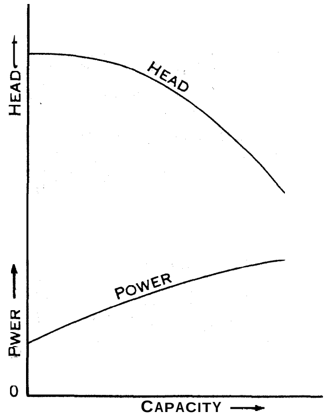

FIG. 3.—PERFORMANCE CHARACTERISTICS OF A FAN AT CONSTANT RUNNER SPEED

As an example, consider a centrifugal fan with blade tips which are forward-curved, that is, the blade tips are curved in the direction of rotation. In general, such a fan has a head characteristic which is flat; it does not change much with change in capacity. In some applications a flat characteristic is desirable. On the other hand! a backward-curved blade tip has a steep head versus capacity curve: that is, there is a marked change in head with capacity. Some cases require a steep characteristic. A radial-blade centrifugal fan (illustrated in fig. 1) has a head characteristic between that of the forward-curved fan and the backward-curved fan. The forward-curved fan is slower, and the backward-curved fan is faster than the radial-blade fan in developing the same pressure boost and capacity.

The efficiency of a fan is the ratio of the useful power added to the fluid divided by the power input to the runner shaft. The nominal or design rating of a fan at a certain speed is the head and capacity at the point of maximum efficiency. Consider a fan operating at different speeds, but with essentially the same efficiency. Certain approximate relations are used for estimating performance. These relations are: the capacity varies directly as the runner speed N; and the pressure boost across the fan varies directly as N^2. Consider a series of geometrically similar fans of different sizes but having similar flow patterns and operating at the same shaft speed and same efficiency. Let D represent the outside diameter of the runner. Some useful approximate relations are: the ian head varies directly as D^2; and the capacity varies directly as D^3. The flow is steady, or practically so, in many installations of a fan and connected system. In some cases, however, there is a marked periodic fluctuation superposed on the main steady flow; this fluctuation is usually called surging. Surging may become dangerous and may limit the useful range of operation of a fan. Surging occurs at low-volume rates of flow, when operation is in a region in which the fan characteristic shows an increase in head or pressure with an increase in capacity. Surging does not occur when the fan characteristic shows a decrease in pressure with an increase in capacity. Surging can be avoided sometimes by bypassing some of the flow from the fan before it enters a particular system in which a lower rate of flow is desired.

Fan noise is an important factor in various applications. A fan may be mechanically efficient but not suitable if it is considered noisy. Noise is a particularly important factor in domestic applications. Fan noise may be reduced by proper blade design. operating conditions, proper balancing and mounting. Fans can be installed in ducts so arranged that the noise is absorbed before it leaves the duct. In general, noise from an air stream is proportional to some mathematical power of the air velocity. Reducing the air velocity reduces the noise. Generally speaking, the lowest fan noise is developed at the point of highest efficiency.

FANCY, display, showing forth, as a philosophical term, the representative power of the mind. "Fancy" is a shortened form of the older "phantasy" and dates from the 15th century. The older form "fantasy," which is now chiefly used poetically, was in its early application synonymous with imagination.

In music, Fancy is the name of an important kind of instrumental composition much favoured in England in the seventeenth century. It had no definite form, its interest depending on the free development, on polyphonic lines, of a single "ayre" or theme. Byrd and Orlando Gibbons, among others, left fine examples. In recent times the name was revived by Mr. W. W. Cobbett to denote a new type of short single-movement chamber work, to encourage the writing of which he offered substantial prizes.

FANE, JULIAN HENRY CHARLES (1827–1870), British diplomat, was born at Florence, Italy, in Oct. 1827, the fifth son of the 11th earl of Westmorland. He was a member of the Apostles club at Trinity college, Cambridge; he had already been attached to his father's legation at Berlin. In 1852 he published some lyric *Poems,* and in 1854 some translations from Heinrich Heine. His lively wit, vigorous pen and quite exceptional charm made him an ideal recruit to the diplomatic service, in which he spent a career as brilliant as it was brief. He was at the Paris congress in 1856, and served two years in St. Petersburg and seven at Vienna. In 186j he became first secretary at Paris, sometimes acting, with skill and judgment, as chargé d'affaires. He retired in June 1868 because of ill health. Fane had married Lady Adine Cowper (b. 1843j in 1866, and was prostrated by her death in Oct. 1868. He died in London on April 19, 1870. (M. R. D. F.)

FANFARE, in music: a short phrase or passage of a bold and rousing character played unaccompanied by a brass instrument or instruments, usually the trumpet, more especially on festive or ceremonial occasions.

FANG, an African tribe occupying the district north of the Ogooué river in the Gabon Republic. The name means "men." They call themselves *Paⁿwe, Faⁿwe* and *Faⁿ* with highly nasalized *n*. They are a finely made race of chocolate colour; some few are very dark, but these are of slave origin. They have bright expressive oval faces with prominent cheekbones. Many of them file their teeth to points. Their hair, which is woolly, is worn by the women long, reaching below the nape of the neck. The men wear it in a variety of shapes, often building it up over a wooden base. The growth of the hair appears abundant, but that on the face is usually removed. Little clothing is worn; the men wear a bark waistcloth, the women a plantain girdle, sometimes with a bustle of dried grass. A chief wears a leopard's skin around the shoulders. Both sexes tattoo and paint the body, and delight in ornaments of every kind. The men fight and hunt, carry muskets, spears for throwing and stabbing and throwing knives with blades broader than they are long. They use crossbows made of ebony to hunt apes and birds. In battle the Fang used elephant hide shields; now apparently discarded.

In 1815 the Fang were an inland people inhabiting the hilly plateaus north of the Ogooué affluents, now south of the Gabon they have reached the sea at several points. Their language is of the Bantu family. The Fang were noted cannibals. Among certain tribes the aged alone were permitted to eat human flesh, which was tabu for all others. The Fang are skilful workers in iron and have a curious coinage called *bikĕi,* little iron imitation axeheads tied up in bundles called *ntet,* ten to a bundle; these are used chiefly in the purchase of wives. They are energetic traders and are skilled in pottery and in gardening. Their religion appears to be a combination of primitive animism and ancestor worship, with a belief in sympathetic magic.

Burton, "A Day With the Fans," *Transactions of Ethnological Society*, new series, vol. 3–4; Mary Kingsley, *Travels in West Africa* (1897); Oscar Lenz, *Skizzen aus West Africa* (1878); R E. Dennett, *Notes on the Folklore of the Fjort* (1898); William Winwood Reade, *The African Sketch Book* (1873); and (chiefly) A. L. Bennett, "Ethnographical Notes on the Fang," *Journ. Anthr. Inst.*, N.S., ii, p. 66, and L. Martron in *Anthropos*, t. i, fasc. 4 (1906).

FANGLOMERATE is a poorly sorted, coarse fragmental rock that is the product of the partial or complete consolidation of material deposited on an alluvial fan, usually in an arid or semi-arid region. The biggest fragments in the rock must be larger than sand size; they may be blocks many feet in diameter. Few of the larger fragments are well rounded as they are in a conglomerate (*q.v.*), and so the rock may be considered one variety of breccia (*q.v.*). The rock fragments are commonly of considerable variety. They reflect more or less faithfully the range of rock types represented in the region of erosion. The interstices between the larger fragments are filled with smaller ones, down to sand, silt or even clay size. The cementing material is usually clay or calcium carbonate.

Fanglomerates form near the heads (apices) of alluvial fans and grade downslope into sandstone or siltstone. The recognition of a fanglomerate, after the characteristic shape of the fan's surface has been obscured by overlying sediments, partial erosion or deformation, is facilitated by the discovery of lateral gradation into sandstone and then siltstone. Rocks called fanglomerates have been found in many parts of the world and in most parts of the geologic column, but especially in the Mesozoic and Cenozoic successions of western North America. (A. O. W.; X.)

FANO, a coast town and episcopal see of the Marches, It. (anc. Fanum Fortunae), province of Pesaro and Urbino, 8 mi. S.E. of Pesaro by rail and 46 ft. above sea level. Pop. (1951), 20,459. S. Croce and S. Maria Nuova contain pictures by Giovanni Santi, the father of Raphael. S. Agostino contains a painting of the Angelo Custode ("the Guardian Angel") by Guercino which is the subject of a poem by Robert Browning. The fine Gothic Palazzo della Ragione (1299) has been converted into a theatre. The palace of the Malatesta has fine porticos and Gothic windows, and there is also an imposing citadel built by them. S. Michele, built against the arch of Augustus, is an early Renaissance building (1475–90), probably by Matteo Nuzio of Fano, with an ornate portal.

Mediaeval Fano had a chequered story and in the 14th century became subject to the Malatesta. In 1463 Pius II added it to the states of the church. Julius II established there in 1514 the first printing press with movable Arabic type. The harbour was restored by Paul V; Fano is a favourite sea-bathing resort.

FANSHAWE, SIR RICHARD, BART. (1608–1666), English poet, translator and diplomat whose version of Cambes' *Lusiad* is a major achievement of English verse translation, was born at Ware Park, Hertfordshire, in June 1608. Educated at Jesus college, Cambridge, in 1635, he was appointed secretary to the English embassy at Madrid. At the outbreak of the Great Rebellion he joined the king. In 1644 he married Anne Harrison, whose *Memoirs* contain an admirable account of her husband's career. In 1648 he became treasurer to the navy, and in 1650 was dispatched by Charles II to obtain help from Spain. Although this was refused, Fanshawe was created a baronet; he rejoined Charles in Scotland and was taken prisoner at the battle of Worcester. On Cromwell's death he re-entered the king's service in Paris, and after the Restoration was appointed ambassador to Portugal and later to Spain. He died at Madrid on June 26, 1666.

Fanshawe published a translation of *Il Pastor Fido* by Baptista Guarini in 1647. A second edition "with divers other poems" (1648) included his version of the fourth book of Vergil's *Aeneid*. His *Selected Parts of Horace* appeared in 1652. The great work of his retirement during the Protectorate was his translation of the *Lusiad* of Cambes (1655). His other works include a version of a comedy by Antonio de Mendoza (1654) and a Latin translation of John Fletcher's *Faithful Shepherdess* (1658). Fanshawe's version of the *Lusiad* is at once a faithful rendering in the original metre and a lively, picturesque English poem. His translation of *Il Pastor Fido* is equally distinguished.

His *Fourth Book of the Aeneid* is in the Spenserian stanza and few translations of Vergil have so well conveyed the nobility and delicacy of the original.

(1701–24); *Memoirs of Lady Fanshawe*, ed. by E. J. Fanshawe (1907); J. W. Mackail, "Sir Richard Fanshawe," *Studies of English Poets* (1926).
(V. DE S. P.)

FAN-TAN, a Chinese gambling game and also the name of a card game. In the gambling game, a square is laid out in the centre of a table, its sides being marked 1, 2, 3 and 4. The banker empties onto the table a double handful of small coins—in China "cash"—beans, or similar articles, which he covers with a metal bowl. The players bet as to what will be the remainder when the pile is divided by four by setting their stakes on the side of the square which bears the number each favours. When all have staked, the bowl is lifted and the banker, with a small stick, removes coins (or beans, etc.) from the heap, four at a time. When the final batch is reached, the number of coins it contains determines the winning number; if four coins, the backer of no. 4 wins; if three, the backer of no. 3 wins, and so on. The banker deducts 25% from each winner's stake; then he pays each winner five times the amount of his stake thus reduced, which is to say, 2.75 to 1 when the true odds are 3 to 1.

The card game fan-tan, may be played by any number of players up to eight. The full pack of 52 cards is dealt out, one card at a time. Thus some hands may contain one more card than others. All players ante to a pool; in some games, players dealt fewer cards than others are required to ante an extra counter.

Only one card is played at a turn. Beginning with eldest hand (the player to the left of the dealer), each in turn must play a card if able; whenever unable to play, he must pay one counter to the pool

The first card played must be a seven. The next player may add a card next in rank and of the same suit—*i.e.*, the eight or the six—or he may play another seven. Thereafter, each must play a card of the same suit and in unbroken sequence with one already on the table, or may play a seven. Sequences build up to the king; down to the ace. The player who first gets rid of all his cards wins the pool, to which each of the others must add one counter for each card remaining in his hand. A player who passes when able to play must pay three counters to the pool as an additional penalty. (R. L. FY.)

FANTASIA, a name in music for a composition possessing little structural form, and having the general style of an improvisation; also for a combination or medley of familiar airs connected together with original passages of more or less brilliance. The word, however, was originally applied to more formal compositions, based on the madrigal, for several instruments. Fantasias appear as compositions of a distinctive type in Bach's works, in the case of which they frequently serve as preludes to fugues, *e.g.*, the "Chromatic Fantasia and Fugue." Brahms used the term for some of his shorter piano pieces, and it was applied on occasion to much larger and more elaborately organized works, alike for the piano and for the orchestra, such as Schubert's "Wanderer" fantasia, Schumann's Op. 17 and Tchaikovski's symphonic fantasia *Francesca da Rimini*. The Italian word is still used in Tunis, Algeria and Morocco with the meaning of "showing off" for an acrobatic exhibition of horsemanship by the Arabs.

FANTI, MANFREDO (1806–1865), Italian general, was born at Carpi on Feb. 24, 1806, and educated at the military college of Modena. In 1831 he was implicated in the revolutionary movement organized by Ciro Menotti (*see* FRANCIS IV, of Modena), and was condemned to death and hanged in effigy, but escaped to France, where he was given an appointment in the French corps of engineers. In 1833 he took part in Mazzini's abortive attempt to invade Savoy, and in 1835 he went to Spain to serve in Queen Christina's army against the Carlists. There he remained for 13 years, rising to a high staff appointment. But on the outbreak of the war between Piedmont and Austria in

1848 he hurried back to Italy, and although at first his services were rejected both by the Piedmontese government and the Lombard provisional government, he was afterwards given the command of a Lombard brigade. In the general confusion following on Charles Albert's defeat on the Mincio and his retreat to Milan. where the people rose against the unhappy king, Fanti's courage and tact saved the situation. He was elected member of the Piedmontese chamber in 1849, and on the renewal of the campaign he again commanded a Lombard brigade under General Ramorino. After the Piedmontese defeat at Novara (March 23) peace was made, but a rising broke out at Genoa, and Fanti with great difficulty restrained the Lombards from taking part in it. But he was suspected as a Mazzinian and a soldier of fortune by the higher Piedmontese officers. He was court-martialled, and, though acquitted. he was not employed again until the Crimean expedition of 1855. In the second Austrian War in 1859 Fanti commanded the second division, and contributed to the victories of Palestro, Magenta and San Martino. After the peace of Villafranca he converted the army of the Central Italian league (composed of the provisional governments of Tuscany, Modena, Parma and Romagna), into a well-drilled body of 45,000 men. He steered a clear course between the exaggerated prudence of Baron Ricasoli, who wished to recall the troops from the frontier, and the impetuosity of Garibaldi, his second-in-command, who was anxious to invade Romagna prematurely, even at the risk of Austrian intervention. Fanti's firmness led to Garibaldi's resignation. In Jan. 1860 Fanti became minister of war and marine under Cavour, and incorporated the league's army in that of Piedmont. In the meanwhile Garibaldi had invaded Sicily with his Thousand, and the king of Sardinia, Victor Emmanuel, decided at last that he too must intervene; Fanti was given the chief command of a strong Italian force which invaded the papal states, seized Ancona and other fortresses, and defeated the papal army at Castelfidardo, where the enemy's commander, General Lamoricière, was captured. In three weeks Fanti had conquered the Marche and Umbria and taken 28,000 prisoners. When the army entered Neapolitan territory the king took the chief command, with Fanti as chief of the staff. After defeating a large Neapolitan force at Mola and organieing the siege operations round Gaeta, Fanti returned to the war office at Turin to carry out important army reforms. His attitude in opposing the admission of Garibaldi's 7,000 officers into the regular army with their own grades made him unpopular, and led to a severe reprimand from Cavour. In 1861 he resigned office and took command of the VII army corps. He died in Florence on April 5, 1865. (L. V.; X.)

FANTI, a Ghanaian people living on the Cape Coast—Elmina-Secondi littoral and hinterland, and speaking a language closely related to Ashanti (*q.v.*). They have an organization similar to that of the Xshanti, and though less warlike in temperament, probably derive from the same stock.

FANTIN-LATOUR, IGNACE HENRI JOSEPH THÉODORE (1836–1904), French artist noted for his paintings of flowers, still life and portraits, was born at Grenoble on Jan. 14, 1836. He studied first with his father, a pastel painter, and then at the drawing school of Lecoq de Boisbaudran. He was the friend of Ingres, Delacroix, Corot, Courbet and others. He exhibited in the Salon of 1861 and many of his more important canvases appeared on its walls in later years, though 1863 found him with Harpignies, Manet, Legros and Whistler in the Salon des Refusés. His style remained independent and academic, however. His portrait groups, arranged somewhat after the manner of the Dutch masters. are as interesting for their subjects as they are from the artistic point of view. "Hommage à Delacroix" showed portraits of Whistler and Legros. Baudelaire, Champfleury and himself; "Un Atelier à Batignolles" gave portraits of Monet, Manet, Zola and Renoir, and is now in the Luxembourg; "Un Coin de table" presented Verlaine, Rimbaud, Camille Péladan and others; and "Autour du Piano" contained portraits of Chabrier. D'Indy and other musicians. His paintings of flowers are perfect examples of the art. In his later years he devoted much attention to lithography. After "L'Anniversaire" in honour of Berlioz in the Salon of 1876, he regularly exhibited lithographs, some of which were examples of delicate portraiture, others being elusive and imaginative drawings illustrative of the music of Wagner, Berlioz, Brahms and other composers. He illustrated Adolphe Jullien's *Wagner* (1886) and *Berlioz* (1888). There are excellent collections of his lithographic work at Dresden, Ger., the British museum and the Louvre. He died on Aug. 25, 1904.

BY COURTESY OF NATIONAL GALLERY OF ART, WASHINGTON, D.C., CHESTER DALE COLLECTION

STILL LIFE BY HENRI FANTIN-LATOUR

FARABI, AL- (MOHAMMED IBN MOHAMMED IBN TARKHAN ABU-NASR AL-FARABI; Lat. ALFARABIUS) (*c.* 870–950), Arabic-writing Moslem philosopher of Turkish origin. was born c. 870 in Transoxiana (the central Asian province north of the Oxus river). Having studied first in Khurasan and then in Baghdad, where he lived for a considerable time, he eventually transferred himself to the court of the Shi'ite ruler of Aleppo, Saif al-Daula. He died near Damascus in 950.

Al-Farabi's teachers, the Christian Arabic philosophers of Baghdad, were late descendants of the 6th-century Christianized school of Alexandria, and his writings show everywhere the influence of this blend of Aristotelian and Neoplatonic thought. Most later Arabic philosophers depend on his achievement. He believed in the essential identity of Plato's and Aristotle's views, following Plato in politics and Aristotle in logic and physics; his metaphysics combine Aristotelian and Neoplatonic thought. His renowned commentaries on the Aristotelian treatises are lost; and his *Paraphrase of Plato's Laws* is written in support of special political theories of his own and is not meant to give an accurate account of the work in all its detail. We have, however, three comprehensive works on the whole of his philosophy. The earliest comprises three books, book i being a discourse on the attainment of happiness, book ii being a survey of Plato's philosophy and book iii dealing with Aristotle. The other two are the *Views of the Citizens of the Perfect State,* which is perhaps the most accomplished of his works, and the *Book of the Government of the State.* The *Aphorisms of the Statesman* is a short work intermediate between the *Views* and the *Book of the Government.* Whereas these books remained unknown to the Latin schoolmen, al-Farabi's *De divisione scientiarum,* a survey of the entire body of philosophical knowledge, including specific Islamic sciences, was translated by Gerard of Cremona and extensively used by Dominicus Gundisalvi in his *De divisione philosophiae.* There were also medieval Latin versions of his treatise *De intellectu* and of some of his writings on music.

The *Book of Gems,* formerly attributed to al-Farabi, is by Avicenna. For an account of al-Farabi's thought, *see* ARABIC PHILOSOPHY.

For the writings on Plato see *Plato arabus,* vol. ii, ed. by F. Rosenthal and R. Walzer (1943), and iii, ed. by F. Gabrieli (1952); for the *Views of the Citizens,* the text ed. by F. Dieterici (1895) and the Fr. trans. by R. P. Janssen *et al.*, *Idées des habitants de la cite' vertueuse* (1949); for the *Book of the Government*, the Ger. trans. by F. Dieterici, *Die Staatsleitung von Alfarabi*, ed. by P. Bronnle (1904); for the *Aphorisms*, the Eng. trans. by D. M. Dunlop in *Iraq*, xiv (1952); for the *De divisione scientiarum*, the text ed. with Lat. and Sp. trans. by A. Gonzalez Palencia, 2 parts (1932); for the *De intellectu*, the text ed. by E. Gilson in *Archives d'histoire doctrinale et littéraire du moyen âge*, iv (1930); for the musical writings, H. G. Farmer, *Al-Farabi's Arabic-Latin Writings on Music* (1934); for other works, F. Dieterici, *Alfarabi's philosophische Abhandlungen*, Ger. trans. (1892), and D. M. Dunlop, articles in *Islamic Quarterly* (1955 ff.).

FARAD. A unit of electric capacity, named for Michael Faraday (*q.v.*). The capacity of a conductor or condenser is one farad when a quantity of electricity, equal to one coulomb increases its potential by one volt. *See* CAPACITOR; ELECTRICITY: *Condensers: Capacitance;* PHYSICAL UNITS.

FARADAY, MICHAEL (1791–1867), English physicist, chemist and physical-chemist or, as he himself would have said. natural philosopher, was the discoverer of electromagnetic induction, of the laws of electrolysis and of fundamental relations between light and magnetism, as well as being the originator of the conceptions that underlie the modern theory of the electromagnetic field. Faraday was born on Sept. 22, 1791, at Newington, Surrey, nhich later became part of the borough of Southwark in south London, but was then in the country. His father was a blacksmith who had migrated from Yorkshire. The family having moved to north London Michael, at the age of 14, was apprenticed to a bookseller and bookbinder, in whose shop he read with keen interest books on science which came into his hands. Having heard Humphrey Davy lecture at the Royal institution and conceived an eager desire to "enter into the service of science," to use his own words, he applied to Davy for employment, sending him, as evidence of his interest, the notes which he had made of the lectures. As a result he was, at the age of 21, appointed assistant to Davy, to help with both lecture experiments and research. He accompanied Davy on a tour in Europe, where he had many menial duties to perform, but also saw much of active scientific research and. in general, expanded his view. As J. H. Gladstone, who knew him well, wrote, "His University was Europe; his professors the master whom he served, and those illustrious men to whom the renown of Davy introduced the travellers."

His first published paper, which appeared in 1816, was of no importance. In 1820 he was devoting much attention to steel, the preparation of a rustless steel being one of his objects, and this work continued for some years, but beyond the finding that small quantities of added metals had a pronounced effect on the properties, no result of importance was obtained. In 1820 Faraday discovered two unknown chlorides of carbon and a new compound of carbon, iodine and hydrogen. It was in this year that the Danish physicist, H. C. Oersted, announced his discovery that a wire conveying an electric current deflected a pivoted magnetic needle to which it ran parallel, a discovery which aroused great interest but was imperfectly understood. Faraday grasped that the force w-as a circular one round the wire and on this basis made in 1821 the first of his great electrical discoveries, that of electromagnetic rotation. A rigid mire, so mounted that it could turn about the point of suspension, hung with its lower end in a pool of mercury. A vertical magnet was fixed with one pole beneath the point of suspension. When a current was passed through the wire it rotated rapidly. This discovery brought Faraday widespread fame, but also some trouble with W. H. Wollaston (*q.v.*), who had been unsuccessfully attempting something similar. In the same year Faraday married Sarah Barnard. The union was a happy one, but childless.

In 1823 Faraday liquefied chlorine, ahich aroused the jealousy of Davy, who considered that he had initiated the work and was entitled to the credit. In consequence he opposed Faraday's election to the Royal society, which nevertheless took place in 1824. The next year Faraday made a chemical discovery of the first importance by isolating benzene or, as he termed it. bicarburet of hydrogen, from a liquid obtained in the production of oil gas. About the same time he was concerned mith a research. to become prolonged, on optical glass, to which he devoted much labour without great immediate result. The "heavy glass" which was one of the products played. however, an essential part in his great discovery of the rotation of the plane of polarization of light in a magnetic field. It was in 1825 that Faraday's position at the Royal institution was improved by his promotion to the post of director of the laboratory. The next year he began to give formal lectures for the members of the institution on Friday evenings, which have continued, as Friday evening discourses. ever since. He also initiated the Christmas lectures for young people, known formally as Christmas Courses of Lectures Adapted to a Juvenile Auditory, of which he himself gave 19 courses. As an inspiring lecturer and as a deviser of effective lecture experiments Faraday was supreme and there are many contemporary accounts of the interest and enthusiasm which his discourses aroused.

The second period of Faraday's researches may be said to have begun in 1831. His mind was governed by the conviction that the various forces of nature with which physics, always termed by him natural philosophy, was concerned were intimately interconnected. The electric current produced magnetic force, and the magnet acted. as he had shown, on the electric current. He was sure that it should be possible to make magnetism produce electricity: in fact as early as 1822 his note book contains the words "Convert magnetism into electricity." From time to time he had tried to produce currents by stationary dispositions of magnets with respect to wires or coils of wire, without success. In ten days in 1831 he carried out a series of experiments convincingly demonstrating the discovery of electromagnetic induction. experiments of such importance that in 1931 the centenary was celebrated at a conference, to which came delegates from all parts of the world, organized by the Institution of Electrical Engineers in London. The most famous experiment was that of the induction ring, a ring of soft iron on which were two different windings of insulated wire, one of ahich mas connected to a simple galvanometer. When the two ends of the other winding were permanently connected to a battery there was no effect, but when the circuit was made or broken the galvanometer indicated a current. A similar effect was obtained with an iron cylinder with a helix wound on it. When, by means of magnets, the magnetic flux in the cylinder was changed, there was a momentary current in the helix. A variation of this experiment was to introduce a magnet into a helix, or to withdraw it. In general, what Faraday showed was that change of magnetic flux through a circuit produced a current in the circuit.

He also rotated a copper disk between the poles of a large electromagnet and showed that a current could be obtained from contacts with the axis and with the edge of the disk—the first dynamo. He soon followed these experiments with others demonstrating the inductive effect of a current circuit on another circuit, without the presence of iron. In discussing these fundamental discoveries Faraday employed the conception of magnetic lines of force to make his ideas clear, for he was no mathematician. Somewhat later, in the course of his researches on static electricity, he developed the analogous conception of lines of electric force, whose course and concentration expressed the various effects. It is in acknowledgment of his fundamental discoveries concerning the functions of dielectrics that the unit of capacity is named the farad (microfarad in more general use). In this mork he discovered the significance of what he termed "specific inductive capacity," later called dielectric constant.

Faraday's conceptions of electric and magnetic force and their interrelations, expressed in terms of his lines of force, were fundamental. It was from them that James Clerk Maxwell (*q.v.*) developed his equations, which lie at the base of all modern theories of electromagnetic phenomena.

It was shortly after his nork on electromagnetic induction that Faraday, once more in search of unity, showed that the five kinds of electricity then distinguished—frictional, galvanic, voltaic, magnetic (induced current) and thermal—were fundamentally the same. "Electricity, nhatever may be its source is identical in its nature." In the same period of his researches he arrived at the basic laws of electrolysis which bear his name. and introduced the terms that are universally used, "anode," "cathode," "anion," "cation" and "electrode."

After this succession of epoch-making discoveries ensued a period of exhaustion, reminiscent of Sir Isaac Newton's nervous breakdown. from which Faraday gradually recovered. The third and last period of his researches began about 1844 and includes as the main discovery that of the rotation of the plane of polarization of light in a magnetic field, in which his heavy glass played an essential part. This, again, was the outcome of a fixed idea that light and magnetism must be in some way connected. In 1850 he tried to establish experimentally a relation between gravity and electricity, concluding his paper with "Here end my trials for the present. The results are negative; they do not shake my strong feeling of the existence of a relation between gravity and electricity, though they give no proof that it exists."

In 1858 he retired to live in a comfortable house near Hampton Court, Surrey, provided by Queen Victoria. At that time he still retained a lively interest in science, but his health and his powers gradually waned and there he died peacefully on Aug. 25, 1867.

Faraday nas possibly the greatest experimental genius the world has known. "He smells the truth," said the German professor F W. Kohlrausch, speaking to John Tyndall. Something incessantly prompted him that certain fundamental relations were waiting to be found and he was not dismayed by dozens of fruitless experiments from persisting until basic discoveries, of the type described here, were finally established. In theoretical physics he provided the fundamental conception, expressed by his lines of force, that the medium was the seat of electromagnetic action, which at the hands of Clerk Maxwell led to the conception of electromagnetic waves. To all his other gifts he added that of being able to express his experimental results and his thoughts concerning them in clear and simple language.

His published works were *Chemical Manipulation* (1827); *Experimental Researches in Electricity* (1839–5j); *Experimental Researches in Chemistry and Physics* (1859); *A Course of Six Lectures on the Clzemical History of a Candle,* ed. by W. Crookes (1861); *On the Various Forces in Nature,* ed. by W. Crookes (1873). His *Diary,* edited by T. Martin, was published in 8 vol. (1932–36).

FARADAY'S LAW: *see* ELECTRICITY: *Faraday's Law of Electrolysis.*

FARAH, a town of Afghanistan, on the river that bears its name on the main road betu-een Herat and Kandahar, 160 mi. S. of Herat and 225 mi. W. of Kandahar. It commands the approaches to India and Seistan from Herat. The town (2,460 ft. above sea level) is a square walled enclosure in the middle of the plain. Because of its unhealthiness it is only occupied by the Afghan regiment quartered there. It is probably the Phra mentioned by Isidore of Charax in the 1st century A.D.

FARAH, a river of Afghanistan. It rises in the southern slopes of Siah-Koh, which forms the southern wall of the valley of Herat, and after a southwest course of about 200 mi. falls into the Seistan Hamun. At the tonn of Farah it is 1jo yd. wide in the dry season with 2 ft of water and a clear, swift stream. It is liable to floods, when it becomes impassable for weeks. The lower valley of the Farah Rud is fertile and well cultivated.

FARAZDAQ, AL- (AL-FERAZDAQ; originally HAMMAM) (*c.* 641–*c.* 728), Arab poet, famous chiefly for his satires, was born at Basra. and at the age of 15 was already known as a poet. He devoted his talent to attacks on the tribes of bani Nahshal and bani Fuqaim. When Ziyad. a member of the latter tribe, became governor of Basra, the poet fled, first to Kufa, and then to Medina. He remained there about ten years, writing political satires on the Bedouin tribes, but taking no other part in political life. He lived a prodigal life, and his amorous verses (in which, as in his life, he indulged in unbridled licence) led to his expulsion by the caliph Marwan I. On the death of Ziyad he returned to Basra, where he secured the favour of Ziyad's successor, 'Obaidallah ibn Ziyad. Much of his verse during this period is concerned with his dispute with his wife, his cousin Nawar, whom he married against her will. Another subject which occasioned a long series of verses was his feud with his rival Jarir (*q.v.*) and his tribe the bani Kulaib. Al-Farazdaq was prevented by fear from taking an important part in political life. He seems, however, to have been attached to the house of 'Ali. During the reign of Muawiya I he entirely avoided politics, but later gave his allegiance to Abdallah ibn Zobair. He died at Basra about 728.

FAR EAST is a regional term commonly used to cover east and southeast Asia. East Asia refers primarily to China, Korea, Formosa and Japan; it usually includes Mongolia as well and on occasion the Pacific littoral of the U.S.S.R. Southeast Asia, sometimes called farther India (*Chinese*: Nan-yang; *Japanese*: Nan-yo), refers to the region between India and China, including Burma, Thailand, Laos, Cambodia, Vietnam, Malaya, Singapore, Indonesia, British Borneo, Portuguese Timor and the Philippines. Although at times India, Pakistan and adjacent territories have been subsumed within the far east concept, they are correctly excluded from it and belong more appropriately within the area known as south Asia (India, Pakistan, Ceylon. Nepal, Bhutan, Afghanistan). In its most restricted sense, the term far east often is equated with east Asia alone.

Historically, the far east described those portions of the Eurasian land mass and archipelagoes farthest from and of greatest interest to the maritime powers of western Europe. It was one of a trichotomy of regional expressions of which the other two were the middle east (south Asia plus Iran and on occasion portions of Soviet central Asia) and the near east (the Levant and northern Africa). The orient is a term popularly connoting all countries of the east (including middle and near East) or of Asia generally.

From the standpoint of North Americans, far east is a cultural and geographical archaism since the term may in fact be regarded as the American farther west and potentially may become the farther north as air communications over the arctic region continue to be expanded. *See* also SOUTHEAST ASIA; and countries referred to above. (N. S. G.)

FAR EAST: RELATIONS WITH THE WEST. The term "far east," as used in this article, applies to Japan, China, eastern Siberia and adjacent portions of eastern Asia. Not until the 16th century, with the opening of the sea routes to India and the far east, did Europeans begin to change the face of Asia. When the Portuguese admiral Vasco da Gama rounded southern Africa and sailed, in 1497–98, to Calicut on the southwestern coast of India, a war to the death began between the Portuguese and the Arabs for control of the Indian ocean and the trade of the Indies. The Arab hold was broken in 1511 with the Portuguese capture of Malacca, entrepôt of trade by sea between the middle and far east. On arriving there the Portuguese came into direct touch with the peoples, cultures, riches and power of the extreme eastern world.

Early European Relations.—The handful of Portuguese who invaded the far east in the 16th century owed their success to their superior arms and ships, their crusading determination, their wisdom in limiting their objectives to relatively isolated places and the haughty confidence of the Chinese court in its ability to deal with the alien intruders at its own convenience. Despite wars between the invading Europeans and China's vassals in Malaysia, relations between Portugal and China might possibly have been established in a mutually satisfactory manner had it not been for the outrages and piratical activities of the Portuguese along the coast of southern China.

The first Portuguese ambassador, Tomé Pires, who arrived in southern China in Aug. 1517, was not permitted to reach Peking until approximately three years later. Moreover, when the letter from the king of Portugal was opened its tone was judged to he lacking in respect. The Portuguese embassy was rejected and Pires was ordered back to Canton where he was imprisoned. Although diplomatic relations were not permitted, trade relations were continued illegally after 1521 at the wish of mercantile elements of both peoples and with the purchased connivance of the Chinese official hierarchy. By 1557 the Portuguese had established a settlement at Macao by consent of local officials. 'Ground rent, symbol of sovereignty, was paid to China until 1849. Only in 1887 did China by treaty confirm Portugal's right of government with perpetual occupation—while Portugal agreed never to alienate the territory and its dependencies without China's consent.

The conquest of Malacca was followed during the autumn of 1511 by the dispatch of a Portuguese expedition to the Moluccas and other islands of the Malay archipelago. Some of the leaders, shipwrecked on the return voyage, are said to have landed on Mindanao. Not to Portugal, however, but to Spain fell the ownership for more than three centuries of the archipelago named, in 1561, in honour of Philip II. In 1521, about nine years after these initial landings, Ferdinand Magellan arrived in these islands after a voyage across the Pacific ocean. In so doing he opened to the country of his adoption the western route to the far east, via the Atlantic and Pacific oceans, and thenceforward the Spanish used Mexico as a base for conquest, trade and religious propaganda in the east. Manila was captured by Miguel López de Legazpi in 1571, and shortly became capital of the colony.

The Portuguese and Spanish were amazed by the numbers and wealth of the Chinese people, their philosophical pacifism and military and naval ineptitude. In 1598, 18 years after the union of the crowns of Spain and Portugal, the Spanish obtained permission to trade at Canton. But Portuguese opposition, in conjunction with the preference of the Chinese for trade at Manila where they could more easily obtain goods from Spain and Mexico, prevented relations of the two peoples on the mainland from developing to any considerable extent along either religious or economic lines. Thus Manila became the clearinghouse for Sino-Spanish trade as Canton had become for Sino-Portuguese. The Chinese in the Philippines increased in numbers and wealth; they, rather than the Spanish, profited from the trade with Mexico.

From 1432 to 1549 Japan was officially in vassalage to China. Meanwhile, in about 1542, shipwrecked Portuguese reached a tiny island off the southern extremity of Kyushu. In this manner were opened Portuguese-Japanese relations which lasted 98 years. For two generations no other Europeans appeared in Japan. With the arrival of the Spaniards, however, toward the end of the 16th century, European relations with Japan—as well as with China—became increasingly complicated. This was a result of national and religious rivalries, carried on between the westerners and the Asians and between the westerners themselves.

As early as 1577, within a generation after the breaking of Japan's vassalage, Toyotomi Hideyoshi was planning the unification of China and Korea with Japan. Before long he was envisaging annexation of Formosa, the Philippines and India as well. On July 25, 1591, he warned the Portuguese viceroy at Goa of his intention to invade India as soon as his "heavenly mission of conquering China" had been completed. On Sept. 15 following he sent a letter to the Spanish governor of the Philippines making similar threats. During the following two years and in 1597–98 two great campaigns were fought in Korea and its waters to force that kingdom to serve as a roadway to China. This effort was defeated when China came to the aid of its Korean vassal.

Out of Hideyoshi's expressed intentions with respect to the Philippines arose the opportunity for Spanish priests to poach upon the Jesuit-Portuguese preserve of Japan. Through Macao, and under the aegis of Portugal, the Jesuits had entered both China and Japan during the latter half of the 16th century. By intelligently directed zeal. subtle diplomacy and scholarship they made their conquests in both countries, hut approximately a generation earlier in Japan than in China. Although anti-Christian decrees had been issued in Japan during 1565, 1568 and 1587, there were in Japan by 1595, an estimated 300,000 converts and 137 Jesuits. In 1593 Governor de Marinas sent an embassy with a reply to Hideyoshi's demand of 1591 that he should travel to Kyushu "to make submission to us." Circumventing a bull of Gregory XIII and a Spanish-Portuguese agreement, four Franciscans now entered upon rival religious propaganda. The Franciscan-Jesuit, Spanish-Portuguese quarrels which ensued strengthened the position of the enemies of the groups concerned, native and alien, especially that of the Protestant Dutch. The Dutch, arriving in Japan in 1600, hated the Catholic Portuguese and Spanish, against whose rule they were rebelling in Europe. Weakened by Hideyoshi's continental wars and fearful of attempts by Spain to conquer the country, Japan attempted the extirpation of Christianity and, around 1640, closed its doors to Europeans (with the exception of a handful of Dutch) for the next three centuries and more.

Even before this Japanese-European drama had reached its climax, other aspects of the far eastern problem, religious and secular, were developing in China. During the period c. 1635–1742 there occurred a cultural-political-religious struggle, generally referred to as the rites controversy, between the Jesuits and their Catholic critics and rivals, chiefly the Dominicans and Franciscans. This centred in the relative values of Chinese and European-Christian culture and the spiritual authority of Manchu emperors and Roman popes. Although no approximate parallel to this problem occurred in Japan, the results in both countries were the same: Christianity and western influence suffered a serious setback.

Contemporaneously with this essentially spiritual and intellectual struggle between China and the west, other difficulties more material in nature were occurring. The Dutch, who had contributed to the collapse of Portuguese influence in Japan, themselves suffered in China at the hands of the Portuguese. Attempts of the Dutch East India company to trade at Canton in 1604, 1607 and 1653 were blocked from Macao; the Dutch attack on that Portuguese stronghold in 1622 was disastrously repulsed; the company's missions to Peking of 1655, 1665 and 1795 effected little of value. Consequent upon their repulse from Macao, the Dutch established themselves (1624) on the primitive island of Formosa whence they were expelled (1662) by Koxinga (Cheng Ch'eng-kung), an adherent of the recently conquered Ming dynasty. Against Koxinga the Hollanders aided the Manchu (Ch'ing) K'ang Hsi emperor (1662–1722), in return for which they were rewarded by having their country listed among the vassals of Peking and by little else.

The western Europeans of the 16th and following centuries approached the far east from the west and south by way of the sea. The Russians approached overland from the west and north. Russia was the first European power to fight—and lose—a war with the Manchu empire and the first to enter into treaty relations with it. In two generations, approximately 1581–1639, the Muscovites pushed across northern Asia, thereby becoming an important factor in the far east. The northern frontiers of the Manchu-Chinese empire not being precisely defined, hostilities were caused by the encroachments and aggressions of the Russians in the Amur river valley. The treaty of Nerchinsk was negotiated in 1689. Russia withdrew from its outposts behind the Argun river and the watershed of the Amur. Transfrontier trade was arranged, and extraterritoriality in part was to be administered by both parties. The form, as well as the content, of the treaty implied equality of the contracting states. Except for provisions in art. v of the Kyakhta treaty of 1727, relations between Russia and China remained essentially unchanged from 1689 to 1858–60—although during the years 1789–91 plans were formulated for the seizure of the Amur valley and possibly Japan as a means of aiding Kamchatka and developing the fur trade. But by the Nerchinsk treaty the Russians were cut off from convenient entrance to the Pacific and from easy access to the marts of eastern Asia. This made it extremely difficult for Russia to establish permanent settlements in its easternmost provinces and to participate readily in the trade and conquest of the far east until after the middle of the 19th century.

The 19th Century.--Although the Portuguese were the first Europeans in modern times to have relations with China and Japan, it was not they but the English and the Americans who, mainly in the 19th century, opened those states respectively to world intercourse. During the middle and later years of this period the far eastern problem became increasingly acute, largely as a result of political and military weaknesses and confusion which prevailed in eastern Asia and of the effects upon western Europe, particularly Great Britain, and later upon the United States, of the Industrial Revolution. Britain's need for raw materials at home and markets for manufactured goods and investments abroad induced that country to take the lead in "opening" China. This was accomplished ultimately by war, in and after 1839, consequent upon more than two centuries of peaceful relations.

From 1635 various diplomatic attempts were made by England to establish intercourse with China on a basis of equality between nations with prevention or removal of irritating exactions upon westerners and extreme limitations upon their trading and religious activities. The mandates from the Ch'ien Lung emperor (1736–96) to King George III, in connection with the embassy of Earl Macartney, 1793, indicate the conflicting aims and viewpoints of the governments concerned at that time and later. The English ruler was commended for his "respectful humility" in sending a "memorial and tribute." The request that an English envoy be permitted to reside in Peking was refused, it being disclosed that China itself had no desire to be represented abroad. "Swaying the wide world, I have but one aim in view, namely to maintain a perfect governance . . . Our dynasty's majestic virtue has penetrated into every country under Heaven and Kings of all nations have offered their costly tribute by land and sea. As your Ambassador can see for himself, we possess all things. I set no value on objects strange or ingenious, and have no use for your country's manufactures." China's goods, however, "are absolute necessities to European nations"; therefore, "as a signal mark of favour" trade might be carried on at Canton — but not, as the English had asked, at "Ningpo, Chusan, Tientsin and other places . . . ," including storage of goods at Peking. As to the propagation of Christianity: "The distinction between Chinese and barbarian is most strict, and your Ambassador's request that barbarians shall be given full liberty to disseminate their religion is utterly unreasonable." Arrogant in tone as the Ch'ien Lung mandates might appear, they no more than manifested the indisputably unique position of the ruler of the Manchu empire and of that vast area's civilization and self-sufficiency.

Another aspect is worthy of note: throughout the documents is indicated the emperor's complete. if intuitive, comprehension of the principle of western international law embodied in the most-favoured-nation clause. For example, "Consider, moreover, that England is not the only barbarian land which wishes to establish relations with our civilization and trade with our Empire: supposing that other nations were all to imitate your evil example and beseech me to present them each and all with a site for trading purposes, how could I possibly comply?"

Having dispatched to China an envoy whose conveyances inland bore flags marked "Ambassador bearing tribute from the country of England," and who presented gifts ("tribute") to the imperial court even though he did not perform the kowtow. Britain was now definitely rated a vassal kingdom. Lord Macartney, however, equally well informed of his own country's strength and of China's weakness in defense forces, was fearful that war would not only upset for an indefinite time the trade in tea and woolens but would also bring Russia into the fray. He therefore concluded that peaceful relations with China were best. For almost half a century longer, despite increasing friction over impositions and limitations upon its trade, England maintained peace with the Manchus and their subjects — as, in general, did the United States from the beginning of its intercourse with them in 1784 to the dissolution of the empire in 1911–12.

During 1839–42 and 1856–60 London took the lead in challenging Manchu-Chinese pretensions to "sway the ten thousand kingdoms," and in insisting upon recognition by Peking of the western state-equality concept. Notwithstanding, London came increasingly to fear collapse of the Manchu empire with inevitable wide-scale confusion and tended fundamentally, almost as definitely as did Washington, to aid the Manchus to maintain their dynasty.

To the previously indicated causes for friction lying back of the first (1839–42) and second (1856–60) Anglo-Chinese wars— in the latter of which France participated — the opium trade must be added. From the 10th century at least the Chinese were acquainted with the medicinal value of opium poppy seeds; from the 15th century opium itself was manufactured in China. Foreign, in contrast to native, opium was imported into China first by the Portuguese, later by other westerners including English and Americans. Until April 22, 1834. the English East India company held a monopoly on English trade with China. Following a precedent established by the Mogul rulers of India, the company began farming out opium in Bengal in 1773, in which year the drug was first imported from Calcutta into Canton. Seven years later the company assumed a monopoly of the Anglo-Chinese trade in the commodity. Determination of the west to have Chinese teas and other products; light demand by the Chinese for western products including English woolens; unwillingness of westerners to drain their lands of and load their ships with silver bullion and specie to pay for Chinese goods; the high value of opium in small bulk and its popularity for purposes of smoking; these explain the phenomenal growth of the opium trade despite the issuance of Manchu imperial antiopium edicts from 1729 on, edicts which were ordinarily disregarded by native officials and nonofficials and aliens alike. Important, however, as was opium in contributing to the outbreak of hostilities in 1839, the war itself, as with that of 1856–60, was basically one between two worlds and two differing conceptions of international relations.

The treaty of Nanking, signed Aug. 29, 1842, between China and Britain opened 100 years of relations between the west and the extreme east based on written agreements. This was followed within a few years by treaties and other types of agreement between China and the United States, France, the kingdom of Norway and Sweden, the German confederation, Russia, Japan and other states. Among the developments of outstanding importance from the wars, ensuing negotiations and the treaties and agreements were: (1) the cession of Hong Kong to Great Britain; (2) the opening first of Canton, Amoy, Foochow, Ningpo and Shanghai, and after 1860 of other coastal and interior cities, as treaty ports for residence and trade; (3) the right of foreign nations to appoint consuls at treaty ports; (4) uniform tariffs of about 5% on most imports and exports; (5) equality of foreign with native officials of corresponding ranks; (6) most-favoured-nation treatment (*q.v.*); (7) extraterritoriality; (8) toleration of both Roman Catholic and Protestant forms of Christianity; (9) legalization, by the provincial and the imperial governments of China, of the opium trade both before and by the treaties of 1858; (10) the residence in Peking after 1860 of foreign envoys; (11) the right of aliens to travel with passports — but not to reside — and of missionaries to hold property, reside and carry on their activities in the interior, *i.e.,* outside of treaty ports, after 1860; (12) the formation of the imperial maritime customs service under western (predominantly British) administration; (13) the legalization of study of the Chinese language by foreigners.

Advance of British power northward in eastern Asia contributed immediately to a renewal of Russian pressure southward. Anglo-Russian rivalry in the far east was but a projection of that in Europe, the near east and the middle east. If the British were to control the deltas — and possibly more — of the chief rivers of China proper why should they not advance to the Amur? In 1847 Tsar Nicholas I appointed Nicholas Muraviev to the office of governor general of eastern Siberia. Three years later Muraviev transferred the Russian naval base from Okhotsk to Petropavlovsk on Kamchatka. On an exploratory voyage, by order of Governor General Muraviev, G I Nevelskoi, a naval officer. discovered that Sakhalin is an island and that therefore the Amur is accessible from the south and not alone from the north as the Russians had previously supposed. Advancing about 20 mi. up the Amur, Nevelskoi raised his flag and established, in 1850, the port of Nikolayevsk. In 1853 he claimed Sakhalin. Meanwhile, he pushed south, establishing posts on the coast of the mainland practically to the border of Korea. Events taking place at this time in Europe foreshadowed the Crimean War and in Jan. 1854 the tsar gave Muraviev complete freedom of action in eastern Siberia. Fearing attack upon Petropavlovsk, the governor general, disregarding Chinese protests, immediately established steamers on the Amur to connect with Kamchatka. This was the first occasion on which the Amur had been traversed by Russians since 1644.

In 1854 an Anglo-French fleet twice attacked Petropavlovsk and was repulsed with severe losses. These victories strengthened Muraviev's hand in his negotiations with Manchu-Chinese officials, as did the transfer of the naval base from Petropavlovsk to Nikolayevsk and the transport down the Amur of several thousand Russian subjects for colonization of the coast. He was not, however, able to obtain the signing (May 1858) of the treaty of Aigun until after the defeats to China administered by the Anglo-French allies (1856–58), and then only by the double persuasion of having on the Amur sufficient force to advance to Peking and of pointing to the danger of England's seizure of that river. By this agreement Russia's sovereignty over the northern left bank of the Amur nas recognized, as was China's over the south bank as far as the Ussuri. The territory between the Ussuri and the sea was to be jointly held for the time. Navigation of the two rivers and the Sungari was to be limited to vessels of the tao empires. In June 1858, by the treaty of Tientsin. which contained the most-favoured-nation clause, Russia obtained through diplomacy all that England and France had won through war. particularly treaty-port rights, including that to trade with China by way of the sea and not as hitherto, merely overland by way of Kyakhta. Following the Anglo-French march on Peking in the autumn of 1860, Russia by additional diplomacy and again without use of arms, obtained on Nov. 14 a convention ceding the territory between the Ussuri and the sea. This became the maritime province of Siberia. In the preceding July (1860) Muraviev had ordered the occupation of the site which was named Vladivostok. To the further annoyance of Japan, Russia's far eastern naval base was moved in 1872 to Vladivostok from Nikolayevsk.

Not alone in farthest Asia did Russia consolidate its position in 1860. By the Peking convention of Nov. 14 Russia was permitted to trade and open consulates in Outer Mongolia and Sinkiang at Urga (Ulan Bator) and Kashgar (Shufu). Continued pressure from the north and northwest upon China, Korea and the kingdom of Japan followed. Rebellions against Chinese rule in Sinkiang in 1864 and 1866 offered opportunity to Russia, in 1871, to occupy Ili. Ten years later, as a result of China's readiness and ability to fight Russia if necessary, the treaty of St. Petersburg was ratified. By this treaty the greater part of the occupied territory, including the most strategic passes, was returned to China in exchange for an indemnity and permission for Russia to open consulates and trade and for Russians to reside in certain cities of Sinkiang and Mongolia. Expansion of Russian trade in the vast territories as far as the Great Wall was also permitted.

In its relations with France regarding the old Xnnamite empire, China was less fortunate. From 1787 a degree of interest in Annam was from time to time evinced by France. Between 1843 and 1857 several expeditions were sent to avenge the deaths of Roman Catholic missionaries. From 1858 to 1862, France and Spain waged war upon Annam which resulted in the cession to France of Saigon, three of six Cochin Chinese provinces and the island of Poulo-Condore (Pulo-Condor) ; a promise in perpetuity by the Annamite emperor to cede territory to no poner other than France; and the payment to France and Spain (which had sent a squadron from Manila) of an indemnity. In 1863 France supplanted Siam and Annam as protector of Cambodia. Four years later the remainder of Cochin China was swallowed to give France control over the outlets of the Mekong river.

France's determination to penetrate the southwestern provinces of China by way of the Red river route led to negotiation of the Franco-Annamite treaty of Saigon in March 1874. Ignoring the vassalage of Annam to China, France recognized the complete independence of Annam and promised protection against external aggression and internal disorder. China, however, continued to assert its suzerainty over Annam, and Franco-Chinese relations steadily deteriorated. By the treaty of Hué, Aug. 25, 1883, Annam was forced to recognize and accept the status of a French protectorate and to agree that all foreign relations, including those with China, should be controlled by France; territory was ceded to French Cochin China; Tongking was put under the administration of French residents; the customs and public works of Annam were brought under French control; French military posts were for an indefinite period to control the course of the Red river. Hostilities between the rival suzerains began in Dec. 1883; after alternating with desultory resorts to diplomacy, they ended in April 1885. When finally, after an expenditure by France of 344,000,000 fr., the treaty of Tientsin was signed on June 9, 1885, the suzerainty of China over Annam was surrendered; the frontier between China and Tongking was delimited in favour of France; and trade over the frontier. which Peking had previously forbidden, was granted.

The results of the Franco-Annamite-Chinese imbroglio of 1858–85 served as a lesson to Japan, which was then being reopened to international intercourse. During the period of Japan's closure, of Russia's overland approach to China and the Pacific and of the western European-American maritime approach. the Pacific ocean routes to Asia had been of minor importance. Transcontinental expansion of the United States; sustained American interest in the present and future markets of China and the potential markets of Japan; application of steam to ocean-going vessels with consequent need for coaling stations; rebuffs and insults to American civilians and naval officials who had called at Japanese ports; mistreatment of shipwrecked Americans cast up on the shores of the archipelago; all these lay back of the Matthew C. Perry expedition of 1853–54.

Long before Perry's arrival, a few Japanese modernists had advocated the reopening of their country. Russians, Dutch, English, French and Americans had also attempted in a variety of ways to persuade the Tokugama officials to change their policy on closure. Had the Fillmore administration made no attempt, or had it failed, Japan would still have been opened. voluntarily or involuntarily, within a comparatively short time. The factor of outstanding significance was. accordingly, not the time but the agent. The United States desired friendship and trade with Japan as it did with China, and it had no more desire to witness the disintegration of the one than of the other. Furthermore. the United States, unlike the western European powers and Russia, was not considered powerful enough to threaten the sovereignty of the independent states of eastern Asia. Japanese-American relations in their first half century were characterized by friendliness.

The Perry treaty of Kanagawa, March 31, 1854, laid the groundwork for the superstructure of foreign rights and interests—essentially paralleling that in China—which limited the sovereignty of Japan for two generations and more. The reactions of Japan to the westerners and their treaties were notably different from those of China Japan was motivated by no deeper admiration and affection for the interests and actions of aliens within its borders than was China, but it set to work in 1868 to construct a powerful government able to meet the requirements of the west without further sacrifices of sovereignty. Japan simultaneously safeguarded the ages-old spiritual core of its life while at the same time modernizing its institutions and working for revision of the treaties that infringed upon its rights as a sovereign nation. At the same time its leaders began to outline a national policy of expansion that was calculated to make Japan the leading nation of the far east.

In Japan the year 1871 marked the passing—in law if not in national thought—of feudalism. The ministry of education was also reorganized and diplomatic missions were dispatched to China and the west. The mission of Lord Tomomi Iwakura to the United

States and Europe (1871–73) was primarily "to study the institutions of the civilized nations, adopt those most suited to Japan, and gradually reform our government and manners, so as to attain the status equal to that of the civilized nations." Little or nothing was accomplished by this mission in obtaining the revision of treaties, but much was gained from the knowledge of conditions in the west which its members carried home. Shortly thereafter, Tokyo took the step, unprecedented for an eastern Asiatic government, of establishing permanent legations in five western countries. This move helped to break down the co-operative policy of European diplomats in the Japanese capital, as Japan's problems were brought directly to the attention of the western governments.

On Sept. 13, 1871, Japan signed at Tientsin a treaty which—since the western powers had treaties with the Manchu empire—was, from the viewpoint of Tokyo, better than no treaty, but which was nevertheless disappointing. Formulated on the assumption of equality of the contracting parties, it was no more satisfactory to China, longtime suzerain of Japan, than to the former vassal intent on "standing with European countries" on a plane superior to that occupied by China. The terms were meticulously reciprocal—and the most-favoured-nation clause was not included. To the momentary consternation of those European adventurers and statesmen who were as assiduous as most of the Japanese, and for the nonce more experienced, in "protecting" the Manchu empire. art. ii of the treaty of 1871 declared it to be "the duty of each [of the contracting parties] to sympathize with the other, and in the event of any other nation acting unjustly or treating either of the two Powers with contempt, on notice being given [by the one to the other], mutual assistance shall be rendered or mediation offered for the arrangement of the difficulty, in fulfillment of the duty imposed by relations of friendship." Instead of following a policy in consonance with this sentiment, Japan set out immediately to wrest leadership in the far east from China, to seek a dominating position in China's foreign relations and to limit as much as possible the influence of the western nations in the affairs of eastern Asia.

While China resorted first to passive, and then. at the turn of the century, to madly active resistance to aliens and the unilateral treaties, Japan patiently used diplomacy through the years 1871–94. In London, on July 16, 1894, one week before the outbreak of war with China, Tokyo succeeded in signing with Great Britain what served as the master treaty of a series providing for gradual removal of limitations upon Japanese sovereignty which went into force simultaneously in 1899. Consular jurisdiction ended in 1899. The conventional tariff remained in force until July 1911; and in March 1937 the powers finally relinquished perpetual leases in the former foreign settlements.

Europeans sought control of eastern Asiatic shores by seizure first of delta areas and river ports, and the Japanese did likewise with the archipelagos and islands controlling the sea approaches to the eastern coast of Asia. From 1868 they officially manifested what they themselves termed a "peculiar" interest in Korea. the mainland territory nearest them. Fear and anger were aroused by the Russian invasion of Sakhalin. but not until after the "restoration" of the tennō (emperor) and the organization of a new government after 1867–68 was Japan able to focus attention upon the complicated Russian problem. Finally, a treaty was signed on May 7, 1875, by which Japan and Russia relinquished their respective claims to Sakhalin and the Kuril Islands. Tokyo rejoiced in an agreement signed on the basis of equality with a power which was considered European, and for 30 years the problem of Sakhalin was shelved.

The Luchu (Ryukyu) Islands between Japan and Formosa had for centuries been vassals of both China and Japan. In 1871, according to Japanese charges, shipwrecked Luchuans were killed by Formosan aborigines. This "incident" offered an opportunity to Tokyo to break Luchuan vassalage to China, to foreshadow a claim to Formosa and to create a precedent followed later in Korea. The king of the archipelago was "invited" to Tokyo and given a Japanese peerage and a pension. Members of the diplomatic corps in Tokyo were informed that henceforth Luchuan foreign relations would be controlled, and obligations met, by Japan. Peking protested, made a feint at military action and, following an ultimatum, signed in Oct. 1874 an agreement of an unprecedented type. The justice of Japan's actions was admitted. and the Manchu empire paid an indemnity. Many of the methods used time and again thereafter were applied by Japan during these years, but to westerners these appeared less meaningful than the unveiling of China's weakness.

While they were attempting to bring the islands off the mainland under their control as rapidly as possible, Japan's leaders were aiming at the same objective in the Korean peninsula. There the deeds of 16th-century Japanese invaders had by no means been forgotten. Korea was, moreover, scornful of its small neighbour's attempts at modernization, desirous of maintaining closed-door policy as regards both east and west, but satisfied to remain vassal to China, and it treated with contumely Tokyo's overtures in 1868 and the following years. Except for fear of Russian or British intervention. war between the two countries would probably have begun in 1873. As a substitute for hostilities. Japan imposed independence upon Korea by the treaty of Kianghwa, Feb. 26, 1876, thereby following French precedent established in Annam approximately two years earlier. Little attention was paid by the west to this indication of Tokyo's determination to upset the balance of power in the far east. Henceforth until its annexation by Japan in 1910 Korea was a paralytic upon the international highway.

In part incidental to the buffeting of Korea; in part as a result of Japan's broader aims; in part because of ancient differences, nonmaterial as well as material, between Chinese and Japanese. war broke out between China and Japan in 1894–95. Japan's easily won victory led to the treaties of April 17, 1895, and July 21. 1896. Japan. by virtue of the most-favoured-nation clause plus rights not hitherto granted to aliens, obtained a position vis-à-vis China stronger than any hitherto held by a western power. Formosa and the neighbouring Pescadores were ceded to Japan; thus the maritime approaches to China were brought under Japanese control and Japan obtained an important base from which to advance indefinitely southward and westward. Likewise ceded—temporarily—was a considerable section of southern Manchuria including mainly the Liaotung peninsula. Indemnity was paid which strengthened Japan's preparation for its second challenge to the west.

Defeat of China and annexation by Japan of territory on the mainland upset the diplomatic equilibrium. Great Britain, having found it impossible to persuade the continental European powers and the United States to intervene in the struggle against Japan, concluded that the friendship of Nippon would be valuable in obstructing Russia's advance. The foundations were laid for the Anglo-Japanese alliance of 1902; and China was conditioned for the secret defensive alliance with Russia of 1896. This alliance, helpful to Russia during the next eight years in its expansion into Manchuria, did China no more good than had art. ii of its treaty of 1871 with Japan. Russia and Germany were determined that Japan must not advance onto the continent, especially in the quarter earmarked as their own preserve, and, with France, they intervened to prevent Japan taking over Manchurian territory. Wounded and furious, Tokyo permitted Peking to pay an additional indemnity and relinquished, temporarily, its hold on Liaotung.

The Early 20th Century.— That nature abhors a vacuum has rarely been more clearly illustrated than during the years 1895–1903 in the scramble for concessions in China and the ensuing Boxer tragedy. Among the concessions made by the Manchu government were the leases, with additional rights, during 1898 of Kiaochow in Shantung to Germany; of Port Arthur (Lii-shun) and Dairen (Ta-lien) on the Liaotung peninsula in southern Manchuria to Russia; of Kwangchowwan in Kwangtung to France; of Weihai-wei in Shantung and the Kowloon peninsula close to Hong Kong to Great Britain. The Manchu empire would almost certainly have been divided by the continental European powers had they been able to agree among themselves and nith Great Britain and the Cnited States. This being impossible. the form of empire and part of its content were preserved, largely through the operation of the power balance. Japan was not yet in condition "to put meddling poners in or [out of] their places" and to attempt to control all of China. Great Britain and the United States had more to gain from trade with the empire as a whole than from exploitation of one annexed part, while at the same time being excluded from the parts annexed by other powers.

The year 1898 marked the flood tide of concession bagging in China and also the transformation of the United States into a Pacific and Asiatic power by the annexation of the Hawaiian and the Philippine islands. In September and November of 1899, partially at the instigation of London, the more than century-old U.S., and English, policy in China of most-favoured-nation treatment (meaning equality of opportunity — but in practice not solely — with reference to trade and commerce) was re-enunciated. Henceforth it was known as that of the open door. The corollary policies of territorial integrity and administrative entity were laid down officially by Secretary of State John Hay on July 3, 1900, during the course of the Boxer outbreak. These policies were formulated primarily in defense of United States (and British) interests; incidentally they were favourable to China and were formally recognized by that state in the nine-power Washington treaty of 1922.

The struggle over China south of the Great Wall was one open to all. The simultaneous struggle for Manchuria and Korea was a relatively more exclusive affair waged between Russia and Japan. Back of the latter, but not very far back, was Great Britain, an ally after Jan. 30, 1902. Great Britain stood by when Japan, having been unsuccessful in persuading Russia to divide Manchuria and Korea with it, struck without declaration of war on Feb. 8, 1904. By the war of 1894–95 China had been eliminated from Korea; by that of 1904–05 Russia was likewise eliminated. Moreover, it was thrust from southern back to northern Manchuria and required to cede to Japan the southern half of Sakhalin. As it had after 1871 so after 1905 Japan made clear its decision to "stand with European countries" in exploiting China rather than, in co-operation with the United States, to aid China to modern nationhood. By this choice Japan came increasingly to look upon China. Europe and the United States as basically its enemies instead of its friends, actual or potential.

Throughout the course of the Russo-Japanese War the neutrality of the United States was friendly to Japan. In April 1905, consequent upon Tokyo's intimation that the U.S. president's good offices were desired to end the war, Theodore Roosevelt stipulated that Japan should maintain the open door in Manchuria and restore that area to China. To this Jutaro Komura, minister for foreign affairs, agreed. Both provisions mere incorporated into the Portsmouth treaty. On Aug. 12, before the signing of the treaty on Sept. 5, the Anglo-Japanese alliance was renewed. By the secretly negotiated Taft-Katsura executive agreement of July 29, 1905, which was based perhaps on President Roosevelt's fear that Japan might attack the Philippine Islands and Japan's desire that the Washington government should maintain a complaisant attitude with respect to Japanese-Korean relations, the United States became a silent partner in the Anglo-Japanese alliance until the Roosevelt administration came to an end on March 4, 1909. The second Anglo-Japanese alliance and the U.S.-Japanese agreement contributed directly to the annexation of Korea.

In 1907, two years after Portsmouth, Japan signed agreements with France and Russia providing for continuance of "sphere-of-influence" and "special-interest" policies in China, a practical nullification of the open-door policy. Successive agreements between Russia and Japan foreshadowing their ultimate absorption of Manchuria and Inner and Outer Mongolia were signed in 1910, 1912 and 1916, the last a secret treaty of alliance which related to "China" and not merely to its dependencies. The 1917 revolution in Russia rendered this secret alliance valueless.

From the ending of the Russo-Japanese War to the outbreak of World War I in 1914, Russia. France, Great Britain and Japan dominated China in almost complete disregard of the United States and its open-door policy. Abdication of the Manchu dynasty (1912) and the establishment of a republic in place of the monarchy considerably aided occidental — including U.S.—and oriental imperialists of all types; *e.g.,* the land-hungry British in Tibet as well as the French. Russians and Japanese elsewhere, the railway concessionaires, exploiters of mines and other sources of raw materials, investment bankers and others.

World War I and After. — Japan took advantage of Europe's absorption in World War I to try to "become the chief nation of the orient" and the western Pacific. The Germans were expelled from Kiaochow following a declaration of war, but Japan consistently refused to send military forces to Europe; the German islands in the Pacific north of the equator were seized; Japanese and British fleets eliminated German naval forces from the Pacific and the Indian oceans; the Japanese naval forces performed valuable services in the Mediterranean in exchange for Britain's promise to support Tokyo's claims to become Germany's heir in the far east.

Tokyo wanted more than Germany's possessions in China and the South seas. In the autumn of 1914 there appeared another of the revelatory documents which so often marked Japan's advances to empire. Known as the Black Dragon memorandum, this one called on the government to "decide upon a course of action towards China which shall be practical in execution." The means was to be "a defensive alliance with [China] under secret terms" by which political, financial and military control of the sometime suzerain would fall to the sometime vassal. With characteristic abruptness Japan presented to Pres. Yuan Shih-k'ai, on the night of Jan. 18, 1915, 21 demands in five groups making clear, among other things, Japan's will with respect to: Shantung, South Manchuria and eastern Inner Mongolia; the future joint control of the Han-yeh-p'ing (iron-mining and iron-smelting) company; the nonalienation of Chinese coastal territory or waters to a "third power"; Japanese Buddhist "missionary propaganda in China"; the employment of Japanese political, military and financial advisers; Japanese railway construction; purchase of munitions from Japan; and Japanese priority in the lending of funds to China.

Of the powers, the United States was the only one in a position to challenge the Japanese actions. Following the dispatch of an ultimatum by Tokyo to Peking, both governments were informed by Washington that it could not "recognize any agreement or undertaking ... impairing the treaty rights of the United States and its citizens in China, the political or territorial integrity of the Republic of China, or the international policy relative to China commonly known as the Open Door policy." Here was clearly foreshadowed the American nonrecognition doctrine announced by Secretary of State Henry L. Stimson on Jan. 7, 1932, as a result of Japan's later aggressions in Manchuria. Nevertheless, Secretary of State William Jennings Bryan had earlier declared that with respect to "Shantung, South Manchuria and east Mongolia, the Cnited States frankly recognizes that territorial contiguity creates special relations between Japan and these districts."

Two Sino-Japanese treaties, with accompanying exchanges of notes, were signed on May 25, 1915, by which Peking acceded to part of the demands, others having been postponed for later consideration. The position of Japan in regard to South Manchuria, eastern Inner Mongolia, Fukien and the Han-yeh-p'ing company was strengthened. Although Japan did not obtain all it had demanded. its aims had been made abundantly clear; these aims, and more, were held as goals during the next quarter century. Not ratified by the Chinese parliament, as constitutionally required, the treaties of 1915 were never considered valid in China by either government or people. Despite Tokyo's objections China entered World War I in Aug. 1917. Thereby it obtained membership in the Paris peace conference and ultimately in the League of Nations.

The peace conference of 1919 (see PARIS, CONFERENCE OF) proved as rich a seedbed for war as any in world history, the east equaling the west in the gravity of issues involved. However, many of the factors contributing to renewal of hostilities long antedated the meeting in Paris; *e.g.,* Sino-Japanese antagonism and the demand for racial equality advanced by the Japanese. In general they were successful in their claims as heir to Germany in Shantung and the northern Pacific islands. The mandating of these archipelagos to Japan constituted another advance southward by water to balance land extension westward. On the racial question the Japanese and the other "coloured" peoples of the earth were defeated.

The rebuffs sustained by China at Paris brought to the fore a strong feeling of resentment against the west. Elsewhere in eastern Asia frustrated national feelings also were powerfully stimulated by Wilson's promise of "self-determination." Many thousands of Koreans made clear their attitude toward their Japanese overlords by a wide-scale peaceful demonstration in 1919 in favour of freedom. The relations of the Indochinese and their French masters improved despite the general attitude of Paris that liberty, equality and fraternity were better suited to French citizens than to Asian subjects. In 1927 the government council for Indochina was reorganized on a membership basis of 25 natives to 35 aliens. In Siam significant steps toward sovereignty were taken when new bilateral treaties were negotiated between 1920 and 1926 to replace the former unilateral treaties.

The Bolshevik revolution of Nov. 1917 caused confusion throughout the Russian empire, dissolved the Russo-Japanese alliance of 1916 and gave the expansionists of Japan an opportunity for the invasion of Siberia. In May and September 1918 the largely Japanese-controlled Peking government signed military and naval pacts with Tokyo for joint operations in Siberia. In July Vladivostok was seized by the allied and associated powers. Japan, France. Great Britain and Belgium desired intervention and at length the Wilson administration proposed to Tokyo a joint Siberian expedition. Contrary to preliminary agreement, Japanese forces greatly outnumbered those of any other intervening power and friction between the United States and Japan appeared for a time before the Armistice in Europe to threaten hostilities. Early in 1920 all intervening troops except those of Japan were withdrawn; the Japanese forces were increased to strengthen their hold on the Transbaikal and maritime provinces and to enable them to seize the northern half of Sakhalin. which they held until the spring of 1925. Intervention, particularly the actions of the Japanese, directly contributed to reunification of Russia under the Bolsheviks. Japanese forces were finally withdrawn from continental Siberia in the autumn of 1922.

Relations between the United States and Japan were not improved by their co-operation in Siberian intervention but were later somewhat brightened by the treaties and agreements negotiated as a result of the Washington conference (*q.v.*). This meeting of the representatives of nine states in or having important interests connected with the far east—but excluding the Russians—was convened in the hope of solving problems threatening the peace of east and west alike. Outstanding among the questions considered were those of U.S.-British-Japanese naval rivalries, renewal of the Anglo-Japanese alliance of 1911 and Sino-Japanese-occidental relations. From the sessions, held Nov. 1921 to Feb. 1922, emerged 7 treaties and 12 resolutions (*see* WASHINGTON, TREATIES OF). Two other treaties were signed outside but during the period of the conference. These mere the Sino-Japanese Shantung agreement and the U.S.-Japanese settlement of the issue over Yap, an important cable station in the Pacific.

The Anglo-Japanese alliance. as unpopular in parts of the British empire as it was in the U.S. (now that Japan rather than Russia appeared to threaten the balance of power in eastern Asia), was superseded by the four-power Pacific treaty. Great Britain, Japan, France and the United States each agreed for a period of ten years to respect the others' position in the Pacific. Japan was considerably strengthened by this agreement, but naval rivalries were temporarily allayed by it and by the five-power naval treaty which fixed a capital-ship ratio of 5–5–3–1.67–1.67 for the United States, Great Britain, Japan, France and Italy respectively, and restricted fortifications in the Pacific.

China participated in the Washington conference in the hope of solving its external problems, particularly those related to limitations on its sovereignty imposed by the unilateral treaties and the treaty-port system. But the position of the foreign powers in China was little affected. The continued confusion in China and the limited evidence offered by the governments and people of that country of their ability to meet the obligations of a sovereign state led the western nations to maintain their special privileges.

By the Sino-Japanese Shantung treaty earlier mentioned, the former German-leased territory of Kiaochow was returned to China—Japan retaining large commercial interests therein and otherwise safeguarding its financial interests in Manchuria. Japan's position was further enhanced inasmuch as the 191 j treaties were fruitlessly protested by the Chinese representatives.

A nine-power "treaty regarding principles and policies to be followed in matters concerning China" was signed on Feb. 6, 1922. The contracting governments, other than the Chinese, bound themselves to respect the sovereignty, independence and territorial and administrative integrity of China and to afford that distracted country opportunity to establish effective rule; also to use their influence toward maintenance therein of the open-door principle. In turn, China undertook for the first time to be guided by this principle. Noble in conception, the nine-power treaty lacked two requisites for a solution of the problems with which it dealt: ability and willingness on the part of the cosignatories, including China, to carry into effect its promises and provisions.

The Washington settlement of 1922 was based primarily upon U.S.-British policies. To a considerable degree it was favourable to China, although the safeguarding there of most of the foreign rights and interests made it clear that that country had failed to attain a majority of its declared objectives. Japan's short-run position was felt to be strengthened but potentially it was weakened —from Japan's viewpoint at least—since an actually independent and strong China must divert Japanese expansion into other channels.

Maintenance of the status quo as desired by Washington and London was unlikely to be long tolerated by Tokyo or Peking or Nanking, and assuredly not by Bolshevik Moscow. Russia's urge to the east and its influence there were about equally marked under tsars and commissars—to the increasing wrath and fear of Japan. No less fear stimulating and wrath inspiring were the development of nationalist-militarist-industrialist-capitalist Kuomintang China and nationalist-militarist-agrarian soviet China, inspired respectively by the U.S. and Britain and by the U.S.S.R. By war and diplomacy Japan attacked both Kuomintang-nationalist and soviet-nationalist China. The Chinese, disunited but determined to recover unity, along with lost sovereignty, territories and national dignities, continued in the third and fourth decades of the 20th century, as they had in times of weakness through the ages, to play off one power or group of powers against another. In the 15 years preceding the outbreak of war in the Pacific in 1937, they made marked progress in removing some of the causes of domestic weakness that had forced them to fall back on such uncertain means of nrotection.

Time after time during the preceding four centuries the far eastern problem had reflected the power struggles of Europe. This was the case with Russo-Chinese relations after 1920, when, having failed to bolshevize Europe, Lenin and his co-workers attacked the western nations through their Asiatic possessions. In China south of the Wall. in Manchuria, in Outer Mongolia and in Sinkiang, the impact of Bolshevism was felt by the Chinese. Tsarist privileges and concessions were largely renounced mhile revolutionary ideology was widely disseminated, and wherever possible the nationalist aspirations of colonial and semicolonial Asia were encouraged. Outer Mongolia was sovietized despite Moscow's recognition of China's sovereignty therein. Throughout the first third of the century the political and social confusion prevailing in China aided both native and foreign predatory elements.

Sun Uat-sen, leading anti-Manchu revolutionary, for a few weeks in 1912 provisional president of the Chinese republic and for 13 years thereafter chief southern opponent of northern Chinese militarists and their Peking governments, strove, while alternately in and out of office in successive revolutionary governments at Canton, to obtain help from the western powers in the implementation of his social. economic and political policies. Disappointed and embittered he turned to Russia early in 1923, and that country, through the third international, sent him political and military advisers and other aid. Reorganized and revivified, the Kuomintang within five years brought most of China under its control, split with and expelled the Russian advisers and established a national government at Nanking. The break between the Kuomintang and the Muscovites in the summer of 1927 marked the failure of the third international's offensive in Asia but it did not end soviet influence in China. This was demonstrated by the sporadic struggles between the Kuomintang and the Chinese soviets during 1927–41, and by the inability of Nanking to eradicate the communist movement as a political and military threat.

Consequent upon Stalin's three five-year plans (1928–42), Siberia — western, northern and eastern — was developed as a potential base of military action. Before these plans could be fully realized, however, Japan's seizure of all Manchuria (1931–32) threatened eastern Siberia, especially rail communications between Moscow and Vladivostok. The Chinese Eastern railway, a product in part of the Sino-Russian secret alliance of 1896, which soviet diplomats had maintained a firm hold on hitherto, was sold in 1935 as a matter of expediency to the Japanese puppet state of Manchoukuo.

Offsetting Japan's advance into northern Manchuria and Inner Mongolia were soviet construction of the Baikal-Amur railway; development of new towns, ports, engineering and industrial projects — conspicuously that of the Angara-Yenisei riverine area — in eastern Siberia; opening in 1932 of the Eurasiatic sea route via the Arctic ocean; double-tracking of parts of the Trans-Siberian railroad; and continued manifestation of Russian interest and influence in Sinkiang, bordering which, not far to the west, the Turkistan-Siberian railway had been completed in 1930.

In 1935 the government of the new commonwealth of the Philippines (preliminary to the attainment of independence by those islands on July 4, 1946) was inaugurated. In that same year, the popular front was adopted by the seventh congress of the third international (*q.v.*). Repercussions of this policy were felt both within China and between China and Japan. Sino-Japanese hostilities were renewed on July 7, 1937. In partial reply to the popular front, and as a precursor to the outbreak of hostilities, the anti-Comintern pact between Nazi Germany and Japan was signed on Nov. 25, 1936. Shortly thereafter adhered to by Italy, this agreement led directly to the triple military alliance of Sept. 27, 1940.

Other events and conditions also made apparent the determination of Japan's militarists to build a new far east consonant with their national mythology and political philosophy. On April 17, 1934, the so-called Amau declaration (after Amau Eiji, a foreign ministry spokesman) was issued. In direct defiance of the open-door doctrine, this declaration enunciated Tokyo's claim to act alone as guardian of "peace and order in eastern Asia," definitely discouraged joint operations by foreign powers in aid of China and expressed determined opposition to their "supplying China with war planes, building airdromes . . . and detailing military instructors or military advisers . . . or contracting a loan to provide funds for political uses." On Dec. 29 of the same year, Tokyo notified of its intention to withdraw from the naval limitation treaty of Washington as of Dec. 31, 1936. A naval race, hitherto avoided, was now begun — immediately by Japan, tardily by the United States — and in less than one year from the expiration of the treaty the U.S.S. "Panay" and three United States merchant vessels were bombed on the Yangtze (Dec. 12, 1937) by Japanese airmen.

Acceptance by Washington of Tokyo's hasty assurance of regret, accompanied by indemnity, contributed to a delay of almost four years before full-dress war broke out between the two chief rivals in the Pacific. This delay permitted U.S. citizens to sell limited quantities of goods on a cash and carry basis to China, and practically unlimited quantities to Japan. The sales to Japan made possible not only that country's sustained attack on China but the destruction, in China, of U.S. lives, property and moral reputation.

World War II and After. — During the years 1938–40 Washington indicated disapproval of Japanese actions in China by loans to China to be repaid in wood oil and tin; by announcing, in Dec. 1938, as if in rebuttal of the Xmau presumption: "This government does not admit . . . that there is need or warrant for any one power to take upon itself to prescribe what shall be the terms or conditions of a 'new order' in areas not under its sovereignty and to constitute itself the repository of authority and the agent of destiny in regard thereto"; by gradually limiting, practically to the point of elimination, exports of commodities needed by Japan's air forces; and by abrogating as of Jan. 1940 the U.S.-Japanese trade treaty of 1911. In China itself the war ground on. Both the nationalists and communists pursued a policy of exchanging territory for time: persevering against Japan through a period of stalemate, exhausting that country while strengthening China and finally counterattacking. Japan, frustrated in China after 1938, decided to seize upon the confusion of western Europe and concluded (April 13, 1941) a five-year nonaggression pact with the U.S.S.R. Despite the opposition of the United States, Japan also decided to effectuate at last its long-meditated policy of advancing into southeastern Asia and the southwestern Pacific. All this brought about increased tension. U.S. Ambassador Joseph C. Grew warned from Tokyo in Jan. 1941 that a surprise attack might be expected. But no agency of government or military authority in the United States was prepared for the Pearl Harbor attack of Dec. 7, 1941. Bitter efforts were made to determine the responsibility for America's unpreparedness, but to little avail.

(H. F. MacN.; D. F. L.)

From 1937 to 1945 China lived in a state of siege. The united front between nationalists and communists permitted both Chinese groups to battle the Japanese while maintaining a truce with each other. After 1941, as the major western powers gradually began to take the lead in the war against Japan, the nationalists and communists became determined to resume their civil war for control of China. Pres. Franklin D. Roosevelt sought by all means to keep China actively engaged in the war against Japan, and continuously worked for the elevation of China to a position of international leadership and heir to Japan as the leading power in the far east. In this policy Roosevelt had neither the wholehearted support of his European allies nor of the Russians, even though all of the antifascist powers recognized and nominally, at least, supported the national government of Chiang Kai-shek.

Chiang (Soviet *Russia* in China, 1957) asserted that "once the war was over, Moscow immediately unleashed its comprehensive plan to conquer China from without and subvert her from within." Though it was not all this simple, Russia certainly took a greater interest in the future of Chinese communism at the end of the war than at the beginning. At the Yalta conference of Feb. 1945, President Roosevelt, under pressure to obtain Russian participation in the war against Japan at the earliest possible date, acceded to a number of Stalin's demands in the far east and promised to secure Chiang's assent. In return for U.S. co-operation, Stalin agreed to conclude a pact of friendship and alliance with the national government of China.

While Russian forces prepared to move against the Japanese in northeastern Asia, a Sino-Soviet treaty was being worked out in Moscow in July 1945. By its terms Russia reaffirmed its formal recognition of the Kuomintang government, its respect for China's full sovereignty over Manchuria and its determination not "to interfere with China's internal affairs." On their side the Chinese agreed to joint ownership of the Manchurian railways, joint use of Port Arthur as a naval base and the opening of Dairen to all nations as a free port. It was also agreed to hold a plebiscite in Outer Mongolia on the question of independence, the result of which was the declaration of Mongolian independence in the fall of 1945.

The final decisions in northeastern Asia, however, were not to be made at the conference table or by voting, but rather by force of arms. While Japan writhed in military defeat, Russian forces carried out an extensive occupation of Manchuria. The surrender of Japan in 1945 was the signal for the opposing forces in China to advance their respective causes. Each side was particularly anxious to gain control over Manchuria, the strategically and economically vital nexus of northeastern Asia. But for the nonce the Russians occupied Manchuria and their inclination was to allow the Chinese communists gradually to take over strategic points and key cities. While the nationalists protested, seconded by dispatches from Washington, no military pressure of consequence could be brought to bear on the firmly entrenched Russians. By the time the Russians carried out a formal withdrawal in the spring of 1946, the Chinese communists had acquired arms, a firm foothold and a staging ground for their subsequent advances into China south of the Wall, where other communist units were already in operation. While Russia gradually moved to the support of the Chinese communists, the United States until 1947 promoted the nationalist cause in international agencies, continuing to give military and technical advice and aid to the Kuomintang armies, and to seek a peaceful solution to the Chinese civil war. The United States also tried to perpetuate the united front by urging both sides to compromise to the point where a coalition government might become viable. To this end Gen. George C. Marshall arrived in China in Dec. 1945 as head of a mediation mission. After a year of frustrating efforts, Marshall gave up his task in despair, concluding that "extremist elements of both sides" made compromise impossible to realize. While Marshall contemplated withdrawal, the United States signed on Nov. 4, 1946, a bilateral commercial agreement with the national government.

The failure of mediation was followed shortly by the withdrawal of U.S. military forces from China. Washington decided to postpone further activities there to concentrate on the containment of communism in Europe. As "the dust settled" in China, it became ever more obvious that time favoured the communists. The Kuomintang government, which had had its chance since 1928, appeared 20 years later to have lost its popular appeal and revolutionary fervour. The communists, attributing most of China's ills to western capitalist exploitation, seemed to offer an opportunity for a fresh start on the road to internal stability, security and independence. Fighting alone, the forces of Chiang Kai-shek were unable to stem the communist advance that was clearly receiving encouragement and stimulation from Russia.

While it may be argued that no amount of U.S. support could have maintained the Kuomintang in power, it is clear that the withdrawal of troops and diplomatic support by the United States in 1947 hastened the collapse of nationalist China. By the autumn of 1949 the communists had taken over intramural China, and the remnants of the Kuomintang forces (numbering about 2,000,000) sought refuge on the island of Taiwan (Formosa), 90 mi. E. of Fukien province.

The proclamation of the People's Republic of China on Oct. 1, 1949, was followed by a complete repudiation of the old treaty structure and the inauguration of a Marxist foreign policy centred on the promotion of world revolution. The United States was clearly identified in Peking's pronouncements as the major "imperialist" enemy and the new regime committed itself to the side of socialism and to co-operation with the U.S.S.R. Peking let it be known that foreign relations in the future would be conducted on its own terms and without reference to China's past commitments. Foreign nationals in China were put under close surveillance, arrested or forced to leave. Diplomatic installations and other foreign properties were seized and strict limitations were imposed on western missionary and educational activities. As a precondition for normal diplomatic relations, Peking demanded from the other nations immediate recognition, severance of ties with the nationalists and China's seat on the Security council of the United Nations.

The first nation to conclude a treaty with the new Peking regime was Russia. On Feb. 14, 1950, the cornerstone in their relations was laid in a bilateral treaty and two subsidiary agreements concluded in Moscow, and notes were exchanged to render null and void Russia's treaty of 1945 with nationalist China. By the terms of these agreements Russia retained a place in the border states, control over which had long been in dispute between the two nations, though the Manchurian railways were to revert to China by 1952. Nominally the treaty was a military agreement against Japan, but in reality it was aimed at "any other state that may collaborate with Japan in acts of aggression." Clearly the prime target was the United States, the country mainly responsible for the occupation and rehabilitation of Japan after 1945. Russia also agreed to advance credits to China, and provisions were made for economic and cultural interchange. Meanwhile, Peking began military action against Tibet to bring that ancient theocracy under its sway before serious interference could come from the outside world.

The future of relations with communist China was hotly debated after 1949 in the UN and among the foreign ministers of the various western countries. In the early months of 1950 Washington pursued a policy of watchful waiting, while Britain and several other western European countries extended legal recognition to the new Peking regime. Russia, in the same period, began to call for the unseating of nationalist China in the UN and for the immediate seating of communist China on the Security council as the government exercising "effective authority" on the China mainland. Any possible success of such efforts was checked by the outbreak of the Korean war on June 25, 1950.

The end of Japanese control over Korea in 1945 brought with it a "temporary" division of the peninsula at the 38th parallel for the purpose of accepting the Japanese surrender. North of this arbitrary line Russian troops carried out the occupation. and south of it U.S. forces disarmed the Japanese and operated under an interim military government. Meanwhile the fires of Korean nationalism, which had been relighted by the spark of hope contained in the Cairo declaration of Dec. 1943 that Korea "in due course shall become free and independent," began to spread both north and south of the parallel. As nationalist leaders jockeyed for position in the ensuing political scramble, the problems of the occupying forces increased. While Koreans tried to stake out their own future, the decision was being taken out of their hands by international arrangements. At the Moscow council of foreign ministers in Dec. 1945 a four-power (United States. U.S.S.R., Great Britain and China) trusteeship mas agreed upon "to prepare Korea for its independence within five years." But this was about all on which Russia and the United States could agree, and after 1945 their military commands went ahead with separate and differing programs designed to lay the foundations for Korea's independent future.

In northern Korea the Russians quickly carried forward a swift economic and social revolution in conjunction with native communist leaders. In the U.S. zone a more gradual program of reorientation was instituted, without much advice or co-operation from native groups. In 1947 the United Nations sent a team to Korea to help in the reunification of the peninsula and to seek ways for bringing an end to the occupation. Despite protests from the Soviet Gnion that it had no jurisdiction in Korea. elections were held in Korea on May 10, 1948, under the supervision of the GN commission. Syngman Rhee and his cohorts emerged victorious from this election, which was conducted mainly south of the parallel, and thereafter went ahead with the organization of a permanent government which claimed jurisdiction over the whole of the country. In the north the communist-sponsored government set itself up on a permanent basis and also claimed to be the legitimate government of the entire peninsula.

The proclamation of the two permanent governments, each claiming the other to be illegal, brought about a local and international stalemate in Korea. Russia recognized and supported the northern government at Pyongyang, and the U.S., supported by the UN. recognized and aided Rhee's government at Seoul. All the parties were dissatisfied by this impasse, and the northern regime sought by propaganda and subversion to undermine Rhee's power. The victory of the communists in China in 1949 encouraged North Korea to even more overt attacks upon its southern rival, culminating in the outbreak of civil war in June 1950.

The armed invasion of South Korea by North Korea was immediately denounced by the Security council of the UN as a breach of the peace. Shortly thereafter C.S. sea and air forces were dispatched from Japan to aid the fleeing South Koreans, and the Security council invoked military sanctions against North Korea. Such a decision was possible because the Soviet Union had temporarily withdrawn from the Security council in an effort to push the UN into recognition of communist China. Officially the communists took the position that no international frontier had been transgressed and that the Korean civil war was legitimately only of concern to the Korean people. Meanwhile U.S. ground forces and British and Australian fleet units were rushed to the scene. Gen. Douglas MacArthur took command of the UN forces nhich fought desperately in the summer of 1950 to retain a toehold in Korea, and which launched a counteroffensive in the autumn that moved swiftly northward.

On the first anniversary of its inauguration, the Peking government warned on Oct. 1, 1950, that it would not stand idly by should "the imperialists wantonly invade the territory of North Korea." MacArthur's forces, nevertheless, continued their northward drive and in mid-October took Pyongyang. By Nov. 1 Chinese "volunteers" in constantly increasing numbers began to appear in North Korea. MacArthur soon proclaimed to the Security council that a "new war," clearly of international magnitude and of greater potential danger to the peace of the rest of the world, was in the process of breaking out in Korea.

The first UN attempt to negotiate the Korean war took the form of an invitation to Peking to send representatives to Lake Success in Nov.-Dec. 1950. While the battle raged in Korea, the Peking delegation charged the United States with aggression in Asia. It was alleged that the United States was the only outside force that persisted in intervening in eastern Asia, that it occupied Japan, that it led the intervention in the Korean civil war and that Washington had resumed its policy of interfering in the Chinese civil war by its decision of June 27, 1950, to seal off the island of Formosa from the mainland. On its side the United States took retaliatory measures in Dec. 1950 by seizing Chinese communists' assets in the United States, by proclaiming an embargo on trade with the China mainland and by advancing additional credits and support to Chiang Kai-shek. On Jan. 20, 1951, the United States introduced a resolution in the UN asking that communist China be branded an aggressor in Korea. Though the Arab-Asian bloc called for compromise, the general assembly on Feb. 1 approved the U.S. resolution, thereby declaring Peking the aggressor in Korea. At this point it seemed as if the war in Korea must settle down to a war of attrition that might at any time precipitate a general war.

In the spring of 1951 the "great debate" over possible future action raged in the U S. MacArthur and a highly vocal minority wanted to bring the stalemate to a quick end by an attack on China directly. The Truman administration, acutely aware that U.S. policies were not winning approval in western Europe or with the Arab-Asian nations, preferred to follow a less drastic policy. The climax in the "great debate" came with the dismissal of MacArthur on April 11, 1951. Though the military stalemate in Korea continued, both sides agreed in the summer of 1951 to inaugurate negotiations for a truce. After repeated deadlocks over a demarcation line, truce teams and exchange of prisoners, a truce agreement was finally arrived at on July 27 (Korean time), 1953.

The Korean war lasted more than three years; the truce talks dragged on for the last two years while the fight continued. Casualties were high for all the parties, especially the Koreans. Over 1,000,000 persons were killed, 2,500,000 found themselves homeless and property damage was estimated at more than $1,000,000,000. Korea remained disunited, devastated and hungry. Perhaps the greatest positive accomplishment of the war was the UN's success, costly as it was, in halting defiant aggression and proving to the Peking regime that it could not act unilaterally and arbitrarily without fear of military retaliation.

While waging war in Korea, the United States was also occupied with bringing the occupation of Japan to an end and preparing Japan for reinstatement in the family of nations. The occupation that had begun with the surrender of Japan in Aug. 1945 went through two phases. Originally it was the objective of MacArthur and the SCXP (supreme commander Allied powers) organization to demilitarize, democratize and re-educate Japan. Beginning in 1948, as conditions in Europe and China became more favourable to the spread of communism, the major objective of the occupation came to be the economic rehabilitation of the country. Though Australia, the Philippines and others protested, the U.S. concern with the spread of communism led MacArthur to adopt policies which aimed at making the Japanese economy viable in an effort to keep Japan from following China down the road to communism.

The United States also took the lead in negotiating a peace treaty with Japan as a cornerstone for future relations. MacArthur proclaimed in March 1947 that Japan was ready for a peace treaty. Immediately a conflict developed between the Cnited States and Russia over procedure, and so for about two years little was accomplished. The spread of communism in eastern Asia led the United States in 1949–50 to press for a Japanese peace treaty, whether or not the communist states were agreeable. Though the Japanese socialists opposed a "one-sided treaty" from the beginning, Washington in the spring of 1950 inaugurated diplomatic conversations and written exchanges with those noncommunist nations which had waged war against Japan. The outbreak of the Korean war in the summer of 1950 highlighted for even some of the most skeptical countries the importance of working out a clear-cut peace formula with Japan. Over the course of the following year a treaty was worked out that was found acceptable by most of the noncommunist nations.

From Sept. 4 to 8, 1951, Japan and its former enemies met in San Francisco to sign the treaty and accompanying agreements. The Russians attended the conference to register their protests, but they refused to sign the treaty. Forty-nine nations, including Japan and a protesting Indonesia, finally signed the document that formally brought to an end the state of war. The treaty acknowledged the return to Japan of full sovereignty over its four main islands and their territorial waters. But Japan was required to recognize the independence of Korea and to renounce all rights to Formosa, the Pescadores, the Kurils, south Sakhalin, the former mandated islands, Spratly and the Paracels. About the Luchu (Kyukyu) Islands and the Bonins, Japan was required to "concur in any proposal of the United States to place them under its trusteeship system." In China, Japan was forced to give up all "special rights and interests." Finally, Japan was obligated to negotiate reparations claims made by countries that had suffered from Japan's wartime depredations. A separate treaty was signed with the United States on Sept. 8 permitting the establishment of American "land, air, and sea forces in and about Japan" with an accompanying promise that similar rights should not be granted "to any third power" without Washington's consent.

The peace treaty and the accompanying security pact did not go into effect until April 28, 1952, and shortly thereafter the occupation of Japan formally ended. Japan's subsequent foreign policy centred upon the problem of increasing exports, maintaining security in a bipolarized world, re-establishing economic and political ties in eastern Asia and in winning admission to the United Nations. For over four years the U.S.S.R. vetoed Japan's admission to the United Nations. But finally in Oct. 1956 a Japanese-Soviet joint declaration was signed in bloscow to restore normal relations between the two countries. Two months later Japan's application for admission to the United Nations was approved, thus enabling Japan for the first time since the war to have an independent voice in the decisions of the nations.

Divisions of opinion over the Korean war and the Japanese peace treaty brought about tensions between the United States and its western European allies. But the issue of Taiwan (Formosa) provoked even more division in policy. Beginning in June 1950 the United States again lent its support to the nationalist cause and in so doing was accused in Europe, Africa and Asia of meddling in the Chinese civil war. Peking persisted in claiming legal jurisdiction over Taiwan and its claims were supported by the communist nations and by the 15 noncommunist states that recognized the government of Mao Tse-tung. In spite of the denunciations of the communists and the protests of other less interested states, the United States after 19jo consistently championed the nationalist cause through military, technical and psychological aid. This policy was based on the belief that Taiwan in the hands of the communists would endanger Japan, Okinawa, the Philippines and southeast Asia. It was also based on the hope that the continued existence of a noncommunist China would give the Chinese, both inside China and in the overseas world, an alternative to communism.

On Formosa itself the direct support from the U.S. made the island of over 10,000,000 people into a heavily armed fortress. Nonmilitary aid helped to strengthen the island's economy which had always been rich in rice. While the Kuomintang government rectified many of its past errors, it continued to maintain tight political control over the island. Its position was strengthened by

U.S. support, and particularly by the conclusion in 1954 of a mutual defense pact. By its terms the United States guaranteed to protect Taiwan and the Pescadores from "armed attack and communist subversive activity directed from without against their territorial integrity and political stability." Meanwhile. Chiang and his cohorts continued to prepare for the day when they would return to the mainland. The communists on the mainland continued to inveigh against the American "imperialists" and promised that they would never relinquish their claim to Taiwan.

Though the United States successfully helped Taiwan remain free of communist control, Peking won a degree of success in Indochina after the conclusion of the Korean truce in 1953. French authority in this peninsula had been seriously undermined during the war, and after 1945 the Indochinese national movement fell increasingly under the influence of the communists. The United States and Great Britain, while fearing the spread of communism into Indochina, urged their French ally to follow the path of negotiation rather than war. For even after seven years of bitter war few permanent successes had been won by French arms. Finally, it was agreed to convene a conference of the four major powers to which Korean and Indochinese representatives might present their conflicting views.

The conference opened at Geneva on April 26, 1954. After three months of parley, the Korean phase of the discussions ended in a deadlock. On July 21, just one year after the initialing of the Korean truce, an agreement on Indochina was concluded despite the fact that the United States was not pleased with some of its conditions. France agreed to withdraw its military forces from the Red river delta, Hanoi and Haiphong, and the Vietminh (League for Independence) agreed to evacuate southern Vietnam and southern Laos and to respect the territorial and political integrity of Cambodia. A neutral commission made up of representatives from Canada, India and Poland was set up to supervise the truce. These agreements in effect permitted the communist-dominated Vietminh to control the northern half of the peninsula and its 12,000,000 persons. The southern half of Vietnam was to remain, temporarily as it turned out, in the hands of the French-approved ruler, Bao Dai. After 1954 few overt changes took place, but communist influence steadily mounted.

Fear of the spread of communism into southern Indochina and the other independent countries of southeastern Asia prompted the western powers under the leadership of the United States to lay foundations for a regional security program. The war and its aftermath had brought colonial control to an end in the Philippines (1946), Burma (1948), Indonesia (1950) and Malaya (1957). Thailand had always managed, though under great difficulty, to retain its independence. With the experiences of China, Korea and Indochina behind them, the leaders of the noncommunist nations, in conjunction with their colleagues in some of the newly independent states, began around 1950 to design a program for stopping the growth of communism in southeastern Asia.

The trend toward collective defense efforts began after it became clear that economic aid would not be enough to keep communism in check. In 1951 the United States, Australia and New Zealand concluded a Pacific defense treaty (known as Anzus), and in the following year organized a Pacific Defense council. At the Asian and Pacific peace conference held at Peking in 1952, the communists characterized the new defense operation as the old imperialism in a new dress.

Communists throughout the world were encouraged to do their utmost to sabotage the economic aid programs, such as Point Four and the Colombo plan.

After the debacle in Indochina, a conference of western and Asian nations was called at Manila for Sept. 1954. The result of this conference was the conclusion of the southeast Asia collective defense treaty and the publication of a Pacific charter. Eight nations took membership in SEATO (Southeast Asia Treaty organization; *q.v.*): Australia. France, New Zealand, Pakistan, the Philippines, Thailand, the United Kingdom and the United States. The object of the charter was to try to reassure the new nations of the benevolent intentions of the western powers and of their desire to see orderly political, economic and social progress in the new states. The treaty pledged the member states "to maintain and develop" their individual and collective capacities to resist armed attack and subversion directed against "the territorial integrity and political stability" of the countries of southeastern Asia, and the southwestern Pacific regions. The participants also agreed to collaborate on economic and technical programs and to establish a council for the co-ordination of their military programs. Conferences on problems of mutual concern were held at Bangkok (1955), Karachi (1956) and Canberra (1957).

Despite many such efforts to bring the other new nations of eastern Asia into alliance with the western powers, neutralism in Asia continued after World War II to grow as an international political factor of significance. After independence it was adopted as the official policy of the governments of India, Burma and Indonesia. And it was an attitude shared by many intellectuals within all the Asian countries. Its proponents asserted that their governments must limit their involvement with both of the great power blocs to preserve their national independence and to give themselves the opportunity to act as a third force in world affairs. Shortly after the end of World War II Prime Minister Jawaharlal Nehru of India sought through a series of conferences to develop regional solidarity, regional co-operation and even a permanent organization for the promotion of Asian unity. These efforts, based as they were primarily upon geographical ties, common problems and general hostility toward colonialism, achieved only a limited success. Nevertheless, the neutralist governments of Asia in combination with the Arab nations were able to throw their collective weight into international negotiations with considerable success. But, as in the case of Indonesia, it appeared that the cost of pursuing a neutralist foreign policy might come high and might have to be paid for in terms of economic dislocations, social unrest and even civil war.

Throughout the history of modern far eastern international relations, China has stood at the centre of affairs, with the possible exception of the period from 1905 to 1945. The major problem after 1949 was that of dealing with a China dominated by communism and closely tied. politically and economically, to the Soviet Union. The United States took the leadership in constructing a defense perimeter to halt the spread of communism through its program of mutual security treaties with Japan, Korea, nationalist China and the Philippines, through its part in the creation of SEATO and by its economic and technical aid programs. By the late 1950s no general far eastern settlement had been agreed to and as a result many issues remained unresolved in the area. At best it might be said that in the bipolarized world of the second half of the 20th century an uneasy truce had been established in the far east.

FAR EASTERN AREA, an administrative unit of Asiatic Russia, created in 1922, upon the fall of the independent Far Eastern People's republic; it occupies 1,072,817 sq.mi., but its population in 1939 was only about 2,338,095. On Oct. 20, 1938, the Far Eastern Area was subdivided into the following two regions:

(1) Maritime (Primorskaia) *Kray*, 64,788 sq.mi., including Ussuri region. Population (1956) 1,305,000; urban 861,000; rural 444,000.

(2) Khabarovsk *Kray*, 315,521 sq.mi., including the Jewish Autonomous *oblast*. Population (1956 est.) 1,140,000; urban, 811,000; rural 329,000.

Eastward from Chaun bay the Arctic ocean forms its northern boundary, and the Bering sea, the Okhotsk sea and the Gulf of Tartary wash its eastern shores. The Yakutsk and Buriat-Mongol Soviet republics lie to the west, the boundary running for the most part along the crests of the Anadyr, Stanovoi and Yablonoi mountains.

Mongolia, Manchuria and Korea lie to the south; the Peking convention of 1860 defined the boundary between Russia and Manchuria as following the Argun, Amur, Ussuri and Sungacha rivers to Lake Khanka, thence crossing the lake westward to the Pai-ling river, thence along a mountain range to the junction of the Hu-pu-tu (Khubtu) with the Suifen river, and thence along the Hunchun river, and along the range of mountains between that river and the sea, up to the Tumen river 6 mi. inland from its mouth. However, most maps show the boundary as running along the whole course of the Hu-pu-tu river. 'The ocean boundary lies along the Bering strait, separating Russia from Alaska and Lawrence island, and passes south of Cape Lopatka separating the Kurile isles from Kamchatka. The Commander islands, off the east of Kamchatka peninsula, and the part of Sakhalin island north of lat. 50°, form part of the Far Eastern area. Much of the area is unproductive, and difficulties of position, structure and climate combine to retard its development.

A great part of Kamchatka has not yet been topographically or geologically surveyed, and uncertainty exists as to the continuity of the Yablonoi and Stanovoi mountains, and as to the northeastern termination of the latter. The relation of the Great Khingan to the Stanovoi is also not yet worked out. Much of Kamchatka, both peninsular and continental, is occupied by mountains, and in the Amur region a range of granitic and schistose mountains, called the Little Khingan, or Bureya or Dousse Alin, runs parallel to the Great Khingan from the north bank of the Amur river, while still further east is the Sikhota Alin range, occupying most of the Maritime territory. The only volcanic activity is in Kamchatka peninsula, where a series of partly active and partly extinct volcanoes runs along the east coast. Kluchevskaya, 16,130 ft., is probably the highest active volcano in Asia.

The Trans-Baikal region, with the Selenga, Vitim and Aldan plateaus, forms part of a terrace rising 3,000 to 5,000 ft. above the general 1,200 to 1,500 ft. level of the high eastern plateau of Asia. Tundra occupies one-third of the Far Eastern area, and in addition part of north Sakhalin is tundra. If these tundra regions are excluded, 64% of the remaining land is forest clad.

The forests may be divided roughly into the following three groups:

(1) the Daurian type stretching from the west of Transbaikal to the Zeya river, consisting mainly of larch and birch, with open prairies which in spring become grassy seas, where the peony, aconite and similar blooms reach a height of 4 to 5 ft.;

(2) the Manchurian type, extending eastward from the Bureya river and southward along the western slopes of the Sikhota Alin range. The prevailing trees are fir, silver fir and Manchurian cedar, amongst which are sprinkled broad-leaved Manchurian varieties, *e.g.*, velvet tree, Greek nut, Manchurian ash, Mongolian oak and a few species of maple;

(3) the Okhotsk-Kamchatka flora occupying Okhotsk and Kamchatka, the eastern slopes of the Sikhota Alin, the northern parts of the Amur region and Maritime territory and the island of Sakhalin. It consists mainly of the Siberian fir and cedar, with a few birch, aspen, alder and poplar trees.

In spite of this wealth, the timber industry is little developed, partly because of the lack of road communication and sea tonnage and partly because of the lack of suitable port facilities; the capital to provide these is lacking. The Amur river forms an excellent summer waterway for timber, but Nikolaevsk at its mouth has no facilities for timber haulage and embarkation. The river is frozen from November to May and at Nikolaevsk to June. Therefore, Vladivostok is the main timber port, but the fact that timber must be carried by rail to it increases the cost and hence puts Russian timber at a disadvantage on the world market. Vladivostok also is the natural outlet for Manchurian timber, and with better dock facilities could double its trade. Oak, cedar, fir and planks of aspen for match manufacture are chiefly exported, while Imperatorskaya bay (now Soviet bay) exports soft woods to Australia, and Olga bay exports pit props. Attempts are being made to replace the export of raw timber by local industries dependent on timber, and match, veneer and plywood factories have been established in the Ussuri valley, while in Transbaikalia, the Amur region and the Maritime territory there are now more than 30 timber mills, those round Vladivostok manufacturing barrels for the fishing industry. At Spasskaya (Yevgenevka) on the Ussuri railway, is a factory producing turpentine, tar, wood alcohol, vinegar, resin and potash.

In spite of destructive exploitation in the past, hunting and trapping still form the chief occupation of the native tribes, and a supplementary source of income for the Russian settlers. The Arctic fox and white bear are found only north of lat. 60°, and the former is not so abundant as in western Siberia. The blue, the red and the black or silver fox are trapped in quantity, especially by the Koryaks. The raccoon dog, a native of China and Japan, is found in the Amur basin and valued for its skin in winter and its flesh in summer. The polar bear is found where there are seals, but the brown or Kamchatkan bear is common in the forests and yields both fur and food; the black or Tibetan bear is found in the south. The Gilyak tribes are specially skilled in bear hunting, and the bear has religious significance for many native tribes. The marten and sable are decreasing; the best sable comes from the Nerchinsk, Amgun and Zeya districts and the poorest quality from Sakhalin. Ermine, glutton, skunk and otter are also decreasing. The hare is trapped for local use, though many tribes will not eat its flesh. Squirrels are not found in Kamchatka, but in the south they are common, and their skin is in great demand for gloves, hoods and carriage aprons. The reindeer is widespread in the tundra region, the Koryaks and Chukchee often owning herds of two to five thousand head, which provide them with meat, leather and means of locomotion. War conditions of 1914–22 had a disastrous effect, and it has been calculated that of 1,622,000 reindeer, only 687,000 survived. The elk is also found, and the wapiti and maral deer are valued for their horns. From the horns of the maral deer a powder called *panty* is obtained which is in great request amongst Chinese physicians. The musk deer is hunted in the Amur region and Sakhalin; its flesh is eaten, its skin used for clothing and its thin leg bones made into arrowheads. The roebuck, stag, rock deer and spotted deer are found, and in the island of Askold near Vladivostok, the siku. The musk ox is extinct, except possibly in Sakhalin.

The Commander islands were at one time famous for the fur seal, but promiscuous killing has greatly diminished its numbers. Near Chita and in the jungles of the Maritime territory, tigers are much dreaded; the snow leopard, lynx and two varieties of wild cat are also found. Fish is abundant and varied, both in the rivers and the sea; many native tribes rely on fish for food in much the same way as we rely on bread. It is salted or frozen for winter use, and towards the end of winter is often eaten in an advanced state of decomposition. The best market for exported fish is Japan. Attempts are being made to foster a tinned fish industry, and Kamchatkan tinned salmon, mainly put up under Japanese direction, finds an increasing market. The scarcity of salt greatly hampers the fish preserving industry, and the government was financing the Yakutsk salt mines on Vilyui river, a tributary of the Lena, to meet the need. Herrings are abundant in Peter the Great gulf and could find a ready market in Siberia if better transport and refrigerator facilities were provided. The Keta or dog salmon is common except in south Kamchatka, and from its skin the natives make sails, clothes and boots. For a detailed account of the numerous kinds of fish see *A Handbook of Siberia and Arctic Russia,* I.D. 1207, London 1920, in which there is also a detailed account of the various native tribes.

Climate.—The climate varies much, since the region extends from 70° N. to 42° N. The northeast corner, including the

Anadyr mountains, lies within the frozen Arctic tundra zone, where summer is very short, with a temperature never rising above 60° F, and winter is long and cold, with a January mean of —10° F to —40° F. Precipitation is slight. Three factors influence the climate of the remaining area, (1) the cold current of the Okhotsk sea considerably lowers the temperature; thus the centre of the frozen Kamchatka desert lies in about the same latitude as Moscow; (2) the south-east monsoon brings rain, especially in July and August, to all the Pacific coastal areas, thus making summer stormy, wet and cool and unfavourable to agriculture; (3) the continental situation and high elevation of Transbaikalia and part of the Amur region cause severe winters, often lasting seven months, though in the remaining five summer months the heat is sufficient to allow sub-tropical plants, *e.g.*, rice, to be grown. The slight snowfall exposes the ground to the severe winter frosts and prevents the cultivation of winter wheat. The range of temperature here may be 70° F, and even at Vladivostok is 64.6' F. The annual rainfall in Transbaikal and the west of the Amur region is 300 to 500 mm.; in the eastern Amur regions and the Maritime territory 500 to 700 mm. and towards the south 700 mm. Dense fogs are common on the coast in summer. Sakhalin and Kamchatka have less severe extremes of climate and heavier rainfall all the year round; in east Kamchatka precipitation is about 1,000 mm. per annum. Ayan, on the south coast of the Okhotsk sea, gets the same heavy rainfall, but the north coast of this sea is completely dry.

Agriculture **and** Industry. — Rumours of rich black earths in the southern parts attracted the first settlers, but black earth exists only in the Transbaikal, where it is of poor quality and rapidly degenerates; climatic conditions here are unfavourable for agriculture. The soils in the Amur region and Maritime territory, formerly accepted as black earths, prove to be dark coloured bog, semi-bog and ash coloured soils; when capital for draining becomes available, they should prove productive. On the narrow coastal fringe, the impenetrable clayey and stony rocks led to bogging and flooding during the semi-tropical summer rains. Agriculture is therefore most favourably carried on in the light, easily worked, muddy alluvial soils of the Amur, Ussuri, Zeya and Bureya valleys. The most densely sown area is round Blagoveshchensk, from which district sown land thins out in every direction; the chief crops are wheat 52·2%, oats 39·3%, grasses 2·2%, potatoes 1·4%, rye 1·3%, other crops being buckwheat, millet, sunflower seed, barley, flax and hemp. Melons are also grown. The Ussuri valley and the district near Vladivostok, especially from Lake Khanka to the Suifen river are well cultivated. Of late years rice has been introduced so successfully that its northern limit is now 49" N., instead of 42" N. Experiments are being carried out with a view to establishing the cultivation of tobacco, sugar-beet and silk; the chief crops at present are oats, wheat and buckwheat. Soya beans are increasingly grown and carrots, potatoes, tomatoes, cabbages and fruits, especially the apple, ripen well in the short summer. Hay in this district is so rank and coarse that cattle sometimes refuse it, Wild grapes are found in the southern Ussuri region. Beekeeping, since its introduction in 1871, forms a valuable supplement to agriculture, except where the opium poppy is grown. The only other cultivated region is in Transbaikal, along the valleys of the Ingoda, Onon and Argun rivers, where irrigation of a primitive kind is practised, rye, oats, wheat and buckwheat forming 92.4% of the harvest. The northern limit of agriculture in the Maritime territory is 43° N., as against 65° N. in the Yakutsk Republic, but a small patch of land near the Tym and Poronaya rivers in Sakhalin, another near the mouth of the Uda river, and a third in the Kamchatka peninsula form tiny islands of possible cultivation much to the north of the general limit. War and civil war diminished the size of the sown area, and the quality of the harvest, which is still (1928) much below the 1913 level. Even then, however, sufficient grain for the needs of the population was not grown. Most imported grain is floated down the Sungari river from Manchuria; the remainder either comes from North America via Vladivostok or from western Russia via the Siberian railway. The home meat supply is also deficient, and fat cattle from Mongolia form a staple import. Dairying and cattle breeding of a fairly intensive type are carried on in the Ussuri region to supply the towns of Khabarovsk and Vladivostok, but are much hampered by insect pests. In Transbaikal an extensive nomad form of cattle-breeding is carried on, the herdsmen often taking their flocks into Manchuria for the winter. Horses are bred and used as working animals in the summer and for posting routes in the winter. The rearing of sheep and goats wherever possible was emphasized by war conditions, which cut off the supply of imported cloth and made the country dependent on homespun. Strong and hardy camels are bred in Transbaikal. Pigs in this region are of poor quality, but in the Ussuri district they are better bred and a bacon industry is developing.

The mineral wealth is as yet not completely surveyed. Gold output has diminished markedly since 1917 and will probably need to be put on a machine using basis in place of the old hand methods; it is mainly obtained from alluvial washings. The rich quartz deposits could not be profitably exploited under present conditions. Climatic conditions make work possible only in summer, and most of the gold is found in places where the ground never really thaws; if the summer is dry, water for washing is deficient; if wet, flooding is troublesome. Population is scanty, roads almost non-existent and the cost of bringing machinery and food supplies is exceedingly heavy. The chief regions are the Nerchinsk, the Zeya and its tributaries, the Bureya, and especially its tributary, the Niman; Blagoveshchensk and Zeya-Pristan have government gold laboratories. The Amgun mines near Kerbinski have proved too costly to exploit, but the Orsk mines on Lake Chlya, near Nikolaevsk, are more successful. The more accessible mines in the Ussuri district are worked out, but a new source has been opened on the Iman river. Quartz gold was extracted formerly from Askold island near Vladivostok. The silver mines of Nerchinsk, in Transbaikal, which were worked as early as 1704 and reached their maximum output in 1774, are no longer worked, since the easily reached layers are exhausted and the Kirghiz silver mines are more productive. Zinc and silver-lead mines are worked near Tyutikha bay and Soviet bay. Wolfram, bismuth, asbestos, platinum, molybdenum, osmiridium and tin are found and many precious stones, unworked for lack of demand. Antimony occurs in quantity in the Amur region. Brown coal of a low calorific value has been mined in the Transbaikal and Amur region since the coming of the railway. In the Maritime territory both brown coal and a better variety are mined for the Ussuri railway, but the best coal is obtained from Sakhalin; the Japanese markedly developed the mines during their occupation. The eastern shores of Sakhalin also produce good quality naphtha, and this and the coal are worked by a Japanese concession. Iron was worked in the Transbaikal in the 18th century and an iron foundry existed at Petrovsk on the Balaga river; it declined after the opening of the trans-Siberian railway, but revived temporarily in 1914–22. Chinese competition, with better fuel and ore conditions, is now reducing its prosperity. The Olga bay iron industry is more prosperous North-east Kamchatka has undeveloped resources of gold. platinum, silver-lead ore, iron, coal, granite, marble and naphtha. In 1925 concessions were granted to the following British firms, (1) "Lena Goldfields" for 30 years. (2) "The Priamur Mines" for 36 years to develop the iron, zinc, lead and silver at present unworked in the Olga bay district. (3) "The Tetukhe Mining Corporation" for 36 years to develop the zinc, silver, lead and sulphate near the Tetukhe river. (4) "The Ayan Corporation" for 36 years to work the gold mines in Kamchatka. The industries of the Far Eastern Area are at present mainly restricted to peasant products for local needs, homespun, sewn leather footwear, flour-milling, etc. Leather is distinctly a peasant industry, except in Vladivostok and the Transbaikal. Vladivostok and Blagoveshchensk are important flour-millirg centres, and a macaroni industry was established at the former town in 1923. Both towns have shipbuilding and repairing industries; the latter for the Amur river fleet. The former Khabarovsk arsenal now produces agricultural implements. The damage to the railway bridges and rolling stock and to the river fleet during 1914–1922 is still felt. Roads are lacking in many places and are often impassable in the rainy season. The opening of the final railway link between Khabarovsk and the Transbaikal in 1914–15, has not yet had time to make its influence felt. Coastal transport is difficult owing to the uncharted seas and the summer fogs and winter ice. The Far Eastern Area thus presents itself as an area of potential wealth as yet undeveloped. Its present exports of timber, fish, furs, coal, oats, beans, rice, hempseed and bran hardly cover its imports of grain, fats, tea, sugar, meat, cattle, agricultural and other implements, machinery and small necessities such as paper, soap and chemicals. The seasonal nature of its industries and the difficulties of agriculture, combined with transport difficulties are a check on colonization, and yet intensive colonization is the only means of creating a demand for'manufactures of a non-seasonal character. Its chief towns are Vladivostok, Khabarovsk, Chita, Nerchinsk (*qq.v.*) and Blagoveshchensk.

Native Tribes.—Many native tribes still survive. Until recently the Palaeo-Siberian races, akin to the North American Indians, occupied all eastern Siberia and some Japanese islands. They have been pressed out by invaders towards the north-east, and of the present 35,000 population of Kamchatka, about 30,000 are natives. The Chukchee are the most important. Their original territory was mainly from east of Chaun bay to the north of the Anadyr region. but the increase of their reindeer herds has caused them to expand, at the expense of the Yukaghirs. They inhabit the tundra and its taiga fringe, seeking the latter for shelter in the autumn and camping in summer near a glacier or in the open tundra. They were probably originally a maritime people who later developed reindeer breeding and they are today divided into the Reindeer and the Maritime Chukchee. The latter live mainly by seal and walrus hunting and their boats are made from walrus hide. The Reindeer Chukchee hunt wild reindeer, wolves, bears and foxes to supplement their reindeer breeding. The Koryak tribe, closely related to the Chukchee, extends from the Stanovoi mountains to the sea, and along the west coast of Kamchatka to lat. 55° N. They are also divided into a Maritime and a Reindeer section, the latter intermarrying with the Chukchee and the former with the Kamchadals. They fish, hunt and breed reindeer, and have developed much artistic skill in carving wood, ivory, whalebone and horn and in basketwork and rug-making. Kamchadal is a name applied to the principal tribe of the Kamchatkan peninsula; pure aborigines are rare, much intermixture between them and escaped convicts having occurred. Their chief occupation is salmon fishing, though some are hunters and trappers. They train sledge dogs and are expert sledge drivers. The Gilyaks of the coastal region on either side of the Amur present an ethnological problem, one type approximating to the Ainu, another to the Tungus and a third being distinct from either. Hunting, fishing and trading are their chief occupations and till recently they carried on a slave trade with the Ainu and Goldi. The bear is their sacred animal, and there is a bear cage near each of their villages. A few Eskimo are found in the north and a few Aleuts in the Commander islands.

Of the Neo-Siberian tribes, sometimes called the Ural-Altaic, the Tungus are the most important in this region; they are a branch of the same Mongolic tribe as the Manchu. They stretch from the Taimir peninsula along the Yenisei valley across the Vitim plateau to the sea coast almost from Korea to Kamchatka; the Amur and Ussuri are Tungus streams. The Lamuts and Olennye of the Chukchee peninsula are a branch of the Tungus. The southern Tungus fall into two linguistic groups, one including the Orochon, Manegir, Birar and Kile, the other the Olcha, Oroke, Negda and Samagir. Physical and linguistic divisions do not, however, correspond, *e.g.*, the Olcha resemble the Gilyaks physically, and the Samagir resemble the Goldi of the Amur, Ussuri and Sungari region. In Transbaikal many Tungus have become sedentary and intermingled with the Russian settlers, but the nomadic cattle-breeding Tungus, forming about 45% of the whole, have preserved their nationality and language and are demanding recognition of an autonomous area The Buriats of Transbaikal are the principal Mongol tribe in Siberia; the eastern branch is known as the Aga-Buriat, as distinct from the Buriat Mongol (*see* BURYAT).

In 1925 the first congress of native peoples of the Transbaikal Amur region and Maritime territory was held. It laid down a broad basis for preserving native cultures and suggested plans, (1) for combating shamanism (*q.v.*), the sale of women, and the spread of such diseases as syphilis, leprosy, etc., (2) for establishing cooperation among the natives to prevent their exploitation, (3) for enabling the natives to adapt themselves gradually to timber and other industries, in view of the fall in the value of hunting and fishing. The congress was significant of a new outlook on problems of the relations of native tribes and incoming settlers and traders. In 1926 a station providing veterinary aid to native reindeer breeders and medical help for the natives was established in St. Lawrence bay near Bering strait.

Colonization.—The history of the opening up of the Far Eastern Area is full of romantic interest, and the hardships suffered in its wild country and Inhospitable climate were perhaps greater than in opening up any other region. The wealth of fur attracted traders from early times. The Cossack Dezhnev in 1648, after whom East Cape has been re-christened Dezhneva, sailed through Bering strait eighty years before Bering, and discovered the Anadyr, where he was joined by other Cossacks who had come by land from the Kolyma river along the Anyui and over the watershed. In 1647 Okhotsk fortress was built and by 1697 Kamchatka was explored and a fortress built at Verkhne-Kamchatsk. In 1643 Poyarkov sailed dbwn the Zeya and the Amur to the Pacific and returned via Okhotsk. In 1649–50 Khabarov, a merchant of Olekminsk sailed down the Amur and wintered at the place which now bears his name. He also selected the future Blagoveshchensk as a suitable site. About this time Verkhne-Udinsk and Nerchinsk were founded, but the Amur was ceded to China in 1689. The final occupation of the Amur is mainly due to Count Muraviev-Amurski, who, in 1849, sent Nevelski to explore the mouth of the river, and Nikolaevsk was founded by him. Two years later de Castries bay and Mariinsk were occupied and outposts established in Sakhalin. The journeys of Middendorf, 1844–45; Akhte and Schwarz, 1852, and in 1854–57 of the Siberian expedition increased the knowledge of and interest in the district. At the same time the Siberian branch of the Russian Geographical Society was formed in Irkutsk as a centre for Siberian research. During the Crimean War, Petropavlovsk in Kamchatka was successfully held against the English and French, and later a flotilla was sent down the Amur to help the Pacific fleet. The settlement of peasants along the left bank began in 1856 with colonies at the mouth of the Kumara, the Zeya and the Sungari, and at the entrance to the Little Khingan gorge. In 1858, by the treaty of Aigun, China ceded to Russia the left bank of the Amur from the Argun to the sea, and the Peking Convention of 1860 confirmed the cession to Russia of the Ussuri region. For some years a zone of free trade existed along the frontier, but this was discontinued in 1912 and much smuggling now goes on. In 1872 Vladivostok was made the Russian Pacific Naval base. In 1896 Russia abandoned the longer and more difficult railway route along the Amur in Russian territory in favour of a joint Chinese-Russian railway through Manchuria to link the Transbaikalia railway with Vladivostok, and in 1898 obtained the lease of Port Arthur, and after the Boxer rebellion of 1900 established herself in Manchuria and Korea. But by the Treaty of Portsmouth 1905, at the end of the Russo-Japanese war, Russia recognized Japan's right to Korea, ceded her rights to Port Arthur and retired from Manchuria. Sakhalin was divided between Russia and Japan at lat. 50° and Japan gained fishing rights in the Bering and Okhotsk seas. Russia was then compelled to build the Amur railway which was completed in 1915. Following on the 1917 revolution, a rising took place in Vladivostok in 1918, and Japanese and British naval forces occupied the town. Much confused fighting took place, Semenov's troops, the retreating Czecho-Slovak army, the White Guards, Allied troops and especially Japanese troops and Bolshevist forces all taking part. From 1920 to 1922 an independent Far Eastern Republic existed, but in November 1922 the Soviet power finally established itself and the Far Eastern Area was incorporated in the R.S.F.S.R., though the Japanese did not evacuate northern Sakhalin until May 1925. Colonization in the area was attended in early days with great difficulties and casualties were heavy. The region of oldest settlement is the Transbaikalia, where Cossacks were established in the middle of the 17th century; thence they were progressively moved eastwards, settling on the Amur river in 1857. In 1869 peasant colonization of the Amur district began and the opening of the Odessa to Vladivostok sea route in 1878, which lessened the transit time from two years of difficult land travel to a few weeks' sea voyage, gave a great impetus to the settlement of the Maritime and Ussuri districts. Besides Cossacks and peasants, political and religious refugees and exiles also settled in the district and have formed a valuable element in the population. Some, notably Bogoras in his studies of the peoples of the Chukchee region, have added considerably to the scientific exploration of the district. Criminal exiles, on the other hand, have been a great source of disorder; many convicts escaped and they and the ex-convicts whose term of imprisonment was completed, frequently terrorized the native tribes and settlers. In 1907 the custom of sending criminals to Sakhalin island was discontinued. After 1925 the Soviet government was offering special facilities to settlers in the far east, especially to those intending to work in the lumbering and fishing industries.

FAREHAM, a market town, seaport and urban district in the Gosport and Fareham parliamentary division of Hampshire, Eng., 13 mi. E.S.E. of Southampton by road and bridge, at the head of a creek opening into the northwestern corner of Portsmouth harbour. Pop. (1951) 45,520. Area 28.7 sq.mi. The ancient church of SS. Peter and Paul belonged to an Augustinian priory founded by Henry I; it has been several times rebuilt.

The fact that Fareham (Fernham in Domesday Book) formed part of the original endowment of the see of Winchester fixes its existence certainly as early as the 9th century. There is evidence to show that Fareham had become a borough before 1261; it is mentioned in Domesday Book as subject to a reduced assessment on account of its exposed position and liability to Danish attacks. It was a mesne borough held by the bishop of Winchester, but by 1835 it had lost this status. It became an urban district in 1894. Fareham was represented in the parliament of 1306, but two years later it petitioned against representation on the ground of expense. A fair was held under grant of Henry III, and in the 18th century was mainly important for the sale of toys; it was abolished in 1871. The modern Monday market developed from the ancient street market.

Fareham in mediaeval times was a free port and had a considerable trade in wool and wine. Its modern trade is in corn, timber and coal, the creek being accessible to vessels of 300 tons. There is a large public abattoir, built in 1949. The principal industries are boatbuilding, light engineering and the manufacture of bricks, coarse earthenware, terra cotta and leather. Among the localities comprising the urban district are Portchester, Wallington! Stubbington. Hill Head, Titchfield, Warsash, Locks Heath, Park Gate, Sarisbury Green, Swanwick and Burridge.

About 3 mi. W. is Titchfield, with a partly Saxon church and the remains of a Premonstratensian abbey of the 13th century, incorporated in a now ruined mansion after the Dissolution. The ruins of Portchester castle? on Portsmouth harbour (3 mi. E. of Fareham), consist of an extensive walled enclosure retaining its Norman keep and showing considerable evidence of Roman workmanship in its outer walls. The castle walls enclose the church of St. Mary, and the grounds are open to the public.

FAREL, GUILLAUME (1489–1565), French reformer, was born of a noble family near Gap, Dauphiné. He studied in Paris under Jacobus Faber (Stapulensis), on whose recommendation he was appointed professor in the college of Cardinal Lemoine.

In 1521, on the invitation of Bishop Briçonnet, he went to Meaux, and took part in efforts of reform within the Roman communion. The persecuting measures of 1523, from which Faber found a refuge at Meaux, determined Farel to leave France. Oecolampadius welcomed him to Basel, where in 1524 he put forth 13 theses sharply antagonizing Roman doctrine, and defended them with so much heat that Erasmus joined in demanding his expulsion from the city.

Farel then thought of going to Wittenberg, but his first halt was at Strassburg, where Bucer and Capito received him kindly. At the call of Duke Ulrich of Württemberg he went in the capacity of preacher to Montbéliard, but was forced to leave early in 1525.

Retracing his steps to Strassburg and Basel, at the end of 1526 he obtained a preacher's post at Aigle, then a dependency of Bern, and, with reference to his protection by that city, adopted the pseudonym Ursinus. He obtained in 1528 a licence from the authorities to preach anywhere within the canton of Bern, but extended his labours to the cantons of Neuchâtel and Vaud, in Oct. 1530 breaking into the church of Neuchâtel with an iconoclastic mob. In 1532 he visited the Waldenses and on the return journey halted at Geneva, then at a crisis of political and religious strife. On June 30, 1532, the Council of Two Hundred had ordained that in every church and cloister of the city "the pure Gospel" should be preached; against this order the bishop's vicar led the opposition. Reaching Geneva in Oct. 1532, Farel at once began to preach at his lodging, and soon attracted crowds. Summoned before the bishop's vicar, he was violently thrust from the court and bidden to leave the city within three hours. He escaped with difficulty to Orbe by boat. Through the intervention of the government of Bern, liberty of worship was granted on March 28, 1533 to the Reformation party in Geneva. Farel, returning, achieved in a couple of years a complete supremacy for his followers. On New Year's Day 1534 the bishop interdicted all preaching unauthorized by himself, and ordered the burning of all Protestant Bibles. This was the signal for public disputations in which Farel took the leading part on the Reformation side, with the result that by decree of Aug. 27, 1535 the mass was suppressed and the reformed religion established. Calvin, on his way to Basel for a life of study, touched at Geneva, and by the importunity of Farel was there detained to become the leader of the Genevan Reformation. The severity of the disciplinary measures which followed procured a reaction under which Farel and Calvin were banished the city in 1538. Farel was called to Neuchâtel in July 1538, but his position there was made untenable, though he remained at his post during a visitation of the plague. When (1541) Calvin was recalled to Geneva, Farel also returned; but in 1542 he went to Metz to support the Reformation there. In 1544 he returned to Neuchâtel. No one was more frequently and confidentially consulted by Calvin. When the trial of Servetus was in progress (1553), Calvin was anxious for Farel's presence, but he did not arrive till sentence had been passed. He accompanied Servetus to the stake, vainly urging him to a recantation at the last moment. Calvin's death, in 1564, affected Farel deeply. He died at Metz on Sept. 13, 1565.

See C. Ancillon, *Vie de G. Farel* (1691); the article in Bayle; M. Kirchhofer, *Das Leben W. Farels* (1831–1833); Ch. Schmidt, *Etudes sur Farel* (1834); F. Bevan, *W. Farel* (1893); J. J. Herzog, in Herzog-Hauck's *Realencyklopädie* (1898).

FARGO, WILLIAM GEORGE (1818–ISXI), pioneer U.S. expressman, was born in Pompey, N.Y., on May 20, 1818. He became a freight agent for the Auburn and Syracuse Railway Co. in 1841, and express messenger between Albany and Buffalo a year later, and in 1843 a resident agent in Buffalo. In 1844 he organized, with Henry Wells (1805–78) and Daniel Dunning, the first express company to engage in the carrying business west of Buffalo. The lines of this company were rapidly extended to Chicago, St. Louis and other western points. In March 1850, when the American Express Co. was organized, Fargo became secretary; in 1852, with Henry Wells, he organized Wells, Fargo and Co. to conduct an express business between New York and San

Francisco by way of the Isthmus of Panamá. In 1861 Wells, Fargo and Co. bought the Overland Mail Co., of which Fargo had been one of the original promoters. From 1862 to 1866 he was mayor of Buffalo, and from 1868 to his death, in Buffalo, on Aug. 3, 1881, he was president of the American Express Co.

FARGO, the largest city of North Dakota, U.S., and the seat of Cass county, lies at the state's eastern boundary on the fertile bottom soils of ancient glacial Lake Agassiz, on the Red River of the North opposite Moorhead, Minn. The population in 1960 was 46,662 by federal census. (For comparative population figures see table in NORTH DAKOTA: Population.)

Founded by the Northern Pacific railway in 1871 in advance of settlement and named for William George Fargo (of Wells, Fargo and company), pioneer American expressman, its early prominence was due to its rail, steamboat and stagecoach facilities at the head of navigation, where it served as an outfitting point for the first settlers. Wheat planting in the mid-1870s disclosed the soil's productivity and attracted emigrants from Europe, especially Scandinavians. The development of wheat growing confirmed Fargo's role as a transportation, marketing and distribution centre. Railroad expansion ended stagecoaching and steamboating but the Red river's water supply became important to industry. The manufacture of farm machinery and food products engage many factories and furnish work for 12% of the city's labour force. One-third of the labour force is employed in wholesale and retail activities. Significantly identified with the city is the North Dakota State University of Agriculture and Applied Science, which was provided for by the state constitution (1889) and established in 1890 by the first legislative assembly. The agricultural experiment station maintains branches at Casselton, Langdon, Edgeley, Minot, Dickinson, Hettinger and Williston.

There are ice rinks and toboggan slides throughout the city in winter. Summer recreation centres in parks, playgrounds, the municipal swimming pools and at the Fargo-Moorhead Symphony orchestra's "Music under the Stars" concerts. (R. R. J.)

FARIDPUR, a municipality and district in the Dacca division of East Pakistan. The town stands on an old channel which debouches southward at the Titulia mouth of the Ganges. It takes its name from a Moslem saint, Farid Shah. Pop. (1951) 25,287.

FARIDPUR DISTRICT has an area of 2,584 sq.mi.; pop. (1951) 2,719,638. In the north the land is comparatively high, with a light sandy soil. From the town of Faridpur the ground slopes until in the south, on the confines of Bakerganj, it becomes one immense swamp, never entirely dry.

The plains between the rivers are almost invariably more or less depressed toward the centre, where usually a marsh or lagoon is found. The Padma (Ganges) flows along the district's northern boundary as far as Goalundo, where it receives the main stream of the Brahmaputra; thence the united stream turns southeastward and forms the eastern boundary. Rice and jute are the chief crops. The subdivisional town of Madaripur (pop,. [1951] 21,005), in the south of the district, is a centre of the jute-baling industry.

FARID UD-DIN 'ATTAR (c. 1150–*c.* 1230), Persian poet and Moslem mystic, whose most famous work, the Mantiq ut-Tair ("Language of the Birds"), describes, allegorically, the religious experience of the Sufis (see SUFIISM). Born in Nishapur, northeast Persia, toward the middle of the 12th century, he was a forerunner of the great Jalal ud-din Rumi (1207–73). He died *c.* 1230, or in any case after 1221, the year in which the Mongols sacked and destroyed his native city; there is therefore no truth in the story that he lost his life in that catastrophe. It seems probable that he ended his days in Mecca, where, in extreme old age, he wrote his last poem, the *Lisan ul-Ghaib* ("Tongue of the Unseen"). His personal name was Abu Talib (or Abu Hamid), Farid ud-din being his title and 'Attar his pen name, chosen because he followed the profession of pharmacist ('attar) or, rather, physician, having a sort of dispensary to which patients came daily for treatment.

As a young man Farid ud-din had traveled widely, visiting Egypt, Syria, Arabia, India and central Asia; he then settled down in his native town, where for 39 years he mas occupied in collecting the verses and sayings of the Sufi saints.

The *Mantiq ut-Tair* is an allegorical poem describing the quest of the birds (*i.e.,* the Sufis) for their king, the mythical Simurgh or Phoenix (*i.e.,* God). As their leader in the search they elect the hoopoe, who had guided King Solomon across the desert to the queen of Sheba, and who describes the long and hazardous journey they must undertake through seven valleys (representing the seven stages of Sufiism). Many excuse themselves and draw back; and of those who finally set out, only 30 birds (si murgh) succeed in entering the presence of the Simurgh, to discover that in so doing they have lost their identity, that they are he and he is they. In this way the poet allegorizes the final stage in the Sufi's progress, "annihilation in God."

The text of the *Mantiq ut-Tair* was published by Garcin de Tassy in 1857, and a French translation followed in 1863. An English version of this translation, The Conference of the Birds, by S. C. Nott, appeared in 1955. Farid ud-din was a prolific writer, and among his other works may be mentioned the *Pand-Nama* ("Book of Counsels"), translated by Silvestre de Sacy (1819); and the prose *Tadhkirat ul-Auliya* ("Memoirs of the Saints"), a series of biographies of the early Sufis (ed. by R. A. Nicholson in *Persian Historical Texts,* 2 vol., 1905–07).

See E. G. Browne, *A Literary History of Persia,* vol. ii (1906–24); H. Ritter, Das *Meer der Seele:* Mensch, Welt und Gott in den Geschichten des Fariduddin 'Attar (1955). (J. A. BL.)

FARINACCI, ROBERTO (1892–1945), Italian politician, was born Oct. 16, 1892, at Isernia in the province of Campobasso. While a young man, he took part in the Italian Socialist movement as a follower of the reformist leader Bissolati. After the armistice of 1918 he changed sides and was one of the first to join Mussolini's Fasci di Combattimento. He founded the Fascist daily paper *Cremona Nuova* and was one of the leaders of the Fascist armed squads (*squadre* d'azione) in southern Lombardy.

When Mussolini came into power, Farinacci became powerful in the new regime. In 1925 (Feb. 12) Mussolini appointed him general secretary of the Fascist party. Under his impulse, the party and the "fascistized" police suppressed the activities of the opposition. In 1926 (March 31) Farinacci was superseded as general secretary by Augusto Turati. In the following years, Farinacci practised law. He became a member of the Fascist grand council in 1935 and was appointed minister of state in 1938. He played an important part in bringing Italy into World War II. After Mussolini's resignation in 1943, Farinacci fled Rome. Late in April 1945 he was executed by Italian partisans. (M. W. S.)

FARINATO (FARINATI), **PAOLO** (c. 1524–1606), Italian painter, engraver and architect, one of the leading painters at Verona of his day, was born at Verona; the year is not recorded but on a picture dated 1603 he claimed to be 79 years old. His father, Giovanni Battista, was also a painter and may have been his first master; later he probably worked under Nicolò Giolfino. Farinato was active almost entirely in Verona. According to Carlo Ridolfi, a Madonna painted by him attracted the attention of Philip II of Spain when passing through Villafranca on Jan. 17, 1549. The first certain date is 1553, for by March of that year his St. Martin altarpiece for the cathedral at Mantua (still in *situ*) is recorded as finished in a joint letter from Farinato, Domenico Brusasorci, Paolo Veronese and Battista del Moro to Cardinal Gonzaga. All these artists had received commissions for Mantua in 1552. Some dated pictures occur at intervals, the last in 1603 ("Miracle of the Loaves and Fishes" in S. Giorgio in Braida, Verona) where Farinato adds his age of 79 to the signature and date. From 1573 onward he kept a diary of commissions with details of some of his work. His last years were divided between domestic squabbles with his sons and furtherance of his belief that he was related to the noble Florentine family of Farinati degli Uberti. His last will is dated July 23, 1606, and he is assumed to have died shortly after. He was buried in S. Paolo at Verona, where he had had his tomb constructed in 1594. Most of his vast output of paintings was for churches in Verona and its environs, where much of it has survived. He was strongly influenced by his younger contemporary Veronese, and also by Parmigianino among others. He also executed a few engravings, some architectural projects which apparently included work on the Castello S. Felice at Verona and very many drawings. It is by his drawings that he is most widely known and represented; an important series of them is in the royal collection at Windsor. Farinato often signed his work with the device of a snail, sometimes accompanied by his initials.

Ridolfi, *Le Maraviglie,* ed. by D. von Hadeln, ii (1924); also D. von Hadeln in Tbieme-Becker, *Künstler Lexicon,* xi (1915). Farinato's diary was published by L. Simeoni in *Madonna Verona,* i–v (1907–11). For the Windsor drawings, *see* A. E. Popham and Johannes Wilde, *The Italian Drawings of the XV and XVI Centuries . . . at Windsor Castle* (1949). (M. LY.)

FARINELLI (1705–1782), whose real name was CARLO BROSCHI, and who was one of the most extraordinary male soprano singers that ever lived, was born on Jan. 24, 1705, at Naples. In 1722 he made his first appearance at Rome in *Eumene.* He sang at Bologna in 1727, where he first met and acknowledged himself vanquished by the singer Antonio Bernacchi (b. 1700). Farinelli appeared in nearly all the great cities of Italy; in 1731 he returned to Vienna after two previous appearances there. He then modified his style from mere bravura to one of pathos and simplicity. He visited London in 1734 and appeared at the Lincoln's Inn Fields theatre in *Artaserse.* After spending three years in England, Farinelli set out for Spain; he remained there for nearly a j years. His voice. employed by the queen to cure Philip V of his melancholy madness, acquired for him an influence with that prince which gave him eventually the power, if not the title, of prime minister. Under Ferdinand VI he held a similar position, and persuaded him to establish an Italian opera. After the accession of Charles III, Farinelli was asked to leave Spain. He died at Bologna on July 15, 1782.

FARINI, LUIGI CARLO (1812–1866), Italian statesman and historian, was born at Russi, near Ravenna, on Oct. 22, 1812. After completing a brilliant university course at Bologna, which he interrupted to take part in the revolution of 1831 (*see* CARBONARI), he practised as a physician at Russi and at Ravenna. In 1843 he was expelled from the Papal States. He resided successively in Florence and Paris, and traveled about Europe as private physician to Prince Jerome Bonaparte, but when Pius IX was elected pope and began his reign with apparently liberal and nationalist tendencies, Farini returned to Italy and was appointed secretary-general to G. Recchi, the minister of the interior (March 1848). However, he resigned with the rest of the ministry on April 29. Pius now sent Farini to Charles Albert, king of Sardinia, to hand over the command of the papal contingent to him. He was again secretary to the ministry of the interior in the Mamiani cabinet, and later director-general of the public health department. He resigned on the proclamation of the republic after the flight of the pope to Gaeta in 1849, resumed it for a while when Pius returned to Rome with the protection of French arms. but when a reactionary policy was instituted, he went into exile at Turin. There he contributed to Count Cavour's paper *Il Risorgimento,* in *La Frusta* and *Il Piemonte,* of which latter he was at one time editor. He also wrote his chief historical work, Lo *Stato Romano dal 1815 al 1850,* in four volumes (1850). In 1851 he was appointed minister of public instruction in the D'Azeglio cabinet, an office which he held till May 1852. In the Sardinian parliament and in the press Farini was a staunch supporter of Cavour (*q.v.*), and urged that Piedmont participate in the Crimean War. When on the outbreak of the war of 1859 Francis V, duke of Modena, was expelled and a provisional government set up, Farini was sent as Piedmontese commissioner to that city; but although recalled after the peace of Villafranca he was determined on the annexation of central Italy to Piedmont and remained behind, becoming a Modenese citizen and dictator of the state. Farini negotiated an alliance with Parma, Romagna and Tuscany when other provisional governments had been established.

Annexation to Piedmont having been voted by plebiscite and the opposition of Napoleon III having been overcome, Farini returned to Turin, when Cavour appointed him minister of the interior (June 1860) and subsequently viceroy of Naples; but he soon resigned on the score of ill-health. Cavour died in 1861, and the following year Farini succeeded Urbano Rattazzi as premier. He resigned in 1863 and died on Aug. 1, 1866.

FARLOW, WILLIAM GILSON (1844–1919), U.S. mycologist and plant pathologist who pioneered investigations in plant pathology; his course in this subject was the first taught in the United States. He was born Dec. 17, 1844, in Boston, Mass., and received his A.B. (1866) and M.D. (1870) degrees at Harvard university. Later he studied in Europe. In 1874 Farlow returned to Harvard where he was professor of cryptogamic (flowerless and seedless plants) botany from 1879 until his death on June 3, 1919, in Cambridge, Mass.

Although his publications were mainly on taxonomic and bibliographic phases of mycology, he also wrote articles on algae, lichens and ferns. His extensive library and collections of fungi, algae, lichens and mosses became the nucleus of Harvard university's Farlow library and herbarium. Several of his students became prominent in botanical fields.

FARM: *see* AGRICULTURE; FARM BUILDINGS; FARM MANAGEMENT; FARM TENANCY; SMALL HOLDINGS.

FARMAN, HENRI (1874–1958), French aviator and aircraft constructor, born in Paris May 26, 1874, was first a painter, later a racing motorist. With his brother Maurice he modified a Voisin pusher biplane and with it won, in Jan. 1908, a £2,000 prize for a circular flight of one mile. In 1909 he set a world's endurance record at the Reims aviation meet. In 1920 he again established a world's endurance record as well as an altitude record. As early as 1908 Henri Farman had a school of aviation and a construction works at Buc, near Versailles. Maurice Farman began to manufacture aircraft at a later date, but in 1912 the brothers merged their interests in the Farman works at Boulogne-sur-Seine, making many planes of their characteristic pusher biplane type for military and training purposes. The 1914 model was extensively used for artillery observation and reconnaissance in World War I.

Farman-type planes derived from the Voisin machine of 1908 which depended on inherent stability for lateral control. The landing gear had wheels. After the Wright brothers' public flights in 1908 first disclosed wing warping for lateral control, Farman machines adopted ailerons, a simpler aerodynamic equivalent. The Wright machines adopted wheels. Subsequently, ailerons and wheeled landing gear came into general use on all planes. He died in Paris on July 18, 1958. (J. C. HR.)

FARM BUILDINGS. The buildings on a farm provide a home for the family and structures needed for farming operations. Ideally the house should afford suitable space and the conveniences, comforts and satisfactions that determine the family's standard of living. The service buildings consist of barns, shelters, storages and working arrangements for animals, crops and products. These buildings should be economical in cost and upkeep, include labour-saving facilities and safeguards against loss or damage, and be readily adaptable to changing needs.

Some types of farming do not require service buildings, nor that the operator live on the farm. In such cases, the operator's dwelling may be located in a town or village or nearby in the open country and animals or crops may be marketed directly from field or pasture. Under some conditions the farmhouse is combined with storerooms, stables, sheds and work areas into one major multipurpose building. Sometimes centralized service buildings are set up to serve a large area.

On general-purpose farms the buildings usually include a dwelling, small structures such as garage, well house, workshop, etc., and whatever service buildings are needed for the particular farm. Needs differ from farm to farm, and between localities, regions and countries. The principal influences that determine choices are type of farming, climate, topography, size of enterprise, income and resources and the habits and customs of people. The buildings are most important on farms that are operated as full-time, profit-making enterprises.

This article deals primarily with farm buildings and their development in relation to the changing needs brought about by the rapidly expanding mechanization of agriculture in the second half of the 20th century, especially in the United States. Problems of investment, construction, materials and planning are discussed briefly in the following paragraphs. Then each major type of building is considered separately.

No one farm has all the buildings described; on the other hand, many types of buildings are not mentioned. Wide differences in kind, size and quality of buildings are found in different climates and on different types of farms. In many parts of the world, especially in underdeveloped areas, farming was still largely on a subsistence basis in the second half of the 20th century and farm dwellings and other buildings were of the most primitive sort. Information about living conditions and agricultural methods and production in various lands will be found in the separate articles on individual countries, and on continents. In addition to the references to related articles given in the sections of this article, *see* FARMSTEAD ARRANGEMENT, U.S. For material on structures designed for processing or storing specific crops the reader is referred to the separate articles on those crops; for example, for information on the construction and design of hop kilns or oast-houses, *see* HOP. The U.S. reader who is interested in a given region or kind of farming may obtain more detailed information from the United States department of agriculture, Washington, D.C., and the college of agriculture in each state. In other countries. the government department or ministry of agriculture should be contacted as the first step in seeking information. In each locality, it is advisable to consult with carpenters, materials dealers and building contractors.

REQUIREMENTS

Constant changes occur in farm-building requirements as new needs appear. Building improvements should take account of field mechanization, electric service. the cost and value of labour and demands for sanitation, disease control and improved products. Industrial development creates new materials and methods, better designs and more efficient equipment. Research brings new knowledge of crop storage, animal housing and product processing.

Building Investment. — Relatively high investments are necessary to provide adequate buildings for major farm enterprises, particularly dairying, poultry raising, tobacco curing and grain conditioning. The farm-building investment in the United States, in the second half of the 20th century, was estimated at $20,000,000,000, which was about one-third of the entire farm real estate value. On many livestock farms the buildings were valued at more than the worth of the land. Spending for repairs, upkeep and new construction was at the rate of $2,000,000,000 a year.

Costs of buildings increased rather steadily in line with the general price level. The cost by the second half of the 20th century was fully double pre-World War II cost and three times that which prevailed before World War I. Building costs consist of about equal proportions for labour and materials.

The building investment on farms went up at a greater-than-average rate as labour-saving devices, sanitation controls and processing equipment were added. But farmers also were in a good position to save by doing some of their own work, remodeling buildings already on the farm and using low-cost, locally available materials.

Construction. — Much on-the-farm construction is done by the farmer, by himself or with the help of neighbours or rural builders. Most farm buildings are constructed on the site, largely by traditional methods, although prefabrication increased greatly after World War II. Small "prefabs" were delivered as complete units while the larger ones were in parts, panels or sections that could be quickly erected on foundations made ready by the owner.

Buildings are set on masonry foundations or built on a framework of treated-wood poles set firmly in the ground. Movable structures and temporary buildings are placed on posts, treated wood or concrete sills, or on concrete floor slabs.

Materials. — Farm-building materials need to be durable, easily worked, resistant to destructive forces and to have special qualities where it is important to obtain insulation, watertightness, smooth surfaces and the like. In the United States, the most widely used materials are softwood planks and board lumber, concrete (both cast-in-place and masonry units), treated poles, plywood, sheet metal (mainly steel and aluminum) and asphalt or asbestos coverings. Common local materials include native lumber, ungraded pit or bank gravel, stone and sometimes bamboo or saplings for framework, thatch for covering and adobe for walls and floors.

Plans. — The ideal building plan provides for the space, shape, arrangement and equipment proven suitable by experience and research. Any one of two or more plans may be equally good and the choice is made according to preference or conditions. Many typical plans have been put into books, bulletins or blueprints, so that excellent designs may be had at little or no cost. Sometimes a building already in use in the community is the best guide to follow.

Each type of building tends to fall into a typical pattern. The combination of plan, materials and typical construction produces the buildings characteristic of a region or type of farming. Examples are the general-purpose barn, silo, corncrib, poultry house and tobacco barn. Many farm needs can also be met by multi-purpose buildings. They should have sturdy frame ork, weather-tight enclosure and unobstructed floor space. They are generally one-story, ground-level structures, often prefabricated. The interior plan and the conditions of temperature, light, air circulation and moisture may be made to suit any one of several needs.

FARMHOUSES

The farm dwelling differs from housing for nonfarming people of comparable tastes and incomes mainly because of its location on and attachment to the farm. Because of obstacles to improvement so often encountered, the condition of farm housing may be less adequate than urban housing on the average. Values are lower, houses are older, more of them are obsolete and the arrangement and equipment are sometimes unsuited to the needs of the present occupants. On the other hand, farmers can contribute labour, supplies and the use of equipment to the improvement of their own houses. Excellent plans and planning aids are available, especially from colleges of agriculture, and modern designs may be used most effectively for the betterment of rural housing.

The farmhouse should first meet the basic requirements for family living, the needs for sleep and rest, sanitation, preparation and serving of food, family group activities and storage of possessions. The unique features of a farmhouse are based largely

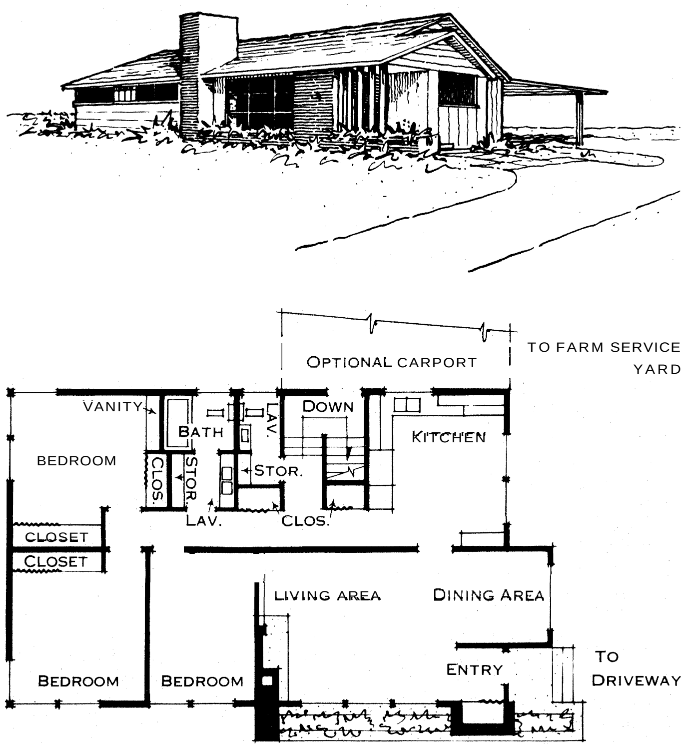

FIG. I. — EXTERIOR VIEW AND PLAN OF ONE-STORY FARMHOUSE OF CONTEMPORARY DESIGN. DESIRABLE FEATURES INCLUDE SIDE ENTRANCE, LARGE KITCHEN. BASEMENT. AMPLE LIVING AREAS AND THREE BEDROOMS upon the nature and pattern of farm life. Farming is a family activity with much traffic in and out of doors and from the back door to barns, fields and gardens. A convenient wash-up space and wrap-storage space are needed, and preferably a toilet and lavatory near the rear entrance. Access to the house is normally from a service yard or drive, so the main entrance should be reached readily from the driveway side. Visitor's parking is needed nearby, and the garage or carport should be attached or adjacent to the house.

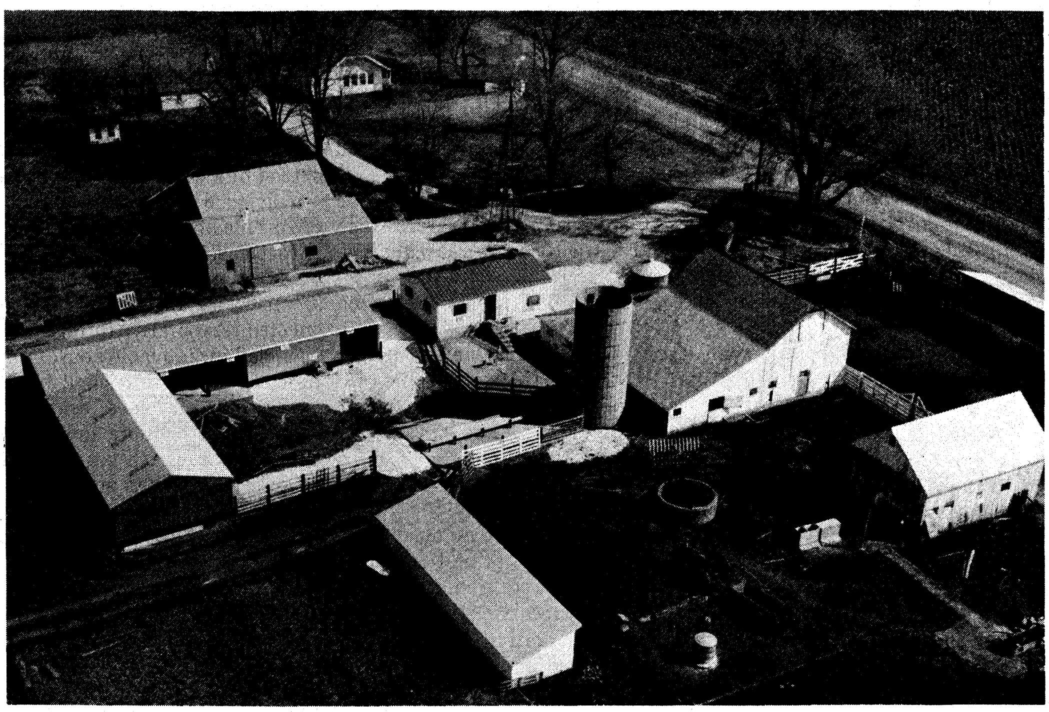
Ample storage and workroom space is needed since farm families do most of their own service work—laundering, canning, processing home-grown food—and often prepare produce for market. The house may also serve as a community meeting place, as a business centre for the farm and for activities in which the entire family takes part. Thus ample living, dining and family rooms are desirable. At least three sleeping rooms are needed for the typical farm family.



BY COURTESY OF BUTLER MANUFACTURING CO.

FIG. 2.— MODERNIZATION OF A MIDWESTERN U.S. FARM: THE OLD BUILDINGS (RIGHT) ARE NO LONGER ADEQUATE AND ARE GIVING WAY TO NEW STRUCTURES (CENTRE AND LEFT) THAT INCLUDE HOG SHELTER, CATTLE HOUSING SHED. FEED LOT. MILKING-MILK ROOM COMBINATION. TOWER SILO AND MACHINERY STORAGE

Since the family cannot move to another house as its needs change, and because one farmhouse over a period of years may be occupied by a succession of families, it is desirable that the house be made highly adaptable by multiuse rooms. It should have portions that can be shut off or opened up as needed and otherwise meet the needs of most families rather than one specific family.

Old houses can be made more livable by remodeling and the addition of new finishes, appliances and utilities. The advent of power-line electricity in rural areas enables the farmer to have a water-supply system, plumbing, sewage disposal, heating and air conditioning and other equipment and appliances fully as adequate as those found in urban housing. The farm owner may largely control his own housing, for it is not necessary to conform to building codes and zoning restrictions that apply in many towns and cities and much freedom is possible in planning and design. There is usually a choice of location and there are no limitations as to facing, lot lines, streets and nearby structures.

See also RURAL ELECTRIFICATION.

BARNS

A barn is a building for the accommodation of animals and of feed and other supplies for their use. Barns are named according to the purpose they serve, as hog barns, dairy barns, horse barns, etc. The principal type in the United States is the general-purpose barn, intended mainly for work horses and mules and their feed supply and also for cows, calves, sheep, hay and grain storage, etc. Although the need for the general barn declined with the advent of tractors and electric service, one or more barns are still found on the majority of North American and European farms. Many have been adapted to other uses.

For horses, it is customary to provide a tie stall 5 ft. wide and 9 ft. long for each animal. A feedbox and hay manger are provided in each stall. A feedway 3 ft. wide in front of the manger and a 9- to 10-ft. alley behind the stall are recommended. Horses may be confined in 12 ft. by 12 ft. box stalls. Mules may be kept together in large pens.

QUARTERS FOR ANIMALS

Dairy Housing.—Buildings and equipment for dairying should aid in producing clean milk, saving labour and maintaining healthful conditions in the herd. For grade-A milk, the buildings must meet requirements of space, light, ventilation and cleanliness prescribed by public-health authorities. Housing for dairy cattle includes a barn, shed or shelter for animals, a place for milking, a room for handling milk, storage for silage, grain and feed supplement, a covered area for hay and bedding, an exercise yard or pen, and facilities for the removal of manure. These should be arranged into an organized unit, adapted to herd size and recommended methods of operation.

The requirements for dairying may be met by either of two housing methods known as the stall-barn and the loose-housing systems. In the stall barn each cow is confined in a stall when in the barn for resting, feeding, milking and watering. Stalls are arranged in rows facing on a feedway and aligned along a gutter next to a walkway. A typical plan has two rows of stalls lengthwise with three alleys or service passages. Total barn width is 34 to 36 ft.. and each stall $3\frac{1}{4}$ ft. to 4 ft. wide. One or more maternity pens, calf pens and feed rooms are included. Hay and bedding are stored in adjacent buildings or in an overhead loft; the milk room is generally attached to the barn by means of a short corridor. Stall barns in the colder areas should have insulated walls and ceilings, and power-operated equipment for ventilation, watering, feed distribution and manure removal. In warm-weather areas the barns are partly open, and cows are housed mainly for feeding and milking.

The loose-housing system is much the more flexible for varying herd size, it may be less costly and is well suited for saving labour and maintaining sanitation. The principal structure is a shed or shelter arranged so that the animals may move freely between the shelter and outside yard. Bedded floor area of about 50 sq.ft. is needed for each cow. Hayracks are placed to form a feeding area under shelter. Hay and bedding may be stored within the same open-type structure. Exercise yards should have 75 to 100 sq.ft. of space, usually paved, for each animal. The silo and silage feed trough should be accessible from the yard. Equipment and gates are placed so power manure loaders can be used to advantage.

The milking room or "milking parlour" is adjacent to the shelter area. Two or more milking stalls are elevated 30 in. above the operator's working space. Doors are arranged so cows can be brought in to be milked, held in the stall and sent back to the yard in an orderly manner. The arrangement should enable the operator to do the milking, care for the milk and control the doors all from one small alley with a minimum of walking. The milking room should be insulated, lighted both by windows and electricity, have smooth, washable surfaces and provision for heat in cold weather.

The milk room or milkhouse for market milk must meet code requirements as to surfaces, light, ventilation, hot water, wash vats and cooling equipment. A small room 8 by 10 ft. may qualify, however 12 by 14 ft. is usually more desirable. In the loose-housing system, the milking and milk-handling rooms are often combined in one structure.

Other buildings for dairying may include shelter and feeding areas and separate pens for calves, growing heifers, dry cows and a herd bull. Bull pens or bull barns are less common on farms as artificial-breeding practices are adopted. See also DAIRY INDUSTRY.

Beef-Cattle Housing.—Beef animals do not require warm, enclosed shelters. Complete protection is provided only for young calves, cows at winter calving and young stock just going on full feed. Otherwise, open-front sheds, paved feed lots and facilities for feeding and removing manure are the main requirements. Adjustment may be necessary to give added protection in areas of heavy snowfall and more covered shelter if rainfall is heavy.

Cow herds for producing young stock need enclosed space for about 10% of the herd at one time, also maternity stalls and calf pens. For general livestock raising and cattle feeding, about 32 sq.ft. of shelter and 60 sq.ft. of paved yard are allowed for each full-grown animal. Feed-trough space is allowed at 30 in. per head, but only 10 in. of self-feeder trough and 20 in. of hay-rack space are needed. Labour is saved by self-feeders for grain and hay, continuous feed bunks along fence lines, paved yards, manure removal with power scoops, automatic waterers and well-arranged gates and drives.

Almost any type of semiopen shelter having nine feet or more of headroom will serve for beef cattle. Trussed roofs are desirable to eliminate interior posts and partitions. Hayracks need to be under shelter; however, outside feeders are used for silage, grain and fresh-cut green forage.

Two typical building arrangements are: (1) sheds 20 ft. wide adjacent to one, two or three sides of a hay and feed storage barn; and (2) open-front sheds or multipurpose buildings facing on a barnyard, with ground-level storage for hay and bedding. Construction may be wood frame or metal on a masonry foundation, or a pole frame with lightweight covering. Some have masonry unit walls. In any case the lower walls to a height of from three to five feet should be of masonry or plank to protect against decay and damage.

Shelters for Sheep.—On the open range, structures for sheep include corrals, dipping vats, lambing and shearing sheds, etc. No attempt is made to shelter the flock as a whole. Farm flocks in mild climates need little housing. In moderate climates open sheds are satisfactory but in severe climates buildings are closed during storms. Floor space of 12 to 15 sq.ft., yard space of 30 to 40 sq.ft. and feed-rack space of 15 to 18 in. per ewe are required. At lambing time extra warmth may be obtained by setting up temporary lambing pens inside the building, covering them in case of cold weather. Dryness and ventilation without drafts are essential in buildings for sheep. Movable feed racks, grain troughs, partition and fence panels are used for quickly adjusting pen size to flock needs, setting up temporary lambing pens, temporary feed lots, controlling grazing area, etc. (*See* SHEEP.)

Hog Housing.—The principal hog-housing need is for the sow and litter for about eight weeks from birth to weaning. Young pigs require sanitary surroundings, temperatures above jo° F. for a few days and protection against being crushed by the sow. After weaning, breeding stock requires only reasonably clean, dry shelter and ample yard space, and fattening hogs gain rapidly and thrive with only minimum housing.

The two principal U.S. systems of hog housing are: (1) movable farrowing houses that can be relocated on clean ground each season; and (2) enclosed central-type houses which usually have concrete floors, smooth walls and insulation. A single-unit movable farrowing house may be no larger than 6 by 7 ft. for sow and litter. An A-shaped house is quite common; often the upper portion is made nearly flat to reduce headroom. The house may be built with or without floor, single walled and with burlap sacking instead of a door. Other house shapes are satisfactory if floor space of 42 to 64 sq.ft. is provided, and headroom is 3½ ft. or more. Movable houses are either prefabricated or home built from standard plans.

Multiunit houses with two, three and four pens are quite common. Two three-pen shed roof houses can be paired and connected temporarily to form six-sow units. Among the advantages claimed for movable houses are low cost, ease of handling, mobility and usefulness for small herds.

The fixed-in-place, central farrowing house is used mainly for herds of 12 or more sows; in cases where two or more farrowing seasons occur each year; and if the enterprise justifies a relatively high investment in structures and equipment. The typical house is one-story high, with an insulated ceiling and having a two-row arrangement of pens and a centre work alley in a 20 to 24 ft. width. Pens are 8 to 9 ft. long from wall to alley, and 6 to 8 ft. across. One or more feed and equipment rooms are included in the house. The more elaborate houses may be equipped with unit heaters, underfloor hot-water pipes or heat lamps over each pen and power fans for circulation. Ceiling heights should not exceed 7 or 73 ft. Windows located in side walls or low in the roof should provide about two square feet of glass area for each pen. Each pen should have an individual watering trough, gates opening onto the centre alley and to an outside runway and guardrails on end wall and partitions to protect little pigs from being crushed.

A modern alternative to the pen is the farrowing stall. It confines the sow so that she may stand up or lie down but cannot move about and overlie her young. A space of about 12 to 18 in. on either side of the confinement stall provides room for the pigs to nurse, sleep or exercise. Heat lamps warm the pigs and help keep the space dry. After one or two weeks the farrowing stall may be removed.

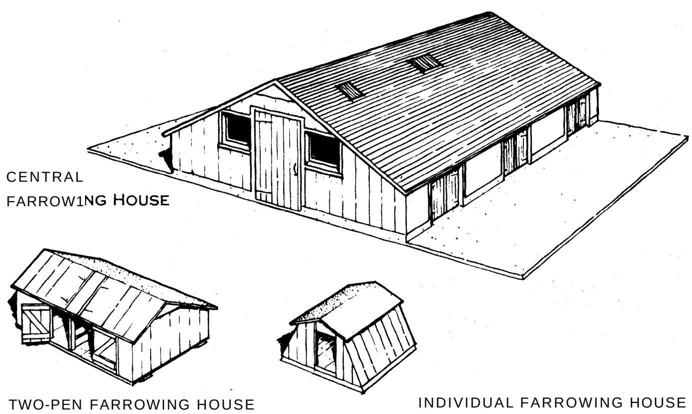


FIG. 3.—PERMANENT AND MOVABLE TYPES OF HOG HOUSES

Minor structures for hog raising include self-feeders, paved feeding floors, summer shades. watering devices, mineral boxes, loading chutes and breeding racks. These are needed with either the movable- or central-house system. Large-scale operators may combine both systems of housing on one farm.

Poultry Brooders and Houses.—Farm poultry houses are used for brooding baby chicks and maintaining laying flocks. A typical brooder house is a 120- to 160-sq.ft., wood-framed, wood-floored, movable structure on skids. Such a house will accommodate 300 chicks for six or eight weeks or until they no longer need heat. An electric or oil-fired brooder stove provides the necessary warmth. Windows in the south wall, insulation in walls and roof and air ducts for ventilation provide the best conditions for growing chicks.

Brooder houses for commercial flocks may be very large—40 by

200 ft. is not uncommon. They differ from small-farm types only in size, construction details and equipment. The larger houses may have several brooder units, underfloor heat or heat lamps, automatic waterers and feeders and fan ventilation. One or more large doors are provided for access by tractor and equipment for removing litter. The houses are used until birds are ready for market or removal to range houses.

Laying houses are similar to brooder or broiler houses in size and construction. A 10 by 12 ft. house is adequate for 30 birds but a 20 by 20 ft. space for 100 hens is a typical unit size. Each 100-hen unit should have 20 nests, 80 linear feet of roost space, one to two waterers, a lighting device and 16 ft. of feed-trough length. Housing for any flock should allow a floor area of $3\frac{1}{2}$ to 4 sq.ft. per bird, and roosts, nests, waterers, lights, etc., in proportion to the requirements for 100 hens. Capacity can be increased and labour reduced by using automatic feeders and waterers and giving close attention to sanitation. For some special conditions, entire houses are equipped with metal cages each accommodating one or two hens.

House sizes range from 20 by 20 ft. up to 24, 30 or 40 ft. wide and 200 ft. or more in length. In the largest establishments, feed storage, egg room and utility space may be in a centre section, with laying-house wings in both directions. If land area is limited, houses may be two or three stories high. Construction varies somewhat with climate, from relatively open shelters to semi-enclosed with partial openings in the leeward wall and fully enclosed, insulated structures. Overhead insulation is often provided by a straw loft, consisting of $1\frac{1}{2}$ to 2 ft. of straw fill over a wood frame, wire-mesh ceiling.

Summer-range shelters are used for growing chicks and replacement pullets. They are built on skids or runners, with light wood or metal framework, raintight roof with wide overhang and wire-netting enclosure. See also POULTRY AND POULTRY FARMING.

CROP STORAGE

Grain Storage.—Wheat, rye, oats, barley, soybeans, grain sorghum and shelled corn must be dried to about $12\frac{1}{2}\%$ moisture content for safe storage in farm-type bins in warm weather. Most grains are dry enough to store when harvested but artificial drying is necessary to reduce moisture in grain crops that are combined or otherwise harvested before they are quite dry.

Drying is accomplished in a few hours by passing the grain through drying machines or drying bins equipped with heating devices and power-driven fans that force warmed air through layers of grain. Moist grain can be kept from spoiling by forcing unheated air through large masses of grain intermittently over periods of weeks or months. However, drying without heat is accomplished only when the air is above 60° F. and the relative humidity is 75% or less.

The most common storages or granaries are: (1) rectangular, wood-framed bins; (2) circular prefabricated metal structures; (3) overhead bins above the driveway in corncribs and feed storages; and (4) flat, ground-level piles on concrete floors in warehouse-type buildings. Capacity of storage is measured in bushels. Each bushel occupies 1.25 cu.ft. of space. A given bin will hold four-fifths as many bushels as there are cubic feet of volume. The heaviest grains weigh 48 lb. per cubic foot, so that bins must be designed to carry heavy loads and pressures.

Typical farm-size bins range from 500 to 2.000 bu. capacity. Several bins within this size range provide more versatile, useful storage than one or two bins having the same total capacity. To maintain acceptable quality, food grains must be stored to safeguard them against dirt, insects and contamination by rodents and birds.

Corn (Maize) Storage.—Shelled corn must be handled and stored in the same way as grain like wheat, barley or soybeans. Since harvesting is most feasible at grain moistures above the safe storage level, field-shelled corn must be dried to near 12% moisture before it is stored. Even when harvested in the ear, the moisture content may be too high for storage in warm weather and drying down to 20% or below may be advisable. Ear-corn drying is generally accomplished by adapting the crib and adding ducts, temporary wall coverings, etc., so that large amounts of air—either cold or heated—may be forced through the crib.

In the principal corn-growing areas much of the crop is stored in the ear; *i.e.,* the kernels are not removed from the cob. Ordinarily the ears are not fully dry when harvested, but because of low winter temperatures little damage occurs until the coming of warm weather; during the intervening months the ears have a chance to dry if well stored. The common type of storage in the United States is a crib sided with wood slats spaced about one inch apart to permit ventilation by the wind; perforated clay or concrete-block walls are also used. The width of crib varies with the climate; in the principal growing areas cribs are 6 to 12 ft. wide with vertical sides 8 to 24 ft. high. A popular type of storage in the corn belt of the United States has a crib on each side of a driveway and grain bins above. A mechanical elevator fills both cribs and bins. A 27 by 40 ft. building with 11-ft. driveway, two cribs 8 ft. wide and 20 ft. deep, will store about 5,000 bu. of ear corn and 2,500 bu. of small grain or shelled corn. Because of the weight of ear corn (28 lb. per cubic foot) and its tendency to arch against walls and over crossbraces, walls must be well tied together with braces that can support safely a large part of the weight above.

Temporary cribs are either circular or rectangular in shape and built of snow fencing or wire mesh or of cribbed poles. Cribs that can be tightly closed are needed in warm regions where it is necessary to fumigate to control insects. For long-time storage it is best to shell the corn from the cobs when dry and store the shelled corn in tight bins. See CORN; CROP DRYING AND PROCESSING; CROP-PROCESSING MACHINERY.

Silos.—A silo is any type of structure or container that affords storage for large masses of high-moisture forage. The most common is the above-ground cylinder or tower silo, made of wood, concrete. masonry staves or blocks.

Tower silos vary from about 10 to 18 ft. in diameter and 30 to 50 ft. in height. Silage must be removed from the top at the rate of about two inches per day to prevent spoilage. For this reason the diameter is made proportional to the amount of silage needed. Height is limited by needed capacity. by the length of the feeding period or by practical considerations of cost and labour. A silo 12 ft. in diameter has 113 cu.ft. in each foot of height. Each foot vertically holds about 2.25 tons of silage weighing 40 lb. per cubic foot. This provides 754 lb. each day if two inches are removed, which is enough for 25 animals fed at the rate of 30 lb. of silage per day. A 12-ft. silo 36 ft. high will hold about 100 tons. (The average weight exceeds 40 lb. per cubic foot at depths greater than 14 ft.)

Silage under the heavy pressures found in upright silos puts a severe strain on the walls. Steel reinforcement is necessary in proportion to the height, as rods in mortar joints, embedded reinforcing in concrete and steel bands on wood or masonry staves. Tower silos have continuous or closely spaced access doors and a ladder.

A silo of unique design is prefabricated with a smooth, noncorroding wall of steel having a porcelain or fused-glass surface. It has an airtight top to reduce spoilage and a power-operated bottom unloader that makes the silage handling operation nearly automatic. This container is also suitable for storing high-moisture grain. shelled corn or ear-corn silage.

The trench silo is most suitable for storing large quantities of green corn or grass at minimum cost. The trench is cut into the ground on a gently sloping site. If made 8 ft. deep. 10 ft. wide at the bottom and 14 ft. at the top, a 60-ft. length gives a capacity of about 100 tons. Earth trenches tend to crumble and cave, so for best results the trench should be floored and the sides lined with four inches of concrete. A variation of the trench is a flat, ground-level bunker silo. It is similar to the trench with concrete floor. vertical or slightly sloping sides of concrete or planks, and open at one or both ends. Flat silos can be adapted for self-feeding by fitting a feeding gate across the end which is moved inward as the silage is consumed. Silage is sometimes stored in circular stacks supported by poles and slat fencing, or in long low ricks. Spoilage is high when temporary methods are used. The history of the development of silos and the use of silage is discussed in the article ENSILAGE.

Hay Storage.--Outdoor stacks, overhead lofts and ground-level roofed-over areas have long been used for loose, uncut, air-dried hay. Weight is about four pounds per cubic ft. and storage space is calculated at 500 cu.ft. per ton. Baling or chopping reduces storage space by one-half, doubles the weight per unit volume and facilitates handling. For these reasons, storage should generally be at ground level, either in low-cost sheds for baled hay or in silolike upright metal hay storages or pole-framed, hire-enclosed structures for chopped hay. For highest quality, legume hay is wilted and only partially dried in the field and air-dried under cover. The barn, loft or other storage then requires a system of air ducts and a power fan to prevent overheating and assure uniform drying. *See* CROP DRYING AND PROCESSING; GRASSLAND.

Storage for Fruits and Vegetables.—The cave or cellar is perhaps the most feasible structure for the home storage of fruit and potatoes and other vegetables. A typical cellar is built partially underground and the upper part is mounded over with earth to prevent freezing and provide fairly uniform conditions of temperature and humidity. Although concrete floor, walls and ceiling are recommended, the floor may be omitted and the ceiling made of logs or timbers treated with preservative. A room 8 ft. wide, 8 ft. high and 12 or more ft. long affords liberal storage and is useful also as a storm shelter. Tile drain, air vent, steps and a doorway are necessary.

Fruits and vegetables are sometimes stored in unheated basement space, insulated ground-level buildings with supplementary heat for cold weather or outdoor pits or mounds covered with straw, stalks, building paper and earth. Under such conditions, only short-time storage of several weeks or a few months is feasible.

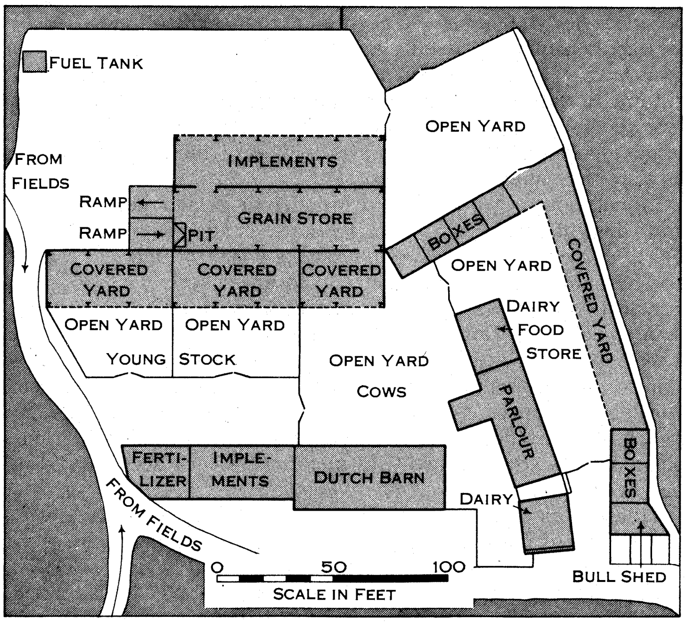
Ideal conditions are obtained only in buildings designed for storage purposes and equipped to maintain control of temperature, relative humidity and air circulation. The cost and labour necessary limit such storages to commercial enterprises or to large specialized farms. The buildings are generally insulated wood-frame structures set on lower walls of masonry. Equipment includes heating systems, refrigeration equipment, electric fans and handling devices such as elevators and conveyers. The buildings are constructed so that humidity in storage rooms can be maintained at about 85% to 90% and temperatures can be kept high enough to prevent freezing and low enough to minimize sprouting and deterioration. White potatoes and most other vegetables should be held at 60° F. for about ten days, then reduced to 50° F. for three-month storage and 40° F. for longer periods. Sweet potatoes (yams) are cured at 85° F., then held at about 55° F., usually in wood-framed, one-story buildings. Apples may be stored at or near 32° F. in well-ventilated storages. *See* FRUIT FARMING: *Harvesting* and *Post Harvest Practices*.

Buildings for Tobacco Curing.—Tobacco "barns" are of two types, for air curing and flue curing respectively. Pole- or post-frame buildings are used for air curing. A barn 32 to 36 ft. wide, 48 or more feet long and having 20-ft. side walls has a capacity for three to four acres of tobacco. Vertical siding is used and about one-third of the wall surface is hinged to allow natural air ventilation in good drying weather. Artificial heat is supplied by coke stoves, oil or gas heaters or a commercial drying unit. Except for a small well-lighted stripping room, the entire space is used for hanging tobacco plants which are strung on four-foot sticks.

For flue curing, the typical building is 17 ft. 8 in. square with 14-ft. side walls. It is tightly built, insulated and fitted with air intakes at the bottom and an adjustable ventilator at the ridge. Because artificial heat is necessary, close attention needs to be given to fire safety, air circulation, humidity control and temperature regulation. Log walls are often used in low-cost barns.

BUILDINGS FOR MACHINERY AND SUPPLIES

Indoor storage of machinery affords protection from weather and animals, makes it easier to maintain a neat, uncluttered farmstead and provides a place for repair and maintenance work. The space is also useful for storing building materials, fertilizers, seeds and other supplies. Machinery-storage buildings should be free from interior posts or other obstructions, have headroom of 10 to 15 ft. over much of the area and doors that will accommodate the largest machines.



ADAPTED FROM A DRAWING IN "FARMER AND STOCKBREEDER"

FIG. 4.— PLANOF A TYPICAL BRITISH FARMSTEAD

Concrete floors are desirable but not necessary. A shed with one side completely open affords fair protection; however, a fully enclosed building is preferable. Post-free construction is obtained by using arches, trusses or heavy beams to support the roof. Walls and roof may be metal or other thin material, or masonry walls with light roof frame and covering may be used. One common design has wood or metal arches spanning the width of the building. The framing members are attached to foundation or floor slab, and covered with any one of several materials.

The minimum practical storage building is about 12 ft. by 24 ft., which is one-car garage size. The two principal farm types are described as follows: (1) the "side-door" building, generally 20 to 32 ft. wide, which has a nearly continuous series of doors in one wall along the length of the building. The narrow width and numerous doors add to the cost if considerable machinery is to be stored. (2) The "end-door" drive-through type, 36 to 48 ft. wide and as long as needed, is best for ample capacity. Doors are located in each end and a centre driveway, kept free of all except wheeled vehicles, gives maximum convenience. Buildings of this type are adaptable to many purposes and are often used for baled hay, grain (with suitable bracing and bulkheads), cattle or sheep. *See* also AGRICULTURE; AGRICULTURE (ARTICLES ON).

FARM COLONY or GROUP FARM, a joint operation of a large farm and some or all of its related enterprises by a group of individuals or families with common social or economic objectives. Such associations may be defined according to their methods of income distribution, as follows:

1. Joint cultivation association: individual farmers pool some of their productive resources, such as land, machinery, livestock and labour. Proceeds of their joint effort are divided on the basis of each member's investment in, and service to, the association.

2. Co-operative corporation farm: several individuals or families co-operatively own or rent a large farm and operate it as a single unit. Income is distributed on the basis of the value of labour contributed by each member.

3. Communal farm: a large farm operated on the principle that each

member must contribute his labour and other resources according to his ability. He benefits from the enterprise on the basis of what the group considers to be his needs.

4. Institutional farm colony: a large farm employing many people, operated by a government or private welfare institution in charge of determining policy. Wages are paid in the form of subsistence in kind (food, housing and clothing), cash or special grants according to the needs of each individual, as determined by management.

Farm colonies generally have been established to serve purposes beyond the mere production of income. They have been conceived as instruments of moral revival, social reform or national resources planning. Operations have tended to be heavily influenced by an ideology. on the basis of which the farms can be classified into four major types: religio-utopian, secular-utopian, socio-economic and welfare. Each of these types is discussed below.

Religio-Utopian.—Most religio-utopian farm colonies have been established by devout believers seeking moral revival by following, for instance, the example of Jesus and his apostles, who are reported to have lived together and "had all things in common . . . and parted them to all men, as every man had need" (Acts ii, 44–45) Some of the early lay Christians lived on communal farms, as do members of certain contemporary Catholic religious orders, which also emphasize celibacy, frugal living and charity. Communal farms have been operated for many centuries by Taoist and Buddhist monks.

During the 18th and 19th centuries, secular farm colonies with religio-utopian ideology were organized by several fundamentalist Protestant sects in the United States. Many of these groups originated during the late Reformation period in southern Germany. There, under the influence of Anabaptist preachers, small groups of disciples who nished to share a common life gradually formed compact communities. They migrated to North America, where cheap land and religious tolerance presented more favourable circumstances for establishing their "Kingdom of God" than did their native lands. Among these groups were the Ephrata community of German Seventh-Day Baptists, who settled in Pennsylvania (1732–1905); the Harmonist disciples of Father George Rapp. who founded the villages of New Harmony, Ind., and Economy Pa. (1814–1905) (see NEW HARMONY); the Separatists at Zoar in Ohio (1819–1898); and the followers of the mystic William Keil, nho pioneered at Bethel, Mo., and Aurora. Ore. (1844–1881). The Shakers (q *v.*), from England, established more than 20 farm colonies after 1778 in states east of the Mississippi river. They believed in celibacy but replenished their ranks by adopting orphans and converting adults, so that there were a few scattered remnants in the second half of the 20th century.

The Amana society, with a membership of about 2,000 persons after mid-20th century, is established in several villages in eastern Iowa. Their ancestors landed in New York in 1842 as the "Community of True Inspiration," which had been founded in 1714 in Württemberg, Ger. The economically communistic principles of the society were abandoned in 1932, when it was transformed into a co-operative stock company. Members or their children are given preference in employment; all are entitled to free medical and dental service, free burial and, if necessary, support in old age by the society.

The Hutterian Brethren form the largest of the contemporary religious communal sects. About 400 migrated from Russia to South Dakota in 1874–77, to settle in three colonies. In the early 1960s they numbered about 13,000, living in about 11j colonies in western Canada (Alberta, Saskatchewan and Manitoba) and in South Dakota, North Dakota, Montana and Washington. The Hutterites emphasize economic self-sufficiency, supporting themselves through diversified farming and stock-raising, and also engaging in carpentry, building, and electrical and machine-repair work, largely for their own use. There has been much change and mechanization in their income-producing activities, in contrast to the stability of their customs governing personal conduct. family relationships and community life. The latter have changed very slonly since 1528, nhen the early Hutterites were forced to flee Switzerland because of their belief in communal living, pacifism and Anabaptist protestantism. They settled in North America after an odyssey of centuries through temporary havens in Bohemia, Hungary and Russia.

During World Wars I and II, the pacifist convictions of the Hutterites were used as rationalization by some people in Canada and the United States to engage in acts of vandalism or to urge restrictive measures against the sect, which is strongly resistant to all pressures for assimilation. In 1944, the Alberta government passed the Communal Property act, which singled out the Hutterites for restrictions on the purchase of land and prohibited such purchases nithin a radius of forty miles of any existing Hutterite community. Legal obstacles to land purchase were also imposed in South Dakota in 1958. Yet a social and psychiatric study of the group from 1949 to 1954 showed that few Hutterites have ever been institutionalized in mental hospitals or jails, or have required public assistance.

Other religio-utopian farm colonies, like those of the then polygynous Mormons in Utah (1840s) and the Oneida Perfectionists in Vermont and New York (1847–81), who advocated eugenics, were of U.S. origin. Many mushroomed into existence under the influence of revivalist preachers. About 67 other such short-lived farms were organized, mostly in the 19th century. (See LATTER DAY SAINTS. CHURCH OF JESUS CHRIST OF; ONEIDA COMMUNITY.)

Among religious pacifists, group communal farm efforts are not uncommon. Many such colonies had a transitory existence in the United States and Great Britain in the decade before World War II. Foremost among them is the Bruderhof movement. In the late 1950s it had about 1,500 members of 20 nationalities in 11 communities in Paraguay, Uruguay, Germany, England and the United States. Since its founding in 1920 by a German pacifist philosopher, Eberhard Arnold, the movement has grown by attracting intellectuals seeking a sense of identification within an idealistic community. The group shares most of the beliefs and some of the practices of the Hutterites, but does not isolate itself from the larger society in which it lives. It favours higher education. The European and North and South American settlements, while nidely separated geographically, have a common sense of identity and give each other mutual support. The members hope to become the focal point of a new order. They publish a bulletin, the ***Plow,*** in English, German, Spanish and Dutch.

Secular Utopian.—These farm colonies generally had a socialist ideology. Ethical concepts of the virtues of co-operation and neighbourliness also played an important role. Like the religio-utopians, they practised complete economic communism, but it was rationalized on the basis of secular expediency and a humanistic belief in the common good rather than on the basis of religious faith. Most of these colonies had a short life span; many broke up within a fen months because of disagreement concerning their ideology and management. The leaders usually had a detailed theoretical program of action to eradicate what they considered to be the antisocial practices of their capitalist contemporaries. Many of the members, honever, had not joined on the basis of any positive program, but were drawn together by a common protest and the hope of escaping from an imperfect world. Other such colonies experienced great difficulty because their members were largely of urban background—persons who had joined in response to urges to live a "simple" and "creative" life in the country but uho lacked previous experience in agriculture and handicrafts. After the initial enthusiasm there mould follow a gradual disillusionment during which many members left because of inability to do the nork.

The English social philosopher. Robert Owen (*q.v.*), "fathered" 17 such colonies in the 1820s, among which New Lanark in England and New Harmony (*q.v.*) in the United States were the most famous. During the 1840s, some 40 U.S group farms based their system on the nritings of the French utopian socialist, Charles Fourier (*q.v.*). The Brook Farm (*q.v.*) group in Massachusetts (1841–47) had many prominent members including Ralph Waldo Emerson and Nathaniel Hawthorne. Seventy-five others are known to have existed. including the French Icarians, who migrated to the new world during the latter 19th century (see CABET, ETIENNE; NAUVOO); the anarchist New Llano group in Louisiana (1914–36); and the short-lived Sunrise community of urban Jewish workers in Michigan (1933–35).

Socioeconomic. — These colonies developed in response to an interest in economic and social efficiency rather than utopian ideology. They were essentially a 20th-century development, although an illustrious forerunner of this type of group farm was the communal colony of the Plymouth pilgrim fathers. During the 1930s, under the New Deal program of rehabilitating low-income farmers in the United States, joint-cultivation types of farm colonies and family-farm homestead projects were established. About 25 co-operative corporation farms were organized, all but one of which were converted in the early 1940s into individually owned farmsteads.

In England, the commissioner for special areas: in co-operation with local authorities and the ministry of agriculture, experimented with small homestead colonies to assist middle-aged men whose prospects for reabsorption into industry during the 1930s seemed remote. A number of central farms were set up, each with a warden in charge. After a year's training the men were transferred to small individual holdings. Subsistence homesteads, providing house and small garden plots for low-income industrial workers were also tried. By 1949, nearly 700 families had been settled on 19 estates of the land settlement association. A manager provided technical guidance, purchased supplies for the entire group and sold its products.

The American and English group-farming experiments were largely a depression phenomenon. They involved people who had little in common but their poverty and who lacked a philosophical identification with the idea of co-operation. Increased agricultural efficiency and mechanization of agriculture during and after World War II led to the virtual disappearance of government interest in further group-farm experimentation, with one noteworthy exception, in the Canadian province of Saskatchewan, after the Co-operative Commonwealth federation came into power. In 1945 the provincial government established a department of co-operation and co-operative development to encourage rural people in pooling their resources to attain greater economic efficiency and a higher standard of living as well as to facilitate the establishment of villages rather than isolated settlements on formerly virgin territory. The government has an educational program and provides credit. By the late 1950s there were more than a dozen such co-operative farms and about 175 associations owning farm machinery, producing fodder or trapping fur-hearing animals co-operatively. Some had been organized on provincial land by veterans of World War II; others were composed of neighbouring farmers or relatives who decided to pool their land and machinery.

The most spectacular use of farm colonies as an instrument of national reconstruction is found in Israel, where co-operative farm settlements produced 80% of the country's food in 1959. Israel's experiences have been closely studied by representatives of other countries, such as India, Burma, Ghana and Nigeria. Beginning in the late 19th century, Jewish migrants from Europe to Palestine often settled in farm colonies for reasons of economy, efficiency and safety, as well as sociability. Members generally shared a common ideology, such as socialist utopianism, ethical humanism or Jewish orthodoxy.

The main forms of modern co-operative settlements in Israel are:

1. Communal farms, called kibbutz or *kvutzah*. They have from 60 to 2,000 members, who work without pay and are supplied with individual housing, clothing, medical care and other personal needs. There are central dining rooms and kitchens, communal kindergartens and, often, children's dormitories. An increasing number of these settlements have established industrial enterprises. Since the foundation of the first one, Deganya, in 1910, some have become quite prosperous. Many are able to provide a good education for the children, maintain communal libraries and recreation buildings and give their members regular vacations. Especially since the establishment of the Israeli government in 1948, there has been a trend toward more privacy for member families, larger allowances for spending money, and private ownership of clothing and furniture.

2. Joint cultivation associations, called moshav ovdim. These settlements are solely agricultural and range in size from 100 to 1,000 persons. They provide more privacy and individualism than is possible in a kibbutz. Members farm their own land, but use much of their machinery co-operatively and do most of their buying and selling on that basis. No property can be transferred to a new family without approval of the elected village council.

3. Co-operative corporation farms, called moshav *shitufi*. These combine the communal production of the kibbutz with the family ownership of a home and garden of the moshav ovdim. Agricultural and industrial resources are owned in common. Work and pay are adjusted to individual family circumstances. Each family in the moshav *shitufi* takes care of its own children and domestic services, such as food and laundry.

Farm colonies also were used to assist Jewish and other religious refugees outside Israel. At the beginning of the 20th century, the Jewish Colonization association established 19 family homestead projects in Argentina for victims of the Russian pogroms; by 1940 these supported a population of 27,000. Several hundred German refugee families were settled during World War II at Sosúa by the Dominican Republic Settlement association, financed by American philanthropists.

Large-scale voluntary mergers of small peasant holdings into joint cultivation associations and co-operative farms have occurred in Mexico, .particularly during the presidency of Lázaro Cárdenas (1934–40). *Ejidos* (land-owning villages) were provided with liberal credit for the purchase of machinery, and were furnished with free technical advice. In India, the religious Bhoodan movement was reported in 1959 to have transformed parts of 500 villages into co-operative cultivation associations, dedicated to improvement in productivity, rural hygiene, education and social development. This movement was inspired by Vinoba Bhave, a follower of Mahatma Gandhi, who walked from village to village persuading landowners to donate part of their holdings to some of their landless neighbours.

Group farming has also been used as an instrument of Communist economic and social policy. In Russia, a number of peasant joint-cultivation associations (tozes) and communal farms, composed mostly of idealistic urban workers who wished to live together under a system without private property, were set up after the Revolution of 1917. These voluntaristic forms of association were abolished under Stalin's regime. Preference was given to state-managed mergers of private land holdings into large, nominally co-operative corporations, the kolkhozy. Peasants were increasingly pressured into joining. Under Stalin, *kolkhoz* managers had to be approved by the Communist party. Further central control over their operations was exercised at regional, state-owned machine-tractor stations, from which heavy farm machinery was rented and agricultural experts were assigned. Vast tracts of virgin land were also brought under cultivation by group farms under direct state control and ownership in the *sovkhoz* form of settlement.

The haste accompanying the forced collectivization of Russian agriculture resulted at first in a great loss of productivity and was accompanied by much suffering, particularly during the early 1930s. Conditions improved gradually, but peasant resistance to involuntary and total "co-operation" did not entirely disappear. After Stalin's death, the Soviet government gradually increased the degree of autonomy of agricultural producer groups. The kolkhozy were allowed to purchase machinery. Machine-tractor stations mere gradually abolished. Peasants were allowed to cultivate small garden plots and to dispose of their products individually, on the open market.

The spread of Communism during and after World War II to eastern Europe and parts of Asia, especially China, was accompanied by forced collectivization of holdings of individual peasants. In Yugoslavia and Poland, after initial widespread organization of farm producer co-operatives by Communist functionaries, peasants were given some power to decide on the degree and kind of co-operation. As a result, most of the *kolkhoz*-type associations were dissolved. During the rebellipn of October 1956 in Hungary, peasants dissolved about 2,500 of the 3,950 collective farms that had been organized after World War II. Collectivization was pushed in China in the late 1950s to facilitate central economic planning and the mechanization of agriculture.

Welfare Group Farms. — These enterprises are operated by schools, mental hospitals, prisons, poor farms and orphan asylums for educational and rehabilitation purposes. They are under the direct supervision of the institution, with the welfare of the charges rather than farm' production ostensibly being the primary objective of the operations. Before World War I such farm colonies were used on occasion to provide for permanently unemployed persons. However, the unemployment-insurance systems developed in many countries after World Wars I and II proved to be a more satisfactory method of relief, although a few of the older rehabilitation colonies remained in operation.

Farm colonies, irrespective of their structure and ideology, provide a mechanism for reducing the isolation of rural existence and for promoting the mechanization and efficiency of production. They have been the object of considerable social and economic study, since they are generally planned on the basis of an explicit rationale and are small enough to be investigated with resources available to social scientists. Edward A. Norman established a research centre in this field, the Rural Settlement institute, later the Group Farming Research institute (1941–56). An International Council for Research in the Sociology of Cooperation was organized in 1953. It has headquarters in Paris and Milan, Italy, and publishes the *International Archives of Sociology of Cooperation.*

FARMER-LABOR PARTY, a minor U.S. political party representing the interests of small farmers and urban workers. The Farmer-Labor party of Minnesota—a state with a large Scandinavian population, politically oriented trade unions and a progressive tradition — grew out of the Nonpartisan league (*q.v.*), which had. become active in that state in 1916. Farmer-Labor candidates were nominated as early as 1918, and in 1920 the party placed a ticket in the general elections but withheld active support from the national party (see *National Farmer-Labor Party,* below). In 1922 the Minnesota party elected a U.S. senator and tno representatives. In 1923 the party became the Farmer-Labor federation and won the election of another senator, to fill an unexpired term; in 1930 its candidate Floyd B. Olson was elected governor of the state. He was re-elected in 1932 and 1934, serving until his death in 1936. In that year the federation gained control of all branches of the state government except the state senate, and elected five U.S. representatives and another senator. The federation supported Robert M. La Follette for president in 1924 and Franklin D. Roosevelt in 1932 and 1936.

A political force in one state only, the Farmer-Labor party was an example of a third party that became in fact, for a limited time and in a limited area, one of the major political parties. The election of Harold Stassen, a Republican, in 1938. and his reelection for tno successive terms, marked the beginning of the end for the party. nhich ceased to function as an independent party in 1944 when it joined forces with the Democrats to form the Democratic-Farmer-Labor party. Hubert Humphrey. U.S. senator from Minnesota, first elected in 1948, was instrumental in bringing about this coalition.

National Farmer-Labor Party. — This group was formed from the National Labor party in one of many attempts to unite small farmers, farm workers and urban trade unionists under one banner. In 1920 it nominated Parley P. Christensen for president and Max S. Hayes for vice-president, but, because it lacked finances and organization and failed to win the support of Progressives, Socialists, the Nonpartisan league or the Farmer-Labor party of hlinnesota, it polled few votes. Capture of party control by militant trade unionists at the 1923 convention in Chicago alienated potential supporters, including the Farmer-Labor leaders; and the party disintegrated. The idea, however, persisted, as evidenced by the formation of the La Follette Progressive party in 1924.

The party's platform was antimonopoly; advocated the nationalization of public utilities, basic industries and banks; and protested labour injunctions as usurpation of legislative power by the courts.

FARMERS UNION, officially the National Farmers union and also known as the Farmers Educational and Cooperative union, was founded by Newt Gresham at Point, Tex., in 1902. Its early leadership and policies justify its being called the natural successor of the farmers' alliances of the 1880s and early 1890s. Initial success in controlling prices by not selling except for specified minimums led to rapid expansion of the union in the cotton states. To bolster this program it was necessary to limit production and ultimately add credit assistance based on crops stored in warehouses. Experience showed the importance of educating the farmers with reference to marketing, credit and tenure; these problems, together with co-operative enterprises, continued to be basic concerns of the union.

In the period from its organization until the mid-1920s the Farmers union was concentrated largely in the south and southwest. Beginning in the early 1920s leaders from the plains states became active and both membership strength and leadership in the Farmers union shifted from the south to the plains states. The union supported legislation to strengthen farmer co-operatives, increase credit available to farmers and increase farm prices. The National Farmers union became badly split in the 1930s on the issue of campaigning for specific office seekers. Those who favoured keeping education and the building of co-operatives as the major task of the union won control of the national offices. During the 1920s and the 1930s there were a number of reorganizations, especially in relation to the business enterprises sponsored.

Following a reorganization in the 1940s the National Farmers union developed a legislative program in support of an expanded program of supervised credit to low-income farmers, increased co-operative marketing, expansion of farm price supports at levels up to 100% of parity and production-control programs as needed to implement price supports.

In the mid-1950s plans were completed to develop potash deposits owned in New Mexico. Although only 24 states had active state Farmers unions, with a membership of about 300,000 farm families, a ten-year expansion program was launched to achieve the goal of an active state Farmers union with affiliated business services in all of the states. Profits from the potash fertilizer business were to be used to finance this expansion program.

The Farmers union from its earliest years differed from the American Farm Bureau federation (*q.v.*) and the Grange (*q.v.*) or National Grange of the Patrons of Husbandry in engaging in more informal co-operative activities with organized labour. in its greater emphasis on the problems of small farmers and in its advocacy of market reforms which often included greater government controls than the other farm organizations were willing to endorse.

Local Farmers unions are formed by ten or more male members.

Often the local unions are organized on township lines. The local unions form and support the county unions which in turn support the state unions. The state Farmers unions sponsor young people's educational and recreational programs. As in the case of the Farm bureau and the Grange, Farmers union locals usually have social and recreational programs for their membership and take an active part in community affairs. *See* also AGRICULTURAL ORGANIZATIONS.

FARMING THE TAXES. A method of collecting taxes indirectly through contractors instead of directly through officials of the state. The system is best known through the *publicani* of Rome, who formed companies or syndicates to farm not only the indirect taxation of the state, but also sources of the state revenues, such as mines, fisheries, etc. (*see* PUBLICANI).

In monarchical Europe the revenue was almost universally farmed. France from the 16th to the 18th century is the most interesting modern example. Because of the hopeless condition of its revenues, the French government was continually in a state of anticipating its resources, and was thus entirely in the hands of financiers. In 1681 the indirect taxes were farmed collectively to a single company (*ferme générale*).

The rapacity of the farmers-general was proverbial, and the detestation in which they were held culminated in the execution of 32 of them during the French Revolution and the sweeping away of the system.

FARMINGTON, a city of San Juan county in northeastern New Mexico, U.S., at the confluence of the San Juan. Las Animas and La Plata rivers. Farmington was first settled in 1876 when Indian lands were opened to homesteaders, and was incorporated as a city in 1901. The region's first business was cattle ranching, but fruit growing was introduced in 1879 and soon there were flourishing orchards. A small rural town throughout the first half of the 20th century, its population was about 3,500 in 1950. The discovery of natural gas and commercial'oil pools in the 1950s turned the city into an oil and gas centre. Pipelines were built to the Pacific coast. drilling operations were intensified and pumping plants were built. Economic growth also was accelerated by construction of Navajo dam, a bureau of reclamation irrigation project 40 mi. upstream on the San Juan river. By 1960 the population reached 23,786, an increase of 654% over the preceding decade. For comparative population figures *see* table in NEW MEXICO: *Population.* (O. R.)

FARM MACHINERY. Farm machinery includes power machines, tractors and field machines or implements and machinery used for saving labour about the farmstead. Specifically, a machine is a device used to transfer, transform or apply energy to do useful work. While machines include hand tools, such tools are not ordinarily considered in the general classification of farm machinery.

This article deals with the influence of farm machinery on agriculture and discusses developments in the use of power machinery in preparing the soil, planting, cultivating, harvesting and threshing. Additional information on specific kinds of farm machinery will be found in the articles CROP-PROCESSING MACHINERY; DAIRY INDUSTRY: *Dairy Machinery and Manufacturing Processes;* HARVESTING MACHINERY; PLANTING MACHINERY; SPRAYING AND DUSTING MACHINERY; TILLAGE MACHINERY and TRACTORS. See also AGRICULTURE; RURAL ELECTRIFICATION.

The development of farm machinery operated by tractors and electric motors put the modern farmer in the capitalist class. On many modern farms the capital investment per worker is greater than the investment per worker in industry. The investment in machinery on U.S. farms, for example, increased 350% during the 20-year period preceding the second half of the 20th century. While farm machinery was not used as extensively in many parts of the world as in the United States, there developed a growing world-wide recognition that improvement in agricultural production required an increase in the use of machines.

The farmer is a director of both mechanical and electrical power. In the second half of the 20th century each farm worker in the U.S. had an estimated 40 h.p. at his command. In 1933 each worker commanded 33 h.p.; in 1920, 5.3 h.p.; and in 1870 only 1.6 h.p. During World War II the tractor power per acre was greater in England than in the United States.

Aside from speeding the farm work and reducing production costs, the use of tractors instead of animals for power on farms also released millions of acres for the production of food and fibre for humans instead of feed for work animals. Pasture areas so released made possible increased production of beef and other livestock. Timeliness, a most important factor in successful agricultural production, was made possible through the use of modern implements and machines powered by tractors.

During early colonial days in America, 85% to 90% of all workers were required to produce the food and fibre needed, meeting the demand less adequately than did slightly more than 10% of all workers in the second half of the 20th century. Wherever modern machinery was used, the agricultural worker was more efficient, an adequate food supply was assured and fewer workers were needed.

THE USE OF POWER

History. — The history of agricultural development is marked by advance in the efficient use of human labour through the use of machines and equipment designed, developed and improved to utilize animal and mechanical power.

The methods used by the American pioneers in tilling their small fields up to the end of the 18th century were little different from those of farmers in ancient Egypt, Greece and Rome. It was still the age of human power.

While animals had been used during the previous years, it was not until the beginning of the 19th century that the age of animal power began to advance. This resulted from the development of better plows, tillage tools, drills, planters and harvesting equipment designed to be drawn by animals. With the development during the first quarter of the 20th century of "big-team" hitches for pulling plows and combines, the use of animal power in the United States, particularly horses and mules, expanded until after World War I.

With the animal power and implements available, the farm labour required to produce a bushel of wheat was reduced from slightly less than three man-hours in 1830 to slightly less than one-half man-hour in 1896 and to one-fourth man-hour by 1930. This time was cut in half by the second half of the 20th century with tractor-operated equipment. With self-propelled machines, the time required was further reduced.

With the advent of the row-crop or general-purpose tractor, mechanical power had taken the place of horses and mules on most U.S. farms by the second half of the 20th century and was rapidly replacing oxen, horses, mules and water buffalo as power units on farms throughout the world.

Steam Engines. — Steam engines were first used as stationary power units, to take the place of treadmills (animal power) and windmills, to operate stationary machines such as grist and feed mills, wood saws and cotton gins. Later, self-propelled steam engines were used for operating stationary threshing machines that were moved from farm to farm. Many of these units were owned co-operatively by a group of farmers who organized a "threshing ring." Because of the heavy weight, such steam tractors never proved satisfactory as power units for drawing farm machines other than the huge plows of 10-, 12-, 16- or 18-furrow capacity used on the Great Plains.

Tractors. — The internal-combustion-engine tractor had its beginning at the turn of the 20th century. The tractor was first developed as a dual-purpose machine — as a draft machine to take the place of teams of horses and other animals and as a stationary power source for operating shellers. threshers. grinders and other belt-driven machines. By the second half of the 20th century, farm implements and machines were designed as an integral part of the operating unit and were quickly and easily interchanged for the work at hand.

An outstanding contribution of the tractor industry was the development in 1935 of hydraulic-control equipment which literally lifts the implements by fingertip control, the implements being easily and quickly detached from or attached to specially designed hitch bars. An extension of the hydraulic system through a remote or "slave" hydraulic cylinder extended hydraulic control to the raising, lowering and adjusting of drawn equipment as well as integral or tractor-mounted tools.

Modern hydraulic-mechanical devices automatically control working depth of tillage implements, relieving the tractor operator of the need for shifting gears or making adjustments as the implement encounters surface irregularities or changes in soil texture. Tractor speed is maintained, with good uniformity in the tillage job.

PREPARING THE SOIL

Plows.—More power is required in the preparation of the land for planting than in any other farm operation. The plow is the world-wide basic tool of agriculture. Use of oxen or horses to draw it was an outstanding contribution to the advance of agricultural production.

The plow was brought to Britain by the Romans. Some early horse-drawn plows were equipped with wheels and designed to be hitched to the horse's tail. This custom of hitching existed in Ireland as late as 1634, when an anticruelty law was passed prohibiting "plowing by the tayle."

A Dutch plow with a wooden moldboard was improved and patented as the Rotherham plow in England in 1730.

Early American statesmen were greatly concerned with the problems of agriculture. In 1788 Thomas Jefferson presented, as an original mathematical treatise, an account of the principle for constructing a moldboard plow, first to the Institute of France and afterward to the board of agriculture in England. Daniel Webster designed and constructed a large plow to be drawn by 10 or 12 oxen. The cast-iron plow was patented in the U.S. in 1797. It was found to be a good plow for use where the soil was sandy and stony.

As the American settlers moved westward, plowing the black prairie soils, high in organic matter, posed a special problem to the farmers who had cast-iron and iron-patched wooden plows. The ingenuity of John Deere, an Illinois blacksmith and plow maker of the 1830s, resulted in a new kind of plow which was made entirely of steel except for the braces, beam and handles. The one-piece share and moldboard of his first steel plow was cut from a mill-saw blade and shaped over a wooden form. This greatly improved plow not only made possible the effective plowing of the black prairie soils, but according to one writer "it cut by at least one-third the animal power needed to turn the soil."

Improvements of plows followed. Soft-centre steel for the moldboard was introduced in 1868; the three-wheel sulky or riding plows were followed by plows designed to be drawn by tractors, and later plows were mounted on tractors, which made plowing much faster, less laborious and often deeper than it was in the days of animal power.

Disk plows, developed toward the close of the 19th century, are used in hard dry soils, in soils that do not scour readily and where extremely heavy trash must be plowed under.

Harrows.—While the plow is the basic implement used in seedbed preparation, other implements have been devised for final preparation of the land to receive the seed. The branch of a tree was the first harrow. A wooden A frame with wooden teeth, and later iron teeth, was an improvement made during the first half of the 19th century. Steel-frame harrows with steel teeth and also a rotary type of harrow similar to the modern rotary hoe were developed in Norway during that period.

The disk harrow is second only to the plow as an implement for use in preparing a seedbed. It came into use in the late 1860s, but was not patented until 1877.

Other harrows have been developed for special uses in addition to seedbed preparation. Examples are the spring-tooth harrow, used for summer fallowing and weed control.

PLANTING AND CULTIVATING

In the early history of agriculture all the sowing of small grain was done broadcast. The farmers of China, India, Japan and Arabia, however, have drilled in their seeds from earliest recorded history. Information on primitive tools and methods used in planting and cultivating will be found in the article AGRICULTURE, PRIMITIVE.

Seeding Machines.—It is believed that the first seeding machine was developed and used by the Chinese about 2800 B.C. The Chinese drill of the middle of the 19th century resembled a wheelbarrow, nith three small, hollow teeth about 28 in. in length which carried the seed from a box supported above the wheels. The Italians had a two-wheeled seeder around A.D. 1600.

Seed and manure drills were in use in England as early as 1649. Jethro Tull (*q.v.*), an English farmer and writer, perfected a machine drill about 1701 and described a drill for planting turnip seed in his *Horse-Hoeing Husbandry* (1731).

In the United States the first patents on a seeding machine were granted in 1799 but it was not until about 50 years later, in 1851, that the force-feed drill was patented. This drill was equipped with a device which controlled the rate of seeding.

Concurrently with this development, in 1848 drills were equipped with manure and seed colters or blades, acting independently of each other, which deposited manure at one depth and covered it, and deposited the seed at a shallower depth and covered it. Within a hundred years, tractor-drawn machines were developed to place commercial fertilizer in relation to seed for the most effective results. Often hitched in huge squadrons, these drills, drawn by a large tractor, could seed a strip 50 ft. wide.

American machines were available in the second half of the 20th century which in one operation prepared the seedbed, with the mulch on the surface, planted the seed and placed the fertilizer. Drills and seeders accurately planted small grass and legume seed of all kinds along with the grain.

Corn Planters.—Row crops grown in hills of one or more plants are usually planted with a planter. The American Indian and the early settlers used a hoe to open a hole in which three or four kernels of corn were dropped and covered with the same tool.

The first American corn planter patent was issued in 1828. A forward step came in 1860 with the development of the cross-checking two-row planter, tripped by hand for checking as the planter crossed marks previously made in the field. The automatic check rower, tripped by a knotted cord placed across the field, was patented in 1875. The planter wire replaced the cord a few years later.

The first tractor-powered planters were the ordinary horse-drawn type adapted to be pulled by a tractor. They were supplanted with tractor-drawn two- and four-row equipment in the early 1930s. The speed and accuracy of these planters made it possible for the operator to control the time of planting, which played an important part in increasing corn yields.

In the second half of the 20th century equipment was introduced that could plant six, eight or more rous. Also planters could be equipped to do a fourfold operation: (1) plant the seed; (2) distribute fertilizer; (3) sow insecticides to kill ground-born parasites; and (4) apply chemical weed killers to kill weeds upon emergence through the surface.

Cotton Planters.—Cotton planters mere not perfected as rapidly as corn planters. The first U.S. patent on a cotton planter was issued in 182j. and a one-mule improved planter was invented about 50 years later. The modern cotton planter is designed so that the plates which carry the seed in the hopper are interchangeable nith plates designed to plant corn, sorghum and other seed. Multiple-ron cotton planters have been perfected.

Special Planters.—Special planters were developed for planting sugar-beet seed segmented to ensure more nearly the proper stand with minimum thinning. Potato planters. with automatic dropping mechanisms, eliminated the slow, laborious job of hand planting. These mechanical planters were designed to open the furrow, space and drop the seed pieces, properly place fertilizer and cover the fertilizer and seed at the proper depth.

Transplanting Machines.—Commercial gardeners and nurserymen who plant large quantities of plants and seedlings use transplanting machines. The essential parts of such a machine are a furrow opener, a water-supply tank, a hopper for fertilizer and blades for covering the fertilizer and forcing the soil about the plant.

Cultivating and Cultivators.—A crop is cultivated to promote growth of the plants and to destroy weeds which absorb moisture and plant food to the detriment of the crop.

To Jethro Tull, referred to above, is credited the development of what he called "horse-hoe husbandry." Horse-drawn cultivators of different types came into general use early in the 19th century. An improved cultivator equipped with three colters, followed by a harrow, and with a wheel at the end of the beam to regulate the depth and to facilitate turning was invented in Scotland about 1818.

A U.S. patent was issued in 1856 for a straddle-row two-horse cultivator. Later, seats were added, and by 1870 a farmer with two horses could cultivate as much as 15 ac. a day with a riding cultivator.

World War I accelerated the need for and use of multiple-row cultivators. Two-row horse-drawn cultivators were replaced first by two-row, then by four-row tractor-mounted cultivators. Larger multiple-row cultivators appeared in the second half of the 20th century to parallel the capacity of multiple-row planters.

Cultivators for special crops, including beets and beans, and for listed crops (crops planted in ridges) and crops on flat surfaces were developed. Rotary hoes are used for early cultivation of corn, cotton, soybeans, potatoes and small grain. This implement pulverizes the soil crust and destroys small weeds before the crop is large enough to be cultivated with a row-crop cultivator.

Weed and insect control through application of sprays and dusts became important as more was learned about insecticides and weed killers. Much of the loss caused by insect pests, plant diseases and weeds can be prevented through the use of spray material where proper equipment is available and when proved practices are followed. Spraying and dusting are done by custom operators and by individual farmers and orchardists. It became common in the U.S. for custom operators to use both ground machines and airplanes equipped with special sprayers and dusters.

HARVESTING

Sickle and Scythe.—The use of the sickle, a small, curved hand tool, for harvesting small grain dates back to 3000 B.C. The scythe, a larger hand cutting tool, was evolved from the sickle. In the second half of the 20th century both of these tools were still used for harvesting grain and grass in many parts of the world.

The cradle scythe was invented in Europe and was brought to America by the early colonists. The early cradle was a device for gathering the grain stems when cut and laying them in a swath for binding.

The grain stripper—a Gallic invention described by Pliny in the 1st century A.D.—is important as an attempt to lessen drudgery by using animal power. It consisted of a two-wheeled ox-propelled cart with a saw-toothed blade set across the open front to strip the heads, which fell into the cart.

Reapers.—Reaping machines developed gradually and simultaneously on both sides of the Atlantic. In America, where there had always been a labour shortage, development of great wheat-growing areas was impossible without machinery. The U.S. Civil War hastened this development.

In 1786 William Pitt of Pendeford, Eng., failed in his attempt to popularize a header with a revolving cylinder with rows of teeth which caught the heads and dropped them into a box.

The first English patent for a reaper was taken by Joseph Boyce in 1799. Invention followed invention, each adding features. until in 1822 Henry Ogle constructed a reaper that used a straight-edged knife blade as a cutter and employed a reel of revolving bars or arms, resembling the modern form, to push grain back upon a platform. Although Ogle's machine never became popular, his principle of the cutter and reel was adopted in all subsequent successful designs.

In 1826 Patrick Bell, a Scottish minister, invented a reaper with a shear-action cutter—movable blades cutting against stationary blades—a principle still in use.

Although the first U.S. patent was granted in 1803, no machine of importance was patented until 1822, when Jeremiah Bailey brought out a combination mower and reaper. The next invention worthy of mention was that of William Manning in 1831. His cutter bar reciprocated, that is, moved alternately from side to side, over guard teeth, as if anticipating designs used by Obed Hussey and Cyrus H. McCormick. Hussey and McCormick experimented with reapers simultaneously. McCormick had his at work by 1831. but Hussey was the first to secure a patent—on Dec. 31, 1833. Each machine utilized the principle of a reciprocating knife cutting against stationary guards or fingers. McCormick's machine employed a divider between cut and uncut grain and a reel to topple cut grain onto a platform.

Inventors then turned their attention to providing an automatic device to deliver the cut grain in a form suitable for binding. This brought the self-rake and the dropper. The self-raking reaper held the field from 18jo to 1870, when it was replaced by the harvester. A harvester included a special mechanism to handle and bind the cut grain into sheaves or bundles ready to be set up in shocks. C. W. and W. W. Marsh patented the first successful harvester in 1858. A canvas delivered the cut grain over the drive wheel to a box from which it was taken and bound by two men riding on the machine. This design set the pattern for future harvesters. However, a mechanical binding mechanism was still lacking. Because twine was very expensive. the first binders used wire, but damage to cattle resulted, so these binders were never popular. John F. Appleby made a successful twine binder which was put on the market in 1880 when twine was cheap enough to be used economically.

Thus the McCormick cutting principle, the Marsh frame and the Appleby binder were combined to produce the successful modern binder. The result was a grain binder that was still used successfully, though on a limited scale, in the second half of the 20th century.

The header, which merely clipped grain heads and elevated them into a wagon rack, was developed in the United States, Canada and Australia. The headed grain was usually stacked for threshing at a later date. Use of the header, along with the binder on a lesser scale, continued as standard harvest procedure throughout the Great Plains wheat areas of the U.S. and Canada until the grain combine became widespread early in the 20th century.

Windrower.—The header's more modern counterpart was the self-propelled or tractor-drawn windrower which cut the standing grain and laid it in a windrow atop the stubble. Separating and cleaning were done by the combine harvester equipped with an attachment to pick up the windrow in place of the regular cutting platform. The practice of windrowing was followed in the Great Plains of the U.S. and Canada, where the grain was cured in the windrow to protect it from late-season weather and pest damage.

Threshing or Thrashing Machines.—Threshing or thrashing is the separation of grain or other plant seeds from their husks or pods. Until the middle of the 19th century the chief methods were flailing by hand or treading by animals on a threshing floor. The modern methods employ either the drawn-type or self-propelled combine harvester. which harvests the ripened seeds and threshes them in one operation.

The first step in the mechanization of threshing came in the 17th century when fanning mills were developed for winnowing Andrew Meikle, a Scotsman. in 1786 built a threshing machine which combined the blow of the flail (*q.v.*) with the rubbing action of the threshing floor, the prototype of present-day threshers, in which beaters were fastened to a revolving drum forcing the grain against the ribs of a sparred concave sieve placed below the drum.

Probably the best known of the early American machines was developed by Hiram and John Pitts of Winthrop, Me., to combine the threshing, separating and winnowing processes in a single machine.

Eventually, the combine replaced the stationary thresher.

Combines.—The development of a combine (that is, a combination harvester and thresher) was concurrent with the development of the reaper, the binder and the threshing machine. A U.S. patent was issued to Samuel Lane on a combined harvester on Aug. 8, 1828. The first combine to be built was patented by H. Moore and J. Hascall of Michigan in 1836, but its use was abandoned because of climatic conditions. Later it was taken to California and used successfully in 1854.

The first combines were drawn by horses; later by steam and internal-combustion tractors. The self-propelled combine was introduced about 1908. This was a significant advancement because it made the combine more maneuverable and more efficient. The self-propelled model could go into a field without running down part of the crop on the first round. Modern self-propelled combines literally put one man in complete command of his harvest.

The combine, although originally built to harvest wheat and oats, is used to harvest many other crops, including legume and grass seeds, beans, sorghum grains and corn.

Corn Harvesters.—Many types of corn harvesters have been developed. The sled cutter, one of the early attempts, cut the stalks, which were put in shocks by the operator. Corn binders were developed later. Husker-shredders are used to remove the ear from the stalk, husk it and shred the stalk for feed and for bedding. The corn picker was developed for use where the stalks were left in the field By mid-20th century more than 90% of all corn grown in the corn belt of central U.S. was harvested with the picker.

A shelling attachment (introduced in late 1950s) for the two-row corn picker enabled the grower to harvest his crop as shelled corn or ear corn. A corn attachment for the self-propelled combine had entered the corn-harvesting field in 1954. The corn attachment picked the ears and passed them on to be shelled and cleaned in the separator. Because of the high moisture content of the corn when harvested by either of these methods, a drying and storage problem was created, which was solved by installing crop driers either on the farm or at the grain elevator.

Haying Machinery.—Hay has always been an important crop where livestock is raised. The tractor-mounted mower, the tractor-mounted rake and pickup baler have taken the place of the sickle, scythe, hand rake and pitchfork in the modern production of the hay crop.

About 1930 proposals for a hay conditioner or crusher attachment for a mower were developed. The purpose of crushing the green hay was to reduce the time required in curing or drying. Several U.S. manufacturers produce this type of machine. Other hay machinery includes various types of rakes, tedders, loaders, balers and forage harvesters of several types. The latter machine may be used to cut and chop a green crop and deliver it into a wagon or truck to be stored as ensilage, dried artificially for hay or fed (green) to stock in the feed lot. It may be used, also, to pick up and chop windrowed field-cured hay for storage in barn or stack. With a row-crop attachment, it is used to harvest standing row crops, such as corn, for ensilage.

Special machinery and equipment are found on farms that produce large amounts of hay. Sweep rakes and hay stackers eliminate much hard labour during the hay harvest. Automatic pickup balers permit one man to do a job formerly done by several. In the late 1950s an attachment was devised for the automatic baler which would toss small bales directly into a wagon drawn behind the baler, further reducing the labour and time required in harvesting. While the handling of loose hay in barns has been done with forks and slings, the chopped hay and bales are handled with blowers and mechanical elevators and barn conveyers.

Crop Driers.—Much progress was made in the development of farm crop driers during the second quarter of the 20th century. Thtse units are designed to dry grain and hay with heated or unheated air. The various types of driers and their uses are discussed in CROP-PROCESSING MACHINERY.

Cotton Harvesters.—The perfection of mechanical cotton harvesters led to the complete mechanization of cotton production in some areas.

Machines for stripping mature bolls of cotton from the stalks were developed during the last half of the 19th century. These strippers were not used to a great extent until 1940, and largely at that time in Texas and Oklahoma, where stormproof cotton, which is stripped or snapped in a once-over operation, is the principal type grown. With a stripper, one man did the work of 20 men snapping by hand. While a bale of cotton was harvested with a stripper in 30 minutes, it took one man about 40 to 50 hours to harvest a bale by hand.

In open-type cotton, which cannot be stripped, the bolls open wide as they mature to expose the cotton fibre for easiest plucking or pulling. The mechanical cotton picker draws the lint from open bolls and leaves the unopened bolls for a later picking. After many years of field testing, the cotton picker was produced commercially in 1941. As a result, large areas of cotton were mechanized in west Texas, Arizona and in southern California, where open-type cotton is raised.

Other Crops.—Other crops are harvested and handled mechanically. Potato diggers were first available in 1886. Few were used until 50 years later. By 1940 machines were in use that dig, clean, grade and bag the potatoes in one trip across the field. Peanuts, sugar beets, sugar cane and castor beans are harvested with machines designed for the particular crop. These crops were largely mechanized in certain areas by the second half of the 20th century.

FARM MANAGEMENT. Farm management has been defined as both a science and an art and also as the business side of farming. It is a science in the sense that it deals with the organization and operation of a farm to obtain maximum continuous profits. As a manager a farmer decides what and how much to produce and hom- to produce efficiently. In deciding how to employ his resources most profitably, the farmer applies principles of economics and of physical and biological sciences and uses technical information from various fields. As an artisan he develops and practises the skills necessary to perform a wide variety of tasks in crop and livestock production.

This article is concerned primarily with the management of commercial farms and contract farming. For information on management factors involved in other types of farming *see* FARM COLONY; FARM TENAKCY; LAND TENURE: ECONOMIC AND AGRARIAN ASPECTS; SMALL HOLDINGS. The role of government in farm management is indicated in the articles on the various countries; *e.g.,* RUSSIA. *See* also AGRICULTURE: *Agricultural Economics.* For additional references *see* AGRICULTURE. ARTICLES ON.

Management is less specialized in farming than in nonfarm business, although in this respect farming is similar to other small businesses. Particularly with the increased capital requirements of modern agriculture, the farmer must perform many of the functions of a business manager. A farmer acquires. rents or borrows the needed resources and decides how they will be used. Since he usually provides much of the capital himself, he also bears much of the risk of success or failure of the business. The farmer is, moreover, an organizer and supervisor of labour and of the use of power and machinery. He is also responsible for buying and selling, increasingly important functions in commercial farming.

Profit is the principal objective in farm management but not the only one. Avoidance or reduction of risk is more important sometimes than maximum future profits. The objective of continuous profits also means that the farm should be so managed that its productive capacity will be conserved by maintaining a high level of soil fertility, by controlling erosion and by keeping buildings and other capital assets in good condition.

Most farms in the western world are family operated. and decisions concerning farm business are closely related to matters concerning the family's welfare and level of living. Thus the objective of maximum profits may be modified by the family's goals with respect to living conveniences, education, recreation, health and many other factors. The farmer must make business decisions that are consistent both with his resources and abilities and with the needs and desires of the family.

PRODUCTION RESOURCES

Every farmer uses three basic factors or resources in his business—land, capital and labour. These are his raw materials. He must select and acquire these resources and decide how and in what proportions they are to be used to obtain high returns from the whole iarm as a business unit.

Land.—Agricultural land varies greatly in slope and drainage and in chemical and physical characteristics of the soil (*q.v.*). In a broad sense. land includes the natural climatic factors with which it is associated. Differences in temperature and rainfall. as well as the soil itself, affect the value of particular land areas and the systems of farming to which the areas are best adapted. High value of crop or grass production is important in successful farm management. The farmer should grow crops that are well adapted to his land and he should produce high yields per acre.

Capital.—Many kinds of capital are employed in farming. Some is fixed or overhead capital—assets that are used over many years. Some is semifixed capital—machinery, breeding livestock and other assets that are productive over a shorter period of years. Working or circulating capital includes market livestock. feed, annual fertilizers and annual cash operating expenses.

Adequate capital is a means of increasing the productivity of both land and labour. It is essential in modern commercial farming. Mechanization and other technological advances ahich increase production also greatly increase capital requirements. In managing a farm many decisions are made with respect to the use of capital. How can limited capital be most profitably employed? How much should be invested in buildings, in machinery, in fertilizer and in feed? When should capital be borrowed, and how should borrowed capital be invested so that it can be repaid from increased earnings and without excessive risk? *See* also FARM BUILDINGS; FARM MACHIKERY.

Labour.—Labour is generally the most expensive resource, the chief input (or cost) in farming. It amounts to one-third of the total inputs on commercial farms in the U.S. The proportion of labour that is hired varies a great deal with the size of the farm and the system of farming. It was estimated that the total labour input on commercial farms in the U S in the second half of the 20th century was composed of about 28% hired workers, 23% unpaid family aorkers and 49% operator's labour. Although the percentage of labour hired varied widely between regions. predominance of the family farm was apparent from these estimates. In Great Britain the situation is considerably different. According to data published by the ministry of agriculture and fisheries, *Farm* Incomes *in England* and *Wales, 1952–53,* hired workers performed 76% of all farm labour. family workers 5% and the farmer and his wife 19%. On many British farms. however, the farmer and his family do most of the work.

Management.—In economic discussions management is considered a fourth factor of production along with land. capital and labour. Although it is the central resource around which a farm plan must be built, management is difficult to evaluate in most farm situations, for it is virtually impossible to distinguish between results of the farmer's activities as a worker and as a manager. or to determine at the end of the year how much he has earned for managing and how much for use of the capital, labour and often land that he has supplied to the business. Many studies of farm records, however, indicate high rewards for good management. There is a wide range. for example, in financial returns of farmers in the same area with similar land resources and markets. but with different levels of management.

Combinations of Resources.—There are extreme differences between regions and between individual farms in total resources used per farm and in the proportions in which resources are combined. These differences are the result of variations in productivity and value of land, in types of farming and in the relative availability of land. capital and labour. There is a great diversity in the size of individual farms. According to official censuses 46% of all holdings in England and Wales in the second half of the 20th century were less than 20 ac. in size, and 3.4% were 300 ac. and larger, excluding rough grazing land. However, the holdings 300 ac. and over included 25% of the acreage of crops and grass. In the U.S. in 1935, farms averaged 1jj ac. per farm; 20 years later the average was 242 ac. However, the average was less than 200 ac. in some farming regions in the southeast and more than 6,000 ac. in some other regions in the Great Plains. Increases in size were general throughout the U.S., the result of mechanization making it possible for one man to operate more area, of the need for larger businesses to attain the benefits of the greater amounts of capital being employed. of the desire to maintain higher standards of living and of lorn-income farmers leaving the farm for better economic opportunities. The table shows differences between selected types of farms in the U.S.

Acres in Farm and Capital Investment, U.S. Farms

Type of farm and region	Acres in farm	Capital, including land	
		Per farm	Per worker
Cash grain farms, corn belt . .	232	$92,000	$60,000
Wheat farms, south Great Plains .	720	76,500	54,000
Sheep ranches, north Great Plains . .	6,189	81,800	28,000
Dairy farms, central northeast .	208	30,000	15,000
Cotton farms, south piedmont .	179	16,300	7,000

Source: U.S. Department of Agriculture, "Farm Costs and Returns, 1956; Commercial Family-Operated Farms by Type and Location, *Agriculture Information Bulletin 176* (1957).

Ownership of Resources.—A farmer may own or rent the farm he operates. Proportions of the resources furnished by the tenant and the landowner vary. Young men with limited funds often start farming in the U.S. under a manager-tenant lease requiring the tenant to furnish only his labour and management and the landowner. land and buildings, livestock, machinery and other operating capital. Under a livestock-share lease. the tenant usually owns the machinery and a half interest in livestock. The tenant under a crop-share lease owns all livestock and machinery, and delivers a share of the crop production to the landowner as rent. Under a cash lease a specified sum is paid for rent The proportion of resources furnished by the tenant increases in the order in which the leasing arrangements are listed above. Likewise, his risks increase, but so do his opportunities to gain the rewards of superior management.

The decision to buy or rent a farm is important. A man with limited capital to invest, for example, could rent a farm that is larger or more productive than one he could afford to buy. As a renter he could invest in equipment and other resources necessary for efficient operation. and from which he could expect a higher rate of return than that which usually could be expected from investment in land. The decision to buy or rent, however. is seldom made on strictly economic grounds. For many individuals the satisfaction, independence or security of owning their own farms is an important factor. See also FARM TENANCY; LAND TENURE: ECONOMIC AND AGRARIAN ASPECTS; SMALL HOLDINGS.

PLANNING THE FARM BUSINESS

A complete farm plan includes a budget showing how resources are to be used and the returns expected. In a general farming region where farmers have a relatively wide choice of profitable alternatives from which to choose a system of farming, the following are logical steps in developing a long-time plan.

Inventory of Natural and Economic Resources.—In initial planning, a soils inventory is a major consideration. The soil of the farm should be described in terms of inherent productivity, extent of erosion, present fertility level and adaptation to particular crops. Condition and capacity of buildings should also be inventoried. And finally, it is important that the farmer inventory the capital he has available for land improvements, purchases of livestock, machinery or buildings and operating needs.

Planning the Cropping System.—The long-time cropping plan is largely determined by the inventory of land resources. Acres of the farm that are too rough, rocky or wet for cultivation will be used for forests or permanent grazing. For the tillable land, the crop, or sequence of crops, should usually be the most intensive and the most profitable that the farmer can grow on that land considering his labour and capital limitations and the need to control erosion.

Planning the Livestock Program.—With the land-use program determined. an estimate can be made of average annual production of crops, allowing for increased yields that will result from the use of legumes, fertilizers and erosion-control practices. Estimates of crop production and the proportion of grains and forage will be an important factor in determining the kinds and amounts of livestock. Other important factors are the labour and capital available, markets and the skill and preferences of the farmer. Livestock often offers a practical way to increase the volume of business on small farms.

Transition to the Long-Time Plan.—Having developed a long-time plan for crop and livestock production, it is necessary to plan the steps by which it is put into operation. The transition may take several years. It will be facilitated by plans for each year of the transition, showing crops to be grown in each field, fertilizers to be applied, investments to be made. etc.

Estimating Income and Expenses.—The final test of a farm plan is an estimate of income. expenses and net returns. By this means the farmer can compare alternative plans or modifications of a plan already being followed. To test alternative plans a partial budgeting procedure can be used. including only those expense and income items that would be changed if the present plan were altered.

EFFICIENT FARM OPERATION

A successful farm business depends not only on a sound plan but on the efficient application of the plan. Efficient operation requires many skills and much judgment on the part of the farmer. He must know and carry out crop and livestock production practices that result in high yields and low costs. He decides whether it is profitable to substitute machinery for labour, and to use more or less fertilizer or feed under existing price and cost relationships. Timeliness is important in many operations. If labour is hired, the farmer must be able to direct the work of others and train them in efficient methods.

Farm Records.—Farming is a complex business, and production and financial records contribute much to success. They make possible an analysis of the business for the purpose of determining its strong and ueak points and serve as a basis for improvements in organization or in operating techniques.

Farm records have been studied to determine why some farms earn significantly more than others and to provide farmers with standards to which they can compare the efficiency of their own farms. The relative importance of different efficiency factors varies with systems of farming and, to some extent, in difierent periods. In general farming areas, however, crop yields usually have more effect than any other factor. Other factors that have an important influence on earnings are efficiency in livestock production, prices at which products are sold, the choice of crops and efficiency in the use of labour and machinery.

Professional Management.—In commercial farming regions many farms are owned by persons who do not operate them. Some owners employ a manager to supervise the operation of the farm with hired labour or to plan and supervise a farm operated by a tenant. In both Great Britain and the U.S. there are societies of professional farm managers, which publish journals and sponsor meetings. They have established professional standards and codes of ethics, and have done much to maintain high professional standards in the fields of farm management, rural appraisal and farm credit.

CONTRACT FARMING

In some cases a farmer produces under a contract with business organizations engaged in processing or marketing his product or in providing him with supplies. Canning companies contract with farmers to produce specified acreages of vegetables or fruits. Broilers are produced under contracts with feed companies, hatcheries or broiler processors. Contract systems are practised with many other farm products in the U.S.

Contracts vary a great deal, but have the same general effects on farm management. The farmer gives up some of his independence in making decisions as to how to produce and in marketing. In return he reduces risk by having a guaranteed market and usually a price that is set in advance. For this security he lessens his opportunity for highest returns from superior skill in production and in buying and selling.

The contracting company furnishes or finances a part of the capital for feed and other supplies or livestock. In return it has a controlled source of supply to process or market, or an expanded market for supplies that it sells to the farmer.

Vertical Integration.—Production, processing and marketing are interdependent stages in providing consumers with farm products. Co-ordination of these stages is desirable. Vertical integration refers to the co-ordination of management decisions in, or control over, two or more of the three stages.

Vertical integration may be accomplished by ownership, by contract or by co-operative action. This is illustrated by examples of integration in the meat industry. A meat-packing company that fattens its own cattle is effecting integration by ownership. A farmer who slaughters his own hogs and sells meat is doing the same thing. If the packing company or a feed company contracts with farmers to produce hogs, integration is by contract. In other words. contract farming is one method of integration. If a farmer co-operative provides its members with breeding stock and feed and markets or processes the meat animals, integration is by co-operative action. Farmers, as members of the co-operative. retain control over the integrated system. Co-operatives throughout the world provide many examples of vertical integration.

(J. E. Ws.)

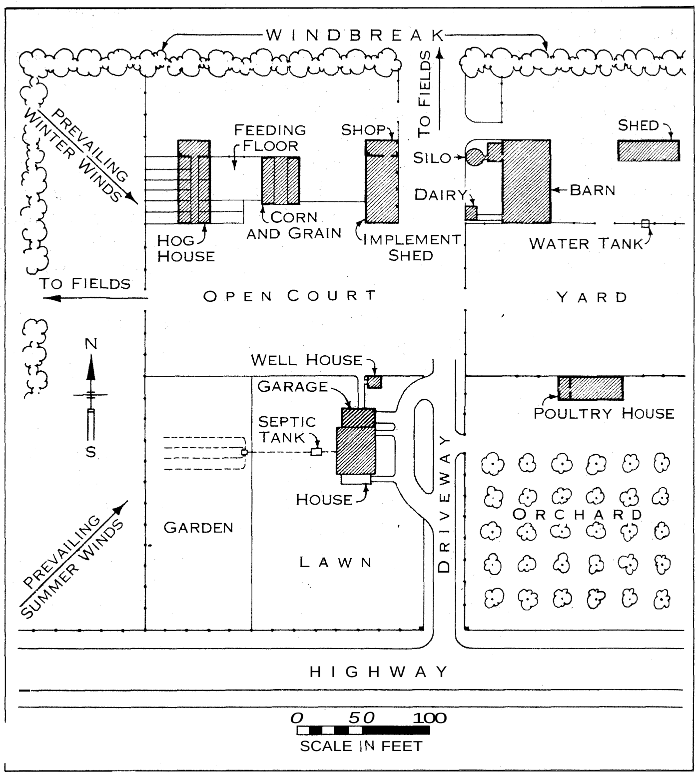
FARMSTEAD ARRANGEMENT, U.S. The farmhouse and farm service buildings along with their associated yards, pens, lots and lanes comprise the typical United States farmstead. Normally the farmstead is located on the land that is being farmed. In pioneer times it was customary to select a site near running water and a stand of timber.

Today the favoured farmstead site is well drained, close to fields and pastures, accessible to power lines and on a good road leading to markets. churches and schools. An area of between five and ten acres which is naturally elevated or sloped gently to the east or southeast is desirable.

The relative position of the various elements comprising a farmstead is influenced by several independent factors. A well-balanced arrangement is a compromise between the limitations inflicted on the site by nature, by the character of the main farm enterprises, by the danger of fire and by the requisites of pleasant farm living.

Natural Influences.—The most unalterable factors in farmstead arrangement are those imposed by nature. They include prevailing winds, sunlight. drainage and natural views.

Prevailing winds are considered in planning the farmstead layout. Feed lots require locations nhere their associated structures can shield workers and livestock from winter winds and where summer air currents will not carry barnyard odours to the farm home. An evergreen windbreak on the north and west sides of the farmstead can shelter the whole area. But it is important not to obstruct air movement immediately around the farmhouse and near structures utilizing natural ventilation for crop drying. To reduce the chances of fire, major structures are placed out of the line of the prevailing winds.



FARMSTEAD LAYOUT IN THE NORTH-CENTRAL UNITED STATES

Sunlight also is a factor in planning farmstead arrangement In addition to giving light, the sun will provide heat and have a sterilizing value in livestock buildings that are oriented to admit a maximum amount of sunlight in the winter. Buildings like corncribs, two-row farrowing houses and stanchion dairy barns need to have the sun on both the east and the west sides. Consequently. they are usually located with the long axis north and south. Poultry houses generally face south with most of their windows on that side.

All areas of the farmstead need good natural surface drainage; the farmhouse occupying the best-drained site. Traffic areas between service buildings and lots also require especially good drainage. A building arrangement that follows the contour of the land will facilitate maintenance. Grading can sometimes redeem a site that would othernise be impractical.

The farmhouse is located where advantage can be taken of views toward naturally attractive features. The best natural view is often of a small lake, a patch of woods or a permanent pasture. Windows in the living portion of the farmhouse are then oriented toward these natural views, and service buildings and lots are kept away from this part of the farmstead.

Major Farm Enterprises. — Farmsteadarrangement is strongly affected by the type of business enterprise for which the farm is suited. While general-purpose farms need a variety of buildings and related lots to accommodate multiple enterprises, more specialized farms need facilities for only one or two.

For efficient chore operations cash-grain farms mainly require storage structures. which are located where they can be conveniently filled and emptied. Shelters for farm machinery are common to most types of farms. They require locations that permit equipment to have ready access to fields by lanes, and where there is ample turning space. A site relatively near the house is suitable, especially if a shop for repairing machinery is incorporated.

Specialized enterprises like dairying require a group of related buildings or integrated units for storing feed and roughage, for housing and exercising livestock. for milking and for preparing milk. Where the major enterprise is feeding cattle and hogs. sheds are arranged about a feed centre which stores roughage, grain and supplements and provides equipment for processing rations.

By the second half of the 20th century many advances had been made in the development and application of automatic equipment for processing feed and distributing it to livestock on the farm. (*See* CROP-PROCESSING MACHINERY.) Electric power assisted by electronic controls have made possible accurate metering, blending. grinding and conveying of feed and roughage with a minimum of hand labour. Mechanical feed-conveying equipment affects farmstead arrangement by allowing wider latitude in locating livestock-feeding areas in relation to the feed-processing centre than do systems depending on gravity for distribution. Later expansion of the enterprise also is easier where mechanical systems have been incorporated.

A farm service yard is an open area that provides access to the principal buildings, lots and lanes to fields. It reduces the need for entry of farm machinery to livestock lots and the open space helps to prevent the spread of fires.

Farm Living Values. — An important but less tangible influence on farmstead arrangement is the value of attractive appearance to the farm family and the community. The farmhouse and the more attractive buildings are placed where they are readily seen from the public road. The, more undesirable views are screened off by buildings and plantings. Deep yards or permanent pastures usually are located next to the public road, keeping the farmhouse 12j ft. or more back.

Unification of the farmstead as a whole helps to improve its appearance. An evergreen windbreak forms a backdrop that gives unity to the over-all setting, as do roof colours and architectural features that are repeated. Ornamental fences and landscape plantings also contribute to the interrelated appearance of buildings and lots.

Trends in Farmstead Arrangement. — In the second half of the 20th century the average size of farms in the United States increased through consolidation of smaller units. Thus the functions of two or more old sets of buildings often have had to be coordinated. On livestock farms one procedure has been to concentrate feed processing at the most centralized set of buildings and use self-unloading wagons to distribute the feed to other centres.

As farms continue to become more specialized, building arrangements reflect this change by further concentrating chore activity centres and by using more automatically controlled equipment. *See* also FARM BUILDINGS; FARM MANAGEMENT.

See Keith H. Hinchcliff et al., *Planning Your Farmstead* (1954); W. A. Foster and Deane G. Carter, *Farm Buildings,* 4th ed. *by* Deane G. Carter, ch. 3 (1954). (K. H. HF.)

FARM TENANCY. Tenancy is one of three major means of organizing agricultural units of production throughout the world. The other two major means are owner operatorship and group or communal tenure: including state ownership. Further discussion of the history and development of the different forms of land tenure and agricultural organization in various lands throughout the world will be found in the article LAND TENURE: ECONOMIC AND AGRARIAN ASPECTS. The article MÉTAYAGE SYSTEM deals with the cultivation of land for a share of the produce. *See* also FARM COLONY; FARM MANAGEMENT; AGRICULTURE: *Agricultural Economics;* LANDLORD AND TENANT; and articles on individual countries and on the continents.

Farm tenancy arises when landowners cannot or do not wish to operate their land and when farm operators cannot afford or do not wish to own the lands they operate. Thus, under tenancy, landowners contribute their lands and various amounts of operating capital and management while tenants contribute their labour and various amounts of operating capital and management. The returns from this pooling of land, labour, capital and management are shared by landlords and tenants in various ways.

In western Europe and North America the usual means of using agricultural lands is through the individual farmer who is either a tenant or an owner-operator. In Africa, in parts of Mexico under the ejido system, parts of the middle east, China and the U.S S.R., various forms of communal and tribal tenures are in practice (see LAND TENCRE, PRIMITIVE).

In areas where land has been alienated to individuals, usually some of these individuals have gained ownership of more land than they could cultivate. Sometimes this occurred as an outgrowth of the feudal structure which characterized the society of Europe in medieval times and of Japan, for example, before the Meiji restoration of 1868. Sometimes it was the result of large Spanish and Portuguese grants of land in newly conquered areas of the new world; grants which still influenced the ownership of land in the second half of the 20th century in Latin America and the southwestern United States. Sometimes it was the result of the appropriation of apparently unoccupied lands in Africa which, in reality, were under some form of tribal tenure and shifting agriculture. In India and Pakistan many landlords originally gained their property as a result of the British delegation of tax-collecting rights, which gave rise to the zamindar and ryotmari systems which were in the process of being eliminated in the second half of the 20th century (see INDIA: Government *and Administration: Finance: Revenue*). In other areas, such as Burma, tenancy has arisen because unstable agricultural prices and low price levels forced many small cultivators to mortgage their lands to moneylenders who eventually gained control when the borrowers defaulted. But in other instances tenancy has arisen because individuals with capital wished to invest in agricultural land and were willing to combine their land with the labour and management ability of some other individual who had little capital.

Regardless of how it arose, farm tenancy in the modern world serves to combine the land resources of the landlord and the labour resources of the tenant into a single operating unit. Under proper conditions this can be economically as efficient as owner-occupancy, as has been demonstrated in the United Kingdom and in the midwestern United States. But when the landlord has too much power — perhaps because of competition for land, credit monopoly or outright intimidation — there may be an arbitrary transfer of income to the disadvantage of the tenant, and there is no incentive for proper cultivation. Under such conditions, poverty ensues, tenants may come to be considered as an inferior social class and many abuses appear.

TENANCY THROUGHOUT THE WORLD

Probably tenants and their families constitute as many as two-fifths of the world's people engaged in agriculture. Thus, around 750,000,000 people live and work on other people's land. There are wide differences in the extent of tenancy throughout the world. In the second half of the 20th century tenancy varied from 65% of all farmers in England and Wales and 77% in Scotland to 5% in Denmark and 5.4% in western Germany. Tenants made up 53% of all farmers in India and 40% of the total in Taiwan. On the other hand, in parts of Thailand tenants were as few as 5% of the total number of farmers. Care should be taken not to associate operator-ownership too closely with a high level of living. Many of the owner-operator farmers in the areas of southeast Asia were heavily in debt and held their land only because moneylenders did not care to take title to the land for themselves.

Within individual countries there were great differences in the extent of tenancy and therefore national averages might be misleading. In the Philippines, for instance, farm tenancy varied from less than 2% of all farmers in the mountain section of Luzon to over two-thirds of all farmers in central Luzon.

Tenancy Improvement. — Governments in both the more advanced and the underdeveloped nations, especially after World War II, showed great interest in improving conditions of tenancy. In the United Kingdom the Agricultural Holdings act of 1948 spelled out tenant rights, giving greater security to tenants. A French law passed in 1946 guaranteed the tenant the right to renew his leases even against the will of the landlord, and provided for compensation if he left. In Brazil the civil code provided that the term of the lease must cover the harvesting of the first crop. In Japan the law of Oct. 1946 provided security for tenants and set maximum levels of rent. In Taiwan rents were limited and minimum conditions of tenancy prescribed by legislation. In India the Bombay Tenancy and Agricultural Lands" act of 1948 provided comprehensive minimum standards for tenancy contracts. Other Indian states, including Hyderabad, Surashtra and West Bengal, passed tenancy legislation.

Properly framed and administered, improved farm-tenancy arrangements in underdeveloped areas offer an important foundation upon which to build a more productive agriculture. Improved tenancy conditions can offer security, fair returns, assurance of future returns for present investments, improved levels of living and the social and political independence of individuals prerequisite to first-class citizenship.

Providing Security. — Paramount in tenure-improvement measures are adjustments favouring security of tenure wherever insecurity is a serious problem. Fortunately, there are several remedial adjustments which are available and which have been used successfully by particular countries. These adjustments include: (1) written lease provisions; (2) a minimum lease term; (3) a minimum termination notice and automatic renewal; (4) restrictions on transfers of leased land; (5) heritability of leases; (6) permanent occupancy and use of rights; and (7) compensation for disturbance.

In an increasing number of nations, tenancy agreements had to be written and meet certain minimum requirements, as mas the case. for instance, in the Netherlands and Sweden. In some of the less developed areas, similar regulations were effectively implemented. In Japan, under the agrarian reform measures following World War II, all tenancy contracts had to be written.

In an effort to lengthen the tenant's planning horizon many nations established a minimum period for an agricultural lease. In the United Kingdom the length of the contract runs for the lifetime of the tenant so long as he practises "good husbandry" and wishes to continue to cultivate his holding. In Belgium the minimum period of lease is nine years. In the Netherlands individual parcels without buildings must be rented for a minimum of 6 years, while farms must be rented for a minimum of 12 years, with, however, provision for adjusting the rent every three years. In the Philippines the tenant has lifetime security of tenure under the Landlord-Tenant Relationships act of 1954, subject to fulfilling statutory requirements. In India the minimum length of time is from five to ten years in different states, and generally the tenant may not be evicted except for default in rent payments, bad cultivation techniques or resumption of the land by the landlord for his own use. In Cuba the minimum period of time is three years. In Mexico the interest of the tenant in any event continues until he harvests standing crops or picks ripening fruit. In Taiwan the minimum period of lease was set at six years, and could be renewed if the tenant desired unless the landlord took back the land for his own cultivation.

Farm and Home Improvements. — Closely allied to the problem of providing security of tenure is the matter of making farm and living improvements on rented lands. Since rented lands are owned by someone other than the operator, and since improvements made on that land usually become the property of the landowner, tenants have little incentive to make improvements which become the property of someone else.

The adjustments usually considered are: (1) compensation for unexhausted vaiue of improvements; (2) compensation for dilapidation~(3) longer-term leases; (4) kind and amount of rental payments.

Perhaps the most highly developed and formal system of compensation is found in the United Kingdom, under the provisions of the Agricultural Holdings act of 1948. Under this act. the tenant has a statutory right to compensation of three general sorts: (1) for long-term improvements; (2) for medium-term improvements; and **(3)** usual improvements necessary for good husbandry (see also LANDLORD AND TENANT).

Provisions for compensation similar to those in the United Kingdom are found in France, the Netherlands and commonly throughout western Europe. But such measures were also being adopted in other countries. In India, for example, several states recognize the right of the tenant to make improvements and claim compensation for them if forced to quit his holding. In Cuba a tenant may claim compensation, upon the expiration of his lease, for improvements made during the first half of the lease. if he can demonstrate that the improvements were necessary to the proper accommodation of his family or his hired labourers, or necessary for proper cultivation of his holding.

Implementing Improvements.—The activities of the Food and Agriculture Organization of the United Nations in providing technical assistance and sponsoring regional land-problem seminars in Campinas. Braz., Bangkok, Thailand, and Salahuddin. Iraq. may be cited as important measures to implement tenancy improvements. Under the leadership of FAO, concerted efforts by the United Nations agencies have been made to assist member governments in their tenancy-improvement efforts. The United States government has contributed to this end by providing land-tenure technicians for various countries such as Japan. the Philippines, South Korea and Vietnam. (See also LAND REFORMS.)

THE UNITED STATES

History.—The history of farm tenancy in the United States begins in the colonial period of the 17th and 18th centuries. Most colonists came to America in search of freedom and land. Settlers in the New England colonies. for the most part, owned the land which they farmed. However, colonies to the south of New England were settled by proprietors with large land grants. Proprietors in the middle Atlantic colonies rented their holdings to tenants and attempted to collect quitrents from the tenants. Terms of the "durable lease" or "incomplete sale" under which these tenants occupied land provided for annual rents in the form of dues and services to the landlord. The landlord retained the option of collecting one-fourth of the sale price or recovering full title to the land at three-fourths of the market price.

The quitrent system hung together for two centuries mainly because few landlords collected the dues and services. Never popular with the occupiers, many of whom came to America to escape European feudal land practices, the system was finally thrown off by the antirent rebellions during the 1840s. Except in the plantation areas of the south, most individual landlords owned only one rented farm after the middle of the 19th century.

With almost unlimited free land to the westward to be had largely for the effort of settling. most colonists refused to tolerate unsavoury tenancy conditions in the colonies and early states. However, some farmers preferred the comforts, safety and improvements of the settled areas over the frontier, and they rented farms in the older areas. As many as one-third of the farms mere rented in a New Jersey county as early as 1843. Although state- and nation-wide statistics on farm tenancy were not obtained until 1880, farm tenancy existed throughout the early development of the nation. At the time of the first nation-wide agricultural census, including detailed farm tenure data, in 1880, 25.6% of all farms were reported being operated by tenants who rented all their land irom landlords. Subsequently. the proportion oi all farms in the U.S. operated by tenants was 28.4% in 1890, steadily increasing to 35.3% in 1900, 37% in 1910, 38.1% in 1920 and 42.4% in 1930. It dropped to 38.7% in 1940, to 26.8% in 1950 and continued to decline in the second half of the 20th century. Tenancy was most prevalent in the midwestern and southern states. For example, in Iowa 38.4% of all farmers were tenants who rented 42.7% of the state's farmland. In addition, 15.9% of the state's farmers rented part and owned part of the land they operated.

Over the years, farm tenancy in the United States arose from a combination of factors. Young farmers without sufficient capital and management experience rented land from owners desiring to retire from active farming. Nonfarmers who acquired land through inheritance or as a hedge against inflation rented their land to farmers without land of their own. During the depressed 1930s many farm owner-operators lost ownership of their farms through foreclosures and excessive debts coupled with low prices for farm products. These farmers became tenants.

A study in Iowa revealed that nine of every ten tenants expected eventually to own the land they operated and these farmers regarded tenancy as a means toward farm ownership (see also FARM MANAGEMENT).

Lease Types.—Farm tenants pay their landlords a share of the products or cash or a combination thereof as rent for the use of land. Of the more than 1,000,000 farm tenants in the U.S. in the second half of the 20th century, 28% paid a share of the crops only, 23% were sharecroppers, 14% paid a share of the crops and in addition some cash rent, 14% paid cash rent only. 9% paid both shares of livestock and crops and the remaining 12% paid various combinations of the above as rent.

Thus, the most prevalent kind of rent was a share of the crops only. These renters are called crop-share tenants. They usually furnish all the labour, machinery and part or all of the operating capital and own the livestock. Crop-share tenants usually pay one-fourth to one-half of the crops as rent to the landlord.

Sharecroppers. the next most prevalent lease type, were most common in cotton- and tobacco-producing areas (see SOUTH, THE). The tenant, or sharecropper, usually furnished the labour only; the landlord furnished machinery. power, seed, fertilizer and other elements of production in addition to the land and improvements. The tenant, or sharecropper, received a share of the crop as a wage for his labour.

Sharecrop-cash tenants are similar to crop-share tenants and differ only by paying some cash in addition to a share of the crops as rent.

Cash tenants pay cash only as rent to the landlord. These tenants pay all operating expenses and receive all returns irom crops and livestock. They hire the land from the landlord for a specified amount of cash as rent. This kind of rent was diminishing in importance in the second half of the 20th century.

Livestock-share tenants pay a share of both the livestock and crops produced as rent. Under the livestock-share lease, the tenant furnishes his labour, the landlord iurnishes his land and everything else is furnished by landlord and tenant jointly. Livestock-share leases. usually on a jo-jo sharing basis. are common among parents and children. This arrangement is an important means whereby parents retire and their children take over operation of the home farm. However, nonrelated tenants and landlords also use this arrangement quite often. The livestock-share lease, most prevalent in the livestock-producing areas of the middle west, was growing rapidly in proportion to other kinds of leases.

Lease Problems and Improvements.—Three major problems plagued leasing arrangements throughout the nation. First, most farm leases were for only one year without automatic renewal. which did not provide the tenant family sufficient certainty of expectations to enable them to become a vital part of the community or to use the farm resources in the most productive manner.

Second. farm leases were influenced largely by past customs and often failed to encourage changing technological improvements in agriculture.

Third, rent payments frequently did not reflect the relative productivity of resources contributed by landlord and tenant, respectively. Changes in prices and costs were not readily reflected in rentals, which lagged behind price and cost changes.

Improvements in farm leases include longer-term leases or annual leases with automatic-renewal provisions unless one party notifies the other four, six or nine months ahead of the end of the lease year. Another improvement is compensation to tenants for unexhausted value of improvements made by the tenant if and when the tenant quits the farm before receiving full benefits from the improvements. The amount of compensation may be determined by the remaining benefits of the improvement at the time the tenant leaves the farm. These remaining benefits may be based upon the original cost of the improvement, replacement cost or productive value. The original cost method is most frequently used. although it fails to reflect price changes and does not necessarily represent productive value. Still another involves making the division of income between landlord and tenant reflect more accurately the productivity of the resources each contributes. Further improvements include provisions for the use of fertilizers, rotation, weed-, insect- and disease-control measures, conservation improvements and other improved farming practices. Finally, leases should be in writing in order to minimize disagreements over their provisions. (J. F. T.)

FARNABY, GILES, English composer, was born in the second half of the 16th century, probably at Truro, where his family lived. He began to study music in 1580, according to his own statement in his *supplicat* when he was taking the degree of bachelor of music at Oxford in 1592. Beyond these facts little is known of his life. His son Richard is one of the composers included in the *Fitzwilliam Virginal Book*. No connection has been traced between Giles and the grammarian and schoolmaster Thomas Farnaby who lived about the same time. The name of Giles Farnaby lives chiefly in his contributions to the *Fitzwilliam Virginal Book*. The fantasia was his favourite form, but his other pieces—bearing such attractive titles as "Giles Farnaby's Dream," "His Rest," "His Humour"; "Up Tails All," "A Maske," "A Toye," "A Gigge"—are full of quaintness and charm. One tiny piece for two virginals is only eight bars long; others, not much longer, are marvelous in their point and precision and intensely musical in feeling.

His *Canzonets to Foure Voices, With a Song of Eight Parts* were published in 1598. Other works are included in Thomas Este's *Whole Booke oj Psalms* (1592) and Ravenscroft's *Psalter* (1621). The madrigal *Come, Charon, Come* is in the Royal College of Music, London; another, *Construe My Meaning*, has been edited by W. Barclay Squire. An autograph volume of *The Psalms of David, to Fower Parts, for Viols and Voyce, the first Booke, Doricke Motets, the Second, Divine Canzonets, Composed by Giles Farnaby, Bachilor of Musicke With a Prelud, Before the Psalmes, Chromaticke* is in a private library in Philadelphia, Pa. *See* the articles "Farnaby," "Virginal Music, Collections of" in Grove's *Dictionary of Music and Musicians.*

FARNBOROUGH, THOMAS ERSKINE MAY, 1st BARON (1815–1886), clerk of the British house of commons, historian and writer on parliamentary procedure, was born in London on Feb. 8, 1815, and was called to the bar at the Middle Temple in 1838. His *Treatise on the Law, Privilege, Proceedings and Usage of Parliament* (1844; 16th ed., 1957) is a standard work on the subject, and has itself influenced parliamentary procedure. Sir Erskine May (he was created knight commander of the bath in 1866) was examiner of petitions for private bills (1846). taxing master of the house of commons (1847), assistant clerk (1856) and clerk of the house of commons (1871–86). His *Constitutional History of England . . . 1760–1860* (1861–63) was revised in later editions by its author. He died in London on May 17. 1886, a few days after his elevation to the peerage.

FARNBOROUGH, an urban district in the Aldershot parliamentary division of the county of Southampton (*i.e.,* Hampshire), Eng., 33 mi. S.W. of London by road. Pop. (1951) 26.271. Area 6.8 sq.mi. It is mainly residential, but is famed as the site of the royal aircraft establishment and has important military and other establishments. A display of civil and military aircraft is held annually by the Society of British Aircraft Constructors. The parish church of St. Peter includes portions of its Norman predecessor and has a wooden belfry at the west end. On the north wall are some 12th–14th century murals.

Above the east side of the main road is Farnborough hill mansion, now a convent but for some time the residence of the former empress Eugénie of France, who built St. Michael's Roman Catholic church in 1887 to receive the remains of Napoleon III and the prince imperial; she too was buried there.

FARNE ISLANDS, a group of 17 main islets with smaller rocks and reefs, about 80 ac. in extent lying $1\frac{1}{2}$ to 6 mi. off the N.E. coast of Northumberland, Eng. They are composed of dolerite, which has resisted the action of the waves, and are a part of the Whin Sill. The largest island, Inner Farne or House, is 16 ac. in extent and has precipitous cliffs up to 80 ft. in height; the other principal islets are Staple, Brownsman, North and South Wamses, Longstone and Big Harcar. The whole group belongs to the National trust and is preserved as a bird sanctuary, for myriads of sea birds breed there. On Inner Farne a small 14th-century chapel stands on the site of the hermitage to which St. Cuthbert (*q.v.*) retired from the priory at Lindisfarne between 676 and 684. He was with difficulty persuaded to leave Farne on his appointment to the bishopric of Lindisfarne and returned to it to die in 687. Longstone lighthouse was the home of the heroic Grace Darling who, with her father, the keeper, rescued survivors of the "Forfarshire" which was wrecked on Sept. 7. 1838, on the Harcars. Also on the group is the powerful Farne lighthouse.

FARNESE, the name of an Italian family which from 1545 to 1731 ruled the duchy of Parma and Piacenza (since 1512 part of the papal states). They appear first as minor feudal lords of Farneto (Farnese) near the lake of Bolsena, tracing their origin perhaps, like so many Italian feudatories, to the reign of the emperor Otto I. From the 12th to the 14th centuries they sustained themselves adroitly in the service of other lords and of various communes, notably Orvieto, where they held office as consuls, *podestà* and bishops. As Guelphs they also served the papacy, first rising to distinction in the person of Ranuccio il Vecchio, who caught the favour of the Colonna and still more of Pope Eugenius IV. Ranuccio received from Eugenius vicariates and fiefs, largely in pledge for his wages as papal *condottiere,* while his sons entered the Roman nobility, one marrying an Orsini, another a Caetani.

Tradition states that Pope Alexander VI was the lover of Giulia Bella, Ranuccio's granddaughter. Certainly it was her brother Alessandro, created cardinal by Alexander VI in 1493 and elected pope as Paul III (*q.v.*) in 1534, who established the family politically. A nepotist like his predecessors, he conferred both titles and lands upon his natural children, the most famous of whom was Pierluigi Farnese (1503–47); it was Pierluigi who in 1545 received from his father the duchy of Parma and Piacenza for an annual *census* of 9,000 ducats. Pierluigi. who had started life as a *condottieve,* proved an able captain but ruthless and dissolute and an insatiable egotist. Nevertheless as a ruler he brought real benefits to his duchy, which had suffered under the listless government of papal legates. He had already improved his ancestral domains as well as the other lands, Castro in the Maremma among them, which Paul had given him; in Parma and Piacenza he showed comparable energy in attacking the privileges and abuses. fiscal and judicial, of the feudal aristocracy and in promoting reforms in agriculture, commerce, industry and the administration of justice: oligarchy gave way to *signoria.* He proceeded. however, with imprudent severity, and a resentful nobility plotted his death, with the support of Ferrante di Gonzaga, the emperor Charles V's governor of Milan, and of Andrea Doria, who sought revenge on Pierluigi for his part in the Fiesco conspiracy (*see* FIESCO). He was murdered on Sept. 10, 1547, and Gonzaga's troops occupied Piacenza.

Pierluigi had several children, for all of whom Paul III generously provided. Alessandro (1520–89), created cardinal at the age of 14, was a man of learning and artistic tastes who attracted the society of scholars and artists, among them Paolo Giovio. Pietro Bembo, Giorgio Vasari *et al.;* it was he who completed the magnificent Farnese palace in Rome, the castle of Caprarola and the church of the Gesù. Orazio, Pierluigi's third son, was made duke of Castro when his father became duke of Parma; he married Diane, the legitimated natural daughter of Henry II of France. Ottavio. the second son (1521–86), married Margaret of Austria (*q.v.*), natural daughter of Charles V. After Pierluigi's death Paul appointed a papal legate to Parma; Ottavio pushed his claims, but did not receive that duchy until the accession of Pope Julius III (1550). This did not end his quarrel with Charles V, for Gonzaga refused to give up Piacenza, and Ottavio was driven into the arms of France (May 1551). Julius, anxious to be on good terms with Charles, ordered Ottavio to surrender Parma to the papal authorities and, on his refusal, deprived him of his Roman fiefs while Charles did the same with those in Lombardy. A French army came to protect Parma, war broke out. and Gonzaga laid siege to the city. But the pope and the French signed a truce (April 1552), and the duke came to an arrangement with his father-in-law whereby his title to Parma was secured; and he eventually regained

Piacenza from Philip II. The rest of his life was spent quietly at home, where he resumed the policy of his father, only with greater moderation, and won the affection of his subjects. At his death in 1586 he was succeeded by his son Alexander Farnese (*q.v.*) (1545–92), the famous general of Philip II of Spain, who spent the whole of his reign in the Flemish wars.

His son and successor, Ranuccio I (1569–1622), issued the constitutions (1594) which gave final form to the ducal administration; he also embellished Parma, building its theatre and reviving its university. But he mismanaged the state finances, borrowed heavily on the Roman market and died in debt. Sombre and suspicious by nature, his reserve was increased by disaffection among the nobility and the discovery of a plot (1611–12), which was violently suppressed. His son Odoardo (1612–46) who succeeded him, was opposite in character to his father; but his failure to pay the interest on the money borrowed in Rome and the desire of Urban VIII to obtain Castro for his relatives, the Barberini (*q.v.*), led to a costly war with the papacy. His son and successor Ranuccio II (1630–94) also had a war with the papacy about Castro, which was eventually razed to the ground. His son Francesco Maria (1678–1727) suffered from the wars between Spain and Austria, the latter's troops devastating his territory. The succession devolved at his death on his brother Antonio (1679–1731), with whom the male line ended. The powers had agreed in the treaty of Seville (1729) that at the death of Antonio the duchy should pass to the *infante* Charles (later Charles III of Spain), son of Philip V of Spain by Elizabeth Farnese (*q.v.*), granddaughter of Ranuccio II; and the treaty of Vienna (1731) confirmed this arrangement. Elizabeth's younger son Philip was recognized as duke by the treaty of Aix-la-Chapelle (1748); meanwhile his brother had become king of Naples and Sicily.

The Palazzo Farnese in Rome, one of the finest specimens of Roman Renaissance architecture: was begun under Paul III, when still cardinal, by Antonio da San Gallo and completed by Cardinal Alessandro under the guidance of Michelangelo (1546). It was inherited by the *infante* Charles, who had most of the pictures removed to Naples when he became king there. It now contains the French embassy and the French school of Rome.

FARNESE, ALEXANDER (1545–1592), duke of Parma and Piacenza, general and statesman, governor general of the Netherlands under Philip II of Spain, was born at Rome on Aug. 27, 1545, and died at the abbey of St. Waast, near Arras, on Dec. 3, 1592. He was the son of Ottavio Farnese, duke of Parma, and Margaret of Austria, natural daughter of Charles V. He accompanied his mother to Brussels when she was appointed governor of the Netherlands, and in 1565 his marriage with the princess Maria of Portugal mas celebrated in Brussels with great splendour, Alexander Farnese had been brought up in Spain with his cousin, the ill-fated Don Carlos, and his uncle Don John of Austria, and after his marriage lived at the court of Madrid. He fought under the command of Don John in 1571 at Lepanto. In the autumn of 1577 Farnese was sent with reinforcements to Don John, then governor general of the Netherlands, and it was mainly his prompt decision at a critical moment that won the battle of Gembloux (1578). Shortly afterward Don John died, and Farnese was appointed to take his place.

In military ability Farnese was inferior to none of his contemporaries, as a skilful diplomatist he was the match even of William the Silent, and he was untroubled by scruples. He fomented the divisions and jealousies between Catholic and Protestant, Fleming and Walloon, and by the treaty of Arras. May 1579, he secured the support of the "Malcontents," as the Catholic nobles of the south were styled, to the royal cause. The reply to the treaty of Arras was the Union of Utrecht, concluded a few weeks later between the seven northern provinces, who abjured the sovereignty of King Philip and bound themselves to use all their resources to maintain their independence of Spanish rule.

Farnese. as soon as he had obtained a secure basis of operations in Hainaut and Artois, set to work to reconquer Brabant and Flanders. Tournai, Maastricht. Breda, Bruges and Ghent opened their gates, and finally he laid siege (1584) to Antwerp. The town was resolutely defended by the citizens under Philip de Marnix, lord of St. Aldegonde, who was assisted by the engineer Federigo Giambelli. Farnese cut off all access to Antwerp from the sea by constructing a bridge of boats across the Scheldt from Calloo to Oordam. On Aug. 15, 1585, Antwerp was compelled by famine to capitulate. The whole of the southern Netherlands was brought once more to recognize the authority of Philip. But Holland and Zeeland continued to defy Farnese (*see* NETHERLANDS).

In 1586 Alexander became duke of Parma and Piacenza, on his father's death. Philip would not permit him to leave the Netherlands; but neither would he permit him to use his veteran army to reconquer the Northern Provinces, though the moment was opportune. The king's whole energies were directed to the preparation of an Invincible Armada for the conquest of England, and Parma was ordered to collect an enormous flotilla of transports and to keep his army concentrated and trained for the projected invasion of the island realm of Queen Elizabeth I. Thus the critical period passed by unused, and in the interval the Dutch had found in the youthful Maurice of Nassau a military genius. Moreover, the accession to the throne of France of Henry of Navarre had relieved the pressure upon the Dutch and placed Parma and his army between hostile forces. The expenditure upon the Armada had depleted the Spanish treasury, and in 1590 Farnese could get no regular supplies of money from the king for the payment of the soldiery, and he had to pledge his own jewels. A mutiny broke out, but was suppressed. Parma now received orders to raise the siege of Paris, which was blockaded by Henry IV. He left the Netherlands on Aug. 3, 1590, at the head of 15,000 troops. By brilliant generalship he outwitted Henry and succeeded in relieving Paris; but owing to lack of money and supplies he was compelled immediately to retreat to the Netherlands, abandoning on the march many stragglers and wounded.

Again in 1591, in the midst of a campaign against Maurice of Nassau. Parma was obliged to march to relieve Rouen. He succeeded but was wounded before Caudebec, and was finally compelled to withdraw his army. He died near Arras on Dec. 3, 1592. He was honoured by a splendid funeral at Brussels, but his body mas interred at his own capital city of Parma. He left two sons, Ranuccio who succeeded him, and Odoardo, who was created a cardinal in 1591 by Pope Gregory XIV. His daughter Margaret married Vincenzo, duke of Mantua.

See L. P. Gachard, *Correspondance d'Alexandre Farnèse, Prince de Parme, gouverneur général des Pays-Bas, avec Philippe II, 1578–1579* (Brussels, 1853); L. van der Essen, *Alexandre Farnèse,* 5 vol. (Brussels, 1933–37); J. M. Rubio y Esteban, *Alejandro Farnesio* (Saragossa, 1939).

FARNESE, ELIZABETH (1692–1766), queen of Spain, was born on Oct. 25, 1692, the only daughter of Odoardo Farnese (d. 1693), eldest son of Ranuccio II of Parma and Piacenza. On Sept. 16, 1714, she was married by proxy at Parma to the widower Philip V of Spain. This marriage was arranged by Giulio Alberoni (*q.v.*) with the concurrence of 'the Spanish *camarera mayor,* the princesse des Ursins (*q.v.*), who hoped to dominate the new queen. Arrived in Spain and met at Jadraque (now in Guadalajara province) on Dec. 23 by the *camarera,* Elizabeth forthwith dismissed her. She then attained complete ascendancy over Philip, and the control of affairs was shared between her and Alberoni. In 1719 she put herself at the head of a division against the French; but the Quadruple Alliance thwarted her plans, Alberoni was banished and the allies made his remaining in exile a condition of peace (1720). Yet from Philip's frustrated abdication to his death (1724–46) Elizabeth remained supreme, directing the whole of Spanish policy so as to secure Italian thrones for her sons: in fact she saw the poners recognize the accession of the eldest, Charles, first to the duchies of Parma and Piacenza (1731) and then to the kingdom of the Two Sicilies (1738) and that of his brother, Philip, to Parma, Piacenza and Guastalla (1748). Kept from power during the reign of her stepson Ferdinand VI, she returned to it when her son became king as Charles III. Besides Charles and Philip, she bore Philip V two other sons and three daughters. She died on July 11, 1766.

FARNHAM, a market town and urban district in the Farnham parliamentary division of Surrey, Eng., 38 mi. W.S.W. of London by road. Pop. (1951) 23.928. Area 14.1 sq.mi. Farnham lies in the valley of the River Wey, whose northern and southern slopes rise to 600 and 500 ft. respectively above sea level. Aldershot camp is 3 mi. N.E. Farnham castle, on a hill north of the town, was, until the creation of the diocese of Guildford in 1927, the palace of the bishops of Winchester; in that year it became the residence of the bishop of Guildford. The castle was first built by Henry of Blois, bishop of Winchester and brother of King Stephen. It was razed by Henry III but rebuilt by the bishop of Winchester. In 1567 and 1j69 Bishop Horne entertained Queen Elizabeth I there.

Farnham was garrisoned for Charles I, suffered during the Civil War and was demolished in 1648. George Morley, bishop of Winchester, restored the episcopal palace within its walls (1662–84). The park of 300 ac. was acquired by the urban council in 1930. The parish church of St. Andrew is a transitional Norman and Early English building with later additions. It was formerly a chapel of ease to Waverley abbey (2 mi. S.E. of Farnham), the earliest Cistercian house in England, founded in 1128 by William Giffard, bishop of Winchester. William Cobbett (*q.v.*) was born in the parish and is buried in the churchyard. The mansion of Moor park was the residence of Sir William Temple (d. 1699) and his wife, Dorothy Osborne (d. 1695). Here Jonathan Swift worked as Temple's secretary (1689–94). Esther Johnson, Swift's "Stella," also lived in the house, her mother being employed by Lady Giffard, Temple's sister.

By the time of the Domesday survey the manor of the bishop of Winchester at Farnham was as large as most of the king's estates. Farnham's position at the junction of the Pilgrims' way and the road irom Southampton to London was important. In 1205 it had bailiffs, and in 1207 it was definitely a mesne borough under the bishop of Winchester. In 1247 the bishop granted the first charter, giving, among other privileges, a fair on All Saints' day.

Henry Cardinal Beaufort is said to have confirmed the original charter in 1410, and in 1566 Bishop Horne granted a new charter. In the 18th century the corporation, a close body, declined, its duties being performed by the vestry, and in 1789 the one survivor resigned and handed over the town papers to the bishop. Farnham sent representatives to parliament in 1311 and 1460. It early became a market of importance and was famous in the late 17th and early 18th centuries for wheat and oats. Hop-growing has been carried on in the neighbourhood since 1597.

FARNWORTH, a municipal borough in the Farnworth parliamentary division, Lancashire, Eng., on the Irwell, 3 mi. S.S.E. of Bolton. Pop. (1951) 28,616. Area 2.4 sq.mi. Most of the inhabitants work in the collieries, cotton mills, iron foundries and joinery works. The town was incorporated in 1939.

FARO, the capital of a district bearing the same name, in southern Portugal; at the terminus of the Lisbon-Faro railway, and on the Atlantic ocean. Pop. (1950) 17,631. Faro is an episcopal see. Its broad but shallow harbour is protected on the south by the long island of Cães, and a number of sandy islets, which, being constantly enlarged by silt from the small river Fermoso, render the entrance of large vessels impossible. Fish, with nine, fruit, cork. baskets and sumach, are the principalarticles of export. Little has been done to develop the mineral resources of the district, which include tin, lead, antimony and auriferous quartz. Faro was taken from the Moors in 1249. It was sacked by the English in 1596, and nearly destroyed by an earthquake in 17jj.

The administrative district of Faro coincides with the ancient kingdom and province of Algarve (*q.v.*).

FARO, one of the oldest of all gambling games played with cards, supposedly named from the picture of a pharaoh on French playing cards imported into Great Britain. It was enjoined by specific mention in English law as early as 1739. A favourite of highborn gamblers throughout Europe in the late 18th and early 19th centuries, Pharaoh was the game at which the young Count Rostof, in Tolstoy's *War and Peace,* lost a fortune. In the United States a writer in 1894 termed it "unquestionably entitled to be called the national American card game." A commonplace in U.S. gaming rooms, especially in the west, until about 191j, the faro bank (marked traditionally by a picture of a tiger as an advertisement outside the house, whereupon playing faro was known as "bucking the tiger"), by 1925 had all but vanished. Faro later continued to be a fixture at licensed gambling houses in Nevada.

The Layout. — In faro a shuffled 52-card pack of playing cards is placed face up in a dealing box. Bets may be placed only against the house. The 13 cards of the spade suit, representing the ranks of all suits, are enameled on a cloth, or layout, on which the bets are placed. A bet may be placed on any rank to win, or (by coppering the bet, that is, placing a copper counter on the chips) to lose; or, by the manner in which the chips are placed on the layout, may cover several ranks.

The Play. — The dealer takes one card from the box. This card, called soda, is not used. The next card taken from the box loses (the house pays the amount of any coppered bet placed on this rank and takes in bets placed on this rank to win). The next card (left showing in the box) wins, and the house pays the amount of any bet placed on that rank to win. The removal of one card and exposure of the next constitute a turn on which bets are settled. Then the dealer removes the exposed card from the box, puts aside another card, which loses, and leaves exposed another card, which wins. The casekeeper keeps on display a running record of which cards have been played and which are still to come, for reference of all players. The last card in the box (called in hock), like soda, does not count.

When cards of the same rank appear in the same turn, and so both uin and lose. the house takes half of each bet on that rank, whether to win or to lose. This is called a split.

When only three unplayed cards remain in the box, players are invited to call the turn, the house paying 4 to 1 (against odds of 5 to 1) to any player guessing correctly the exact order in which these cards will appear. If the last three cards include a pair (called a cathop) the house pays 2 for 1 to anyone who calls the order.

Stuss is a variant of the game in which the cards are dealt from a pack held face down in the dealer's hand, not from a dealing box, and when a split occurs the house takes all the bets on that rank, instead of only half of them.

See A. H. Morehead *et al.,* The *New Complete Hoyle* (1956).

(A. H. Md.; F. Hs.)

FARQUHAR, GEORGE (1677–1707), British dramatist, son of William Farquhar, a clergyman, was born in Londonderry, Ire., in 1677. He was educated at Trinity college, Dublin. He became an actor on the Dublin stage. but in a fencing scene in Dryden's *Indian Emperor* he forgot to exchange his sword for a foil, with nearly fatal results to a fellow actor, and never acted again.

At the suggestion of Robert Wilks, the comedian. Farquhar wrote his first play, *Love and a Bottle,* which was performed at Drury Lane in 1698. His second comedy, *The Constant Couple* (1699), ridiculing the pilgrimages to Rome in the jubilee year. was enthusiastically received. Wilks as Sir Harry Wildair contributing largely to its success. In 1701 he wrote a sequel, *Sir Harry Wildair,* and in 1702 *The Inconstant,* borrowed from Fletcher's *Wild Goose Chase.* In the same year he published a volume of miscellanies, *Love and Business,* containing a "Discourse on Comedy," defending the English neglect of the dramatic unities. In 1703 he married, in expectation of a fortune which did not materialize. The rest of his life was a constant struggle against poverty. His other plays are *The Stage Coach* (1704), a one-act farce from the French; *The Twin Rivals* (Drury Lane, 1702); *The Recruiting Officer* (Drury Lane, 1706); and *The Beaux'*

Stratagem (Haymarket, 1707). This is the best of his plays, and long kept the stage. Genest notes 19 revivals up to 1808. It was revived again at the Lyric, Hammersmith, in 1927. The plot concerns the adventures of two embarrassed gentlemen who travel as master and servant, in the hope of marrying a fortune. Archer, the supposed valet, was one of Garrick's best parts. Before Farquhar had finished writing the second act of *The Beaux' Stratagem* he was taken mortally ill, but he finished the play, for which he had been paid in advance. It was staged on March 8, shortly before his death, which occurred April 29, 1707.

Farquhar marks the end of the true Restoration tradition. Instead of the intellectual foil play of his predecessors he gives something of the cheerful singlestick of Elizabethan comedy, while his return to the romantic treatment of love, whether regarded as a disastrous lapse into the "luscious" or a breath of purer air, is at any rate fatal to the maintenance of the Restoration atmosphere.

Farquhar's dramatic works were published in 1728, 1742 and 1772, and by Thomas Wilkes with a biography in 1775. *See* also A. C. Ewald, *Dramatic Works of George Farquhar, With Life and Notes,* 2 vol. (1892) ; L. I. Guiney, *A Little English Gallery* (1894) ; *The Beaux' Stratagem,* ed. *by* H. Macauley Fitzgibbon (1898); *The Best Plays of George Farquhar,* ed. *by* William Archer (1906); H. Ten E. Perry, *The Comic Spirit in Restoration Drama* (1925).

FARRAGUT, DAVID GLASGOW (1801–1870), U.S. admiral who won fame as a Union commander during the Civil War, was born on July 5, 1801, near Knoxville, Tenn. At New Orleans he formed a close friendship with Capt. David Porter of the navy, who adopted his young namesake and put him in the navy in 1810. Farragut went to sea the next year on board the U.S.S. "Essex" with Porter, who took every opportunity to throw responsibility on the boy. Farragut commanded a prize with ability when only 12 years old, served with credit in the "Essex's" desperate fight with H.M.S. "Phoebe," and returned to the United States to go to school. The next few years were devoted alternately to service afloat and to school. He learned French, Italian and Arabic. Before he was 20 he was already an accomplished officer. In 1823 the navy department placed Commander Porter in command of a squadron to destroy the pirate strongholds in the West Indies. Farragut accompanied Porter. and active service ashore and afloat may be said to have completed Farragut's education. He had even had practice in handling a steamer and went home in 1824 in command of the U.S.S. "Ferret." Routine service followed for many years.

The Civil War opened in the spring of 1861, and in Dec. 1861 he was assigned to command the West Gulf blockading squadron, with orders to enter the Mississippi river and capture New Orleans. The strategic plan of the administration for the reduction of the seceding states assigned a great role to the navy. While the armies in the field were to oppose the Confederate forces, the task of the navy was to cut the hostile armies from their sources of supply overseas, for which they expected to pay by exporting cotton. The first step of the navy was to establish a blockade of the coast from the Chesapeake to the Rio Grande. By the end of 1861 this blockade was becoming fairly effective, but munitions of war landed in Mexico were finding their way along the Red river and the Mississippi to Confederate armies. The second great strategic operation of the navy was to seize control of the Mississippi and stop the supply of foodstuffs and munitions coming from the southwest. An army in conjunction with a flotilla of river craft undertook this task from the north, while Farragut with the same purpose moved from the open sea against New Orleans, the metropolis of the south, where success would secure him a valuable base for subsequent advance. The war department believed that the forts on the river below the city should be reduced by mortar fire before attempting to thrust wooden ships past them, but Farragut carried out his own bolder plan of running by them in the dark and was completely successful on April 24, 1862. His position above the forts cut them off from the city. Troops from the transports outside could land almost under his protecting batteries and the result was the surrender of the forts and the city. Against Farragut's opinion, the department insisted on his proceeding farther up the river, but the time was inopportune and nothing important was then accomplished. But the following year, when Grant's army was occupied before Vicksburg, Farragut greatly aided him by passing the heavy works at Port Hudson below the Red river and stopping traffic along that stream. Vicksburg fell in July 1863 and the Mississippi was soon in Federal control to the great loss of the Confederate armies fighting in Tennessee and Virginia. Farragut now turned his attention to entering Mobile bay, where he expected an army from the north to meet him and so to cut off another great slice from the Confederacy, but the troops were employed elsewhere. Mobile bay was formed by a long sandspit enclosing a large inlet. It was defended by several forts, of which the strongest was Ft. Morgan at the end of the spit close to the channel. A line of mines obliged ships to pass close to Ft. Morgan, and besides the heavy ironclad "Tennessee" covered the approaches. Farragut had to wait till he had monitors to pit against the "Tennessee" and on Aug. 5, 1864. he entered in two columns, the monitors leading and the wooden frigates following, each with a gunboat lashed to her port side. Farragut in the "Hartford" held the second place in his column. The leading monitor, "Tecumseh," in her anxiety to engage the "Tennessee," crossed the mine field and was blown out of the water. The "Brooklyn," leading the wooden column, stopped: her head fell away; the line drifted in confusion while the tide swept all upon the fort. This was the great moment of Farragut's life. Disaster was imminent. With instant decision he shouted "Damn the torpedoes" to the hesitating "Brooklyn," and swung his own ship clear of her and headed across the mines which had just been fatal to the monitor. The mine cases rattled against the bottom but none exploded and the fleet followed on and anchored triumphantly above the fort. Then the "Tennessee" came out from the shelter of the fort and after a hard fight, in which the wooden ships repeatedly rammed her, she was reduced to impotence and surrendered. The forts were now isolated and surrendered one by one. Ft. Morgan waiting till the troops lying outside in transports had landed their siege guns and brought them into action. Farragut's health now forbade further active service. His work was over. He had been made rear admiral in 1862, vice-admiral in 1864 and admiral in 1866. In 186; he went to Europe and paid a round of ceremonial visits to the seaports of the great powers. He died at Portsmouth, N.H., on Aug. 14, 1870.

(W. L. R.; X.)

FARRANT, RICHARD (*d.* 1580), composer of English church music, became a gentleman of the Chapel Royal in the reign of Edward VI, but resigned his post in 1564 on being appointed master of the children of St. George's chapel, Windsor. It is stated by Hawkins that Farrant was also one of the clerks and organists of St. George's chapel. and that he retained these posts till his death. Many of his compositions are printed in the collections of Barnard and Boyce. Among the most admired of them are a service in G minor, and the anthems "Call to Remembrance" and "Hide Not Thou Thy Face." It is doubtful uhether Farrant is entitled to the credit of the authorship of the beautiful anthem "Lord, for Thy Tender Mercies' Sake." No copy of the music under his name appeared in print till 1800, although it had been earlier attributed to him. Some writers have named John Hilton, and others Thomas Tallis, as the composer. Farrant died on Nov. 30, 1580.

FARRAR, FREDERIC WILLIAM (1831–1903), English theologian, was born on Aug. 7, 1831. in the fort of Bombay, where his father, afterward vicar of Sidcup, Kent, was a missionary. His early education was received in King William's college, Castletown, Isle of Man, a school whose external surroundings are reproduced in his school tale, *Eric; or, Little by Little.* In 1847 he entered King's college, London, and was led by F. D. Maurice to the study of Coleridge, whose writings had a profound influence upon his faith and opinions. He went up in 1851 to Trinity college, Cambridge, where he became a fellow in 18j6.

On leaving the university Farrar became an assistant master, first at Marlborough college and then (1855) at Harrow. In 1871 he was appointed headmaster of Marlborough college, and in the following year chaplain in ordinary to the queen, becoming canon of Westminster and rector of St. Margaret's, Westminster, in 1876. Farrar's first book was his schoolboy story *Eric* (1858), followed by *Julian Home* and *Lyrics of Life* (1859) and by *St. Winifred's; or the World of School* (1862). His Hulsean lectures were published in 1870 under the title of *The Witness of History to Christ. The Life of Christ,* which was published in 1874, passed through a great number of editions. His volume of sermons on *Eternal Hope* (1877)—in which he called in question the dogma of everlasting punishment—caused much controversy but helped to mollify the harsh theology of an earlier age. In 1879 appeared *The Life and Works of St. Paul,* followed by *The Early Days of Christianity* (1882) and other popular works. Farrar was a copious contributor of articles to various magazines, encyclopaedias and theological commentaries. In 1883 he was made archdeacon of Westminster and rural dean; in 1885 he was appointed Bampton lecturer at Oxford and took for his subject "The History of Interpretation." He was appointed dean of Canterbury in 1895. He died at Canterbury on March 22, 1903.

FARRAR, GERALDINE (1882–), U.S. dramatic soprano, was born at Melrose, Mass., on Feb. 28, 1882. Her musical education was received in Paris under Trabedello and in Berlin under Lilli Lehmann. When only 19 she made her debut at the Royal Opera house, Berlin, as Marguerite in *Faust,* Oct. 15, 1901, and continued to sing there each season until 1914. In Nov. 1906 she appeared at the Metropolitan Opera house as Juliette in *Roméo et Juliette* and was a favourite prima donna of the New York stage until her retirement on April 22, 1922. She afterward took her own company on the road and last appeared on the concert stage in 1931.

FARRELL, JAMES AUGUSTINE (1863–1943), U.S. steel executive, was born in New Haven. Conn., Feb. 15, 1863. He began work as a labourer and in a series of rapid promotions became general manager of the Oliver Steel Wire company. When that company was absorbed by the United States Steel corporation in 1901, Farrell became the foreign sales agent for all United States Steel subsidiaries; in 1903 he became head of the subsidiary United States Steel Products Export company. Farrell served as president of United States Steel from 1911 to 1932. He died in New York city on March 28, 1943. (J. R. Lt.)

FARRELL, JAMES THOMAS (1904–), U.S. writer known especially for his detailed fictional explorations of the lower middle class Irish on the south side of Chicago, where he was born, Feb. 27, 1904. Educated in parochial schools and at The University of Chicago, he supported himself at various jobs before becoming established as a writer. In his writing Farrell attempted to present and analyze honestly and painstakingly social groups and what he called "social structures," in a modified version of early 20th-century naturalism. Of more than 30 volumes of fiction he published, the titles are fairly evenly divided between the novel and the short story, though his exhaustive analysis of a section of American urban life required the expanded scope of a linked series of novels. The most famous of these was the first, a trilogy describing the life of "Studs" Lonigan in a deteriorating middle-class section of Chicago (*Young Lonigan,* 1932; *The Young Manhood of Studs Lonigan,* 1934; and *Judgment Day,* 1935). The style followed both social and speech idioms with scrupulous consistency and the work revealed the hero's decline in terms of the decline of the milieu. Subsequently, Farrell drew from one of the lesser figures of his trilogy, Danny O'Neill, for five novels (1936–54); a third hero, Bernard Clare (or Carr), was the subject of another trilogy (1946–1952). These sequences—the first in particular—were likely to stand as Farrell's major achievement.

Of his nonfiction, *A Note on Literary Criticism* (1936) is important for its criticism of the Marxist view of literature; *Reflections at Fifty* (1954) is a volume of reminiscences.

See Joseph Warren Beach, *American Fiction, 1920–1940* (1941); Wilbur Merrill Frohock, *The Novel of Violence in America* (1950); Charles C. Walcutt, *American Literary Naturalism* (1956). (F. J. Hn.)

FARRIER AND FARRIERY, the name given generally either to the professional shoer of horses or in a more extended sense to a practitioner of the veterinary art; farriery is the term for his business. Primarily the art of farriery is identical with that of the blacksmith, insofar as he makes and fixes shoes on horses (*see* HORSE-SHOES); he is liable in law for negligence, as one who holds himself out as skilled; and he has a lien on the animal for his expenses. William the Conqueror is supposed to have introduced horseshoeing into England, and the art had an important place through the middle ages, the days of chivalry and the later developments of equitation. In modern times it has been closely allied with the general progress in veterinary science and in the knowledge of the anatomy and physiology of the horse's foot and hoof.

FARRUKHABAD, a city, tehsil (subdivision) and district in the Allahabad division of Uttar Pradesh, India. The city is near the right bank of the Ganges, 77 mi. N.W. of Kanpur. It forms a joint municipality with Fatehgarh, the civil headquarters and military station of the district. Pop. (1951): Farrukhabad-cum-Fatehgarh city 80,332 (incl. 6,127 in Fatehgarh cantonment); tehsil (485 sq.mi.) 379.806. At Fatehgarh is the government gun-carriage factory; other industries include cotton printing of curtain material and the like, and the manufacture of gold lace, metal vessels and tents.

FARRUKHABAD DISTRICT has an area of 1,645 sq.mi. It is a flat alluvial plain in the middle Doab. The principal rivers are: the Ganges, which has a course of 87 mi. either bordering on or passing through the district; the Kali Nadi or Kalandar (84 mi.) and the Isan (42 mi.), both tributaries of the Ganges; and the Arind which, after a course of 20 mi. in the south of the district, passes into Kanpur. The Kanpur branch of the Ganges canal passes through the south of the district. Principal products are rice, wheat, barley, millets, pulses, cotton, sugar cane and potatoes. Pop. (1951) 1,092,641. Tobacco, potatoes and fruit, cotton prints, scent and saltpetre are among the principal exports.

In the early part of the 18th century Mohammed Khan. governor of Allahabad and later of Malwa, established a considerable state of which the present district of Farrukhabad was the nucleus, founding the city of Farrukhabad in 1714. After his death in 1743 his sons were embroiled by Safdar Jang, the nawab vizier of Oudh, with the Rohillas and afterward with the Marathas, the struggle ending by the country's becoming tributary to Oudh. In 1801 the nawab vizier ceded to the British his lands in this district. In 1804 the Marathas, under Holkar, ravaged this tract, but were utterly routed by Lord Lake at Farrukhabad. During the mutiny the titular nawab was reinstated on the throne. The English military residents took shelter in the fort, which they held until July 4 when, the fort being undermined, they endeavoured to escape by the river. One boat succeeded in reaching Cawnpore, only to fall into the hands of Nana. Its occupants were made prisoners, and perished in the massacre of July 10. The other boat was stopped on its progress down the river, and all those in it were captured or killed except four who escaped. The prisoners were conveyed back to Fatehgarh, and murdered there by the nawab on July 19. The rebels were defeated in several engagements, and on Jan. 3, 1858, the English troops recaptured Fatehgarh fort.

FARS, a province or *Ostan* of Iran, bounded on the north by the *Ostans* of Khuzistan and Isfahan, on the east by Yezd and Kerman and on the south by the Persian gulf. It lies roughly between 50° and 57° E. and 26° and 32° N., with an area of 66,255 sq.mi., and is composed of a great number of districts grouped together into about 20 subprovinces, each under a governor. The coast towns of Bushire, Lingeh, Bandar Abbas, Jask. Chahbar and some other smaller places, though not all geographically within the boundaries of Fars, form a separate administrative district known as the "gulf ports" or "southern ports" under a governor appointed from Tehran.

At Fars, the ancient Parsa or Persis (*q.v.*), remains of early man were found. Flint implements of Paleolithic character, were found northeast of Shiraz and a village of the Chalcolithic period. as the ending Neolithicum is called, with objects of remarkable craftsmanship was unearthed near Persepolis (*q.v.*). A part of Fars belonged to ancient Elam, the seat of a very early Persian civilization, and to the Elamite empire which reached its'peak in the 12th century B.C. While Fars is no longer considered the birthplace of the Achaemenian empire, since the region of Anshan northwest of Fars seems entitled to this claim, on its soil are to be found the most important remnants symbolizing the glory of the Achaemenians, the ruins of Pasargadae built by Cyrus the Great, 559–529 B.C. and those of Persepolis, begun by Darius and continued by his son Xerxes.

Climatically, Fars may be divided into *garmsir* and *sardsir*— the warm and cold regions. The former extends from the coast to the foothills running parallel to it and includes the coastal districts of Liravi, Haiat Daud, Rud Hillah, Angali, Shabankareh, Zira, Dashtistan, Tangistan and Dashti. The *sardsir* embraces the mountainous parts of the province which form a succession of ridges, prolongations of the Zagros chain, running from northwest to southeast and intersected by elevated plains, some of which are fertile and afford good pasture. The highest of these mountains, the Kuh Dina in the northwestern part of the province, has an elevation of 14,029 ft. The rivers are the Rud Hillah and Mund, and a notable feature is the great inland depressions or salt lakes near the middle of the province into which several inland streams drain. The chief town of the province is Shiraz (*q.v.*), 182 mi. N.E. of Bushire, and other populous centres are Niriz, Lar, Abadeh, Darab, Jahrum. Arsinjan. Ardakan, Fasa, Bastak, Kazerun, Firuzabad and Minab (under Bandar Abbas, *q.v*). The population is (1956) 1,494,649. The most important tribes are the Kashgai of Turkic origin and speech, the Khamseh of Arab origin and speech and the Lak, a branch of which gave to Persia one of its most beneficent rulers, Karim Khan Zand (1750–79), founder of the Zand dynasty which preceded that of the Kajars.

Many districts of Fars are comparatively fertile, but some are impoverished by droughts, ravages of locusts and past misgovernment. The products consist principally of cereals, tobacco, fruits and opium, with a little cotton. The wine of Shiraz is highly thought of in Iran and is, on occasions, of excellent quality. Tobacco, of excellent quality, is grown mainly around Fasa, Darab and Jahrum for home consumption, and rosewater is exported from Maimand. Sulfur and lead are found. (P. Z. C.; X.)

FARTHING, the smallest English coin, equal to the fourth of a penny (A. S. *feórtha,* "fourth," +*ing,* "diminutive"). It became a regular part of the coinage from the reign of Edward I, and was, up to the reign of Mary, a silver coin. No farthing was struck in the reign of Elizabeth, but a silver three-farthing piece was issued in that reign, with a profile bust of the queen crowned, with a rose behind her head. and inscribed "E.D.G. Rosa sine spina." The copper farthing mas first introduced in the reign of James I, a patent being given to Lord Harington of Exton in 1613 for the issue of copper tokens of this denomination. It was nominally of six grains weight, but was usually heavier. Properly, the copper farthing dates from the reign of Charles II, in whose reign also was issued a tin farthing, with a small copper plug in the centre, and an inscription on the edge, "Nummorum famulus 1684." No farthings were issued in the reign of Queen Anne, though a number of patterns were prepared. In 1860 the copper farthing was superseded by one of bronze. In 1842 a proclamation was issued giving currency to half farthings, and there were several issues, but they were demonetized in 1869. In 1897 the practice was adopted of darkening farthings before issue, to prevent their being mistaken for half sovereigns. *See* also NUMISMATICS.

FASCES, in Rome, bundles of elm or birch rods from which the head of an ax projected, fastened together by a red strap. As the emblem of official authority, they were carried by the lictors, in the left hand and on the left shoulder, before the higher Roman magistrates, at the funeral of a magistrate, behind the bier. The lictors and the fasces were so inseparably connected that they came to be used as synonymous terms. The fasces represented the power over life and limb possessed by the kings; later, the consuls were preceded by 12 fasces. Within the precincts of the city the ax was removed, in recognition of the right of appeal (*provocatio)* to the people in a matter of life and death; outside Rome, however, each consul retained the ax. Valerius Publicola established the custom that the fasces should be lowered before the people, as the real representatives of sovereignty; lowering the fasces was also the manner in which an inferior saluted a superior magistrate. A dictator had 24 fasces (including the ax, even within the city); other magistrates had fasces varying in number, with the exception of the censors, who, possessing no executive authority, had none. A victorious general, who had been ,saluted "imperator" by his soldiers, had his fasces crowned with laurel. Under the empire, the laurel was regarded as distinctive of the imperial fasces.

In Italy, the fasces were adopted as the emblem of the Fascist party *(see* FASCISM).

FASCISM is the name of a political attitude which puts the nation-state or the race, its power and growth, in the centre of life and history. It disregards the individual and his rights, as well as humanity, in the exclusive interest of the nation. As a political technique it follows the lead of totalitarian bolshevism as a single-party state with strict regimentation of all aspects of national life. The name fascism was first used by the movement started by Benito Mussolini in March 1919. Later on it became the general name for similar movements in other countries, among which German National Socialism (*q.v.*) was the most prominent. The Italian word *fascismo* is derived from the Latin *fasces,* "bundles," denoting in ancient Rome a bundle of rods with an axe, borne before Roman magistrates as a symbol of authority.

Among the intellectual forerunners of fascism were two Frenchmen, Georges Sorel and Charles Maurras, and an Italian, Vilfredo Pareto. Pareto, an economist and sociologist, developed a cyclical theory of social change and of the rise of new elites. Georges Sorel, the theoretician of revolutionary syndicalism, emphasized the creative role of violence in history. His doctrine of direct action mas firmly opposed to mediation and compromise, which he regarded as signs of the decadence of the *bourgeoisie.* Through direct action in the spirit of violence, a new social elite was to lead the proletariat into a new epoch of history and civilization in opposition to plutocracy. His Italian followers applied his theory of a heroic proletariat not to a class but to the Italian nation, which they regarded as a proletarian nation in relation to the western plutocratic democracies. . Charles Maurras was the father of "integral nationalism" in France. He opposed the ideas of the French Revolution, emphasized the precedence of French national self-interest before all other considerations and stressed foreign policy as the foremost field of activity of the state. His newspaper *L'Action française* had little influence in France except under the Pétain regime. Its Italian counterpart, *L'Idea nazionale,* struck much deeper root in Italian soil.

The origins of the fascist movement in Italy are to be found both in the wave of disillusionment and at the same time in the exacerbated nationalism which swept Italy after 1918. Even before World War I Enrico Corradini had propagated a doctrine of extreme and belligerent nationalism, which had fanned enthusiasm for the Libyan war of 1911 and for imperial expansion. The poet Gabriele d'Annunzio had exalted in verse and prose not only the mission of a victorious Italy, but also the love of danger, adventure and war. In the military coup by which he with a legion of black-shirted followers gained possession of Fiume in Sept. 1919, and during the 16 months in which he as *duce* ruled the city, D'Annunzio introduced a constitution foreshadowing the "corporative state" and all the rites, salutes, allocutions and mass shouts which later became characteristic of the fascist movement. Mussolini himself before 1914 had been a leading member and editor of the Italian Social Democratic party, but he had always represented the tendencies of revolutionary syndicalism with their emphasis upon direct action and enthusiastic will. Against the attitude of his party, Mussolini supported Italy's entrance into the war in the fall of 1914; on Nov. 15 he founded his own newspaper, the *Popolo d'Italia,* in Milan, which called itself an organ of combatants and producers and carried the social revolutionary motto by Blanqui, "Who has steel has bread," and Napoleon's saying, "The revolution is an idea which has found bayonets." Mussolini's first famous editorial bore the characteristic title "Audacity."

In the social unrest and moral confusion which followed the war of 1914–18, Mussolini founded the Fasci di Combattimento on March 23, 1919, in Milan. The new group had no definite program; at first Mussolini was still a revolutionary syndicalist who preached the expropriation of the land, the mines and all means of transportation. It was not until the beginning of 1921 that he allied his group openly with the propertied classes, with the landowners and the industrialists. But whatever his sociological affiliations, he was moved throughout by a fierce nationalism and by the love of violence and adventure.

When he ran in Milan for a parliamentary seat in the elections of Nov. 16, 1919, he got less than 5,000 votes out of 346,000. But the deep social unrest prevailing in Italy in 1920 gave Mussolini a chance, and though the danger of any bolshevist or socialist success had entirely faded by the end of the year, Mussolini and his squads of violent young men appeared to the frightened upper classes as a guarantee of security. Thus, with the army conniving. Mussolini's followers set for themselves the task of "restoring order" and breaking up the socialist and progressive movements and organizations. With a boastful ruthlessness, with the proud sacrifice of all ethical scruples to success, the local *squadristi*, under the leadership of men such as Dino Grandi, Balbo. Roberto Farinacci and others. set out for the conquest of power in the name of youth against nhat they called "the tottering parliamentarism" of the "senile" and undecided liberals. The lack of resistance on the part of the government. the army and the police emboldened the fascists, who had formed themselves into the National Fascist party in Nov. 1921.

In the folloning year Mussolini completely abandoned his original socialist. antimonarchist and anti-Catholic program. He had no definite doctrine to offer. "Our program is simple: we wish to govern Italy. They ask us for programs, but there are already too many. It is not programs that are wanting for the salvation of Italy, hut men and will power." On Oct. 28, 1922, the famous "march on Rome" was staged. Though the Fascists and the Nationalists were outnumbered in the Italian parliament by ten to one, and though with some show of resolute action the Fascists could easily have been stopped, the king refused to sign the proclamation of the state of siege which his government had prepared. and on Oct. 29 invited Mussolini to form the new government Though the new prime minister at first accepted a coalition cabinet and preserved some of the forms of the iiberal state, within a very few years all the trappings of parliamentarism were gone, all other parties outlawed. all civil liberties and constitutional guarantees suppressed and a full dictatorship established. The process was accelerated by the reaction of the country and of the civilized world to the murder of the socialist deputy Giacomo Matteotti in June 1924, on the eve of his exposure of the graft and corruption of the Fascist party. Highest Fascist officials were alleged to have been implicated in the murder. In his effort to save his regime from the outraged feelings of the country, Mussolini established a totalitarian order in which the state was completely identified nith the Fascist party. nhich in turn was identified with its leader. Though he professed to fight bolshevism, he successfully adopted its methods, without, however, being able to carry them. in the different climate of Italy, as far as they were carried in Russia and later on in Germany. The different *squadristi* organizations had been reformed on Feb. 1, 1923, as the Milizia \-olontaria per la Sicurezza Nazionale.

Fascism in its beginnings was not a doctrine and had no clearly elaborated program. It was a technique for gaining and retaining power by violence, and with an astonishing flexibility it subordinated all questions of program to this one aim. But it was dominated from the beginning by a definite attitude of mind which exalted the fighting spirit, military discipline, ruthlessness and action and rejected contemptuously all ethical motives as weakening the resoluteness of will. Fascism is power politics and *Realpolitik* in their most naked form; all theoretical considerations are subservient to what is regarded as the "inexorable dynamics" of the factual situation. Ultimately everything depends upon the ever-changing decisions of the leader, decisions which cannot be discussed. but are blindly obeyed and immediately executed. Thus fascism could present itself in a given situation as a bulwark of the social order against social revolution, against Marxism and the proletariat, and could in a different situation become the propagandist and spearhead of a proletarian world revolution against conservatism and wealth, against *bourgeoisie* and capitalism.

With its stress upon the irrational, upon instincts and activism, fascism insists upon the "iron logic of nature" which will always make the strong prevail over the weak, the more resolute over the irresolute, and thus aims at educating the nation to develop its strength, courage and resolve. and by these means to ensure its victory. All fascist activity is devoted to this preparation for what it regards as the inevitable and beneficial struggles which form the life of nations. Fascism, therefore, repudiates above all the idea of peace and harmony. "War alone brings up to their highest tension all human energies and puts the stamp of nobility upon the peoples who have the courage to meet it. Fascism carries this antipacifist spirit over even into the lives of individuals. It is education for combat." These words by Mussolini are amplified by his famous statement that "War is to the man what maternity is to the woman. I do not believe in perpetual peace; not only do I not believe in it, but I find it depressing and a negation of all the fundamental virtues of man." Therefore, to continue in Mussolini's words, "The whole nation must be militarized. . . I consider the Italian nation in a permanent state of war." The creed of fascism is heroism, the praise of audacity and danger, devotion and sacrifice for the nation and its necessary wars.

Fascism regards itself as a rejection. a complete and uncompromising denial of the principles of liberalism and democracy, as elaborated and realized in the British, American and French revolutions of the 17th and 18th centuries. It is a return to an authoritarian order, based upon the subordination of the individual and the inequality of caste and rank. The liberty of the individual is denied in favour of the state, the inequality of men is proclaimed as immutable and beneficial. The "bourgeois" achievements which liberalism had secured from the time of the English revolutions of the 17th century on have not only been abandoned. but derided and combated. From the beginning fascism acted as the implacable enemy of democracy and of the rights of man. Society is to be built strictly upon a hierarchical order: the leaders are not to be elected, nor are they to be responsible to the people; on the contrary, the people are responsible to the leaders whose appointment depends only upon those above them. Military discipline and blind obedience are to permeate the whole of civilian life. One of the famous slogans of fascism was *credere, obbedire, combattere* ("have faith. obey, fight"), and another was *Mussolini* ha *sempre ragione* ("Mussolini is always right").

The 18 years of the Fascist regime from 1922 to 1940 were devoted to the military preparation of the Italian nation for a coming struggle for what was regarded as the mission of the Italian people, the rebirth of the Roman empire. To this goal the economic life of the country was completely subordinated. Fascist economy, like communist economy, can be regarded as a permanent war economy. The authoritarian and centralized pattern of political life found its replica in the new economic institutions. Fascist inefficiency in Italy did not allow. however, the full realization of governmental goals. Much of the *stato corporativo (see* CORPORATE *STATE)* remained in the blueprint stage.

The basic law of April 3, 1926, established six main economic sectors, within which capital and labour were represented by national confederations of employers and employees. The professions were organized in a separate national confederation. However, civil servants, government officials of all kinds and teachers were placed under the direct control of the secretary of the Fascist party, because their employer was, directly or indirectly, the state. The economic corporations, too. were not regarded as independent agencies. but as instruments of public administration dependent upon the will of the head of the government. With the approach of the Abyssinian War of 1935–36 the control of all economic activities by the party was intensified. This control apparently did not increase the efficiency and productivity of the Italian economy, either in the outright military field or in the nominally civilian areas. The Italian military debacle in World War II revealed the glaring inefficiencies and insufficiencies of Fascist economics. The standard of living and the real wages of the Italian workers and farmers remained extremely low in comparison with other European countries throughout the 20 years of the Fascist regime. Nevertheless, the Fascist leadership did not cease painting a picture of coming Italian grandeur for the benefit of the Italian masses. The cult of the Roman empire and of its expansion was stimulated in every possible way.

In a speech before the senate on March 30. 1938, Mussolini painted a glowing picture of Italian armed strength and military preparedness. Italy, he declared. could raise an army of 9,000,000 men, of whom 5,000,000 were first-line fighters, ready to hurl themselves, under his personal direction, against any enemy. According to him, this army was amply supplied with the most modern instruments of destruction which would enable it to break through the stoutest defenses in conformity with the fascist maxim that the war must be decided within a few months. The powerful navy was principally composed of recently launched vessels which were to be used with boldness and decision. The air force was equal to any and would rain death and destruction on enemy territory. The quick success of Italian arms in any struggle would be guaranteed by ample reserves of supplies and by the fact that Mussolini himself would assume command of the operations.

When Italy. greedy for conquest, entered the war in 1940 to deal the deathblow to the British empire and its idea of liberty, the sordid reality, the inefficiency and corruption of Fascism were quickly revealed. The Italian armies and navy were everywhere ignominiously defeated, and Mussolini's regime was overthrown by the king in Italy in July 1943. It was saved by the Germans for a temporary existence as a Fascist republic in northern Italy. But the Anglo-U S. advance put an end to it in the spring of 1945; Mussolini died an ignoble death at the hands of partisans.

In many ways fascism can be regarded as an exaggerated and even absolutized nationalism which entirely obliterates both individualism and humanity. The nation becomes the supreme arbiter, its service the one supreme duty. Only actions, thoughts and sentiments which help to increase the power of the nation can be called good. This absolute devotion to the nation—not to a nation which is governed by ethical rules of divine or of rational origin, but to one which is an end in itself and which is entirely identified with the fascist party and its leader—becomes the guiding principle of all education in fascism.

This education is not confined to the schools alone nor to the youth organizations of the fascist party; like bolshevism in Russia. it determines everything printed in the press and in periodicals, heard over the radio, presented on the screen or stage, so that it ultimately colours every thought and every sentiment of the people. This kind of indoctrination works especially well because no other information or critical attitude or independent inquiry is ever allowed to reach the people. Fascism leads also to a complete destruction of all free cultural and intellectual intercourse with other nations.

But fascism is not a national attitude in the sense that it would be confined to certain nations. Though it is true that fascism finds a much better soil for its growth in the cultural and social traditions of certain nations, it represents a general attitude which can be found everywhere. Its rise was facilitated by the growing complexity of life in the age of masses and machines and by a feeling of disillusionment and cynicism in the postwar generation after 1914. Democracy, which has grown up in the last 300 years. represents, with its emphasis upon individual responsibility and individual decisions, the most difficult societal system, requiring a definite human maturity. Fascism can in many ways be regarded as an escape from this difficulty into the irresponsibility of following a leader who deprives the masses of their liberty and maturity but promises them social security and economic progress. Fascism. however, was in such complete opposition to the trends of the 18th and 19th centuries that its emergence found democracy completely unprepared for the heavy and decisive blows which its implacable enemy intended to deal it, through propaganda, terror and war. Thus it happened that fascism, which in the 1920s seemed confined to Italy, became in the 1930s a world-wide movement which put democracy not only on the defensive, but into mortal danger.

Mussolini could say in 1934, "Since 1929 fascism has become not merely an Italian phenomenon, but a world phenomenon." On Oct. 25, 1932, he had assured his audience at Milan of the coming world leadership of fascist Italy. "Today, with a fully tranquil conscience I say to you, that the twentieth century will be the century of fascism, the century of Italian power, the century during which Italy will become for the third time the leader of mankind." In that Mussolini was at least partly wrong, because the following years proved very quickly that even in the case of a world-wide victory of fascism the leadership would not fall to Italy. but to Germany, which in 1933 joined the ranks of the fascist powers and very quickly dwarfed Italy in importance.

Fascist principles had become accepted by 1936, to a varying degree. by the governments of Austria, Hungary, Poland, Rumania. Bulgaria. Greece and Japan. In most of these countries fascist parties were formed which imitated not only the doctrinal concepts of the Italian and German movements but also many of their external symbols, though every country had its peculiar national tradition expressed. Thus. while the Italian fascists donned black shirts and the Germans brown. the fascists in Hungary donned green shirts and used the cross and arrow instead of the fasces or swastika. In some of these countries the local fascist brand was a product of popular movements, not created by the government. This was the case in Rumania, where a young lawyer. Corneliu Zelea-Codreanu, founded in 1927 a Legion of the Archangel Michael for the Christian and racial renovation of Rumania, which later developed into the terrorist organization of the Iron Guard and. when disbanded by the government, constituted itself as a party, Totul pentru tara ("Everything for the fatherland"). Though this party had fought enthusiastically for a pro-German orientation of Rumanian policy, it was nevertheless sacrificed by the Germans to the needs of the hour and succumbed in bloody and tormented internal strife. Similarly, a full-fledged fascism came to poner in Greece under the leadership of Gen. Joannes Metaxas, who on Aug. 4. 1936, inaugurated the "third Hellenic civilization" with its symbol, the Spartan salute. The warlike virility of ancient Sparta and the imperial splendor of Byzantium were to be revived.

But the most important gain achieved by fascism outside of Italy and Germany was the fascist conquest of Spain The civil war started by Gen. Francisco Franco from Spanish Morocco on July 17, 1936, ended with the victory of the insurgents in March 1939. By a decree of Aug. 4, 1939, Franco assumed "in its entire plenitude the most absolute authority. The Chief is responsible only to God and to History." During World War II Spain supported, as far as its economic misery and backwardness permitted. the other fascist pouers. In July 1942, when fascist victory still seemed probable, Franco asserted that totalitarianism had "amply demonstrated its superiority" over democratic institutions. The Spanish fascist party, the Falangists, revived the dream of the great Spanish empire of the golden century, which had attempted to impress its civilization upon the whole world and which had ruled in the Americas and in the Pacific.

The victory of fascism in Spain seemed to bear witness to the growing international strength of fascism and to the apparent weakening of democracy Thus, fascist attitudes and movements could even infiltrate the democracies. Fascist propaganda mas relentlessly active. not only in Europe but throughout the western hemisphere. People were induced to believe in the "breakdown" of capitalism and in the inevitable upsurge of the "nave of the future." The German and Italian governments devoted special efforts to the organization of citizens of German and Italian descent abroad. and tried to teach them to put their loyalty to their racial origins above their loyalty to the country whose citizens they were. Fascist influence was very strong in France. but relatively weak in Britain.

In the United States the great number of fascist-type groups, the competition of presumptive leaders and their division into Protestant and Catholic groups prevented the formation of a strong fascist organization. This failure is explained by the habitual Republican or Democratic preferences of most citizens, the strength of popular optimism as to the future (reinforced for many by the efforts, if not always the success, of the New Deal in coping with the depression) and the insulating effects of the federal system, most notably upon Huey Long's "share-the-wealth" movement in Louisiana. A further factor was the strong traditional attachment of most U.S. citizens to the U.S. constitutional system. In Latin America the Integralista movement in Brazil was the outstanding example of a fascist party. In Asia a number of superpatriotic terrorist organizations of young officers and students tried to stamp out the influences of western liberalism in Japan and to bring Japan back to the military virtues and disciplines of the old order. Thus, by 1939, fascism had gained a rapidly growing strength over a wide geographic area.

The strength of fascism in the international scene mas much increased by the close co-operation of the leading fascist powers. From 1936 on, Germany and Italy entered into a number of political. cultural, economic and military agreements, and in 1937 this "axis" was extended to include Japan. While the fascist countries co-operated closely and formed their own "League of Nations" in the so-called Anti-Comintern pact which was later joined by Spain and Hungary. the democratic nations did not co-operate, and instead of strengthening the League of Nations as a bulwark against aggression. allowed it to disintegrate. Thus the world became safe for the aggression of fascist powers.

After 1938 the German form of fascism, known as National Socialism. became so predominant that it impressed its peculiar character upon all other (and even upon the older) forms of fascism. This is especially true of the acceptance of anti-Semitism by Italian and even Japanese fascism. Japan has no Jews and practically has never had any Jewish problem. The number of Jews in Italy was insignificant; they had been completely assimilated into the national life, had participated prominently in all Italian national movements and wars, and many of them from the beginning had belonged to the Fascist party, had been for years in Mussolini's inner circle. Official Fascist sources had repeatedly declared anti-Semitism an absurdity. But in 1938 Italian fascism suddenly accepted the German racial theory.

In May 1939 Italy and Germany concluded an outright defensive and offensive military alliance. The Soviet-German agreement of Aug. 1939 forced a reorientation in fascist propaganda. Until then fascism had always insisted that its official arch enemy was communism, and National Socialism especially had reserved its most violent diatribes for "Jewish communism," of which Moscow was regarded as the seat and centre. Now the propaganda against communism ceased entirely; National Socialism laid a new emphasis on its own proletarian revolutionary character which explained and made possible its understanding with communism. The attacks on "Jewish communism" were replaced by even more vitriolic attacks on "Jewish capitalism" and democracy, which was sometimes called plutocracy, the heart of which seemed to be first London, and then Washington.

The year 1939, with the conquest of the Czechs and Poles by Germany, gave the National Socialists also an opportunity to apply their fascist theories of racial inequality to other peoples than the Jews.

In the war which broke out in Sept. 1939 between Germany on the one hand and Britain and France on the other, fascists and communists not only collaborated against Poland, but joined in the denunciation of France and Britain as imperialist plutocracies and as responsible for the war. Later, Pres. Franklin D. Roosevelt was singled out by fascists and communists as a warmonger. On Sept. 27, 1940, Germany! Italy and Japan concluded, in Berlin, a formal fascist alliance with the intention of imposing "the new order" of fascist authoritarianism upon Europe, Asia and Africa. The new pact denied any hostile intention against the Soviet Union; in fact it was followed by a pact of friendship and neutrality between Japan and the U.S.S.R. in April 1941. During that year the attacks against the United States became more and more violent. On Oct. 23 the *Stampa* of Turin, one of Italy's best-known newspapers, depicted Secretary of State Cordell Hull and President Roosevelt as "throbbing with rage as they use phrases from the ghetto from which the latter has descended."

The fascists tried to prepare for the easy conquest of the democracies by undermining their understanding of the situation and by breaking or mollifying their will to timely action. The most refined technique of propaganda was coupled with a strategy of terror to produce the desired disintegration of the democracies. Since the time when the Spanish insurgents declared that the conquest of Madrid. which was then still in the hands of the republican government and which was being attacked by four columns moving toward the city. would be helped by a "fifth column" of Franco sympathizers within the city, the expression has been frequently used to designate the conscious and more often unconscious helpers of totalitarian penetration into the democracies. Fascist propaganda was ingenious in sowing disunity and distrust among the democracies, fulminating against "British imperialism" in the United States, against "Yankee imperialism" in Latin America, and narning the British of U.S. "intention" to liquidate, and partly inherit. the British empire. Depending upon the audiences for nhich it was destined, fascist propaganda raised doubts about democracy equally from the rightist as well as from the leftist point of view.

Though the fascist powers succeeded in conquering a large number of countries. they could in no way quench the spirit of national resistance. Small groups, succumbing to anti-British and anti-Semitic propaganda, everywhere co-operated with the Germans. Thus in France the defeat of June 1940 gave a reactionary group under Marshal Pétain, Pierre Laval and Admiral Darlan the chance of seizing power. Democracy in France was officially abolished, the achievements of the French Revolution abandoned and vilified, the famous symbols, "liberty, equality, fraternity," discarded in exchange for a mixture of the old French pre-Revolutionary order and an imitation of the German-Italian fascist models. In Norway a Major Vidkun Quisling established, with German help, a pro-German, anti-British government. Only in Poland were the Germans unable to find any "Quislings" or collaborators. The heroic uprising in Warsaw in Xug. 1944 under General Bor marked the climax of the spirit of resistance. which made itself felt in all countries overrun by the fascist alliance.

Fascism, which started in the early 1920s as a movement of purely Italian national significance, had entered at the beginning of the 1940s the struggle for world domination, so as to make the 20th century a fascist century. But its plans miscarried. World War II, started by the fascist great powers, ended in complete defeat for them.

Fascism survived the defeat of World War II only in Spain and in Argentina. In the German Federal Republic and in Japan the foundations of democracy were successfully laid, and one could hardly speak of a rebirth of fascism. The situation in Italy was different. Attempts at the revival of fascism were made, first in 1946 by Guglielmo Giannini who founded a newspaper and organization called *L'Uomo qualunque* ("The Common Man"). and later and more successfully by the Movimento Sociale Italiano. In the 1950s fascist attitudes gained in influence in France, especially in connection with the war in Algeria. A racialist policy recalling fascist attitudes was followed in the Union of South Africa uhen the elections of May 26, 1948. brought the Herenigde Nasionale party, the Reunited National party, under the leadership of Daniel Malan to power.

Fascist influences could be seen in the party's more extreme wings, the Nuwe Orde ("New Order") under Oswald Pirow, and the Ossewabrandwag ("Guard of the Oxen Cart") led by J. F. van Rensburg.

The stronghold of fascism in the western hemisphere was Argentina. There, in June 1943, a group of army officers who were deeply impressed by German National Socialist military achievements seized power. This group called itself G.O.U., Grupo de Oficiales Unidos ("Society of United Officers"). The three initials were also understood to stand for *gobierno, orden, unidad,* "authoritarian government," "order" and "national unity." The dominant figure among these officers was Juan Perón. On Oct. 17, 1945, he seized power, and the "glorious October seventeenth" was declared a national holiday in 1951. On Feb. 24, 1946. Perón was elected president of the Argentine republic. He tried to win over the masses, the *descamisados,* the "shirtless ones," to whom he promised far-reaching social reforms and a relentless fight against capitalism and Yankee plutocracy. He accused North American imperialists of wishing to dominate Latin America and presented his own system as a true democracy of social justice. He was supported by his wife, Eva Perón, who was the head of the María Eva Duarte de Perón Welfare foundation. Her death on July 26. 1952, weakened his hold on the people in spite of the proud slogan, Perdn *cumple,* "Perón accomplishes things." He was overthrown in Sept. 1955 by the armed forces. The legacy which he left was similar to that which Mussolini had left in Italy—widespread corruption, a profoundly shaken economic position and a rapid rise in the cost of living.

(H. Ko.)

FAST AND LOOSE, a cheating game played at fairs by gypsies and sharpers. A strap, usually in the form of a belt, is rolled or doubled up with a loop in the centre, and laid edgewise on a table. The showman then bets that the loop cannot be caught with a stick or skewer as he unrolls the belt. As this looks to be easy to do the bet is often taken, but the sharper unrolls the belt in such a manner as to make the catching of the loop practically impossible.

From this game is taken the colloquial expression, "To play fast and loose."

FASTI, the plural of the Latin adjective *fastus,* but more commonly used as a substantive (derived from fas, meaning what is allowable by divine law). Fasti dies came to mean the days on which law business might be transacted without impiety, corresponding to modern "lawful days." The word fasti itself then came to be used to denote lists or registers of various kinds, which may be divided into two great classes.

1. Fasti *diurni,* divided into urbani and *rustici,* an official yearbook, with dates and directions for religious ceremonies, market days, etc. Until 304 B.C. the lore of the calendaria remained a monopoly of the priesthood; but Gnaeus Flavius then published the forum tables containing the requisite information. This list was the origin of the public Roman calendar. Ovid's Fasti is a poetical description of the Roman festivals of the first six months, written to illustrate the Fasti published by Julius Caesar after he remodeled the Roman year.

2. Fasti *magistrales, annales* or historici were concerned with everything relating to the gods, the emperors. etc., and the feasts and ceremonies established in their honour. They came to be denominated *magni,* by way of distinction from the bare calendar, or fasti *diurni.* Of this class, the fasti consulares were a chronicle of events in which the several years were denoted by the respective consuls. The fasti triumphales contained a list of persons who had obtained a triumph. The word fasti thus came to be used in the sense of "historical records." A famous specimen of this class is the fasti *Capitolini,* so called because deposited in the Capitol by Alexander Farnese, after their excavation from the Roman Forum in 1547. A considerable number of fasti of the first class have been discovered; but none older than the time of Augustus. The Praenestine calendar, arranged by the famous grammarian Verrius Flaccus, contains the months of January. March, April and December and a portion of February. The tablets give an account of festivals, as also of the triumphs of Augustus and Tiberius. Some kinds of fasti included under the second general head were. from the very beginning, written for publication. The Annales Pontificum—different from the calendaria properly so called—were annually exhibited in public on a white table, on which the memorable events of the year, with special mention of the prodigies, were set down in the briefest possible manner. In fact, all the state offices had their fasti corresponding in character to the consular fasti named above.

FASTING, in the strict sense of the word, denotes complete abstention from food and drink; but it is commonly applied also to the use of a diet somewhat severely limited, either by the rejection of certain customary kinds of food or by a diminution of the total quantity of food consumed. Fasting, in the former sense, is generally required in preparation for a surgical operation; in the latter sense it is often recommended for health's sake, and is voluntarily undertaken by many. Occasionally an individual will keep a prolonged fast, in the stricter sense, as a public view, in order to earn the reward of entertainment by giving a demonstration of unusual vitality. In recent times fasting has been used as a means of protesting against the alleged injustice of the law of the land, and even of defeating that law, the hunger-strike being practised with such persistency that it has led either to the release of the protesting prisoner or to his death. A close resemblance is to be seen between this modern application of the practice of fasting and an older use of it as an expression of overmastering desire and stern intention in the quest of justice. Thus men of different lands and ages have bound themselves by an oath to take no food until they have performed some act of revenge for their own honour, or for the sake of their people (cf. Acts xxiii. 12); and among the Celts it was not uncommon for a man who was refused a lawful request, to "fast against" the one who had denied him his right, so as either to persuade him to an act of justice or to bring upon his head the blood of the oppressed.

Commonest by far, however, of all the uses of voluntary fasting, in the past and at the present time, is its practice as an act of self-denial with definite religious intention. By the greater number of religions, in the lower, middle, and higher cultures alike, fasting is largely prescribed; and where it is not required it is nevertheless practised to some extent by individuals in response to the promptings of nature.

I. Religious Sanctions and Regulations.—Fasting is practised by all the peoples of the lower cultures, in which it is supported by the rudimentary science which takes the form of magical lore, as well as by a variety of crude religious beliefs. Special discipline is laid upon medicine-men and other experts, for the perfecting of their abnormal powers and for the ready performance of their peculiar tasks. But when danger threatens in all its many forms, fasting is required of individuals, of groups, and of the whole community, for the avoidance of various hostile influences; and the fear of punishment at the hands of the tribal authorities (including the gods), and, still more, of automatic results of a terrible nature, is sufficient to secure the strictest obedience.

Among the religions of intermediate development, now extinct, that of the Celts laid some stress on the practice of fasting, while the religion of the Teutons appears to have found little or no place for it. The ancient Mexicans and Peruvians resembled the Babylonians and Assyrians in that fasting was largely used by them in connection with penance and the offering of sacrifice; and, though the records do not show that fasting bulked very large in the religious life of the ancient Egyptians, there are clear indications of its use. The Romans appear to have used the practice but little until they came under the influence of the later Greek religion, in which fasting was required of all initiates by the guardians of the mystery-religions, and recommended to individuals by philosophers of various schools, Cynics, Stoics, Pythagoreans, and Neo-Platonists.

In the Far East, Hindu and Jain ascetics are committed by their faith to very severe fasting in conjunction with numerous other austerities; and abstinence in lesser degree is imposed upon Hindus generally by the requirements of caste-law, and by the performance of due accompaniments of pilgrimages and of preparation for certain festivals. Primitive Buddhism recommends moderation rather than extreme self-deprivation; but in practice in its various developed forms the religion covers a considerable amount of fasting, especially in Tibet, in direct contradiction of the Buddha's teaching. The higher Taoism of China imposes periods of strict abstinence upon its professors; and Confucianism has followed the practice of its great expounder in approving the customary observance of fasting as a preparation for the worship of ancestral spirits.

Judaism requires an annual fast on the Day of Atonement. For a long time the Jews observed four other annual fast-days appointed during the Babylonian exile to commemorate the siege and destruction of Jerusalem; and a fifth day was added subsequently in remembrance of the three days' fast of Esther. Additional voluntary fasts on the part of individuals were common, and at the beginning of the Christian era, Monday and Thursday in each week were kept as voluntary fast-days by the stricter Jews (cf. Lc. xviii. 12). The Qur'ān (ii. 179 sqq.) requires all Muslims other than young children and idiots to observe the ninth month (Ramadan) of the year as a fast, food and drink being forbidden from sunrise to sunset during each of the 30 days. Any who are prevented from keeping the fast by sickness or by the necessity of travelling, must fast for an equivalent period at another time. Voluntary fasts are also recommended on certain days in the year; and fasts are required in recognition of responsibility for specified offences and in discharge of obligation for the same: Muslim mystics (Sufis) and members of the darwesh orders practice much additional fasting for their special purpose of communion with the Divine.

In the Christian world there exists, at the present day, considerable diversity of opinion and practice in the matter of fasting; but on a historical survey it may be said that in no other religion has fasting been more widely approved, more rigorously required, and more extensively practised. The Founder Himself laid down no rules on the subject. He fasted (Lc. iv. 2); He declared that fasting would have a place in the practice of His followers (Mk. ii. 19 seq.); and He required that fasting, like the almsgiving and prayer with which it is associated, should be without ostentation (Mt. vi. 16 seq.). But it was left to the Church to prescribe the rules that were to govern the corporate practice of the fast. Out of the voluntary use of individuals there gradually arose a common mind and a common discipline, according to which a fasting preparation was required by the Church for the due observance of appointed festivals, and for the reverent reception of the benefits of Holy Baptism and Holy Communion. The preparation for the feast of Easter developed slowly from a fast of one day, 40 hours (the time during which the Lord's body rested in the tomb), two days or more, to the full 40 days of Lent; and in close association with it the pre-baptismal fast came to be required of catechumens. The fasting varied in rigour according to locality, but on the whole it involved real self-denial, and in places was literally a complete abstention from food and drink. From the 2nd century it began to be the custom in some countries to fast on Wednesday and Friday in each week, these days being knoun as "stations," when Christians considered themselves to be on guard. Under the influence of the Montanists this fasting increased in strictness, and by the end of the 4th century it had become a universal custom in the Church, Saturday being added to Friday as a "superposition" in many parts of the West. By the same date the fast before Communion, dictated long before this time by a growing appreciation of the full significance of the sacrament, had also become oecumenical. Dispensation from this fast, in particular, seems to have been very rarely granted, only the dying being recognized as necessarily exempt. Bishops prescribed additional fasts for their own dioceses as occasion required; voluntary fasts were added to these obligatory acts of discipline at the discretion of individuals; and, with the growth of monastic communities from the middle of the 4th century, special fasts began to be largely used.

The Eastern Church took an independent line in the development of appointed fast-days, and its present practice differs considerably from that of the Church in the West. In Lent the Saturdays (with the exception of Easter Even) are excluded from the fast as well as the Sundays. The Fast of the Apostles lasts for a week from the octave of Pentecost, which is the Sunday of All Saints, or in some cases until June 29, which is the Feast of St. Peter and St. Paul. The fortnight before the Feast of the Repose of the Virgin, which is celebrated on August 15, is kept as the Fast of the Mother of God. The Fast of the Nativity of our Lord, beginning on November 15, lasts until Christmas, thus covering a period of 40 days. And the Wednesdays and Fridays throughout the year are fast-days. The fast before Communion is generally insisted on.

The post-Reformation Church of Rome continued to fast, as in the middle ages, during Lent, on the Ember Days and Rogation Days, on the days appointed as Vigils, and on Fridays, the Wednesday and Saturday fasts having practically lapsed; but in 1781 a reduction was made in the severity of the fasting required of the English Roman Catholics by the introduction of a distinction between fasting and abstinence. Recent years have seen further concessions, and the new *Codex Juris Canonici*, issued in 1917, shows that abstinence from flesh meat is alone required on days of abstinence, no restriction being laid upon the quantity of food taken. Days of fasting which are not marked also as days of abstinence admit of any kind of food being taken at the one full meal that is allowed, flesh meat being forbidden, however, at the two smaller meals which are permitted. The strict fast before Communion, rarely excused at all before the present century, may now be modified in the case of any who are in serious ill-health, dispensation being granted both to lay-people and to priests.

At the Reformation the Church of England included in its Book of Common Prayer a list of days of fasting or abstinence, the two terms being used synonymously, and required that notice of these days should be given in church. No directions for their observance were issued, the matter presumably being left to every man's conscience; yet there can be no doubt that the list was issued with serious intention, for provision was made by law for the granting of dispensations by the archbishop of Canterbury, by diocesan bishops, and by incumbents of parishes, according to the nature of the case (25 Hen. VII., cap. 21, 5 Eliz., cap. 5). The list includes the 40 days of Lent, the Ember-days at the four seasons, the three Rogation-days, and all the Fridays in the year, except Christmas Day. The fast before Communion was not referred to; but in the form provided in 1661 for the ministration of baptism to such as are of riper years, the first rubric states that candidates "may be exhorted to prepare themselves with prayers and fasting for the receiving of this Holy Sacrament." On the whole the practice of English churchmen after the Reformation included less and less fasting until the time of the Tractarian movement. It was never entirely lost, and there were notable revivals of the practice in the Wesleyan and Evangelical movements; but the recovery of a true sense of its earlier obligation and importance and of a steady persistence in its practice dates from the second quarter of the 19th century. Special stress has been laid by the followers of the Tractarians upon the necessity of the fast before Communion; and this, together with the evangelical opposition which it has aroused, led to the insertion in the revised Prayer Book which was presented to parliament in 1928 of a new rubric stating that "It is an ancient and laudable custom of the Church to receive this Holy Sacrament fasting. Yet, for the avoidance of all scruple, it is hereby declared that such preparation may be used or not used, according to every man's conscience in the sight of God." The new Prayer Book also revised the list of days of fasting or abstinence, exciuding the Epiphany when it chances to fall on a Friday, and the Fridays in the octaves of Christmas, Easter, and the Ascension, and adding the Vigils before the Nativity of our Lord, Pentecost, St. John the Baptist, All Saints and St. Andrew.

In the other Reformed churches and in the Free churches which have separated themselves from the Church of England, fastinghas had its place; but the sense of its importance has generally diminished, and there has arisen not a little prejudice against its use.

II. Purposes of Fasting.—In any general survey of the different types of religious fasting, it is important to remember that great diversity exists between the mind and motives of men of different cultures and religions who yet do the same thing for what is ostensibly the same purpose, and that, in consequence, it is highly erroneous to suppose that the religious value of any one variety of fasting is constant in all cases that admit of being placed in that particular class.

(1.) Purificatory Fasting.—Under the influence of the mistaken idea that it is that which enters into a man which defiles him, the rejection of food and drink is often practised by those who would avoid every possibility of the contagion of evil at times of special importance. In the lower culture the initiation of lads and girls to adult membership of their tribe, admission to secret societies, and entry into the married state, are prefaced by a period of fasting, mainly on the basis of this idea; and the same precaution has much to do with the fasting that belongs to the ritual of mourning after a death and of preparation for the reception of sacred food. The endurance of fasting leads, sometimes, to the experience of seeing visions and hearing voices, and it is naturally adopted as a means thereto by "holy" men of all sorts who interpret the operation of the method they use with a physical or a psychological emphasis according to their understanding. Again, fasting is practised as a preparation for spiritual and sacramental communion, because the spirit is intent on its guest. For the sake of its own purgation and freedom of activity, it subordinates the desire for bodily food to the craving for spiritual sustenance. This is the ultimate basis of the Christian fast of purification before Communion. It is not prompted by a Manichaean conception of matter, but is due solely to concentration on the things of the Spirit and an ancillary rejection for the time being of the means of physical life. Thus, in the Church of England homily "of Fasting" the second "end" sperified is "that the spirit may be made more earnest and fervent to prayer"; and Hooker says (Eccl. Pol. v. 72) that the object of fasting is "to temper the mind, lest contrary affections coming in place should make it too profuse and dissolute."

(2.) *Sympathetic* Fasting.—The practice of fasting after a death is complex in its origin and significance. It may be connected with the sacrifice involved in making provision for the dead; it may have to do with the placation of the ghost; it may be purificatory, or it may be a contradiction of normal practice intended to sever connection with the departed; but in most cases it is undoubtedly to be regarded also as an expression of grief, whether formal or sincere. Such sympathetic fasting becomes a recurring practice in the case of a saint or deity who has conferred benefits and is to be duly honoured. Thus March 24 was observed as a day of fasting and mourning in the ritual of the Mater Magna, in memory of the mother's grief for Attis; the Shi'ah Muslims similarly commemorate the martyrdom of 'Alī and his two sons, Hasan and Husain; and the Christian observance of Lent is largely inspired by the thought of fellowship with Christ in His suffering during the 40 days in the wilderness and during the events leading to His death.

(3.) Penitential Fasting.—In the minds of wrongdoers who are suffering or anticipating the reward of sin and convicted by their consciences, fasting serves to attest the genuineness of their repentance, to turn aside the wrath of the offended gods, and either to forestall and cancel at an easy rate the punishment due to them, or to denote a readiness to accept whatever is right, if only reconciliation may be had. At the lowest there is a large element of commercialism; at its best it is the expression of a truly contrite heart, and is associated with "prayers and supplications" and with "strong crying and tears." Such penitential fasting is found particularly in Jewish and Christian practice; and it may be said of all Christian restraint in the matter of food and drink that it partakes of this character.

(4.) Meritorious Fasting.—The fasting that is undertaken in order to obtain reward or to secure power is sometimes held to work magically, as in the Intichiuma ceremonies of the tribes in Central Australia, where fasting is practised for the increase of the totem food supply. Or again, it is a personal appeal for favour, as when Jain girls fast in order to win a good husband and a happy married life. Both ideas are mingled in the fasting which is practised as a means of gaining power to exorcise evil spirits and to secure the "holiness" which is the reward of works of supererogation.

(5.) Disciplinary Fasting.—This figures in those religions attaching great importance to moral conduct, and it is regarded as a reasonable and useful practice, even by those who consider all other forms of fasting to be misconceived and vain. When it is undertaken as a reaction from surrounding voluptuousness, and in protest against prevailing licence, it is apt to be unduly severe; but normally it is a reasonable part of the soul's preparation for the maintenance of self-control in times of strong temptation. The Lenten discipline of Christians is shared by not a few to whom its religious significance makes no appeal, solely because they recognize its moral value.

III. Criticism and Rejection of Fasting.—Fasting may be an irksome discipline, and there are many who, having absolved themselves from its practice, find reasons why it is no longer required.

Thus, it is frequently urged that the strenuous conditions of modern life make it practically impossible, and that the use of frequent and light meals renders unnecessary a discipline which was, perhaps, of some service when men ate less frequently but more immoderately. The plea of difficulty and inutility may be reinforced by arguments drawn from quite a different quarter. Zoroastrianism taught that "he who fasts commits a sin," for he rejects that which is good, in so doing he tortures in himself another part of the good creation, and he weakens himself for the conflict with evil which is his proper work. Protests have also been made in the name of true religion by Old Testament prophets and early Christian writers, who have resented the abuse of fasting as a formal and merely external act, unblushingly offered as the accompaniment of an immoral life. "Behold, in the day of your fast ye find your own pleasure, and exact all your labours. Behold, ye fast for strife and contention, and to smite with the fist of wickedness: ye fast not this day so as to make your voice to be heard on high." (Isai. lviii. 3 seq.) To the rebuke of the religious critic may be added the unfavourable verdict of some who regard the matter from medical and psychological standpoints, doubt as to the wisdom and efficacy of fasting as an aid to devotion and self-control being seriously increased by the citation of numerous cases in which physical and mental evil has resulted from excess.

In spite of such criticism the practice of fasting persists, and it is likely to continue so long as men are capable of religious and moral aspiration. For it has the authority of very widespread use from time immemorial; it is supported by ecclesiastical authority in by far the greater part of Christendom; and, above all, it is rooted in some of the strongest emotions incident to human nature. There will always be the few who practise fasting rigorously, according to the strict interpretation of the term; the many will no doubt continue, according to a growing fashion, to regard fasting as a term which covers self-denial in general, and will impose it upon themselves in a variety of forms, including the discipline of some sort of abstinence in respect of food and drink at stated times. (O. H.)

FASTOLF, SIR JOHN (d. 1459), English soldier, in some part the prototype of Shakespeare's Falstaff, was the son of a Norfolk gentleman, John Fastolf of Caister and is said to have been squire to Thomas Mowbray, duke of Norfolk, before 1398. He served with Thomas of Lancaster in Ireland during 1405 and 1406, and in 1408 made a fortunate marriage with Millicent, widow of Sir Stephen Scrope of Castle Combe in Wiltshire. In 1413 he was serving in Gascony, and took part in all the subsequent campaigns of Henry V. in France. He must have earned a good repute as a soldier, for in 1423 he was made governor of Maine and Anjou, and in February 1426 created a knight of the Garter. But later in this year he was superseded in his command by John Talbot. On Feb. 12, 1429 when in charge of the convoy for the English army before Orleans he defeated the French and Scots at the "battle of herrings" On June 18 an English force under the command of Fastolf and Talbot was defeated at Patay. According to the French historian Waurin, who was present, the disaster was due to Talbot's rashness, and Fastolf only fled when resistance was hopeless. Other accounts charge him with cowardice, and John of Bedford at first deprived him of the Garter, though after inquiry he was honourably reinstated. This incident was made unfavourable use of by Shakespeare in Henry *VI*. (pt. i. act. iv. sc. i.). Fastolf continued to serve with honour in France, and was trusted both by Bedford and by Richard of York. He returned home in 1440, when past sixty years of age. But the scandal against him continued, and during Cade's rebellion in 1451 he was charged with having been the cause of the English disasters through minishing the garrisons of Normandy. In his later days he showed himself a grasping man of business. A servant wrote of him: — "cruel and vengible he hath been ever, and for the most part without pity and mercy" (*Paston* Letters, i. 389). He had large estates in Norfolk and Suffolk, and a house at Southwark, where he also owned the Boar's Head Inn. He died at Caister on Nov. 5, 1459. There is some reason to suppose that Fastolf favoured Lollardry, and this circumstance with the tradition of his braggart cowardice may have suggested the use of his name for the boon companion of Prince Hal, when Shakespeare found it expedient to drop that of Oldcastle. In the first two folios the name of the historical character in the first part of Henry VI. is given as "Falstaffe," not Fastolf. Other points of resemblance between the historic Fastolf and the Falstaff of the dramatist are to be found in their service under Thomas Mowbray, and association with a Boar's Head Inn. But Falstaff is in no true sense a dramatization of the real soldier.

The facts of Fastolf's early career are to be found chiefly in the chronicles of Monstrelet and Waurin. For his later life there is much material, including a number of his own letters, in the *Paston Letters*. There is a full life by W. Oldys in the *Biographia Britannica* (1st ed., enlarged by Gough in Kippis's edition). See also Dawson Turner's History of Caister Castle, Scrope's History *of Castle Combe*, J. Gairdner's essay On the Historical Element in Shakespeare's Falstaff, ap. *Studies in English History*, Sidney Lee's article in the *Dictionary of* National Biography, and D. W. Duthie, *The* Case of Sir John Fastolf and other Historical Studies (1907).

FAT, the name given to certain animal and vegetable products which are oily solids at ordinary temperatures, and are chemically distinguished as being the *glyceryl* esters of various fatty acids. (See OILS. FATS AND WAXES.) Fat is a normal constituent of animal tissue, being found even before birth; it occurs especially in the intra-muscular, the abdominal, and the subcutaneous connective tissues. In the vegetable kingdom fats especially occur in the seeds and fruits, and sometimes in the roots. Physiological subjects concerned with the part played by fats in living animals are treated in the articles, CONNECTIVE AND SUPPORTING TISSUES; NUTRITION; OBESITY; METABOLIC DISEASES.

FATALISM, the attitude of mind which accepts whatever happens as having been bound or decreed to happen. Such acceptance may be taken to imply belief in a binding or decreeing agent; and the development of this implication in ancient Greek and Roman mythology, with its personified Moirai, Fata or Parcae, is discussed in the article FATE. Here, however, we are concerned with fatalism in its relation to later modes of thought.

We may speak loosely of fatalism as synonymous with determinism; but it is useful to make a distinction. Whereas determinism (*q.v.*) can be represented as compatible with moral responsibility, fatalism properly understood would reduce practical ethics to nothing but the advice that we should resign ourselves indifferently to the course of events. Strict fatalism, therefore, is not to be sought in the major Christian controversies arising from differences between Augustinian and Pelagian, semi-Pelagian or Molinist doctrine on free will, on grace and on predestination (*qq.v.*), wherever the notions of merit and of guilt (sin) retain any sense of actuality. Among Christians, indeed, the Quietists, with their uncritical reliance on inspiration, may be regarded as having in practice approached more closely to the fatalistic norm of behaviour than any of the commonly recognized partisans of determinism, Calvinists, Jansenists, etc.

Primitive Islam taught that everything is ruled by the decree of almighty God; but influence from pre-Islamic fatalism in Arabia and fatalistic doctrines in Iranian religion (especially Zervanism) soon changed this tenet into belief in an inexorable fate (kismet, *nasib*), and submission to the will of God became resignation to fate's decree. (See Helmer Ringgren, Fatalism in Persian Epics [Uppsala, 1952] and Studies in Arabian Fatalism [Uppsala, 1955].)

The common confusion between "fate" and "chance" can be removed by linguistic analysis. The proposition "it happened by chance" means that there appeared to be no intrinsic necessity for a coincidence; and this is obviously different from saying that something happened of necessity, by fatal design. Misunderstanding arises only when the proposition is put into the form "chance caused it to happen," which is admissible colloquially but is nonsensical if taken literally. The calculation of probability (*q.v.*) is an attempt to introduce an element of fatal order into the field of chances.

FATA MORGANA. A mirage frequently seen in the Straits of Messina, consisting of an apparent vertical elongation of an object situated on the opposite shore.

See MIRAGE.

FATE. The idea of fate as an impersonal force that absolutely predetermines all events was, to the ancient world as it is to the modern, a philosophical or theological conception rather than a popular notion. For Greece, the nearest approach to such an idea was the concept of an "allotment" (moira, *moros,* aisa), made to an individual either by the gods together or by Zeus alone: it was now and then almost identified with Zeus. The individual could not escape the portion of misfortune contained in it, though, according to the *Odyssey,* he might increase this through his own folly, as Aegisthus did by deliberate neglect of a divine warning. Patroclus (*Iliad* xvi, 845) says that his death is due to Zeus and Apollo, but four lines later blames "cruel moira and the son of Leto" (Apollo). Again, the Iliad states that it was the *moira* of Achilles to die soon after he had killed Hector. But he had his choice, for he might have preferred to stay quietly at home, in that case to enjoy a long but inglorious life. There might be a *moira* for a whole nation, at least in post-Homeric belief. Persia, according to Aeschylus, was apparently to conquer in Asia but to meet misfortune overseas—a doom foolishly precipitated by Xerxes. On occasion the "allotment" was personified. In Homer. a man must undergo "such things as Moira (Aisa) span upon the thread of his birth," in which connection he sometimes mentions the Clothes (Spinners). Often the plural form moirai is found. The Moirai were conceived as very old women (though art does not represent them so). From the time of Hesiod onward they were even given individual names—Clotho (Spinner), Lachesis (Allotter) and Atropos (Inflexible). Some fanciful persons, much later, assigned different tasks to the three; the holding of the distaff to Clotho, the spinning to Lachesis and the cutting of the thread to Atropos (see H. J. Rose. Handbook of Greek *Mythology,* p. 24 and references). But fundamentally the Moirai belonged to folk belief; their primary function was to assist at a birth and then and there to determine the career of the child, as the Moires still do in modern Greece.

The Romans identified their obscure native deities the Parcae with the hloirai, and, evidently under the influence of Greek myth, pluralized their *fatum,* the "spoken" decree of the gods. Tertullian mentions Fata *scribunda,* Fates who write — presumably, the child's destiny. The phraseology is archaic. and the idea of writing seems to be Etruscan, not native Latin. The identification of the Parcae with the Moirai rested on a very doubtful etymology deriving Parcae from pars. This use of fate had an interesting development. When the neuter gender became extinct in spoken Latin. its plural came to be thought of as a feminine singular; hence

Italian *fata*, French *fée*. The Fates had become a fairy. See also ANANKE; FATALISM; NORNS. (H. J. R)

FATEHPUR, a municipality, with tehsil, and a district in the Allahabad division of Uttar Pradesh, India. The town is 73 mi. S.W of Allahabad by road and rail. Pop. (1951): town 24,301; tehsil (642 sq mi) 358,151.

FATEHPUR DISTRICT has an area of 1,625 sq.mi. It is in the extreme southeastern corner of the Doab or tract of country betneen the Ganges and the Jumna, which respectively mark its northern and southern boundaries. The central part is almost perfectly level and consists of highly cultivated land interspersed with tracts impregnated with saltpetre (*usar*) A ridge of higher land, forming the watershed of the district, runs along it at an average distance of about 5 mi. from the Ganges. The country near the banks of the two rivers is cut up into ravines and nullahs running in all directions, and is almost entirely uncultivable. Besides the Ganges and Jumna the only rivers of importance are the Pandu, a tributary of the Ganges, and the Arind and Nun, both falling into the Jumna.

The area comprising this district was conquered in 1194 by the Pathans; but after a desperate resistance, it was wrested from them by the Moguls. In 1736 it was overrun by the Marathas, who retained possession of it until, in 1750, they were ousted by the Pathans of Fatehpur. In 1753 it was conquered by the nawab of Oudh. In 1765, by a treaty between the East India company and the nawab, it was made over to the Delhi emperor, who retained it till 1774, when it was again restored to the nawab wazir's dominions. Finally in 1801, the nawab, by treaty, reconveyed it to the company in commutation of the amount which he had stipulated to pay in return for the defense of his country. In 1951 the population was 908,985. Trade is mainly agricultural, but Fatehpur is noted for ornamental whips, and Jafarganj for artistic curtains.

FATEHPUR-SIKRI, a town in Agra district, Uttar Pradesh, India, 26 mi. S.W. of Agra. Pop. (1951) 8.959. The modern town lies beside one of Akbar's capitals, a site chosen as auspicious as the result of the birth of three sons to the emperor, one of whom, Salim, became the emperor Jahangir. These events followed upon Akbar's visit to the hermit Salim Chishti (d. 1572) at Sikri. Thereupon, he personally directed the building of a mosque and a tomb for the hermit, and gradually surrounded it with a magnificent series of private and public buildings from 1572 onward. The whole is enclosed in a battlemented wall of red sandstone with nine gateways. Sikri was Akbar's favourite residence, but after 1588 he ceased to use it as a capital and it became deserted. Although it is a Moslem foundation the buildings show strong Hindu influences. These may be seen in the palace of Jodh Bai, Akbar's wife, with its blue enamel roof, and in the Hawa-khana, whose decorative elements derive from western Indian architecture. Even the tomb of Salim Chishti, of white marble inlaid with mother of pearl. its windows magnificent with marble tracery, has brackets to support the cornice whose elaborate style shows clear Hindu influence. Other notable buildings are the houses of Miriam and Birbal, the latter with exuberantly carved decorations and an unusual roof, and the Diwan-i-Khas (private audience hall), with a single central pillar of carved red sandstone whose capital bears the ends of four diagonally radiating galleries, the whole forming an audience platform for the emperor and his ministers. The Jamma Musjid (great mosque), symmetrical in plan. has a fine façade, but its great glory is the southern gateway, the Buland Darawaza (victory portal), which has been described as the most perfect architectural achievement in India. The sandstone used, now weathered to a glorious rose colour, was soft when quarried, and thus particularly sensitive to the delicate work of skilful carvers; and the whole has preserved the artistic conception of a great emperor. (A. H. CE.)

FATHER, the begetter of a child, the male parent. The word is used of male ancestors more remote than the actual male parent, and of ancestors in general, and is the orthodox term for the First Person of the Trinity. One who stands as a spiritual parent to another is his "father," *e.g.*, godfather, and bishops or archbishops are given the title Right or Most Reverend Father in God. In the Roman church the pope is the Holy Father, while "father" is applied to a "regular," a member of one of the religious orders, and so to a confessor, whether regular or secular, and to any Roman priest. It is also used sometimes of sub-members of a religious society or fraternity in the English church. Of transferred uses, other than religious, mention may be made of the application of the word Father to the first founders of an institution, a constitution, an epoch, and so on; thus the earliest, settlers at Plymouth, Mass., are called Pilgrim Fathers, the earliest settlers in other portions of New England, Puritan Fathers, and the framers of the United States constitution are the Fathers of the Constitution. In ancient Rome the members of the senate are the Patres *conscripti,* the "conscript fathers." The senior member of a society is often called the father. Thus the member of the British house of commons or of the U.S. house of representatives, who has sat for the longest period uninterruptedly, is the father of the house.

See FATHERS OF THE CHURCH.

FATHERS OF THE CHURCH. The "fathers of the Church" are the great bishops and other eminent Christian teachers of the earlier centuries, who were conspicuous for soundness of judgment and sanctity of life, and whose writings remained as a court of appeal for their successors, especially in reference to controverted points of faith or practice. A list of fathers drawn up on this principle will begin with the Christian writers of the 1st century whose writings are not included in the New Testament: where it ought to end is a more difficult point to determine. Perhaps the balance of opinion is in favour of regarding Gregory the Great (d. 604) as the last of the Latin fathers, and John of Damascus (d. *c.* 760) as the last of the fathers of the Greek Church. A more liberal estimate might include John Scotus Erigena or even Anselm or Bernard of Clairvaux in the West and Photius in the East. The abbé Migne carried his Latin patrology down to the time of Innocent III. (d. 1216), and his Greek patrology to the fall of Constantinople (1453); but, while this large extension of the field is much to the advantage of his readers, it undoubtedly stretches the meaning of *patrologia* far beyond its natural limits. For ordinary purposes it is best to make the patristic period conterminous with the life of the ancient Catholic Church. In the West the Church enters the mediaeval stage of its history with the death of Gregory, while in the East even John of Damascus is rather a compiler of patristic teaching than a true "father."

A further question arises. Are all the Christian writers of a given period to be included among the "fathers," or those only who wrote on religious subjects, and of whose orthodoxy there is no doubt? Migne, following the example of the editors of *bibliothecae patrum* who preceded him, swept into his great collection all the Christian writings which fell within his period; but he is careful to state upon his title-page that his patrologies include the "ecclesiastical writers" as well as the "fathers" and "doctors" of the Church; and an "ecclesiastical writer" is not necessarily orthodox. It is clear that in the circumstances the terms "father," "patristic," "patrology" must be used with much elasticity, since it is now too late to substitute for them any more comprehensive terms.

By the "fathers," then, we understand the whole of extant Christian literature from the time of the apostles to the rise of scholasticism or the beginning of the middle ages. However we may interpret the lower limit of this period, the literature which it embraces is immense. Some method of subdivision is necessary, and the simplest and most obvious is that which breaks the whole into two great parts, the ante-Nicene and the post-Nicene. This is not an arbitrary cleavage; the Council of Nicaea (A.D. 325) is the watershed which actually separates two great tracts of Christian literature. The ante-Nicene age yields priceless records of the early struggles of Christianity; from it we have received specimens of the early apologetic and the early polemic of the Church, the first essays of Christian philosophy, Christian correspondence, Christian biblical interpretation: we owe to it the works of Justin, Irenaeus, the Alexandrian Clement, Origen, Tertullian, Cyprian. In these products of the 2nd and 3rd centuries there is much which in its own way was not surpassed by any of the later patristic writings. Yet the post-Nicene literature, considered as literature, reaches a far higher level. Both in East and West, the 4th and 5th centuries form the golden age of dogmatic theology, of homiletic preaching, of exposition, of letter-writing, of Church history, of religious poetry. Two causes may be assigned for this fact. The conversion of the empire gave the members of the Church leisure and opportunities for the cultivation of literary taste, and gradually drew the educated classes within the pale of the Christian society. Moreover, the great Christological controversies of the age tended to encourage in Christian writers and preachers an intellectual acuteness and an accuracy of thought and expression of which the earlier centuries had not felt the need.

The ante-Nicene period of patristic literature opens with the "apostolic fathers," *i.e.* the Church writers who flourished toward the end of the apostolic age and during the half century that followed it, including Clement of Rome, Ignatius of Antioch, Polycarp of Smyrna and the author known as "Barnabas." (The term *patres apostolici* is due to the patristic scholars of the 17th century. *See* Lightfoot, *St. Clement of Rome,* i. p. 3; "sub-apostolic" is perhaps a more accurate designation.) Their writings, like those of the apostles, are epistolary; but editions of the apostolic fathers now usually admit also the early Church order known as the *Didachē,* the allegory entitled the *Shepherd* of *Hermes,* and a short anonymous apology addressed to one Diognetus. A second group, known as the "Greek Apologists," embraces Aristides, Justin, Tatian, Athenagoras and Theophilus; and a third consists of the early polemical writers, Irenaeus and Hippolytus. Next come the great Alexandrians, Clement, Origen, Dionysius; the Carthaginians, Tertullian and Cyprian; the Romans, Minucius Felix and Novatian; the last four laid the foundations of a Latin Christian literature. Even the stormy days of the last persecution yielded some considerable writers, such as Methodius in the East and Lactantius in the West. This list is far from complete; the principal collections of the ante-Nicene fathers include not a few minor and anonymous writers, and the fragments of many others whose works as a whole have perished.

In the post-Nicene period the literary output of the Church was greater. Only the more representative names can be mentioned here. From Alexandria we get Athanasius, Didymus and Cyril; from Cyrene, Synesius; from Antioch, Theodore of Mopsuestia, John Chrysostom and Theodoret; from Palestine, Eusebius of Caesarea and Cyril of Jerusalem; from Cappadocia, Basil, Gregory of Nyssa and Gregory of Nazianzus. The Latin Rest was scarcely less productive; it is enough to mention Hilary of Poitiers, Ambrose of Milan, Augustine of Hippo, Leo of Rome, Jerome, Rufinus and a father lately restored to his place in patristic literature, Niceta of Remesiana. Gaul alone has a goodly list of Christian authors to show: John Cassian, Vincent of Lerins, Hilary of Arles, Prosper of Aquitaine, Salvian of Marseilles. Sidonius Apollinaris of Auvergne, Caesarius of Arles, Gregory of Tours.

The period ends in the West with two great Italian names, Cassiodorus and Pope Gregory I, after Leo the greatest of papal theologians.

The reader to whom the study is new will gain some idea of the bulk of the extant patristic literature, if we add that in Migne's collection ninety-six large volumes are occupied with the Greek fathers from Clement of Rome to John of Damascus, and seventy-six with the Latin fathers from Tertullian to Gregory the Great. The Greek patrology contains, however, besides the text, a Latin translation, and in both patrologies there is much editorial matter.

For a discussion of the more important fathers the student is referred to the articles which deal with them separately. In this place it is enough to consider the general influence of the patristic writings upon Christian doctrine and biblical interpretation. Can any authority be claimed for their teaching or their exegesis, other than that which belongs to the best writers of every age? The decree of the council of Trent (*ut nemo . . . contra unanimum consensum patrum ipsam scripturam sacram interpretari audeat*) is studiously moderate, and yet it seems to rule that under certain circumstances it is not permitted to the Church of later times to carry the science of biblical interpretation beyond the point which it had reached at the end of the patristic period. Roman Catholic writers, however, have explained the prohibition to apply to matters of faith only, and in that case the Tridentine decree is little else than another form of the Vincentian "canon," *curandum est* ut *id teneamus quod ubique, quod semper, quod ab omnibus creditum est.* The fathers of the first six or seven centuries, so far as they agree, may be fairly taken to represent the main stream of Christian tradition and belief during the period when the apostolic teaching took shape in the great creeds and dogmatic decisions of Christendom. The English reformers realized this fact; and notwithstanding their insistence on the unique authority of the canon of Scripture, their appeal to the fathers as representatives of the teaching of the undivided Church was as wholehearted as that of the Tridentine divines. Thus the English canon of 1571 directs preachers "to take heed that they do not teach anything in their sermons as though they would have it completely held and believed by the people, save what is agreeable to the doctrine of the Old and New Testaments, and what the Catholic Fathers and ancient Bishops have gathered from that doctrine."

The patristic writings are no longer used as an armoury from which opposite sides may draw effective weapons, offensive or defensive; nor on the other hand are they cast aside as the rubbish of an ignorant and superstitious age. All patristic students now recognize the great inequality of these authors, and admit that they are not free from the faults of their times; it is not denied that much of their exegesis is untenable, or that their logic is often feeble and their rhetoric offensive to modern taste. But against these disadvantages may be set the unique services which the fathers still render to Christian scholars. Their works comprise the whole literature of the Church during the decisive centuries which followed the apostolic age. They are important witnesses to the text of the New Testament, to the history of the canon, and to the history of interpretation. It is to their pages that we owe nearly all that we know of the life of ancient Christianity. We see in them the thought of the ancient Church taking shape in the minds of her bishops and doctors; and in many cases they express the results of the great doctrinal controversies of their age in language which leaves little to be desired.

BIBLIOGRAPHY.—*Encyclopaedia of Religion and Ethics* (with Index vol.), Smith and Wace's *Dictionary oj Christian Biography,* Herzog-Hauck's *Realencyklopadie,* Bardenhewer's *Patrologie* and *Geschichte der altkirchlichen Litteratur,* Harnack's *Geschichte der altchristlichen Litteratur bei Eusebius* and Ehrard's *Die altchristliche Litteratur und ihre Erforschung.* The contents of Migne's patrologies are given in the *Catalogue général des livres de l'abbé Migne,* and a list of the writers in the Greek *Patrologia* has been compiled by Dr. J. B. Pearson (Cambridge, 1882). Migne's texts are not always satisfactory, but since the completion of his great undertaking two important collections have been begun on critical lines—the Vienna edition of the Latin Church writers, *Corpus scriptorum ecclesiasticorum Latinorum,* and the Berlin edition of the Greek writers of the ante-Nicene period, *Griechischen christlichen Schriftstellern der ersten drei Jahrhunderte.*

For English readers there are three series of translations from the fathers, which cover much of the ground; the Oxford *Library of the Fathers,* the *Ante-Nicene Christian Library* and the *Select Library of Nicene and Post-Nicene Fathers.* Satisfactory lexicons of patristic Greek and Latin are still a desideratum: but assistance may be obtained in the study of the Greek fathers from Suicer's *Thesaurus,* the *Lexicon of Byzantine Greek* by E. A. Sophocles, and the *Lexicon Graecum suppletorium et dialecticurn* of Van Herwerden; while the new great *Latin Lexicon,* published by the Berlin Academy, is calculated to meet the needs of students of Latin patristic literature. For a fuller list of books useful to the reader of the Greek and Latin fathers *see* H. B. Swete's *Patristic Study* (2nd ed. 1900); Edgar J. Goodspeed, *A History of Early Christian Literature* (1941); Fulbert Cayre, *Manual* of *Patrology (1936).*

FATHOM, a measure of length, being the distance from the tip of one middle finger to the tip of the other, when the arms are stretched out to their widest extent (a word common, in various forms, to Scandinavian arid Teutonic languages; cf. Danish *favn,* Dutch *vaam* and Ger. *Faden,* and meaning "the arms extended"; the ultimate origin is a root pet, seen in the Gr. *πεταννύναι,* to spread). This length has been standardized to a measure of 6 ft., and as such is used mainly in soundings as a unit for measuring the depth of the sea.

Fathom is also used in the measurement of timber, when it is equivalent to 6 sq.ft.; similarly, in mining, a fathom is a portion of ground running the whole thickness of the vein of ore, and is 6 ft. in breadth and thickness.

The verb "to fathom," *i.e.,* to sound or measure with a fathom line, is used figuratively, meaning to go into a subject deeply, to penetrate, or to explore thoroughly.

FATIGUE, a condition of impairment, resulting from prolonged mental or physical activity or both, usually removable by rest. The term is used ambiguously, sometimes referring to the organic state of exhaustion or lowered energy following work; sometimes to the feelings of tiredness or boredom experienced at such times; and often to the decline in efficiency of performance during a continuous work session. S. H. Bartley used the term fatigue for the lowered feelings and the term impairment for the organic tissue changes.

Research in pilot fatigue and in combat and operational fatigue in World War II and the Korean war led to a broader use of the term to describe the effects of factors other than work, such as sleep loss, fear and emotional strain, cold and high altitude, or sheer ennui from immobility and endless waiting with nothing to occupy the mind. In industry, it is realized that fatigue symptoms can result from a wide range of factors, such as low morale, frustrated drives, poor working environment or unsatisfactory socio-economic status.

Through all these meanings of fatigue there runs a common thread, but research fails to show any close correspondence between changes in organic state, subjective feelings and performance level. Thus a worker may suffer considerable deterioration in his feelings even though his output remains high. Attempts to find an organic decrement to parallel closely the decrement in the output of workers have been successful only in grossly muscular types of performance. Hence, fatigue must be considered a complex, mutually independent group of deteriorative changes that are ordinarily reversible (*i.e.,* overcome by adequate rest and change of activity) but that in extreme cases can cause irreversible organic damage or severe mental disturbance.

Measurement of Fatigue. — Because of its complex nature, fatigue must be measured from three different angles: the subjective, the physiological and the objective.

Subjective. — The first of these is difficult to do accurately, even though it is by far the most significant for the worker himself, because it is concerned with his own feelings of discomfort, satiation, pain and weariness. To measure these qualitative changes, the worker rates himself, at stated intervals during the work session, on a feeling-tone scale, indicating the degree of his tiredness at that moment. These ratings are plotted on a graph to show the course of development of subjective fatigue. Investigators agree in finding a much more rapid decline in feelings than in output of work; but in the long run those persons who show the greatest deterioration in feelings also show the largest drop in efficiency.

Physiological. — On the physiological side, fatigue is measured by changes in the energy exchange rate of the body, called the metabolic rate. This can be done by recording pulse, blood pressure, temperature and breathing; or by analyzing the products of metabolism, such as the amount of carbon dioxide expired from the lungs in relation to the oxygen intake, or the quantity carried off through the blood stream of such waste products as lactic acid, phosphorus, cholesterol, creatinine, or glandular secretions such as the 17-ketosteroids from the adrenal cortex. These methods yield reliable results when gross muscular work is involved, but the changes accompanying predominantly mental or sedentary work are small and difficult to measure reliably. This type of work yields increases in metabolic rate up to 28%, but part of this must be attributed to the muscular and emotional components of the task. All mental work is accompanied by tensions in the small muscles in and about the head and neck, and even in the larger skeletal muscles of posture. Much of it also involves emotional strain, with resulting use of extra energy by the glands and smooth muscles controlled by the autonomic nervous system. Muscle tensions are measured by recording electrical action currents directly from the muscles.

Emotional tension is reflected in a changed resistance of the skin to a weak electric current passed through it and can be recorded with a galvanometer.

Objective. — Fatigue is measured from the objective or functional side in one of two ways: either by analyzing the worker's performance to determine the output in successive periods of a continuous work session, or by testing his efficiency periodically in some brief activity other than the set task. After 1950 researchers used the critical flicker fusion rate rather widely for this purpose. This is the speed at which a disk consisting of alternate black and white sectors must be rotated to be seen as a uniform gray surface by the observer. Fatigue lowers this rate. When it is desired to study muscular fatigue in a limited part of the body, an ergograph is used, such as the finger ergograph invented by Angelo Mosso (1890). This permits the subject to pull his finger repeatedly against a known weight, recording the extent of each pull until exhaustion is reached. The resulting record, called an ergogram, typically shows a short period of maximum output, followed by a slow decline, which is accelerated toward the end. The breakdown occurs in a very few minutes, depending on the weight pulled. More complex tasks, using the whole body, show a less rapid decrement and may even undergo an improvement for a time, called warming up.

Mental tasks show a similar declining output curve, but rarely does complete exhaustion occur; frequently an equilibrium is reached, at which level work can go on indefinitely. Mental workers actually obtain short involuntary rests at frequent intervals, called blocks, of which they themselves may not be aware. This may indicate the operation of an automatic protective mechanism of the nervous system. It is not the difficulty of the mental task in the usual sense that determines the severity of the fatigue decrement, but rather its sameness, continuity and uninterestingness. Some psychologists prefer to distinguish this type of decrement from genuine fatigue, calling it satiation or boredom. They point out that it is not a real capacity change, merely a weakening of motive.

Fatigue in Industry. — Although occasional studies of fatigue in industrial workers were made as early as 1893, it was not until World War I, when industry was called upon to meet excessive production demands, that systematic research was begun. Typical of the agencies set up for this purpose is the Industrial Fatigue Research board of Great Britain. Studies of a wide variety of determinants of efficiency have been made. Although increased production is a major objective in such research, the health and welfare of the worker have not been ignored as ends in themselves. Attention has been directed to ways of alleviating fatigue and improving morale.

Studies fall into two general categories, those concerned with causal factors in the work itself, and those having to do with the worker's environment, both physical and social, at work and outside.

Length of Work Day and Rest Pauses. — When attempts have been made to add extra hours to the work day or work week, as was tried in England as a war emergency step, with schedules up to 60 hours per week, the long-run effects were detrimental; a return to previous schedules was soon made. Apparently a work day of 8 hours and a work week of 4—44 hours are optimal. Next in importance to length of day are the frequency and length of rest pauses. If pauses are short, they must be more frequent, especially in heavy work. As to the manner in which the rest is spent, it depends on the task. With physical tasks, the rest time is best spent in complete relaxation. With light tasks or mental work, however, there is some profit from change of posture, light entertainment, conversation or a "coffee break."

Too long a break may make resumption of work harder, because it necessitates warming up to the task again. Often the recuperative effect of a change of task is nearly as beneficial as a rest.

Methods of Working. — Sometimes the nature of the task is less important than the manner in which it is performed. Time and motion study, begun by F. W. Taylor, has revealed many ways of reducing energy expenditure through analysis of the manner in which tasks are performed.

Industrial physiology, by concentrating attention on the physiological cost, has contributed much to the reduction of fatigue while maintaining output at a maximum. An important problem in all repetitive work is that of monotony and its dulling effect on attention. With the rapid growth of automation after 1950, new problems in fatigue of this type arose. Workers who formerly performed active manipulations came to act as mere observers or checkers, and the problem of maintaining alertness at a maximum became acute. In this type of work boredom sets in, sensory acuity is reduced and attention wanders, with serious consequences to efficiency.

Work Environment. — Chief among the factors in the work setting causing accelerated onset of fatigue are inadequate lighting, too weak or improperly diffused to avoid glare or eliminate shadows; excessive amounts of noise, creating nervous tension; and poor atmospheric conditions. The latter includes such special factors as temperature. humidity, ventilation and air circulation. Workers can endure reasonably high temperatures if humidity is low, and even the discomfort from excessive humidity combined with heat can be lessened if the air is in rapid circulation. Stale air is depressing, but becomes less so when adequately circulated. When temperatures rise to above 100° F., however, with humidity constant, fatigue onset occurs twice as fast as in temperatures between 40° and So°. Excessive heat produces rapid pulse, inadequate blood circulation, cramps, heat stroke and exhaustion. Some relief is gained by increasing chloride intake. In certain industries the atmosphere is contaminated by fumes or toxic dust; this adds to worker fatigue by undermining physical health, thereby increasing accident rates.

General Environment. — Industrial psychologists have found that fatigue and boredom of workers are importantly related to social factors, such as the amount of recognition received from management. irritations from supervisors or fellow workers, and financial or other personal worries not having a direct relation to the job. One of the studies frequently quoted in support of this is that of Roethlisberger and Dickson, performed at the Hawthorne plant of Western Electric company. This study, which was planned to determine the effects on output of periodic rest periods during the work day. demonstrated instead the stimulating effect on workers of being given special recognition by management. The workers chosen for the study were placed in a special room and given special attention with reference to lunches and other details, in order to maintain controlled conditions. As a result, their production improved, regardless of whether they were given rest periods or not. L. Hornstra (19jj) considers fatigue a psychosomatic expression of partial frustration. It is lessened to the degree that work is satisfying and congenial, and even when the task itself is disagreeable the situation as a whole may be satisfying provided needs are being met through performance of the task.

FATIGUE OF METALS is the progressive change of structure and mechanical properties of metals produced by frequently repeated or fluctuating loading. Specifically: the term is applied to the progressive deterioration of the cohesion of metals as a result of which fracture is produced by the repetition of stress cycles of maximum intensity appreciably lower than the stress intensity that would cause fracture upon a single application.

The majority of mechanical failures of structural and machine parts occurring in operation can be attributed to fatigue. A number of fatal accidents to airplanes were found to be the result of fatigue, mainly of wing spars; the accidents in 1954 involving two of the early Comet jet airliners were attributed to fatigue failures in the pressure cabin. Thus in the design of aircraft. particularly long-range transport planes with expected service lives exceeding 30,000 flying hours. structural fatigue has emerged as a major design problem.

The physical appearance of a fatigue fracture is significantly different from that of a fracture produced by a single load application. Moreover, fatigue fractures occur suddenly, without noticeable permanent deformation, and thus apparently without preliminary warning, unless the surface of the repeatedly stressed part is kept under careful observation for incipient and growing cracks.

The characteristic appearance of the fracture surfaces indicates the progressive nature of the transcrystalline fatigue-failure mechanism: a smooth zone of brittle separation, showing clamshell markings (traces of the fatigue crack at various stages of growth) starts from one or several local faults, usually located at the surface, and spreads gradually inward until the remaining cross section fails, producing a separation surface of coarse crystalline appearance. The smooth portion of the separation surface is frequently discoloured by oxidation. particularly when the fatigue cracks take years to grow to critical size.

Historical Survey. — Fatigue fractures were observed and reported as soon as metals were used under conditions of repeated or fluctuating stress. The first published report (Germany. 1837) referred to fractures observed in steel cables used in mine hoists. In 1842 the problem emerged in England in connection with failures in locomotive axles, and was discussed in 1849 and 1850 in a series of meetings of the Institution of Mechanical Engineers. In 1849 the so-called Iron Commission, appointed "to inquire into the application of iron to railway structures," published its report containing an investigation (by H. James and D. Galton) into the behaviour of cast-iron bars subjected to pulsating bending strains; in this investigation the concept of an endurance or fatigue limit was first established; below this limit fatigue does not exist.

Between 1858 and 1870 the results of an extensive series of classical experiments on iron and steel subjected to repeated axial, torsional and bending stresses were published by A. Woehler, a German engineer.

The term fatigue was introduced into the engineering literature in 1854 in a paper by F. Braithwaite in the Proceedings of the Institution of Civil Engineers, following a suggestion of Joshua Field, fellow of the Royal society, then president of the institution. The term is used with respect to repeated stressing due to mechanical forces (mechanical fatigue), to repeated transient temperature forces caused by temperature cycling in machine parts operating at elevated temperatures (thermal fatigue) as well as to noise from jets or other sources (acoustic fatigue).

The volume of fatigue research has increased considerably since 1870: first in connection with the development of locomotives and rolling stock of increasing weight, leading to increasingly severe fatigue effects in rails and bridges; later in connection with the development of heavy machinery (marine engines, turbines), as well as with the use of high-strength steel in automobile construction; and, finally, in connection with the use of lightweight alloys in the construction of airplanes. as well as the use of high-temperature alloys for heat exchanger and other machine parts subject to elevated temperatures. including nuclear reactor parts. most of which are subject to thermal fatigue.

The application of the metallurgical microscope in the study of the structural changes in metals produced by repeated stresses initiated a new phase of research. The classical work. between World Wars I and II. on microstructural changes under repeated stresses by H. J. Gough, provided the first basic knowledge concerning the micromechanism of fatigue. and laid the foundation for subsequent research work aided by improved microscopic techniques and the development of the electron microscope.

Many of the important but very complex engineering problems. such as the effect of the dimensions of the stressed parts, the accumulation of damage under variable stress amplitudes, the effect of combinations of various types of stress, the effect of residual stress fields, etc.. are still largely unsolved, with the result that engineering design for fatigue relies heavily on empirical safety factors and large-scale prototype testing

Micromechanism of Fatigue. — Tno stages can be distinguished in the progress of fatigue: (1) that of initiation of damage, ending in the formation of submicroscopic cracks; and (2) that of growth of microscopic and macroscopic cracks. Such distinction attempts to delimit the stage of propagation of an optically resolvable crack from the stage preceding its visual identification. The latter is closely related to the heterogeneous plastic glide under repeated stressing which differs significantly from that produced by a single stress application.

The effect on the crystal structure of rapid cyclic stressing is a sharp concentration of glide processes in widely and fairly regularly spaced glide bands ("striations") observable on the polished metal surface, which tend to grow steadily in width and in intensity. It is within the most pronounced striations that fatigue cracks are initiated at an early stage of repeated stressing, and along which they subsequently propagate. The concentration of slip into striations may be due to the development, with increasing number of applied stress cycles, of localized elevated temperatures.

That localized thermal softening has a significant effect in the initiation of fatigue cracks is suggested by the observation within the striations of heat stains in certain metals and of recrystallization, polygonization, diffusion and precipitation in other metals and alloys. (See also ALLOYS.)

Surface Effects. — Corrosion and Fretting Fatigue. — The initiation of fatigue damage at or near surfaces of cyclically stressed parts is the cause of the pronounced surface sensitivity of fatigue performance. Any effect that impedes the slip or blocks it before it reaches the surface impedes or delays the process of crack initiation and thus increases the fatigue life. The creation of very thin surface layers subject to high-intensity compressive residual stresses resulting from the elastic restraint on enforced volume expansion of this layer imposed by the unstrained core is particularly effective.

The volume expansion may be produced by forcing foreign particles into the atomic lattice near the surface (carburizing, nitriding, cyaniding), or by cold-working the surface layer (shot-peening, cold-rolling). Similarly, changes produced in the surface by mechanical polishing and grinding are highly effective in increasing the fatigue life. (See SURFACE HARDENING; IRON AND STEEL INDUSTRY: Theory of Hardening and Tempering.)

Surface effects are particularly significant when the stress gradients are steep, with the maximum stress intensity at the surface coinciding with the residual compression (bending, torsion, roots of notches).

Fatigue life is reduced by any mechanical effect that induces premature localized slip in the surface, such as tool marks and other accidental defects, as well as drill holes and grooves. It is also sharply reduced by surface damage resulting from the effects of a corrosive medium, particularly when the corrosive action is simultaneous with the repeated stressing (corrosion fatigue); in general the corrosive effect of fluids on metal surfaces is amplified by fatigue stressing. Most wetting fluids, without necessarily being chemically corrosive (for instance distilled water), reduce the fatigue life of many metals in comparison with their fatigue life in air; however, surface damage by chemical corrosion (for instance in sea water) accelerates this effect considerably. Even air is corrosive with respect to fatigue: tests in vacuum suggest a slight increase of fatigue life with decreasing pressure.

Surface damage inducing fatigue cracking is also caused by relative motion of the cyclically stressed surface with reference to other metal surfaces in rubbing contact with it. The rapidly developing friction heat and surface oxidation produces "fretting fatigue" which is characteristic of fatigue failures in bearings, grips and particularly riveted or bolted connections of cyclically stressed structures.

Statistical Aspects. — The number N of stress cycles of amplitude S that is sustained prior to fracture (fatigue life) increases as the amplitude decreases. The form of the relation between S and N (Woehler diagram or S-N diagram) depends on the type of stress (tension, torsion, bending or combined stress), the geometry of the stressed structural part (local concentrations of stress), the range of the repeated stress cycle (difference between maximum and minimum stress) and the mean (sustained) stress on which it is superimposed, as well as on environment (temperature, corrosive atmosphere, radiation). It is limited, on the one hand, by a minimum stress amplitude, the "fatigue limit" S_0, which decreases with increasing N, on the other, by a minimum number of stress cycles, the "minimum life" N_0, which increases with decreasing S. Fatigue fractures do not occur unless the stress amplitude S is larger than S_0, and the number of its repetition N larger than N_0.

The fatigue life N associated with a specified stress amplitude S or with a sequence of variable stress amplitudes is a highly statistical variable, probably because the micromechanism of fatigue damage is closely related to local imperfections of the surface and of the crystal structure. Depending on the degree of control imposed on the conditions of repeated stressing and on the geometry and surface conditions of the stressed part, as well as on the environment, the fatigue life under relatively well-controlled, nominally identical conditions is subject to a range of variation (ratio between the maximum and minimum values) of about five to ten; the range increases with increasing number of tests.

The prediction of the fatigue life on the basis of tests or observations is, therefore, subject to considerable error, and the characteristic relation between S and N cannot be definitely specified. To every combination (S, N) the numerical probability P (between zero and one) that this combination will in fact produce fracture, or the probability $l = (1\text{-}P)$ that it will not produce fracture must be attributed. The S-N relation is thus a three-dimensional S-N-P or S-N-l relation, and the fatigue life is represented by the "mortality function" $P(N)$ or the "reliability function" $l(N)$ expressing, respectively, the probabilities of fracture P or of survival l at different values of N. The functions are limited by the minimum life N_0 for which $P(N_0) = 0$ or $l(N_0) = 1$; as N_0 tends toward infinity, S_0 tends toward the true endurance limit. The S_0-N_0 diagram below and along which survival is certain thus delimits the range of fatigue under constant stress amplitudes.

Prevention of Fatigue. — The large majority of mechanical service failures in modern engineering practice are the result of fatigue. Therefore, the importance of adequate fatigue design can hardly be overestimated. While selection of fatigue resistant rather than high-strength metals and the improvement of their fatigue performance by surface treatment are of considerable importance, the most significant preventive factor is the careful design of even the smallest structural detail so as to avoid sharp re-entrant corners, abrupt changes of sections and other sources of intense stress concentration, as well as sources of fretting fatigue.

FATIMA (FATIMA BINT MOHAMMED THE PROPHET) (c. 606–632), daughter of the prophet Mohammed by his first wife, Khadija, was born in Mecca. She married her cousin 'Ali ibn Abi Talib (see ALI), a devoted follower of Mohammed, and their sons, Hasan and Husain (see HASAN AND HUSAIN), became the only male perpetuators of Mohammed's line.

This Family of the House of Mohammed was hounded by misfortune. Fatima and 'Ali were the losers whenever they clashed with 'A'isha, the favourite wife of Mohammed. Both felt that they were deprived of their inheritance by Abu-Bakr (*q.v.*), the first caliph.

Fatima died in Medina shortly after Mohammed, but her memory has been kept alive through the tragic history of her family and descendants, many of whom were massacred for political reasons in 680 at Karbala, Iraq.

As Fatima's family failed politically, disappointed followers, the Shi'a, endowed its members with great moral virtues, religious insight and. finally, with divinity. In this process the role of Fatima "the virgin" is curiously similar to that of the Virgin Mary in Roman Catholicism. She is accorded a high place of honour in heaven. Her symbol, "the Hand of Fatima," is frequently displayed in religious processions.

Fatima's husband and sons became the first Imams or spiritual leaders of Shi'ite Islam, which still expects the return of one of their descendants as the divine Mahdi who shall rule on earth. Sunnite, or orthodox, Islam also venerates the Family of the House but absolutely refuses to endow any of them with a divinity denied even to Mohammed.

Several Shi'ite dynasties claimed descent from Fatima. The most important was the Fatimid caliphate (909–1171; see FATIMITES) of north Africa, Egypt and Syria, which withstood the crusaders but succumbed to Saladin.

(N. A.)

FÁTIMA, a village and sanctuary in Santarém district, central Portugal, about 18 mi. E. of Leiria by rail, on the tableland of Cova da Iria. The sanctuary is dedicated to the Virgin Mary, and the celebrations held there on the 12th and 13th of each month from May to October are attended by great numbers of pilgrims.

On May 13, 1917, three young peasant children, Lucia dos Santos (or Abóbora) and her two cousins, Francisco and Jacinta Marto, saw a vision of a lady while tending sheep at a spot now marked by a small chapel. In accordance with her promise, the vision was repeated on the 13th of each month until October, except for August when the children were at Valinhos pasture (near Aljustrel, the village of their birth), where they saw the lady on Aug. 19.

The lady revealed herself on Oct. 13 as the Lady of the Rosary and asked for a chapel to be built for her there. After initial opposition the visions were accepted as the appearance of the Virgin Mary by the bishop of Leiria on Oct. 13, 1930. In the same year, Papal indulgences were granted to pilgrims and devotion in other ways mas also favoured.

The content of the devotion consists of frequent recitation of the rosary, works of mortification for the conversion of sinners, devotion to the Immaculate Heart of Mary, the consecration of Russia to the Immaculate Heart, prayer for world peace and a communion of reparation by the faithful on the first Saturday of each month.

The first national pilgrimage to Fátima took place in 1927 and the Basilica was begun in 1928 and consecrated in 1953. With a 213-ft. tower surmounted by a 7-ton bronze crown and a crystal cross, and flanked by hospitals and retreat houses, it faces a vast square, in which is the little Chapel of the Apparitions.

The celebrations include the blessing of the sick and a torchlight procession in which the crowned image of the Virgin of Fátima is carried. Numerous cures have been reported, though publicity for them has not been sought.

See C. C. Martindale, *The Message of Fatima* (1950).

FATIMITES, also called FATIMIDS, the name of a dynasty called after Fatima, daughter of the prophet Mohammed, from whom and her husband the caliph 'Ali, son of Abu Talib, they claimed descent. The dynasty is also called 'Obaidi (Ubaidi) after 'Obaidallah, the first sovereign, and 'Alawi, a title which it shares with other dynasties claiming the same ancestry. Three sovereigns, who reigned in northwestern Africa before the annexation of Egypt, are worthy of mention: al-Mahdi 'Obaidallah 297 (909); al-Ka'im Mohammed 322 (934); al-Mansur Isma'il 334 (945). For the history of the Fatimite caliphs in Egypt, see EGYPT: History.

The dynasty owed its rise to the attachment to the family of the Prophet which was widespread in the Moslem world and the belief that the sovereignty was the right of one of its members. Because, however, of the absence of the principle of primogeniture there was difference of opinion as to the person whose claim should be enforced, and a number of sects arose maintaining the rights of different branches of the family. The Fatimites were supported by those who regarded the sovereignty as vested in Isma'il, son of Ja'far al-Sadiq, great-great-grandson of 'Ali, through his second son Husain. Of this Isma'il the first Fatimite caliph was supposed to be the great-grandson. The line of ancestors between him and Isma'il is, however, variously given, even his father's name being quite uncertain; and in some of the pedigrees even Isma'il does not figure.

Apparently when the family first became of political importance their Alid descent was not disputed at Baghdad, and the poet al-Sharif al-Radi (d. A.H. 406: A.D. 1015), in whose family the office of naqib (registrar of the Alids) was hereditary, appears to have acknowledged it (*Dīwān,* ed. Beirut, p. 972). When their success became a menace to the caliphs of Baghdad, genealogists were employed to demonstrate the falsity of the claim, and a considerable literature, both official and unofficial, rose in consequence. The founder of the dynasty was made out to be a scion of a family of heretics from whom the terrible Carmathian sect had originated; later on (perhaps because of the role played by Jacob, son of Killis, in bringing the Fatimites to Egypt), the founder was made out to have been a Jew, either as having been adopted by the heretic supposed to be his father, or as having been made to personate the real 'Obaidallah, who had been killed in captivity.

The uncertainty of the genealogies offered by their partisans makes the problem insoluble. What seems to be clear is that secretly within the Abbasid empire propaganda was carried on in favour of one or other Alid aspirant, and the danger which any such aspirant incurred by coming forward openly led to his whereabouts being concealed except from a very few adherents. What is Known then is that toward the end of the 3rd Islamic century the leader of the sect of Isma'ilites, who afterward mounted a throne, lived at Salamia, near Emesa (Homs), having agents spread over Arabia, Persia and Syria and frequently receiving visits from pious adherents who had been on pilgrimage to the grave of Husain. Such visitors received directions and orders such as are usual in secret societies. One of these agents, Abu 'Abdullah al-Husain called al-Shi'i, said to have filled the office of censor (muhtasib) at Basra, received orders to carry on a mission in Arabia and is said at Mecca to have made the acquaintance of some members of the Berber tribe Kutama, south of the Bay of Bougie. These persons persuaded him to travel home with them in the character of teacher of the Koran, but according to some authorities the ground had already been prepared there for a political mission. He arrived in the Kutama country in June 893 and appears very soon to have been made chief, thereby exciting the suspicion of the Aghlabite ruler of Qairwan, Ibrahim ibn Ahmad, which, however, was soon allayed. His success provoked a civil war among the Berbers, but he was protected by a chief named Hasan ibn Harun, and displayed sufficient military ability to win respect. Nine years after his arrival he made use of the unrest following on the death of the Aghlabite Ibrahim to attack the town of Mila, which he took by treachery and turned into his capital; the son and successor of Ibrahim, Abu'l-'Abbas 'Abdullah, sent his son al-Ahwal to deal with the new power, and he defeated al-Shi'i in some battles, but in 903 al-Ahwal was recalled by his brother Ziyadatallah, who had usurped the throne, and put to death.

At some time after his first successes al-Shi'i sent a messenger (apparently his brother) to the head of his sect at Salamia, bidding him come to the Kutama country and place himself at the head of affairs, since al-Shi'i's followers had been taught to pay homage to a mahdi who would at some time be shown them. It is said that 'Obaidallah, who now held this post, was known to the court at Baghdad and that on the news of his departure orders were sent to the governor of Egypt to arrest him: but by skilful simulation 'Obaidallah succeeded in escaping this danger and with his escort reached Tripoli safely. Instructions had by this time reached the Aghlabite Ziyadatallah to be on the watch for the mahdi, who was finally arrested at Sijilmasa (Tafilalt) in the year A.H. 292 (A.D. 905); his companion, al-Shi'i's brother, had been arrested at an earlier point, and the mahdi's journey to the southwest must have been to elude pursuit.

THE EARLY FATIMITES

The invitation to the mahdi was premature, for Ziyadatallah had sent a powerful army to oppose al-Shi'i, which, making Constantine its headquarters, had driven al-Shi'i into the mountains: after six months al-Shi'i secured an opportunity for attacking it and won a complete victory. Early in 906 another army was sent to deal with al-Shi'i, and an earnest appeal came from the caliph al-Muktafi, addressed to all the Moslems of Africa, to aid Ziyadatallah against the usurper. The operations of the Aghlabite prince were unproductive of any decided result, and by Sept. 906 al-Shi'i had got possession of the important fortress Tubna and some others. Further forces were immediately sent to the front by Ziyadatallah, but these were defeated by al-Shi'i and his officers, to whom other towns capitulated, till Ziyadatallah found it prudent to retire from al-Urbus or Laribus, which had been his headquarters, and entrench himself in Raqqada, one of the two capitals of his kingdom, Qairwan being the other.

By March 909 Raqqada had become untenable, and Ziyadatallah resolved to flee from his kingdom; he made for Egypt and thence to Iraq: .his final fate is uncertain. The cities Raqqada and Qairwan were immediately occupied by al-Shi'i, who proceeded to send governors to the other places of importance in what had been the Aghlabite kingdom and to strike new coins, which, however, bore no sovereign's name. Orders were given that the Shi'ite peculiarities should be introduced into public worship.

Al-Shi'i's Victories.—In May 909 al-Shi'i led a tremendous army westward to the kingdom of Tahert, where he put an end to the Rustamite dynasty and appointed a governor of his own; he thence proceeded to Sijilmasa where 'Obaidallah lay imprisoned, with the intention of releasing him and placing him on the throne. After a brief attempt at resistance, the governor fled, and al-Shi'i entered the city, released 'Obaidallah and presented him to the army as the long-promised imam. The day is given as Aug. 26, 909. 'Obaidallah had been in prison more than three years. Whether his identity with the mahdi for whom al-Shi'i had been fighting was known to the governor of Sijilmasa is uncertain. If it was, the governor and his master the Aghlabite sovereign might have been expected to make use of their knowledge and outwit al-Shi'i by putting his mahdi to death. Opponents of the Fatimites assert that this was actually done and that the mahdi presented to the army was not the real 'Obaidallah, but (as usual) a Jewish captive, who had been suborned to play the role.

The chief command was now assumed by 'Obaidallah, who took the title "al-Mahdi, Commander of the Faithful," thereby claiming the headship of the whole Moslem world: Raqqada was at the first made the seat of the court, and the Shi'ite doctrines were enforced on the inhabitants, not without encountering some opposition. Revolts which arose in different parts of the Aghlabite kingdom were, however, speedily quelled.

The course followed by 'Obaidallah in governing independently of al-Shi'i soon led to dissatisfaction on the part of the latter, who, urged on it is said by his brother, decided to dethrone their mahdi, and on the occasion of an expedition to Ténés, which al-Shi'i commanded, organized a conspiracy with that end. The conspiracy was betrayed to 'Obaidallah, who took steps to defeat it, and on the last day of July 911 contrived to assassinate both al-Shi'i and his brother. Thus the procedure which had characterized the accession of the Abbasid dynasty was repeated. It has been conjectured that these assassinations lost the Fatimites the support of the organization that continued to exist in the east, where the Carmathians figure as an independent and even hostile community, though they appear to have been amenable to the influence of the African caliph.

Establishment of the **Dynasty.**—'Obaidallah had now to face the dissatisfaction of the tribes whose allegiance al-Shi'i had won, especially the Kutama, Zenata and Lawata: the uprising of the first assumed formidable proportions, and they even elected a mahdi of their own, one Kadu ibn Mu'arik al-Mawati, who promulgated a new revelation for their guidance. They were finally defeated by 'Obaidallah's son Abu'l-Kasim Mohammed, who took Constantine, and succeeded in capturing the new mahdi, whom he brought to Raqqada. 'Obaidallah ousted other opponents by ruthless executions. By the middle of the year 913 by his own and his son's efforts he had brought his kingdom into order. After the style of most founders of dynasties he then selected a site for a new capital, to be called after his title Mahdia (*q.v.*), on a peninsula called Hamma (Cape Africa) south-southeast of Qairwan. Eight years were spent in fortifying this place, which in 921 was made the capital of the empire.

Invasions of Egypt.—After defeating internal enemies 'Obaidallah turned his attention to the remaining Abbasid possessions in Africa, and his general Habasah ibn Yusuf in the year 913 advanced along the northern coast, taking various places, including the important town of Barca. He then advanced toward Egypt, and toward the end of July 914, being reinforced by Abu'l-Kasim, afterward al-Ka'im, entered Alexandria. The danger led to measures of unusual energy being taken by the Baghdad caliph Muktadir, an army being sent to Egypt under Mu'nis and a special post being organized between that country and Baghdad to convey messages uninterruptedly. The Fatimite forces were defeated, partly because of the insubordination of the general Habasah, in the winter of 914, and returned to Barca and Qairwan with great loss. A second expedition was undertaken against Egypt in the year 919, and on July 10 Alexandria was entered by Abu'l-Kasim, who then advanced southward, seizing the Fayum and Ushmunain (Eshmunain). He was presently reinforced by a fleet, which, however, was defeated at Rosetta in March of the year 920 by a fleet despatched from Tarsus by the Abbasid caliph Muktadir, most of the vessels being burned. Through the energetic measures of the caliph, who sent repeated reinforcements to Fostat, Abu'l-Kasim was compelled in the spring of 921 to evacuate the places which he had seized and return to the west with the remains of his army, which had suffered much from plague as well as defeat on the field. On his return he found that the court had migrated from Raqqada to the new capital Mahdia (*q.v.*). Meanwhile other expeditions had been despatched by 'Obaidallah toward the west, and Kekor (Kakur) and Fez had been forced to acknowledge his sovereignty. The remaining years of 'Obaidallah's reign were largely spent in dealing with uprisings in various parts of his dominions, the success of which at times reduced the territory in which he was recognized to a small area.

Al-Ka'im.—'Obaidallah died on March 4, 933, and was succeeded by Abu'l-Kasim, who took the title al-Ka'im biamr allah. He immediately after his accession occupied himself with the reconquest of Fez and Nekor, which had revolted during the last years of the former caliph. He also despatched a fleet under Yakub ibn Ishak, which ravaged the coast of France, took Genoa and plundered the coast of Calabria before returning to Africa. A third attempt made by him to take Egypt resulted in a disastrous defeat at Dhat al-Humam, after which the remains of the expedition retreated in disorder to Barca.

The later years of the reign were troubled by the uprising of Abu Yazid Makhlad al-Zenati, a leader who during the former reign had acquired a following among the Berber tribes inhabiting the Jebel Aures, including adherents of the 'Ibadi sect. After having fled for a time to Mecca, this person returned in 937 to Tauzar (Touzer), the original seat of his operations, and was imprisoned by al-Ka'im's orders. His sons, aided by the powerful tribe Zenata, succeeded in forcing the prison, and releasing their father, who continued to organize a conspiracy on a vast scale and by the end of 943 was strong enough to take the field against the Fatimite sovereign, whom he drove out of Qairwan. Abu Yazid proclaimed himself a champion of Sunni doctrine against the Shi'is, and ordered the legal system of Malik to be restored in place of that introduced by the Patimites. Apparently the doctrines of the latter had as yet won little popularity, and Abu Yazid won an enormous following, except among the Kutama, who remained faithful to al-Ka'im.

On the last day of Oct. 944, an engagement was fought between Qairwan and Mahdia at al-Akhawan, which resulted in the rout of al-Ka'im's forces, and the caliph's being shortly after shut up in his capital, the suburbs of which he defended by a trench. Abu Yazid's forces were ill-suited to maintain a protracted siege, and since, because of the former caliph's forethought, the capital was in a condition to hold out for a long time, many of them deserted and the besiegers gained no permanent advantage. After the siege had lasted about ten months Abu Yazid was compelled to raise it

(Sept. 945); the struggle, however, did not end with that event, and for a time the caliph and Abu Yazid continued to fight with varying fortune, while anarchy prevailed over most of the caliph's dominions. On Jan. 13, 946, Abu Yazid shut up al-Ka'im's forces in Susa which he began to besiege and attempted to take by storm.

Mansur.—On May 18, 945, while Abu Yazid was besieging Susa, the caliph al-Ka'im died at Mahdia. and was succeeded by his son Abu Tahir Isma'il, who took the title Mansur. He almost immediately relieved Susa by sending a fleet, which joining with the garrison inflicted a severe defeat on Abu Yazid, who had to evacuate Qairwan also; but though the cities were mainly in the hands of Fatimite prefects, Abu Yazid was able to maintain the field for more than two years longer, while his followers were steadily decreasing in numbers and he was repeatedly driven into fastnesses of the Sahara. In Aug. 947 his last stronghold was taken, and he died of wounds received in defending it. His sons carried on some desultory warfare against Mansur after their father's death. A town called Mansura or Sabra was built adjoining Qairwan to celebrate the decisive victory over Abu Yazid, which, however, did not long preserve its name. The exhausted condition of northwest Africa resulting from the protracted civil war required many years of peace for recuperation, and further exploits are not recorded for Mansur, who died on March 19, 952.

Widening Authority. — His son, Abu Tamim Ma'add, was 22 years of age at the time and succeeded his father with the title Mu'izz lidin allah. His authority was acknowledged over the greater part of the region now constituting Morocco, Algeria and Tunisia, as well as Sicily, and he appears to have had serious thoughts of endeavouring to annex Spain. At an early period in his reign he made Jauhar, who had been secretary under the former caliph, commander of the forces, and the services rendered by this person to the dynasty made him count as its second founder after al-Shi'i. In the years 958 and 959 he was sent westward to reduce Fez and other places where the authority of the Fatimite caliph had been repudiated; after a successful expedition he advanced to the Atlantic. As early as 966 a fresh invasion of Egypt was prepared; but it was delayed, it is said, at the request of the caliph's mother, who wished to make a pilgrimage to Mecca first; and her honourable treatment by Kafur when she passed through Egypt induced the caliph to postpone the invasion till Kafur's death.

DECLINE OF THE FATIMITES

After the conquest of Egypt in 969 (see EGYPT: *History),* Mu'izz resolved to follow Jauhar's pressing invitation to enter his new capital Cairo. With his arrival there in Aug. 972 the centre of the Fatimite power was transferred from Mahdia and Qairwan to Egypt, and their original dominion became a province called al-Maghrib, which immediately fell into the hands of a hereditary dynasty, the Zeirids, acknowledging Fatimite suzerainty. The first sovereign was Bulukkin, also called Abu'l-Futuh Yusuf, appointed by Mu'izz as his viceroy on the occasion of his departure for Egypt; separate prefects were appointed for Sicily and Tripoli; and at the first the minister of finance was to be an official independent of the governor of the Maghrib. On the death of Bulukkin in 984 he was succeeded by a son who took the royal title al-Mansur, under whose rule an attempt was made by the Kutama, instigated by the caliph, to shake off the yoke of the Zeirids, who originated from the Sanhaja tribe. This attempt was defeated by the energy of Mansur in 988; and the sovereignty of the Fatimites in the Maghrib became more and more confined to recognition in public prayer and on coins and to the payment of tribute and the giving of presents to the viziers of Cairo. The fourth ruler of the Zeirid dynasty, called Mu'izz, endeavoured to substitute Abbasid suzerainty for Fatimite: his land was invaded by Arab tribesmen sent by the Fatimite caliph, with whom in 1051 Mu'izz fought a decisive engagement, after which the dominion of the Zeirids was restricted to the territory adjoining Mahdia; a number of smaller kingdoms rising up around them. The Zeirids were finally overthrown by Roger II of Sicily in 1148.

The Last **Fatimite** Caliph. — After the death of al-Adid, the last Fatimite caliph in Egypt, in 1171 some attempts were made to place on the throne a member of the family, and at one time there seemed a chance that the Assassins, who formed a branch of the Fatimite sect, might help in this project. In 1174 a conspiracy for the restoration of the dynasty was organized by 'Umarah of Yemen, a court poet, with the aid of eight officials of the government; it was discovered and those who were implicated were executed. Two persons claiming Fatimite descent took the royal titles al-Mu'tasim billah and al-Hamid lillah in the years 1175 and 1176, respectively; and as late as 1192 we hear of pretenders in Egypt. Some members of the family are traceable till near the end of the 7th century of Islam. The doctrines of the Fatimites as a sect: apart from their claim to the sovereignty in Islam! are little known, and we are not justified in identifying them with those of the Assassins, the Carmathians or the Druses, though all these sects are connected with them in origin. A famous account is given by Makrizi of a system of education by which the neophyte had doubts gently instilled into his mind till he was prepared to have the allegorical meaning of the Koran set before him and to substitute some form of natural for revealed religion. In most accounts of the early days of the community it is stated that the permission of wine drinking and licentiousness and the community of wives and property formed part of its tenets. There is little in the recorded practice of the Fatimite state to confirm or justify these assertions; and they appear to have differed from orthodox Moslems rather in small details of ritual and law than in deep matters of doctrine. Their legal system. as standardized in the writings of the *kadi* of al-Mu'izz, al-Nu'man, was generally in close agreement with the Malikite school of orthodox Islam. The feature of their political organization which distinguished them from other Moslem dynasties and caused them to be regarded with hostility and suspicion was the emphasis laid upon missionary propaganda, particularly among the depressed artisan classes in the cities. the chief missionary *(da'i)* being one of their principal secretaries of state.

FATTY ACIDS or ALIPHATIC CARBOXYLIC ACIDS, a class of compounds of carbon, hydrogen and oxygen that are important in industry and in biochemistry. Fats and fatty oils are formed in chemical reactions in which fatty acids and glycerin take part. The many derivatives of fatty acids are prepared by modifying the hydrocarbon chain or by utilizing the reactions of the carboxyl group.

See BIOCHEMISTRY: *Fats and Amino Acids;* CARBOXYLIC ACIDS; HYDROGENATION; OILS, FATS AND WAXES: *Fat Hardening or Hydrogenation;* SOAP.

FAUBOURG, the French name for a portion of a town which lies outside the walls, hence properly a suburb. The name survives in certain parts of Paris, such as the Faubourg Saint-Antoine, the Faubourg Saint-Germain, etc., which have long since ceased to be suburbs. It may be derived either from *fors-bourg,* "outside the borough" (*cf. forbourg, fourbourc,* 13th century; and *horsborc,* 14th century); or from *faux-bourg,* "false borough" *(cf. falsus burgus,* which occurs in very late medieval Latin).

FAUCES, in anatomy, is the passageway between the mouth and the pharynx. It is bounded above by the soft palate and below by the tongue. On either side are the anterior and posterior pillars between which lie the tonsils. In architecture fauces is a term given by Vitruvius to narrow passages on either side of the tablinum, through which access could be obtained from the atrium to the peristylar court in the rear; therefore the term often applied to narrow connecting passages in Roman houses. See also ANATOMY, GROSS; MOUTH; SALIVARY GLANDS: THROAT.

(F. L. A.)

FAUCHER, LÉONARD JOSEPH (LÉON) (1803–1854), French politician and economist, was born at Limoges on Sept. 8, 1803. With the revolution of 1830 he was drawn into active political journalism on the Liberal side. He was on the staff of the Temps from 1830 to 1833, when he became editor of the *Constitutionnel* for a short time. He was editor from 1839 until 1842 of the *Courrier Français*. Faucher belonged in policy to the dynastic left, and consistently preached moderation to the more ardent Liberals. He advocated a customs union between the Latin countries to counterbalance the German *Zollverein,* but narrowed his proposal in 1842 to a customs union between France and Belgium. In 1843 he visited England to study the English social system, publishing the results of his investigations in a series of *Études sur l'Angleterre* (2 vol., 1845), published originally in the *Revue des deux mondes.* He was elected in 1847 to the chamber of deputies for Reims as a free-trader. After the revolution of 1848 he represented the department of Marne in the constituent assembly, where he opposed the limitation of the hours of labour, the creation of the national relief works in Paris and the abolition of the death penalty. Under the presidency of Louis Napoleon he became minister of public works, and then minister of the interior, but was compelled to resign office on May 14, 1849. In 1851 he was again minister of the interior until Napoleon declared his intention of resorting to universal suffrage. He died at Marseilles on Dec. 14, 1854.

His miscellaneous writings were collected (2 vol., 1856) as *Mélanges d'économie politique et de finance,* and his speeches in the legislature were printed in vol. ii of *Léon Faucher, biographie et correspondance* (2 vol., 18: 5).

FAUCHILLE, PAUL AUGUSTE JOSEPH (1858–1926), French authority on international law, born at Lille, Fr., on Feb. 11, 1858, studied law in Paris. His doctorate thesis, *Du blocus maritime* (Paris, 1882), remains a classic of international comparative law. He was responsible for the second edition of Henry Bonfils' *Manuel de droit international public* (1898), which he was subsequently to expand till it became the monumental *Traité,* 4 vol. (1922–26). He established, under the auspices of the University of Paris, the Institut des Hautes Études Internationales in 1920.

Fauchille died at Fontenay-aux-Roses (Seine) on Feb. 9, 1926.

FAULHABER, MICHAEL (1869–1952), German Catholic churchman and prominent opponent of the Nazis, was born at Heidenfeld on March 5, 1869. He studied philosophy and theology in Würzburg and Rome and was ordained a priest in 1892. He was a lecturer at the University of Würzburg (1899–1903) and professor of theology (Old Testament) at the University of Strasbourg (1903–10), subsequently serving as bishop of Speyer (1911–17) and archhishop of Munich and Freysing (1917–52). He was created a cardinal in 1921. Faulhaber collided early with the Nazis: whose neopaganism was repugnant to him. and he played a part in causing the failure of Hitler's putsch in 1923. Ten years later. with the Nazis in power. he delivered to vast thrones his famous sermons entitled *Judaism, Christianity, and Germany* (translated by George D. Smith. 1954). He emphasized that the teachings of the New Testament were but a logical sequel to those of the Old. and that exceptions taken to the latter were basically exceptions to the moral law in general. He added that the German tribes had become civilized only after they had been converted to Christianity and that Christian values were fundamental to German *Kultur.* Throughout these sermons. as well as those which were to follow until the collapse of the Third Reich, there runs a thread of vigorous criticism of Nazi theories and Nazi practices which the cardinal repeated in communications to the government. An attempt on his life was made in 1934, and his residence was attacked in 1938.

He died in Munich on June 12, 1952.

Cardinal Faulhaher's book *The Women of the Bible* appeared in English in 1938 (new ed. 1955). Among his other publications was *The Moral Teachings of the Gospels* (1936; *Die Sittenlehre des Evangeliums*). (F. A. Hs.)

FAULKNER (FALKNER), **WILLIAM** (1897-1962), U.S. author, was born on Sept. 25, 1897, at New Albany, Miss., into a family with deep southern roots. He was, among other things. an aviator in World War I, a student at the University of Mississippi. a postmaster, a Hollywood writer, a farmer and winner of the 1949 Nobel prize in literature. He died July 6, 1962.

After false starts as poet (*The Marble Faun* [1924]) and novelist (*Soldiers' Pay* [1926], *Mosquitoes* [1927]), he discovered his métier with his third novel, *Sartoris* (1929), the first in a series of works, laid in "Yoknapatawpha" county, Miss., on the past, present and future of the south. The "saga" includes, most notably, *The Sound and the Fury* (1929), *As I Lay Dying* (1930), *Light* in *August* (1932), *Absalom, Absalom!* (1936), "The Bear" (in *Go Down, Moses, and Other Stories* [1942]), and *Intruder in the Dust* (1948).

Divided into four sections, the first three of which are given to the streams of consciousness of three brothers in the Compson family — Benjamin, an idiot; Quentin, a Harvard student who commits suicide; Jason, a mean-spirited storekeeper — The *Sound and the Fury* chronicles the decay of a patrician family. *As I Lay Dying,* another stream-of-consciousness novel which moves kaleidoscopically through 15 minds, recounts the bizarre odyssey of the poor-white Bundrens, who, after awaiting the death of Mrs. Bundren, journey against all odds 40 mi. to bury her. *Light in August* counterpoints the stories of Lena Grove, placidly walking across the south in search of the father of her unborn child, and Joe Christmas, who, uncertain of his colour, vacillates between white and black, finally to be lynched as a Negro. *Absalom, Absalom!* is an impressive record of the rise and fall of the plantation dynasty of Thomas Sutpen, whose career before, during and following the Civil War becomes a symbol of the race-contorted history of the south.

"The Bear," one of Faulkner's most powerful stories and a key to his central themes, celebrates the initiation into manhood of Isaac McCaslin through the hunting of an animal at once legendary, symbolic and superbly actual, and at the same time treats movingly the problem of interracial relations. *Intruder in the Dust* combines the story of the Negro Lucas Beauchamp charged with the murder of a white man, the maturing of the boy "Chick" Mallison who helps exonerate Beauchamp in a rather crudely contrived detective yarn, an overwrought plea by Chick's uncle Gavin Stevens for southern autonomy, and the analysis of "not a racial outrage but a human shame." Outside the Yoknapatawpha series, Faulkner's most ambitious work was the 1955 Pulitzer prize novel, *A Fable* (1954), a modern rendering of Passion week in which the Unknown Soldier of World War I, as the latter-day Christ, speaks against the corruption of the world's leaders and for the faith of the mass of humanity.

Dealing with all levels of southern society, Faulkner saw the south as doomed by its sinful exploitation of land and man. U.S. readers first found Faulkner's experimental style prolix, turgid and unnecessarily obscure, and his characters excessively brutal. But the nightmare world which these readers came to accept as a set of symbols for personal and social disintegration, more readily impressed European readers, to whose violently changing lives and societies Faulkner addressed himself with particular force both naturalistically and symbolically. Emphasizing the presence of the past, the power of doom, and the value of endurance, Faulkner transcended his region and his country to speak to the world.

FAULT. In geology, a fault is a dislocation in the rocks of the crust of the earth. The fault plane or surface is a fracture along which the rocks on opposite sides have slipped past each other. Most, if not all, earthquakes are due to movement along faults. Faults range in size from those that are detected only under the microscope to others that are many hundreds of miles long. In some instances, the movement is distributed over a fault zone composed of countless individual faults that occupy a belt hundreds of feet wide.

FIG. 1.— GRABEN AND HORST

Origin. — Faults are due to compressional or tensional forces that cause fracturing in the earth's crust. Thrust faults are the result of compressional forces where the easiest relief is upward.

Strike-slip (wrench or lateral) faults are similarly due to horizontal compression, but in such cases the easiest relief was in a horizontal direction at right angles to the compressional force. Gravity faults, also called by some geologists normal faults, are often considered to be the product of horizontal tension in the crust, but this tension may be the result of vertical compressional forces acting from below.

Classifications and Examples.—A gravity fault or normal fault is one in which the hanging wall has gone down relative to the footwall (the block above the fault plane or surface is called the hanging wall; the block below is called the footwall, fig. 4); such movement involves lengthening of the crust of the earth at right angles to the strike of the fault.

Gravity faults are found throughout the world. In the Great Basin province of Utah and Nevada, such faults bound many of the mountain ranges on one or both sides. The mountains have been uplifted relative to the adjacent valleys many thousands of feet along these faults. One of the best examples is that along the west side of the Wasatch range of Utah. The Teton range of Wyoming is bounded on the east by a large gravity fault. A block that has dropped relatively downward between two gravity or normal faults dipping toward each other is a graben (fig. 1). The Rhine graben of Germany, bounded on both sides by gravity faults, is 180 mi. long and 20 to 25 mi. wide. A block that has been relatively uplifted between two gravity faults that dip away from one another is a horst (fig. 1). A tilted block that lies between two gravity faults dipping in the same direction is a tilted fault block.

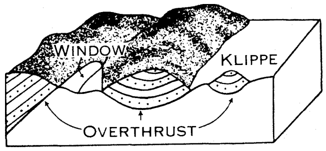
FIG. 2.—THRUST FAULT, (T) THROW. (H) HEAVE

A thrust fault (fig. 2) is one in which the hanging wall has gone up relative to the footwall; it involves a shortening of the crust of the earth at right angles to the strike of the fault. Some thrust faults are folded, generally after displacement along them has ceased. Thrust faults with an initial low angle of dip and a net slip measured in miles are often referred to as overthrusts (fig. 3).



BY COURTESY OF MARLAND P. BILLINGS

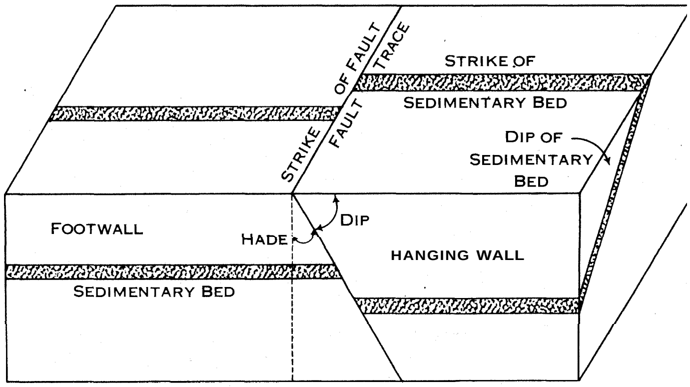
FIG. 3.—OVERTHRUST SHOWING WINDOW AND KLIPPE

One of the best known thrust faults in North America, the Lewis overthrust, is found along the east side of the Rocky mountains in Glacier national park of Montana. Along this thrust ancient Pre-Cambrian rocks have been thrust eastward over younger Cretaceous rocks for at least 10 mi. Large thrust faults are also characteristic of the Appalachian region in the so-called Valley and Ridge province of Virginia and Tennessee.

Along the Moine overthrust in the northwest highlands of Scotland the Moine schists have been thrust northwestward for at least 15 mi. Thrust faults along which the movement is tens of miles are common in the Alps. Many overthrusts have been folded and deeply eroded. In places erosion may cut so deeply that in a circular or elliptical area the footwall block is completely surrounded by the hanging wall block; this is called a window (fig. 3; Fr. *fenêtre,* Ger. *Fenster).* Elsewhere, an isolated mass of the hanging wall may be completely surrounded by the footwall; this is known as a thrust outlier (fig. 3; Fr. *écaille,* Ger. *Klippe*).

In another group of faults the dip is essentially vertical and the movement is largely horizontal. Such faults are called strike-slip faults. wrench faults or lateral faults. Along a series of faults trending northwestward in California, the northeast block has been displaced southeasterly relative to the block southwest of the fault. During the San Francisco earthquake in 1906 the maximum movement along the San Andreas fault was 21 ft. The total movement along this fault during the last few millions of years appears to have been several tens of miles. Another large fault of this type is the Great Glen fault that extends northeast-southwest across Scotland from Inverness to Oban. Along this fault the block to the northwest has moved southwesterly 65 mi. In the South Island of New Zealand the northeasterly trending Alpine fault is a strike-slip fault along which the displacement is many tens or even hundreds of miles.

Movement Along Faults.—In describing movement along faults the intersection of the fault plane with the surface of the earth is called the fault trace (fig. 4). The trend or direction of



BY COURTESY OF MARLAND P. BILLINGS

FIG. 4.—TERMINOLOGY APPLIED TO FAULTS

the fault trace is called the strike and is defined by the angle the trend makes with a north-south line. Faults may be vertical, horizontal or inclined at any angle. Although the angle of inclination of a specific fault tends to be relatively uniform, in some instances the inclination may differ considerably from place to place. The angle of inclination measured from the horizontal is called the dip (fig. 4). The angle of inclination or deviation from the vertical is called the hade.

The walls of the fault plane in many instances are smoothly polished and marked by scratches called slickensides. These scratches indicate the direction in which the two blocks on opposite sides of the fault plane have moved relative to each other. In some instances, the rocks along a fault plane have been crushed to a very fine-grained claylike substance known as fault gouge. In other cases the fragmental rock is relatively coarse-grained with fragments ranging from an inch in diameter to many feet; such material is known as fault breccia (*q.v.*) or crush breccia.

In general. the displacement of the blocks on the opposite sides of the fault plane must be considered in relative terms; the absolute movement relative to some datum, line or plane such as sea level, is generally unknown. The movement along a fault may be rotational, in which the blocks rotate relative to one another, or translatory, in which no rotation is involved.

Although it is clearly recognized that a rather elaborate terminology is necessary to describe the relative movements along faults and the effects on the disrupted strata, complete unanimity of definition has not been achieved. The most common terminology and the one adopted here is a modification of the terminology advocated by a committee of the Geological Society of America in 1912.

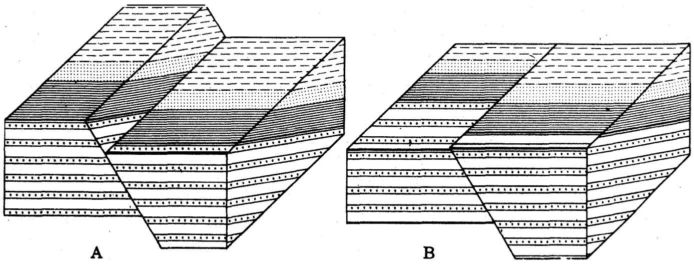
FIG. 5.—TERMINOLOGY APPLIED TO MOVEMENT ALONG FAULTS, (AB) NET SLIP. (AC) STRIKE SLIP, (CB) DIP SLIP, (AE) VERTICAL SLIP. (ED) HORIZONTAL SLIP

The net slip is the total displacement; it is the distance measured on the fault surface between two formerly adjacent points situated on opposite sides of the fault plane (*nb* of fig. 5). The inclination that the net slip makes with a horizontal line in the fault plane is called the pitch or rake (angle *cab* of fig. 5). To describe the net slip quantitatively, it is necessary to give its pitch, the amount of the displacement and the direction of the relative movement. The strike slip, measured in the fault



BY COURTESY OF MARLAND P. BILLINGS

FIG. 6.— EFFECTOF FAULTING ON DISRUPTED STRATA, (A) BEFORE EROSION (B) AFTER EROSION

plane, is the horizontal component of the net slip (bd of fig. 5). The dip slip is the component of the net slip measured directly down the dip of the fault plane (cb of fig. j). The vertical slip is the vertical component of the net slip; it is a measurement of the relative vertical movement along the fault plane (ae of fig. 5). The horizontal slip is the horizontal component of the dip slip; it is a measurement of the relative movement of the two blocks toward or away from each other (ed of fig. 5).

Effect on Disrupted Strata.— The apparent movement of a fault may be very different from the actual movement. Thus, in fig. 6 (A), the hanging wall has moved down relative to the footwall. But when the left-hand block has been eroded to the level of the right-hand block (fig. 6 [B]), their relation suggests that the right-hand block moved forward relative to the left-hand block. Of course. this might actually have been the case, and a solution of such problems is possible only if some other planar feature, such as a dike or an older fault, has also been displaced by the fault. The throw and heave are measured in a vertical section at right angles to the trend of the fault plane (fig. 2). The throw *(t)* is the vertical component of the apparent movement in such a section; whereas the heave (*h*) is the horizontal component. Many geologists define throw and heave differently; defining throw the same as vertical slip and heave the same as horizontal slip (as defined above).

For discussion of faults in relation to the occurrence of gas and oil see FORAMINIFERA; GEOPHYSICAL PROSPECTING; MINE PROSPECTING AND DEVELOPMENT. See also GEOLOGY; EARTHQUAKE.

FAUNUS, an Italian rural deity. the bestower of fruitfulness on fields and cattle. As a herdsmen's god he was identified with Inuus, the fertilizer of cattle. His identification with the god worshiped at the Lupercalia (*q.v.*) is controversial. He is above all a woodland deity and identified with the sounds of the forest; thus he is called Fatuus ("the speaker") and has a female counterpart, Fatua or Fauna, either his daughter or wife, allegedly identical with the Bona Dea (*q.v.*). He is sometimes prophetic (as in the *Aeneid,* vii), and as Incubo has charge of nightmares and buried treasure (cf. fairies, pucks, etc.). He is identified with the Greek Pan (*q.v.*) and under this influence may be pluralized: fauni, woodland spirits conceived as satyrs (*q.v.*). Rationalizing mythologists made him an early king of Latium, the son of Picus and father of Latinus. He had two festivals (Faunalia): on Dec. 5 in the country, an occasion of gaiety and spirited dancing (Horace, *Carmina,* iii. 18); and an urbanized form on Feb. 13 (Ovid, Fasti, ii, 193 ff.), which took place at the temple of Faunus in Rome.

FAURE, FRANÇOIS FÉLIX (1841–1899), president of the French Republic, was born in Paris on Jan. 30, 1841, the son of a small furniture maker. He made a fortune as a tanner and merchant at Havre. and was elected to the National Assembly on Aug. 21, 1881. He sat on the Left, interesting himself chiefly in matters concerning economics, railways and the navy. He was undersecretary for the colonies (1882–85 and 1888), and in 1893 was made vice-president of the chamber. In 1894 he obtained cabinet rank as minister of marine under Charles Dupuy. In the January following he was unexpectedly elected president of the Republic upon the resignation of Jean Paul Casimir-Périer. His fine presence and his tact on ceremonial occasions rendered the state some service when in 1896 he received the tsar of Russia at Paris, and in 1897 returned his visit, after which meeting the momentous Franco-Russian alliance was publicly announced.

The latter days of Faure's presidency were embittered by the Dreyfus affair, which he was determined to regard as chose *jugée.* But at a. critical moment in the proceedings he died (Feb. 16, 1899).

See E. Maillard, Le Prdsident F. Faure (1897); P. Blupsen, *Félix* Faure *intime* (1898); and F. Martin-Ginouvier, F. Faure devant l'histoire (1895).

FAURÉ, GABRIEL (1845–1924), French musical composer, was born at Pamiers (Ariège) on May 12, 1845. He studied at the school of sacred music directed by Niedermeyer, first under Dietsch. and subsequently under Saint-Saens. He became "maître de chapelle" at the church of the Madeleine in 1877, and organist in 1896. Fauré was made professor of composition at the Conservatoire (1896), and director (1905). He retired in 1920 and died on Nov. 4, 1924. His work at the Conservatoire. extending over nearly a quarter of a century, had great importance in the history of French music. Roger-Ducasse. Ravel and Florent Schmitt were among his pupils. He himself wrote music in all forms. but his fame rests mainly on his exquisite songs and on a considerable body of original and interesting chamber music Recognition came to him slowly, probably because of the quality of unexpectedness in his compositions. Among the more familiar of his chamber music works are two sonatas for violin and pianoforte. two sonatas for violoncello, a posthumous string quartet and two quintets for pianoforte and strings. For a bibliography of his works see Octave Séré, Musiciens *français,* d'aujourd'hui (jth ed. 1910).

FAURIEL, CLAUDE CHARLES (1772–1844), French scholar and writer who played a considerable, though unspectacular, part in the revival of historical and literary studies in France after 1815. He was born at St.-Étienne on Oct. 21. 1772, and received a good education in the Oratorian colleges of Tournon and Lyons. Republican by conviction, he served in the army before becoming private secretary to the minister of police, Joseph Fouché (*q.v.*), in 1799 and then, three years later, resigned the post when affronted by the ambition of Bonaparte. About. this time his first literary efforts—some articles in the *Décade philosophique* (1800)—won the approval of Madame de Staël, and he contracted with Madame de Condorcet a liaison which lasted until her death in 1822. His friendship with François Guizot procured for him, after the July revolution in 1830, the chair of foreign literature at the Sorbonne, and in 1836 he was elected to the Académie des Inscriptions. He died at Paris on July 15, 1844.

Fauriel was a reluctant writer and an unreliable historian, but his undoubted scholarship and particularly his tenure of office at the Sorbonne were largely responsible for the subsequent development of the study of comparative literature in France. His publications include Chants *populaires* de la *Grèce moderne* (2 vol., 1824–25), a work serving the causes of poetry and Greek independence and the first to bring Fauriel before a wide public; *Histoire* de la Gaule *méridionale sous* la domination des *conquérants germains* (4 vol., 1836), the only completed section of a projected general history of southern Gaul; *Histoire* de la *Croisade contre* les *hérétiques* albigeois (1837), a translation of a provençal poem on the Albigensian crusade; and two posthumously published works—Histoire de la *poésie provençale* (3 vol., 1846; Eng. trans., 1860) and Dante et les origines de la langue et de la *lit*te'rature italiennes (2 vol., 1854).

Fauriel's *Mémoires* were found with the papers of Madame de Condorcet and were published by L. Lalanne under the title Les *Derniers Jours du Consulat* (1886; Eng. trans., 1885).

See also J. B. Galley, Claude Fauriel (1909).

FAUST (FAUSTUS), the name of a magician and charlatan of the 16th century who has become famous in legend and literature. The real Faustus died *c.* 1540, but the scanty references to him in contemporary sources suggest the possibility that there were two men (Georgius and Johann) using that surname. In 1507 it is known that a certain Georgius Sabellicus, calling himself Faust Junior. the chief of necromancers, the second magus, palmist, astrologer and so on, obtained toward the end of Lent the post of schoolmaster at Kreuznach. Ger., through the good offices of Franz von Sickingen, "a man very fond of mystical lore." He grossly abused the trust placed in him by indulging in "the most dastardly form of lewdness" with the boys and fled from punishment, as is reported in a letter from Johannes Tritheim. abbot of Sponheim monastery, near Kreuznach. Two years later. on Jan. 1j, 1509, a certain Johannes Faust *"ex Simern"* was granted the degree of B.A. by the faculty of theology in the University of Heidelberg. and the university matriculation records show that he was placed first on the list of 1j and duly paid his fees. According to Conrad Mutianus Rufus, canon of St. Mary's church, Gotha. in Sept. 1j13 Georg Faust, "the demigod of Heidelberg." was heard bragging and boasting in an Erfurt inn. The account book of the bishop of Bamberg records that on Friday. Feb. 10, 1520, Dr. Faust received ten gulden for casting the bishop's horoscope. Kilian Leib, prior of Rebdorf in Bavaria, says that on June 5, 1528, a Georgius Faustus of Helmstedt claimed to be the commander and preceptor of the knights of St. John at Hallestein. on the borders of Carinthia. Only ten days later, on June 15, 1528, the records of Ingolstadt show that Dr. Georg Faust was banished from the town as a soothsayer; and Dr. Faust. "the great sodomite and necromancer." was refused a safe conduct by the city of Niirnberg on May 10, 1532. On June 25, 1535, "the famous necromancer" Dr. Faust was in Münster, where. as reported in the *Waldeck Chronicle,* he prophesied accurately that the bishop would recapture the city that evening. Finally. "the philosopher Faust" seems to have prophesied accurately early in 1540 "a very bad year" for the Venezuelan expedition, according to Philipp von Hutten, who met his death on it.

This is the last mention of Faust while he was still alive. He appears to have been fairly well known and widely traveled. probably not without education, but with an evil reputation. All the observers are agreed about this; but opinions were divided about his prowess in magic. The humanists, and Tritheim in particular. scoffed at his claims and derided him as a braggart. The fampus classical scholar Joachim Camerarius (1500–74) speaks of his "juggler's tricks"; and Philipp Begardi, a physician in Worms, said that his promises were great and so was his fame, but that his deeds were "very petty and fraudulent." The contemporary demonologists. with the exception of Xugustin Lercheimer and Johannes Wier. who showed him up as a trickster in *De praestigiis daemonum,* ignored Faust almost completely, and no serious history of magic has ever included him among the noted practitioners. But the Reformed clergy. Luther and Melanchthon among them. strengthened the widespread and popular belief in the diabolical powers of "the famous necromancer." A Swiss Protestant pastor, Johannes Gast, who had once dined with Faust in Basel, declared in his *Sermones conviviales* (1548) that the dog and horse with him were demons and that the wicked sorcerer had finally been strangled by the devil. Faust himself, by referring more than once to the devil as his *Schwager* ("crony'! or "brother-in-law"), probably gave rise to this flight of fancy which brought him into line with a perdurable tradition. From time immemorial those who were credited with supernatural powers were also rumoured to have died violent or mysterious deaths; and the legend of Faust as it developed thereafter was the 16th-century Lutheran version of the myth of the magus. among whose earliest known representatives were the Persian magi.

The sages and mages of antiquity were greatly revered and believed to be of divine origin. but they mere also greatly dreaded because of their mysterious power, and from the earliest times magic was abused in the hands of charlatans and evil-intentioned practitioners. Magicians as a class were already losing caste under the Roman empire when Christianity precipitated their downfall by claiming a monopoly of miracles; and the church's striking declaration *Habet diabolus Christos suos* ("The devil has his own Christs") effected a revolution in public opinion which transformed the pagan deities into demons and their priests into devil worshipers. The mighty magus of ancient times was reduced to the status of a black magician, a downfall that was symbolically and dramatically represented in the legend of Simon Magus (*q.v.*). On the other hand the legend of Theophilus of Adana, who, in order to regain the office from which he had been deposed, agreed to serve the devil and gave him a sealed denial of Jesus Christ, first brought into prominence the notion of an infernal pact, which had been admitted by St. Augustine and other fathers of the church and which derived from Jewish incantation ceremonies. Mariolatry saved Theophilus from the consequence of his bargain; but a species of diabolatry (belief in the almost unlimited power of the devil), which flourished among the early Lutherans, spelled eternal damnation for Faust, and all the more so because he had recourse to magic in order to satisfy his craving for knowledge. This was evil in itself according to the antihumanistic tendency of the Reformed Churches. The *Sturm und Drang* writer Friedrich Maximilian von Klinger later deliberately identified the hero of his sombre novel *Fausts Leben, Tnten und Höllenfahrt* (1791) with Johann Fust of Mainz, the reputed coinventor of printing. who died in 1465; and both hc and Heinrich Heine declared that the confusion had arisen in the popular mind because of superstitious fear of the dissemination of knowledge.

It may seem strange that such a shady and relatively obscure sorcerer as Faust should have become the representative black magician of his age rather than his far more famous contemporaries. Tritheim. Xgrippa von Nettesheim. Paracelsus and Nostradamus. who were also involved in occult speculations and practices and were also suspected of commerce with the devil. But Faust attained to posthumous fame because of his first biographer. the anonymous author of the first *Faustbuch,* published by Johann Spies in Frankfurt-on-Main in 1587. The book is of unequal merit; for bookmaking of the crudest kind underlies the collection of magical feats which forms its nucleus. These tales, taken from Lercheimer and other demonologists. had been told about the ancient magi and retold in the middle ages and later about such reputed wizards as Virgil, Merlin. Simon Magus, Gerbert (Pope Silvester II), Albertus Magnus. Roger Bacon, Zyto and many more. They were now attributed to Faust, baldly and badly narrated and still further disenchanted by the clodhopping humour shown at the expense of Faust's dupes. Disenchantment also spoils the evocation of Helen of Troy, a devil disguised as a wanton, doll-like minx; but the genuinely poetic idea which summons her up from Hades to ensure Faust's damnation set Christopher Marlowe's imagination aflame and is one of the reasons why the legend put on immortality. The other is to be found in the intense conviction of the author. a God-fearing, devil-fearing Lutheran, of the truth of the tale he was telling. His descriptions of the nether regions and of the fearful state of mind of his heart-hardened hero have spiritual intensity and are still impressive, as can be seen from Thomas Mann's highly effective use of many such passages verbatim in his *Doktor Faustus* (1947). Moreover, in the creation of Mephostophiles (for whose name. of which this was the original form. he was also responsible), the author attained to such realism in his presentation of the savage. embittered, remorseful and yet ruthless fiend as to inspire unquestioning belief.

The book ran like wildfire through Europe. It was translated speedily into Low German. Danish. Dutch. English and French, and. somewhat later, into Polish and Czech, while revised and augmented editions, one of them in rhyme, followed on each other's heels in Germany. Its career was halted there by the appearance in 1599 of Georg Rudolf Widmann's *Faustbuch,* which dislocated and swamped the sadly diminished tale with a spate of learned and sermonizing commentaries and further disfigured it by retelling it with a rabidly anti-Catholic and anti-Semitic bias. This version was re-edited in 1674 by Johann Nikolaus Pfitzer and cut into little hits by Christlich Meynenden in 1725 to form a popular chapbook, by which time the original Spies version was forgotten.

But it had served its turn; for the Elizabethan prose translation by "P. F., Gent." in 1592 or earlier inspired Christopher Marlowe's *The Tragicall History of D. Faustus* (published 1604), in which the tragic power and passion latent in the original attained a summit unsurpassed in Faustian literature. Marlowe, who followed his source closely, took over a good deal of the farcical element and introduced a comic subplot, thus admitting elements of decay into the tragic organism which, decomposing the legend with a speed almost equal to the swiftness of its flowering, brought it finally to the compost heap with William Mountfort's *The Life and Death of Doctor Faustus. With the Humours of Harlequin and Scaramouche* (1697) and John Thurmond's pantomime *Harlequin Doctor Faustus* (1724). It underwent a similar but less radical deterioration in Germany, where English strolling players presented Marlowe's drama early in the 17th century. German versions soon supplanted the probably mangled English text and, to judge by the playbills and accounts which have survived, sensationalized it with many spectacular effects, introduced some indigenous elements and diversified it with a great deal of clowning. Faust dramas of this kind were enacted for 200 years on the popular stage; and the puppet-play texts, many of them still extant, suggest that on the whole the Marlovian scheme was adhered to in the booths, as well as on the boards. The puppet plays themselves, streamlined and artless: with some tense and moving scenes, allowed a large part to Casper the clown; but, however much shortened Faust's part might be in consequence, his tragic end was often floodlit with poetry, and his eternal damnation was never in doubt.

This fact had to be taken into account by the fabricators and editors of the extremely lucrative magical manuals circulating at the time. With a view to increasing sales, they used Faust's name on the title page and sometimes in the body of incantation ceremonies deriving ultimately from Akkadian-Chaldean inscriptions through the Greco-Roman papyri and Jewish rituals; and in order to reassure prospective purchasers of these various so-called Faustian *Höllenzwänge* ("harrowings of hell"), they either wrote preambles showing how the dangerous bilateral pact with the devil could be avoided or they ignored the subject and concentrated on the unilateral pact which constrained the spirits to obedience without any bodily or spiritual harm to the exorcist. The great Faustian ritual classic *Magia Naturalis et Innaturalis* (in the Weimar grand-ducal library and well known to Goethe) went even further. After giving the text of the unilateral pact, it also communicated the wording of a bilateral pact, with the soul of the exorcist at stake, and then gave the religious ceremony to be performed in order to break the agreement. Exceedingly pious in tone, these manuals mere in great demand during the 17th and 18th centuries, when it was believed that with their help buried treasure could be located and raised; and they popularized the notion that infernal pacts could be renounced by the grace of God.

But the name of Gotthold Lessing is the first great name associated with the salvation of Faust in literature. The desire and pursuit of knowledge appeared to this enlightened rationalist as one of the noblest instincts of the human mind, and he left a scheme and some scenes pointing toward the hero's reconciliation with God. Published in 1784. they had great influence; and from then onward the innumerable Faustian authors have been divided into two camps: the traditionalists and the salvationists. Even before the appearance in 1808 of Goethe's *Faust,* part i, with its promise of salvation in the prologue, several dramatists had attempted to realize this ideal; and others continued to do so both before and after the publication of his *Faust,* part ii, in 1833, although the awe-inspiring conclusion to this masterpiece of modern literature should have discouraged his successors. For it is more than salvation to which Goethe's Faust attains in the final act, which is an apotheosis of the hero as a representative of striving and seeking humanity, who may spend a lifetime erring but will be redeemed by the active pursuit of knowledge and truth. Goethe is unique in having solved the seemingly insoluble problem of grafting a humane and rationalistic ethic onto the dire assumptions of the legend; but the introduction of love interest into the cosmic conflict with the appearance of Gretchen diminished its grandeur in Faustian literature as a whole, although this is not nearly so much the case with the tragic traditionalists, on some of whom Don Juan and Byron have left their mark. None of them can hold a candle to Marlowe; but there are works of real interest, power and beauty among them. Klinger's and Thomas Mann's contributions have already been mentioned. To them should be added: Adelbert von Chamisso, *Faust, Ein Versuch* (1804), Christian Grabbe, *Don Juan und Faust* (1829), Nikolaus Lenau, *Faust: Ein Gedicht* (1836), Woldemar Nürnberger, *Josephus Faust* (1847), Heinrich Heine, *Doktor Faust: Ein Tanzpoem* (1851) and Paul Valéry, *Mon Faust* (1946). None of these poets has been able to accept Goethe's optimistic conclusion; and Lenau and Valéry, in particular, have stressed the dangers inherent in the notion of attaining to absolute knowledge with its correlative poaer. In their works the annihilating instinct of mankind faces the incorruptibility proclaimed by Goethe; and the fear of the Faustian spirit of insatiable scientific inquiry has been given modern expression.

FAUSTINA, ANNIA GALERIA, the younger, daughter of Antoninus Pius, and wife of Marcus Aurelius Antoninus. She is accused by Dio Cassius and Capitolinus of gross profligacy, and was reputed to have instigated the revolt of Avidius Cassius against her husband, but this may be untrue, as he was always devoted to her. She died in A.D. 175 or 176 (so Clinton, *Fasti rom.*) at Halala, near Mount Taurus, in Cappadocia, whither she had accompanied Aurelius. Charitable schools for orphan girls (hence called *Faustinianae*) were founded in her honour.

See Capitolinus, *Marcus Aurelius;* Dio Cassius lxxi. 22, lxxiv. 3; E. Renan, in *Mélanges d'histoire et des voyages,* 169–195.

FAUSTUS, SAINT of Riez (*c.* 400–*c.* 490), bishop of Riez, France, and one of the chief exponents of Semi-Pelagianism, was born in Roman Britain about the year 400. He and probably his family went to southern Gaul in the first years of the 5th century. Faustus joined the newly founded monastic community on the Îles de Lérins, of which he became the third abbot about 433. After some 20 years as abbot. Faustus was elected bishop of Riez in the Basses-Alpes and from then on played a leading role in the ecclesiastical life of 5th-century Gaul. He died about 490. Although he was liturgically venerated as a saint before the 19th century in Riez (feast day, Sept. 28), this cultus has completely disappeared.

Faustus was a significant theologian and a celebrated preacher. His sermons, many of which were reworked and used by Caesarius of Arles (*q.v.*), can still be found attributed to other names in the sermon collections gathered in 6th-century France. As a theologian, Faustus in his two books *De gratia* gave the final form to the Gallic anti-Augustinianism today called Semi-Pelagianism. For Faustus, grace was indeed necessary for true virtue and salvation, but he conceived grace as something extrinsic to man, which was rendered operative through man's own natural initiative toward salvation (*credulitatis affectus*). Without naming Faustus but citing his very words, the second Council of Orange (529) rejected Faustus' doctrine.

Faustus' works were printed by J. P. Migne, *Patrologia Latina,* vol. lviii, 523–557, and A. Engelbrecht, *Fausti Reiensis opera,* in the series "Corpus Scriptorum Ecclesiasticorum Latinorum," vol. xxi (1891).

See G Weigel, S J., *Faustus of Riez* (1938). (G. Wl.)

FAUVISM: *see* Painting.

FAVARA, a town of Sicily. province of Agrigento. 8 mi E. of the city of that name by rail. Pop. (1951), 25,2jj An agricultural centre with sulfur and other mines, and a fine castle (1280) of the Chiaramonte family.

FAVART, CHARLES SIMON (1710–1792), French dramatist and one of the creators of French *opéra comique,* was born in Paris. Nov. 13. 1710. After his father's death he carried on his business as pastry cook, meanwhile writing librettos for light operas. He became stage manager of the Opéra Comique in 1743, and in 1745 married Marie Duronceray (1727–72), a singer and actress. She attracted the attentions oi Maurice de Saxe, Favart's patron, who used his power over them both to make her his mistress. Favart's best play, *Les Trois Sultanes* (1761), is a comedy based on a similar triangular situation. Here song and dance play a less important part than in Favart's other works, the best of which is *La Chercheuse d'esprit* (1741). Favart became director of the Opéra Comique in 1758. He died in Belleville. May 12, 1792. His *Mémoires et correspondance littéraires, dramatiques et anecdotiques* (1808) throws light on the writer and his times.

See A. Font, *Favart. L'opera-comique et la come'die-vaudeville au XVII^e^ et XVIII^e^ siècles* (1894); A. Iacuzzi, *The European Vogue of Favart* (1932). (*D.* Ks.)

FAVERSHAM, a market town, river port and municipal borough in the Faversham parliamentary division of Kent, Eng., on a creek of the Swale, 9 mi. W.N.W. of Canterbury by road. Pop. (1951) 12,293. Area 4.7 sq.mi. It is a member of the Cinque Port of Dover. The Early English church of St. Mary of Charity (restored in 1754) has some remains of frescoes (*c.* 1305) on one of the columns and 14th-century paintings in the chancel. A brass cornmemorates King Stephen. whose remains are said to have been transferred at the Dissolution to a tomb in the Trinity chapel from the Cluniac abbey which he founded. Matilda, his queen, was also buried in the abbey. The fragment of the outer gateway that remains forms part of the house wherein Thomas Arderne (Arden) was murdered in 1550. This event is the theme of *The Lamentable and True Tragedie of M. Arden of Feversham in Kent,* one of the earliest English domestic dramas.

Faversham's grammar school was founded in 1527, forfeited at the Dissolution and restored by Elizabeth I in 1576. The original building (1587) still exists.

Traces of Roman settlement have been found, but the town (Favreshant in Domesday Book) owed its early importance to its situation as a port on the Swale near Watling street and surrounded by fertile country. In 811 it was called the king's town "of Fefresham" and a witenagemot was held there under Athelstan. In 1086 it was assessed as royal desmesne, and a market held. When King Stephen founded the abbey in 1147, he endowed it with the manor and hundred of Faversham. which caused many disputes between the abbot and men of Faversham concerning the abbot's jurisdiction.

Faversham was probably a member of Dover from the earliest association of the Cinque Ports, certainly as early as Henry III, as shown by a charter of 1252. All the liberties of the Cinque Ports were granted to the barons of the town in 1302. The governing charter till 183j was that of Henry VIII, granted in 1545 and confirmed by Edward VI.

Faversham creek is navigable up to the town for vessels up to 300 tons. The shipping trade is considerable, chiefly in oils. timber, agricultural feeding stuffs and fertilizers: both coastwise and from continental ports. The oyster fisheries were formerly managed by a very ancient guild, the Company of Free Dredgermen of the Hundred and Manor of Faversham, but since 1929 by the statutory company. Hops and cherries are largely grown in the neighbourhood. Brewing. brickmaking. the quick ireezing and canning of fruit and vegetables and the grading and packing of apples and pears are carried on. There are a shipyard and light engineering works in the town, also large oil depots.

FAVORINUS (fl. and century A.D.), skeptical philosopher and sophistic rhetorician of the Roman empire. whose life. as he said. was remarkable because "being a Gaul, he lived as a Greek; being a eunuch [an androgyne], he was sued for adultery: and, being in dispute with the emperor, he suffered nothing." Born in Arles, he is known to have lived in Rome. in Athens, in Corinth and in Ephesus and to have been highly esteemed for his learning and for his eloquence. Plutarch, Herodes Atticus and Aulus Gellius were his friends; Polemo of Laodicea, his bitterest rival. Falling into disfavour with the emperor Hadrian, he appears to have retired to comfortable exile in Chios until the end of the reign.

Favorinus wrote philosophical discourses. declamations, a *Miscellaneous History* and memoirs. His serene discourse *On Exile* was printed by M. Norsa and G. Vitelli from a Vatican Greek papyrus in 1931. Editions of Dio Chrysostom (*q.v.*) include two orations (xxxvii and lxiv) now usually ascribed to Favorinus: the *Corinthiaca*, an outstanding specimen of rhetorical exercise in the Asianic style; and *On Fortune.* Only fragments remain of his other works; the historical ones are collected by C. Miiller, *Fragmenta historicorum Graecorum,* iii (1849).

BIBLIOGRAPHY.—Philostratus and Eunapius, *Lives of the Sophists,* Eng. trans. *by* W. C. Wright (1922); W. Schmid, "Favorinus," Pauly-Wissowa, *Real-Encyclopadie der classischen Altertumswissenschaft,* vi (1909); W. Schick, *Favorin . . . und die antike Erziehungslehre* (1912).

FAVRAS, THOMAS DE MAHY, MARQUIS DE (1744–1790), French royalist, was born on March 26, 1744, at Blois. In 1772 he became first lieutenant of the Swiss guards of the count of Provence (afterward Louis XVIII). He retired in 177j and married in 1776 Victoria Hedwig Caroline, princess of Anhalt-Bernburg-Schaumburg, whose mother, deserted by her husband Prince Carl Ludwig in 1749, had found refuge with her daughter in the house of Marsbal Soubise. After his marriage he went to Vienna to press the restitution of his wife's rights, and spent some time in Warsaw.

In 1787 he was authorized to raise a patriotic legion to help the Dutch against the stadholder William IV and his Prussian allies. Returning to Paris at the outbreak of the French Revolution, he became implicated in schemes for the escape of Louis XVI. He was commissioned by the count of Provence, through the comte de la Chbtre, to negotiate a loan of 2.000.000 fr. from the bankers Schaumel and Sartorius. Favras was betrayed, however, and, with his wife. was arrested on Christmas eve, 1789.

In the course of a trial of nearly two months' duration the witnesses disagreed, and even the editor of the *Révolutions de Paris* (no. 30) admitted that the evidence was insufficient, but an armed attempt of the royalists on the Chhtelet on Jan. 26, which was defeated by La Fayette, sealed his fate. He was hanged on the Place de Grève on Feb. 19, 1790.

Favras was generally regarded as a martyr to his refusal to implicate the count of Provence, and Madame de Favras was pensioned by Louis XVI.

The official dossier of Favras's trial for high treason against the nation disappeared from the Châtelet, but its substance was preserved in the papers of a clerk.

FAVRE, JEAN ALPHONSE (1815–1890), Swiss geologist, born at Geneva on March 31. 181j, was for many years professor of geology in the academy at Geneva and afterward president of the federal commission with charge of the geological map of Switzerland. One of his earliest papers was "On the Anthracites of the Alps" (1841). and later he gave special attention to the geology of Savoy and of Mont Blanc and to the ancient glacial phenomena of those Alpine regions. He died at Geneva in June 1890.

FAVRE, JULES CLAUDE GABRIEL (1809–1880), French statesman, was born at Lyons on March 21, 1809, and was an advocate by profession. From the time of the revolution of 1830 he declared himself a republican. After the revolution of 1848 he was deputy for Lyons to the constituent assembly. On Dec. 2, 1851, he tried with Victor Hugo and others to organize an armed resistance to Louis Napoleon in the streets of Paris.

After the coup d'etat he withdrew from politics, resumed his profession and distinguished himself by his defense of Felice Orsini, the perpetrator of the attack against the life of Napoleon III.

In 1858 he was elected deputy for Paris, and was one of the "five" who gave the signal for the republican opposition to the empire. In 1863 he became the head of his party, and delivered a number of addresses denouncing the Mexican expedition and the occupation of Rome. These addresses, eloquent, clear and incisive, won him a seat in the French academy in 1867. With Thiers he opposed the declaration of war against Prussia in 1870, and at the news of the defeat of Napoleon III at Sedan he demanded from the legislative assembly the deposition of the emperor.

In the government of national defense he became vice-president under Gen. Louis J. Trochu, and minister of foreign affairs, with the onerous task of negotiating peace with victorious Germany. He proved to be less adroit as a diplomat than he had been as an orator, and committed several irreparable blunders. His statement on Sept. 6, 1870, that he "would not yield to Germany an inch of territory nor a single stone of the fortresses" was a piece of oratory which Bismarck met on Sept. 19 by his declaration to Favre that the cession of Xlsace and of Lorraine was the indispensable condition of peace. He arranged for the armistice of June 28, 1871, without knowing the situation of the armies and without consulting the government at Bordeaux. He neglected to inform Gambetta that the army of the east (80,000 men) was not included in the armistice, and it was thus obliged to retreat to neutral territory.

Favre withdrew from the ministry, discredited, on Aug. 2, 1871, but remained in the chamber of deputies. Elected senator on Jan. 30, 1876, he continued to support the government of the republic against the reactionary opposition until his death on Jan. 20, 1880.

His works include many speeches and addresses, notably *La Liberte' de la presse* (1849), *Défense de F. Orsini* (1866), *Discours de réception à l'Académie française* (1868), *Discours sur la liberte' intérieure* (1869).

In *Le Gouvernement de la Défense Nationale*, 3 vol., 1871–75, he explained his role in 1870–71. After his death his family published his speeches in eight volumes.

See G. Hanotaux, *Histoire de la France contemporaine* (1903, etc.); also E Benoît Lévy, *Jules Favre* (1884).

FAVUS, a highly contagious ringworm of the scalp, occurring occasionally also on other parts of the skin and in the nails. It is endemic among the poor population in many areas of eastern and southeastern Europe and in the middle east. It is uncommon in western Europe and in the U S. Favus is caused by the invasion of the skin and the hair by fungi of the Achorion group, leading to the formation of hard, cup-shaped, sulfur-yellow crusts with a mouse-nestlike odour. In contrast with other fungous diseases of the scalp, favus irreparably destroys the hair follicles. Unsightly permanent spotty baldness and scarring result in the involved areas.

Treatment of this disease is difficult, particularly because many members of one family may have it and transfer it to each other. *See* also RINGWORM OF THE SCALP. (RD. B. S.)

FAWCETT, HENRY (1833–1884), English politician and economist, was born at Salisbury on Aug. 25, 1833, the son of a successful businessman. He was educated at King's College school, London, and at Peterhouse and Trinity hall, Cambridge. He was seventh wrangler in 1856, and was elected to a fellowship at his college. He then entered Lincoln's Inn. His brilliant prospects, however, were shattered when he was blinded by a shooting accident in 1858. Nevertheless he fished, rowed, skated, walked and rode, and even learnt to play cards and at Trinity Hall, Cambridge, he entered cordially into the social life of the college. He now specialized in political economy. He was a loyal follower of Mill, and as a popularizer of his economic theory and a demonstrator of its principles by concrete examples he had no rival. His power of exposition was illustrated in his *Manual oj Political Economy* (1863), of which in 20 years as many as 20,000 copies were sold.

In 1863, Fawcett stood and was elected for the chair of Political Economy at Cambridge. He was already known in political circles as an advanced Radical, and in 1865 he was elected M.P. for Brighton. In 1867 he married Millicent, daughter of Newson Garrett of Aldeburgh, Suffolk (*see* FAWCETT, DAME MILLICENT GARRETT, G. B. E.).

Fawcett was a severe critic of Liberal Administration and protested against the limited scope of the Elementary Education Bill, Gladstone's method of abolishing army purchase, certain grants to the royal family, and methods of Indian finance. In short he was a thorough going radical who was looked at askance by the Liberal Party. Constructively he accomplished some reform in Indian finance methods, and secured public attention to the preservation of commons, and of New Forest and Epping Forest. As an opponent of the Disraeli government (1874–80) Fawcett came more into line with the Liberal leaders. When the Liberal party returned to power in 1880 Gladstone offered Fawcett a place in the new government as postmaster-general (without a seat in the cabinet). He showed himself a most capable head of a public department. To his readiness in adopting suggestions, and his determination to push business through instead of allowing it to remain permanently in the stage of preparation and circumlocution, the public was mainly indebted for five substantial postal reforms:—(I) The parcels post, (2) postal orders, (3) sixpenny telegrams, (4) the banking of small savings by means of stamps, (5) increased facilities for life insurance and annuities. In connection with these last two improvements Fawcett, in 1880, with the assistance of James Cardin, took great pains in drawing up a small pamphlet called *Aids* to *Thrift,* of which over a million copies were circulated gratis. A very useful minor innovation of his provided for the announcement on every pillar-box of the time of the "next collection." In the post office, as elsewhere, he was a strong advocate of the employment of women. Proportional representation and the extension of franchise to women were both political doctrines which he adopted very early in his career, and never abandoned. He died at Cambridge on Nov. 6, 1884, and was buried in Trumpington churchyard, near Cambridge.

In the great affliction of his youth Fawcett bore himself with a fortitude which it would be difficult to parallel. The kindness evoked by his misfortune, a strongly reciprocated family affection, a growing capacity for making and keeping friends—these and other causes tended to ripen all that was best, and apparently that only, in a strong but somewhat stern character. His acerbity passed away, and in later life was reserved exclusively for official witnesses before parliamentary committees. Frank, helpful, conscientious to a fault, a shrewd gossip, and a staunch friend, he was a man whom no one could help liking.

See Leslie Stephen, *Life of Henry Fawcett (1885).*

FAWCETT, DAME MILLICENT GARRETT, G.B.E. (1847–1929) the eighth child of Newson Garrett, merchant shipowner of Aldeburgh, Suffolk. Educated at a private school, she married at 20 Professor Henry Fawcett M.P., afterwards postmaster-general. Her husband's blindness and the perfect sympathy between them led to the closest interdependence of their activities. Under his inspiration she wrote an elementary manual on political economy. After his death in 1884 she lived in London with her sister Miss Agnes Garrett and her daughter Philippa, who like her father achieved the distinction of being Senior Wrangler at Cambridge.

Her best known work was begun immediately after marriage and continued for 50 years, as a leader—after the first few years the chief leader--of the constitutional movement for women's suffrage. The changes it wrought in women's status are typified by the fact that in 1867, after her first speech at the first meeting advocating women's suffrage, she and another were referred to in parliament as "two ladies, wives of members of this House, who had disgraced themselves" by speaking in public. Yet the quality of the supporters whom the movement immediately secured is shown by those who spoke at the same meeting—J. S. Mill, Charles Kingsley, John Morley, Sir Charles Dilke, James Stansfeld, Professor Fawcett.

The work that ensued put a heavy strain on Mrs. Fawcett's predominant qualities—her invincible tenacity of purpose, unfaltering faith in ultimate victory combined with sagacious appreciation of present difficulties, and unfailing humour. Practically every session for 50 years, save when the nation was at war, a

Woman's Suffrage bill was introduced into parliament, occasionally to achieve a second reading victory, but always to be talked out, blocked or defeated. Every year's work meant a growing volume of meetings, petitions, processions, press campaigns, etc. After 1905, when the militant suffrage campaign began, this army became divided into two main forces, which fought separately without turning their arms against each other.

Mrs. Fawcett was always passionately patriotic. During the South African War, the Government sent her to investigate the concentration camps for Boer women and children. The report she produced vindicated (her opponents said white-washed) their administration. The outbreak of the World War was the heaviest blow of her political life. Immediately the whole strength of her organization was turned to efforts for "sustaining the vital forces of the nation." In Jan. 1918, the national change of heart towards women's claims for which her patient work had paved the way, was consummated by the passing of the Representation of the People Act, enfranchising about six million women. A year later, her National Union of Women Suffrage Societies having become the National Union for Equal Citizenship, she retired from active leadership. She wrote *The Women's Victory end* After (1919), and *What I Remember* (1924). The order of D.B.E. was conferred on her after the war, and she was given the G.B.E. in 1925. She died in London, Aug. 5, 1929. (E. F. R.)

FAWKES, GUY (1570–1606), English Gunpowder plot conspirator, the only son of Edward Famkes of York, a member of a Yorkshire family and advocate of the archbishop of Tork's consistory court, mas baptized at St. Michael le Belfrey at York on April 16, 1570.

His parents being Protestants. Fawkes was educated at the free school at Tork. Soon after his father's death his mother remarried. Fawkes's stepfather was connected with many Roman Catholic families and was probably a Roman Catholic himself, and Fan kes became a zealous adherent of the old faith. In 1593 he went to Flanders and enlisted in the Spanish army, assisting at the capture of Calais by the Spanish in 1596 and gaining some military reputation.

The **Gunpowder** Plot.——In 1604 Thomas Winter, at the instance of Robert Catesby (*q.v.*), in whose mind the Gunpowder plot had now taken definite shape, introduced himself to Fawkes in Flanders, and as a "confident gentleman," "best able for this business," brought him on to England as assistant in the conspiracy. Shortly afterward he was initiated into the plot, after taking an oath of secrecy, meeting Catesby, Thomas Winter, Thomas Percy and John Wright at a house behind St. Clement's. Since he was unknown in London, and because of his exceptional courage, coolness and probably his military experience, Fawkes was entrusted with the actual accomplishment of the design; when the house adjoining the parliament house was hired in Percy's name, he took charge of it as Percy's servant, under the name of Johnson. He acted sentinel while the others worked at the mine in Dec. 1604. and on the discovery and hiring of the adjoining cellar, beneath the house of lords. he arranged in it the barrels of gunpowder, which he covered with firewood and coals and with iron bars to increase the force of the explosion.

When all was ready in May 1605, Fawkes was dispatched to Flanders to acquaint Sir William Stanley (who had betrayed the city of Deventer to the Spaniards in 1587) and the intriguer Hugh Owen with the plot. He returned in August and brought fresh gunpowder into the cellars to replace any spoiled by damp. A slow match mas prepared which mould give him a quarter of an hour in which to escape from the explosion. For the discovery of the scheme, see GUNPOWDER PLOT.

Fawkes behaved with the utmost fortitude when arrested. He refused stubbornly to give information concerning his accomplices: on Nov. 8 he gave a narrative of the plot, but it was not till the 9th when the fugitive conspirators had been taken at Holbeche. that torture wrung from him their names. His signature to his confession of this date, consisting only of his Christian name and written in a faint and trembling hand, is probably a ghastly testimony to the severity of the torture which James had ordered to be applied if he would not otherwise confess. He was tried, together with Robert and Thomas Winter, John Grant, Ambrose Rokewood, Robert Keyes and Thomas Bates, before a special commission in Westminster hall on Jan. 27, 1606.

Fawkes suffered death in company with Thomas Winter, Rokewood and Keyes on the 31st, being drawn on a hurdle from the Tower to the parliament house, opposite which he was executed. He made a short speech on the scaffold, expressing his repentance, and mounted the ladder last and with assistance, being weak from torture and illness.

FAYAL, a Portuguese island forming part of the Azores archipelago. Pop. (1950) 23,923; area, 66 sq.mi. Fayal (*i.e.,* "the beech wood") was so called from the former abundance of the *Myrica faya,* which its discoverers mistook for beech trees. It has an excellent harbour at Horta (*q.v.*), a town of 8,614 inhabitants. Cedros (2,912) and Feteira (2,525) are the other chief towns. The women of Fayal manufacture fine lace from the agave thread. They also execute carvings in snow-white fig-tree pith, and carry on the finer kinds of basketmaking. A small valley, called Flamengos, perpetuates the name of the Flemish settlers, who have left their mark on the physical appearance of the inhabitants. (See AZORES.)

FAYETTEVILLE, a city of Arkansas! U.S., the seat of Washington county, is located in a circle of hills: part of the beautiful Ozarks. The home of 13 governors, and Archibald Yell: the first congressman from Arkansas, a historic stop on the Overland Mail route, Fayetteville is the site of the University of Arkansas (established 1871). There was no settlement there when the city was staked as a site for the county seat in 1828. The city was first named Washington Courthouse, but changed to Fayetteville, after Fayetteville, Tenn.. in 1829. It was incorporated in 1836, received a city charter in 1859, which was abolished by act of the legislature in 1867; was reincorporated as a town in 1869; and in 1906 again became a city. The town acquired an educational reputation through its early schools, especially Sophia Sawyer's Female seminary (1839) and Arkansas college (1852). The latter was the first degree-granting college in Arkansas.

Within 30 mi. of both the Missouri and Indian territory borders, Fayetteville suffered severely during the Civil War. The battle of Pea Ridge (March 7–8, 1862) was fought in neighbouring Benton county and the battle of Prairie Grove (Dec. 7, 1862) just 10 mi. west of town. After the battle of Fayetteville (April 18, 1863) the town was held by federal troops until the end of the war. The dead of thqse battles are buried in Fayetteville's National and Confederate cemeteries.

While industry exists, Fayetteville is primarily a residential community. For comparative population figures see table in ARKANSAS: Population. (W. J. LE.)

FAYETTEVILLE, a city of North Carolina, U.S., the seat of Cumberland county and one of the state's oldest and most historic towns. The city is 50 mi. S.S.W. of Raleigh on the west bank of the Cape Fear river at the head of navigation, 120 mi. from the ocean. The town is located in a region noted for its production of cotton, tobacco and other crops. For more than a century this area was the centre of the nation's naval stores industry, the chief products being tar and turpentine. After 1870 this industry declined and finally disappeared. Textiles and lumber are the largest industries. Others include tobacco sales warehouses, food processing, cotton seed, fertilizer, furniture, brick and stone. It has had a council-manager form of government since 1949.

Highland Scots established the original settlement there in 1739 and named it Campbellton. A few years later other Highlanders founded the village of Cross Creek, one mile northwest of Campbellton, where they found two creeks whose currents crossed. In 1783 the two settlements united and were incorporated as Fayetteville, the first community so honouring the Marquis de La Fayette. Fayetteville served as the state capital from 1789 to 1793. There on Nov. 21, 1789, the second state ratifying convention approved the Constitution of the United States, which had been rejected the previous year at Hillsboro By 1820, with a population of approximately 3,500, Fayetteville was second only to Wilmington in size and commerce. It was the centre of the state's "wagon trade" and in the 1850s was the eastern terminal of the longest plank road ever built in the United States. Gen. William T. Sherman occupied the town in March 1865.

Points of interest include the Market House (built in 1838), which houses a public library and historical museum; the armory of the Fayetteville Independent Light infantry, organized in 1793; the State Teachers' College for Negroes (founded in 1877 and one of the earliest schools of its kind); and many monuments and old halls and houses. About 10 mi. northwest of the city are Fort Bragg and Pope air force base.

For comparative population figures *see* table in NORTH CAROLINA: *Population.* (H. T. *L.)*

FAYOLLE, MARIE EMILE (1852–1928), French soldier, entered the Polytechnique in 1873, joined the 16th regiment of artillery in 1875, entered, in 1889, the École de Guerre, where he was professor of the artillery course 1897–1907 and where, against orthodox opinion, he urged the importance of concentration of fire and the obstacle it offered to an attacker. Made a general of brigade in 1910, Fayolle, on the outbreak of World War I, was given command of the 70th reserve division, which, with the 77th, formed under Gen. Henri Pétain the 3rd army corps and played a brilliant part in the offensive of hlay 1915. In June 1915 Fayolle was given command of the 33rd corps, uhich he directed during the attack at Souchez and Vimy of September; in Feb. 1916 he was given the 6th army, which took part in the battle of the Somme, and in May 1917 succeeded Pétain at the head of the centre group of armies (holding the Champagne and Verdun fronts). After a few weeks in Italy he was recalled in Feb. 1918 in expectation of the German offensive, and in March took command of all the forces engaged between Péronne and Barisis—the reserve army group—and definitely checked by March 31 the German attempt to break through; he also carried out the two great offensives of July 18 and Aug. 8, 1918, and after the Armistice was entrusted with the occupation of the Rhine provinces. General Fayolle became a marshal of France on Feb. 21, 1921. He died on Aug. 27, 1928.

FAYRFAX, ROBERT (1464–1521), English composer, called by Anthony à Wood "the prime musician of the nation," was born at Deeping Gate, Lincolnshire. on April 23, 1464. Nothing is known of his career until 1497, when he was granted the first of a series of benefices by way of reward for his services as a singer and composer. He is referred to as one of the "Gentlemen of the King's Chapel," a position he held until the year of his death. Since Chapel Royal duties were of an occasional nature. Fayrfax was able to settle at St. Albans, Hertfordshire, where he directed the choir and played the organ at the abbey from 1498 onward. He gained the degrees of bachelor and doctor of music at Cambridge in 1501 and 1504 respectively, and wrote a five-part motet, *Aeterne laudis lilium,* for Elizabeth of York, who visited St. Albans in 1502. The work submitted for his Cambridge doctorate was the Mass *O quam glorifica,* based on a hymn melody for Vespers of the Assumption.

Fayrfax was made a "poor knight" of Windsor in 1514, and so received an extra pension; his position was such that frequent requests were made for the provision of music destined for court entertainments. On every New Year's day from 1516 to 1519 he was paid considerable sums of money for copying or composing books of songs and anthems. His greatest hour came in June 1520. when he was called upon to take charge of the Chapel Royal musicians when they accompanied Henry VIII to his meeting with Francis I at the Field of Cloth of Gold. Fayrfax died at St. Albans on Oct. 24, 1521.

The Masses by Fayrfax are based on antiphons such as *Regali ex progenie* (Nativity of the Blessed Virgin Mary), *Tecum principium* (Christmas) and *Alloquio dulcis,* the first nord of whose fifth line—"Albanus Domini laudans mirabile nomen"—gives the Mass its title and shows it to be in honour of St. Alban. The music of Fayrfax, which was published by the American Institute of Musicology (1960), proves him eminently worthy of the praise bestowed on him during his lifetime. (D. W. ST.)

FAYUM (FAIYUM), a *muhafazat* (governorate) of upper Egypt. having an area of 691 sq.mi. and a population (1960) of 839,000. The capital, Medinet-el-Fayum, is 81 mi. S.S.W. of Cairo by rail. The Fayum proper is an oasis in the Libyan desert, and is connected with the Nile by the Bahr Yusuf, which reaches the oasis through a gap in the hills separating the governorate from the Nile valley.

Southwest of the Fayum, and forming part of the governorate, is the Gharak depression. Another depression, entirely barren, the Wadi Rayan, covering 280 sq mi., lies west of the Gharak. The whole region is below sea level. and save for the gap mentioned is encircled by the Libyan hills. The lowest part of the governorate, the northwest end. is occupied by the Birkat Qaroun, or Lake of Qaroun, whose surface level is 140 ft. below that of the sea.

Differing from the typical oasis, the fertility of which depends on the nater obtained from springs, the cultivated land in the Fayum is formed of Nile mud which is brought down by the Bahr Yusuf and distributed from it by irrigation canals. More than 400 sq mi of the Fayum is cultivated, the principal crops being cereals and cotton. Completion of the Assuan dam, ensuring a much fuller supply of water, enabled thousands of acres of land to be brought under cultivation. Three crops are obtained in 20 months.

The governorate is noted for its figs and grapes, the figs being of exceptionally good quality. Olives are also cultivated. Rose trees are very numerous and most of the attar of roses of Egypt is manufactured in the governorate. The Fayum also possesses an excellent breed of sheep. The Lake of Qaroun abounds in fish.

hledinet-el-Fayum (or Medina), the capital of the governorate, is a great agricultural centre. pop. (1957) 89,448; area. 8 sq.mi. Mounds north of the town mark the site of Arsinoe, earlier Crocodilopolis. where was worshiped the sacred crocodile kept in the Lake of Moeris (*q.v.*). Besides Medina there are several other towns in the governorate, among them Senuris and Tomia to the north of Medina and Senaru and Abuksa on the road to the lake, some of which are served by railways. Near the lake are many ruins of ancient villages and cities. Fayum did not figure in the military operations of the summer and fall of 1942, Rommel's army having advanced and retreated along the coast line farther north. The British 8th army, however, took precautions against a possible drive farther south through the desert toward Cairo.

See H. J. L. Beadnell, *The Topography and Geology of the Fayum Province of Egypt* (1905); "Preliminary Report on Neolithic Pottery . . . From the Northern Fayum" in *Man,* no. *96 (1925).*

FAZUGHLI, a village and area in the Southern Fung district, Blue Nile province, Sudan, on the Blue Nile river, on the borders of Ethiopia. The area, composed of Fazughli East and Fazughli West, has a population of (1956) 13,507. The inhabitants are Bertat, Gumuz and other Negroid tribes, with Fung chiefs, of whom the principal is the Mek, living near Jebel Fazughli. His kingdom was part of the old Fung empire *(see* SENNAR). The villagers wash gold on the banks of the Blue Nile and in the beds of numerous watercourses. Pop. of village (1956 est.) 1.000. At Geissan, a trade route comes in from Abyssinia, by which coffee, cattle and gold are imported. The chief crop is millet and coarse tobacco is also grown along the river. (A. W. M. DY.)

FEALTY: *see* FEUDALISM; SEIGNORY.

FEAST AND FESTIVAL, as the terms are used in religion, are essentially synonymous ("festival" being the adjective form used also as a noun), properly describing an anniversary that is observed with rejoicing; "feast" is thus the opposite of "fast" *(see* FASTING). More generally, "feast" and "festival" also are applied to all such annual ceremonies and are not confined to those observed with rejoicing. This article deals only with festivals in early religions and in modern non-Judaeo-Christian religions. The feasts of the Christian liturgical year are described in the article CHURCH YEAR, and in many separate entries such as EASTER; CHRISTMAS; etc. Jewish festivals are discussed in the article

JEWISH HOLIDAYS. The word holiday ("holy day") in the purest sense also means a religious festival, but it has come to be used to describe any day on which a community or individual is relieved from the obligation of work, and hence has a largely secular connotation; secular holidays are discussed in the article HOLIDAY.

Major religious feasts and festivals, with few exceptions, are annual. The religious year not only represents a span of time but is also a representation of sacred events of the past eternally recurring. Just as the Christian year beginning with Advent is a re-enactment of sacred events, the year in other religions also presents a sacred cycle. Among historic religions, the cyclic re-creation of time is most explicit in the Zoroastrian New Year. The unrestrained character of most New Year festivals represents cyclic chaos before creation, and is most pronounced in primitive religions, though it survives in the Hindu *holi* and similar rites.

Festivals have an educational and social as well as religious character. In primitive cults having no written records, seasonal recital of mythology at festival time serves the function of transmitting traditional lore within the tribe. Festivals bind a religious group into a unity transcending family and local ties. Muslims of Arabia and Indonesia come into a socioreligious relationship despite separation by common observance of the festival associated nith the fast of Ramadan. Continuity between living and dead is maintained by communal offerings at festivals. and the cosmic order underlying social order is maintained by honouring the gods. Unity of "denominations" within religions, such as Shivites in Hinduism or Shi'ites in Islam, is secured by sectarian observances. The solidarity of the Greek or Mesopotamian city was celebrated by festal worship of the local deity, while larger political solidarity was preserved by subordinating local festivals in the context of a great national calendar. In primitive religions the festivals of the village deity perform the same role.

Great feast days recapitulate the history of religion in any given place. The pre-Christian cult of the dead in northern Europe survives in All Saints' day. The Thai New Year includes older primitive and Hindu aspects incorporated into the later Buddhist celebration. and the Sikh festival of hola is an adaptation of the older Hindu *holi*.

Primitive Religions. — The religious and social or tribal aspects of festivals cannot be separated, all activities being endowed with a religious or at least traditional character. In the Fiji Islands the inauguration of a new chief is celebrated as the re-creation of the world. In the Trobriand Islands the *baloma,* or spirits of the dead, are invited to join in harvest festivities. After dancing and feasting, they are dismissed. In this way the co-operation of the spirits with the living is assured. Among many groups, including Indian tribes of British Columbia, the entire social structure is transformed at festival times, religious ceremonial being performed by secret societies embracing the entire tribe rather than by usual social units. Initiation into manhood involves whole tribes in public festivities. Harvest, beginning of hunting, fishing or plowing seasons, first-fruit and harvest, and totemic gatherings are the commonest occasions for festivals in primitive societies.

Mesopotamia. — The cultures of the Tigris-Euphrates valley from the 4th millennium B.C. to the Persian conquest in the 6th century B.C displayed great continuity in religion. The central idea underlying festivals was that man was created for *dullu,* service of the gods, and that such service would assure man's well-being. Heaven nas an exact counterpart of earth, the gods having human characteristics. Worship included feeding, mashing and entertaining images. Daily service by priests was climaxed by great seasonal festivals. New Year (Akitu) in spring was the only festival celebrated continuously in all periods. Lasting from the 1st to the 10th of Nisan (March/April), it included a recounting of the Epic of Creation, public penance by the king for any misdeeds affecting the state, and divination of prosperity for the coming year. The king. then assumed the role of Tammuz, the vegetation god, and was married to the goddess Ishtar, thus assuring divine rule. The midsummer festival of Tammuz was widely celebrated. In addition to these, each temple had its own local calendar. The temple in which festivals were celebrated included a large court through which worshipers would pass, deposit gifts and hear liturgies. The role of the worshiper was passive, priests performing all cultic acts. (See also BABYLONIA AND ASSYRIA: Religion.)

Egypt. — The Egyptian cultus bore some external resemblance to the Mesopotamian. Most festivals were celebrated by priests alone. On a few great festivals, however, images of gods were fed and entertained by being carried in procession. The "coming forth" of Min, the fertility god, was typical. The statue was carried in public by priests together with lettuces, Min's sacred plant. The image was placed on a throne and offerings presented. Dancing and feasting accompanied such "comings forth." The greatest festivals were observed by towing barges bearing portable shrines along the Nile. The festival of Opet in which the god Amon was towed by the king's barge from Luxor to Karnak lasted as long as 27 days. At the Feast of the Valley Amon was towed to the graves of the kings to pour libations. Festivals in honour of the dead with offerings and lights were held at the beginning of each year.

The purpose of these and most Egyptian festivals was to celebrate and maintain the continuity of the living, the dead and the gods. Later cults included that of Osiris (*q.v.*), which spread to the Greek world. This included annual performances or religious dramas which developed into the well-known Hellenistic mysteries. After Osiris' coming forth in procession to be killed by his mythological foe, several days of mourning were held before his rising, which was celebrated with general festivity by his devotees. Mystery cults with their dramatic celebration embodied an element of personal devotion and offered salvation by identification of the devotee with the god which was not found in the official cult. the influence of which declined in Hellenistic times. (See also EGYPT: History: *Ancient* Religion; MYSTERY.)

Greece. — Festivals of ancient Greece were local in origin, each city-state having its o n calendar. The feasts of the country dneller were agricultural and chthonic, the gods of the Olympic pantheon being honoured in cities. The great festivals of 5th-century Athens. the influence of which extended to the rest of Greece, were the Dionysia and the Panathenaea (*qq.v.*). Processions, such as that portrayed on the frieze of the Parthenon, were a prominent feature of each festival. Public feasts were held, the citizens being entertained at the expense of the city. Drama. particularly tragedy, and games were parts of celebrations. Sparta's chief feast was the Hyacinthia. The festival of Soteria (deliverance) was held at Delphi. Festivals were observed with civic holidays which became secularized in later times. The religious meaning of the official cults declined in Hellenistic times, and mystery cults imported from Egypt and Asia Minor rose in importance. Festivals of these cults were celebrated only by initiated devotees. The mysteries of Osiris mentioned above were typical. (*See* also AGRIONIA; APATURIA; BUPHONIA; CARNEIA; DELIA: DAPHNEPHORIA; DEMETRIA; DIASIA; ANTHESTERIA; DELPHINIA; PYANOPSIA; THARGELIA; THESMOPHORIA.)

Rome. — The official cult of Rome included festivals for most of the gods of the pantheon. The oldest cult was the domestic worship of the hearth, which was elaborated into the cult of the vestal virgins who tended the hearth fire of the state. As the Greek pantheon was romanized, Greek characteristics of celebration were adopted. The festival of Mars (*q.v*), the war god, mas distinctively Roman, however. Celebration included a war dance by priests, running and rapid dancing being methods of instilling martial power. The feast of Saturn (*q.v.*) resembled a Greek harvest feast. Social distinction was forgotten, and all restrictions relaxed; thus the Saturnalia became associated with all forms of licence.

All festivals of the official calendar were civic holidays, and keeping the feasts was required by patriotism. The civil character of religion after the establishment of the empire became more pronounced, and imported mystery cults and Christianity answered actual religious needs. The cult of the Great Mother of Asia Minor, Cybele, and of Mithra, an Iranian deity, were popular. The great festival of Cybele was kept at the beginning of spring when the goddess was borne in procession to music. The story of the goddess seeking the body of her dead lover, and of the revival of Attis, was related. The mourning and rejoicing paralleled that of the Osiris cult of Egypt. (See also AMBARVALIA; BACCHANALIA; LECTISTERNIUM; LUPERCALIA.)

Northern Europe. — Festivals of pagan Germanic, Celtic and Slavic peoples were seasonal and observed with feasting and drinking, often to excess: They were generally celebrated in sacred groves. Four great seasonal festivals were kept: autumn (harvest), winter (Germanic Yule), spring and midsummer. At Germanic festivals sacrificial animals were eaten. According to the Ynglinga Saga, Odin ordained autumn sacrifices to celebrate a good year, Yule for growth and summer for victory. Among Saxons the dead were commemorated at autumn, while winter commemorations were common in Scandinavia. Celtic festivals were solar in character. The main ones were Sambain (Nov. 1) and Beltane (*q.v.;* May 1). On these days bonfires were lighted to represent the waning and waxing sun, and worshipers danced around the flames to acquire the power of the sun. These were essentially fertility rites. The May queen and May king of Beltane have survived in folk custom. At these times household fires were rekindled. Feb. 1 and Aug. 1 were also celebrated. Among Slavs the summer and winter solstices were major festivals. Popular pagan festivals were assimilated to saints' days after Christianization. St. John's eve (June 23) assumed characteristics of older midsummer festivals, and the Germanic cult of the dead was associated with All Saints' day. Ceremonial bathing at midsummer among pagan Slavs was reinterpreted as baptism.

Iran. — The festivals of ancient Iran have survived in the Parsee (Zoroastrian) community of Bombay, composed of refugees from Islamic invasions of the 8th century. Of the character of festivals in ancient times little is known, most information coming from Arab narratives of the middle ages. Each month of the Zoroastrian year had one sacred day (yasan) in honour of one of the *Amesha Spentas* (beneficent spirits) and *Yazatas* (angels) of Ahura Mazda. The great Parsee festivals are Nauruz (New Year), the feast of Mihrajan (Mithra), the 6th of Fravartin and the 11th of Din, birth and death days of Zoroaster. There are also six seasonal feasts celebrating the creation of heaven, water, earth: trees, animals and man, each lasting five days. The last also commeniorates the dead, a platform being erected in each home to bear flowers and fruit for the dead. Nauruz is also the feast of Ahura Mazda and the traditional day of creation, the celebration of which represents an annual re-creation of time. Ritual fire, the devotional centre of the Parsee temple, is rekindled.

Islam. — The great festivals of Islam are limited by tradition to two celebrated in conjunction with two of the "five pillars," or religious obligations, of Islam; pilgrimage (hajj) and the fast of Ramadan (*q.v.*). Few festivals other than these have developed, and such as have are shunned by the more orthodox. Cults of saints exist among mystical brotherhoods (dervish orders) and in the sectarian faith of Iran and parts of India (Shi'ism). Mohammed's insistence on the equality of believers, however, discouraged a multiplicity of saints' days. The radical break of Islam with earlier Arab paganism excluded older folk festivals from the calendar. The nomadic character of early Muslim life and the desert ideal of simplicity has been a deterrent to extravagant celebration such as that of Hinduism where local traditions are strong.

The pilgrimage which each Muslim is to perform at least once in life unless prevented by illness begins on the 8th of Dhu 'l-Hijja, the last month of the Muslim year. Having performed preliminary devotions, the pilgrim sets out from Mecca for the Mount of Mercy (Jabal ar-Rahma) about nine miles distant. On his return two days later, sacrifices are offered in the wayside village of Mina. The "great festival" (id *al-kabir* or 'id *al-adha;* Turkish *Qurban Bairam,* "Sacrifice Bairam") is celebrated throughout the Muslim world for three days beginning on the day of sacrifice in Mina. New clothes are worn, friends visited and gifts exchanged. The communal prayers are of a more archaic and solemn form than usual. The other major festival follows the fast of Ramadan, the ninth month. During this month no food is eaten from sunrise to sunset. During the first three days of the following month, Shawwal, the "little festival" (id as-Saghir or 'id *al-fitr,* "Festival of Fast-Breaking"; Turkish *Küchük* Bairam) is celebrated. Graves are visited and decorated on both festivals. (See also BAIRAM; RAMADAN.)

While orthodox (Sunnite) Islam does not sanction other feast days, sectarian (Shi'ite) Islam and the mystical Sufi tradition have introduced others such as the *maulid* (birthday) of the Prophet, first celebrated in 1207. Festivals of saints (*wali*) preserve primitive traits and are celebrated at local sanctuaries. The feast of Nebi Musa (Moses) is observed at a shrine near Jericho. Birthdays of founders of dervish orders regarded as saints by members of the brotherhoods are observed. The chief festival in Shi'ite Islam is the 10th of the month of Muharram, which commemorates the death of Husain, son of the caliph Ali, regarded by Shi'ites as the legitimate leader of the faithful and successor of the Prophet. His tomb in Iraq is a place of pilgrimage. A passion play depicting the death of Husain is performed. Among other Muslims, this day is remembered as the traditional day on which Adam and Eve were expelled from the Garden, and on which Noah left the ark. Other lesser days include Lailat al-qadr ("Night of Power") and the 15th of Shaaban, which, while not an official New Year, is kept with festivities resembling New Year celebrations. Such local unofficial festivities are often overladen with local superstitions.

Holy days of other faiths have been assimilated to popular Islamic usage. The day of 'Ashura (10th of Muharram) was the original fast day in imitation of the Jewish Day of Atonement before Mohammed prescribed the entire month of Ramadan. The Coptic Easter is observed by Egyptian Muslims, though naturally without its Christian meaning, and the Zoroastrian New Year (Nauruz) is observed in Iran. None of these, however, is sanctioned by orthodoxy.

All festivals are movable, the Muslim calendar consisting of a year of lunar months totaling 354 days. After 33 years! festivals are celebrated in all months of the western calendar. This removes the great feasts from the influence of non-Islamic seasonal rites, despite persistence of local customs in some unofficial celebrations. New Year festivities, prominent in other religions, have a minor role in Islam.

Buddhism. — Since Buddhism originated not as a popular religion but as a monastic order, the earliest festivals were associated with the monastic calendar and initiation into the *Sangha* (order). The first popular festivals commemorated events in the life of the Buddha. Buddhism, originating in the 6th century B.C. in India, spread rapidly throughout eastern Asia, but became extinct in its own homeland by the late middle ages. Thus festivals vary with country and sect. and have assimilated characteristics of various cultures. The festive calendar of northern (Mahayana) Buddhism, which recognizes several mythological Buddhas, Bodhisattvas and sectarian founders, is more complex than that of the southern (Theravada) school, where these figures are unknown.

Southeast Asia. — Festivals of Thailand illustrate the celebrations of the Theravada. Influences from pre-Buddhist indigenous and Hindu sources are prominent. Trut, or New Year (March/April), is of a mixed character. Buddhist monks exorcise ghosts from the vicinity and are presented with gifts. Oblations are made to various gods of Hindu origin. As people meet. water is playfully thrown by one on the other. Gambling, usually frowned upon, is permitted for the three-day festival. The main religious festival is Wesak (Pali Vishakha-puja), celebrated on the full moon of the month Vishakha (April/May), commemorating the birthday, enlightenment and death of the Buddha. Lasting for three days, it includes distribution of food and alms, decoration of dwellings with garlands and lanterns, and offerings of flowers to Buddha images. Captive birds are released in memory of the Buddha's compassionate nature. Other festivals include those at the beginning and end of the *vassa,* or rainy period, from June to October, when monks remain in the monastery. This is the traditional time for taking vows. The Magha-puja festival celebrates the Buddha's exposition of the *patimokkha,* or rule of monastic discipline. At the royal temple 1,250 tapers are lighted to commemorate the exposition to a like number of original monks.

Festivals in Burma and Ceylon follow the Thai pattern. Lesser festivals are associated with pilgrimage sites such as the temple containing the relic of the Buddha's tooth in Kandy, Ceylon.

Tibet.—Festivals in Mahayana lands vary greatly. In Tibet the birthdays of Padmasambhava (8th century A.D.), founder of Buddhism in Tibet, and Tson-k'a-pa (14th century), founder of the dominant sect, are celebrated in addition to events in the life of the Buddha. New Year (February) is celebrated with feasting, visiting and a relaxation of monastic discipline. The chief festival is sMon-lam (supplication), following the three-day New Year. Special religious observances are held for 11 days. Festivals of the various Bodhisattvas ("gods" of northern Buddhism) are also held. A feature of most Tibetan festivals is the propitiation of demons, a vestige of the Bon religion of pre-Buddhist days. This is prominent in the "Procession of the Thunderbolt" (Phurba, Sanskrit Vajra), an annual expulsion of demons from the country. This and most other major festivals are celebrated with fairs and masked plays.

China.—Specifically Buddhist festivals include the Buddha's birthday, when images are taken from temples, bathed and clothed, and legendary birthdays of various Mahayana figures, notably Kwan-yin, Bodhisattva of mercy; Mi-li Fo (Maitreya Buddha); and 0-mi-to Fo (Amida Buddha). On these days fairs are held near temples with theatrical performances.

Japan.—All sects join in celebrating the Buddha's birthday with floral offerings. Each of the sects observes the birthday of its founder and favourite Mahayana Buddha, these celebrations often exceeding those of the historical Buddha in elaborateness. Thus the sects of Zen, Shin, Shingon. Nichiren, Jōdo and others have their own calendars. Theatrical performances using classical dance forms are often given. One of the oldest festivals, Urabon-E, with elaborate temple dances re-enacts the story of Moggaliputta, the disciple of Buddha who saved his mother from hell by his offerings to the *Sangha*.

Jainism.—Like Buddhism, Jainism arose as a monastic movement in the 6th century B.C., but has not spread beyond India. Major festivals are associated with the monastic year. They are restrained in character, Jainism being intensely ascetic. The eight days of Pajjusana in August is a period of penance. During these days the birthday of Mahavira, founder of the Jain order, and the giving of the *Kalpa Sutra*, an important scripture. are celebrated with processions. Other festivals include an adaptation of the Hindu Diwali, and legendary birthdays of the 23 *tirthankaras*, predecessors of Mahavira, the last of a series of saviours. The strict sect of Digambaras observes the bathing in milk of the huge statue of the tirthankara Gommateshvara in Mysore several times each century.

Hinduism.— Festivals of contemporary India are derived from the sectarian Hinduism of the period after the writing of the Puranas (*c.* 4th century A.D.). Ancient festivals were mostly seasonal and observed with sacrifices described in the Vedas. The "four month festivals" were celebrated at the end of winter and at the beginnings of the rainy season and autumn. The Ashvamedha (horse sacrifice) was the most elaborate Vedic festival. Probably a spring fertility rite in origin, it was celebrated by a king who wished to claim universal sovereignty. A horse was let loose for a year to wander, protected by a royal guard which claimed for the king all land covered. At the end of the year, it was returned and sacrificed amid much feasting and unrestrained celebration. Vedic festivals were similar to those of other early Indo-European peoples, but as the Aryan invaders were absorbed by indigenous Dravidian peoples, these festivals fell into disuse and were replaced by those of medieval Hinduism.

Modern festivals are mostly connected with the worship of the great gods Shiva, Vishnu (generally in form of one of his avatars or incarnations) and Shakti. Many are associated with a place of pilgrimage sacred to a deity. Seasonal festivals, as holi, are celebrated by all sects and are popular, not sectarian, in origin. Some festivals are common to northern India, others to the south where Dravidian culture is strong. Many are purely local and are observed with fairs.

Holi, perhaps least religious in character, has features of a fertility rite. It is celebrated for five days in March/April with bonfires, unrestrained street dancing and processions. Red powder is thrown by celebrants on each other, and images of gods are borne in decorated cars. In Orissa the spring festival is associated with the Dolayatra (swing festival) in which images of Krishna, an avatar of Vishnu, and his consort Radha are ceremonially entertained in a swing. A seasonal festival restricted to the Dravidian south is Pongal, or the boiling of new rice. This is celebrated for three days and is the traditional Tamil New Year. In Bengal the New Year is marked by the worship of the Ganges.

Sectarian festivals are numerous among the devotees of Vishnu, since that god has several avatars. He is worshiped at Puri in Orissa as Jagannath (Juggernaut; *q.v.*), or lord of the norld, his image being pulled in an immense car by devotees at the Rathayatra festival (June/July). Prayers, offerings. dancing and bathing are performed and religious narratives read. A Krishna festival of the Maratha country is the Rasayatra commemorating the dancing of the god with the cow-maids (*gopi*) of legend. The birthday of Krishna is celebrated in August/September and that of Rama, another avatar, is celebrated in March/April. In all festivals the image is bathed, clothed and entertained according to ritual prescription (*puja*) and Puranas are read.

Shiva has no avatars, and so his calendar is simpler. The 14th day of each lunar period is especially sacred, and that of Magha (January/February) is observed as the Shivarati festival.

The great festival of Shakti (called also Durga and Kali), consort of Shiva worshiped as a deity in her own right in Bengal, is the Durga-puja. Celebrated in September/October, it is a time for family reunion and social gathering as well as religious observances. Animal sacrifices, virtually unknown elsewhere, are offered in Calcutta.

Purification by bathing is a feature of most Hindu festivals. This is particularly evident at those observed at places of pilgrimage located at confluences of rivers.

Other major festivals include Dashara (worship of the Ganges), Lakshmi-puja (goddess of wealth), Sarasvati-puja (goddess of knonledge) and Diwali. celebrated at night with lights. Birthdays of traditional sages and founders of sects are also celebrated.

Hindu festivals have spread to the predominantly Buddhist lands of southeast Asia and Nepal. They are preserved unmixed with other types in Bali. (See also HINDUISM: Festivals.)

Sikhism.— Festivals of Hinduism have been adapted by Sikhism, a monotheistic faith founded in the Punjab in the 16th century by the Hindu reformer Nanak. The orgiastic Hindu holi has been refined and the red powder thrown is allegorized as sat nam ("true name"; *i.e.*, of god), the name having been changed to *hola*. The Sikh calendar also includes festivals of the gurus, or teachers, and of martyrs.

China.—Popular Chinese religion is an amalgam of Confucian, Taoist and Buddhist beliefs imposed on a background of more primitive folk belief. Great Confucian festivals such as the imperial sacrifices at solstices and equinoxes are no longer observed, Confucianism as a state religion having collapsed with the fall of the empire. Specifically Buddhist (see above. Buddhism) or Taoist festivals are observed only by a small percentage of the population, though each religion has had a profound influence on popular festivals. The carnival spirit of later Taoism is particularly evident. Festivals associated with temples, Buddhist or Taoist, are local in spirit and usually accompanied by fairs and theatrical performances. The specifically religious motivation is secondary to the social character of the holiday.

The great festivals are seasonal. New Year is celebrated officially for a month beginning in late January or early February. It is preceded by an expulsion of demons and by theatrical performances. Offerings are made to gods of hearth and wealth, and to ancestors. The spring festival (Ch'ing-ming) is observed with sweeping of graves and rekindling of hearth fires. Ceremonial meals at ancestral tombs and family reunions mark the festival, which usually coincides with Easter. Before the rise of Buddhism in China, the festival had an agrarian fertility quality which has been displaced by the commemoration of the dead, The Feast of the Souls in August and the winter festival in November also commemorate the dead. The midautumn festival, like New Year, is a festival of the living and gay in character. An altar is built out-of-doors and "moon cakes" are offered to the "old man in the moon." This is a family festival, and the role of women is prominent. In addition to these seasonal festivals, each temple may have its own patron deity whose birthday is celebrated. Such festivals are rooted in village life.

Japan. — Shinto, the ancient religion of Japan, was obscured by the introduction of Buddhism in the 6th century A.D., though it survived as a popular nature religion, particularly in rural areas. and in mixed form with Buddhism. The revival of Shinto and its purification from Buddhist elements began in the 17th century, but was completed only with the Meiji restoration of 1868. The present form of festivals is therefore recent, though elements of celebration are ancient. Purification is a prominent feature of all Shinto festivals. Ceremonial bathing, food and cloth offerings and waving of "purification viands" with recitation of ritual formulas (norito) are modes of ritual, New Year is celebrated with ceremonial house cleaning, giving of presents, presentation of cakes to household shrines, and offerings of rice to sources of household water. Many Shinto festivals are observed at local shrines.

After 1945 and the disestablishment of Shinto as the state religion, the religious meaning of the festivals diminished, though they remain as legal holidays. "Sect Shinto," a generic term covering various cults of modern origin, observes birthdays of sect founders as well as days of patron deities. (See also SHINTO: Shinto After *World* War II.)

Traditional Festivals and Modern Thought. — The growth of modern nationalism and the impact of western civilization, leading to either religious reform or secularism and an attendant decline in the value of tradition, has diminished the meaning of many festivals. This is particularly true of China, Japan and to some extent India. While in Muslim lands religious observances re-enforce political unity and, internationally, Islamic solidarity, traditional piety has diminished. In China the spring festival has been perpetuated under communism, though without religious overtones, Modern Hindu philosophy and religious reform have resulted in a calculated neglect, on the part of the educated classes, of traditional festivals rooted in Puranic lore. As modern trends modify traditional beliefs, festivals are reinterpreted, secularized or discarded in many cases.

FEATHER, a horny outgrowth of the skin peculiar to birds. Collectively, in any individual, feathers form a complete body covering. While they are supposed on good general grounds to have evolved from the scales of reptilian ancestors, no intermediate gradations are known to exist between the two. Birds may therefore be distinguished from all other animals by the possession of feathers alone, though this class is distinguished from others by many characters (see BIRD). Feathers are composed entirely of a single horny substance, keratin, but in spite of this fact they are among the most remarkable of organic structures with reference to the variety and complexity of their structure and function.

A complete adult feather is bilaterally symmetrical and comprises a tapering axial rod, the shaft (rachis), to which are attached a large number of lateral tapering rods, barbs (rami), forming an acute distal angle with the rachis, and carrying many minute elongated barbules (radii) both on their distal and proximal faces, uhich interlock with those of adjacent barbs so as to form a coherent membrane, the vane (vexillum), in the exposed portion of the feather. In the covered basal portion the barbs do not cohere and their structure is loose and fluffy. The outer (dorsal) surface of the vane differs notably in colour and also in other respects from the ventral surface.

The rachis exhibits clearly differentiated dorsal, ventral and lateral surfaces, and tends to be quadrangular in cross-section. It is structurally continuous nith a short cylindrical quill (calamus), which is inserted in a pit of the skin, the follicle, and uhich differs also from the rachis by complete absence of barbs; the calamus possesses a terminal opening, the inferior umbilicus, enclosing the papilla, and a ventral pit, superior umbilicus, at its junction nith the rachis from which small tufts of barbs or a complete afterfeather emerges. The calamus is hollow and the cavity is subdivided by a series of horny concave partitions, persistent remains of the feather caps that protect the apex of the pulp during the growth of the feather. The fibrous wall of the rachis on the other hand encloses a relatively massive medulla composed of air-filled vesicles of microscopic size, and thus the rachis combines strength and lightness.

The barbs are somewhat lath-shaped, set on edge and tapering to a point Their intimate relation to the rachis may be brought out by dissecting a feather previously softened by a bath of 5% caustic potash. The dissection shows that the lateral surfaces of the rachis are composed of flattened bases of barbs, the barb petioles, bent at an obtuse angle from the free portion of the barbs, overlapping one another serially and bound firmly to the central part of the rachis by keratin fibres. Each petiole carries an extension of the series of proximal barbules which thus appear in the intact feather to arise from the rachis itself. The distal barbules overlap the proximal barbules of the next barb, and each bears a series of hooklets (hamuli) which catch in a groove continuous along the surface of the proximal series. This arrangement ensures firmness of union together nith freedom of movement. In the fluffy, covered portion of a body feather the barbules become relatively long delicate threads (cilia) and do not bind the successive barbs together. In the different kinds of feathers of the same species and a fortiori of different species, there is an immense amount of variation of the structures described above.

The afterfeather (called in older literature aftershaft or hyporachis) is borne on the ventral surface of contour feathers with its own ventral surface applied to the homologous surface of the main feather. Its shaft is inserted in the superior umbilicus of the main feather, with which it shares a common calamus. Its degree of development is highly variable not only in different birds, but also in different tracts of the same bird. In the cassouary and emu the afterfeather is equal in length and size to the main feather; but in other birds it does not exceed the length of the fluffy portion of the main feather, usually much shorter, and always narrower and entirely fluffy in structure. In fowl it is well-developed in unspecialized contour feathers, but is practically absent, or represented only by a few barbs, in the flight and tail feathers. Pattern, rarely present, is a mirror image of the corresponding portion of the main feather due to a kind of twinning process in its origin.

Kinds of Feathers and Their Arrangement. — The definitive plumage (teleoptiles) bears the full brunt of the external environment during the active life of the individual, and during the long process of evolution of birds has become extraordinarily diversified. It is customary to distinguish three main kinds of definitive feathers in any individual: first, the contour feathers. including all those visible externally uhich define the form of the body; second, the filoplumes; and, third, the down feathers (plumules). Among the contour feathers, those of flight (remiges). and the tail feathers (rectrices, steering feathers) are specially distinguished from the general body covering. Contour feathers are not, as popularly supposed, evenly distributed over the surface of the body of the bird, but arise only from certain tracts (pterylae), separated by regions of almost naked skin (apteria). To this rule the only exceptions are the ostrich-like birds (superorder Palaengnathae), the penguins (order Sphenisciformes) and the South American "screamers" (family Anhimidae), in vrhich the even distribution of plumage has probably been secondarily acquired. The classical work on the pterylosis of birds is that of Nitzsch; cf., also, Nenton's *Dictionary* of *Birds.* The pterylae differ in their conformation in different species of birds and hence are of service in systematic ornithology.

The wing tract comprises the flight feathers proper (remiges) and their coverts (tectrices). The former comprise primaries, arising from the hand, and attached to its skeleton; secondaries, arising from the forearm, and attached to the ulna; and tertials, arising from the upper arm, and attached to the humerus. The latter comprise on the upper surface of the wing the greater, median and lesser coverts, the first of which cover the bases of the remiges, the second and third overlapping in ascending order with decrease of size. The dorsal (spinal) tract extends the whole length of the bird, excepting the head, along and on each side of the spinal column. In fowl this tract may be subdivided from in front backwards, though not separated by apteria, into the regions of the hackles, the cape, the back, and the saddle, which are distinguished by the forms and patterns of the constituent feathers. This tract is highly variable in different species of birds. On the ventral surface of the bird are the breast tracts, which are paired, extending from the neck backwards in diverging pterylae, betueen which is a ventral (abdominal) tract, extended on either side of the middle line around the region of the umbilicus and meeting in front of the anus. The tracts of the ventral surface of the body are likewise highly variable in different groups and species of birds. The tail tract includes the tail feathers (rectrices) and their coverts. In addition to the above, there are to be distinguished the head tract, the humeral tract (scapulars), the femoral tract and the crural tract.

Filoplumes are inconspicuous hair-like feathers arising at the bases of contour feathers and bearing a small tuft of barbs at the apex. They appear to be present in all birds, but only in certain species do they project beyond the contour feathers (*e.g.,* on the thighs of cormorants).

The down feathers are usually completely concealed by the contour feathers. They are usually scanty and occur both in the pterylae and apteria, but they form in many birds, such as gulls and ducks, a thick underclothing comparable to the underfur of seals. Their barbs do not form coherent vanes, but are long, loose, soft and fluffy. Their structure is much simplified and a rachis may be entirely lacking. In herons they reach a special development and form large patches on the breast and thighs, known as powder down, and their tips disintegrate into a fine scaly powder which becomes distributed over the plumage to which it lends a peculiar sheen; and apparently the powder also functions as protection against wetting.

The nestling down (neossoptiles) are the first feathers to be formed from the papillae of the tracts, and thus they occupy the positions of the definitive contour feathers by which they are later replaced. They develop before hatching in most birds and constitute the downy covering of the chicks. Each consists of a circlet of delicate barbs attached directly to a horny ring (the calamus), a shaft being lacking. They are soon pushed out of their follicles by the developing juvenile feathers and lost. Filiform barbules occur in a roughly paired arrangement best developed near the bases of the barbs.

Moulting. — If a feather is lost for any accidental reason the papilla at the bottom of the follicle is capable of replacing it immediately. But in addition to this there is in all birds a naturally occurring annual shedding and replacement of all feathers; this is known as moulting. Feathers, like hairs, are dead structures, but their growth is not so continuous; each rapidly attains a certain length in its growth and must then serve all purposes until it is replaced. The general purpose of the annual moult may thus be conceived to be a process of compensation for the wear and tear of the bird's existence. It occurs at a variable time after the breeding season, and is usually gradual. In penguins, however, the entire plumage is shed at one time. Flight feathers are usually shed and replaced in a certain order and the poner of flight is not lost. In many birds there is a second moult intimately related to the breeding season. The males of ducks and geese assume an inconspicuous "eclipse" plumage similar to that of the female after this moult, which follows immediately after the breeding season, and retain it for several months; during a large part of this time the birds are incapable of flight owing to simultaneous loss of the flight feathers, but when they are replaced the decorative male plumage is resumed. In other birds a special "nuptial" plumage covering the mating and breeding season is assumed in males, and dropped soon after the young appear. The process of moulting is a severe strain on the bird owing to the tremendous supply of blood to the skin necessary for the growth of the new feathers.

The Development of Feathers. — Feathers arise from cutaneous papillae consisting of a relatively massive dermal core covered by a thin layer of epidermis; those of contour feathers make their first appearance in embryonic life as elevations on the surface of the body. In the case of fowl they arise between the sixth and ninth days of incubation, and are grouped from the first in the definitive feather tracts. New papillae are not formed thereafter and there is therefore complete correspondence in number and arrangement between the embryonic papillae and the contour feathers of the adult. Before hatching, the papillae become sunk beneath the surface of the skin in tubular follicles lined with epidermis and opening on the surface of the skin. After the formation of the nestling feathers. new feathers arise from the papillae at the bottom of the follicles after moulting or plucking of the preceding feather. The papilla is necessary for the origin of a feather; if it be destroyed, no feather forms thereafter from the operated follicle; it is in fact a true feather germ. nhich has the capacity to form a feather characteristic of the age. the sex and tract of the individual to which it belongs.

The developing papilla gives rise to a feather cylinder enclosed in a horny sheath. which soon emerges from the mouth of the follicle ("pin-feather"). As the cylinder grows in length the sheath ruptures at its apex and the tip of the feather formed within emerges and unfolds, the remainder following during the process of growth. The cylinder is composed of a thick epidermal wall and a dermal core (the pulp), richly supplied with blood for the nutrition of the rapidly growing feather. In the epidermal wall three layers may be distinguished: the external *stratum corneum* nhich forms the sheath, a thick *stratum intermedium* which forms the feather, and an internal *stratum cylindricum* in immediate contact with the pulp. These layers are derived from a ring of embryonic epidermal cells, the "collar," which surrounds the persistent dermal papilla, the immediate source of the pulp. Feather cylinders are inclined posteriorly from the start and thus exhibit an external (dorsal) surface, corresponding to the dorsal surface of the feather along which the rachis of the feather develops, and an internal (ventral) surface. This is an expression of an innate bilateral symmetry of the papilla nhich may be demonstrated by rotating the papilla along its long axis. in which event the resulting feather is inverted with its ventral surface up and its dorsal surface down. Papillae also possess the innate specific properties of the tracts to which they belong. so that, *e.g.,* a papilla of the saddle tract transplanted to the breast tract produces a saddle feather in the new location. Supplementing these two innate properties of the papilla, bilateral symmetry and tract specificity, parts of papillae tend to retain their prospective significance; striking results may be shown by transplanting a dorsal sector of one papilla to a groove in the ventral surface of another, producing twin conjoined feathers in a single follicle face to face—of the same sort if the graft be from the same tract or of different sorts if the graft be from a different tract. Bfodifications of the same technique may lead to the production of single "chimaera" feathers, part of which exhibits the characters of one tract and the remainder those of another. In short, these three properties of the papilla permit a variety of experiments analogous to those performed on the egg in experimental embryology.

The organization of the feather cylinder may be clearly shown in preparations in which the wall of the cylinder is split longitudinally. beginning at the opening of the collar, and spread out flat with the inner surface up. This represents a fixed moment in a moving panorama. The apexes of the barbs of opposite vanes —at this time "ridges" of the stratum intermedium — meet in the ventral line of the cylinder; the bases arise from the collar and the rachis. As the panorama moves each barb ridge increases in length (axial growth) and moves along the collar towards the rachis to which it becomes attached (tangential growth). Thus each barb, when completely formed, describes a half spiral in the wall of the cylinder. Within each ridge the barbules differentiate.

The axial growth of a regenerating feather is very rapid: about the middle of its period of growth the increase in length of a saddle feather of a Brown Leghorn capon is about 2 mm. per day, that of a feather from the posterior part of the breast tract is about 2.5 mm. and that of a tail feather about 5 mm. All of this growth takes place near the collar and the type and pattern of the feather is determined in the same region. The total time required for regeneration of feathers also varies in the different tracts, rates and time combining to determine the length finally attained.

Colours of Feathers. — Among the factors that combine to form the colours of feathers, the behaviour of certain cells, originating external to the feather germ proper, is of outstanding significance. These are the pigment-bearing cells (melanophores). When fully formed, they are very large cells filled with black. brownish or reddish granules, and are situated in a row near the summit of the barb ridges along their entire length during the development of the feather. They send out processes along the rows of the barbule-forming cells and feed the granules into each cell, gradually exhausting their supply in this function. Thus the pigmentation of the vane is determined. An excellent account of this process may be found in R. M. Strong's paper. Similarly the pigmentation of the shaft and of the barbs is derived from the melanophores.

Melanophores have a very curious origin. They have been traced back to the neural crest of the embryo, situated on each side of the spinal cord. They are at first small unpigmented cells (melanoblasts), which have the capacity of migrating into areas to be pigmented later, such as the choroid coat of the eye as well as into the feather germs, there increasing in size and developing their pigment. It is possible to catch them in transit by removing small pieces of skin and underlying neural crest cells at about 70 hours of incubation of a chick embryo, and to demonstrate their presence in the case of a pigmented breed by grafting the piece to an embryo of the same age of a white breed of fowl. If the transplant is made to one wing bud, a chick results which has one wing with pigmented feathers and the other wing with white feathers. Moreover, if the donor belongs to a barred breed of fowl, the barred pattern forms on the host feathers of the pigmented wing; but if the donor belongs to a solid black breed the pigmented wing of the host is solid black. This may be generalized by saying that the genetic constitution of the donor determines the behaviour of their melanophores.

The range of colours determined directly by the melanophores is limited to black, gray and brownish. Other pigmentary colours are produced by the presence of diffuse (nongranular) fatty pigments (lipochromes) present in appropriate cells; red is always so determined, and orange and yellow usually. Such chemical, or absorptive, colours remain the same from whatever angle, with reference to the source of light, they may be examined.

Structural colours are produced by a superficial colourless layer of extreme thinness, ranging slightly above or below 1/1000 mm., overlying pigment; in transmitted light only the colour of the pigment appears — gray or yellowish in the green feathers of a parrot for instance. In the case of blue feathers, there is. in addition to the superficial colourless layer, a layer of polygonal cells with highly refractive walls overlying brown, black or orange melanophores. Blue never occurs as a pigment. All metallic or prismatic colours, to which the flashing brilliance of hummingbirds, for example, is due, are structural colours. These change, as is well known; they alter with the position of the observer with reference to the source of light, "always in the order of the rainbow." This iridescence is due to the nature of the thin superficial colourless layer. The more generally accepted view has been that the superficial layer, oning to fine striation, acts like a grating dispersing the light in prismatic fashion; but the eminent physicist A. A. Michelson (1911) regards this as exceptional and classes the phenomenon of iridescence with the reflection from polished metal surfaces or thin layers of aniline dyes.

Sexual Dimorphism of Feathers and its Control.—We may take the well-known difference in plumage between hen and cock of the domestic fowl to begin with. Breeding is more or less continuous throughout the year and the plumage does not show seasonal variations; the feathers of the body of the hen are relatively uniform and inconspicuous in form, colour and pattern, while those of the male are much more diversified in the various tracts. This, however, is not the case in all breeds; in Seabright Bantams, as an example, the males also are "hen-feathered." In a highly dimorphic breed, such as the Brown Leghorn, the male is quite resplendent compared with the modest female. The long, drooping, lacy, golden feathers of the saddle tract of the cock, compared with the short, round-tipped, stippled feathers of the hen of this breed, are a good example. However, the same potentialities are present in both sexes, and the differences are due mainly to the sex hormone of the female secreted by the ovary which suppresses cock plumage. If the ovary of the female be removed, the bird assumes the plumage of the cock, whereas castration in the male does not modify the type of its plumage, however fundamentally it may alter other sex-characters. In the Seabright, the testes of the male likewise suppress cock plumage, and castrates of both sexes are cock-feathered.

Here is a relatively simple mechanism for control of sexual plumage dimorphism. But it is by no means the only, or perhaps even the most common, mechanism of control in birds. Where the sex dimorphism is seasonal, as is usual in wild birds, and the male dons his decorative plumage only for the short breeding season after a second moult, castration often does not alter the seasonal change, which is attributed to action of the genes (*e.g.*, the indigo bunting, and African weaver finches). In pheasants, the sex dimorphism of the feathers seems to rest on a combination of genic and endocrine factors (Danforth). In short, whatever the functional significance of the sex dimorphism of plumage may be, it appears to depend in different cases upon different mechanisms of control presumably evolved to suit different habits of life in most cases.

(F. R. L.)

Commercial Applications of Feathers. — The chief purposes for which feathers become commercially valuable may be comprehended under four divisions: — (1) Bed and upholstery feathers; (2) quills for writing; (3) ornamental feathers; and (4) miscellaneous uses.

Bed and Upholstery Feathers. — The qualities which render feathers available for stuffing beds, cushions, etc., are lightness, elasticity, freedom from matting and softness. These are combined in the most satisfactory degree in the feathers of the goose and allied aquatic birds. Goose feathers and down, when plucked in spring from the living bird, are most esteemed. The down of the eider duck, Somateria *mollissima,* is valued above all other substances for lightness, softness and elasticity; but it has some tendency to mat, and is consequently more used for quilts and in articles of clothing than unmixed for stuffing beds. The feathers of swans, ducks and the domestic fowl are also largely employed for beds; but in the latter bird, the feathers are harsher and less downy than are those of the natatorial birds generally.

Quills for Writing. — The earliest period at which the use of quill feathers for writing is recorded is the 6th century; and from that time till the introduction of steel pens early in the 19th century they formed the principal writing implements of civilized communities. It has always been from the goose that quills have been chiefly obtained, although the swan, crow, eagle, owl, hawk and turkey all have been laid under contribution. Swan quills are better than are those from the goose, and for fine lines crow quills have been much employed. Only the five outer wing feathers of the goose are useful for writing, and of these the second and third are the best, while left-wing quills are more esteemed than those of the right as they curve outward and away from the writer using them. Quills obtained in spring from living birds are the best.

Ornamental Feathers. — Feathers do not appear to have been much used in Europe for ornamental purposes till the close of the 13th century; during Elizabeth's reign feathers began to occupy an important place as headdress ornaments of women. Ostrich feathers hold a pre-eminent position among ornamental feathers; and the ostrich is the only bird reared exclusively for the sake of its feathers. Ostrich farming is one of the established industries of South Africa, and is also practised in North Africa, Argentina, Arizona and California. The feathers are cut from the living animal and the stumps withdrawn later. In the male, the long feathers of the tail and wings are white, and the short feathers of the body are jet black, while the tail and wing feathers of the female are white, tinged with a dusky gray. The feathers of the male are consequently much more valuable than those of the female, and are separately classified in commerce. The art of the plumassier embraces the cleaning, bleaching, dyeing, curling and making up of ostrich and other plumes and feathers.

In addition to those of the ostrich, the feathers of certain other birds form articles of steady commercial demand. Among these are the feathers of the South American ostrich, Rhea *americana,* the marabout feathers of India obtained from *Leptoptilos dubius* and L. *javanicus,* and of Africa from L. *crumeniferus,* the aigrettes of the heron, the feathers of the various species of birds of paradise, and of numerous species of hummingbirds.

Miscellaneous Applications of Feathers.—Quills of various sizes are extensively employed as holders for the sable and camel hair brushes used by artists, etc. Feather brushes and dusters are made from the wing feathers of the domestic fowl and other birds; those of a superior quality, under the name of vulture dusters, being really made of American ostrich feathers. A minor application of feathers is found in the dressing of artificial flyhooks for fishing. (W. P. P.)

FEATHER STARS, the popular name for the beautiful starfish (*q.v.*) of the class Crinoidea (see ECHINODERMA), from their branched feathery arms; also called comatulids.

FEATHERSTONE, an urban district in the Pontefract parliamentary division of the West Riding of Yorkshire, Eng., 9 mi. E. of Wakefield. Pop. (1951) 13,935. Area 6.9 sq.mi. Roman remains have been found in the area. Purston park has been developed, and the town hall was opened in Jan. 1956. The town's main industries are coal mining and agriculture.

FEATLEY or FAIRCLOUGH, **DANIEL** (1582–1645), English divine, was born at Charlton, Oxfordshire, on March 15, 1582. His varied activities included a "scholastick duel" with James I in 1625, and the publication of (1) the report of a conference with some Jesuits in 1624, (2) a devotional manual entitled *Ancilla Pietatis* (1626), (3) *Mystica Clavis,* a Key opening divers *Difficult* Texts of *Scripture* in 70 Sermons (1636). He was appointed provost of Chelsea college in 1630, and in 1641 was one of the subcommittee "to settle religion." He sat in the Westminster assembly 1643, and was the last of the Episcopal members to remain. For revealing its proceedings he was expelled and imprisoned. He died at Chelsea on April 17, 1645.

FEBRONIANISM, the name given to a powerful movement within the Roman Catholic Church in Germany, in the latter part of the 18th century, directed towards the "nationalizing" of Catholicism, the restriction of the monarchical power usurped by the papacy at the expense of the episcopate, and the reunion of the dissident churches with Catholic Christendom. It was thus, in its main tendencies, the equivalent of what in France is known as Gallicanism (*q.v.*). The name is derived from the pseudonym of "Justinus Febronius" adopted by Johann Nikolaus von Hontheim (*q.v.*), coadjutor bishop of Trèves (Trier), in publishing his work De statu ecclesiae *et* legitima potestate Romani *pontificis.*

Papal Fallibility. — The main propositions defended by "Febronius" were as follows: The constitution of the Church is not, by Christ's institution, monarchical, and the pope, though entitled to a certain primacy, is subordinate to the universal Church. Though as the "centre of unity" he may be regarded as the guardian and champion of the ecclesiastical law, and though he may propose laws, and send legates on the affairs of his primacy, his sovereignty (*principatus*) over the Church is not one of jurisdiction, but of order and collaboration (*ordinis et consociationis*). The Roman (ultramontane) doctrine of papal infallibility is not accepted "by the other Catholic Churches" and, moreover, "has no practical utility." The Church is based on the one episcopacy common to all bishops, the pope being only *primus* inter pares. It follows that the pope is subject to general councils, in which the bishops are his colleagues (*conjudices*), not merely his consultors; nor has he the exclusive right to summon such councils. The decrees of general councils need not be confirmed by the pope nor can they be altered by him; on the other hand, appeal may be made from papal decisions to a general council. As for the rights of the popes in such matters as appeals, reservations, the confirmation, translation and deposition of bishops, these belong properly to the bishops in provincial synods, and were usurped by the papacy gradually as the result of a variety of causes, notably of the False Decretals (see DECRETALS). For the health of the Church it is therefore necessary to restore matters to their condition before the False Decretals, and to give to the episcopate its due authority. The main obstacle to this is not the pope himself, but the Curia, and this must be fought by all possible means, especially by thorough popular education (*primum adversus* abusum ecclesiasticae potestatis remedium), and by the assembling of national and provincial synods, the neglect of which is the main cause of the Church's woes. If the pope will not move in the matter, the princes, and notably the emperor, must act in co-operation with the bishops, summon national councils even against the pope's will, defy his excommunication, and in the last resort refuse obedience in those matters over which the papacy has usurped jurisdiction.

The Revolt of the Princes. — The views of Febronius had but little originality. In the main they were those that predominated in the great general councils of Constance and Basel in the 15th century; but they were backed by him with such a wealth of learning, and they fitted so well into the intellectual and political conditions of the time, that they found a widespread acceptance. The book, indeed, was at once condemned at Rome (February 1764), and by a brief of the 21st of May the pope commanded all the bishops of Germany to suppress it. The papal condemnation met with a very mixed reception; in some dioceses the order to prohibit the book was ignored, in others action upon it was postponed pending an independent examination, in yet others (nine in all) it was at once obeyed "for political reasons," though even in these the forbidden book became the "breviary of the governments." The Febronian doctrine, in fact, exactly fitted the views of the German bishops, which were by no means disinterested. It must be remembered that the bishops were at this time great secular princes rather than Catholic prelates; with rare exceptions, they made no pretence of carrying out their spiritual duties; they shared to the full in the somewhat shallow "enlightenment" of the age. As princes of the Empire they had asserted their practical independence of the emperor; they were irked by what they considered the unjustifiable interference of the Curia with their sovereign prerogatives, and wished to establish their independence of the pope also. In the ranks of the hierarchy, then, selfish motives combined with others more respectable to secure the acceptance of the Febronian position. Among secular rulers the welcome given to it was less equivocal. Even so devout a sovereign as Maria Theresa refused to allow "Febronius" to be forbidden in the Habsburg dominions; her son, the emperor Joseph II., applied the Febronian principles with remorseless thoroughness. In Venice, in Tuscany, in Naples, in Portugal, they inspired the vigorous efforts of "enlightened despots" to reform the Church from above; and they gave a fresh impetus to the movement against the Jesuits, which, under pressure of the secular governments, culminated in the suppression of the society by Pope Clement XIV. in 1773.

Roman Victory. — Whether the "Febronian movement" would have led to a reconstitution of the Roman Catholic Church on permanently Febronian lines must for ever remain doubtful. The French Revolution intervened; the German Church went down in the storm; and in 1803 the secularizations carried out by order of the First Consul put an end to the temporal ambitions of its prelates. Febronianism, indeed, survived. Karl Theodor von Dalberg, prince primate of the Confederation of the Rhine, upheld its principles throughout the Napoleonic epoch and hoped to establish them in the new Germany to be created by the congress of Vienna. He sent to this assembly, as representative of the German Church, Bishop von Wessenberg, who in his diocese of Constance had not hesitated to apply Febronian principles in reforming, on his own authority, the services and discipline of the Church. But the times were not favourable for such experiments. The tide of reaction after the Revolutionary turmoil was setting strongly in the direction of traditional authority, in religion as in politics, and that ultramontane movement which, before the century was ended, was to dominate the Church, was already showing signs of vigorous life. Moreover, the great national German Church of which Dalberg had a vision — with himself as primate — did not appeal to the German princes, tenacious of their newly acquired status as European powers. One by one these entered into concordats with Rome, and Febronianism from an aggressive policy subsided into a speculative opinion. As such it survived strongly, especially in the universities (Bonn particularly had been, from its foundation in 1774, very Febronian), and it reasserted itself vigorously in the attitude of many of the most learned German prelates and professors towards the question of the definition of the dogma of papal infallibility in 1870. It was, in fact, against the Febronian position that the decrees of the Vatican Council were deliberately directed, and their promulgation marked the triumph of the ultramontane view (see VATICAN COUNCIL, ULTRAMONTANISM, PAPACY). In Germany, indeed, the struggle against the papal monarchy was carried on for a while by the governments on the so-called *Kulturkampf,* the Old Catholics representing militant Febronianism. The latter, however, after Bismarck "went to Canossa," sank into a respectable but comparatively obscure sect, and Febronianism, though it still continued some hold on opinion within the Church in the chapters and universities of the Rhine provinces, became practically extinct in Germany. The Modernist crisis (1907) brought no challenge to Catholic unity in Germany, since Catholic scholarship there was far enough advanced to parry the blow easily. The effect of the Hitlerian doctrines on the German Catholic population was not entirely clear at the start of World War II.

BIBLIOGRAPHY —*See* A Fortescue's article "Febronianisrn" in Hasting~*Encyclopaedia of Religion and Ethics,* and the article of Friedrich Lauchert in the *Catholic Encyclopedia.*

FEBRUARY (Lat. *Februarius*) is the second month of the modern calendar, with 28 days (29 in bissextile or leap years). In the early Roman calendar it was the 12th month, primarily devoted, in anticipation of the new year, to ceremonies of purification and the cult of the dead: hence its name, derived from februare, "to purify."

The designation of leap-year day as February 29 is relatively modem and only gradually prevailed. In the Julian calendar, as still in some liturgical calendars, the extra day was inserted before the 24th. This accounts for the term bissextile, since the Romans (counting back, inclusively, from March 1) called both days the sixth. (F. R. WN.)

FÉCAMP, a seaport and bathing resort of northern France, in the *département* of Seine-Maritime, 28 mi. N.N.E. of Havre on the Ouest-État railway. Pop. (1954) 17,193. The town stands at the mouth of the small river Fécamp, and occupies the bottom and sides of a narrow valley opening out between high cliffs.

The town grew up round the nunnery founded in 658 to guard the relic of the True Blood which, according to the legend, was found in the trunk of a fig tree drifted from Palestine to this spot, and which still remains the most precious treasure of the church. The original convent was destroyed by the Northmen, but was re-established by Duke William Longsword as a house of canons regular, later converted into a Benedictine monastery. King Richard I greatly enlarged this, and rebuilt the church. The dukes of Normandy improved the harbour, but later the town was overshadowed by the rising port of Havre.

The abbey church of La Trinité dates mostly from 1175 to 1225, and has a fine central tower and chapel screens. The *hôtel-de-ville* with a municipal museum and library occupy the remains of the abbey buildings (18th century). The church of St. Btienne (16th century) and the Benedictine liqueur distillery[1], are of some interest. There are a tribunal and chamber of commerce, a board of trade arbitrators and a nautical school. The harbour is tidal with docks capable of receiving ships drawing 26 ft. at spring-tide, 19 ft. at neap-tide. Fishing for herring and mackerel is carried on and Fecamp sends a large fleet to the codbanks of Newfoundland and Iceland. The chief exports are oil cake, flint, cod and Benedictine liqueur. Imports include coal, timber, tar, hemp and peanuts. Steam sawing, metal-founding, fish-salting, shipbuilding and repairing, and the manufacture of ship's biscuits and fishing-nets are among the industries.

FECHNER, GUSTAV THEODOR (1801–1887), German scientist and philosopher, who pioneered in psychophysics, was born on April 19, 1801, at Gross-Sarchen, Lower Lusatia, where his father was pastor. Fechner took his degree in biological science in 1822 at the university in Leipzig, where he spent the rest of his life. He became interested in mathematics and physics and was appointed professor of physics in 1834, but, after a long illness and partial blindness, turned in 1843 to the study of philosophy, experimental aesthetics and psychophysics. He died at Leipzig on Nov. 18, 1887.

Fechner's philosophy conceives the world as highly animistic, even plants and the stars being animated; God, the soul of the universe, has an existence analogous to man, and natural laws are the modes of the unfolding of God's perfection. Fechner was a remote disciple of Friedrich von Schelling and learned much from Johann Herbart.

Though he received attention as a philosopher, Fechner's fame stems chiefly from his experimental work described in Elemente der Psychophysik (1860), which he intended merely as verification for his philosophy. The basic postulate of Fechner's psychophysics was that mind and body appear to be separate entities but are actually only different sides of one reality. What appears from a subjective viewpoint as the mind appears from an external or objective viewpoint as the body; Fechner uses the illustration that a circle appears concave or convex depending on whether or not the observer stands inside or outside the circle. The apparent dualism is due to the impossibility of taking both viewpoints simultaneously.

Fechner's originality lies in his development of psychophysical methods by which experienced sensation could be measured in relation to the physical magnitude of the stimulus.

Through his psychophysical experiments he derived an equation between stimulus and sensation, and thus, he believed, between body and mind, and he felt that this demonstrated the validity of

[1]The liqueur is said to have been made by the monks as far back as 1510; since the Revulution it has been produced by a secular company. The familiar legend D.O.M. (*Deo Optimo Maximo*) on the bottles preserves the memory of its original makers.

the identity hypothesis. The equation, Fechner's law, which states that the intensity of a sensation is proportional to the logarithm of the stimulus, can be written

$$\text{sensation intensity} = C \log \text{stimulus intensity},$$

where C is a constant that must be experimentally determined for each sense modality. Ernst Heinrich Weber had originally postulated this constancy in 1834. and the formula is therefore sometimes called the Weber-Fechner law. The law has been criticized on logical grounds, and experimental evidence indicates that it does not have the universal applicability Fechner claimed. Nevertheless. it has proved useful, particularly to researchers in vision and hearing.

Through his influence on Wilhelm Wundt (*q.v.*), Fechner's psychophysical methods and formulations became one of the cornerstones of early psychology. *Elemente der Psychophysik,* though its philosophy did not stand the test of time, gave psychology methods for the measurement of sensation and thereby results that could be expressed in the language of mathematics.

Fechner's chief works, in addition to *Elemente der Psychophysik*, are: *Massbestimmungen uber die galvanische Kette* (1831); *Das Biichlein vom Leben nach dem Tode* (1836; Eng. trans., 1882); *Nanna, oder iiber das Seelenleben der Pflanzen* (1848); *Zendavesta, oder über die Dinge des Himmels und des Jenseits* (1851); *Vorschule der Asthetik* (1876); *Die Tagensansicht gegeniiber der Nachtansicht* (1879). In addition to scientific and philosophical papers, he wrote poems and satires under the pseudonym of Dr. Mises.

FECHNER'S LAW: *see* FECHNER, GUSTAV THEODOR; PSYCHOPHYSICS; WEBER'S LAW.

FECKENHAM, JOHN (*c.* 1515–1584), English ecclesiastic, last abbot of Westminster, was born at Feckenham, Worcestershire. Educated at Gloucester hall, Oxford, as a Benedictine student, he was professed at Evesham. On the surrender of the abbey to the king (1540), he became chaplain to Bishop Bell of Worcester and to Bonner of London, and in 1544 received the living of Solihull. About 1549 Cranmer sent him to the Tower of London, but being released by Mary in 1553, he was made prebendary of St. Paul's, rector of Finchley, then of Greenford Magna, chaplain and confessor to the queen, and dean of St. Paul's (1554). He was sent by the queen to prepare Lady Jane Grey for death, and when Elizabeth was sent to the Tower, Feckenham interceded for her, even at the cost of displeasing the queen.

The royal abbey of Westminster having been restored to its primitive use, Feckenham was appointed abbot in 1556 On the accession of Elizabeth. he opposed all legislation for changes in religion, and, when the hour of trial came, refused the oath of supremacy, rejecting also Elizabeth's offer to remain with his monks at Westminster if he would conform to the new laws. The abbey was dissolved (July 12, 1559), and within a year Feckenham was sent by Archbishop Parker to the Tower. After 14 years' confinement, he mas released on bail and lived in Holborn, where he devoted himself to works of charity. In 1577 he was committed to the care of Cox of Ely with strict rules for his treatment; and in 1580 he was removed to Wisbeach castle where he died on Oct. 16, 1584.

See E. Taunton, *English Black Monks of St. Benedict* (1897).

FEDERAL BUREAU OF INVESTIGATION (FBI). Established in 1908 as the investigative arm of the U.S. department of justice. the Federal Bureau of Investigation is a fact-finding agency which does not evaluate the results of its investigations or recommend prosecutive action. In general, it is responsible for the enforcement of all federal criminal statutes except those specifically delegated to other federal agencies. In 1958 there were approximately 140 federal matters over which it had investigative jurisdiction. The two primary areas of FBI activity are general investigations and security operations. Within the latter field, it has jurisdiction over espionage, sabotage and subversive activities on a nation-wide scale.

In addition to investigating violations of laws of the United States. the FBI is charged aith collecting evidence in cases in which the United States is or may be a party in interest and with other duties imposed by law. It reports the results of its investigations to the attorney general, chief legal officer of the United States. his assistants and the various U.S. attorneys in federal districts throughout the United States for decisions as to prosecutive action. The FBI is also a service agency which assists law enforcement agencies in identification, technical and training matters.

History. — Originally known as the Bureau of Investigation, the FBI was created by the then attorney general Charles J. Bonaparte on July 26. 1908. The internationally known name, Federal Bureau of Investigation, was adopted on July 1, 1935.

In 1924 John Edgar Hoover was appointed director of the bureau by Harlan Fiske Stone, then attorney general, and he was reappointed by each succeeding head of the department of justice. Hoover inaugurated the policies which constitute the foundation of the present organization. Political considerations were divorced from personnel appointments, and promotions were placed on a merit basis.

Less than a decade after this reorganization, the FBI was faced with enlarged responsibilities. A wave of lawlessness in the early 1930s aroused considerable public concern. Local police officers, often inadequately trained and hampered by the restrictions imposed by state boundaries, were unable to cope effectively with the modern weapons and transportation available to organized criminal gangs. To meet this situation, congress passed a number of laws which extended the jurisdiction of the FBI. In 1932 the federal kidnapping statute was enacted, making unlawful the interstate transportation of a kidnapped person. All kidnapping cases referred to the FBI the following year were solved. The federal Bank Robbery act was passed in 1934 to stem the rising tide of bank robberies. Again in 1934, special agents of the FBI were authorized by congress to carry firearms and to make arrests. With the passage of these and other crime bills, the FBI was given authority to act against the criminal gangs which previously had met little effective opposition. In 1934 alone, three vicious fugitives who had gained national notoriety were killed. John Dillinger, Charles Arthur (Pretty Boy) Floyd and Lester Gillis, alias "Baby Face" Nelson, met death while resisting arrest. In 1935 Russell Gibson and Kate and Fred Barker fell before the guns of special agents. The arrest of Alvin Karpis by Hoover in 1936 marked the end of the powerful Barker-Karpis gang, while Alfred James Brady and an accomplice were killed in a gun battle with FBI agents in 1937. Numerous other kidnapers, bank robbers and lesser criminals were sent to federal penitentiaries during this period.

The war on crime was not halted but was overshadowed as the inteniational developments leading to World War II placed additional responsibilities on the FBI. During this period, federal statutes relating to subversive activities were the basis for counteraction by the bureau against intelligence operations of foreign powers. Several espionage agents were arrested before the outbreak of hostilities in Europe On Sept. 6. 1939, a presidential directive was issued providing that the FBI should take charge of investigative work in matters relating to espionage. sabotage, subversive activities and related matters. The president also called upon all enforcement officers, both federal and state, to report all information in these fields promptly to the FBI, which was charged with the responsibility of correlating this material and referring matters under the jurisdiction of any other federal agency with responsibilities in this field to the appropriate agency. The FBI's responsibility in these matters was reiterated by presidential directives of Jan. 8, 1943, and July 24. 1950. By agreement, the armed forces handle investigations concerning their uniformed personnel. This action by the president obviated the confusion experienced in World War I when more than 20 agencies investigated security in the United States.

The scientific techniques which had been developed by the FBI in its war against organized gangsterism were employed to thwart the spy and the saboteur. In June 1941 the FBI climaxed its investigation of a Nazi espionage ring in New York city with the arrest of 33 persons. All pleaded guilty or were convicted in federal court.

An efiective pan-American intelligence force was created under the bureau's leadership to oppose the activities of Axis spy and sabotage rings in the western hemisphere. From July 1, 1940, through June 30, 1946, more than 15,000 Axis operators and sympathizers in South America were expelled, interned or rendered harmless. More than 460 spies, saboteurs and propaganda agents were apprehended, and 30 secret radio transmitters were eliminated.

In 1939 the FBI undertook a program of surveying industrial plants engaged in the manufacture of strategic war material. Before it had concluded its responsibility in this program, more than 2,300 plants had been surveyed and recommendations made for their protection. In the period preceding the attack on Pearl Harbor new field offices were opened in the continental United States and its territorial possessions. Additional personnel was trained by the FBI to investigate the flood of complaints regarding suspicious activities which citizens were encouraged to report, and its rolls of clerical and investigative employees reached an allotted peak of 14,300.

A mass of intelligence information had been accumulated by Dec. 7, 1941, when Japan attacked at Pearl Harbor. By the following day. 1,771 potentially dangerous enemy aliens had been arrested and detained. As formal declarations of war were made, German and Italian aliens, known or suspected to be dangerous, were arrested. In all, more than 16.000 such apprehensions were made by the FBI with the assistance of local law enforcement authorities in an orderly manner and in marked contrast with the disorganized vigilante activities of World War I. Precautions against espionage and sabotage were increased.

In 1942 eight saboteurs, landed by submarine from Germany, were quickly taken into custody. German plans to send such groups to the United States every six weeks were thwarted. Two additional saboteurs were dispatched by Germany in 1944 and were quickly apprehended. The normal channels for enemy agents to enter the country were closed, and spies were then sent to the United States as refugees. Spies intercepted by the FBI often became double agents. identifying other espionage agents and transmitting misleading information to their principals.

After the war the nation found itself confronted with a crime wave of serious proportions. In 1945 major crimes increased 12.3% over 1944. Crime in 1946 continued its upward trend, increasing 7.6% over 1945. The war-born scarcity of consumer goods created a lucrative market for stolen merchandise and contributed to the reactivation of old criminal gangs. The finely geared machinery of the FBI was able to face this condition without pause.

During the postwar period there was increased public concern in matters relating to Communism and the infiltration of government and essential industry by persons whose loyalty was subject to question. On Aug. 1, 1946, congress passed the Atomic Energy act, charging the FBI with the responsibility of determining the character, associations and loyalty of employees of the Atomic Energy commission and of all persons having access to restricted atomic energy data. Following the issuance by the president on March 21, 1947, of executive order 9835, the FBI was given the duty of investigations concerning the loyalty of employees and applicants for positions in the executive branch of the federal government. The result was to increase greatly the investigative work of the FBI.

On April 5, 1952, congress transferred responsibility for the bulk of applicant-type investigations to the United States civil service commission, and provided that the FBI should handle those cases where information indicated questionable loyalty or where the position involved was sensitive and important.

On July 20, 1948, 12 leaders of the Communist party were indicted under the Smith act as members of a conspiracy teaching and advocating the overthrow of the constitutional form of government of the United States by force and violence. Following the trial and conviction of 11 of these leaders, the FBI arrested other Communist officials. Other investigations by the FBI in the security field developed evidence of plots to transmit government secrets and information relating to atomic energy and other secret projects to foreign nations. It scrutinized even more closely organizations which advocated policies not in keeping with the United States' constitutional form of government.

Statistics. — The effectiveness of FBI operations is indicated by the statistics reflecting its accomplishments through the years. In the five-year period which ended June 30, 1952, 34,629 fugitives had been located in cases investigated by the FBI. Fines, savings and recoveries in bureau cases totalled more than $227,400,000, and there were 44.746 convictions in cases which were presented in court during that five-year period.

The close of the 1952 fiscal year brought to 438 the number of cases investigated by the FBI under the federal kidnapping statute. Of these, 436 were solved. In the 1952 fiscal year alone there were 156 convictions in bank robbery cases investigated by the FBI. These convictions resulted in sentences totaling 1,533 years and fines and recoveries amounting to $2 53,369.

Six years later, during the 1958 fiscal year, convictions in cases investigated by the FBI rose to 11,457, resulting in sentences totaling more than 30.000 years and fines totaling more than $1,666,000. Also, more than 9,000 fugitives were apprehended and recoveries resulting from FBI investigations totaled more than $130,000,000, including 16,500 stolen automobiles. Not shown in statistical data, however, are the accomplishments of the FBI in the area of security and counterespionage investigations.

Co-operative Services. — The FBI Laboratory. — On Nov. 24, 1932, the FBI laboratory mas established to provide scientific crime detection facilities to authorized law enforcement agencies. Services of the FBI laboratory are available cost-free to state and municipal law enforcement agencies, as well as to other government agencies. Its technical equipment ranges from simple laboratory instruments to complicated spectrographs and huge copying cameras Its technicians, who represent many fields of chemistry, physics and engineering, include experts in firearms identification, serology, spectrography, metallurgy, explosives, hair and fibre analyses and handwriting identification. During the fiscal year which ended June 30, 1958, the laboratory completed 165,462 scientific examinations of 137,142 specimens of evidence. Examinations in the laboratory clear the innocent as well as convict the guilty. Laboratory experts are available to testify without charge in state courts concerning the results of their examinations.

The Identification Division. — A national fingerprint file was established on July 1, 1924, when the FBI was given custody of 810,188 fingerprint cards previously maintained by the U.S. penitentiary at Leavenworth, Kan., and by the International Association of Chiefs of Police. Approximately 20,000 fingerprint cards are received each working day far processing at the Identification division. By July 1958 the FBI had more than 149,000,000 fingerprint cards in its continuously increasing identification files. In addition to fingerprints submitted on criminal charges, these included fingerprints of military personnel, government employees, aliens, prisoners of war and private citizens who voluntarily submitted their fingerprints for protection against loss of identity in the event of amnesia or disfiguring fatal accidents.

Police Instruction. — In 1935 the FBI National academy was established to train selected members of law enforcement agencies as police executives and instructors for their local departments. The 12-week training course is conducted at Washington, D.C., and at the FBI academy on the U.S. marine base in Quantico, Va., by members of the FBI training staff and recognized outside experts. No tuition or fees are charged. The two sessions of the National academy, completed during the 1958 fiscal year, raised the total of graduates to more than 3,500. Among these graduates were police officers and officials from every state as well as several other countries and U.S. territorial possessions. The benefits of their training had been transmitted to thousands of their fellow police officers. Approximately 25% of these graduates were the heads of their law enforcement agencies.

At the request of local authorities, the FBI co-operates in police training schools, affording training in such matters as firearms, fingerprint classification. traffic control, defensive tactics and other courses of value to law enforcement. In its annual conferences with state and local law enforcement agencies, the FBI provides a medium for the discussion of common problems related to law enforcement in the various local areas. Such publications as the FBI *Law Enforcement Bulletin* and the *Uniform Crime Reports* bulletin further aid in keeping law enforcement officers abreast of developments in crime detection and trends in crime. Published monthly, the FBI *Law Enforcement Bulletin* provides a medium for exchange of ideas between law enforcement agencies. The *Uniform Crime Reports* bulletin is a statistical analysis of local crime on an annual and semiannual basis. Tabulations on offenses committed are submitted to the FBI monthly and annually by more than 5.500 law enforcement agencies throughout the United States.

Administrative Organization. — Headquarters of the FBI are maintained in Washington, D.C., where all administrative and investigative functions are co-ordinated. Serving under the director are an associate director, two assistants to the director and several assistant directors who control such activities as the domestic intelligence. investigative. training and inspection, records and communications, administrative and identification divisions and the FBI laboratory. In 1958 there were 53 field offices of the FBI in key cities in the United States and its territories. Each field office was headed by a special agent in charge who was responsible to the director for the supervision of the bureau's activities in his field division. Under his direction were varying numbers of special agents. assigned according to the needs of the service. (J. E. H.)

FEDERAL COUNCIL OF EVANGELICAL FREE CHURCHES. This body was formed to give expression to the unity in matters of spiritual principle which had been found to exist among the evangelical free churches of England and to co-ordinate their activities and resources. It represents the denominations as organized corporate bodies. Though its aims are convergent with those of the National Council of Evangelical Free Churches. its constitution and area of operation were defined differently.

The original document consisted of a "Declaratory Statement concerning Common Faith and Practice" (with a preamble) and a constitution. The governing body of the federation was organized as a federal council. consisting of representatives elected annually by the supreme authorities of the federating churches; but its powers were advisory and not executive except under conditions explicitly defined.

See ECUMENICAL MOVEMENT.

FEDERAL GOVERNMENT is the government of a federal community. Such a community is characterized by a territorially diversified pattern of foci of attention. objectives, values, interests and beliefs that calls for two levels of government. one to deal with the common, the other with the ter itorially diverse and differentiated loci of attention. Since such patterns'are rarely stable over any considerable period of time. federal government is highly dynamic and the equilibrium of power is continually shifting. The political system of which the federal government is the most important part, and which is often called federalism, is. therefore. a process rather than a static design. This point needs emphasizing in order to bring out the contrast with older conventional views, which laid stress on the problem of sovereignty (*q.v.*) and the resultant distinction between a federal state (*Bundesstaat*) and a federation (or confederation') of states *(Stuatenbund)*. While not without importance. especially for international law. this dichotomy obscures rather than illumines the vital aspects of federalism and federal government.

While federal systems have had primary importance in providing the opportunity for separate communities to organize themselves in larger unities. as illustrated by the history of Switzerland. the United States. Canada. Australia. Germany and a host of more recent examples. a federalizing process may also be important in solving problems of overconcentration of governmental power, as is demonstrated by the Commonwealth of Nations, the French union and a number of formerly colonial situations, such as Algeria and Puerto Rico.

Federal governments often evolved out of leagues or confederations. It was so in the United States, Switzerland and the Netherlands. Hence, federal government typically exhibits some of the organizational features of confederations. In the early city leagues, no less than in the Swiss and Dutch unions, the American confederation and finally the League of Nations and the United Nations, there is always found a charter or agreement, embodying three features: (1) an assembly of representatives of the constituent members; (2) an executive organ of some sort; and (3) an arbitral or judicial body; arbitration is ordinarily supposed to eliminate the recourse to arms between members. The common objectives of these confederations were different, but there was always the objective of defense against dangers to which all the members were alike exposed.

Distribution of Legislative Functions. — Because of the variety of possible origins. every federal government is likely to be different from every other. The composition of federal representative assemblies as well as the distribution of their legislative functions shows this clearly. Many federal constitutions contain long catslogues of what the federal legislature may do; the United States constitution is relatively simple as compared with the German basic law. It goes without saying that such divisions of the "competencies" — that is, the sphere within which each may operate — must and will vary according to time and place. Economic and social life, military and geographical factors, all play their role in determining the particular arrangement. Jurists have made a great deal of the difference between a central government with powers specifically delegated to it. such as that of the United States, Switzerland and Germany, and one in which the powers are specifically delegated to the provinces, as is the case in Canada. What really matters is that there be some balance between the two, and that whatever distribution of functions might be delegated, it is the constitution that determines the governmental structure as a whole.

A comparison of the several federal constitutions shows that certain matters, such as foreign affairs. customs, money and currency. posts and national defense. are invariably attributed to the federal authorities. On the other hand, certain matters, such as education and cultural affairs. the police and local government, are usually left to the component units. But the focal point of modern life, namely, the economy in all its ramifications of technology, welfare and taxation. is handled with the widest variation, created by judicial interpretation of the constitution as well as by amendments broadening the scope of federal jurisdiction.

Amending Process. — Every federal system of government provides for participation of local units in the process of amending and altering the constitution. How do the local units — states, cantons, *Länder*, provinces, dominions or whatever—actually participate? Through their representatives in the federal representative assembly. or directly. or both? In the United States, as in Switzerland. the provisions for constitutional amendments developed organically. In both countries the component states' representatives in the federal representative assembly as well as the component states themselves have to assent by qualified majorities. In the Cnited States the state legislatures or special conventions ratify amendments proposed by congress; in Switzerland amendments proposed by the federal legislature (or by a popular initiative) are ratified by a majority of the cantons as well as by a majority of the Swiss people.

In Germany under the Weimar republic, no direct participation of the provinces *(Lander)* was required. This omission shows how weak was German federalism of the period between World Wars I and II. A feeble substitute for *Lander* participation was provided, but it was never actually invoked. Following this tradition, the amending power in the post-World War II Bonn constitution (*Grundgesetz,* or basic law) was lacking in federalistic character also, though the requirement of a two-thirds majority in the states' council (*Bundesrat*) proved of.some consequence.

In some of the later federal systems, notably the proposed European Political Community. real participation of the component units was provided, coupled with provisions that distinguished between more and less important articles of the constitution.

Federal Executives. — The second feature of a confederation appertains to the executive sphere. The component units have a part either in selecting the federal executive, or in conducting the executive work for the whole, or in both. The federal structures in the United States, Switzerland, Germany and the dominions of the British Commonwealth all exhibit such arrangements. To be sure, the local units have only a small share in selecting the federal executive. Thus, in the United States, voting by the states in the electoral college is a partial recognition of the states; the president is not elected by a majority of the whole people but by a majority of state majorities.

Another form of state participation as such in the executive sphere is the constitutional right of the U.S. senate to advise on and consent to presidential appointments "Senatorial courtesy" reinforces this power. Another recognition of the states' position is the civil service rule according to which each state is given a certain quota of appointments. In Switzerland, the president and the executive council are elected by the two houses of the legislature; hence the cantons have an important voice. The strength of local autonomy is further recognized in certain customs: Bern and Zurich are always represented on the council, and council seats are evenly distributed among the other cantons. This means primarily that the French- and Italian-speaking cantons get at least one or tno members.

Constitutional Judiciary. — A judicial body for the settlement of disputes between central and local authorities is found in all federal systems. In the United States the supreme court is charged with this duty. Though on the whole favouring the federal government, it has not followed a one-sided course as between the central and local governments. The court was, indeed, nationally minded under Chief Justice John Marshall (1801–35). and several of his most famous decisions, such as *McCulloch* v. *Maryland* and Gibbons v. Ogden, asserted positions that favoured the central government. Later on, the court, in the course of the slavery controversy, shifted toward a states' rights position, which culminated in the ill-starred Dred Scott decision (1857). After the Civil War, the court returned to its earlier outlook. There was prevalent a feeling that the war had settled all questions in tavour of the central government.

At mid-20th century the court seemed to be federally minded in matters of civil rights, but inclined toward a states' rights point of view in certain other respects. Whatever the merits of detailed issues under dispute, however. the notion of judicial settlement of such disputes between local and central authorities remained as a clear indication of the federal nature of the U.S. governmental structure.

This is likeaise the case in Switzerland, and it is noteworthy that provisions about the administration of federal legislation by the cantons have not resulted in complications similar to those that arose in Germany under the Weimar republic This may be explained by several facts: no single canton is large in relation to the federation as a whole; the cantons have been less sharply divided by partisan issues (neither Communism nor Fascism assuming serious proportions); and the central government has practised marked moderation in employing force, relying rather upon persuasion and other kinds of pressure. Under the 1949 basic la , the Germans, it appeared, would follow similar methods.

Commonwealth and Dominions. — Interesting special problems in federalism are presented by the Commonwealth of Nations and the dominions composing it. The commonwealth represents a very loose federal system, which in terms of the antiquated approach must be described as a kind of league. Yet common citizenship, the bonds of a common cultural tradition and language, as well as informal institutional arrangements of various sorts, including the commonnealth conferences, provide a working federal bond among the several members. For example, it is often overlooked in discussions of this matter that Canada still formally depends upon the British parliament for amendments of its constitution. Nor can the weight of what remains of the British Colonial empire, administered by the United Kingdom, be gainsaid.

Australia and Canada provide two outstanding examples of working federalism. Their institutional setup is interesting in terms of the relation of federalism to parliamentarism; for they effectively combine the cabinet system of parliamentary government, on both the federal and the local level, with a functioning federal system. Canadian federalism is reinforced by the powerful sense of local differentiation and autonomy in the French-speaking part of Canada; in both Canada and Australia the continental dimensions of their territory make a territorial distribution of power natural. Elsewhere in the commonwealth, the federations of Rhodesia and Nyasaland (1953) and The West Indies (1958) present other examples of experimentation with various federal forms of government.

After 1947 India evolved a diversified federal system of its own that provided the basis for solving the problem of how to organize an effective democratic government for its richly differentiated people. It is the most complex federal system ever devised. Some would deny it true federal character because of the broad powers granted to the central government. But the weight of local traditions — linguistic, religious, cultural — is so great that the provinces tend to gain rather than lose in strength. The system is still evolving and the end is not in sight, but it is possible to argue that without the techniques of federalism, Indian constitutional government could not have been achieved.

European Unification. — The same may be emphatically asserted regarding the unification of Europe. Actually, the federalizing of Europe is taking the form of functional integration. Instead of setting up a federal union by concerted constitutional action, European states negotiated a series of separate treaties in particular functional areas. They also created a very loose framework, the Council of Europe, centred at Strasbourg, France, in which, after 1949, the 16 member states consulted with each other about common problems. A representative assembly, composed of delegates of the several parliaments, urged common action, though it possessed purely consultative functions. Its major achievements, besides creating a certain camaraderie and habits of working together, were in the cultural sphere; it was specifically excluded from the consideration of military problems. In the general field of economic co-operation, the Organization for European Economic Cooperation (O E.E.C.), inaugurated as the co-ordinating body of the European Recovery program, was operative; its most effective work was in overcoming currency problems through its subsidiary, the European Payments union (E.P.U.). Finally, in the military field, the Western European union (W.E.U.) sought to implement policies of the North Atlantic Treaty organization, but its activities were not of great consequence; it took the place of the unrealized European Defense Community (E.D.C.).

Besides these rather loose efforts toward federalizing all of Europe, much bolder efforts were undertaken by "Little Europe," the six states that mere ready to form a much closer union than the rest, namely. France, the German Federal Republic. Italy and Benelux (Belgium, the Netherlands and Luxembourg). They formed in 1951 the European Coal and Steel Community (E.C.-S.C). which began operation in 1953 as an effective supranational administration of two basic industries through the territory of the "Six." After the failure of the E.D.C. and its associated proposal for a European Political Community (E.P.C.), the Six formed a European Economic Community (E.E.C.) (1957) and a European Atomic Energy Community (Euratom). The first was to establish a common market, by elimination of all tariffs within the next 12 to 15 years and conjointly to develop common economic policies and a free movement of persons and capital. The second was to pool the resources of the Six for the development of nuclear energy. Europe's energy resources at mid-century were insufficient and growing more so; hence the development of nuclear energy appeared to many to be the means of economic survival. These two communities shared, as planned in early 1958, a representative assembly (not fully legislative, however) with the E C S.C.; it was also planned that they would have a common court.

Association: A New Dimension of Federalism. — The European developments sketched above raise an issue that has also cropped up elsewhere. How can states that do not feel ready to share fully in a federal union participate on a more limited scale? The answer given in Europe is: association. In the European Economic Community treaty, for example, it was provided that other states or union states might become associated with the community. The specific proposal was that of establishing a "free trade area" of adjoining states.

The United States, confronted with the problem of how to give maximum autonomy to Puerto Rico, which desired to preserve its cultural identity while yet remaining part of the United States, granted to the people of Puerto Rico the status of an associated state; the Free and Associated Commonwealth of Puerto Rico represented a novel departure for U.S. federalism. When the German Federal Republic was organized. west Berlin wished to participate but could not become a state because of the four-power control over all of Berlin. Consequently the free part of the city became "associated" with the federal republic; though not voting, its representatives participated fully in federal legislation, and the republic's laws applied to it. As with Puerto Rico. Berlin received substantial aid from the federal union with which it was associated

Conclusion.—Federalism is intimately related to modern constitutionalism. There is nothing in the distinction between federalism and decentralization that would imply an inherent superiority of one over the other; their advantages and disadvantages can be contrasted only in terms of the peculiar conditions of the time and place under which a particular government is supposed to operate A federal governmental structure provides a spatial or territorial, as distinguished from a functional, division of powers. Such a division operates as a rather effective restraint upon the abuse of governmental powers by the central authorities. Indeed, in many situations it is more likely to be effective than a functional division. for the latter can be more readily overcome by the extraconstitutional activities of a national party organization. In other words, what federalism does is to mobilize firmly entrenched local powers in support of the constitution and to offer them protection under the constitution as well. Localized groupings are treated in a manner analogous to the treatment of the individual citizen, to whom a sphere of relative independence, of civil liberties is likewise guaranteed.

Besides the constitutional considerations, there is a great advantage in providing an opportunity under a federal system for limited experimentation in one or more of the component units. This, however, may have perilous consequences. These dangers of federalism were illustrated in Germany. It is strange that the legend could grow up later that it was centralization that favoured Hitler, when, as a matter of fact, it was the relative autonomy of Bavaria that provided the seedbed for Hitlerism before and after the beer hall *Putsch* in Munich in 1923. It was likewise the autonomy of the *Länder* in the matter of citizenship that enabled Thuringia, after it had become National Socialist, to confer German citizenship upon Hitler, nithout which he could not legally have become either a candidate for the presidency or chancellor. By analogy, any markedly federalistic structure may provide a potential foothold and jumping board for an emergent totalitarianism. whether of the right or the left.

Federal structures of government share with all formalized constitutionalism the difficulty of adjusting a relatively rigid scheme to the shifting exigencies of a dynamic industrial society. Under modern conditions, areas of friction are bound to develop where technological change radically alters the conditions under which government has to be conducted. With competencies constitutionally divided between the central government and the local governments, as they are in the United States, governmentai functions emerge that can be performed only by one of these units and for uhich no prior constitutional provision has been made. The rigidities that arise, however. from such a division of powers are inherent in the federal scheme and are the price that must be paid for the advantages of greater variety and local freedom.

FEDERALIST PARTY. The Federalist party organized the national government of the United States under the constitution of 1787. It may be regarded as in various important respects, the lineal predecessor of the U.S. Whig and Republican parties. The name "Federalists" (see ANTI-FEDERALISTS) was first given to those who championed the adoption of the constitution. Later it applied exclusively to a specific political group, less inclusive than the Federalists of 1787, which developed during the presidency of George Washington.

The palpable weaknesses of the Confederation of 1781–89 and the very real threats to the survival of the American nation were the reasons for the rallying together of this group. They sought an "energetic" central government because they feared "the mutability of the laws of the states", as James Madison put it The Confederation had demonstrated its inability to protect property rights, provide a public revenue, uphold the fiscal integrity of government, maintain and expand commerce and come to an understanding with Britain. The economic depression of 1785–86 once more unleashed leveling tendencies—resumption of paper-money issues in the states. assaults on contracts and the Shays's Rebellion. In consequence, the conflict over the constitution—and the appearance of political parties in America—was the difference largely between two kinds of property interests and not, as Jefferson put it later, between two philosophical positions. The Federalists were not aristocrats and monarchists, the anti-Federalists were not democrats. The Federalists saw political stability and economic growth in terms of sound fiscal policy. establishment and protection of banking and the expansion of commerce. The anti-Federalists spoke for the agricultural interests which, frequently weighed down by debt, were cheap-money men and hostile to tax programs of imposts and excises. The mechanics and artisans of Massachusetts, identified with commerce, were Federalists. The large land (and slave) owners of Virginia and the Carolinas were anti-Federalists. Most of the Federalists of 1787–88 became members of the later Federalist party.

The political group which became known as the Federalist party may be regarded as definitely organized practically from 1791; it was led, leaving President Washington aside, by Alexander Hamilton and John Adams. Hamilton's domestic and foreign policies gave the party its program and created the bitter hostility to it that made it so short-lived. He started out with the assumption that the constitution gave the central authority broad powers; he believed it necessary to use them to create a government with integrity and honour so that private accumulation could occur with safety, foreign credits and investment would be revived and diversification of economic enterprise take place. These required positive action by government, notably as regards debt management, money and credit, banking and stimulation of trade. In foreign relations. they required a settlement with Britain politically and commercially, and neutrality as war raged in Europe. Over the decade of the 1790s, the Federalists stood for the following: (1) the support and the achievement of the Hamilton program of the funding of the old Revolutionary War debt and the assumption of the state debts, the passage of excise laws, the creation of *a* central bank, the maintenance of a tariff system and favourable treatment of United States shipping; (2) neutrality in the war between France and Britain, breaking out in 1793; (3) approval of the Jay treaty of 1794, terminating the difficulties with Britain; and (4) the grant of crisis powers to the central government in 1798–99, when French demands almost forced open war. These measures achieved the survival of the republic, linking public and private credit. expanding commerce and foreign investment in America and assuring peace.

They provoked deep resentment and were bitterly fought; on these issues the first U S. political parties were formed. The Republicans (Democratic Republicans, later, the Democratic party), led by Thomas Jefferson and James Madison, were suspicious of central authority, friendly to the French Revolution and hostile to Britain. While the Federalists controlled the government until 1801. their incapacity or unwillingness to organize politically, their neglect of the arts of consultation, persuasion and discipline, and their failure to devise a program of broad national appeal (including agriculture, small property generally. and the little producers) doomed them. Hamilton in 1799 understood this. Should not. he wrote to one of his correspondents, a wider program be laid out, one that "will extend the influence and promote the popularity of government?" But then it was too late. The Federalists had been made synonymous with "favouritism. influence and monopoly." They never again held national office after Jefferson's victory in 1800. See DEMOCRATIC PARTY (U.S.).

Nevertheless the accomplishments of the Federalists were great. They organized the new federal government in all its branches, giving it an administrative machinery that in the main endured; they established the doctrine of neutrality toward European conflicts that stood America in such good stead while it continued a poor and defenseless country and was preoccupied with its own continental expansion; they laid the basis for the enduring friendship with Britain; and fixed the practice of a liberal construction of the constitution — not only by congress but above all by the United States supreme court, which, under the leadership of John Marshall (who had been appointed chief justice by Pres. John Adams), impressed enduringly on the national system large portions of the Federalist doctrine. These political accomplishments and the economic ones of fiscal integrity, credit worthiness and protection of the investing process and property are their impressive achievements and their claims to memory.

After 1801 the Federalist party never regained power. In attempts to do so, it impaired its morale by internal dissension. by intrigues and by inconsistent factious opposition to Democratic measures on grounds of ultrastrict construction. It took up, too, the Democratic weapon of state rights. and in New England carried sectionalism dangerously near secession in 1808 and also in 1812–14 during the movement, in opposition to the War of 1812, which culminated in the Hartford convention. By 1817 it was practically dead as a national party. It is sometimes said that Federalism died because the Republicans took over its principles of nationality and accepted its economic ideas. This is true in part. But it fell principally because its great leaders. John Adams and Alexander Hamilton, became bitter enemies; because neither was even distantly comparable to Jefferson as a party organizer and leader; because the party could not hold the support of its original commercial. manufacturing and general business elements; because the party opposed sectionalism to a growing nationalism on the issues that ended in the War of 1812; and because, after 1801, it failed to adjust itself to the growing democratic spirit of the country. In New England. where it persisted longest, it represented a "cordial union between the clergy, the magistracy. the bench and bar and respectable society" (Henry Adams); this inevitably had to fail in a dynamic. expanding America.

FEDERAL RESERVE SYSTEM, THE. The federal reserve system is the central banking authority of the United States; as such it acts as a fiscal agent for the U.S. government, is custodian of the reserve accounts of commercial banks, makes loans to commercial banks, and is authorized to issue federal reserve notes which constitute a large fraction of the hand-to-hand currency of the country. Thus it has many of the functions characteristic of the Bank of England and of continental European central banks (see CENTRAL BANK).

Origins of the System. — Prior to the establishment of the federal reserve system and subsequent to the liquidation of the second Bank of the United States in 1836, there was no central banking institution in the United States. The provisions of the National Bank act of 1863, and the banking customs which emerged as a consequence thereof, produced a monetary and banking system which tended to concentrate the reserves of the commercial banks of the country in a small number of banks in a few financial centres, notably New York, with the result that unusual demands for currency or credit would periodically produce great financial stringency in the important financial centres. with consequent deflationary results. Similarly, the National Bank act did not provide a system for changing the quantity of currency so that it would be responsive to the changing needs of the business community or to the continued growth of the nation's economy. (See BANKING: History of Banking in the *United* States.)

In 1908 following the financial panic of 1907, congress established a national monetary commission, which came to be known as the Aldrich commission from its chairman, Sen. Nelson W. Aldrich, to study the requirements of a sound monetary system and to make legislative recommendations. The proposals of the national monetary commission were not embodied unchanged in the subsequent legislation, but the results of its work supplemented by the studies of others were influential in the discussions which led to the passage of the Federal Reserve act signed by Pres. Woodrow Wilson on Dec. 23, 1913. The Federal Reserve act has subsequently been amended, notably in 193j.

The Structure of the System. — The federal reserve system consists of (1) the board of governors of the federal reserve system; (2) the 12 federal reserve banks; (3) the federal open market committee; (4) the federal advisory council; and (5) the member banks. The functions of each of these will be treated in turn.

The Board of Governors. — The hoard of governors of the federal reserve system (known until 1935 as the federal reserve board) consists of seven members appointed by the president of the United States and confirmed by the senate. They are appointed for 14 years, one seat becoming vacant every two years. The chairman of the board is appointed by the president, from the membership of the board, for a period of four years. The members of the board of governors, which has its headquarters in Washington, D.C., devote their full time to the business of the board; they must not be directors, officers, employees or stockholders of any bank and not more than one of them may be appointed from any one federal reserve district. The president, in appointing members of the board of governors is required "to have due regard to a fair representation of the financial, agricultural, industrial and commercial interests, and geographical divisions of the country."

The board of governors of the federal reserve system is, in most respects, and in all important respects, the body which both supervises and controls the operation of the federal reserve system. The board determines the reserve reauirements of the member banks within the statutory limits it reviews and determines the discount rates established by the 12 federal reserve banks, it reviews the budgets of the federal reserve banks, its staff of examiners examines the operations of each of the federal reserve banks at least once a year, and in a number of other ways exercises substantial control over the operations of the system. The degree to which such control has been centralized in the board of governors was significantly increased in the Banking acts of 1933 and 1935.

The Federal Reserve Banks. — The country has been divided into 12 federal reserve districts in each of which there is a federal reserve bank. The districts are not necessarily coterminous with state boundaries. Federal reserve banks, all but two of which at mid-century had branches. are located. in order of the number given to the federal reserve district, in (1) Boston, Mass.; (2) New York city; (3) Philadelphia, Pa.; (4) Cleveland, O.; (5) Richmond, Va.; (6) Atlanta, Ga.; (7) Chicago, Ill.; (8) St. Louis, Mo.; (9) Minneapolis. Minn.; (10) Kansas City, Mo.; (11) Dallas. Tex.; and (12) San Francisco, Calif.

A federal reserve bank is a privately owned corporation established pursuant to the Federal Reserve act to serve the public interest. While it is privately owned (by the member banks; see below) the stockholders do not have the powers ordinarily associated with the stockholders of privately controlled corporations. Each member bank is required to subscribe to the stock of the federal reserve bank of its district in an amount equal to 6% of the member bank's capital and surplus. Half of this amount must be paid in while the remainder is subject to call. The maximum dividend which a federal reserve bank may pay to its member bank stockholders is 6% per annum.

Each federal reserve bank is governed by a board of directors of nine members. Three members, known as class A directors and three known as class B directors are elected by the member banks of the district. The class A directors may be bankers; the Class B directors must be actively engaged in the district in commerce, agriculture or industry and must not be officers, directors or employees of any bank. The class C directors are appointed by the board of governors. They must not be officers, directors, employees or stockholders of any bank. One of the class C directors is designated as chairman of the board and one as deputy chairman. The chairman of the board is by statute a federal reserve agent.

Thus a majority of the directors of a federal reserve bank are not active bankers and three, including the chairman and deputy chairman are not elected by the stockholders but appointed by the board of governors. The board of directors of a federal reserve bank is responsible for the conduct of the bank's affairs subject to the supervision of the board of governors.

This supervision while not detailed as to administrative procedure is significant. The board of governors must approve the appointment of the president and first vice-president of a federal reserve bank and the salaries of all officers and employees of each federal reserve bank are subject to approval by the board of governors.

The degree of control over the operations of the federal reserve banks by the board of governors of the federal reserve system together with the statutory limit on dividends payable to stockholders and with the practice of the federal reserve banks of paying 90% of earnings after dividends to the treasury as an interest charge on outstanding notes effectively results in the operation of the federal reserve banks in the public interest. Profit to the federal reserve banks is thus not a consideration in the formation of policy.

The Federal Open *Market Committee.*—This committee consists of 12 members, of which 7, the members of the board of governors serve *ex officio,* while j members are elected by the federal reserve banks. One of the five elected members is always chosen by the New York federal reserve district; the remaining four are chosen from federal reserve districts grouped for the purpose. The board of governors, if unanimous, always has a majority vote in the open market committee.

The committee is responsible for the determination of policy for the federal reserve banks operating as a system with respect to the purchase and sale of securities. This responsibility provides the system with one of its most powerful instruments of control over the money supply (*see* belon).

The Federal Advisory *Council.*—The council consists of 12 members each elected by the board of directors of one of the several federal reserve districts. It meets no less than four times a year. While its role is purely advisory, the board of governors being free to accept, reject or modify its advice, it may be influential in the formation of policy for the system.

The Member Bunks.—These consisted in the late 1950s, of some 6,750 banks of nhich approximately 4.850 were national banks; the remainder were banks chartered by the several states. All national banks (*i.e.,* banks operating under charters issued by the federal government) are required to be members of the federal reserve system. Banks operating under state charters may become members of the system if they meet the qualifications for membership and if accepted by the federal reserve system. The member banks represented something less than half of the banks of the U.S.; however, they held about 75% of the total bank deposits and more than 85% of total demand (commercial) deposits. Thus the policies of the federal reserve system have a direct effect on a large segment of total demand deposits, which constitute the largest part of the means of payment in the country, and indirectly influence the remainder.

Membership in the federal reserve system provides the member bank with certain advantages. The federal reserve banks are "banker's banks!' and they perform a variety of services for the member banks in that capacity. Among the most important of these is the clearing of checks which is done without cost to the member banks. *(See* CLEARINGHOUSE.)

The federal reserve banks also, free of cost or at a nominal charge, collect notes, drafts, maturing securities, etc., for the member banks, crediting the proceeds to the member bank's reserve account with the federal reserve bank. The federal reserve banks make coin and paper money available to the member banks without handling or shipment costs.

In addition to the important services noted above, the federal reserve banks hold the reserve deposits of the member banks and stand ready to make loans to member banks when the latter find it necessary temporarily to augment their reserve accounts in order to support an appropriate volume of loans and deposits (see BASKING: Principles *of* Banking) without disposing of other assets.

Membership in the federal reserve system does impose upon the member banks, however, some duties and responsibilities which are believed to deter some state chartered banks from seeking it. It requires member banks to comply with the reserve requirements established pursuant to law by the board of governors of the federal reserve system. The reserves must be held as deposits (without interest) with the federal reserve bank of the district in which the member bank is domiciled and they will in almost all cases be a larger proportion of deposits than will be true for a nonmember bank subject only to state law and regulation. Member banks must submit to regular examinations by the authorities of the federal reserve banks as well. in the case of national banks, as by the comptroller of the currency and in the case of state chartered member banks by the state banking authorities. They must honour all checks drawn upon them at par; *i.e.,* they must levy no remittance charges associated therewith. They must, moreover: hold assets of a quality somewhat higher than those permitted by the banking laws of many of the states.

Monetary and Credit Policies of the Federal Reserve System.—These policies, springing from the exercise of certain powers given to the system by statute, represent in terms of their influence upon the degree of economic stability. upon the level of economic activity and upon the price level. responsibilities which go far beyond the service functions described above. The federal reserve system through its power to alter the size, the availability and the cost of commercial bank reserves may influence greatly the magnitude of commercial bank deposits in the United States. Loans made by the commercial banks ordinarily emerge as increased deposits either in the bank making the loan or in another bank. Since member banks are required to hold a given proportion of their deposits as reserve accounts with the federal reserve banks, changes in the proportion which must be so held, changes in the cost of temporarily augmenting the reserves through loans from the federal reserve banks, or changes in the total size of the commercial bank reserves of the system will have effects upon the volurne of new loans and deposits (see BANKING: Principles of Banking). The federal reserve system exercises its regulatory powers in several ways. the most important of which may be described as the instruments of indirect control.

These instruments have to do with (1) the determination of the legal reserve ratio; *i.e.,* the proportion of its deposits which a member bank must hold in its reserve account; (2) the control of the discount rate, sometimes referred to as the re-discount rate; and (3j the control of open market operations; *i.e.,* the purchase or sale of securities in the open market by the federal reserve banks. Following a discussion of the bases of monetary and credit policy, the use of each of these will be described below.

The purposes of federal reserve policy are to facilitate the creation of a financial climate conducive to high level economic activity and to economic stability. The prevention of inflation or deflation, rapid rises or falls in the general price level. are essential parts of the task. Thus in a period of substantial inflationary pressure, particularly as is the typical case, when this emerges in a period of full or nearly full employment, the federal reserve system might be expected to use its powers in such a way as to restrict the growth of or actually reduce the supply of money.

On the other hand. in a period in which the signs of a recession appear or in a period of serious depression the system might be expanded to take action tending to lead to an expansion in the supply of money. It must be remembered that the term money as is used here refers principally to bank deposits, the most important means of payment (see QUANTITY THEORY OF MONEY).

Actions leading to either of the two results mentioned above may be taken through the exercise of any one or more of the instruments of indirect control mentioned above. Possible actions under circumstances in which inflationary pressures are strong and that, therefore. make efforts to reduce the actual or potential money supply, in order, include the following: (1) the federal reserve system might consider raising the legal reserve ratio. This action would increase the proportion of deposits which commercial banks are required to hold in deposit with the federal reserve banks and thus reduce the amount of new loans they could make. Since loans give rise to deposits, the potential money supply would be reduced. Any excess reserves in the system (excess reserves = actual reserve balances less required reserves) would be reduced or eliminated.

(2) Federal reserve bank sales of securities in the open market at the discretion of the federal open market committee would tend to reduce the actual size of commercial bank reserves. When the federal reserve sells securities the purchasers of the securities pay for them with checks on their deposits. This reduces deposits and since the amounts of the checks will be charged to the reserve accounts of the banks on which they are drawn, bank reserves are reduced. If, of course, the member banks should themselves purchase the securities, they will pay for them, in effect, by drafts upon their own reserve accounts. In any case. then. open-market sales of securities by the federal reserve banks have the effect of reducing bank reserves. Thus member banks will find themselves increasingly pressed to accommodate their loan customers and the actual or potential volume of deposits will be reduced.

(3) In the circumstances likely to follow upon open-market sales. the member hanks more frequently might be required to seek loans from the federal reserve banks of their respective districts. If, then, the federal reserve banks increased the interest rate—the discount rate at which such loans are available — member banks would find it increasingly costly to augment their reserves in this way. They mould, therefore, tend to be more restrictive and more selective in making loans. which tendency would be reinforced by the higher interest rates member banks would charge their customers as a consequence of the greater cost of reserves resulting from an increase in the federal reserve bank discount rate.

Thus to increase the reserve ratio. to undertake sales of securities in the open market and to increase the discount rate, would serve separately or in combination. to restrict the rate of credit expansion and thus reduce the actual or potential money supply. Clearly. opposite policies would be called for in a period of recession or in a period of deep depression. In such circumstances, the federal reserve system might be expected to reduce the legal reserve ratio, to reduce the discount rate and to undertake open-market purchases of securities. These steps taken separately or in combination could be expected to increase excess reserves. reduce the cost of temporary augmentation of reserves and produce an increase in the actual size of member bank reserves. Thus banks would be encouraged to increase their loans to customers. the potential money supply would be larger than otherwise would be the case and, if the demand for loans on the part of the business community is strong, loans and deposits will rise.

The instruments of indirect control described above have generally been conceded to be more powerful with respect to the prevention of inflation in times of high level economic activity than they are in connection with policies directed toward producing a revival from a period of depression. It should be noted that in the mid-1950s there was some growing controversy respecting the ability of the federal reserve through monetary policy alone to prevent an inflation.

In connection with attempts to prevent inflation under conditions of full employment, federal reserve has upon occasion supplemented the indirect controls described above with a series of selective controls. One of these relates to the control by the federal reserve of the margin requirements involved in the purchase of securities. The board of governors of the federal reserve system has, since 1934, had the power to limit the amount which lenders may make available on securities. Variable percentage requirements have been in effect since the inception of the program. ranging from 40% for several years prior to World War II to 100% in 1946 and 1947.

By executive order of the president of the United States in 1941, the federal reserve system was authorized to control the terms upon which credit could be extended to consumers for the purchase of important consumer durable goods. The regulation terminated in 1947, was reinstated briefly in 1948. terminating in the summer of 1949, was reinstated again after the outbreak of the Korean war and the authority to impose such regulations was finally repealed in the Defense Production act as amended in 1952. The consumer credit regulations sought to reduce the expansion of credit by controlling the minimum down payment required for the purchase of consumer durable goods and by controlling the maximum length of the amortization period of the loan and thus controlling the size of monthly payments. Similar regulations relating to the financing of real estate purchases were in effect from late 1950 until Sept. 1952.

Relation of the Federal Reserve System to Government. — The federal reserve system is an agency of government theoretically independent of the executive branch. The appointment of the members of the board of governors for terms of 14 years so arranged that one vacancy normally will occur every two years is designed, in part. to provide a substantial degree of independence. The board of governors is, of course, responsible to the congress of the United States.

Many students of banking and financial affairs hold the view that the federal reserve system should occupy such an independent position as an agency of government on the ground that the exercise of power over the banking system and over the supply of money should not be subject to political influence.

In general and with one notable peacetime exception. the independent conduct of the system's affairs has not been modified. During World War I, when the system was in its infancy, and again during World War II the system did, of course, accommodate itself to the full in providing means to facilitate the financing of the huge wartime expenditures. During these periods. large budgetary deficits had to be financed and the federal reserve system followed credit policies designed to ease the process.

In the period immediately subsequent to World War II, the policy of the treasury designed to insure continued low interest rates on the public debt involved the federal reserve system in practices which made the exercise of its normal powers to control the size and rate of expansion of the money supply difficult or impossible. This situation became clarified by the "accord" of March 1951 in which, it was announced. the treasury and the federal reserve system had reached agreement "with respect to debt management and monetary policies to be pursued. . . ." Thereafter. the federal reserve system again undertook with increasing independence of action to influence the flow of money and credit in the interest of controlling inflation and maintaining economic stability. FEDERAL SAVINGS AND LOAN ASSOCIATION: see SAVINGS AND LOAN ASSOCIATION.

FEDERAL THEATRE PROJECT. Established on

Aug. 27, 1935, at a time when many theatre artists were unemployed, the Federal Theatre project was organized by the U.S. government under the Works Progress administration. Federal Theatre groups were set up wherever the relief rolls showed enough theatre people to operate a company; nine out of ten members had to come from relief rolls. and $9.00 out of $10.00 had to be spent for security wages. The object of Federal Theatre was twofold: to give employment to needy professionals in socially useful projects which would rehabilitate them and develop their skills; and to bring to thousands of people, hitherto unable to afford theatregoing, a theatrical program national in scope, regional and state in operation, and worthy of government support.

Employment of so many people (12,700 in 1936; 7,900 in 1939) required a broad program, including productions of the classics, children's theatre, religious plays, musical comedy, marionettes, circus, vaudeville, dance and radio. Special emphasis was given to regional festivals such as *The Lost Colony,* outdoor drama, Manteo, N.C., and to productions in San Francisco, where Federal Theatre built its own theatre out of admission funds. Federal Theatre also gave impetus to new plays such as *It Can't Happen Here,* by Sinclair Lewis, which opened simultaneously in 21 cities. The most effective new theatre form developed by Federal Theatre was the Living *Newspaper,* characterized by vivid exposition of factual material in a flashing, often witty, series of blackouts. Such dramatizations as *Power* and *One Third of a Nation* played to crowded houses throughout the country.

A service bureau acted as a clearinghouse, where plays were written. translated and tested in. production and where contracts were signed, royalties paid and research was carried on. The service bureau published *Federal Theatre Magazine,* a graphic story of nationwide theatre, and *Continental Theatre,* at that time the only magazine in the country giving monthly translations of news from European theatres.

Federal Theatre productions were seen by about 25,000,000 people, an estimated 65% of whom had never previously seen a play. Companies also toured various public and private institutions. By Oct. 1938 Federal Theatre was receiving widespread critical acclaim; 2.600 of its members had been returned to private employment; and although over half of Federal Theatre companies were giving free shows, box office admissions had reached the $2,000,000 mark. Support from schools, churches and many business, professional and community organizations was increasingly enthusiastic. Federal Theatre, however. was also sharply criticized. especially for its "Living Newspaper" series. From mid-1938, allegations that the project was communistic were made and the house of representatives subcommittee on appropriations voted to eliminate Federal Theatre. In spite of wide support from spokesmen in New York and Hollywood, all theatre unions and leading critics, Federal Theatre was ended on June 30, 1939.

See Hallie Flanagan, ***Arena: An Adventure in the American Theatre*** (1941). (H. F. D.)

FEDERAL TRADE COMMISSION, THE, a U.S. administrative agency. was created by federal legislative enactment in 1914. Congress gave the commission two distinct powers. The first was couched in language similar to that previously given to the bureau of corporations, which had been organized under the department of labour and commerce in 1903. In fact. the bureau had been transferred to and became a part of the commission. Under this power, the commission could investigate corporations and business and report its findings to congress, the president or the public at large. It could also, at the request of congress or either house, or the president or the attorney general, make investigations and report the results. The commission. in the industrial world. was to keep the public and the administrative and legislative departments of the government informed of the conditions in the several industries and to make special economic and legal studies and inform congress.

The second great power entrusted to it came into play when in the interest of the public welfare the commission deemed it necessary to issue a complaint against any offending business unit that was practising an unfair method of competition. It required the offender to reply, and testimony was taken under oath relative to the issue involved.

The statute required the commission either to dismiss the complaint in the event that the testimony was insufficient to establish an unfair method of competition in interstate commerce or, if a case was made out, to issue an order to cease and desist from the offending method. Many of the complaints issued have been based upon charges made by one competitor against another.

The policy of the commission in its earliest days was not to name the offender publicly but to make findings and issue an order to cease and desist. Since this did not seem to halt the practices complained of, the commission later named the offenders publicly when a complaint was issued.

Simultaneously with the passage of the Federal Trade Commission act, congress passed the Clayton Antitrust act, approved Oct. 15, 1914. Under it congress entrusted the commission with the prevention of unlawful price discriminations, tying contracts, stock acquisitions in competing corporations and interlocking directorates. The purpose of these provisions was to prevent certain practices which were regarded as lessening competition or tending to monopoly. but which it was feared would not always in themselves be sufficient to bring the person who practised them within the scope of the Sherman Antitrust act of 1890.

The commission was not long in finding that when one competitor in an industry violated legal rules of practice it was soon followed by many others. This frequently resulted in a deluge of complaints which would have absorbed more time than the legal section could spare. Thus a procedure called the Trade Practice submittal was inaugurated. The name was later changed to that of Trade Practice conference. In these conferences members of the industry concerned were assembled to consider and adopt fair trade practice rules to be submitted to the commission for its approval, the conferences being held under the auspices of the commission. After being subjected to public hearing and full consideration, the approved rules were promulgated by the commission. The early beginnings of the conference method go back as far as 1919. The commission thereafter held many industry trade conferences and set rules for the different trade or industrial groups. These cover industries whose capital investment and annual volume of sales total several billions of dollars.

An outstanding advantage of this method of regulating business practices is that it effectuates the wholesale abandonment and prevention of unfair methods of competition and trade abuses voluntarily, co-operatively and simultaneously. Correction is thus brought about on a friendly basis and at substantial saving of time and expense to the government and to business, and. at the same time, the public and industry generally are shielded from harmful effects of bad practices.

This plan worked so well that in some instances it brought about general correction of harmful practices throughout an entire industry without incurring the expenditure. of time and money which would otherwise be required to eradicate these evils by compulsory action through legal proceedings instituted against individual offenders.

Bforeover, this procedure of the commission afforded industry a means of proper self-regulation and co-operative effort nith the assistance and supervision of the government. Under the rules, industry and trade receive official guidance and assurance as to the inhibitions of the law. The rules constitute a convenient and authoritative code whereby manufacturers, distributors and buyers may readily be informed as to what the legal requirements are as they apply to the particular industry or trade. Law observance is promoted.

The rules operate as an effective deterrent to violations which result from ignorance, carelessness or even indifference, beside assisting in making compulsory correction more efficient. Consumer rights are carefully protected, and members of the industry who desire to serve the public conscientiously and with increased satisfaction are aided. The trade practice conference procedure thus came to be widely recognized as an official activity productive of great public good.

In order to speed up action with respect to complaints filed and to offer the respondent the privilege of disposing of his case without the cost of a trial, the commission devised a procedure before issuance of a complaint and trial of permitting the respondent to sign a statement of fact and agreement to discontinue the alleged unfair method of competition or practice, the subject matter and form of'the stipulation being prepared under supervision of the commission in accordance with the facts as disclosed by its investigation.

Administration of the Clayton act had for some time demonstrated its inadequacy as a restraint upon the growth of monopoly. The result was an amendment by the Robinson-Patman act on June 19, 1936. Designed to eliminate certain unfair and discriminatory practices not prohibited by the Clayton act and believed by congress to be injurious to commerce. the Robinson-Patman act, broadly speaking, was to promote equality of opportunity in business and check a tendency toward monopoly disclosed as a result of the Federal Trade commission's chain-store investigation, the investigation by a special committee of the house of representatives of the lobbying activities of certain groups. and congressional committee hearings held during consideration of the act itself. The act was not directed at any particular type or size of business organization but was applied to all merchants, large and small alike. It prohibited discriminations in price to purchasers of commodities of like grade and quality where the effect of such discriminations was substantially to lessen competition, in any line of commerce, unless such discriminations were justified by savings attributable to economies of operation effected by the particular method in which commodities were manufactured for, or were sold or delivered to. the purchaser receiving the discrimination. This passing on of savings by sellers to buyers was made permissive, however, not mandatory.

The Federal Trade Commission act was broadly amended March 21, 1938. by what is known as the Wheeler-Lea act. There were several reasons which induced congress to make these amendments. In a case before the supreme court of the United States in 1931, involving what was considered by the commission to be a dangerously misleading and false advertisement, the court held that the commission had no authority to ban the false advertising because it did not appear that the unfair practices were "methods of competition in commerce."

Congress accordingly amended the act so as to make unfair or deceptive acts or practices in commerce unlawful as well as unfair methods of competition, thus granting the purchasing or consuming public the same protection against unfair practices that a merchant or manufacturer already enjoyed against the unfair methods of a dishonest competitor. Congress also provided definite and substantial civil penalties, through suits to be brought by the attorney general, for violation of the commission's order to cease and desist after they became final. The review by the courts of the commission's orders to cease and desist, through the filing of petitions to review or set aside the same, was amended so as to require thereafter the petition to be filed within 60 days. Otherwise, the commission's order became final, and its violation thereafter subjected the offender to suits for civil penalties.

Prior to the passage of later amendments, there was no penalty for violation of the commission's orders, unless they were violated after they had been affirmed by a circuit court of appeals of the United States. Proof of such violation, after the order had been affirmed by the circuit court of appeals. formed the basis for contempt proceedings. Such proceedings might be brought in cases where. on review sought by the respondent, the courts affirmed the commission's orders, if such orders were thereafter violated.

The hearing examiners became an initial trial court on June 1, 1950. Appeals from that court might be made to the commission by respondents and commission attorneys, or the commission might schedule the issue for review on its own motion.

In response to the demand for greater consumer protection in the case of the deceptive advertising of commodities whose use might affect the public health. congress specifically prohibited the dissemination of the false advertisements of food, drugs, cosmetics and therapeutic devices.

Where the use of such commodities might be injurious to health, or where they are falsely advertised with fraudulent intent, criminal penalties are imposed. In a further effort to grant adequate protection to the public during the period pending the issuance of and final action upon the commission's complaint, the commission was authorized to bring suit in the several U.S. district courts, or in territorial courts, to enjoin the dissemination of the false advertisements of food, drugs, devices or cosmetics. Such temporary injunction was to remain in effect until the order of the commission to cease and desist became final. unless the complaint was dismissed by the commission or the order to cease and desist was set aside by the court on review.

Advertising over the radio became so extensive and so constantly necessitated the determination of what is fair and unfair in advertising through that medium that the commission, in 1938, established a Radio and Periodical division. This division took over the duties theretofore handled by the commission's Special Board of Investigation and, at the same time, its supervision was extended so as to cover mail-order catalogues and foreign-language newspapers. Thousands of pages of magazine and newspaper copy and thousands of radio and television continuities are scanned yearly. and the commission keeps in close touch with broadcasters and their clients. It was found necessary for the commission in the field of medicinal advertisements to add to its staff medical men as consultants.

The commission continued to operate under the Federal Trade Commission act as later amended and the Clayton Antitrust act (including the Robinson-Patman and Antimerger amendments) and was also authorized to act in a quasi-judicial and quasi-legislative capacity by acts dealing with export trade, wool and fur products labelling, flammable fabrics, trademarks, etc. Through its orders to cease and desist and through other means such as formal litigation leading to mandatory orders and voluntary co-operation the FTC protected businessmen from unfair competition and the consuming public from false, deceptive or dangerous trade and advertising practices.

(See also INTERSTATE COMMERCE.) (H. TH.; X.)

FEDERATION OF BRITISH INDUSTRIES. The Federation of British Industries is the largest national voluntary organization representing productive industry in the Cnited Kingdom. It was founded in 1916 and incorporated by royal charter in 1923. Through it industrial policy is shaped and expressed both nationally and internationally, and industry can develop activities to help itself. It has no connection with any political party. Apart from labour questions the scope of its work covers the whole range of industrial activity.

All the leading trade associations representing British industries are members, together with several thousand individual firms. Its governing body, the grand council, is elected by members every three years; about two-thirds of its members represent trade associations and the remainder individual firms and each of the ten F.B.I. regional councils. It is advised by 19 standing committees and many subcommittees dealing with specialized subjects ranging from taxation to overseas trade, and by the regional councils elected by members in the region, which deal with local issues and help to keep members in touch with the centre and vice versa. The president is elected annually, but usually holds office for two years. The staff of about 160 is under a director-general, assisted by a general secretary and four directors. The head office is in London and there are also offices in 14 industrial centres in the United Kingdom and representatives in about 100 countries overseas. By representations to ministers, by evidence to official inquiries. through government committees and by continuous liaison with government departments, the federation seeks to safeguard the interests of industry and to persuade the government in the fields of legislation and administration to create and foster conditions nationally and internationally in which industry can flourish. It also seeks to acquaint the press and the public with industry's problems and points of view and to give a lead to industry itself. Its expert staff gives direct service to members on export problems and many technical subjects such as taxation, fuel efficiency and trade effluent. (D. L. W.)

FEDERER, HEINRICH (1866–1928), a prolific Swiss novelist. was born at Brienz. Oct. 7, 1866. and died at Ziirich. April 29,

1928. Destined for the priesthood, he had to give up his pastoral duties because of his health and thenceforth devoted himself to literary work. He is one of the most poetic, richest and delectable of the so-called *Heimatkünstler,* or authors dealing mainly with native subjects, while his Roman Catholicism introduces a note that is rather unusual in German Swiss literature. His second subject was Italy, especially the Abruzzi. Among the best-known of his novels are *Berge und Menschen* (1911), *Jungfer Therese* (1913), *Das Mätteliseppi* (1916; his own favourite) and *Papst und Kaiser im Dorf* (1924). His short stories are equally charming, such as *Sisto e Sesto* (1913), an extraordinarily popular book and the collection under the title of *Lachweiler Geschichten* (1911). Federer's last work was a volume of reminiscences of his youth. *Am Fenster* (1927).

FEE, an estate in land held of a superior lord on condition of the performance of homage or service (*see* FEUDALISM). In English law "fee" signifies an estate of inheritance (*i e.,* an estate descendable to the heirs of the grantee as long as there are any in existence) as opposed to an estate for life. It is divisible into three types: (1) fee simple; (2) conditional fee; (3) fee tail. A fee farm rent is the rent reserved on granting a fee farm; *i.e*, land in fee simple, to be held by the tenant and his heirs at a yearly rent (*See* RENT.) Fee may also mean payment for professional services

FEEBLE-MINDEDNESS: *see* MENTAL DEFICIENCY.

FEEDS, ANIMAL. The materials on which animals are fed differ widely in chemical composition and nutritive value. For convenience they are divided into two general classes: concentrates and roughages. Concentrates include a large variety of feeds that have a high value because they are rich in easily digested nutrients, such as starch, fat and protein, and are low in fibre. or woody material, which is not well digested. Roughages have a much lower value because they are relatively high in fibre and contain less of the more digestible nutrients.

Good nutrition is necessary if animals are to be able to maintain health and produce satisfactory amounts of milk, eggs, meat. wool or work. Animals require each day food furnishing sufficient amounts of protein; energy. chiefly supplied by the carbohydrates and fat; essential minerals; and vitamins. Plenty of water and air are also needed.

This article deals with the nutritional value, supply and utilization of (1) proteins; (2) carbohydrates and fat; (3) minerals; (4) vitamins; (5) composition and valuation of animal feeds; (6) important concentrate feeds; and (7) important roughages. In addition to related articles referred to in this article, *see* also for production, marketing and other information on specific feeds the articles on such individual crops and products, as ALFALFA; CORN; COTTONSEED; SOYBEAN, etc.

Material on storage and processing and on feeders will be found in the articles CROP PROCESSING MACHINERY; FARM MACHINERY; FARM BUILDINGS. For feeds and feeding practices for specific animals *see* articles such as CATTLE; PIG; SHEEP etc

Protein.—A certain minimum amount of protein is needed for the daily repair of muscles, internal organs and other tissues of the body. In addition to this maintenance need, animals that are growing require much larger amounts of protein for the growth of the muscles and other parts of the body. Since milk, eggs and wool contain much protein, additional amounts of protein are needed for their production. Physical work, even hard work. does not perceptibly increase the protein requirement, because carbohydrates and fat can furnish the needed energy.

Proteins are complex substances. made up of a variety of amino acids. In the digestion of food the proteins are largely broken down into these amino acids, which are absorbed into the blood to nourish all parts of the body. For animals with simple stomachs, including humans, monkeys, swine, poultry, dogs, cats, hamsters, rabbits. guinea pigs mink and rats, the kind or quality of the protein in the ration is more important than the amount. These animals require daily the correct amounts of the following ten essential amino acids: arginine, histidine, isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan and valine. In addition to these, poultry need glycine and glutamic acid for growth. High quality protein contains the correct amounts of the essential amino acids. Such protein is supplied by eggs, milk and milk products, fish meal and meat by-products, and by soybean oil meal. Poor quality protein, such as found in corn grain (maize) contains too little of one or more essential amino acids to meet the needs of animals. Those feeds having poor quality proteins are made useful by combining with them other feeds which supply the lacking amino acids.

Fortunately, the quality of the protein in the food is of little importance for ruminants, including cattle, sheep, goats and the other animals that have four stomachs with a large paunch or rumen. This is because the bacteria that are important in the digestion of food in the paunch are able to make complete proteins. containing all the essential amino acids, from simpler nitrogen-containing compounds. They use the simple nitrogen compounds to build proteins in their cells. Then further on in the digestive tract, the animals digest the bacteria and thus secure by this indirect means protein of high quality from a food that might originally have had poor protein. By this method cattle and sheep are able to use urea, a nitrogen compound synthesized from the air, in place of protein. which is sometimes scarce and expensive. Only the ruminant animals can use urea instead of protein. Very young ruminants, such as calves. lambs and kids, however, need plenty of good-quality protein until the paunch develops sufficiently for this bacterial process to become well established. *See* also PROTEINS.

Carbohydrates and Fat.—Since the body temperature of warm-blooded animals is considerably above the usual temperature of the air, food nutrients must be oxidized, or burned, in the body to supply the necessary heat. In addition, even animals at rest must have a certain amount of energy-producing nutrients to enable them to carry on their normal vital functions. Growing animals need more energy than mature ones that are being merely maintained, because of the storage of energy-rich nutrients (protein and fat) in the growing tissues. For rapid fattening, for milk production and for work additional amounts of energy must likewise be supplied.

The need for heat and energy can be met by carbohydrates such as starch or sugar, or by fat. If the food of an animal furnishes more protein than is required for the special protein functions, the excess protein can be oxidized in the body to supply heat or energy.

Some of the carbohydrates in feeds, especially starch and sugars, are easily digested by animals and therefore have a high nutritive value. On the other hand, the complex carbohydrates that form the fibre of plants are digested less completely. Also, there is a large loss of energy in the process, this energy being converted into heat in the body. It thus can help keep the body warm, but has no value for productive purposes. Therefore, fibre has a low value in comparison with starch or sugar. Although humans and such animals as swine, poultry, dogs, cats and other animals with simple stomachs can digest but little of the fibre in feeds. cattle, sheep and goats are able to make much better use of it. This is because fibre is digested through the bacterial action that occurs in the paunch. or rumen of these animals. Horses and rabbits are also able to use fibre fairly well. as similar bacterial digestion takes place in the blind gut, or caecum. a greatly enlarged part of the large intestine. These classes of farm animals can, therefore, be fed to a considerable extent, and in some cases entirely, on hay and other roughages which are high in fibre.

Fat in feeds has a high value because it is highly digestible and because it supplies about two and one-quarter times as much energy as does starch or sugar. While fat has this high nutritive value, it can be replaced by an equivalent amount of digestible carbohydrates in the food, except for small amounts of essential fatty acids. It was found in experiments with laboratory animals, and pigs and calves, that very small amounts of certain fatty acids. especially linoleic and linolenic, contained in some fats, are necessary for growth and health. However, usual feeds supply ample amounts of these acids unless they have been removed by processing. *See* also CARBOHYDRATES; OILS, FATS AND WAXES.

Minerals. — Certain mineral nutrients are fully as essential for animal life as are protein. carbohydrates and fat. Among these are common salt (sodium chloride), calcium, phosphorus. sulfur, potassium, magnesium, manganese, iron. copper, cobalt, iodine. zinc, molybdenum and selenium. The latter six of these elements are poisonous to animals if excessive amounts are eaten.

All farm animals generally need common salt in addition to that supplied by their feeds, and they should be supplied nith it regularly. Of the other essential minerals. phosphorus and calcium are most apt to be lacking, because they are heavily drawn upon to produce bones and also milk. Good phosphorus supplements are steamed bone meal, dicalcium phosphate, or defluorinated phosphates (especially processed to remove most of the mineral element fluorine, which may injure animals). Calcium may readily be supplied by ground limestone, ground shells or marl that is high in calcium.

Small amounts of iodine are needed by the body for the formation of thyroxine, an iodine-containing compound secreted by the thyroid gland. This controls the rate of metabolism or body processes. A serious deficiency of iodine may cause goitre, a disease in which the thyroid gland enlarges greatly in a vain effort to produce thyroxine. In certain regions there have been heavy losses of newborn pigs, lambs, kids, calves and foals from goitre. The young so affected are born dead or weak, and the pigs are usually nearly hairless. Experiments have proved that this trouble can be prevented by supplying small amounts of iodine to the mother animals before the young are born. The simplest method has been to use iodized salt during this period instead of ordinary salt.

In a few districts the soil and forage are deficient in copper and cobalt, which are needed along with iron for the formation of hemoglobin, or red colouring matter of the red blood cells In these districts farm animals may suffer seriously from anemia. or a lack of red blood cells, unless the deficiency is corrected by means of a suitable mineral supplement. Trace amounts of molybdenum also are needed for certain enzymes in animal tissues. However, excess amounts of molybdenum are found in the soil and legume forages in limited areas of England, Holland, Australia, New Zealand and the U.S. Forages in these areas may cause severe diarrhea and loss of pigmentation in the hair coats of cattle. These symptoms can be prevented or corrected by feeding copper salts. Iron, which is used in hemoglobin formation, is amply supplied in all animal feeds, except milk. The only practical problem with iron deficiency occurs in young suckling pigs, before they start to consume other feeds in addition to milk.

Though manganese is essential for animals, sufficient is supplied by the usual rations for all farm animals except poultry. A lack of manganese may cause the nutritional disease of chicks and young turkeys called slipped tendon, or perosis, and also may cause a failure of eggs to hatch. Sufficient manganese is readily furnished in poultry rations by adding one-quarter pound of manganese sulfate to each ton of feed. So far as is known. the other minerals that are essential for farm animals are provided in ample amounts in their ordinary rations.

A number of practical rations for swine have been shown to result in zinc deficiency, especially in the presence of an excess of calcium. Adding 100 parts per million of zinc carbonate will overcome the symptoms otherwise observed, which include retarded growth rate and severe scaliness and cracking of the skin, called parakeratosis. A trace of selenium is necessary for normal health of animals, but the excessive amounts found in forages in some regions prove poisonous to animals and may cause death loss.

To furnish both calcium and phosphorus, livestock may be allowed free access to such a mixture as 60 lb. dicalcium phosphate and 40 lb. common salt. Trace mineralized salt should be used uhen copper or cobalt may be deficient. It is a good plan also to allow animals access to common salt separately, so that they will not be forced to eat more of the other minerals than they require to get the amount of salt they need. Mineral supplements are relatively inexpensive, and therefore suitable mixtures can be fed when there is any probability of rations being deficient in mineral elements. See FERTILIZERS AND MANURES: Influence of Fertilizers on Livestock and Human Food.

Vitamins. — The numerous scientific discoveries concerning the vitamins had a profound effect upon livestock farming by increasing the efficiency of animal production and preventing serious nutritional diseases. For example, before the functions of vitamins were known, pigs that were born in the fall in colder climates often failed to thrive, and many became paralyzed or died from pneumonia or other diseases. This fall-pig problem was solved through the use of improved rations that provided an ample supply of the essential vitamins.

Vitamin A is the vitamin that is most apt to be lacking in livestock feeds. It is required for growth, reproduction, milk production and even for the maintenance of mature animals. A serious deficiency makes animals especially subject to diseases of the respiratory tract, and thus pigs fed rations lacking vitamin A often die of pneumonia.

Feeds of plant origin that have a high vitamin A value really contain little or no actual vitamin A, which is colourless. Instead, they contain yellow-coloured carotene, which animals can readily convert into vitamin A. All green growing crops are rich in carotene, therefore animals that are on good green pasture have an abundant supply. In curing green crops into hay in the field some of the carotene is destroyed but enough remains so that well-cured, green-coloured hay is nearly always high in vitamin A value. The carotene content of green forage crops is preserved still better by making them into silage. Most seeds and their by-products have little or no vitamin A value. A notable exception is yellow corn, which has considerable, while white corn has little or none.

When cattle, sheep and horses have good pasture during the growing season and receive well-cured hay or hay and silage during the winter. they have an ample supply of vitamin A. For swine that are not on pasture, 5% to 10% of good quality alfalfa hay or other legume hay can be included in the ration as insurance against a lack of this vitamin. Alfalfa meal is also included in most commercial poultry rations to supply this vitamin.

Next to vitamin A, attention is given to vitamin D in livestock feeding. This vitamin is needed to enable animals to assimilate and use the minerals, calcium and phosphorus. A deficiency of the vitamin causes serious bone diseases such as rickets in young growing animals. Fortunately. sunlight that has not passed through window glass has vitamin D value. This is because the ultraviolet rays of sunlight penetrate the skin of animals and produce vitamin D from the provitamin in the tissues. It is strange that green forage crops growing in the bright sunlight contain little or no vitamin D. However, in the field-curing of hay considerable vitamin D is developed through the action of the sunlight on ergosterol in the hay crops Cod-liver oil and certain other fish oils are very rich in vitamin D.

Livestock that are outdoors in the sunlight much of the time have a plentiful supply of vitamin D. Under winter conditions in cold regions, cattle, sheep and horses ordinarily get ample amounts from the hay they are fed. Including 5% to 10% good-quality field-cured legume hay in swine rations during the winter not only supplies vitamin A, but also usually provides sufficient vitamin D. Because poultry have especially high vitamin D requirements, special vitamin D supplements are included in their rations, particularly under winter conditions, or when they are confined away from the direct sunlight.

The vitamins included in the vitamin B group are not important in the feeding of cattle, sheep and other ruminants. This is because the bacteria that aid in digestion in the paunch, or rumen, synthesize these vitamins and consequently provide such animals with plenty. Very young calves that are being raised on milk substitutes and other special diets may benefit slightly by the addition of yeast, a rich source of these vitamins, to their ration. Poultry, swine and other simple-stomached animals also require the B vitamins in their diets. The B vitamins include thiamine. riboflavin, niacin, pantothenic acid, choline. biotin, folic acid, vitamin B_6 and vitamin B_{12}. There is evidence that there are still other factors in this group (see VITAMINS). Of the B vitamins, riboflavin, niacin, pantothenic acid and vitamin B_{12} are the ones most likely to be deficient in ordinary feeds and at times special supplements are needed by pigs, poultry and laboratory animals for best results Choline may also be deficient in poultry feeds. The other B vitamins are found in adequate amounts in typical feeds so that special sources are usually unnecessary. Some of the B vitamins (biotin and inositol) and also vitamin K are synthesized by bacteria in the intestinal tract of animals and therefore the amount in the feed is of no importance

Vitamin E is necessary for normal hatchability of eggs, and it plays a role in preventing muscle stiffness and paralysis (dystrophy) in lambs and calves under certain conditions. Except for these instances natural feeds contain ample vitamin E to meet the needs of animals. Vitamin C, which prevents scurvy in humans and guinea pigs can be synthesized in the bodies of other animals and need not be supplied in their food.

Composition and Valuation **of** Feeds.—In order to combine the various feeds that may be available into rations that will meet the nutritive requirements of animals it is necessary, first of all, to have definite knowledge concerning their chemical composition. In the usual chemical analysis of feeds all the compounds are grouped for simplicity and ease of analysis into the following general classes: dry matter; protein; fat; crude fibre, often called merely fibre; nitrogen-free extract; and mineral matter or ash. The nitrogen-free extract includes the more digestible and valuable carbohydrates, such as starch and sugar. Analyses for the mineral elements, calcium, phosphorus, cobalt, copper, zinc and others, are sometimes made.

The standard reference books on livestock feeding and the publications of the U.S. National Research council contain extensive tables showing the chemical composition of many different feeds. Chemical analyses show merely the total amounts of the various classes of nutrients that a particular feed contains, but they do not give definite information concerning the extent to which animals can digest and use the nutrients. Digestion experiments are, therefore, conducted with animals to determine the amounts of nutrients in various feeds that are actually digestible. From the results of such studies the percentage of digestible protein and the amount of digestible energy, is commonly stated. The percentage of "total digestible nutrients" may also be calculated. This is the sum of the digestible protein, the digestible fibre, the digestible nitrogen-free extract and the digestible fat, the last being multiplied by 2.25. This is done because one pound of fat supplies two and one-quarter times as much energy as does one pound of digestible carbohydrates.

Tables stating the percentages of digestible nutrients in various feeds furnish useful information concerning their values. However, certain losses of energy occur during the absorption and utilization of food which are not deducted in determining the digestible nutrients The most important of these additional losses is the loss of energy in the work of digestion and metabolism. It is easy to see that energy is required for the movements of the jaws in chewing, for the movements of the digestive tract and for the increased work of the heart and lungs during digestion. Also the secretion of the digestive juices requires energy, and there are losses of energy in the heat produced by fermentations in the digestive tract. The energy used up in these processes takes the form of heat. and it may help to warm the body. However. it cannot be used for other purposes, because the body has no ability to convert heat into other forms of energy.

A further loss occurs through the speeding up of the body processes which always follows the eating of food. While nutrients are being absorbed from the digestive tract following a meal, more heat is produced than at other times. This effect is familiar to all of us, for we know that if we eat a meal when we are chilly, we will soon feel decidedly warmer. Likewise, if we eat too heartily in hot weather, we will suffer even more from the heat.

The losses of energy in the work of digestion are much higher in the case of feeds that are high in fibre than with grain and other concentrates that are low in fibre and therefore readily digested. For example, 30% of the energy in the nutrients from corn grain is used up in this work of digestion, while the loss is 60% in the case of wheat straw.

Many years ago O. Kellner in Germany and H. P. Armsby in the United States conducted long-continued experiments to determine the net nutritive values of typical feeds after all these losses were deducted. Their results and the studies of others on this question furnished valuable information concerning the actual productive value of typical feeds. Kellner expressed his results in terms of starch values, in which one pound of digestible starch is taken as the unit of energy. This system of measuring the net nutritive value of feeds has been widely used in European countries. In the United States, the method of Armsby has been generally followed, in which digestible energy, metabolizable energy. or net energy values are used.

TABLE *I.—Composition and Digestible Nutrients in Typical Livestock Feeds*

	Dry matter %	Protein %	Calcium %	Phosphorus %	Digestible protein %	Digestible energy kcal./lb.
Roughages						
Alfalfa hay	90.5	15.3	1.47	0.24	10.9	1.02
Timothy hay	89.0	6.6	0.35	0.14	3.0	0.99
Corn silage	27.6	2.3	0.10	0.07	1.2	0.37
Grass silage	25.8	3.2	0.32	0.12	1.9	0.31
Concentrates

Wheat bran	89.1	16.0	0.14	1.17	13.0	1.33

Source: NRC Publication 464

In Table I is shown the composition of some typical feeds with respect to dry matter, protein, calcium and phosphorus. The digestible protein and digestible energy values are also shown. Such values are useful in deciding which feeds will supply the nutrients needed by animals. Standard books contain tables showing the nutrient requirements of animals of various ages and sizes. Using these tables and others shoving the composition of feeds, it is possible to calculate the amounts of various feeds necessary to supply the nutrients needed by animals.

Important Concentrate Feeds.—First in importance among the concentrates are the cereal grains and the high-grade by-products of these grains that are secured in milling them for human food or in processing them for other purposes. All of the cereal grains, such as corn (maize), oats, barley, wheat and the grain sorghums, are rich in starch and high in digestibility, but they are low in protein and also in calcium, one of the important bone-building mineral nutrients. Moreover, their protein is of rather poor quality. The cereal grains are excellent livestock feeds when their deficiencies are made good by other feeds or by special supplements, such as amino acids, vitamins and minerals. They can to a considerable extent be used interchangeably. Certain cereal by-products are rich or fairly rich in protein, while others are low in this nutrient. In the first class are the by-products from milling wheat—wheat bran and wheat middlings; corn gluten feed, the chief by-product from the manufacture of starch from corn; brewers grains and brewers yeast from beer manufacture; and distillers grains from the production of distilled liquors and alcohol. Low-protein cereal by-products include hominy feed, the corn by-product from the manufacture of hominy and brewers grits; and corn feed meal, the by-product from making corn meal for human food.

Important among the concentrates are also other seeds, especially certain legume seeds, such as soybeans, field peas, horse beans (broad beans) and peanuts. The legume seeds are all high in protein, and soybeans and peanuts are also so high in fat, or oil, that they are important sources of oil for human food and industrial purposes.

From the processing of soybeans, peanuts and other oil-rich seeds for oil production, various oil meals are secured as by-products. In the older methods of processing these seeds, the fat, or oil. was removed by subjecting the crushed seeds to great pressure in hydraulic presses or in continuous screwlike expellers, but the oil meals thus produced still contained 5% or more of fat. In the newer solvent process, oils are extracted from the crushed seeds with a fat solvent, and the oil meals may contain less than 1% fat.

While solvent-process meals have very little fat, they are a little higher in protein than the hydraulic- or expeller-process oil meals, and are satisfactory feeds.

In the case of cottonseed and peanuts, which have woody hulls or husks, these are generally removed before the oil is separated in order to secure a more complete recovery of the oil and to produce a by-product with greater feeding value. Where the hulls are not removed. the by-product cannot legally be called oil meals in the United States, but are termed cottonseed feed and peanut feed. In Great Britain these by-products are called undecorticated oil meals.

Cottonseed oil meal, soybean oil meal and peanut oil meal all generally contain at least 41% protein and rank high in digestibility and feeding value. Cottonseed oil meal should not form more than about 9% of the rations for swine, to avoid injury from the effect of gossypol, a compound contained in varying amounts in this feed. However, cattle may safely be fed larger proportions of cottonseed oil meal. Newer processes have been devised for removing the gossypol and such meal can be fed to pigs and poultry in larger amounts. Linseed oil meal, the by-product from flax seed, has someuhat less protein, usually containing 32% to 34%. Because of its palatability and its laxative and conditioning effect, it is one of the most popular livestock feeds. Coconut oil meal, or copra oil meal, has only about 20% protein but ranks high as a feed for dairy cows.

From the beet sugar and the cane sugar factories come beet molasses, beet pulp and cane molasses or blackstrap molasses. These are palatable feeds, low in protein and high in carbohydrates. Important animal by-products are meat scraps and tankage from the meat packing plants, fish meal from fish processing plants and poultry waste and feather meal from poultry dressing plants. These usually have 50% or more of protein, which is of excellent quality and are, therefore, valuable protein supplements for swine and poultry. Excellent protein is also supplied by the dairy by-products — skim milk, buttermilk and whey, all available as dried products.

Important Roughages. — Among the roughages, first place should be given to the pasture plants for they generally furnish, during the growing season, most of the feed for beef cattle and sheep, much of that for dairy cows and even important amounts for swine and poultry. Because pasture usually supplies nutrients more cheaply than do harvested crops, it is important to fertilize and manage pastures so that an abundance of palatable forage is provided over as long a period as possible. For seeding pastures, a combination of grasses and legumes is used that is best adapted to the particular area. All green, actively growing pasture crops are fair to rich in protein and high in vitamins. When pasture plants become mature and weathered, their feeding value is greatly reduced.

Next in importance among roughages are the various kinds of hay, which is merely a grass or legume forage crop preserved by drying. Legume hay such as alfalfa or clover is much higher in protein, in calcium and usually in vitamin A value than is grass hay. Late cut hay, either legumes or grasses cut in the late bloom or seed stage of maturity, is worth much less than hay cut before the plants are in bloom or in the early bloom stage as it is less palatable, much higher in fibre and lower in protein and vitamins. Early cut and well-cured grass hay may even equal average legume hay in feeding value. except for the lower protein content. The use of special barn-drying procedures whereby air, sometimes heated, is blown through the partially dried hay to complete the drying process makes it possible to produce excellent quality hay even during rainy periods with little or no weather damage. Barn drying of hay often avoids the extensive loss of nutrients from leaching by rain and from prolonged exposure to the sun. *(See* also CROP DRYING AND PROCESSING; GRASSLAND.)

Green forage crops, such as corn, sorghum and the legumes and grasses, are preserved for winter feeding in the form of silage by placing the chopped forage in tower silos or in pits or trenches in the ground *(see* ENSILAGE). Silage is widely used, in addition to hay, as roughage for dairy cows, beef cattle, sheep and mature swine. Root crops, such as mangels or rutabagas (swedes), are raised extensively in some European countries for stock feed.

The straws from the cereal grains and corn cobs are very high in fibre and low in digestible nutrients. They can be utilized best for cattle, sheep or horses that are being maintained and not being fed for production or work. Such fibrous feeds require special supplements of protein, minerals and vitamins to give satisfactory results. *See* also NUTRITION; AGRICULTURAL EDUCATION AND RESEARCH.

FEELING, PSYCHOLOGY OF. The term "feeling" refers to the perception of events within the body. The term is a verbal noun denoting the action of the verb "to feel," which derives etymologically from the Middle-English verb *felen,* "to perceive by touch, by palpation." It soon came to mean, more generally, to perceive through those senses which are not referred to any special organ. As the known special organs of sense were the ones mediating the perception of the external world, the verb "to feel" came also to mean the perception of events within the body. Psychologists disagree on the use of the term "feeling." The definition above accords with that of R. S. Woodworth, who defines the problem of feeling and emotion as that of the individual's "internal state." Many other psychologists, however, still follow Kant in equating feeling to pleasantness and unpleasantness. In this article this narrow definition is avoided because it does violence to common usage without yielding any corresponding systematic advantages.

Subjectivity of Feeling. — Perception of external objects lends itself to verification by other people. When I perceive a book on my desk I can check on the presence or nature of the object perceived by asking others whether they see the book and how it looks to them. When I perceive a state of inflammation within my body—of my appendix, for example—no such simple checking on the presence and nature of the inflammation is possible. This obvious diiference between the perception of external and internal events is expressed by stating that feeling is characteristically subjective.

Problems of Feeling. — A consequence of the subjectivity of feeling is that its study is concerned with two relatively disparate problems. In studying the perception of an external object — of a book, for instance, we know perfectly well what the object is which we are perceiving, and our only problem is to ascertain how we perceive it. In studying the perception of an event within the organism, we often know practically nothing of the nature of this event. In consequence we are faced with two relatively distinct problems, namely, the problem of *how* we perceive the event and the problem of *what* the event is which we perceive.

In many instances of feeling, almost nothing about the nature of the event perceived was known until the 20th century. As a result, motivational systems were developed in which behaviour was related to events defined only in terms of a behavioural consequence. verbal or otherwise. An example is hedonism (*q.v.*), in which behaviour is considered to be determined by pleasure and displeasure. For rough predictions, hedonism is a useful doctrine. The fact, however, that all that is known essentially about pleasures is that they are called pleasures by the subject prevents any detailed systematic development of hedonism. Indeed, it leaves open the possibility that the correlation between pleasure and seeking behaviour is simply due to the fact that the subject labels as pleasures the events which he is in the habit of seeking.

Study of Internal Sensitivity. — After the 1850s great progress was made in knowledge of the internal sensitivity of the organism. (For details of this progress. *see* E. G. Boring's *Sensation and Perception in the History of Experimental Psychology,* ch. 13–14.) An idea of its magnitude is gained by noting that, whereas in 1846 E. H. Weber distinguished only two senses in addition to sight, hearing, taste and smell. C. J. Herrick in 1931 distinguished 23 classes of receptors involved in such additional senses. Much information has been gained on the perception of relatively simple localized stimulation within the body. It is known, for instance, that moderate increases in temperatures of the skin are perceived as warmth, moderate decreases as cold, checkerboard combinations of moderate increases and decreases as heat, intense increases as pain. Comparable information has not been gained, however. on the perception of such presumably widespread and heterogeneous internal states as the emotions.

Perception of Emotions.—A milestone in the psychology of feeling was William James's well-known theory of emotion, first formulated in 1884 and often called the James-Lange theory. The best-known formulation was presented by James in 1890, in his *Principles of Psychology* (vol. ii. p. 449), in which he wrote:

> Our natural way of thinking about the coarser emotions is that the mental perception of some fact excites the mental affection called the emotion, and that this latter state of mind gives rise to the bodily expression. My theory, on the contrary, is that *the bodily changes follow directly the perception of the exciting fact, and that our feeling of the same changes as they occur is the emotion.*

Subsequent evidence indicates that the perception of an emotion is not merely the perception of muscular and glandular responses. Indeed, James admitted this in 1894 by adding that the perception which initiates the emotion is affective in nature. Subsequent evidence also indicates. however, that the James-Lange theory is essentially correct, in that there is an internal sensory basis for feeling.

If emotion is in part a perception initiated by bodily responses, it is obviously desirable to know what these responses are. The best single answer to this question came from the work of the physiologist W. B. Cannon, who in a long series of experiments was able to show that the major emotions involve excitation of the sympathetic division of the autonomic nervous system, and that such excitation, because of the diffuse conduction, gives rise to a widespread set of specific responses of smooth muscles and glands—increase in heart rate, increase in blood pressure, inhibition of peristaltic movements, increased perspiration and many others. Carney Landis and William A. Hunt also showed that a loud sound yields a complex but highly specific skeletal startle response in man, and other investigators discovered a number of specific emotional pattern responses of the skeletal musculature in animals.

Search for "Affective Elements."—155th the emphasis of early experimental psychology on analysis of consciousness into elements. the question quite naturally arose: Does feeling consist of special affective elements? Attempts to answer this question led essentially to chaos. Wilhelm Wundt and E. B. Titchener held that there were special affective elements, different from sensations. Theodor Ziehen and Carl Stumpf denied the existence of such special affective elements. The two basic views were in turn starting points for further divergences. Titchener held that affective elements involved only one qualitative dimension, pleasantness-unpleasantness. Wundt held that they involved three: pleasantness-unpleasantness, strain-relaxation and excitement-depression. Those who agreed to the sensory nature of affective elements were likewise at odds. Ziehen considered pleasantness-unpleasantness to be an attribute of all sensations. Stumpf considered pleasantness-unpleasantness to be an attribute only of certain specific sensations, which he called feeling-sensations.

It is understandable how such disagreement could arise. An affective element, like any other entity in science, is a "construct"; it is not itself a datum, but a concept constructed by the psychologist to systematize his data; thus different psychologists may construct different concepts of affective elements. The fact that the disagreement did arise, however. suggests that the type of concept involved does not lend itself to successful systematization.

Something positive, however, came out of this chaotic chapter in the psychology of feeling, namely, the agreement of all these writers that pleasantness-unpleasantness is an important characteristic of feeling. A consequence of this was that the emphasis on psychophysics, so prevalent at the turn of the century, yielded, in the field of feeling, a very extensive psychophysics of affective value, as the dimension pleasantness-unpleasantness is called in English.

PSYCHOPHYSICS OF AFFECTIVE VALUE

Methods of Measurement.—Affective value is usually measured by one of the three so-called methods of impression. (1) In the method of single stimuli, the observer judges the affective value of a stimulus on a subjective scale. extending from very unpleasant through indifferent to very pleasant, usually involving five or seven steps. These steps are often represented numerically. (2) In the serial method the observer establishes the rank order of a set of stimuli with respect to affective value. This is done sometimes by having the observer select the most pleasant stimulus from the original set, then the most pleasant from the remaining stimuli, and so forth. sometimes by having him arrange the stimuli in a spatial order indicating their rank with respect to pleasantness. (3) In the method of paired comparison the observer judges the relative pleasantness of all possible paired combinations of a set stimuli. Thus, if stimuli a, b and c were involved, he would first be presented with a and b and judge nhich is the more pleasant, then with *b* and c and judge which of these two is more pleasant, and then with c and a and judge which of these two is the more pleasant. The frequency with which a stimulus is preferred, when paried successively with all the others, is considered a measure of its affective value.

The method of single stimuli, as described above, makes use of a scale defined in terms of categories. The work of S. S. Stevens in sensory psychophysics indicates that scales defined in terms of categories have a curvilinear relation to scales defined in terms of direct magnitude estimation. The face validity of the latter scales is greater. and Stevens' work shows that they yield remarkably simple and stable relations in sensory psychophysics. It is quite possible that the method of single stimuli with direct magnitude estimation will also prove fruitful in the measurement of affective value.

Relation of Affective Value to Intensity of Stimulation.—By and large, weak stimuli are judged to be indifferent, moderate ones pleasant, strong ones unpleasant. This is not, however. invariably the case. The best data on this relationship are those of R. Engel for the field of taste. Engel had observers judge

FIG. 1.—AFFECTIVE VALUE OF COMMON SALT SOLUTIONS AS A FUNCTION OF STRENGTH OF STIMULUS. SEVEN OBSERVERS IN SEVEN SITTINGS. THE FIGURE SHOWS ALSO THE IDEAL STIMULUS RANGES FOR PLEASANTNESS AND UNPLEASANTNESS (AFTER ENGEL)

the affective value of various concentrations of sweet, sour, salt and bitter solutions in terms of the four categories: indifferent, pleasant. unpleasant and doubtful. His results are presented in fig. 1 to 4. It will be noted that. although the data for sour, salt and bitter conform to the principle stated above. those for sweet do not. Sweet apparently continues to be judged pleasant no matter how high the concentration.

Relation to Quality of Stimulation.—The relation of affective value to intensity of stimulation, discussed above, implies that to be thoroughgoing, a comparison of the affective value of two or more qualities must involve the complete functions relating affective value to intensity for these qualities. Even for an incomplete comparison the data must refer to corresponding inten-

sities in the case of the various qualities and must be expressed in terms of the same units. Few of the data on the relation of affective value to quality satisfy even the latter two conditions. When further account is taken of affective growth and decay. discussed below, it is not surprising to find that available results on the relation of affective value to quality of stimulus are often conflicting.

Engel's data on taste do not satisfy the requirements set forth above. Nevertheless, it seems safe to draw the following conclusions: (1) If intensity is measured in terms of multiple of thresholds, the order of pleasantness is, for the major part of the scale of intensities, sweet, sour, salt, bitter. (2) If, however, intensities are measured in terms of concentrations, the order of the tastes varies with the concentration; at 5%, sugar alone is pleasant; at 1% salt alone; at 0.1% sour alone.

In the case of vision the work of J. P. Guilford yields excellent data on the relation of aifective value to hue, with brightness and saturation held constant (fig. 5). As Guilford used not only a set of 18 colours. varying only in hue, but also 22 additional colours introducing variations in brightness and saturation, he was able further to specify, by an ingenious statistical analysis, the relative role of hue, brightness and saturation in determining affective value, and also their joint effectiveness in this respect. His conclusions were as follows:

(1) Hue determined AV [Affective Value] to the extent of about 67 percent for the women and 16 percent for the men. . . . (2) Tint [brightness] determined AV about 20 percent for the women, but only 5 percent for the men. In both cases, the lighter the tint, the more pleasing the color, all other things being equal. (3) Chroma [saturation] determined AV only about 5 percent for the women, but 13 percent for the men, the more saturated colors being preferred to the less saturated. (4) The three attributes combined account for at least 71 percent of the AV of color for women and 26 percent for the men. (J. P. Guilford, "The Affective Value of Color as a Function of Hue, Tint and Chroma," *Journal of Experimental Psychology*, 17:369 [1934].)

FIG. 3.— AFFECTIVE VALUE OF SOLUTIONS OF TARTARIC ACID AS A FUNCTION OF STRENGTH OF STIMULUS. SEVEN OBSERVERS IN SIX SITTINGS (AFTER ENGEL)

With respect to tactile, kinaesthetic and organic sensitivity, knowledge of the relation of feeling to quality of stimulation is in a curious state. On the one hand, despite the close traditional relation between these senses and feeling, there is little experimental evidence relating affective value directly to quality of stimulation. On the other hand. there is strong evidence relating affective value to specific qualities of experience. The reason for this paradoxical situation is probably the obvious difficulty of ascertaining the nature of internal stimulation.

In 1924 J. P. Nafe published the results of an extensive experiment on the nature of conscious feeling. Observers were given a great variety of affective stimuli and asked to describe carefully and fully the resulting feelings. All observers ultimately agreed in describing pleasantness and unpleasantness as sensory pressures. In terms of quality, pleasantness was reported to be a bright pressure, unpleasantness a dull one. A subsequent experiment by Young suggested strongly that the identification of feeling with pressures was caused by laboratory atmosphere. An experiment by William A. Hunt, however, indicated that the basic correlation between pleasantness and bright pressure and between unpleasantness and dull pressure is correct.

Relation to Form. — Much specific information is available on the relation of affective value to form. This comes in part from the cumulative experience of artists, in part from experimental aesthetics (see AESTHETICS). One instance is the codification of

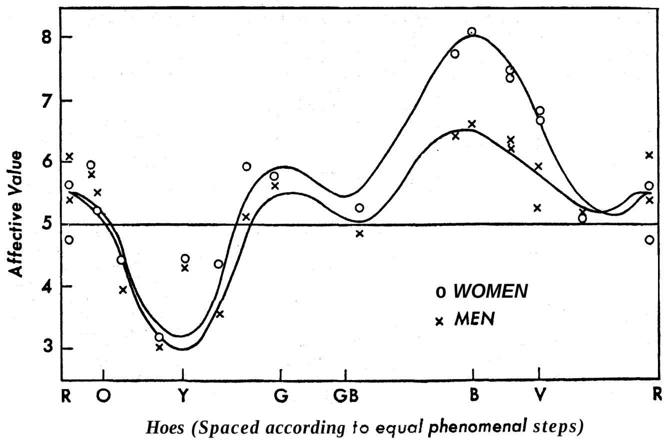
FIG. 4.— AFFECTIVE VALUE OF SOLUTIONS OF CANE SUGAR AS A FUNCTION OF STRENGTH OF STIMULUS. TEN OBSERVERS IN SIX SITTINGS (AFTER ENGEL)

knowledge concerning music in the form of rules of melody and harmony. Another is the demonstration of the aesthetic superiority of the golden section: *i.e.*, of the division of a line at such a point that the ratio of the smaller part to the larger part is the same as the ratio of the latter to the whole.

Many attempts have been made to organize this specific information under a few general principles, but in many cases the principles are not stated with sufficient rigour to allow them to be tested experimentally. An exception to this failing is afforded by George D. Birkhoff's mathematical formulation of the classical principle. According to Birkhoff, the aesthetic measure of an object is given by the relation $M = \frac{O}{C}$ where M represents the aesthetic measure, O the orderliness and C the complexity. O and C are in turn defined, for various classes of aesthetic objects, in terms of specific and observable elements of form. Experimental tests of this measure, particularly the work of C. M. Harsh and his co-workers, show that it accords as well with the average judgment of a group of observers as does, on the average, the judgment of a single observer, and further that it corresponds closely to the judgments of those observers who emphasize the criterion of simplicity.

Relation to Repetition of Stimulation. — There is no question but that affective value varies with repetition of the stimulus. In one experiment, for instance, repetition of popular music re-



FROM "JOURNAL OF EXPERIMENTAL PSYCHOLOGY," 17 342–370 (AMERICAN PSYCHOLOGICAL ASSOCIATION, 1934)

FIG. 5.—AFFECTIVE VALUE OF COLOURS AS A FUNCTION OF HUE (FROM GUILFORD)

sulted in a decrease in affective value, repetition of classical music in an increase. In another it was found that when children were made to taste a single substance day after day for several weeks, their liking for such a substance as chocolate and their dislike of such a substance as vinegar both decreased markedly as the experiment progressed.

There is considerable question, however, as to what principle is involved in these variations of feeling. (1) One principle, which may be called the principle of growth and decay, states that with repetition there is an increase of pleasantness or unpleasantness to a maximum. followed by a subsequent decay. (2) Another principle, that of habituation, states that repetition results only in a decrease of pleasantness or unpleasantness. (3) A third principle, that of psychological satiation, states that decrease in pleasantness or unpleasantness does, indeed, usually accompany repetition, but that its effect is due not simply to repetition but to loss of interest. Choice between these alternatives is not possible on the basis of available data. The most promising approach would seem to be through the study of food preferences in the rat, in which past experience and nutritional status can be fully controlled.

FOOD PREFERENCES IN ANIMALS

Study of feeling, as noted above, is complicated by the fact that the event being perceived is not open to direct inspection by others—by an experimenter, for instance. A promising approach to the problem of what is being perceived when an object is judged pleasant or unpleasant is the study of food preferences in animals.

P. T. Young, who worked extensively in this field, distinguished three principal methods. (1) In the method of choice, two foods are presented simultaneously for a brief time; the choice, if any, made by the animal is noted, and the foods are then removed. Repetition of this procedure allows a quantitative statement of preference in terms of the frequency of choice of the two foods. (2) In the method of continuous exposure. two foodstuffs are again presented simultaneously, but in this case the presentation is of relatively long duration—Young used periods of 4 to 900 seconds. The criterion of preference here is the time spent by the animal in eating each of the two foods. (3) In the method of self-selection, extensively used by C. P. Richter, a nutritionally adequate set of foods or food components, each presented in a separate container, is continuously available to the animal. The criterion of preference here is the amount of each food or food component consumed by the animal per unit of time, usually per day.

The close relation of food preferences to need is well demonstrated by the work of Richter on self-selection of diets. An early experiment (1936) dealt with rats whose adrenal glands had been removed surgically. Normally such animals die in 10 or 1j days after the operation, apparently because of excessive loss of salt. Richter found that when given free access to salt, adrenalectomized rats took a sufficient amount to keep themselves alive and well. In some animals the salt intake increased 15-fold after adrenalectomy. Much the same picture developed in the case of rats whose parathyroids had been removed. Under ordinary conditions such animals show symptoms of tetany and eventually die. With free access to calcium lactate they lived indefinitely. In one animal voluntary intake of calcium lactate was increased 12-fold after the operation.

These findings suggested that normal animals might be able to select of their own accord the amounts of nutritive components they need. To test this hypothesis, Richter (1938) selected ten substances representing the ten dietary components thought to be necessary in a rat's diet, and gave a group of rats free access to these materials, presented in separate containers. The ten substances, together with the dietary components which they represent, are listed below:

Substance	*Dietary component represented*
1. Casein, autoclaved and purified	Protein
2. Sucrose	Carbohydrate
3. Olive oil	Fat
4. Sodium chloride (3% solution)	Sodium
5. Calcium lactate (2.4% solution)	Calcium
6. Dibasic sodium phosphate (8% solution)	Phosphorus
7. Potassium chloride (1% solution)	Potassium
8. Cod-liver oil	Vitamins A and D
9. Dried baker's yeast	Vitamin B complex
10. Wheat germ oil	Vitamin E

Richter found that the rats fed by this method remained in excellent condition, as judged by such criteria as growth and general activity. It is clear, therefore. that when given the opportunity, rats select dietary components in accordance with their nutritive needs.

What mechanism is here involved? Richter found that the preference threshold of rats for saline solutions was much lower in adrenalectomized rats than in normals. On the basis of these and other data, he concluded that a specific nutritive deficiency decreases the taste threshold for the substance involved, and that this lowered threshold results in selection and increases intake of that substance. Subsequent work by Carl Pfaffmann and his associates confirmed Richter's finding with respect to the preference threshold, but further showed that the taste threshold. determined electrophysiologically, was not affected by adrenalectomy. It follows that Richter's equation of preference threshold and taste threshold was wrong, and consequently that his theory was to that extent also wrong.

Later attempts to identify the mechanisms underlying food preferences include a series of elegant experiments by E. Stellar and R. A. McCleary, who studied the effect of preloading rats' stomachs with various solutions on the rats' preferences for those solutions. Stellar's conclusions from his own work with salt solutions were as follows:

> Water drinking and the drinking of salt solutions are under the control of at least three factors: taste and other sensory mechanisms in the mouth, gastric distention, and dehydration produced by the osmotic effects of hypertonic solutions on the stomach. The ascending limb of the preference-aversion [function] is partly a matter of response to dehydration, but, more particularly, is an increasing response to increasing taste stimulation. The descending limb is partly due to negative stimulation of the mouth, hut is largely the result of the increasing inhibition of drinking produced by increasingly hypertonic solutions in the stomach. (Stellar, Hyman and Samet, *Journal of Comparative and Physiological Psychology,* 47:225–226 [1954]).

The effect of one of these factors, the sensory factor, was studied extensively by P. T. Young, who concluded that results involving this factor may best be interpreted by assuming a so-called "intervening variable" termed "affective process" and defined by the relations found in the study of preferences. Such an intervening variable can be rigidly defined and can serve to systematize findings of studies of preferences. To do so gives a simple answer to the question, "What is the state perceived when we judge an event to be pleasant?" The answer is: an affective process; *i.e.,* a concept systematizing preference behaviour. This answer may well be right. But until more is learned about the nature of concepts, the answer is not very informative.

EFFECTS OF REWARDS AND PUNISHMENTS ON BEHAVIOUR

The study of the effects of rewards and punishments on behaviour constitutes another promising approach to the problem of what is being perceived when an object is judged pleasant or unpleasant. By far the best information on this subject came from the work of B. F. Skinner and his associates. Skinner pointed out that mankind is especially interested in behaviour that has an effect on the environment (operant behaviour), and that this kind of behaviour tends to be influenced by the feedback of its consequences (reinforcement). If now we arrange a situation in which one particular effect on the environment—depression of a bar by a rat—has one particular consequence—the making available of a pellet of food to the rat—we can study the way in which the frequency of the operant *bar-press* is related to the frequency of the reinforcement *food-pellet available,* and also to *deprivation* with respect to food and the occurrence of a signal predicting the reinforcement, the *discriminative stimulus.* Such situations are provided by so-called Skinner boxes, which also provide effective insulation from environmental disturbances, a system for recording the bar-presses or target-pecks and a system for programing the reinforcements. If it is remembered that Skinner's operant is defined in terms of specific effects on the environment, not of specific movements, it is clear that a Skinner box provides an extremely ingenious way of studying what the layman would term the effects of reuards and punishments on purposive behaviour.

In the case of rewards, the relation with which Skinner was especially concerned was that between frequency of operant and schedule of reinforcement. as distinct from, for example, kind of reinforcement. Reinforcement can follow every bar-press (continuous reinforcement) or only some (intermittent reinforcement). In the latter case it can follow the first bar-press after a given time (interval reinforcement) or the *n*th occurrence of a bar-press (ratio reinforcement). Furthermore, both interval and ratio may be fixed or variable. Also, reinforcement may be stopped completely. The effects on frequency of operant of many instances of all these schedules, and also of many combinations of schedules, were explored by Skinner and his associates (for details, *see* C. B. Ferster and B. F. Skinner, *Schedules of Reinforcement* [1957]). Most of the work was done on pigeons, but enough mas done on higher organisms and man to indicate that the principles found have great generality. The result is a vast enrichment of knowledge of how to control behaviour through rewards.

With respect to punishment. the outstanding findings of Skinner and his associates were (1) that moderate punishment does not eliminate permanently the operant behaviour which it follows, but only decreases its frequency temporarily, and (2) that the relative effects of different schedules of punishment are much the same as those of different schedules of rewards.

What is the physiological mechanism by which rewards and punishments influence behaviour? A great step toward answering this question was made by James Olds and Peter Milner in an experiment published in 1954. Olds and Milner ran rats in a Skinner box in which pressing of the bar yielded for the rat not a pellet of food but an electric shock in the brain by means of implanted electrodes. When the electrodes were implanted in the septal region, lying just in front of the thalamus, bar-pressing increased definitely as a function of such electrical "reinforcement."

THEORY OF FEELING

Sense Organs Involved.— In his famous work, *The Integrative Action of the Nervous System* (Yale University Press. 1906) C. S. Sherrington distinguished between three main groups of sense organs on an anatomical and functional basis. These groups and their fundamental characteristics are indicated in the table.

Sherrington went on to point out that a salient character of most of the reactions of the receptor-organs other than distance receptors is affective tone, and that they are particularly closely

Main Groups of Sense Organs and Their Fundamental Characteristics

Loci	Groups	Receptor-organs	Characteristics
Surface	Exteroceptive: Distance	light sound odours	End organs numerous. Connections closer to skeletal musculature than visceral; closely connected to vascular organs
	Exteroceptive: Other	contact warmth cold pain	
	Interoceptive	taste chemical other?	End organs few; afferent fibres few; connections closer to visceral musculature than skeletal. Closely connected to vascular organs
Underlying	Proprioceptive	in muscles in tendons in joints in blood vessels	Stimuli are events in organism

connected with consummatory reactions. This view of Sherrington's amounts to a definite hypothesis as to the sense organs involved in feeling: all sense organs other than the visual, auditory and olfactory.

Nature of Events Perceived.--What events are perceived in feeling? This question amounts to asking, "What internal events are identified by the organism?" and this in turn amounts to asking, "What internal events are invariant for a given identification by the organism?" In the special case of human organisms, identification is judged most readily in terms of specificity of verbal response.

So far as present knowledge is concerned, feeling is largely the perception of muscular contractions. Hunger pangs are in the main perceptions of hunger contractions in the stomach. Fear is in part the perception of complex pattern of muscular contractions. The pain called angina pectoris is the perception of the contractions of the heart musculature deficient in blood supply. Headache is thought to be the perception of tension of the neck muscles.

This is not to say that feeling is solely the perception of bodily movements. Temperature changes. changes in pressure, changes in chemical condition within the body are also perceived. The homeostatic mechanisms of the body. however, tend to minimize such changes. In any case, little information is available concerning the perception of such events.

Feeling a Feedback.— Whether or not the principal events perceived in feeling are muscular contractions, it seems pretty clear that such events are principally reactions of the organism. In the case of muscular contractions, this is naturally obvious. It is true also. however, of chemical and temperature changes so largely controlled by homeostasis. A consequence of this is that feeling is potentially a mechanism by which the internal consequences of reactions of the organism may feed back into the nervous system and affect subsequent reactions. Is this potentiality actually realized? To some extent. yes. Stellar, as noted above, considers that eating behaviour is in part influenced by a taste factor. Again, under certain conditions of intractable pain the patient may be considerably benefited by section of nerves mediating pain sensitivity. G. Razran reported an experiment by E. S. Ayrapetyants showing that a dog can be taught to lift its paws when visceral changes occur. This technique seems very promising for the study of feedback effects of feeling on behaviour.

Categorization of Internal Events.—So far, the theory of feeling has been simple and straightforward. We now come to a feature of feeling which has continued to puzzle psychologists for centuries. Subjects perceiving internal events very often characterize them as pleasant or unpleasant. What is being identified in the case of such a characterization?

Two things should be noted at once in this connection. The first is that characterization with respect to pleasantness or unpleasantness is but one of several characterizations often applied by a subject to events within his organism. Wundt, for instance, considered feeling to have the dimensions of tension-relaxation and excitement-depression besides pleasantness-unpleasantness The second thing to note is that characterizations with respect to pleasantness or unpleasantness are also applied to objects outside the organism — to colours, for instance.

A widespread view is that the basic feature of perception is categorization. "Perception," according to J. S. Bruner, "involves an act of categorization. Put in terms of the antecedent and subsequent conditions from which we make our inferences, we stimulate an organism with some appropriate input and he responds by referring the input to some class of things or events" ("On Perceptual Readiness," Psychological Review, 64:123 [1957]). According to this view the only difference between identifying an internal event by the word "pain" and identifying it by the word "pleasant" would be in the specificity of the identification. In both cases a class of events would be identified, a relatively small one in the case of pain, a large one in the case of pleasant. From this point of view, characterization as pleasant is a verbal response generalized to a large number of stimuli, and the only problem is to determine the way in which this generalization takes place. This is presumably by the selective effects of social approval and disapproval. What, however, guarantees that the responses "pleasant" to candy and warmth and "unpleasant" to vinegar and electric shock shall be useful, and thus maintained by social approval and disapproval? It is not the presence of common affective elements.

Sucrose is a reward which increases the frequency of antecedent behaviour. Almost all subjects judge sucrose to be pleasant. The same correlation is found for a large number of different substances. The suggestion is obvious that reward value and categorization as pleasant are closely related. The older interpretations of this relation started from the categorization, inferred a conscious affective element, and explained the rewarding effect as a consequence of this element. In effect, this interpretation proposed that a substance has reward value because it is consciously perceived as pleasant; *i.e.*, produces a state of consciousness in the person that contains the conscious affective element of pleasure. Psychologists have never been able to agree on the nature of this element. Worse yet, this explanation does not reveal how the substance evokes the element in consciousness or how, once evoked, the element influences behaviour.

One modern alternative to this view replaces the conscious affective element by a so-called intervening variable defined in terms of the stimulus-response relationships involved in both rewarded behaviour and the behaviour of categorizing as pleasant. An example of this view is that of P. T. Young, who termed the resulting intervening variable an affective process (see above, Food Preferences in Aninzals).

A second modern alternative eschews both conscious affective elements and affective processes in the form of intervening variables. The starting point here is that certain events are reinforcing in the sense that the behaviour which they follow increases in frequency, and the categorization is interpreted simply at the naming of this class of events. An example of this view is that of F. S. Keller and W. N. Schoenield, who write:

> When someone tells us that an object, a color or a design is "pleasant" or "unpleasant," he is reporting upon his own reactions to that object, color, or design. A positive, or a negative, reinforcer has been presented or withdrawn; a change in behavior has taken place, including, perhaps, incipient movements of approach or withdrawal; these movements (or others) provide the S ~(essentially, cues) for his verbal responses—his "affective judgments." (Principles of Psychology, Appleton-Century-Crafts, Inc., p. 350 [1950]).

Role of Categorization **of Behaviour.**—Both these modern alternatives, it might be added. are consistent with Freud's doctrine of motivation and that of John Dollard and N. E. Miller, who combine the Freudian clinical approach with the experimental approach of Clark Hull. Freud held that neurotic behavior was largely determined by repressed affective processes. This is essentially to hold that categorization, in terms of pleasantness and unpleasantness, is a factor in motivation — witness the difference between neurotic and normal — but not a basic one — witness the motivation of the neurotic. Dollard and Miller hold a similar view. "Labeling" emotion facilitates the adjustment of the individual, but emotion is an effective factor in motivation, whether labeled or not.

FEHMIC COURTS, certain tribunals which, during the middle ages. exercised a powerful jurisdiction in Germany, and more especially in Westphalia. They are best regarded as survivals of ancient Teutonic local courts. Their alternative name of "free courts" is due to the fact that all freeborn men were eligible for membership and also to the fact that they claimed certain exceptional liberties. Their jurisdiction they eventually owed to the emperor, in whose name they exercised the power of life and death. The sessions were often held in secret, and these the uninitiated were forbidden to attend, on pain of death. Legend and romance have combined to exaggerate the sinister reputation of the Fehmic courts; but modern historical research has proved that they never employed torture, that their sittings were only sometimes secret, and that their meeting-places were always well known. They were, in fact, a survival of an ancient and venerable German institution; and if, during a certain period, they exercised something like a reign of terror over a great part of Germany, the cause of this lay in the condition of the times. which called for some powerful organization to combat the growing feudal anarchy.

The system became important after the division of the duchy of Saxony on the fall of Henry the Lion, when the archbishop of Cologne, duke of Westphalia from 1180 onward, placed himself as representative of the emperor at the head of the Fehme. The organization now rapidly spread. Every free man, born in lawful wedlock, and neither excommunicate nor outlaw, was eligible for membership. Princes and nobles were initiated, and in 1429 even the Emperor Sigismund himself became "a true and proper *Freischöffe* of the Holy Roman Empire." By the middle of the 14th century the sworn associates of the Fehme were scattered in thousands throughout Germany, known to each other by secret signs and passwords, and all of them pledged to serve the summons of the secret courts and to execute their judgment.

The organization of the Fehme was elaborate. The head of each centre of jurisdiction (*Freistuhl*), often a secular or spiritual prince, sometimes a civic community, was known as the *Stuhlherr*, the archbishop of Cologne being, as stated above, supreme over all (*Oberststuhlherr*). The actual president of the court was the Freigraf (free count) chosen for life by the Stuhlherr from among the Freischoffen, who formed the great body of the initiated. Of these the lowest rank were the Fronboten or *Freifronen*, charged with the maintenance of order in the courts and the duty of carrying out the commands of the Freigraf. The immense development of the Fehme is explained by the privileges of the *Freischöffen*; for they were subject to no jurisdiction but that of the Westphalian courts, whether as accused or accuser they had access to the secret sessions, and they shared in the discussions of the general chapter as to the policy of the society. At their initiation these swore to support the Fehme with all their powers: to guard its secrets, and to bring before its tribunal anything within its competence that they might discover.

The procedure of the Fehmic courts was practically that of the ancient German courts generally. The place of session, known as the Freistuhl (free seat), mas usually a hillock, or some other well-known and accessible spot. The *Freigraf* and Schoffen occupied the bench, before which a table, with a sword and rope upon it, was placed. The court was held by day and, unless the session was declared secret, all freemen, whether initiated or not, were admitted. The accusation was in the old German form; but only a *Freischöffe* could act as accuser. If the offence came under the competence of the court; *i.e.*, was punishable by death, a summons to the accused was issued under the seal of the Freigraf. This was not usually served on him personally, but was nailed to his door, or to some convenient place where he was certain to pass. Six weeks and three days' grace were allowed, according to the old Saxon law, and the summons was thrice repeated. If the accused appeared, the accuser stated the case, and the investigation proceeded by the examination of witnesses as in an ordinary court of law. The judgment was put into execution on the spot if that was possible. The secret court, from whose procedure the whole institution has acquired its evil reputation, was closed to all but the initiated, although these were so numerous as to secure quasi publicity; and the members present were bound under pain of death not to disclose what took place. Crimes of a serious nature, and especially those that were deemed unfit for ordinary judicial investigation—such as heresy and witchcraft—fell within its jurisdiction, as also did appeals by persons condemned in the open courts, and likewise the cases before those tribunals in which the accused had not appeared. The accused if a member could clear himself by his own oath unless he had revealed the secrets of the Fehme. If he were one of the uninitiated it was necessary for him to bring forward witnesses to his innocence from among the initiated, whose number varied according to the number on the side of the accuser. but 21 in favour of innocence necessarily secured an acquittal. The only punishment which the secret court could inflict was death. If the accused appeared, the sentence was carried into execution at once; if he did not appear. it was quickly made known to the whole body, and the *Freischöffe* who was the first to meet the condemned was bound to put him to death. A knife with the cabalistic letters was left beside the corpse to show that the deed was not a murder.

That an organization of this character should have outlived its usefulness and issued in intolerable abuses was inevitable. With the growing power of the territorial sovereigns and the gradual improvement of the ordinary process of justice, the functions of the Fehmic courts were superseded, though they were only finally abolished by order of Jerome Bonaparte, king of Westphalia, in 1811. The last *Freigraf* died in 183j.

FEIJOA, a small tree (*Feijoa sellowiana*) of the myrtle family (Myrtaceae, *q.v.*), closely related to the guava (*q.v.*) and often called pineapple guava. It is a native of southern Brazil, Paraguay, Uruguay and parts of Argentina and is cultivated in various mild climates for its highly esteemed fruit. The tree grows about 15 ft. high and has olivelike leaves, dark green above and silvery-gray beneath, and large white flowers which are purplish-crimson within. The oblong fruit, about 2 in, long and dull green in colour marked with crimson, has a translucent, melting pulp with a delicious pineapple flavour. When mature the fruits fall, but must be kept in a cool place until sufficiently soft for eating. They are made into jam and jelly and are also crystallized. The feijoa was introduced into southern Europe in 1890 and about 10 years later was taken to California where it became extensively cultivated. The tree requires a dry climate, such as that of southern France and parts of California; it does not thrive in the moist climate of Florida and Cuba. It is usually propagated by seeds, which come fairly true to type, but cuttings may be rooted under glass and whip grafting effected by using seedlings with stems of the thickness of an ordinary lead pencil. Choice varieties are also perpetuated by the layering of low branches.,

FEIJOO Y MONTENEGRO, BENITO JERÓNIMO (1676–1764), Benedictine monk and scholar, one of the first Spanish essayists, was born at Casdemiro, Orense, Oct. 8, 1676. In his *Teatro critico universal* (1726–39) and *Cartas eruditas y curiosas* (1742–60) accepted ideas about education, medicine, science, justice, national character, literature and even the miraculous elements in religion were put to the test of rational doubt, personal experiment and the weight of erudite reference. He is the first characteristic figure of Spanish "enlightenment," aware of foreign progress and yet deeply patriotic. He died at Oviedo, Sept. 26, 1764.

See G. Delpy, *L'Espagne et l'esprit européen. L'oeuvre de Feijdo, 1725–1760* (1936). (R. F. B.)

FEININGER, LYONEL (1871–1956), U.S. modernist painter. known for the crystalline clarity and transparent structure of his seashores and cityscapes, was born on July 17, 1871, in New York city. He left the United States for Germany in 1887 to study music, but decided to become an artist instead. Music, however, was the first and principal influence in his life and art. Feininger studied painting in Hamburg, Berlin and Paris between 1887 and 1893 and then worked as a cartoonist for German humour magazines and the *Chicago Tribune*. Under the influence of the Cubists—especially Robert Delaunay—he began to paint important canvases around 1910 and soon established his own style. utilizing prismatic interpenetrating planes of colour. This work, with its intersecting light rays, so impressed the Blue Rider artists (Franz Marc and Wassily Kandinsky) that Feininger was invited to exhibit with them in Berlin in 1913. After World War I, Feininger joined the staff of the famous Bauhaus workshops and soon found himself in the company of Paul Klee as well as Kandinsky. The structural direction of his own work was closely akin to the aim of the Bauhaus: a synthesis of art, science and technology. In 1936, after the Nazi access to power, Feininger returned to the United States. During the remainder of his life he strove, in both oil and water colour, for the most sensitive refinement of his visionary, yet orderly, crystalline world. He died on Jan. 13, 1956, in New York city.

See A. J. Schardt and Alfred Barr, *Lyonel Feininger* (1944). (P. H. S.)

FEKE, ROBERT (*c.* 1705–*c.* 1750), U.S. portrait painter, whose work maintains the proud stance of a recent colonial aristocracy and achieves a surprising degree of sensuous splendour, was born at Oyster Bay, N.Y., on an unknown date. The place and date of his death are also unknown. Further uncertainties about his being termed a mariner, about his supposed travels and about his artistic training cause differences of opinion among scholars, but the record of his work is reasonably clear. This work was done from time to time in Boston, Mass., and Philadelphia. Pa.; but his home was in Newport, R.I., where he married Elinor Cozzens in 1742 and was visited in 1744 by a Scottish doctor, Alexander Hamilton, who noted the event vividly in his *Itinerarium*. About 1j portraits are signed and dated, and his manner is distinctive enough to warrant his authorship of about 50 more. Five examples in the Walker Art building, Bowdoin college, Brunswick, Me., include the most impressive of all, the "Samuel Waldo." Feke's observation of character was sporadic. The interest of his work is mainly in its technical development of colour and rendering of textures, despite its definite awkwardness.

See H. W. Foote, *Robert Feke, Colonial Portrait Painter* (1930); *L.* Goodrich, *Robert Feke* (1946). (VL. B.)

FELDSPAR or FELSPAR, a name applied to a group of minerals of great importance. Silicates of aluminum with potassium, sodium and calcium, and, rarely, barium, they constitute practically 60% of igneous rocks and serve as a basis of classification of these rocks, being important constituents, for example, of granite, syenite, diorite, gabbro and peridotite (*q.v.*). They occur in schists and other metamorphic rocks and through the processes of decomposition are sources of kaolin and other clays and of much of the world's soil. Following discussion of colour and chemical composition, feldspar is discussed in terms of its crystal structure, polymorphism, unmixing at low temperature and other properties.

Feldspar (predominantly potassium-rich) is used industrially in the manufacture of porcelain, and it also forms an important constituent of many ceramic glazes. Some of the coloured varieties are occasionally used as gems (moonstone) and for ornamental purposes. *(See* CHINAWARE; POTTERY AND PORCELAIN: *Modern Ceramic Techniques.)*

The name feldspar was used by J. G. Wallerius in his *Mineralogy* (1747) in the Swedish form *feltspat,* meaning "fieldspar," but it was subsequently written felspar by Richard Kirwan, who erroneously assumed the derivation of the name from *fels,* "a rock." The term felspar is used only in Great Britain. In German the old name is preserved in *Feldspat.*

A vast number of names exist to designate the different feldspar varieties. They are based on one or more of the following properties: chemical composition; crystallographic symmetry; morphological appearance; state of homogeneity or inhomogeneity; twinning; colour; lustre; and crystal-optical behaviour. They comprise a single mineral species ranging from the alkali potash feldspars (orthoclase or microcline and sanidine), the sodium feldspars (albite and analbite) and the potash-sodium (sanidine-analbite) series through the sodium-calcium feldspars (plagioclases).

The general characters and crystal structure of the feldspars are discussed below. Since certain of the feldspars can crystallize in more than one distinct form, either in the monoclinic or the triclinic systems, they are classified as polymorphous, and this character of polymorphism is discussed in relation to their chemical composition.

Feldspar has been the subject of considerable research relating to the origin of igneous rocks, the processes by which minerals are formed and the behaviour of solid solutions: in addition to the material in this article on unmixing of feldspars in solid solution at low temperatures, *see* GEOCHEMISTRY: *Geochemistry* of *the Lithosphere;* PETROLOGY: *Habit* of *Igneous Rocks.*

GENERAL CHARACTERS

The feldspars are fairly hard (about 6 on Mohs' scale) and relatively light for minerals (specific gravity ranges from 2.55 to 2.76).

Colour.—Pure feldspars are colourless, but as a result of the presence of minute inclusions or the development of alteration products, most natural feldspars are pink, brown, green, gray or dark. Bright green microclines are called amazonstone. Copper-red varieties (colour caused by iron oxide) are called aventurine. Iridescent varieties are moonstone, peristerite and labradorite.

Chemical Composition.—The chemical composition varies considerably, inasmuch as the feldspars form several series of solid solutions. The chemical formulas of the pure end members can be written as:

1.	$KAlSi_3O_8$	Alkali feldspars
2.	$NaAlSi_3O_8$	Alkali feldspars / Plagioclases
3.	$CaAl_2Si_2O_8$	Plagioclases
4.	$BaAl_2Si_2O_8$	Celsian

Members of the series between 1 and 4, that is, with barium replacing part of the potassium, are called hyalophane. Celsian and hyalophane are rare and of minor importance, and they will not be treated here in detail.

The distinction between alkali feldspars and plagioclases is not always clear-cut, because alkali feldspars may contain appreciable amounts of calcium and plagioclases may contain potassium. Feldspars may be considered alkali feldspars if they are monoclinic or if in the triclinic case the atomic ratio potassium/calcium is larger than one. They may be called plagioclases if they are triclinic and this ratio is smaller than one. Whereas the potassium-rich feldspars do not contain much calcium (and the calcium-rich ones do not contain much potassium), feldspars rich in sodium can take sizable amounts of both potassium and calcium (about 10 atomic per cent of each).

CRYSTAL STRUCTURE

Main Features.—As a first step in the process of understanding some of the most important features of the feldspar structure, *see* in fig. 1 the model of the more simple structure of a silica (SiO_2) modification, cristobalite. Note that every silicon atom is surrounded tetrahedrally by four oxygen atoms and that each oxygen atom is surrounded by two silicon atoms. Thus the structure is made up of SiO_4 tetrahedrons in such a way that each oxygen shares two tetrahedrons. The whole arrangement is a relatively loose SiO_2 framework with significant voids.

The framework is electrostatically balanced: one Si^{4+} plus two O^{2-}. This formula, SiO_2, multiplied by four equals Si_4O_8. If some of the Si^{4+} are replaced by Al^{3+}, one obtains $(AlSi_3O_8)^{1-}$ or $(Al_2Si_2O_8)^{2-}$. To neutralize this framework in which Si^{4+} is partially replaced by Al^{3+}, additional positive ions must be inserted within the voids of the structure.

FIG. 1.—UNIT CELL OF THE STRUCTURE OF CRISTOBALITE, A MODIFICATION (CUBIC) OF SiO_2. IN THE ACTUAL STRUCTURE THE OXYGEN AND SILICON IONS ARE CONTIGUOUS, AND THE RADIUS OF AN OXYGEN ION IS ABOUT FOUR TIMES THAT OF A SILICON ION

The feldsppr structure contains K^+, Na^+, Ca^{++} ions within the voids of an $(AlSi_3O_8)^{1-}$ to $(Al_2Si_2O_8)^{2-}$ framework to balance the negative charge. The number of the inserted positive ions K, Na, Ca to the total of (Al + Si) ions is always 1:4.

Symmetry.—The main features of the feldspar structure may be discussed through the use of the cubic cristobalite structure. The actual feldspar structure is too complex to be discussed here in detail. The feldspars have a symmetry much lower than cubic; it is monoclinic or triclinic depending on composition, temperature and distribution of the aluminum and silicon ions within the $(Si,Al)_4O_8$ framework.

All feldspars can be referred to a system of co-ordinates that differonly slightly for the differentvarieties. The extreme values for the crystallographic axes are *a:b:c* from 0.66:1:0.56 to 0.63:1:0.55; and for the angles between the axes are a from 90° to 95°; β from 116° to 117°; γ from $87\frac{1}{2}$° to $90\frac{1}{2}$°.

In those cases where α and γ = 90° the symmetry is monoclinic. If a and/or γ + 90° the symmetry is triclinic. All plagioclases are triclinic. Virtually continuous changes from monoclinic to triclinic symmetry are known or can be hypothesized as a function of changing composition, temperature or aluminum/silicon distribution.

Unit Cell.—The unit cell based on the conventionally chosen system of co-ordinates has the following approximate lattice constants (in Å = 10^{-8} cm.):

a (K rich) = 8.58; (K poor, Na rich) = 8.12
(K poor, Ca rich) = 8.18
b = 12.8 to 13.0
c = 7.1 to 7.2

Angles *a*, β, y are given above.

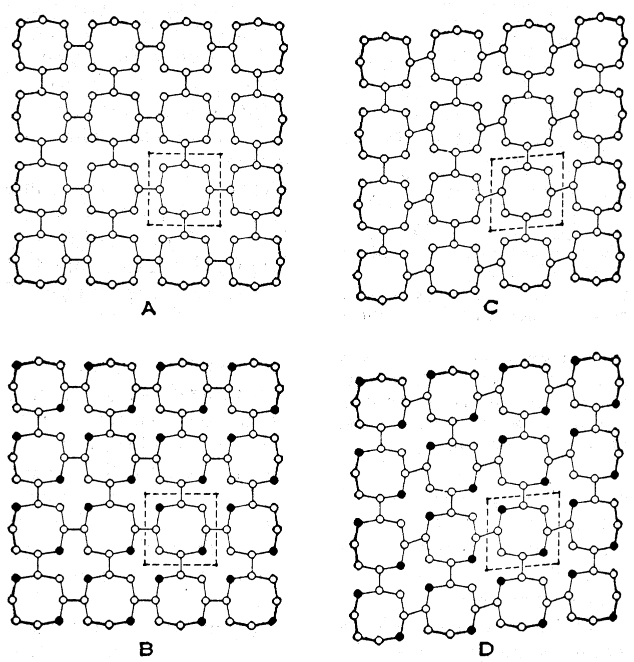
This cell contains four feldspar molecules $X(Si,Al)_4O_8$ where X = K,Na,Ca. It is side centred. X-ray photographs of the calcium-rich plagioclases (anorthite) indicate that their cell has a doubled *c* axis and is not side centred (due to an ordered superstructure of the aluminum and silicon atoms and of the calcium positions). Eight anorthite molecules ($CaAl_2Si_2O_8$) are in this doubled cell.

POLYMORPHISM

Potash Feldspar **($KAlSi_3O_8$).**—There are at least two polymorphic modifications. The modification stable at low temperature is the triclinic microcline, the one stable at high temperature is the monoclinic sanidine. Both modifications occur in nature. Long heating (months) at approximately 1,000° C. (near the melting point, which is 1,170° C.) changes microcline to sanidine. On the other hand, attempts to produce microcline either from sanidine or by direct synthesis were not successful. All potash feldspar synthesized in laboratory experiments appears to be sanidine. Geological times seem to be necessary for the formation of microcline. Whereas the crystal structure of sanidine became rather well known through the work of W. H. Taylor and his co-workers, the structure of microcline had not yet been determined in the

1950s. There was. however, evidence from both X-ray investigations and from several experiments concerned with the physical-chemical behaviour of the alkali feldspars to justify the hypothesis that the difference between sanidine and microcline is the result of a different distribution of the aluminum and silicon ions within the $AlSi_3O_8$ framework.

Fig. 2(A) and 2(B) show schematically in two dimensions how



BY COURTESY OF FRITZ LAVES

FIG. 2—TWO-DIMENSIONAL SCHEMATICS REPRESENTING THE SYMMETRY RELATIONS OF THE ALKALI FELDSPARS. (A) AND (B) DEPICT THE SANIDINE-MICROCLINE RELATION: CHANGES OF SYMMETRY AS A CONSEQUENCE OF DIFFUSIVE TRANSFORMATION. (A) AND (C) SHOW THE SANIDINE-ANALBITE RELATION: CHANGES OF SYMMETRY AS A CONSEQUENCE OF DISPLACIVE TRANSFORMATION. IN (C) AND (D), THE ANALBITE-ALBITE RELATION, NO CHANGE OF SYMMETRY OCCURS, DESPITE DIFFUSIVE TRANSFORMATION. THE ALUMINUM AND SILICON IONS ARE RANDOMLY DISTRIBUTED IN (A) AND (C); IN (B) AND (D) THEY ARE ORDERED

a difference in the aluminum/silicon distribution can produce a differencein symmetry. In both figures the dots represent the positions of aluminum and silicon. In fig. 2(A) the dots are not distinguished from one another, indicating that each position may be either aluminum or silicon; the aluminum and silicon are randomly distributed. The arrangement is symmetrical with respect to a vertical mirror plane. If, as drawn in fig. 2(B), the aluminum atoms are not distributed at random but take special positions. the mirror plane vanishes. Fig. 2(A) represents the disordered monoclinic case and fig. 2(B) (more or less distorted as in fig, 2[D]) represents the ordered triclinic case. The change from the one to the other might be called a diffusive transformation, as a diffusion of aluminum and silicon is necessary for the process. Obviously a diffusive transformation must be a more or less continuous process and its rate depends on the rate of the aluminum or silicon diffusion Considering the general structure of feldspars in which the aluminum and silicon atoms are tightly fixed by the relatively strong bonds to the oxygens that surround them one might suspect that the rate of exchange of aluminum and silicon is very low, esueciallv at low temneratures.

The crystallographic differences between microcline and sanidine are:

		Microcline	Sanidine
axes	a	8.58	8.56
	b	12.97	13.03
	c	7.22	7.18
angles	a	90° 39'	90°
	β	115° 56′	116°
	γ	87° 42′	90°

In the light of the above discussion, the following observations may be summarized:

1. Natural sanidines are known only from rocks that have been relatively quickly cooled. The disordered state appears to have been "frozen in."

2. Synthetic potash feldspar is apparently always monoclinic. No synthesis of triclinic microcline has been reported. Laboratory experiments apparently are of insufficient duration to allow the production of the ordered state.

3. There is evidence (interpretation of the twinning exhibited by microcline) that most potash feldspars, now microcline, originally crystallized as a monoclinic (disordered) modification. The transformation to the triclinic (ordered) state took place slowly with the passage of time.

4. Natural potash feldspars exist with angles α and y between 90° and those values characteristic for microcline, indicating that the diffusive transformation to the state stable at low temperature has not gone to completion.

5. Microcline when held at high temperature (1,000° C.) transforms slowly to sanidine (within months). During this process the values of angles α and y change continuously toward go° as a function of time. Similarly the optical properties change continuously from those of microcline to those of sanidine during such heat treatment.

6. Microcline is usually twinned. The width of the twin lamellae may range from millimetre size to submicroscopical bands (occasionally within the same twinned crystal). The over-all optical behaviour of such portions with submicroscopical twinning is more or less monoclinic and the optical properties of such material are very similar to those of common orthoclase.

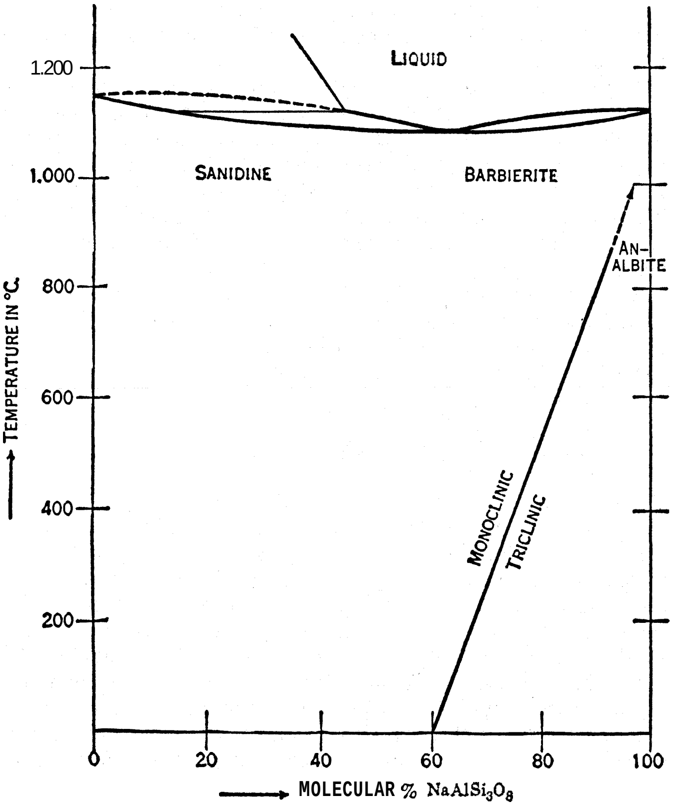
7. It seems thus that those orthoclase crystals (which also appear monoclinic but are not sanidine), the optical behaviour of which approaches that of very finely twinned microcline. are distinguished from sanidine by a different aluminum/silicon distribution. Therefore, common orthoclase might be considered a5 somehow intermediate between sanidine and finely twinned microcline. This viewpoint is supported by X-ray evidence (qualitative interpretation of diffuse scattering).

8. Potash feldspar found in low-temperature veins and similar deposits is distinguished by a characteristic morphology (combination of prism, basal pinacoid and orthodoine or the forms [110], [001], [101]). It is usually glassy, or at least colourless, and is called adularia. As revealed by optical and X-ray investigations many adularia crystals consist of a virtually monoclinic core (with properties similar to common orthoclase) and a more or less triclinic rim. The triclinic portions of the rim follow a characteristic sector pattern and are arranged to each other in such a way that a monoclinic symmetry governs the morphology of adularia crystals.

Sodium Feldspar (**$NaAlSi_3O_8$**).—Two different modifications are known: albite, stable at low temperature; and analbite (or high albite), stable at high temperature. The transformation temperature lies around 700° C. Probably the structural differences between albite and analbite are analogous to those between microcline and sanidine; *i.e.,* the aluminum/silicon distribution is an ordered one in albite and a disordered one in analbite. In accordance with this hypothesis is the fact that it takes a month or more at about 1,000° C. to transform albite into analbite. As in the potash feldspars, no reversal of this process has been noted. Sodium feldspar crystallized in the laboratory has always proved to be analbite. even when synthesized at temperatures as low as zoo° C. Apparently laboratory times are too short to produce an ordered aluminum/silicon distribution.

It has been shown in the case of potassium feldspar how the change of the state of order/disorder is connected with a change of symmetry. Both modifications of sodium feldspar, analbite and albite have, however, the same (triclinic) symmetry. The diffusive transformation from albite to analbite and vice versa is therefore not accompanied by a symmetry change. The possibility of such relations is shown schematically in fig. 2(C) and 2(D).

Sanidine-Analbite Series (**$KAlSi_3O_8$–$NaAlSi_3O_8$**).—Sanidine and analbite form a virtually continuous series of mixed crystals at high temperature. These mixed crystals can be preserved at low temperature by cooling rapidly enough to prevent the diffusive transformation and the unmixing that starts below about 560° C. (see below). Fig. 3 shows the phase diagram of this series that is stable only at high temperature but unstable (undercooled) at low temperature. Mixed crystals that are potassium rich are monoclinic from room temperature up to the melting point, whereas sodium-rich members undergo a so-called displacive transformation, the transformation temperature being a function of the potash/sodium ratio. This kind of transformation that does not involve any change of the aluminum/silicon positions can be depicted schematically by the relations between fig. 2(A) and 2(C). As usual in the case of displacive transformations the modification stable at higher temperature has a symmetry higher than that of the modification stable at low temperature. Because no diffusion is involved in this kind of transformation it can take place very rapidly. It is neither possible to freeze in the monoclinic symmetry by quenching nor to retain the triclinic symmetry by quick heating.



BY COURTESY OF THE UNIVERSITY OF CHICAGO PRESS: FROM "JOURNAL OF GEOLOGY," VOL. 60

FIG. 3.— PHASE DIAGRAM (NOT STABLE BELOW ABOUT 700° C.) OF THE SERIES SANIDINE-ANALBITE, BARBIERITE (see TEXT FOR EXPLANATION)

A publication (1952) by W. S. MacKenzie indicates that the line which in fig. 3 divides the monoclinic field from the triclinic one meets the sodium end of the diagram slightly below the melting point of $NaAlSi_3O_8$ (if equilibrium is reached by a prolonged heat treatment), so that at very high temperatures a monoclinic $NaAlSi_3O_8$ modification may exist. Such a modification was earlier proposed (on the basis of optical examination of natural material) and given the name barbierite, but its reality as a mineral has been disputed.

In summary, the alkali feldspars can be subdivided in the following way:

Al/Si distribution disordered
- K rich. sanidine (monoclinic, at high temperature)
- Na rich: barbierite (monoclinic, at very high temperature)
- Analbite (triclinic, at high temperature)

Al/Si distribution ordered
- K rich: microcline (triclinic, at low temperature)
- Na rich: albite (triclinic, at low temperature)

Unstable intermediate states are known at the potassium-rich side as common orthoclase and adularia (the latter predominantly as a low-temperature mineral).

The Plagioclases ($NaAlSi_3O_8$–$CaAl_2Si_2O_8$).—The polymorphism of the plagioclases appears to be very complex. Some details have already been given above for the sodium-rich end of the series. A. Kohler showed in 1942 that the optical properties of plagioclases that reach equilibrium at high temperature differ from those that approach equilibrium at low temperature. Some X-ray investigations with calcium-rich plagioclases have shown that there are significant differences between the sodium-rich and the calcium-rich plagioclases as far as polymorphous behaviour is concerned. This difference seems to result largely from the different aluminum-silicon ratio of the end members, which is 1:3 for the sodium end and 2:2 for the calcium end. The aluminum/-silicon ratio which equals 2:2 in anorthite ($CaAl_2Si_2O_8$) seems to be responsible for its superstructure, which is not found in the alkali feldspars. The *c* axis of the unit cell of anorthite is approximately twice that of albite. Another difference is that the anorthite unit cell is not side centred, a fact that appears to result from the position of the calcium ions compared with the position of the sodium (potassium) ions in the structure of the alkali feldspars. These conclusions have been drawn from the X-ray behaviour of anorthites after they were subjected to different heat treatments. The X-ray reflections which indicate that the unit cell is not side centred show a varying degree of diffuseness as a function of temperature (F. Laves and J. R. Goldsmith, 1951). After treatment at 1,500° C. these reflections are so diffuse that they almost disappear; after treatment at 1,000° C. all reflections are sharply defined. The reflections that correspond with those observable in photographs of the alkali feldspars remain sharp up to the melting point (1,550° C.). Heat treatment at intermediate temperatures produces intermediate diffuseness in the affected reflections. The time required to reach equilibrium is of the order of ten minutes.

The difference in structural properties of $NaAlSi_3O_8$ and $CaAl_2Si_2O_8$ leads to the conclusion that no complete solid solution series of mixed crystals is possible in the strictest crystallographic sense. not even at high temperatures. On the other hand. there is no reason to doubt the existence of a virtually complete solid solution series as established by N. L. Bowen as early as 1913.

The plagioclases are given different names as a function of their chemical composition: albite (0% to 10% anorthite [An]) ; oligoclase (10% to 30% An) ; andesine (30% to 50% An) ; labradorite (50% to 70% An) ; bytownite (70% to 90% An) ; anorthite (90% to 100% An).

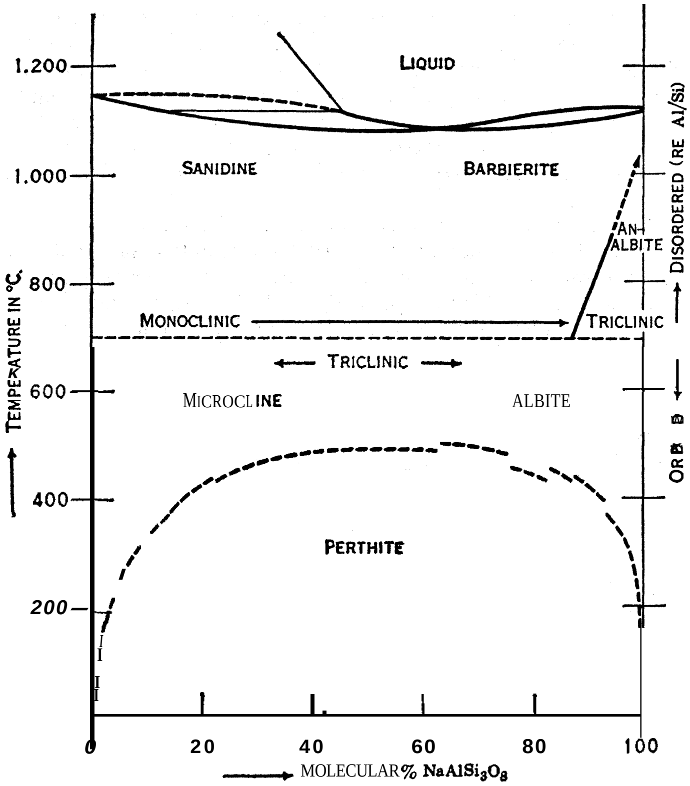
UNMIXING AT LOW TEMPERATURE

The feldspars form virtually complete solid solutions at elevated temperatures. At low temperatures they unmix (if this process is not suppressed by relatively quick cooling). The degree of unmixing (as far as coarseness and composition of the unmixed products is concerned) is principally a function of temperature and time. The observation of natural feldspars and the interpretation of experimental work leads to the conclusion that the process of unmixing is much more readily accomplished in alkali feldspars than in plagioclases. This can be understood by the fact that the tightly bonded aluminum and silicon ions are much more reluctant to move by diffusion than the potassium, sodium or calcium ions (Goldsmith. 1952).

Unmixing of Alkali Feldspars.— Because all alkali feldspars have the same aluminum/silicon ratio (1:3) the unmixing process does not involve any aluminum/silicon diffusion. The first step will be the formation of potassium- sodium-rich domains by concentration fluctuations of sodium and potassium within the $AlSi_3O_8$ framework, with differences oi concentration that exceed those always present in a random distribution within a mixed crystal. If more time is available under favourable temperature conditions, these domains will develop into truly unmixed regions. and finally may even be observed macroscopically. In the beginning of the process the $AlSi_3O_8$ framework is still common to both the potassium-rich and the sodium-rich domains. As the unmixing process proceeds stress will be increased because of the difference in lattice constants of the potassium-rich and sodium-rich feldspars. This stress will finally lead to a truly two-phase system composed of potassium feldspar and sodium feldspar, separated by discontinuous phase boundaries. This material is called perthite. Earlier stages—where the phases are distinguishable only under a powerful microscope—are called microperthite. If the unmixing is developed on such a small scale that it can be detected only by X-ray methods or deduced by several other means, the material is called cryptoperthite. If the unmixed areas cannot be seen directly (even with a powerful microscope) but are the cause for a beautiful (white to blue) opalescence or schiller lustre displayed in characteristic crystallographical directions. one speaks of moonstone (*q.v.*). In fig. 4 a phase diagram is proposed with more detailed information on the temperatures at which unmixing should occur (if equilibrium is established) and on the compositions of the different phases in equilibrium.

Unmixed alkali feldspars usually show the potassium-rich material as the host in which the sodium-rich material is precipitated. The opposite is occasionally observed, plagioclase the host and the potassium-rich material precipitated within it. This material is usually called antiperthite.

Besides the degree of unmixing into potassium-rich and sodium-rich areas, the appearance of the products found in nature is further complicated by the different degree of aluminum/silicon order-disorder (discussed above) that may exist. The potassium-



BY COURTESY OF THE UNIVERSITY OF CHICAGO PRESS FROM "JOURNAL OF GEOLOGY," VOL. 60

FIG. 4.— PHASE DIAGRAM OF THE ALKALI FELDSPARS (IN PART HYPOTHETICAL)

sodium feldspars, especially those that are soda rich, exhibit a confusing variety of crystallographic and optical properties. This is a consequence, in addition to order-disorder relations, of composition and of variation in the temperature of the displacive transformation (discussed above). The symmetry change induced by this transformation may also produce twinning that may be submicroscopic. These complications are responsible for the uncertainties and confusion in descriptions found in many textbooks of the "mineral" anorthoclase, which does not exist as a true species.

The term anorthoclase is best defined as a feldspar of the composition between $Or_{70}Ab_{30}$ and $Or_{10}Ab_{90}$. It may or may not be homogeneous; it may be monoclinic or triclinic, or a mixture of both forms.

Unmixing of **Plagioclases.**—The plagioclases form a virtually complete series of mixed crystals at elevated temperatures from $NaAlSi_3O_8$ to $CaAl_2Si_2O_8$ (analbite-anorthite). Portions of this series are unstable at low temperature. There are (X-ray and optical) indications for two gaps of miscibility: (1) between albite and oligoclases; (2) between oligoclase and bytownite. The X-ray evidence for the first gap is the coexistence of reflections characteristic of two different feldspar structures in single-crystal photographs of plagioclases of compositions near $Ab_{90}An_{10}$. The optical indication for this gap is a characteristic bluish schiller exhibited by many plagioclases of this composition which are called peristerite. The second gap is inferred from ghost reflections on X-ray photographs of plagioclases, the composition of which lies between $Ab_{70}An_{30}$ and $Ab_{30}An_{70}$. These ghost reflections can be explained if one assumes periodically changing composition within the crystals. The optical indication for this gap is the beautiful schiller of all colours exhibited by many plagioclases in this compositional range, a schiller that is known as labradorizing.

Little is known, however, of the phase relations in the plagioclase feldspar system.

No textures within plagioclases are known that resemble those of the perthites in the alkali feldspars. In the alkali feldspars only the rather readily mobile potassium and sodium ions are required to move for a separation into $KAlSi_3O_8$ and $NaAlSi_3O_8$. In the plagioclases sodium and calcium can be segregated into $NaAlSi_3O_8$ and $CaAl_2Si_2O_8$ only if a simultaneous transport of aluminum and silicon ions takes place to maintain electrostatic neutrality.

The great difficulty involved in migrating aluminum and silicon even for short distances, as in the case of changing a disordered distribution to an ordered one (which does not involve large concentration changes), has been discussed.

OTHER PROPERTIES

Morphology and Twinning.— All feldspars show a similarity of crystal form, generally prismatic but flattened parallel to the side pinacoid face [010], or elongated parallel to the axis a with small prism faces. Sodium-rich sanidines (usually high in calcium) that are known from the rhombporphyries commonly have a characteristic habit with a rhomb-shaped cross section. They are elongated parallel to the *c* axis, only the prism and orthodome faces [110] and [201] being developed. The habit of adularia has been discussed. All feldspars cleave readily parallel to the basal pinacoid [001] and side pinacoid [010], producing angles of 90° in the monoclinic varieties and oblique angles in the triclinic ones. Twinned crystals are common and the twinning serves to distinguish various members of the group both in hand specimens and by optical methods under the microscope. In the monoclinic series the most common twin laws are the Carlsbad (twin axis *c*), the Manebach (twin plane [001]) and the Baveno (twin plane [021] or clinodome). In the triclinic series, in addition to these three laws the albite law (twin plane [010]) and the pericline law (twin axis b) are very common. They are usually developed as multiple twinning, visible (occasionally only microscopically) as fine striations on the cleavage planes, albite and pericline on [001] and pericline on [010]. Mechanical twinning after the albite and pericline law can be produced easily in analbite but not in albite, another physical consequence of the difference in the aluminum/silicon distribution.

Synthesis, Melting Point and Alterations.— With the exception of hyalophane, which contains barium, feldspars of all compositions have been prepared synthetically, but only as the high-temperature modifications, even at temperatures at which the low-temperature modifications are stable (see above). The alkali feldspars melt in the vicinity of 1,100° C. Addition of calcium raises the melting temperature to 1,550° C. for pure anorthite. Feldspars readily suffer chemical alteration, the most common products being kaolin, sericite, various zeolites and calcite. The anorthite-rich plagioclases, especially under conditions of retrograde metamorphism, break up into albite and a group of calcium aluminum silicates including prehnite, zoisite, epidote and garnet, this assemblage being referred to as saussurite. Albite is the most stable of the feldspars under the action of weathering and is commonly found in detrital sediments and as an authigenic, that is, formed in place and unaltered, mineral. Potassium feldspar is also known as an authigenic mineral in sediments (adularia or microcline).

More detailed information on mineralogical and crystallographical items and conceptions used in this article is given under CRYSTALLOGRAPHY and MINERALOGY. (F. H. L.; X.)

BIBLIOGRAPHY.—For more details and a survey of the pertinent literature on which this article is based *see:* F. Laves, "Phase Relations of the Alkali Feldspars," *Jour. Geol.*, vol. 60 (1952); J. R. Goldsmith, "Diffusion in Plagioclase Feldspars," *Jour. Geol.*, vol. 60 (1952); W. S. MacKenzie, "The Effect of Temperature on the Symmetry of High Temperature Soda-Rich Feldspars," *Am. Jour. Sci.*, Bowen volume (1952); H. Sørum, "Studies on the Structures of Plagioclase Feldspars," *Kgl. Norske Videnskab. Selskabs Skrifter*, no. 3 (1951).

Detailed descriptions of the physical properties of the different feldspar varieties are given in textbooks of mineralogy as listed in the article on MINERALOGY, and in the book of A. N. Winchell, *Elements of Optical Mineralogy*, part ii, *Descriptions of Minerals*, 4th ed. (1951).

FELDSPATHOID, one of a group of rock-forming minerals similar to the feldspars (see FELDSPAR) in general chemical composition but with a lower ratio of silica to alkalies or containing chloride. sulfide, sulfate or carbonate radicals. They are never associated with primary quartz. Nephelite (nepheline) and leucite (*qq.v.*) are the most important members of the group: sodalite, noselite, hauynite or haüyne (for these three see SODALITE) and cancrinite are rarer feldspathoids that occur only as accessory minerals in rocks; kalsilite and kaliophilite are phases of $KAlSiO_4$.

Structurally the feldspathoids are tectosilicates, the SiO_4 and AlO_4 groups being linked as in the feldspars with the metal atoms and the radicals fitting into cavities in this framework. They are all easily decomposed by acids which distinguishes them from feldspars. This property is associated with the high Al:Si ratio; the aluminum is removed in solution, the structure then collapsing, often with the formation of gelatinous silica.

Among the more important rocks characterized by the presence of feldspathoids are the intrusive nephelite-syenite and ijolite (*qq.v.*) and the lavas phonolite (*q.v.*), tephrite, basanite and nephelite-basalt. Nephelite is abundant in the nephelite-syenites of Arkansas. in the United States. Canada, Greenland, India. Norway and the U.S.S.R.: cancrinite and sodalite are frequently associated with nephelite as at Bancroft, Ont., and Miask, South Urals. (W. F. FG.; C. E. T.)

FELIX, SAINT, OF VALOIS (1127–1212), one of the founders of the order of Trinitarians (Order of the Most Holy Trinity), was born in the district of Valois, France, on April 19, 1127. He became a hermit in the forest of Galeresse, where he remained until 1187 when his disciple John of Matha (1160–1213) suggested to him the idea of establishing an order of monks who should devote their lives to the redemption of Christian captives from the Saracens. Obtaining the sanction of the pope about 1198, they founded the mother house at Cerfroid in Picardy. Felix died at Cerfroid on Nov. 4, 1212, and is commemorated on Nov. 20.

The Trinitarians (also known as Mathurins) had about 800 houses during the 15th century when their influence was at its greatest. In the 20th century the only surviving body was the Barefooted Trinitarian order, with fewer than joo members. centred at S. Crisogono in Trastevere, Rome. An order of Barefooted Trinitarian Sisters was established early in the 17th century.

FELIX, the name of three popes and two antipopes.

ST. FELIX I (d. 274), pope from 269 to 274, was elected on Jan. 5, 269, to succeed Dionysius. Felix was author of an important dogmatic letter on the unity of Christ's person (see P. Jaffé and W. Wattenbach, Regesta, n. 140). He was the focus of the emperor Aurelian's decision settling the dispute between Paul of Samosata (*q.v.*), deposed bishop of Antioch, and Domnus, his successor, in favour of him with whom "the bishops in Italy and Rome should communicate" (Eusebius, *Hist. Eccl.,* vii, 30). He died on Dec. 30, 274, and his feast day is May 30.

FELIX II (d. 365), antipope, was irregularly installed in 355 following the emperor Constantius' banishment of Pope Liberius. He was forced by popular pressure to retire upon Liberius' return in 358.

ST. FELIX III (d. 492), pope from 483 to 492, succeeded Simplicius on March 13, 483. His excommunication of the patriarch Acacius for Monophysitic sympathies in 484 was followed at Constantinople by a 35-year schism. Felix' synod of March 487 fixed conditions for readmission to the church of Africans who had been rebaptized by the Arian Vandals. He died on March 1, 492, and his feast day is Feb. 25. (H. G. J. B.)

FELIX IV (d. 530), properly Felix III, pope from 526 to 530, owed his election (on July 12, 526) to the influence of Theodoric, king of the Ostrogoths. After Theodoric's death, the election was freely confirmed. Felix wrote to Caesarius of Arles on St. Augustine's doctrine on grace and again condemned Pelagius and his disciples. He converted pagan temples into the Church of SS. Cosmas and Damian. To avoid a disputed succession Felix adopted the expedient of naming his own successor, the archdeacon Boniface (Pope Boniface II). Felix died on Sept. 22, 530. Dioscorus u-as elected as antipope, however, but when he died after a few weeks Boniface was recognized by all. (J. V. HN.)

FELIX V (Amadeus VIII of Savoy) (1383–1451). the last of the antipopes, was born on Dec. 4, 1383, and in 1391 became count of Savoy. In 1416 Savoy was erected into a duchy and in 1418 Amadeus added Piedmont to his dominions. In 1434 he retired to a hermitage at Ripaille near Thonon, France, where he founded and governed an order of knights-hermits. After the schismatic council of Basel deposed Eugenius IV. it elected Amadeus on Nov. 5, 1439, although he was not in orders. Amadeus accepted the election on Jan. 5, 1440, and was consecrated and crowned on July 24. As antipope, Felix V won scanty support, and he renounced his claims in 1449. He died at Geneva on Jan. 7, 1451. (E. A. R.)

FELIX, a missionary bishop from Burgundy, sent into East Anglia by Honorius of Canterbury (630–631). Under King Sigebert his mission was successful, and he became first bishop of East Anglia, with a see at Dunwich, where he died and was buried, 647–648.

FELIXSTOWE, an urban district and seaside town in the Sudbury and Woodbridge parliamentary division of East Suffolk, Eng., 11 mi. S.E. of Ipswich by road. Pop. (1961) 17,254. Area 6.2 sq.mi. Though on the east coast, it faces south and has a frontage both to the North sea and to the estuary of the Orwell opposite Harnich. with which it is connected by Eastern Region railway ferry. There is a small dock for yachts and river shipping. The church of St. Peter and St. Paul, mainly Early English, has traces of Norman work in the 12th-century nave. The town is built partly on a high cliff and slopes down to sea level toward the southwest where the beach is shingly with some sand; the sea mall and promenade, 2 mi. long, are laid out with public gardens and pavilions. and there is a promenade pier. Felixstowe has good golf links, and the open tournament of the East of England lawn tennis championship is held there in August. There are 11 yacht clubs within a 20-mi. radius of Felixstowe and yachting takes place in Harwich harbour and the Deben, Orwell and Stour rivers; there are also connections by steamer with Ipswich, up the Orwell. Near the dock is an R.A.F. seaplane station. The chief industry is catering for visitors, but there is some flour milling. glove making and manufacture of electrical components. The vicinity has yielded numerous Roman remains, and a 4th-century Roman fort off Reed pond (now destroyed by the sea) formed part of the coast defense of the Litus Saxonicum (the Saxon shore).

FELL, JOHN (1625–1686), dean of Christ Church (Oxford), bishop of Oxford and benefactor to Oxford university and its press, was born at Longworth, Berkshire. on June 23. 1625, the son of Samuel Fell, himself canon and later dean of Christ Church. John Fell became a student (*i.e.*, fellow) of Christ Church at the age of 11, and took his degree in 1643. During the Civil War he fought on the royalist side, being deprived of his studentship in 1648. He continued to live in Oxford. and nith a few friends carried on Church of England services throughout the Commonwealth (he had been ordained in 1647). At the Restoration in 1660 he was made canon and then dean of Christ Church. He was vice-chancellor. 1666–69. In 1676 he became bishop of Oxford while remaining dean. He died in Oxford on July 10, 1686.

Fell restored in the university the good order instituted by William Laud that had been lost during the Commonwealth, compelling attendance at lectures and keeping examiners up to their duties. In his own college of Christ Church he restored the main quadrangle (Tom quad) and built the tower over the gate, where he hung the bell (Great Tom) that still tolls nightly at 9 P.M. He instigated the building of the Sheldonian theatre, in which he installed the university press. He presented it with learned fonts acquired abroad, set up a type foundry and encouraged the foundation of a paper mill at Wolvercote, near Oxford. The "Fell" type that he introduced was discontinued in the 18th century, but rediscovered in 1874 and brought back into use. The university press printed Fell's own books, including editions of Theocritus, Aratus, the New Testament, Athenagoras, Theophilus of Antioch, Clement of Alexandria and Cyprian.

The verse

I do not love thee, Dr. Fell,
The reason why I cannot tell;
But this I know, and know full well,
I do not love thee Dr. Fell

is reputed to be the extempore translation of Martial's epigram

Non amo te, Sabidi, nec possum dicere quare;
Hoc tantum possum dicere, non amo te

made at Fell's request by the satirist Thomas Brown in order to avoid being expelled from the college for some undergraduate offense.

See C. E. Mallet, *A History of the University of Oxford*, vol. 2 (1924); *A Specimen of the Several Sorts of Letter Given to the University by Dr. John Fell, Oxford, 1693* (facsimile, 1928). (G. Hu.)

FELLAH (pl. FELLAHIN), Arabic for "plowman" or "tiller," a term used in Arabic-speaking countries, especially Egypt, to designate the peasantry as opposed to the Arabs of the desert and the townsfolk. See EGYPT: *Administration and Social Conditions: Living Conditions.*

FELLENBERG, PHILIPP EMANUEL VON (1771–1844), Swiss educator, was born on June 27, 1771, at Bern, Switz. He purchased in 1799 the estate of Hofwyl, near Bern, intending to make agriculture the basis of a new system, which he had projected, for elevating the lower and rightly training the higher orders of the state and welding them together in a closer union than had hitherto been deemed attainable. For some time he carried on his labours in conjunction with Pestalozzi, but incompatibility of disposition soon induced them to separate. Fellenberg's scheme at first excited a large amount of ridicule, but gradually pupils came to him from every country in Europe, both for the purpose of studying agriculture and to profit by the high moral training which he associated with his educational system. Fellenberg died on Nov. 21, 1844.

FELLING, an urban district in the Gateshead East parliamentary division of Durham, Eng., forming a southeastern suburb of Gateshead. The urban district stretches north to the Tyne and includes eight parishes. Pop. (1961) 35,602. The large industrial population is employed in the neighbouring collieries and manufactures, such as engineering, paint making at Felling Shore and Pelaw, and radar equipment at Bill Quay.

FELLOW, by origin a partner or associate, hence a companion, comrade or mate. The Old English *féolage* meant "a partner in a business." The word was, therefore, the natural equivalent for *socius,* a member of the foundation of an incorporated college, as Eton, or a college at a university. In the earlier history of universities, both the junior and senior members of a college were known as "scholars," but later, as now, "scholar" was restricted to those members of the foundation still *in statu pupillari,* and "fellow" to those senior graduate members who had been elected to the foundation by the corporate body, sharing in the government and receiving a fixed emolument out of the revenues of the college, as at Oxford and Cambridge. The academic usage of the term which dates back to the medieval university is generally applied to the members of the governing body or to holders of certain stipendiary positions called fellowships established for a fixed number of years and devoted to special study or research. The word is also used to designate privileged members of various learned societies and institutions.

In the United States the word first appeared in the 1650 charter of Harvard university which provided for five fellows among the officials of the governing body. However, in common usage the term "fellow" is applied in U.S. colleges and universities to selected students who have been awarded stipends for a year or more for graduate or postgraduate study. The selection of fellows is based mainly on intellectual and personal attributes, but financial need also may be considered. (J. M. Bk.)

FELLOWS, SIR CHARLES (1799–1860), British archaeologist, was born at Nottingham, where his family had an estate. In 1827 he discovered the modern ascent of Mont Blanc. He travelled in Italy, Greece and the Levant, and many of his sketches were used in illustrating *Childe Harold.* In 1838 he went to Asia Minor, making Smyrna his headquarters. He entered Lycia and explored the Xanthus from the mouth at Patara upward. Nine miles from Patara he discovered the ruins of Xanthus, the ancient capital of Lycia, and about 15 mi. farther the ruins of Tlos. He published his results in *A Journal Written During an Excursion in Asia Minor* (1839). Late in 1839, under the auspices of the British Museum, he again set out for Lycia, accompanied by George Scharf, who assisted him in sketching. This second visit resulted in the discovery of 13 ancient cities, and in 1841 appeared *An Account of Discoveries in Lycia, Being a Journal Kept During a Second Excursion in Asia Minor.* A third visit was made late in 1841, after Fellows had obtained a firman by personal application at Constantinople. He shipped a number of works of art for England, and in the fourth and most famous expedition (1844) 27 cases of marbles were dispatched to the British Museum. His chief discoveries were at Xanthus, Pinara, Patara, Tlos, Myra and Olympus. In 1845 he was knighted. He died in London on Nov. 8, 1860.

In addition to the works above mentioned, Fellows published the following: *The Xanthian Marbles; Their Acquisition and Transmission to England* (1843), a refutation of false statements that had been published; *An Account of the Ionic Trophy Monument Excavated at Xanthus* (1848); a cheap edition of his two *Journals,* entitled *Travels and Researches in Asia Minor, Particularly in the Province of Lycia* (1852); and *Coins of Ancient Lycia Before the Reign of Alexander; With an Essay on the Relative Dates of the Lycian Monuments in the British Museum* (1855).

FELLTHAM, OWEN (1604?–1668), English author best-known for his essays entitled *Resolves, Divine, Morall, and Politicall,* was born about 1604. He became the earl of Thomond's steward sometime before 1640, and spent most of his life at Great Billing, Northamptonshire, or at the earl's house in London, where he died on Feb. 23, 1668.

The first edition of the *Resolves* (1623) contained 100 essays written "when the author was but 18." The 2nd edition, *Resolves, a Second Centurie* (1628), contains a further 100 essays, and in the later editions the order of the two centuries is reversed. In the 8th edition (1661) the original 100 short, pithy essays are replaced by 85 more diffuse ones. Felltham's striking images, some of which were borrowed by the poet Henry Vaughan, are more original than his ideas. The 1661 edition included *A brief Character of the Low-Countries under the States,* printed separately in 1652 but written after a visit to Holland (*c.* 1628), some letters, and *Lusoria, or Occasional Pieces,* 41 poems including "An Answer to Ben Jonson's New Inn Ode" (he also contributed an elegy to *Jonsonus Virbius,* 1638), and the song "When, dearest, I but think on thee," erroneously attributed to Sir John Suckling. No further additions were made until *A Form of Prayer compos'd for the Family of the Right Honourable the Countess of Thomond* was added to the 12th edition (1709). The *Resolves* were reprinted from the 2nd edition in Temple Classics (1904).

See the articles by F. S. Tupper, *Modern Language Notes,* liv (1939); J. Robertson, *Modern Language Notes,* lvii (1943) and *Modern Language Review,* xxxix (1944). (J. Rn.)

FELO-DE-SE, a self-murderer; *i.e.,* a suicide. Not until the Suicide act, 1961, were criminal penalties for suicide and attempted suicide abolished in England. The Homicide act, 1957, provided that the survivor of a suicide pact is guilty of manslaughter rather than murder. Formerly, the property of a suicide was forfeited to the crown and his corpse subjected to degradation. Until 1823 a suicide was buried on the highway with a stake driven through the body. Virtually all such penalties were abolished before the end of the 19th century. There is great diversity in the U.S. law relating to suicide. In some jurisdictions suicide is declared a crime, and in many states an attempted suicide is punishable. Some states have held one who assists another to kill himself guilty of murder. There is substantial authority for the proposition that one who accidentally kills another while attempting suicide is guilty at least of manslaughter. (F. A. A.)

FELONY. In the English common law of crimes, offenses are classified as treasons, felonies or misdemeanours. In the modern law of England the procedures distinguishing trials of treason and felony cases were virtually eliminated by the Treason act, 1945. The law of the United States generally classifies crimes as either felonies or misdemeanours. The word felony appears first to have been applied to conduct disruptive of the feudal bond between vassal and lord, which had as its consequence the forfeiture of the fief or the lordship, as the case might be. Very early in the history of English law, however, the term was given to heinous offenses of other kinds. The most distinctive consequence of a felony conviction was the forfeiture of the felon's goods or lands to the crown. Forfeitures were abolished in England by the Forfeiture act of 1870 and have only rarely been authorized by U.S. criminal law. (See CONFISCATION AND EXPROPRIATION.) At the common law all felonies except mayhem (*q.v.*) were punishable by death. Whipping was substituted for the death penalty in cases of petty larceny by a 13th-century statute. In reality, however, recognition of "benefit of clergy" in the English law relieved the felon from capital punishment in many cases (see CLERGY, BENEFIT OF). The procedures of felony trials differed from those for other offenses. In the early law one charged with felony could not call witnesses in his behalf. Not until 1837 was the defendant's right to be represented by counsel at the trial given statutory recognition.

The consequences of commission or conviction of a felony are numerous and important in the modern law. In the Anglo-American countries one who has been convicted of a felony may be rendered ineligible to hold offices of public trust. In the United States the convicted felon suffers the loss of civil rights. such as the right to vote, not all of which are restored upon completion of the sentence. In many jurisdictions deadly force may be employed to prevent the escape of a felon from a valid arrest. Such force may also be employed to prevent the commission of a felony or, in some jurisdictions, a violent felony. In some states of the U.S. the court is obliged to provide counsel to indigent defendants in felony trials but not in those for misdemeanours.

Among the felonies recognized at common law were murder, manslaughter (see HOMICIDE), arson, rape, robbery, burglary and larceny (*qq.v.*). The number of felonies has been significantly enlarged by legislation, particularly in the modern period. The law of England has employed no consistent principle to determine the classification of an offense as a felony. In some instances crimes classified as misdemeanours involve greater social peril than many statutory felonies, and penalties for a misdemeanour may exceed those authorized for some felonies. In the United States the distinction between felony and misdemeanour is usually governed by the penalties attached to the offense. Thus a felony is often defined as an offense punishable by imprisonment in the state penitentiary, while a misdemeanour is punished by fine or a term in a local jail. Tested by any rational standard the classification of offenses in both the U.S. and English law is capricious and unsatisfactory. The need for legislative reconsideration of this important matter is common to most of the Anglo-American countries.

'See CRIMINAL LAW; MISDEMEANOUR; see also references under "Felony" in the Index volume. (F. A. A.)

FELSINA, a city founded by Etruscans on the site of modern Bologna (*q.v.*) in the Reno valley *c.* 510 B.C. Etruscan Felsina is known almost entirely from graveyards situated outside the city (notably at the Certosa, a monastery about 1 mi. W. of it) and from the remains of the large buildings inside the city.

Before Etruscan times, however, the Bologna.area was an important centre of Villanovan Iron Age cultures of the central European Urn Field type which dominated north and west central Italy from the Po river to northern Campania, and which in Tuscany and Latium provided the ethnic substratum of Etruscan culture (see VILLANOVANS; ETRUSCANS). Villanova. the type site, is 5 mi. N.W. of Bologna, and the cemeteries west of Bologna form the basis on which all Villanovan material culture is divided into phases: Benacci I (c. 1050–900 B.C.); Benacci II (c. 900–700 B.C.); and Arnoaldi (c. 700–450 B.C.), the latter overlapping but culturally distinct from the Etruscan period, to which belong Certosa period graves.

Cremations of Benacci I are characterized by rough biconical cinerary urns with impressed geometrical ornament. Bronze metalwork includes lunate razors, fibulae, elaborate horse bits and belt plaques of beaten raised work. In Benacci II pottery was elaborate, often exotic, and vessels of hammered bronze (buckets, cups and trays) showing Hallstatt (*q.v.*) connections become characteristic. Arnoaldi mas a phase of commercial prosperity and innovation in which close links were formed with Atestine culture (see ESTE). Pottery bore stamped designs of birds and humans; iron was prodigally used for weapons, chariots, etc; hammered bronze work, after first showing the influence of Vetulonia (*q.v.*) metalwork, produced (c. 500 B.C.) a series of attractive ceremonial buckets (situlae) with raised designs depicting scenes from Villanovan life. Gold jewelry and glass were known.

The Arnoaldi graves are culturally sharply separated from the Etruscan graves of the Certosa. These and the tombs of the Giardini Margherita were rich in Etruscan 5th–6th century metalwork (situlae, cistae and candelabra). Numerous fine Attic redfigure vases attest trade relations with Greece by way of Spina and the Adriatic. The earliest Etruscan tombs were marked with horseshoe-shaped stelae, carved in local Villanovan style.

By 350 B.C. Felsina had fallen to invading Gauls (Boii), who called it Bononia. It was captured by Romans in 196 B.C. and colonized in 189 B.C., and was linked in Roman times by the Via Aemilia with Rimini and by the Via Flaminia with Rome.

See A. Grenier, *Bologne villanovienne et étrusque (1912).* (WM. C.)

FELSITE, in petrology, a field name originally applied to older (pre-Tertiary) volcanic rhyolites and trachytes in which devitrification or other alteration has rendered the matrix dense and usually compact (see RHYOLITE; TRACHYTE).

Under the microscope the groundmass may often be resolved into exceedingly fine-grained quartz and feldspar. Well-formed crystals (phenocrysts) of quartz, orthoclase and plagioclase feldspar and biotite are usually present and sometimes abundant.

The German equivalents (felsophyre, felsite-porphyry) were originally separated from rhyolite proper solely on the basis of the difference in the megascopic appearance of the groundmass. In Britain, and to nearly as great an extent in America, however, the field name felsite came to be applied to any clearly nonbasaltic but otherwise unidentifiable fine grained volcanic or hypabyssal rock. Hence, the adjective "felsitic," meaning fine grained. The broadness of its denotation made it an extremely useful field term but condemned it for any other purpose. (F. Cs.)

FELSPAR: see FELDSPAR.

FELT, a class of fabrics or fibrous structures obtained through the interlocking of wool, fur or some hair fibres under conditions of heat, moisture and friction. Other fibres will not felt alone but can be mixed with wool, which acts as a carrier. Three separate industries manufacture goods through the use of these properties. The goods produced are wool felt in rolls and sheets. hats. both fur and wool, and woven felts, ranging from thin billiard tablecloths to heavy industrial fabrics used for dewatering in the manufacture of paper.

Felts of the nonwoven class are considered to be the first textile goods produced and many references may be found to it and its uses in the histories of ancient civilizations. The nomadic tribes of north central Asia still produce felts for clothing and shelter, utilizing the primitive methods handed down from antiquity.

Wool felts of the "true" or nonthread structure class are produced as both rolls and sheets. Roll felts are made in thicknesses from $\frac{1}{32}$ to $1\frac{1}{2}$ in., and up to 80 in. wide and 60 yd. long. Sheet felts are produced up to 4 in. thick usually as 36 in, squares but other rectangular sizes as well as ovals and circles are made. Wool felts of the better grades are made of all wool but the felting power of wool is such that as little as 10% wool in a blend with non-felting fibres is sufficient to produce a felt.

The wool fibres selected for felting are usually less than $1\frac{1}{2}$ in. in length and must be of good felting quality and strength. The fibres are scoured, treated to remove tar, paint and vegetable matter such as burrs, and then opened and blended to form a batch. The prepared blend is fed to a carding machine, which further opens, blends and combs the fibres into a web of single fibre thickness that is laid down on an endless apron to form a batt. In most roll felt manufacture two or more cards are set at right angles to each other so that the web from at least one is laid down at right angles to the others to produce "cross" in the batt and dimensional stability in the finished felt.

The carded batts are produced to predetermined weights, after which one or more batts, but usually several to a felt, are laid up on the hardening machine and sprayed with water. Hardening consists of drawing the moistened laid up batts between aprons across a steam chamber. Steam is forced into the batts to activate the fibres, after uhich the steamed section is drawn beneath a heavy heated platen. The platen is lowered onto the moist, hot batt and is agitated in a horizontal plane.

The heat, moisture and friction is sufficient to felt and interlock the fibres from the individual batts into a unified mass. After a requisite time the platen is raised, the hardened section drawn forward, and the next area, which has been steamed meanwhile, is subjected to the action of the platen. This operation is plate hardening; a similar operation done on a continuous basis between rollers is called roller hardening.

After the hardening operation, the lightly felted piece is rolled and allowed to cool and drain. Only the thickness of the batts is affected by hardening whereas area shrinkage or felting up to as much as 50% is accomplished in the next operation known as fulling. The hardened batt is passed through a fulling aid, usually a solution of soap or acid, although occasionally warm water will suffice, and is rolled up and placed in the fulling mill. One type of fulling mill consists of a binlike receptacle with a concave front, straight sides and a back that consists of one or more movable hammers that pound, turn and shrink the goods to the desired dimensions.

The scouring, dyeing, treating and finishing operations that follow are done much as for the production of woolen cloths. Sheet felts follow much the same process except that after carding the batts are cut up and plied to specified sizes and weights and then hardened, fulled and washed as individual sheets. Maximum dimensional stability, density and strength are obtained in the sheet felt process.

Hair felts, widely used in polishing operations, are made much as described above for sheet felts and are an important specialty item to the wool felt industry.

The uses of felt are myriad. Some of the more important include wicking, absorption, vibration isolation, insulation, padding and packaging, polishing, sealing and gasketing, as well as apparel and decorative fields.

Most felts are made to close specification requirements, particularly for mechanical and industrial applications where high standards of quality, reproduction and tolerances are constantly met.

Hat felts are made of both wool and fur. Wool hats are made much as already described for wool felts except that a narrow web is taken from the card and is collected on an egg-shaped mandrel. Two cone-shaped pieces are obtained from this starting shape by further felting operations from which the finished hat bodies are shaped and formed. Beaver, hare and rabbit furs are among the fibres used in fur felt hats and all of these must first be treated with strong chemicals in an operation known as carrotting in order to provide the fibres with optimum felting power.

In the manufacture of fur felt hats a blend of furs is air laid on a rotating perforated cone surface with a wet cloth and with a vacuum pulling from within. The fur collects and is removed as a fragile cone shape. After many wet finishing operations, including dyeing, the felted cone is molded to a rough hat shape. Many more dry finishing operations are required to reduce the rough hat to the finished article.

The manufacture of woven felts follows to a large degree the conventional woolen cloth practice. Wools of selected fineness, length and felting property are scoured, blended, combed and spun into yarns. The yarns are woven into the rough cloth structure required depending upon the type of end goods planned. The rough cloth is soaped and fulled or milled in the fulling mill where felting or shrinkage is carefully controlled to preset dimensions after which scouring, dyeing in the case of some of the lighter cloths, and other textile finishing operations follow.

Some special felts for the papermaking trade are made as endless belts zoo in. or more in width. Highly skilled operators hand weave or join the ends to produce the endless belt so that no joint or seam is discernible. Special machines are used to make this class of woven felts since the goods must be run as belts and therefore have to be loaded and unloaded from the side of the machines rather than from the front or back as is conventional.

(T. J. G.)

FELTHAM, an urban district in the Feltham parliamentary division of Middlesex, Eng., about 15 mi. W.S.W. of Charing Cross, London, by road. Pop. (1951) 44,861. Area 7.7 sq.mi. Hanworth, in the southern part of the district, was a royal hunting seat much favoured by Henry VIII; the castle was burned down in 1797 but the moat still remains. The records in the 19th-century church of St. George date back to 1300 and Oriel school has been so named because Adam de Brome, rector in 131j, founded Oriel college, Oxford. In Bedfont, in the northern part of the district, many Roman relics have been found. The parish church of St. Mary by the village green dates from the 12th century, and early English mural paintings have been found there.

The district includes part of London airport, most of Feltham marshalling yard which contains about 39 mi. of sidings, the central ordnance depot of the Royal Army Ordnance corps, the second oldest borstal institution (see BORSTAL SYSTEM) in the country and the ship hydrodynamics laboratory of the National Physical laboratories.

FELTON, CORNELIUS CONWAY (1807–1862), **U.S.** classical scholar, was born on Nov. 6, 1807, in West Newbury, Mass. His annotations on Wolf's text of the Iliad (1833) and his Greece, *Ancient* and Modern (2 vol., 1867) were outstanding works. He graduated from Harvard college in 1827, taught at various academies, and joined the Harvard faculty in 1829. In 1860 he became president of Harvard, a position he held until his death, at Chester, Pa., on Feb. 26, 1862.

Felton was a man of unusual intellectual breadth, and vigorously opposed the growing neglect of the humanities in American universities. He edited many classical texts and made several translations.

FELUCCA: see BOAT.

FENCE. **A** fence is a man-made barrier erected to restrict the movement of men or animals across boundaries. In early historical times the term was used in the sense of defense or of anything that served as a defense or protection as against heat, cold, rain or evil but especially against enemies, the Great Wall of China being the most awe-inspiring example. Castle walls of the middle ages, stockades of pioneer America, thorn fences of African villages and barbed wire entanglements of modern wars are examples of the continued use of fences as protection from foes. (See FORTIFICATION.)

As civilization advanced, fences were constructed to confine animals within bounds or keep them out of fields, to exclude unwelcome trespassers, and to enhance the beauty of buildings, gardens and fields.

Materials and methods of constructing fencing on farms reflect changes in technical development. Before the discovery of manufacturing methods for steel fencing, farmers built from materials readily available. Settlers of stony land cleared their fields of stone and erected fences by the expedient of piling stones about the field boundaries. Where stones were not abundant. timber, sod and living or quickset hedges formed fences. When properly trimmed, hedges make a permanent fence as attested by the English privet fence, the Osage orange and the multiflora rose of the United States. Hawthorn (*q.v.*) has been used in England since Roman times. Various species of cactus have long been used for living fences. especially in southern Mexico and Latin America and in Africa. Mud, adobe. brush and wattled fences have been widely employed in sparsely timbered areas; homesteaders in Kansas sometimes made fence posts from native limestone. Farmers with ample timberland chose to construct fences of wood.

In the United States in colonial days, five types of common wood fences were: split rail laid in a zigzag pattern, sometimes called worm; mortised and tenon; stake and bunk; jack pole or jack and pitch pole; and picket. In the mortise and tenon fence, rectangular holes were cut through the posts to support the straight rails, hewed to fit into the holes. The stake and bunk was constructed by placing rails in a straight line into a ladderlike structure of two posts with wooden spacers between them and mounted on a bunk or block. Jack pole and pitch pole fences were both built on X-shaped post structures. Poles to form the fence ran horizontally on the common jack pole fence, but were placed diagonally with one end resting on the ground in the pitch pole fence.

Farmers on the plains of Russia and the United States built earth fences of sod or turf since this material was readily available and low rainfall allowed them to stand over a period of years.

Wire for fencing was first used in the 1800s. Barbed wire and woven wire were developed between 1860 and 1883 when the first woven wire was produced for sale. The industry grew rapidly. In 1923 there were 552 styles of woven wire being produced and sold in 2,072 sizes of packages in the United States. The national bureau of standards of the United States worked to reduce this great variety. Five standard styles of barbed wire were developed, all of them packed in standard 80-rod rolls. Woven wire with rectangular mesh and hinged joints serves for most farm field use. Eight principal sizes are identified by number such as 939-6-11. This means that the wire has 9 horizontal line wires, is 39 in. tall, has vertical stay wires 6 in. apart, and the wires are 11-gauge, except the top and bottom line wires. All wire is galvanized for corrosion resistance, Hinged joint woven wire is packed with 20 rods in each roll.

Other forms of steel fencing include lightweight poultry netting from 12 to 72 in. tall, with 1- or 2-in. mesh; and heavy weight link fence as used by industry.

Post durability is an important factor in determining the life of a steel fence. Reinforced concrete, steel and wood are popular post materials. Although the heart woods of some species such as black locust. catalpa, cedar. cypress, juniper, mulberry and Osage orange have fairly good decay resistant properties, scarcity of these species created demands for preservative treated posts. Wood preservatives are classified as either oils such as coal-tar creosote and petroleum solutions of pentachlorophenol, or water-borne salts such as copper sulfate and sodium arsenate. These materials have been effective in prolonging post life when properly applied

Traditionally, posts were placed 1 rod ($16\frac{1}{2}$ ft.) on centre in the farm fence line, but later standards recommend a 14 ft. on centre spacing. Special bracing must be constructed at the corners and at 20-rod intervals along straight lines of woven wire. Tests conducted at Iowa State college showed that an effective brace system is composed of three well-set posts 8 ft. 6 in. on centre. Two horizontal compression braces are supported on dowels set 8 to 12 in. below the top of these posts. The two braced panels are tied with diagonal tension members made of four strands of smooth galvanized 9-gauge wire twisted tightly to pre-stress the assembly.

Electric fences are for temporary use where close confinement is not essential. Since they are not a physical barrier, but a symbol of electrical shock in the mind of livestock, they are seldom satisfactory as a permanent fence. (See RURAL ELECTRIFICATION.) When using impulsive electrical charge on fence wire, safety precautions such as outlined in the regulations of British Standard 1222, "Battery-operated electric fences." should be followed. Insulators on the wire should resist passage of current to the ground when submitted to a 1,000 volt potential. See also WIRE.

FENCING. Modern fencing (Fr., *escrime;* Ital., *scherma*) is a world-wide sport derived from the ancient art of offense and defense with a sword. It is practised with three different weapons: the foil, épée (or dueling sword) and sabre. Each weapon has its own history, characteristics and rules; but the objective of all modern fencing is to score by touching the opponent's target and to avoid being touched.

In earlier days fencing was also practised with wooden weapons. such as the quarterstaff, singlestick and cane. Other obsolete forms include the Japanese game *kendo,* similar to quarterstafl but highly conventionalized as to ceremony and method of scoring; the German students' duels (*schläger-mensur*) designed as a test of courage rather than skill; and bayonet fencing, found in certain military establishments.

Modern fencing, from the point of view of the number of competitors and nations represented, has been a major Olympic sport since the games were revived in 1896. Its ruling body, the Fédération Internationale d'Escrime (F.I.E.), founded in 1913, comprises about 60 countries and conducts annual world championships except in Olympic years. The Amateur Fencers League of America is affiliated with the F.I.E. Fencing is predominantly a participant (rather than a spectator) sport than can be enjoyed competitively by a varied age group and by both men and women.

This article deals with the historical background and development of fencing as a sport, fencing weapons and equipment, rules and customs of fencing and fencing technique including footwork and fundamentals of foil, épée and sabre fencing.

Historical Background.— In the history of fencing; two great overlapping eras may be discerned. The first spans the period from ancient times to the 19th century, during which the art of swordsmanship was studied primarily for its practical utility (see SWORD). The second is the period of fencing as pure sport; in terms of the modern game, it dates roughly from the 18th century to the present day.

Although the sword was the chief weapon of battle until the introduction of gunpowder, relatively little is known about the technique of swordsmanship prior to 1400. The legendary skill of the heroes of Greek, Roman, Germanic and medieval epics seems to have been based mostly on strength and agility. During the golden age of chivalry the two-handed sword used by both knights and footmen was intended to crack heavy armour by powerful strokes with the edge. When, in the 15th century, the invention of firearms destroyed the effectiveness of heavy armour, the trend toward lighter, better-balanced weapons led to greater reliance on skill in the handling of the sword. Quick-firing weapons gradually rendered the sword obsolete in warfare, but the prevalence of dueling and brigandage required continued attention to the art of swordsmanship as a matter of personal safety. Guilds of professional fencing masters were organized and at times enjoyed great social prestige.

For a time fencing masters jealously guarded their knowledge, giving lessons behind closed doors, restricting practice to pupil and teacher, and forbidding disclosure of their "secret thrusts," or coups, which often cost fortunes to learn. Beginning in the 16th century, however, the publication of illustrated fencing treatise opened the way for testing the various theories and methods of swordsmanship. It seems clear that the secret thrusts of old Mere basic actions improved to a high degree of efficiency through long practice and concentration, with particular attention to the factors of surprise, timing and distance, which are still the keys to success in the sport of fencing.

From a technical viewpoint, the edge of the weapon seems to have been used exclusively until about 1500; thereafter preference was given to the one-handed rapier, and the faster and deadlier point thrust gained ascendancy. The rapier was used chiefly for offensive purposes; the defense was entrusted to the left hand, which carried a buckler or cloak and. eventually, a dagger for use at close quarters. Footwork at first was based on the elaborate geometic designs of Spanish masters, but was improved by the discovery of the effectiveness of the lunge during the second half of the 16th century. The next major advance was the use of a single weapon for both offense and defense. which led to the modern fencing position with the body in profile to offer the 'smallest target and to increase the reach of the lunge. With the development of the riposte or counteroffensive after the parry, the fundamental structure of modern swordplay with the thrusting weapon was completed, largely by Italian masters, by the beginning of the 17th century. Further refinements resulted from the introduction of the smallsword after 1650, the invention of the French foil about the same time. the evolution of the dueling sword with a rigid triangular blade and the development of a rough mask for practice in the 18th century.

Although the cutting weapon never disappeared, its technical development was much slower. The single-edged broadsword. or backsword. remained the "Englishman's traditional weapon" until the reign of Elizabeth I; it was used for offensive purposes, with a buckler for defense. A basket-hilt sabre was used in Germany for students' duels. The heavy cavalry sabre. which remained a weapon of war until modern times, featured wide circular movements from the wrist and parries made by countercuts. However, by modern standards. the handling of these weapons required only rudimentary skill. Technical advances were made chiefly by Italian masters in the 19th century, and resulted from the prevalence of sabre duels in Italy and eastern Europe under rules similar to those prevailing for combat with the thrusting weapon.

Even a brief history of fencing must refer to the symbolic importance of the sword in ceremony and social status over the centuries and to the ancient notion that the duel (*q.v*) was an acceptable method of settling disputes. Faith in divine judgment on the outcome characterizes the individual combats between Paris and Menelaus and between Ajax and Hector in the Iliad, the Germanic judicial institution of trial by battle and the chivalric tradition of the middle ages. Later, the duel was justified as a remedy for the deficiencies of the law in matters of personal honour. The duel had great impact upon the development of fencing as a sport. not only with respect to the technique of handling the weapons but also in the traditions of courtesy embodied in the punctilious dueling codes.

Development of Fencing as a Sport.—Foil Fencing.—The pivotal fencing bout (not a duel) in Hamlet indicates that friendly tests of skill in swordsmanship were well established by the year 1600. But fencing did not develop into a distinct game with its own rules for at least another century. The credit for this achievement is usually given to D. Angelo and G. Danet, who wrote treatises on fencing in the middle of the 18th century. The equipment for the new sport included the foil, originally designed as a practice weapon for the smallsword, and the metal practice mask with a horizontal eye slit. The rules were based on certain conventions of play originally adopted for safety reasons prior to the introduction of the mask. These conventions limited the target to the trunk of the body, and provided an orderly alternation of play between the contestants by specifying that the attack had the "right of way" until it was parried; then the defender's riposte had the right of way until it was parried, and so on. Following the invention of the wire-mesh mask around the year 1800, the new game made rapid strides. The rivalry of the French and Italian schools of foil fencing gave rise to the first great international tournaments. Emphasizing precision of movement, split-second timing. deception and counterdeception, fencing has been likened to a game of chess in the variety and intricacy of its actions; and its containment within the framework of the phrase d'armes or sequence of play turns the bout into a courteous but spirited argument Until the end of the 19th century, all the outstanding fencers were foil players An electrical scoring apparatus was adopted for international foil competitions in 1956.

Sabre Fencing dates from the middle of the 19th century, when the Italian masters introduced a light practice weapon and adapted the conventions of foil play to it. The limited target excluded the legs. and the orderly alternation of play was required. However. scoring could be done with both the point and the cutting edges. thus adding a new dimension to the diversity and complexity of the actions. Early in the 20th century, a number of masters in Hungary notably I. Santelli and L. Borsody, revolutionized the technique of sabre fencing by favouring a weapon no heavier than the foil and by emphasizing speed, co-ordination and other athletic aspects of the game. By the middle of the century, the popularity of the cut-and-thrust weapon rivaled, and in many countries surpassed. that of the classical foil.

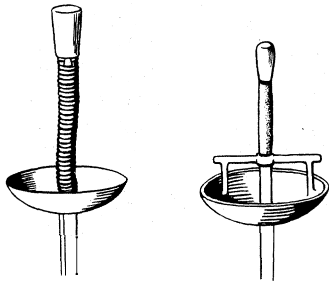

FIG. I — FRENCH (LEFT) AND ITALIAN (RIGHT) FOIL HANDLES

Épée Fencing began late in the 19th century as a reaction against the conventions of foil play and a tendency to score on "form" rather than effectiveness. A number of amateurs became interested in fencing outdoors for a single touch anywhere on the body with blunted dueling swords under rules that reproduced the prevailing conditions of the duel. The French term for the dueling sword, *épée* de terrain, indicates the original purpose of the new game exactly, but this realistic fencing soon followed the foil and sabre into the realm of pure sport. The special character of épée fencing was preserved through the elimination of conventions, although the number of touches per bout was increased to three in 1932 and to five in 1955. The decisive change came with the adoption of the electrical scoring apparatus in 1935, which led to an open game. with ample room for highly individualistic styles. that made CpCe fencing the most popular form of the sport in international competition. Épée fencing is one of the sports in the modern pentathlon, the others being running, swimming, riding and shooting.

Fencing Weapons and Equipment.—Because of the modern emphasis on speed. fencing weapons are usually lighter than the maximum weight permitted by the rules: 500 g. (17.637 oz.) for foil and sabre, 770 g. (27.16 oz.) for CpCe. The maximum overall length of foils and épées is 1.100 mm. (43.307 in); of sabres, 1.050 mm. (41.338 in.). Blades are made of finely tempered steel, with a maximum length of 900 mm. (35.433 in.) for foil and CpCe, and 880 mm. (34.646 in.) for sabre.

The foil is the only weapon used by both men and women. Its two principal forms are the French and Italian (fig. 1). The French favour a plain handle about eight inches long, slightly curved to fit the palm of the hand along the base of the thumb, with a pommel used chiefly for balance. The Italian handle is shorter and straight, with a crossbar about two inches from the guard; balance is obtained by a strap that binds the weapon to the wrist. In both types the weapon is held firmly with thumb and forefinger. while the other fingers control the movement of the point. With the Italian handle, the top joint of the middle finger hooks over the crossbar; this and the strap provide a somewhat stronger grip than the French handle (fig. 2). The latter, however, gives greater freedom of action to the fingers and wrist, particularly at close quarters. Other types of handles have been designed to combine the best features of the French and Italian styles, but have never attained the popularity of the older han-

FENCING, 16TH CENTURY AND MODERN

Top left: The long weapons and the geometrical designs of Spanish fencing masters of the 16th century. A circle was inscribed in a square intersected by chords, and pupils were instructed by this diagram

Top right: Two-handed sword against rapier in a match. The rapier, a straight two-edged sword used chiefly for thrusting, took the place of the espadon when the use of armour was discontinued and the heavier weapon was no longer required

Centre left: Beginning of salute at start of bout. The weapon is moved toward the person saluted and then is brought down sharply

Centre: The guard position with the Italian foil, which is strapped to the wrist

Centre right: Parrying with sabre (rear fencer) in fifth position against an opponent's cut to the head

Bottom left: Épée (dueling sword) fencer stop thrusts his opponent, who has started to attack, and catches him just above the wrist

Bottom right: Women's foil match showing a lunge in attack (left) being parried in fourth position

dles. Under the rules, disarmaments have no effect on the score, since touches after disarmament are not counted. The foil guard is normally circular, with a maximum diameter of 120 mm. (4.724 in.). The blade is rectangular in section. very flexible, tapering to a blunted tip; however, the electrical foil button is rounded and burred to insure registration of hits that land squarely on or off the target.

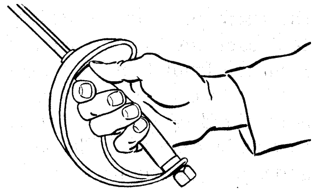

FIG. 3.— SABREGRIP

The construction of the CpCe is similar to that of the foil, but the Italian style of handle is not widely used. The guard is larger, 135 mm. (5.415 in.) in diameter, and sometimes mounted off-centre. The blade is triangular in section and fairly rigid; a special tip with three small prongs is used with nonelectric weapons to facilitate judging. In the electrical weapon, the tip is rounded and burred, and is fitted with a spring capable of resisting a pressure of 750 g. (26.455 oz.) before the apparatus registers a touch.

The sabre handle is plain and slightly curved. It is grasped so that it lies clear of the palm at the fleshy base of the fingers (fig. 3). The blade is V-shaped and narrow; it is rigid on the theoretical cutting edges, but quite flexible on the flat plane. The guard sweeps around the back of the hand to the pommel. so that it protects the knuckles against cuts; in size the guard must pass through a gauge 150 mm. (5.905 in.) by 140 mm. (5.512 in.). the flat of the blade being parallel to the 150 mm. sides.

All fencers wear a strong wire-mesh mask, a white suit made of closely woven canvass or gabardine, a glove with a cuff that overlaps the sleeve of the jacket and flat-soled shoes. Women must wear chest protectors. With the electrical CpCe and foil, the equipment includes a body cord that hooks up to the central apparatus; in foil fencing a metallic vest is also required. An elbow guard is optional in sabre fencing.

Rules and Customs of Fencing.—Since 1914, when the international rules were codified. the sole criterion for judging formal competitions has been the number of touches scored. Bouts are judged by five officials. The president of the jury starts and stops the play and awards the touches. Two judges watch each contest and announce, by raising a hand, when a hit has landed on or off the target. However, when the electrical apparatus is used for CpCe or foil, there is only one official. In informal bouts each fencer acknowledges the touches he receives.

In international events, bouts are held indoors on linoleum or cork strips about 2 m. (6 ft. $6\frac{3}{4}$ in.) wide and 18 m. (59 ft.) long. If a fencer retreats more than 4 m. (13 ft. $1\frac{1}{2}$ in.) in foil and 10 m. (32 ft. $9\frac{3}{4}$ in.) in CpCe and sabre, he is penalized one touch; if he steps off the side of the strip, he loses 1 m. (3 ft. $3\frac{3}{8}$ in.) in distance.

At the beginning of the bout, the contestants face each other in the centre of the strip and salute by raising their weapons (guard level with the chin) and bringing them smartly down. At the command "On Guard," the fencers put on their masks and take a guard position. The president then asks "Ready?" and. if neither fencer says "No," orders them to "Fence!" The contestants are free to fence as they please, each trying to touch his opponent and to avoid being touched, until "Halt!" is called.

In CpCe the entire body is valid target; in foil and sabre the target is limited (fig. 4) and hits on the invalid parts of the body stop the action. Since Jan. 1, 1960, the target for women (who participate in foil fencing only) has been the same as that for men and the target has been the same for the electrical and nonelectrical apparatus. If both contestants are hit, but with a sufficient time difference, only the first touch counts. If the hits are simultaneous, a touch is scored against both fencers in CpCe; but in foil and sabre the hit that has the conventional right of way prevails. After each score, the fencers go back to the centre and play is started again as before; if no touch is awarded, play is resumed at the point nhere it was halted.

Infighting is alloned, but as soon as there is a clinch (*corps-à-corps*), so that the fencers cannot use their weapons freely, the bout must be stopped. In CpCe a fencer is permitted to force the clinch without penalty, but in foil and sabre this is considered a violation of the conventions of play; the fencer is warned and then is penalized one touch for each offense. In all weapons dangerous play and unnecessary roughness are strictly forbidden.

Under F.I.E. rules bouts for men in all three weapons are fenced for five touches; women's foil bouts are for four touches. When one contestant has received the specified number of touches, each fencer salutes his opponent and the jury, and then shakes hands with and thanks his adversary.

Major individual competitions are held by the round-robin pool system. The entries are grouped into pools of six to ten contestants who fence one another, with the top one-third to one-half qualifying for the next round. The elimination process is repeated until only eight or nine fencers remain for a final round robin. Places are determined by the number of victories scored in the final round; ties for first are fenced off, but for other places ties are resolved in favour of the competitor who has received the fewest touches, and if a tie still exists the one who has scored the most touches gets the highest ranking. A number of national championships are conducted on this basis only up to the point where 16 or

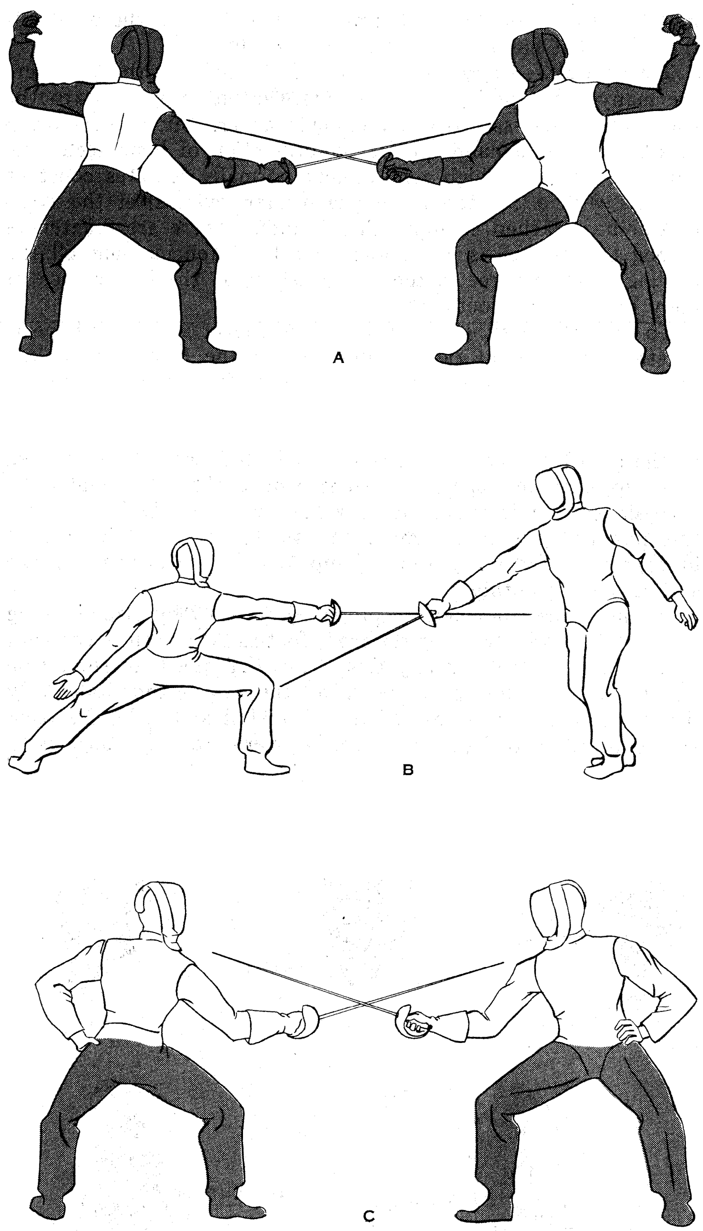

FIG. 4.— VALID TARGETS FOR (A) FOIL; (B) EPEE; (D) SABRE FENCING

Unshaded area indicates target. The target for women's foil is the same as that for men. The bib, no longer valid target in foil, must not extend below the collarbone. The lower limit of the sabre target is a horizontal line passing through the angle formed by the thighs and trunk of the fencer when in the guard position

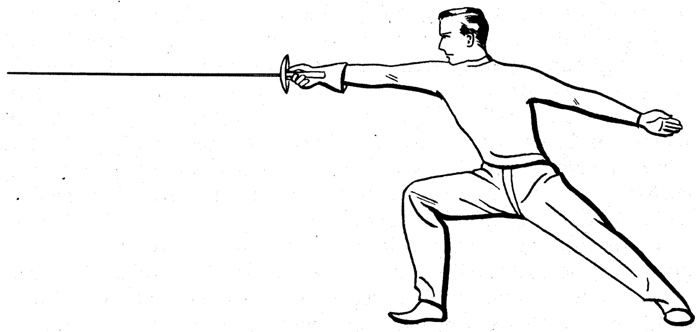

FIG. 5.—THE LUNGE IN FOIL AND ÉPÉE FENCING

32 contestants remain; then the competition proceeds on the basis of direct elimination, each match being fenced for the best two out of three bouts.

The pool system is also favoured for team events in the world and Olympic championships, with a final round of four teams. Each team consists of four fencers and two alternates, and each match is for 16 bouts. If the match ends at 8-all, the winner is the team that has received the fewer touches.

Technique. — Body Balance and Footwork. — Although there are many excellent books on fencing, the best way to learn the sport is to take lessons from a qualified teacher. Successful fencing in all weapons demands perfect co-ordination of hand technique and footwork, and high achievement normally requires constant training with a competent fencing master, even after the competitor has reached championship calibre. There are differences among the exponents of various schools of fencing, but all the leading masters agree in their emphasis upon the importance of body balance and footwork.

To take the basic guard position the fencer stands with heels together and feet at right angles so that the front foot points at the opponent; then he moves the front foot about $1\frac{1}{2}$ 'lengths forward, bends both knees distributing the weight evenly on the legs, and keeps the trunk erect. The sword arm is usually in one of the guard positions; the back arm in foil and CpCe is raised, palm up, shoulder high and then is bent at the elbow and wrist for balance, but in sabre the back hand rests on the hip. From this position, the fencer must be able to advance (front foot first), retreat (rear foot first), jump forward or backward, lunge and recover smoothly.

In the lunge, the body is propelled forward by straightening the back leg and advancing the front foot as far as consistent with balance and control; usually this means that the knee should be directly over the instep at the end of the lunge. Simultaneously the sword arm is fully extended and, in foil and CpCe, the back arm is also extended (fig. 5). The recovery from the lunge is to the guard position by flexing the rear leg and bringing the front foot back, or by advancing the rear foot to its normal distance from the front foot. Occasionally the *flèche* or running attack is used instead of, or as a continuation of, the lunge. This action is executed by bringing the back foot forward ahead of the front foot as in running. The *flèche* increases the reach of the fencer, and is particularly useful in CpCe and sabre, but it sacrifices balance and control of recovery and must be used judiciously.

Footwork is the key to the mastery of distance and timing; an otherwise perfectly executed attack will fail if the weapon cannot reach the target. or if the opponent can see the action coming in ample time to parry or retreat.

Fundamentals of Foil Fencing. — Facing his opponent, a fencer can see the "open lines, of attack" according to the position of the defensive hand. The four possibilities are high-outside, high-inside, low-outside. low-inside (fig. 6). There are two guards for each line: 3rd and 6th for high-outside, 1st and 4th for high-inside, 2nd and 8th for low-outside and 5th and 7th for low-inside. In the first-named guard for each line, the weapon is held with the fingernails down (pronation); most foilsmen, however, hold the weapon with the nails up (supination), and the preferred guards are 6th and 4th (fig. 7). When a fencer is in 6th, the elbow should be turned in so that it is six to nine inches in front of the flank, and the weapon should be held so that it forms a straight line from elbow to tip. The tip should be level with and slightly to the right of the opponent's mask.

The simplest attack is a straight thrust into an open line. If the blades are in contact (engaged) on a closed line, the attacker may pass his point into an open line by a small movement of the tip, or he may force an opening by a beat or by exerting pressure upon and gliding along the opponent's blade. When the weapon is held in supination, the point on reaching the target should cause the blade to form an upper arc.

The defender may avoid the attack by retreating or sidestepping, but the parry is preferred because it gains the right to riposte. Parries may be straight or circular (counterparries). The straight parry is made by a blocking movement or a sharp beat — usually executed without displacing the elbow — that meets the opponent's blade in the line of the attack. The counterparry consists of a small circle with the point that picks up the opponent's blade and carries it back to the guard position from which the parry was begun. Parries are numbered according to the guard positions where they block the opposing blade. The preferred foil parries in the high lines are 4th and 6th, and the corresponding counterparries; in the low lines, 7th and 8th. In the Italian school, the 7th parry is called the semicircle (*mezzocerchio*). Occasionally 2nd and 5th are used, but 1st and 3rd are practically obsolete.

To avoid the parry, the attacker may resort to timing, force or guile. He may attack so fast from close distance that the defender cannot react quickly enough to parry. He may control the opponent's blade by a bind or envelopment, catching the weak part of the defensive blade (the third nearest the point) with the strong part of his own (the third nearest the guard) in a semicircular or circular motion. He may make a feint and then deceive the defender's effort to parry; or he may make a false attack, intending that it be parried, in order to parry the defender's riposte and score on the counterriposte.

The defender after a successful parry has a similar choice of tactics on the riposte. In addition, if the attack is delayed or made in two or more movements, the defender may counterattack by a stop thrust, but if both contestants are hit, the stop to be valid must land before the final movement of the attack has begun. The same principle applies when the attacker makes a remise or counterattack against a delayed or composite riposte.

Fundamentals of *Épée* Fencing. — The basic analysis of the lines of attack, guards and parries is the same for CpCe as for foil, since both are thrusting weapons only. An impressive number of champion épéeists have based their game on the fundamentals of foil fencing, adapted to the larger target. The contestants tend to keep farther apart than in foil. and to take an intermediate guard position on the outside line, with the arm more or less extended and the weapon parallel to the ground (fig. 8). Attacks

and ripostes are frequently aimed at the wrist and forearm, and occasionally the mask or knee. To reach the body it is usually necessary to combine an advance-or jump with the lunge, or to make a *flèche*. As far as possible, offensive actions are made in opposition, blocking the adversary's blade in order to prevent the stop thrust; and parries must be made with the strong part of the blade, raising or low-ering the hand to achieve the same result.

A number of outstanding épée fencers, however, avoid engagements of the blade and base their game on angled shots under and over the opposing arm both on attack and defense, relying on shifting distance, and accuracy of point in the stop thrust more than on parry and riposte. Tall men with long arms find this style particularly effective, especially with the electrical apparatus that registers only the first of two touches if it is one-twenty-fifth of a second ahead. A few strong fencers follow almost the opposite tactics. developing their game around the straight-arm guard, with the arm fully extended so that it and the weapon form a straight line from shoulder to point.

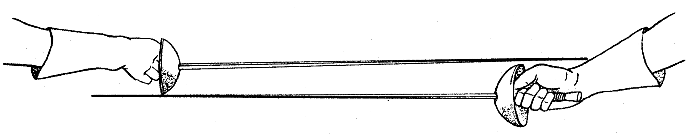
With the épée the fencer can attain a fair level of proficiency by capitalizing upon his individual resources more easily than with other weapons, and the less skillful fencer has a better chance to win any one bout than with foil or sabre. However, consistent victories are open only to the stronger and more complete fencers.

Fundamentals of Sabre Fencing. — The availability of the cutting edges as well as the point for scoring and the inclusion of the head in the target give the sabre all of the technical and tactical variations of the foil and a special brilliance of its o n. For proper control. the sabre must always be firmly grasped by the fingers and its direction must be guided precisely by the wrist and forearm. The upper arm and shoulder should be as relaxed as possible, in order to achieve lightness and speed. Hard-hitting results from a lack of proper blade control and is a discourtesy to the opponent.

Hits with the point are made in pronation, so that the blade bending against the target mill form an upper arc. Cuts with the front edge (the side away from the thumb) to the opponent's outside line — the sword arm, flank and right cheek — are delivered horizontally with the hand in pronation by a forward motion ending in a light tap on the target; the same motion is used in cuts to the head or the inside of the sword arm except that these are made vertically with the thumb uppermost Cuts to the left cheek and chest are usually made on the way back from a full extension of the arm, by a slicing motion with the hand in three-quarter supination; full supination is used only in horizontal cuts to the low inside areas of the target.

The basic guards and parries in sabre are five in number. 1st is for low-inside, 2nd for low-outside, 3rd for high-outside, 4th for high-inside, and 5th for the head (fig. 9). By far the commonest guard is 3rd. The elbow is close lo the body, the sword hand is level with the right hip, the wrist is cocked so that the sabre is almost vertical and turned so that the front edge will meet squarely a horizontal cut to the outside. The principle of meeting cuts with the front edge near the guard also applies to parries in all positions because of the slenderness of the sabre blade. Against cuts, straight blocking parries are preferred. Circular or counterparries are mainly used against point thrusts or to break up composite attacks.

The most important parries are 3rd, 4th and jth, because they offer the greatest opportunity for scoring on the riposte. Cuts to the low line will often be met by low 3rd and low 4th for that reason; but 2nd and 1st may be preferable in certain sequences of play. Thus, if the defender is in 2nd, he can more easily parry a chest cut with 1st than with 4th, and if he is in 5th he can more



ADAPTED FROM J MARTINEZ CASTELLO'S "THEORY AND PRACTICE OF FENCING

FIG. 8.—STOP-THRUST TO THE WRIST FROM THE STRAIGHT ARM OR INTERMEDIATE GUARD POSITION IN ÉPÉE FENCING

easily parry a flank cut with 2nd than with 3rd. The fastest riposte from 2nd is a horizontal cut to the upper arm or right cheek; the commonest riposte from 1st is a vertical cut to the head executed with a clocknise quarter turn of the wrist and forearm. The Italian school developed a 6th parry to protect the head, with the hand close to the left cheek, but the awkward position makes blade control and the riposte difficult, and for that reason the parry has become obsolete.

The complex range of possible actions with point and edge militates against static defense in sabre and enhances the value of the stop cut or thrust. The inclusion of the arm in the target, on the other hand, requires constant vigilance against the stop and favours the development of second intention attacks that draw the defender's stop in order to parry it and score on the riposte. The influence of the Hungarian school, however, has been in the direction of simplification. The fencers keep far enough apart so that it is difficult to reach the opponent by a simple lunge. Balance and mobility, timing and an exact sense of distance, decisive simple attacks on the *flèche,* direct or preceded by a sharp beat, and lightning ripostes are typical of modern sabre play.

For a list of Olympic champions, see OLYMPIC GAMES.

GLOSSARY

Attack. — A series of movements by which one tries to touch the opponent.

Beat. — A sharp tap made on the opponent's blade in order to deflect it.

Bind. — A pushing movement by which one contacts the opponent's blade and brings it from one'line into another.

Closing in, or corps *à* corps. — This occurs when the weapon guards or the fencers' bodies come together in such a way as to prevent the free use of the weapon by either fencer. Closing in is penalized in the conventional weapons (foil and sabre).

Conzposite attack. — An attack in more than one movement, *e.g.,* feint of straight thrust and disengage.

Composite parry. — A combination of defensive actions employed in meeting a composite attack.

Counter or circular *parry.*—A defensive movement executed by making a small circle with the point of the weapon around the opponent's blade, thereby deflecting it in the same line off the target.

Counter-riposte, — A riposte that follows the parry of the opponent's riposte.

Cutover or *coupé.*—An attack made by passing one's blade over the point of the adversary's blade by raising the point with a movement of fingers and hand and bending the arm very slightly, then extending to touch in the opposite line.

Disengage. — An attack made by passing the point into an open line with a small semicircular movement around the opponent's guard.

Envelopment.—A continuous binding movement executed so that the point of the weapon makes at least one complete circle.

False attack. — An attacking action meant to be parried so that the attacker may score on a redoublement, counter-riposte or stop thrust against the riposte.

Feint. — The semblance of an attack made to impel the defender to move his guard.

Flèche, or running attack. — A walking or running forward action.

Glide. — A sliding thrust along the opponent's blade usually with a slight pressure.

Jump. — An advance in which both feet move forward at same time.

Lunge.—A forward movement in which the back leg is straightened and the front foot advanced as far as consistent with balance. The sword arm is usually extended.

March. — An advance in which the forward foot is moved before the rear foot.

On guard, or en *garde.*—The position taken before the fencers begin combat.

Parry. — A defensive action with a direct or circular movement of the blade.

Redoublement.—A second attack after the first has been parried, but not followed immediately by a riposte.

Remise. — A stop thrust or cut on a riposte or counter-riposte.

Riposte. — The defender's counterattack following a parry.

Simple parry. — A direct blocking or beating movement of the defensive blade to deflect the attacking blade off the target.

Stop *thrust.*—A counterattack against the opponent's attack or riposte, intended to land with a sufficient time advantage over the opponent's action to score a touch.

Straight thrust or cut. — A simple attack made without contact of the blades or along the opposite blade if the opponent contacts one's blade without exerting pressure.

Time thrust or 'cut. — A counterattack that is both a parry and a riposte, by closing the line where the attack is to be completed.

C. Roux, *L'escrime dans les universitds allemandes* (1885). On similar subjects, see Alfred Hutton, *The Cavalry Swordsman* (1867) ; T. A. McCarthy, *Quarter-Staff* (1883); Allanson Winn and Phillips Wolley, *Broadsword and Singlestick* (1898).

The bi-monthly organ of the Amateur Fencers League of America, *American Fencing,* contains technical articles as well as current reports of competitions. (M. A. DE C.)

FÉNELON, FRANÇOIS DE SALIGNAC DE LA MOTHE (1651–1715), French writer and archbishop of Cambrai, was born at the château of Fénelon in Périgord on Aug. 6, 1651. His father, Pons, comte de Eknelon, was a country gentleman of ancient lineage, large family and small estate. He was educated at home and at the neighbouring University of Cahors. In 1666 he came to Paris, under charge of his father's brother, Antoine, marquis de Fénelon, and in 1669 he entered the college of St. Sulpice. He contemplated a missionary journey to the Levant. but the plan was vetoed, and he remained at St. Sulpice till 1679, when he was made "superior" of a "New Catholic" sisterhood in Paris—an institution devoted to the conversion of Huguenot ladies. In the winter of 1685, just after the revocation of the Edict of Nantes, Fénelon was put at the head of a mission to the Protestants of Saintonge. To Fénelon such employment was clearly uncongenial; but if he employed bribery and espionage among his proselytes. his general conduct was kindly and statesmanlike. But neither in his actions nor in his writings is there the least trace of that belief in liberty of conscience ascribed to him by 18th-century philosophers.

Meanwhile the marquis de Fénelon had introduced his nephew into the devout section of the court, dominated by Mme. de Maintenon. He became a favourite disciple of Bossuet, and at the bishop's instance undertook to refute certain metaphysical errors of Father Malebranche. In the philosophical *Treatise on the Existence of God,* which he wrote for the purpose, Fénelon rewrote Descartes in the spirit of St. Augustine. More important were his *Dialogues on Eloquence,* pleading for greater simplicity and naturalness in the pulpit and urging preachers to take the scriptural, natural style of Bossuet as their model, rather than the coldly analytic eloquence of his great rival. Bourdaloue. His *Treatise on the Education of Girls* was probably the most influential of all Fénelon's books: and guided French ideas on the question all through the 18th century. It holds a most judicious balance between the *pre'cieuses,* enthusiasts for the "higher" education of their sex, and the heavy Philistines. who thought that the less girls knew the better they were likely to be. Fénelon sums up in favour of the cultivated housewife; his first object was to persuade the mothers to take charge of their girls themselves, and bring them up to be suitable wives and mothers in their own generation.

The Royal Tutor.—In 1689 Fénelon was gazetted tutor to the duke of Burgundy, eldest son of the dauphin and eventual heir to the crown. The character of this strange prince has been drawn once for all by Saint-Simon. Brilliant, passionate to the point of mania, but utterly weak and unstable, he was capable of developing into a saint or a monster, but quite incapable of becoming an ordinary human being. Fénelon transformed him into a devotee, exceedingly affectionate, earnest and religious but woefully lacking in tact and common sense.

Fénelon's tutorship ended with his disgrace in 1697, before the pupil was 1j.

The abiding result of his tutorship is a code of carefully graduated moral lessons—the *Fables,* the *Dialogues of the Dead* (a series of imaginary conversations between departed heroes) and finally *Télémaque,* where the adventures of the son of Ulysses in search of a father are made into a political novel with a purpose. Not, indeed, that Fénelon meant his book to be the literal paper constitution some of his contemporaries thought it. Like other Utopias! it is an easygoing compromise between dreams and possibilities. Its object was to broaden Burgundy's mind and ever keep before his eyes the "great and holy maxim that kings exist for the sake of their subjects, not subjects for the sake of kings." Here and there Fénelon's work is prophetic of the age of Rousseau —in the fervid denunciation of war, the belief in nature and the fraternity of nations. He has a truly 18th-century belief in paternal government. Mentor proposes to "change the tastes and habits of the whole people, and build up again from the very foundations." Fénelon is on firmer ground when he leads a reaction against the mercantile system of Colbert, or insists on the importance of agriculture. Valuable and farsighted as were these ideas, they fitted but ill into the scheme of a romance. Seldom was Voltaire wider of the mark than when he called *Télémaque* a Greek poem in French prose. But although no single feature of the hook is Greek, there hangs round it a moral fragrance only to be called forth by one who had fulfilled the vow of his youth and learned to breathe, as purely as on "the double summit of Parnassus," the very essence of the antique.

Mme. **Guyon.**—*Télémaque* was published in 1699. Four years before. Fénelon had been appointed archbishop of Cambrai, one of the richest benefices in France. Soon afterward. however, came the great calamity of his life. In the early days of his tutorship he had met the Quietist apostle, Mme. Guyon (*q.v.*), and had been struck by her ideas. These he developed along lines of his own, where Christian Neoplatonism curiously mingles with theories of chivalry and disinterestedness, borrowed from the *pre'cieuses* of his own time. His mystical principles are set out at length in his *Maxims of the Saints,* published in 1697. Here he argues that the more love we have for ourselves, the less we can spare for our Maker. Perfection lies in getting rid of selfhood altogether—in never thinking of ourselves. or even of the relation in which God stands to us. The saint does not love Christ as his Redeemer, but only as the Redeemer of the human race. Bossuet (*q.v.*) attacked this position as inconsistent with Christianity. Fénelon promptly appealed to Rome. and after two years of bitter controversy his book was condemned by Innocent XII in 1699. One of the results of the quarrel was Fénelon's banishment from court, for Louis XIV had ardently taken Bossuet's side. Fénelon was exiled to his diocese, and during the last 18 years of his life he was only once allowed to leave it.

Even Saint-Simon allows that his episcopal duties at Cambrai were perfectly performed. His diocese was administered with great strictness, and yet on broad and liberal lines. Saint-Simon bears the same witness to his government of his palace. There he lived with all the piety of a true pastor. yet with all the dignity of a great nobleman. With all its luxuries, his house remained a true bishop's palace, breathing the strictest discipline and restraint. And of all this chastened dignity the archbishop was himself the ever-present, ever-inimitable model—in all that he did the perfect churchman. in all the high-bred noble, in all things, also, the author of *Télémaque.*

The blot on this ideal existence mas his persecution of the Jansenists (*see* JANSENISM). Fénelon's theories of life were different from theirs. and they had attacked his *Maxims* of *the Saints,* holding that visionary theories of perfection were ill-fitted for a world where even the holiest could scarce be saved. To suppress the Jansenists he was even ready to strike up an alliance with the Jesuits and force on a reluctant France the doctrine of papal infallibility. His time was much better employed in fitting his old pupil. Burgundy, for a kingship that never came. Louis XIV seldom allowed them to meet, but for years they corresponded, this exchange of letters became still more frequent in 1711, when the wretched dauphin died and left Burgundy heir apparent to the throne. Fénelon now wrote a series of memorable criticisms on the government of Louis XIV. Much more clearly than most men, he saw that the Bourbons were tottering to their fall.

In 1712 Burgundy died. and with him died all his tutor's hopes of reform. From this moment his health began to fail, though he mustered strength enough to write the *Lefter to the French Academy* (1714), a series of general reflections on the literary movement of his time. As in his political theories. the critical element is much stronger than the constructive. Fénelon was feeling his way away from the rigid standards of Boileau to "a Sublime so simple and familiar that all may understand it." But some of his methods were remarkably erratic; he was anxious, for instance, to abolish verse, as unsuited to the genius of the French. In other respects, however, he was far before his age. The 17th century had treated literature as it treated politics and religion; each of the three was cooped up in a watertight compartment by itself. Fénelon was one of the first to break down these partition walls and insist on viewing all three as products of a single spirit, seen at different angles.

A few weeks after the *Letter* was written, Fénelon met with a carriage accident. On Jan. 7. 171j, he died at the age of 63. Fénelon has been made by turns into a sentimentalist, a mystical saint, an 18th-century *philosophe,* an ultramontane churchman and a hysterical hypocrite. And each of these views, except the last, contains an element of truth. More than most men, Fénelon "wanders between two worlds--one dead, the other powerless to be born." He came at a time when the characteristic ideas of the 17th century—the ideas of Louis XIV, of Bossuet and Boileau—had lost their savour, and before another creed could arise to take their place. Hence, like most of those who break away from an established order, he seems by turns a revolutionist and a reactionary. Such a man expresses his ideas much better by word of mouth than in the cold formality of print; and Fénelon's contemporaries thought far more highly of his conversation than his books. Saint-Simon has left a portrait of Fénelon as he appeared about the time of his appointment to Cambrai—tall, thin, well built, exceedingly pale, with a great nose. eyes from which fire and genius poured in torrents, a face curious and unlike any other, yet so striking and attractive that, once seen, it could not be forgotten. There were to be found the most contradictory qualities in perfect agreement with each other—gravity and courtliness, earnestness and gaiety, the man of learning, the noble and the bishop. But all centred in an air of high-bred dignity, of graceful, polished seemliness and wit—it cost an effort to turn away one's eyes.

BIBLIOGRAPHY.—The best complete edition of Fénelon was brought out by the abbé Gosselin of Saint Sulpice, 10 vol. (1851). Gosselin also edited the *Histoire de Fénelon* by Cardinal Bausset, 4 vol. (1850). Modern authorities are E. de Broglie, *Fe'nelon à Cambrai* (1885); P. Janet, *Fe'nelon* (1892); L. Crouslé, *Bossuet et Fdnelon,* 2 vol. (1894); J. Lemaitre, *Fdnelon* (1910). In English there are: E. K. Sanders, *Fe'nelon, His Friends and Enemies* (1901); Lord St. Cyres, *François de Fe'nelon* (1906); *see* also the *Quarterly Review* (Jan. 1902); M. Masson, *Fénelon et Madanze Guyon* (1907).

FENESTELLA, Roman historian and encyclopaedic writer, flourished in the reign of Tiberius. If the notice in Jerome be correct, he lived from 52 B.C. to A.D. 19 (according to Pliny, *N.H.*, xxxiii, 35 B.C.–A.D. 36). Taking Varro for his model. Fenestella represented the new style of historical writing which discussed curious incidents and customs of political and social life and literary history. He was the author of an *Annales,* probably from the earliest times down to his own days. The fragments indicate the great variety of subjects discussed: the origin of the appeal to the people *(provocatio);* the use of elephants in the games; the wearing of gold rings; the introduction of the olive tree; the material for making the toga; the cultivation of the soil; details as to the lives of Cicero and Terence. The work was much used by Pliny the elder, Asconius Pedianus (the commentator on Cicero), Nonius, and the philologists.

Fragments in H. Peter, *Historicorum Romanorum fragmenta* (1883); *see* also monographs by L. Mercklin (1844) and J. Poeth (1849); M. Schanz, *Geschichte der rom. Litt.*, ed 2 (1901); Teuffel, *Hist. of Roman Literature,* p. 259. A work published under the name of L. Fenestella *(De magistratibus et sacerdotiis Romanorum,* 1510) is really by A. D. Fiocchi, canon and papal secretary, and was subsequently published as by him (under the latinized form of his name, Floccus), ed. by Aegidius Witsius (1561).

FENESTRATION, an architectural term applied to the arrangement and proportions of windows on the outside walls of a building. The structural nature of load bearing masonry walls usually limits the size, number, and placement of exterior windows. When curtain walls (nonload bearing) are used, the windows may be sized and placed in accordance with the needs of the plan. or exterior appearance.

When a building is sheathed completely in glass (*e.g.,* Lever house, New York city) the term applies to the size and proportions of the panes and supporting members as well as to the proportional relations between the various panes.

See also WINDOW. (H. MN.)

FENG HUANG, one of the four symbolical creatures which in Chinese mythology were believed to keep watch and ward over the Celestial empire. It was begotten by fire, was born in the Hill of the Sun's Halo, and its body bears inscribed on it the five cardinal virtues.

It has the breast of a goose, the hindquarters of a stag, a snake's neck, a fish's tail, a fowl's forehead. a duck's down, the marks of a dragon, the back of a tortoise, the face of a swallow, the beak of a cock, is about six cubits high and perches only on the wu-tung tree. Its appearance heralds an age of universal virtue. The name is Chinese for "phoenix."

FENGTIEN, province of Manchuria: *see* MANCHURIA.

FENG YÜ-HSIANG (1880–1948), Chinese military leader, was born in Chaohsien in the province of Anhwei, and was generally known as "the Christian general" from his early adoption of Christianity of a Baptist and Evangelical type. His education and training were purely military, and he saw active service under Chao Erh-feng in Tibet in 1909. In 1912 he was in Sian in the 20th division under the command of Lu Yung-hsiang. At the revolution he had attained the rank of major and uas at Shanhaikwan; from there he was promoted brigade commander in the army controlling Chihli and the capital. His acceptance of, and consistent adherence to, Republican principles dated from this period and formed a salient feature of his subsequent career. Under Wu Pei-fu he took part in the defeat of the Anfu group, and thereafter reorganized his famous 11th division.

General Feng obtained his first independent command early in 1921 when his division was dispatched into Shensi to restore order in that province, and in August, upon the death of the military governor, he was given the acting appointment. Both as *tuchun* of Shensi, and in Honan, Feng and his troops earned the highest encomiums. The complete suppression of banditry, the discouragement of poppy cultivation, extensive road construction works and an effort to re-establish honesty in public accounts were among the measures standing to his credit, while strict discipline and an active if somewhat Corybantic display of Christian practices in his army were evidence of his zeal for good administration.

Shortly afterward his division was transferred to Peking, where its disciplined efficiency and the strength of purpose of its commander made their influence felt. In the spring of 1923 Feng was appointed commissioner of frontier defense for the northwest, but because of the unstable political position in the capital he deferred taking up his new duties. With his assistance Li was driven from office in June by Tsao Kun, who then assumed the presidency. During the ensuing year he became convinced of Tsao Kun's inability to form a stable government and he opposed the resumption of the war against Chang Tso-lin. By a coup de main he descended upon Peking, causing the defeat and flight of Wu, and in co-operation with Chang he installed Tuan Chi-jui as "chief executive," thereafter leaving for the northwest. In Kalgan, Suiyuan and Paotowchen, his administrative gifts again found scope. Colonization plans for Mongolia and suppression of lawlessness marked his stay. Adhering to the Kuomintang, he co-operated with the Nationalist allies in 1927.

Feng was expelled from the Kuomintang in 1929 but reinstated in 1931. After the start of the Chinese-Japanese war he was commander of the "People's Allied Anti-Japanese army," and was a leading governmental and military figure during World War II.

At the close of the war, his growing opposition to the Chiang Kai-shek government resulted in his political exile to the United States, where he led an opposition movement aimed at removing Chiang from power. He was again expelled from the Kuomintang on Jan. 7, 1948.

He died in an accidental fire aboard a Russian vessel which left New York for Odessa on July 31, 1948.

FENIANS or FENIAN BROTHERHOOD, an Irish-American revolutionary secret society active 1863–70. The name was derived from *fiann, fkinne,* the legendary band of warriors in Ireland led by Finn Mac Cumhaill *(see* FINN MAC CUMHAILL). The society was founded in the United States in 1858 by John O'Mahony (1816–77), who had been concerned in William Smith O'Brien's rising in Ireland in 1848. James Stephens collaborated with him in Ireland. and founded the *Irish People,* a revolutionary journal, in Dublin in 1863. The Irish wing of the society was sometimes called the Irish Republican (or Revolutionary) Brotherhood, a name which continued to be used after Fenianism proper had virtually died out. Members bound themselves by an oath of "allegiance to the Irish Republic, now virtually established." The organization had ramifications in every part of the world, the Fenians being found in Australia, South America, Canada and above all the United States, as well as in centres of population in Great Britain such as London, Manchester and Glasgow. Fenianism, however, never gained much hold on the tenant farmers or agricultural labourers in Ireland. The movement was denounced by the priests of the Catholic Church.

The movement became more active after a convention held at Chicago, Ill., under O'Mahony's presidency in Nov. 1863. The close of the American Civil War in 1865 brought its greatest opportunity. Irishmen who had borne arms flocked to Ireland, and plans were made for a rising. The government, well served as usual by informers, now took action. In Sept. 1865 the *Irish People* was suppressed. Several prominent Fenians received prison terms; Stephens, however, succeeded in escaping to France. The Habeas Corpus act was suspended in 1866, a considerable number of persons were arrested and some small disturbances were put down by the police.

In 1867 there were minor risings in Kerry and elsewhere in Ireland and an intended attack on Chester castle was frustrated. On Sept. 18, 1867, when two Fenian prisoners were being conveyed through Blanchester, the prison van was attacked and a police sergeant killed. For this three men named Allen, Larkin and O'Brien were hanged on Nov. 23; they are frequently called the "Manchester martyrs." On Dec. 13, 1867, in an unsuccessful attempt to rescue Fenian prisoners in Clerkenwell prison, London, the prison wall was blown down with gunpowder, causing the death of 12 persons and the maiming of about 120 others.

Late in 1865 the brotherhood in the U.S. had split, one wing under O'Mahony (and later John Savage) advocating action in Ireland, the other under William Randall Roberts (1830–97) desiring to attack Canada. The Roberts wing attempted the Canadian invasion at the end of May 1866. John O'Neill (1834–78) crossed the Niagara with perhaps 600 men. He defeated a detached column of Canadian volunteers at Ridgeway (June 2) and escaped from Canada that night before other troops could close in on him. The returning Fenians were arrested by U.S. patrols but soon released.

The Roberts Fenians continued their threats and repeatedly obliged the Canadian government to make defensive preparations. O'Neill succeeded Roberts in Jan. 1868. In May 1870 another raid, on the Vermont border, was defeated by Canadian forces and O'Neill again was arrested by U.S. authorities. His final enterprise, against Manitoba in 1871, was frustrated by U.S. troops. Canada sought, but did not obtain, compensation from the United States for damage done by these expeditions organized on U.S. soil. In Ireland in 1870 Michael Davitt (*q.v.*) was sentenced to prison for Fenian activity; before his release in 1878 the name Fenian was becoming obsolete.

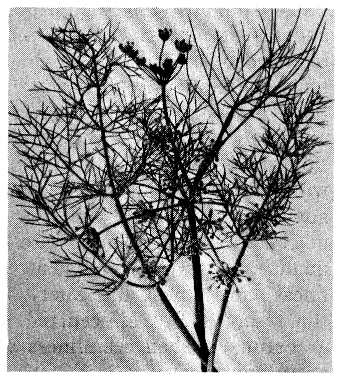
Denieffe, *Personal Narrative of the Irish Revolutionary Brotherhood* (1906); Sir James O'Connor, *History of Ireland, 1798–1924*, 2 vol. (1925); C. P. Stacey, "Fenianism and the Rise of National Feeling in Canada at the Time of Confederation," *Canadian Historical Review* (Sept. 1931). (C. P. St-.)

FENNEC, the name applied to several desert-dwelling species of fox, characterized by the great length of the ears and small size. The true fennec (Vulpes zerda) inhabits north Africa and is pale in colour with a short, black-tipped tail. South of the Zambezi the group reappears, being represented by the ass fox (*V. cama*), a dark-coloured, long-tailed species. The northern fennec (V. famelicus) is intermediate between the fennecs and typical foxes. See FOX.

FENNEL, Foeniculum *vulgare,* a perennial plant of the family Umbelliferae (*q.v.*), from two to three or (when cultivated) four feet in height, having leaves three or four times pinnate, with numerous linear or awl-shaped segments, and glaucous compound umbels of about 15 or 20 rays, with no involucres, and small yellow flowers, the petals incurved at the tip. The fruit is laterally compressed, five ridged, and has a large single resin canal or vitta under each furrow.

The plant appears to be of south European origin, but is naturalized in the eastern U.S. and is met in various parts of Britain and temperate Eurasia. The dried fruits of cultivated plants have an aromatic taste and odour and are used for the preparation of fennel water, valued for its carminative properties. The blanched shoots are eaten and the seeds are used for flavouring.

Giant fennel is Ferula *communis,* a member of the same family, often cultivated, and native to the Mediterranean region, where the pith of the stem, which grows from 8 ft. to 12 ft. high, is used for tinder. Hog's fennel or brimstonewort (*Peucedanum officinale*) is another member of the Umbelliferae.



J. HORACE MCFARLAND CO.

FENNEL (FOENICULUM VULGARE)

FENNER, DUDLEY (c. 1558–1587), English puritan divine, was born in Kent and educated at Cambridge university but, becoming an adherent of the Presbyterian Thomas Cartwright (1535–1603), had to leave without taking his degree. He followed Cartwright to Antwerp and preached to the English congregation there. The leniency shown by Archbishop Edmund Grindal encouraged him to return to England, and he became curate of Cranbrook in 1583. In the same year, however, he was suspended and imprisoned for refusing to sign an acknowledgement of the queen's supremacy and of the authority of the Prayer Book and articles.

After his release he became chaplain in the Reformed church at Middleburgh, where he died in 1587.

Fenner's works rank among the best expositions of the principles of puritanism; see list in Cooper's Athenae Cantabrigienses (Cambridge. 1858–61).

FENNY STRATFORD: see BLETCHLEY.

FENRIR or FENRIS, in Scandinavian mythology a water demon in the shape of a huge wolf, was the offspring of Loki and the giantess Angurboda. He grew so large that the gods, in fear, had him chained up. He broke the first two chains. The third, a magic bond made of the sound of a cat's footsteps, a woman's beard, the roots of a mountain. a fish's breath and a bird's spittle, held him until Ragnarok (Judgment day), when he escaped and swallowed Odin but was slain by Vidar, the latter's son.

FENS, a district in the east of England possessing peculiar characteristics and a distinctive history. It lies largely south and west of the Wash, in Lincolnshire. Huntingdonshire, Cambridgeshire and Norfolk. Its extreme length from Lincoln to Cambridge is about 73 mi.; its extreme breadth from Peterborough to Brandon is about 36 mi. Across its surface. the Witham, Welland, Nene and Great Ouse rivers flow into the Wash, but the original drainage of the area has been largely replaced by artificial channels.

In origin the fenland is essentially a flooded Jurassic clay plain which had for its limits the harder rocks around—chalk to the north and south, and resistant Jurassic rocks to the west. The surface of this Jurassic plain was uneven, and its higher portions projected above the general level of the surface to become the "islands" of the historical period, Ely, March and so on. The whole region emerged from the complicated events of the various phases of the Ice Age with its islands capped uith boulder clay but with its basin character unchanged. All subsequent time has aitnessed the filling up of this basin by the various agents of sedimentation. leaving the Wash of the present day as the remnant of a much larger indentation of the sea.

The postglacial deposits are of tno kinds. To the north, on the seaward side around the Wash, are marine silts and clays, while south of this belt of silt, an expanse of black peat covers the whole area except where the islands protrude above the surface. The thickness of the peat now varies from a few inches to ten ft. and more, but before the drainage took place the peat was very much thicker (see below). It was this peat area that the cartographers of the 17th century described as regiones *inundatae,* and in that area lay the main effort of draining from the 17th century onward. Except for some outlying peat areas and for the seaward margins, the silt zone was not in need of such extensive draining. The main emphasis of any history of fenland draining must therefore be upon the southern peat area.

EARLY ATTEMPTS AT DRAINING

The condition of the Fens during Roman times has aroused considerable speculation from time to time, but aerial photography has shown that in Romano-British times (50 B.C.–A.D. 450) some of the area, especially on the siltlands and on certain islands, was occupied by cultivators who tilled the soil in small rectangular or irregularly shaped fields upon a system of agriculture which is associated with the Celtic fringe of Britain and which was quite unlike the open-field system of the Anglo-Saxon invaders. All this stands in great contrast with later conditions in the Fenland. To explain the transition is one of the major problems that await solution. The alternative answers are: (1) that the Romans, with their highly developed political organization and engineering skill, practised artificial drainage with conspicuous success and that their works fell out of repair after the occupation was over; (2) that the deterioration was the result of natural agencies, a silting up of watercourses, or a basic land subsidence in post-Roman times. Both answers may be correct. In the state of knowledge in the mid-1950s it is unsafe to be dogmatic because too many associated problems await investigation.

Whatever the cause of the transformation, by Anglo-Saxon times the region had become marshy country but thinly settled, for a time forming a frontier area between the Anglo-Saxon states of East Anglia and Mercia. On the islands in the midst of the marsh many religious houses mere founded during the 7th and 8th centuries, at Crowland. Thorney, Ely and elsewhere, and these continued despite the raids of the Danes from the 9th century to the 11th. The Domesday survey of 1086 shows that villages were limited to the silt area in the north and to the islands; settlement was impossible on the peat area because there the soil provided no stable foundations on which to build. Normal arable agriculture seems to have been restricted to the islands and to the silt belt. Fishing and the gathering of reeds and rushes were important occupations, especially in the peat area.

The whole of fen life during the middle ages was dominated by the necessity of maintaining the banks and channels to prevent flooding, and it is clear that a number of practices established "time out of memory" had grown up to regulate the management of the Fenland streams. From the middle of the 13th century there began a series of commissions of sewers appointed by the crown to enforce repair and to settle disputes about the maintenance of banks. There was no sign of any large-scale project of reclamation, but there was a continuous piecemeal encroachment upon the edges of many fens and this seems to have been very general. Contemporary references to occasional enclosures and local "raising from the fen" are many. and they resulted in new meadow and pasture and even in arable land. The process of improvement seems to have been particularly active on the silt areas, and a comparison of 14th-century statistics with those of the Domesday Book brings out the fact that the siltlands of Lincolnshire and Norfolk had been improved so much that they were many times as wealthy as the uplands around. The peatlands remained a poor country, still sparsely populated.

The economic life of the area was. however, disturbed four times by local campaigns: in 1070–71 when Hereward the Wake defied the Normans; in 1139 and 1142 during the anarchy of Stephen's reign; in 1216 when some barons held out against King John; and in 1265 during the reign of Henry III. On each occasion, a group of people seized the Isle of Ely and fortified it. A period of amphibious guerrilla warfare followed until the forces of the king mere able to gain an entrance across the marsh. But long after the last defense of the island was over the tradition of Ely as a camp of refuge continued.

Shortly before the end of the 15th century a hint of changes to come was provided by the work of Bishop John Morton, who seems to have been the first person to carry out a large design for draining. He made a straight cut, about 12 mi, long, from Stanground near Peterborough to Guyhirne, in order to convey the waters of the Nene in a direct line to Wisbech; it is still known as Moreton's Leam. Coming at the close of the middle ages, it pointed the way forward to a new regime.

During the 16th century, complaints about the maintenance of banks and channels continued. The upkeep of any channel involved many interlocking interests, and the dissolution of the monasteries in 1536–39 served only to increase the confusion of divided responsibilities. The commissioners of sewers were finding it increasingly difficult to maintain the "ancient custom" of the fen. But, as Samuel Hartlib wrote, "in Queen Elizabeth's dayes, Ingenuities. Curiosities, and Good Husbandry, began to take place." During the later years of the 16th century various schemes and experiments prepared the way. At last, in 1600 came "An Act for the recovering of many hundred thousand Acres of marshes." Of the many stretches of marsh in the kingdom, that of the great Fenland itself provided the most spectacular opportunities for draining.

17TH-CENTURY DRAINING

The passing of the act in 1600 did not mean, however, that difficulties were over. Common pasture rights were a most important feature of predrainage economy, and the fenmen, living largely on the perquisites of the commons, resented any suggestion of interference with their traditional livelihood. There was, moreover, much debate about ways and means, and nothing effective was done for another generation. At length, some fenmen approached Francis, 4th earl of Bedford, the owner of 20,000 ac. near Thorney and Whittlesey, who contracted to drain within six years all the expanse of peat in the southern Fenland later known as the Bedford level. An agreement was drawn up in 1630. In the following year, 13 coadventurers (so called because they "adventured" their capital) associated themselves with the earl, and in 1634 they were granted a charter of incorporation. Their hope was to turn this expanse of "great waters and a few reeds" into "pleasant pastures of cattle and kyne"; and they secured the services of the Dutch engineer Cornelius Vermuyden (1590–1677), who had been at work upon the reclamation of the Axholme marshes. Under his direction, drains and sluices were made. Chief among these was the Old Bedford river extending from Earith to Salter's Lode, 70 ft. wide and 21 mi. in length. In 1637 the level was judged to have been drained according to the agreement of 1630.

But complaints and petitions showered upon the privy council, and royal feeling turned against the corporation. The inner history of this change in royal favour is obscure; at any rate, in the following year the award was set aside, and the king himself undertook to complete the draining; the services of Vermuyden were retained. Soon, however, the fen difficulties mere overshadowed by greater troubles, for the Civil War broke out in England.

During the Civil War (1642–49) the draining was in abeyance, but the project had not been forgotten. After much negotiation, an "Act for the draining of the Great Level of the Fens" was passed in May 1649; and the jth earl of Bedford and his associates were "declared to be the undertakers of the said work." Despite the continued hostility of the fenmen, activity was restarted in the Fens. The earlier works were restored; banks were made, sluices built and channels scoured. In particular, the New Bedford or Hundred Foot river was cut, running parallel to the Old Bedford river, about half a mile to the east. Between the two rivers a strip of land was left open, partly to provide a reservoir for surplus water in time of flood, and partly to enable a heavy flood discharge to be carried with a small surface gradient, or, as Vermuyden put it. "so that the water in time of Extremity may goe in a large roome to keepe it from rising too high." This strip, called the Hundred Foot Washes, has continued to serve these purposes. Various other cuts and sluices were also made, and in March 1652 the level mas formally adjudged to be drained. It was divided into three portions—north, middle and south. In the decade that followed the organization for preserving the works of the drainers was completed until, in 1663, the General Drainage act was passed.

In the Northern Fenland there was nothing to compare with this great work. It is true that various arrangements were made for draining individual stretches of fen, but, taken as a whole, the northern effort was sporadic in character and small in achievement.

Generally speaking, the fen commoners of Lincolnshire remained in possession of their ancient privileges.

At first. great success followed upon the work of the drainers in the Bedford level. Cultivation was introduced on lands which, as far as record went, had never before known a plow. The crops grown on the newly reclaimed land were numerous and varied: wheat, oats, barley, turnips, beans, peas, coleseed, chicory, mustard, hemp and woad. As Thomas Fuller said in 1655, "the best argument to prove that a thing may be done, is actually to do it."

But despite many praises, it was soon evident that all was not well in the Bedford level. Some of the complaints were only to be expected, disputes about the allotment of the reclaimed land and about the management of the new drains. These were problems of routine administration and could be settled by negotiation and compromise. But there were other difficulties of a much more fundamental character; they nearly brought the work of the drainers to disaster, and they have remained important considerations ever since. They are of two kinds, connected respectively with the lowering of the peat surface and the condition of the tidal rivers that flow through the Fens.

LOWERING OF THE PEAT SURFACE

Neither Vermuyden nor any of his associates apparently foresaw, when they planned and executed their schemes, that as soon as they began to drain the Fens the surface of the peat would become rapidly lower in level. This lowering was attributable in part to the shrinkage of the peat and in part to the wasting away of the peat surface as a result of bacterial action and cultivation. As a result, the surface of the peat soon became lower than the level of the rivers into which it drained. This difference in height can be seen along many of the fen channels; they are at a higher level than the land through which they flow. There soon came a time when the water of the small drains right in the heart of the peat area could no longer flow into the main channels. The amount of lowering varies from place to place, but even a very small rate of lowering becomes critically important over a period of years. The surface of the undrained peat must have stood at about 10 or 12 ft. or so above Ordnance Datum. By the 1950s the surface of much of the drained peat stands at about Ordnance Datum, or just below. It must also be remembered that a basic subsidence of land relative to the sea has been postulated, and this may have been upward of three feet since the 17th century.

Windmill Drainage. — What had seemed a promising enterprise in 1652 had become a tragedy by 1700. There was but one way to save the situation, the substitution of an artificial for the natural drainage by gravity. Water was pumped from small dike to drain and from drain to river. It was this introduction of windmills for pumping purposes that saved most of the drained fens from being reinundated. As the 17th century passed into the 18th century, windmill drainage became more and more frequent, and the windmills imparted a distinctive character to the landscape.

But the windmill was far from being a perfect engine. It was at the mercy of gale and frost and calm. It was never very powerful, and it soon ceased to provide a satisfactory solution to the problem of clearing water from the drains. For, as the surface of the peatlands continued to subside, the windmill became increasingly ineffective. The paradox was that the more the evils of lowering were combated by more effective draining, the more rapidly the peat surface continued to sink. Thus it was that the works of one generation became inadequate for the needs of the next. Inundations grew frequent. By the end of the 18th century, according to Arthur Young, there were many fens "all waste and water," where 20 years previously there had been "buildings, farmers and cultivation." He could only be "shocked at the sight of this desolation," and even went so far as to say that "the total ruin of the whole flat district must ensue." Other evidence bears out his impression of desolation. Moreover, not only were there large stretches of the Bedford level relapsing into "waste and water," but there were still some tracts that had never been drained at all; in the west, in Huntingdonshire, were the large reed-bordered lakes of Whittlesey mere and Ramsey mere. Fishing and fowling continued to be characteristic Fenland occupations. The large copper butterfly, Lycaena *dispar*, too, was not yet extinct in the area, nor was the ague against which the fenmen indulged in brandy drinking.

Outside the Bedford level, in the Northern Fens, the work of draining had been taken up again in the 18th century. There, effort was more divided than in the Bedford level, for the arrangement of upland and coast disposed the area into a number of separate tracts. Conditions varied from place to place; several districts had been brought into cultivation, but, as in the Southern Fens, complaints about inundation were frequent. In many of these northern districts, too, stretches of original fen lingered on, nursing the old economy based on fishing, fowling, reed cutting and the like. In wintertime, the East fen, the West fen and Wildmore fen (lying north of Boston, Lincolnshire) consisted of a mass of lakes connected by "narrow reedy straits"; even in dry summers the East fen "deeps" were covered on an average by about two feet of water.

The Steam Engine. — But before the first quarter of the 19th century was over a great change for the better had come over the whole area. There were still floods bringing with them a reminder of former conditions, but improvement was making itself felt decade by decade, indeed "almost annually." As one traveller in 1828 put it, "swampy land, . . . but drained more and made more cultivable every year." The main factor responsible for this transformation early in the 19th century was the introduction of the steam engine for pumping. At first there was delay and hesitation, and not until 1819–20 was the first steam-driven pump set up. Many others soon followed, and the Fenland was greatly relieved from the threat that had hovered over it at the end of the 18th century. So effective were the new engines that one of the most characteristic elements of the landscape of the fen for more than 100 years was doomed to disappear. Windmills fell into disuse and were replaced by pumping stations, though here and there some windmills still lingered on into the 20th century. There were other changes also, for the great scoop wheels that had been in use since the 17th century were replaced after 1850 by the more effective centrifugal pumps. It was an Appold centrifugal pump that, in 1851, was used to drain Whittlesey mere, the last remaining large stretch of water in the Fenland. From then on, the area benefited by the increasing technical improvements of the age. To overcome the continued lowering of the peat surface increasingly powerful pumping units were frequently installed.

The Diesel Engine. — After about 1913 diesel engines were used to supplement the steam engines, and today the latter have been almost entirely superseded. Diesel engines have the great advantage that they can be started up quickly at short notice, and they are much more suitable for intermittent running than steam engines.

The Care of Banks. — But the advent of improved pumping facilities did not solve all the problems produced by the lowering of the peat surface. The miles of banks brought into being in the 17th century, and increased in later times, need constant care. Many of these banks were originally constructed or repaired with poor materials and in great haste. The continued lowering of the adjoining surface increases the weakness of the banks, and they strain unevenly toward the fen to reveal unsuspected weaknesses in time of flood. The danger is not only that of overflowing but also of seepage. No matter how good the repair of the upper portion of a bank has been, it must frequently rest upon foundations that are not so good in many places. There is risk, therefore, of the upper portion of a bank slipping over the lower portion when subject to a great head of water. A number of crises emphasized the danger presented by the banks. In the spring floods of 1937 and 1939, for example, breaches in one of the smaller banks caused flooding near Soham, and in 1937 it was feared that the western barrier bank of the two Bedford rivers might give way at one point, thus allowing the great mass of water in the washes to pour over the surrounding countryside. The alarms of these and other years culminated dramatically in the great floods of March 1947, when several banks were breached, and large stretches of cultivated land were inundated. The breaches were repaired and the summer was spent in rehabilitation aided by government grants.

THE TIDAL RIVERS

As a result of the lowering of the peat surface, two water-level systems came into being: one, the low-level system of the internal drains of the Fens .themselves; the other, the high-level system of the large rivers that flow through the Fens from the uplands down to the sea. The problem of disposing of the water of the low-level drains was solved by pumping, but that of protecting the drained lands from the high-riding rivers, especially in time of flood, remained. The real difficulty is that of securing a quick discharge of floodwater.

After the early days of the draining much attention was concentrated on the condition of the outfalls of the fen rivers into the Wash. In a normal river the current of water is strong enough to force its way out to sea and so keep both channel and estuary clear. But the Fenland rivers are far from normal. The downward force of the fresh waters in the gently graded streams is no match, especially in summer, for the strong tidal flow each day. The incoming tide, moreover, brings large quantities of silt from the Wash. With swift flood tides and weak ebb tides deposition is inevitable, and the fresh-water discharge is able to maintain a channel of only limited capacity. The result is that in very wet weather, with large quantities of water pouring down from the uplands, high water levels are inevitable in the great Fenland rivers. The great fen controversies of the 18th and 19th centuries were largely outfall controversies concerned with topics such as the mechanics of silting. the formation of sandbanks and the disposition of sluices. In the early part of the 19th century the Ouse reached the sea through a channel of varying width, filled with shifting sandbanks; in the Nene, "ships of large burden could no longer reach" Wisbech; the Welland estuary, too. was full of shoals; that of the Witham was in no better plight. There was much conflict of opinion and interest about all these matters. Nor were the controversies ended even in the 1950s. But the increasing technical equipment of the 19th and 20th centuries enabled some improvements to be made in the outfalls of the Ouse, the Nene, the Welland and the Witham. New and straight channels were made to cut off bends in their estuaries; training walls were built out to sea; and various measures were taken to improve the conditions of the channels generally. But despite much effort the results in many cases were not as great as were hoped for.

An important feature of the tidal rivers are the sluices necessary to prevent the tidal waters from passing up some of the rivers and cuts. On the Witham are the Grand sluice and the Black sluice; on the Nene, the North level sluice; on the Ouse, the St. Germans sluice and Denver sluice. Upon Denver sluice depends the safety of the southern part of the Bedford level, and it has become the most famous of the Fenland sluices. Immediately below the sluice the waters of the Hundred Foot river fall directly into the Ouse. Consequently when there is a great volume of upland water passing down the Hundred Foot river, the level of water on the seaward side of the sluices never falls sufficiently low for the sluice gates to be opened long enough to provide an adequate runoff for the waters of the South level. These waters can only accumulate within the straining banks of their rivers and drains. A crisis is therefore always liable to be produced by a combination of (1) heavy land floods, (2) a high spring tide and (3) adverse wind conditions. A new feature in fen investigation was the experimental model set up at Cambridge in 1935 by the Great Ouse Catchment board, with the object of providing data for the study of tidal and silting conditions both in the Wash and in the river itself.

But no amount of work in the outfalls can much alter the low tide, and particularly the high tide, levels of the sea; nor can it appreciably alter the surface gradient of the river water upstream. Yet it is upon this surface gradient, as much as anything, that the discharge of a river depends. Alterations at the river outfalls, while producing local and temporary results, have had insufficient effect in lowering water levels higher up the rivers. Moreover, with the lowering of the peat areas, the high flood gradients of these rivers have been greatly increased because the flood discharge is unable to spread far beyond the normal river channels because of the high banks needed to protect the low-lying country around. Opinion in the South level has, therefore, shiited the emphasis from attempts at outfall improvements to other measures for lowering the surface gradients of the high-level rivers during flood.

Following the severe crisis of 1939, new proposals for lowering the flood levels in the Great Ouse were evolved after much discussion. Two main groups of works were envisaged, together with their associated sluices: (1) a "cutoff channel" along the eastern margin of the Fenland to intercept the upper waters of the Lark, Little Ouse and Wissey and convey them to a point near Denver; (2) a relief channel from Denver, running northward for about 10½ mi to enter the estuary above King's Lynn, and accompanied by a small flood reservoir near Denver. Work on this Flood Prutection scheme was in progress in 1956.

DRAINAGE ADMINISTRATION

Looming above all technical questions connected with the lowering of the peat surface and the condition of the tidal rivers, there was the great problem of administration. The outstanding difficulty lay in the lack of any single authority along the course of a river and in the absence of adequate co-operation among existing authorities. The responsibilities of the Bedford Level corporation did not extend beyond the maintenance of the major rivers. In order, therefore, to meet the new situation produced by the lowering of the peat, groups of landowners were forced to supplement the larger drainage scheme by local district enterprise. The first drainage district was formed by act of parliament at Haddenham near Ely in 1727, and it created a principle that was soon followed at frequent intervals. The whole of the Fens came to consist almost entirely of small districts, each dependent for its internal drainage upon small cuts leading to a main drain which in turn discharged its water by pumping into one of the major rivers. Each of the statutory districts had its own authority with full control over the internal drainage of its area, with wide powers of local taxation and with powers of negotiation with adjacent bodies over matters of common concern.

The necessity for co-operation was repeatedly urged, and many advocated the establishment of authorities responsible for the whole length of each main river. Bills were introduced into parliament in 1877, 1878, 1879 and 1881 with the idea of setting up conservancy boards, but difficulties of rating were among the main reasons that prevented their success. The tangle of authorities, working with antiquated powers and inadequate resources, remained for another 50 years. At last, in 1927, a royal commission was set up to examine the working of the 361 drainage authorities in England and Wales. The remedy it suggested was the same as that advocated in 1877, the establishment of conservancy boards, each with exclusive control over a main river and "clothed with supervisory powers (in order to secure co-ordination of effort) over the internal drainage authorities." It suggested, too, that the ancient formula of benefit should be abolished and that the new authorities should be empowered to levy rates over the whole of their respective catchment areas, recognizing a distinction between uplands and lowlands. This report formed the basis for the Land Drainage act of 1930. Thus there came into existence the catchment boards of the Great Ouse, the Nene, the Welland and the Witham (and Steeping). By another act of 1948, these catchment boards were replaced by river boards with somewhat enlarged pouers.

MODERN FENLAND AGRICULTURE

The improvements in draining that marked the 19th century were paralleled by agricultural changes. Indeed, only a fertile soil could have supported the heavy drainage rates that the improvements involved. One great innovation about 1830 was the introduction of the practice of "claying the land;" *i.e.,* digging up clay from below the peat and spreading it over the surface. Everywhere there were signs of prosperity, and a survey of 1848 could speak of the rich pastures and luxuriant crops of the district. Despite this prosperity the Fenland shared in the general ebb that marked English agriculture from the '70s onward, and conditions were bad locally. But in many ways the Fenland did not suffer as much as the upland around. The introduction of new crops helped to save the situation. Potatoes proved the "mainstay of the fen farmer" according to one report; vegetables and fruit, too, were becoming important. The first orchard had been planted in the Wisbech area as early as the '50s. In the '80s and '90s many farmers were forced to adopt a fresh form of husbandry, and so turned to market gardening and fruit farming. Flowers, too, spread, and Lincolnshire bulbs became famous. Thus, from the agricultural depression of the 19th century, the 20th century inherited the foundations of prosperity, and the Fenland became one of the richest arable areas in England, supporting the traditional crops such as wheat, but characterized by potatoes, flowers, small fruits and market garden crops; a newcomer on the southern peats was the sugar beet. But when World War II broke out there were still some patches of ill-drained derelict land. In the national endeavour to increase food production their black peat soil was made to yield its richness as elsewhere in the Fenland.

A few isolated stretches of peat fen have survived, and are of special interest from a botanical and entomological point of view. Along the western edge of the Fens; for example, is Wood Walton fen to the north of Huntingdon. Along the eastern edge are Chippenham fen and Wicken fen not far from Newmarket. The latter belongs to the National Trust and has been the scene of much investigation. It is about a square mile in extent and its waterlogged surface stands several feet higher than that of the adjoining peatlands. It is not strictly "natural," because the water levels are manipulated, the channels are kept open, and the fen is periodically cut over. Left to itself, most of its surface would become covered with bushes, and the fen species of plants and animals would he reduced or exterminated. Carefully controlled, Wicken fen gives an idea of what the "vast and deep fen" as a whole was like before Vermuyden's day.

FENTON, EDWARD (d. 1603), English navigator. son of Henry Fenton and brother of Sir Geoffrey Fenton (*q.v.*), was born in Nottinghamshire. In 1577 he sailed in command of the "Gabriel," with Martin Frobisher's second expedition for the discovery of the northwest passage. and in 1578 he was second in command in Frobisher's third expedition, in the "Judith." In 1582 he was put in charge of an expedition which was to sail round the Cape of Good Hope to the Moluccas and China, and to obtain any knowledge of the northwest passage that was possible without hindrance to his trade. The voyage was a failure. He spent his time quarrelling with his officers, and only reached Brazil. In 1588 he had command of the "Mary Rose," one of the ships of the fleet that was formed to oppose the Armada. He died 15 years later.

See Richard Hakluyt, *Voyages,* vol. iv.

FENTON, ELIJAH (1683–1730), English poet, was born at Shelton. near Newcastle-under-Lyme. He graduated from Jesus college, Cambridge, in 1704, and became a schoolmaster.

Fenton was the coadjutor of Alexander Pope in his translation of the Odyssey. He was responsible for the 1st, 4th, 19th and 20th books. He produced an edition of John Milton, with a life (1725), which went through an amazing number of editions; also one of Edmund Waller (1729). Other works were two collections of poems (1708 and 1717) and *Mariamne,* a tragedy (1723). He died at East Hampstead. Berkshire, in July 1730. His epitaph in the parish church was written by Pope.

See S. Johnson, *Lives of the English Poets,* ed. by G. Birkbeck Hill, vol. ii (Oxford, 1905); W. W. Lloyd, *Elijah Fenton, His Poetry and Friends* (Hanley, 1894); E. Harlan, *Elijah Fenton, 1683–1730* (Philadelphia, 1937).

FENTON, SIR GEOFFREY (c. 1539–1608), English writer and politician, was the son of Henry Fenton of Nottinghamshire and brother of Edward Fenton the navigator. He is said to have visited Spain and Italy in his youth; possibly he went to Paris in Sir Thomas Hoby's train in 1566, for he was living there in 1567, when he wrote *Certaine tragicall* discourses *written oute of Frenche and Latin,* a free translation of François de Belleforest's French rendering of Matteo Bandello's *Novelle.* Fenton's other works are as follows: *Monophylo* (1572), *Golden* Epistles gathered out of Guevarae's workes as other authors . . . (1575), Historie of *Guicciardini,* translated out of French by *G. F.* (1579) and a number of Protestant tracts. Through Lord Burghley he obtained, in 1580, the post of secretary to the new lord deputy of Ireland, Lord Grey de Wilton. He held the secretaryship until the end of his life by the favour of Elizabeth, whom he kept informed of the activities of her other servants in Ireland. Under James I he shared the post with Sir Richard Coke. Fenton died in Dublin on Oct. 19, 1608, and was buried in St. Patrick's cathedral. He had two children, a son, Sir William Fenton, and a daughter, Catherine. who in 1603 married Richard Boyle, 1st earl of Cork.

Grosart (1886–88); *Certaine Tragicall Discourses,* ed. by R. L. Douglas, 2 vol. (1898), "Tudor Translation Series," vol. xix, xx (introd.).

FENTON, LAVINIA, afterward Duchess of Bolton (1708–1760), English actress, the original Polly Peachum of John Gay's Beggar's Opera, was probably the daughter of a naval lieutenant named Beswick, but she bore the name of her mother's husband. Her first appearance was as Monimia in Thomas Otway's *Orphans* in 1726 at the Haymarket theatre, London. She then joined the company of players at the theatre in Lincoln's Inn Fields. Miss Fenton made her greatest success in 1728 as Polly Peachum, and a famous painting by William Hogarth shows her in one of the Beggar's Opera scenes. She ran away with Charles Paulet, 3rd duke of Bolton, a man much older than herself, who married her after the death of his wife in 1751. She died at Greenwich on Jan. 24, 1760.

See C. E. Pearce, *Polly Peachum* (1913).

FENTON, former civil parish. Staffordshire, Eng., which after 1922 formed three wards in Stoke-on-Trent (*q.v.*). Originally known as Lane Delph, it is a purely industrial district. China and earthenware are manufactured.

FENUGREEK (Trigonella *foenum-graecum*) is a slender, pubescent annual of the legume family, native to the Mediterranean region. The plants are erect, loosely branched, 20 to 30 inches tall with trifoliate leaves and yellowish-white flowers. The slender pods are 3 to 6 inches long, curved, and distinctly beaked. It is cultivated in parts of central and southeastern Europe, western Asia, the India subcontinent and North Africa. The seeds are used externally in poultices for boils, abscesses, carbuncles, etc., and internally as an emollient for inflammation of the digestive tract. They have long been used as the principal ingredient of "condition powders" for cattle and horses. Fenugreek seeds are also used in various ways for human food—mixed with flour for bread. eaten raw or boiled, and as a constituent in curry powders. In India the young plants are used as a pot herb and in North Africa the crop is utilized for hay. A small acreage is grown in California, largely as a green-manure crop. (Q. J.)

FENWICK, ETHEL GORDON (1857–1947), British nurse and journalist, was born at Spynie House, Morayshire, on Jan. 26, 1857, the daughter of David Davidson Manson. In 1881 she was appointed matron of St. Bartholomew's hospital, London. She married in 1887 a gynaecologist, Bedford Fenwick, and devoted herself to the work of organizing the nursing profession and raising its status by state registration. An act of parliament for this purpose was passed in 1919. Mrs. Fenwick became, in 1893, honorary editor of The British Journal of Nursing. She was founder of the Royal British Nurses association in 1887, the International Council of Nurses in 1899, the National Council of Nurses in 1904 and the British College of Nurses Ltd. in 1926, and was president of the last three associations. She died on March 13, 1947.

FENWICK, SIR JOHN (*c.* 1645–1697), English conspirator, came of an old Northumberland family. He had a successful military career, 1667–88, and was M.P. for Northumberland, 1677–85. He was a partisan of James II, and after the Revolution at once began to plot against William III, for which he underwent a short imprisonment in 1689. He publicly insulted Queen Mary in 1691, and it is practically certain that he was implicated in the schemes for assassinating William which came to light in 1695 and 1696. After the seizure of his fellow conspirators, Robert Charnock and others, he went into hiding, but was arrested in June 1696. To save himself he offered to reveal all he knew about the Jacobite conspiracies; but his confession was damaging but not conclusive, being confined to charges against leading Whig noblemen. Sufficient evidence of treason was doubtful, but the Whigs secured the passage of a bill of attainder. Fenwick was beheaded in London on Jan. 28, 1697.

FEODOROVNA, MARIE: see Marie Feodorovna.

FEOFFMENT, in English law, during the feudal period, the usual method of granting or conveying a freehold or fee (see Fief; Fee). The essential elements were livery of seisin (delivery of possession), which consisted in formally giving to the feoffee on the land a clod or turf or growing twig as symbol of the transfer of land, and words by the feoffer declaratory of his intent to deliver possession to the feoffee with a "limitation" of the estate intended to be transferred. This was called livery in deed. Livery in law was made not on but in sight of this land, the feoffer saying to the feoffee: "I give you that land; enter and take possession." Livery in law, in order to pass the estate, had to be perfected by entry by the feoffee during the joint lives of himself and the feoffor. It was usual to evidence the feoffment by writing in a charter or deed of feoffment; but writing was not essential until the Statute of Frauds. By the Real Property act, 1845, all corporeal hereditaments were declared to be in grant as well as livery; *i.e.,* they could be granted by deed without livery. (See Laws of Real Property and Conveyancing.)

FER-DE-LANCE (Trimeresurus atrox), a poisonous American pit viper. Reaching a length of 7 ft. it resembles a rattlesnake (*q.v.*) in appearance, but without the "rattle" of the latter, and is found almost throughout Central and South America. Its bite is often fatal. The fer-de-lance feeds on rats and other small animals.

FERDINAND, a name borne at various times by European sovereigns and princes (Span. Fernando or Hernando; Ital. *Ferdinando* or Ferrante; in O.H G. Herinand, "brave in the host").

FERDINAND (1577–1650), elector and archbishop of Cologne, son of William V., duke of Bavaria, was born on Oct. 7, 1577. He was educated by the Jesuits at the university of Ingolstadt, and in 1595 became coadjutor archbishop of Cologne. He became elector and archbishop in 1612 on the death of his uncle Ernest, whom he also succeeded as bishop of Liége, Munster and Hildesheim. He supported the league founded by his brother Maximilian I., duke of Bavaria, and wished to involve the leaguers in a general attack on the Protestants of north Germany. The duke refused to accede to his brother's wish; but, in spite of these temporary differences, Ferdinand sent troops and money to the assistance of the league when the Thirty Years' War broke out in 1619. In 1647 he joined his brother Maximilian in concluding an armistice with France and Sweden at Ulm. Ferdinand came into conflict with the citizens of Liége; and when the peace of Westphalia freed him from his enemies, he was able to crush the citizens and deprive them of many privileges. Ferdinand died at Arnsberg on Sept. 13, 1650, and was buried in the cathedral at Cologne.

FERDINAND I. (1793–187j), emperor of Austria, eldest son of Francis I. and of Maria Theresa of Naples, was born at Vienna on April 19, 1793. In his boyhood he suffered from epileptic fits, but as his health improved he was not excluded from the succession. In 1830 his father caused him to be crowned king of Hungary. In 1831 he was married to Anna, daughter of Victor Emmanuel I. of Sardinia. The marriage was barren. When Francis I. died on the 2nd of March 183j, Ferdinand was recognized as his successor, but his incapacity was so notorious that the conduct of affairs was entrusted to a council of state, consisting of Prince Metternich (*q.v.*) with other ministers, and two archdukes, Louis and Francis Charles. They composed the *Staatsconferenz,* the ill-constructed and informal regency which led the Austrian dominions to the revolutionary outbreaks of 1846–49. (See AUSTRIA, EMPIRE OF) The emperor, who was subject to fits of actual insanity, and in his lucid intervals was weak and confused in mind, was a political nullity. His popular name of Der Gutige (the kindly man) expressed as much derision as affection. Ferdinand had artistic and musical taste. In the presence of the revolutionary troubles, which began with agrarian riots in Galicia in 1846, and then spread over the whole empire, he was helpless. He was compelled to escape from the disorders of Vienna to Innsbruck on May 17, 1848. He came back on the invitation of the diet on Aug. 12, but soon had to escape once more from the mob of students and workmen who were in possession of the city. On Dec. 2 he abdicated at Olmutz in favour of his nephew, Francis Joseph. He lived under the supervision of doctors and guardians at Prague till his death on June 29, 1875.

See Krones van Marchland, Grundriss der oesterreichischen *Geschichte* (Vienna, 1882), which gives an ample bibliography.

FERDINAND I. (1503–1564), Roman emperor, was born at Alcalá de Henares on March 10, 1503, his father being Philip the Handsome, son of the emperor Maximilian I., and his mother Joanna, princess of Castile and Aragon. In April 1521 the emperor granted to him the archduchies and duchies of upper and lower Austria, Carinthia, Styria and Carniola, adding soon afterwards the county of Tirol and the hereditary possessions of the Habsburgs in south-western Germany. About the same time Ferdinand was appointed to govern the duchy of Wurttemberg, which had come into the possession of Charles V.; and in May 1521 he was married at Linz to Anna (d. 1547), a daughter of Ladislaus, king of Hungary and Bohemia. In 1521 also he was made president of the council of regency (Reiclzs-regiment), appointed to govern Germany during the emperor's absences, and the next five years were occupied with imperial business, in which he acted as his brother's representative, and in the government of the Austrian lands.

In Austria and the neighbouring duchies Ferdinand sought at first to suppress the reformers and their teaching, a policy which increased his difficulties in quelling risings in the districts under his rule after the Peasant's War broke out in 1524. In August 1526 his childless brother-in-law, Louis II., king of Hungary and Bohemia, was killed at the battle of Mohacs, and the archduke at once claimed both kingdoms, both by treaty and by right of his wife. He was chosen king of Bohemia in October 1526, and crowned at Prague in the following February. But in Hungary John Zapolya, supported by the national party and soon afterwards by the Turks, offered a sturdy resistance. Although Ferdinand was chosen king at Pressburg in December 1526, and after defeating Zapolya at Tokay was crowned at Stuhlweissenburg in November 1527, he was unable to take possession of the kingdom. The Bavarian Wittelsbachs, incensed at not securing the Bohemian throne, were secretly intriguing with his foes; the French, after assisting spasmodically, made a formal alliance with Turkey in 153j; and Zapolya was a very useful centre for the enemies of the Habsburgs. A truce made in 1j33 was soon broken, and the war dragged on until 1538, when by the treaty of Grosswardein, Hungary was divided between the claimants. The kingly title was given to Zapolya, but Ferdinand was to succeed. Meanwhile, in January 1531, he had been chosen king of the Romans, or German king, at Cologne. He had earned this honour by his loyalty to his brother, Charles V., whom he had represented at several diets. In religious matters the king was now inclined to steer **a** middle course, and in 1532 he agreed to the religious peace of Nuremberg, receiving in return from the Protestants some assistance for the war against the Turks. In 1534, however, Philip, landgrave of Hesse, and his associates had succeeded in conquering Wiirttemberg (*q.v*) on behalf of its exiled duke, Ulrich, and neither Charles nor Ferdinand could send much help to their lieutenants. They were consequently obliged to consent to the treaty of Cadan, made in June 1534, by which the German king recognized Ulrich as duke of Wiirttemberg though under Austrian suzerainty.

In Hungary the peace of 1538 was not permanent. When Zapolya died in July 1540 a powerful faction refused to admit Ferdinand's right of succession, and put forward Zapolya's young son John Sigismund as a candidate. The cause of John Sigismund was espoused by the Turks and by Ferdinanti's other enemies. The king repeatedly sought to make peace with the sultan, but his envoys were haughtily repulsed. In 1544, however, a short truce was made. This was followed by others, and in 1j47 one was concluded for five years, but only on condition that Ferdinand paid tribute for the small part of Hungary which remained in his hands. The struggle was renewed in 1j51 and was continued in the same desultory fashion until 1562, when a truce was made which lasted during the remainder of Ferdinand's lifetime. During the war of the league of Schmalkalden in 1546 and 1547 the king had taken the field primarily to protect Bohemia, and after the conclusion of the war he put down a rising in this country with some rigour. About 1546 he began to take up a more independent position in imperial politics. Although Charles had crushed the league of Schmalkalden he had refused to restore Württemberg to Ferdinand; and he gave further offence by seeking to secure the succession of his son Philip, afterwards king of Spain, to the imperial throne. In 1551 Ferdinand agreed that Philip should be his own successor. Events caused these plans to be dropped, but there was a rift between the brothers. During the short war between the emperor and Maurice, elector of Saxony, in 1552 Ferdinand's attitude was lukewarm. He negotiated the treaty of Passau with Maurice in 1552, and in 1555 after the conduct of imperial business had virtually been made over to him, and harmony had been. restored between the brothers, he was responsible for the religious peace of Augsburg. Early in 1556 Charles abdicated and on March 24. Ferdinand was crowned at Frankfort. The emperor's short reign was mainly spent in seeking to settle the religious differences of Germany, and-in efforts to prosecute the Turkish **war** more vigorously. Although he held firmly to the Roman Catholic Church he sought to obtain tangible concessions to her opponents; but he refused to conciliate the Protestants by abrogating the clause concerning ecclesiastical reservation in the peace of Augsburg, and all his efforts to bring about reunion were futile, though he secured the privilege of communion in both kinds from Pius IV. for the laity in Bohemia and in various parts of Germany. In November 1562 he obtained the election of his son Maximilian as king of the Romans, and died in Vienna on July 2j, 1564. His family had consisted of six sons and nine daughters.

Ferdinand sought to consolidate his Austrian lands, reformed the monetary system in Germany, and reorganized the Aulic council (*Reichshofrat*). Less masteriul but more popular than his brother, whose character overshadows his own, he was just and tolerant, a good Catholic and a conscientious ruler.

Oberleitner, *Österreichs Finanzen und Kriegswesen unter Ferdinand I.* (Vienna, 1859); E. Rosenthal. *Die Behördenorganisation Kaiser Ferdinands, I.* (Vienna, 1887); and W. Bauer, *Die Anfänge Ferdinands I.* (Vienna, 1907).

FERDINAND II. (1578–1637), Roman emperor, was the eldest son of Charles, archduke of Styria (d. 1590), and a grandson of the emperor Ferdinand I. Born at Gratz on July 9, 1578, he was trained by the Jesuits, finishing his education at the university of Ingolstadt, and became the pattern prince of the counter-reformation. In 1596 he undertook the government of Styria, Carinthia and Carniola, and after a visit to Italy began an organized attack on Protestantism which under his father's rule had made great progress in these archduchies. About 1615 it was agreed that Ferdinand, who already had two sons by his marriage with his cousin Maria Anna (d. 1616), daughter of William V., duke of Bavaria, should succeed Matthias in the elective kingdoms of Hungary and Bohemia and should be the next German emperor. (See HABSBURG: Genealogy.) The elder archdukes renounced their rights in the succession; the claims of Philip III and the Spanish Habsburgs were bought off by a promise of Alsace; and the emperor consented to his supersession during his lifetime in Hungary and Bohemia. In 1617 Ferdinand, who was just concluding a war with Venice, was chosen king of Bohemia, and in 1618 king of Hungary; but his election as German king, or king of the Romans, delayed owing to the anxiety of Melchior Klesl (*q v*) to conciliate the Protestant princes, had not been accomplished when Matthias died in March 1619. Before this event, however, an important movement had begun in Bohemia. The Bohemian Protestants suddenly realized that their religious, and possibly their civil liberties, were seriously menaced by the choice of Ferdinand as king. They declared Ferdinand deposed, and elected the elector palatine of the Rhine, Frederick V., in his stead; and the struggle between the rivals was the beginning of the Thirty Years' War. At the same time Gabriel Bethlen, prince of Transylvania, invaded Hungary, while the Austrians rose and joined the Bohemians; but having seen his foes retreat from Vienna, Ferdinand hurried to Frankfort, where he was chosen emperor on Aug. 28, 1619.

To deal with the elector palatine and his allies the new emperor allied himself with Maximilian I., duke of Bavaria, and the Catholic League, who drove Frederick from Bohemia in 1620, while Ferdinand's Spanish allies devastated the Palatinate. Peace having been made with Gabriel Bethlen in December 1621, the emperor could turn his attention to crushing the Protestants. In 1623 the Protestant clergy were expelled from Bohemia; in 1624 all worship save that of the Roman Catholic church was forbidden; and in 1627 an order of banishment against all Protestants was issued. A new constitution made the kingdom hereditary in the house of Habsburg, gave larger powers to the sovereign, and aimed at destroying Bohemian nationality. A fresh rising in Austria was put down by the aid of the Bavarians in 1627, and Ferdinand could fairly claim that in his hereditary lands at least he had rendered Protestantism innocuous.

The renewal of the Thirty Years' War in 1625 was caused mainly by the emperor's vigorous championship of the cause of the counter-reformation in northern and north-eastern Germany. (See THIRTY YEARS' WAR.) In March 1629 Ferdinand and his ad. visers felt themselves strong enough to take the important step towards which their policy in the Empire had been steadily tending. Issuing the famous edict of restitution, the emperor ordered that all lands which had been secularized since 1552, the date of the peace of Passau, should be restored to the church, and prompt measures were taken to enforce this decree. The result mas the outbreak of the third period of the war. The comparative failure of the imperial arms was due, in the initial stages of the campaign, to Ferdinand's weakness in assenting in 1630 to the demand of Maximilian of Bavaria that Wallenstein should be deprived of his command; and also to the genius of Gustavus Adolphus; and in its later stages to his insistence on the second removal of Wallenstein, and to his complicity in the assassination of the general (see WALLENSTEIN, ALBRECHT WENZEL EUSEBIUS VON). The peace of Prague, concluded in 1635, marks the definite failure of Ferdinand to crush Protestantism in the Empire, as he had already done in Austria and Bohemia. The emperor, however, refused to allow the inhabitants of his hereditary dominions to share in the benefits of the peace. During these years Ferdinand had also been menaced by the secret or open hostility of France. The last important act of the emperor was to secure in 1636 the election of his son Ferdinand as king of the Romans. A few weeks afterwards, on Feb. 15, 1637, the emperor died at Vienna, leaving, in addition to the king of the Romans, a son Leopold William (1614–1662), bishop of Passau and Strasbourg.

W. Lamormaini,* edited by B. Dudik (Vienna, 1848 fol.); Raffaele de Cesare, *La fine di un regno* (1908–09). *See* also bibliography under THIRTY YEARS' WAR.

FERDINAND III. (1608–1657), Roman emperor, was the elder son of the emperor Ferdinand II., and was born at Gratz on July 13, 1608. Educated by the Jesuits, he was crowned king of Hungary in December 1625, and king of Bohemia two years later, and soon began to take part in imperial business. Wallenstein, however, refused to allow him to hold a command in the imperial army. The young king was appointed the successor of the famous general when he was deposed in 1634; and as commander-in-chief of the imperial troops, he was nominally responsible for the capture of Regensburg and Donauworth, and the defeat of the Swedes at Nördlingen. Having been elected king of the Romans, or German king, at Regensburg in Dec. 1636, Ferdinand became emperor on his father's death in the following February, and showed himself anxious to put an end to the Thirty Years' War. But he was reluctant to grant religious liberty to the Protestants, and anxious to act in unison with Spain. In 1640 he had refused to entertain the idea of a general amnesty suggested by the diet at Regensburg; but in 1648 he assented to the treaty of Westphalia (*q.v.*). Owing to Ferdinand's insistence the Protestants in his hereditary dominions did not obtain religious liberty at this settlement. After 1648 the emperor was engaged in carrying out the terms of the treaty and ridding Germany of the foreign soldiery. In 1656 he sent an army into Italy to assist Spain in her struggle with France, and he had just concluded an alliance with Poland to check the aggressions of Charles X. of Sweden when he died on April 2, 1657. Ferdinand was a scholarly and cultured man, an excellent linguist and a composer of music. His first wife was Maria Anna (d. 1646), daughter of Philip III. of Spain, by whom he had three sons: Ferdinand, who was chosen king of the Romans in 1653, and who died in the following year; Leopold, who succeeded his father on the imperial throne; and Charles Joseph (d. 1664), bishop of Passau and Breslau, and grand-master of the Teutonic order. The emperor's second wife was his cousin Maria (d. 1649), daughter of the archduke Leopold; and his third wife was Eleanora of Mantua (d. 1686). His musical works, together with those of the emperors Leopold I. and Joseph I., have been published by G. Adler (Vienna, 1892–1893).

See M. Koch, *Geschichte des deutschen Reiches unter der Regierung Ferdinands III.* (Vienna, a vols., 1865–66).

FERDINAND I. (1373–1416), king of Aragon, called "of Antequera," was the son of John I. of Castile by his wife Eleanor, daughter of the third marriage of Peter IV. of Aragon. As infante of Castile Ferdinand had played an honourable part. When his brother Henry III. died at Toledo, in 1406, the cortes was sitting, and the nobles offered to make him king in preference to his nephew John. Ferdinand declined. As co-regent of the kingdom with Catherine, widow of Henry III. and daughter of John of Gaunt by his marriage mith Constance, daughter of Peter the Cruel, Ferdinand proved a good ruler. As king of Aragon his short reign of two years left him little time to make his mark. Having been bred in Castile, where the royal authority was, at least in theory, absolute, he showed himself impatient under the checks imposed on him by the *fueros*, the chartered rights of Aragon and Catalonia. His most signal act as king was to aid in closing the Great Schism in the Church by agreeing to the deposition of the antipope Benedict XIV., an Aragonese. He died at Ygualada in Catalonia on April 2, 1416.

FERDINAND, MAXIMILIAN KARL LEOPOLD MARIA (1861–1948), king of Bulgaria, fifth and youngest son of Prince Augustus of Saxe-Coburg and Gotha, was born on Feb. 26, 1861. In 1879 he travelled with his brother Augustus to Brazil, and the results of their botanical observations were published at Vienna, 1883–88, under the title of *Itinera Principum S. Coburgi*. Ferdinand was a lieutenant in an Austrian hussar regiment when he was elected prince of Bulgaria, on July 7, 1887, in succession to Prince Alexander, who had abdicated in 1886. He assumed the government on Aug. 14, 1887, but Russia for a long time refused to acknowledge the election, and he was accordingly exposed to frequent military conspiracies connived at by the Russian government. The firmness and vigour with uhich he met all attempts at revolution were at length rewarded, and his election was confirmed in March 1896 by the Porte and the Great Powers. On April 20, 1893, he married Marie Louise (1870–99), eldest daughter of Duke Robert of Parma. The prince adhered to the Roman Catholic faith in which he had been brought up, but his son and heir, the young Prince Boris, was received into the Orthodox Greek Church on Feb. 14, 1896, with the Tsar, Nicholas II, as godfather. This event marked a real rapprochement with Russia. In 1908 Ferdinand married Eleanor (1860–1917), a princess of the house of Reuss. Later in the year, in connection with the Austrian annexation of Bosnia-Herzegovina and the crisis with Turkey, he proclaimed the independence of Bulgaria and took the title of king or tsar. (See BULGARIA and EUROPE: *History.)*

King Ferdinand in 1911 was the instigator of the Balkan league between Bulgaria, Serbia, Greece and Montenegro, which was formed in 1912 and enabled these four states to declare war against Turkey that same year. This pact provided for the future division of the Balkan peninsula, reserving to the arbitration of the emperor of Russia the solution of any doubtful claims. The war started in Oct. 1912, before the conclusion of the Treaty of Ouchy, which put an end to the Italo-Turkish War (Oct. 15). Under the command of King Ferdinand, the Bulgarian army dealt' the most rapid and decisive blows to the enemy; victorious on the battlefields of Kirk Kilisse and Lule Burgas, and having conquered most of Macedonia and Thrace, it started on the open road to Constantinople. Europe grew alarmed; the Great Powers brought about the armistice of Dec. 3, 1912, and the London conference, which started on Dec. 13.

These discussions, however, ceased abruptly, and military operations were resumed on Feb. 3, 1913. The Bulgarian armies attacked at Gallipoli and Chatalja, and after a gallant siege entered Adrianople on March 26, 1913. However, the Treaty of London which followed did not sanction these victories, and its decisions instead of inaugurating peace, provoked a war between the Balkan States, which began on June 30, 1913, by a simultaneous attack of the Serbs and Bulgarians. The former allies became bitter rivals, Rumania and Turkey joining Montenegro, Greece and Serbia against Bulgaria, who, finding herself closed in by four enemies at once, was forced after a few weeks of brave but useless resistance, to submit unconditionally to the victors' terms. The Treaty of Bucharest, signed on Aug. 10, 1913, annihilated in one stroke the brilliant results obtained through the heroism of the Bulgarian armies in 1912–3. It deprived Bulgaria of all her conquests including the town of Silistra and part of the Dobruja and gave to the Serbians and Greeks the province of Macedonia for which Bulgaria had made all the sacrifices of the first Balkan War. This treaty was the principal cause of Bulgaria's participation in the World War on the side of Germany. It explains the resentment of King Ferdinand and his government against the other Balkan States. Had the Allied Powers in 1914 guaranteed the revision of the Treaty of Bucharest, Bulgaria would have co-operated with them; but as they failed to do so, Germany was able, by illusory promises, to induce Bulgaria, who felt she had been unjustly treated, to fight for the German cause. These German manoeuvres did not succeed at once, for King Ferdinand began by proclaiming the neutrality of Bulgaria in Nov. 1914.

During May 1915 the Bulgarian Government sounded the four Great Powers, with regard to the fulfilment of Bulgaria's legitimate claims in Macedonia. As no concrete answer was returned, King Ferdinand turned to Germany, where his application was received with great cordiality. Berlin made lavish promises at once. German envoys hurried to Bulgaria, with a view to persuading the King and the Government to conclude a military alliance with Germany. The desire for revenge against Serbia, Greece and Rumania inspired Ferdinand to bind Bulgaria to the Central Powers. On Sept. 21, 1915 he gave the order for general mobilisation, though his Government advised armed neutrality. In view of this equivocal situation Russia sent an ultimatum to Bulgaria on Oct. 4, 1915, which was succeeded by formal declarations of war against Bulgaria on the part of Serbia, France, Great Britain and Italy, Bulgaria was definitely in the German camp; under General Gekoff, commander-in-chief, her armies were victorious on most of the battlefields of Macedonia, Thrace and Rumania, in 1915, 1916 and 1917, against the Serbs, and against the Rumanians. The Kaiser, the king of Saxony and the king of Württemberg all paid official visits to King Ferdinand at Sofia. However, in Sept. 1918, the Bulgarian army, discouraged by innumerable hardships, was defeated at Dobropole, Macedonia, by the Allied troops. This was the sign for a general retreat. An armistice was signed at Salonika on Sept. 30 which ended the war between Bulgaria and the Allies. After this catastrophe King Ferdinand abdicated in favour of his son Boris on Oct. 4. 1918, and left Sofia the same evening for Coburg, Germany. He died there on Sept. 10, 1948. (A. ST.)

FERDINAND I. (1423–1494), also called Don Ferrante, king of Naples, the natural son of Alphonso V. of Aragon and I. of Sicily and Naples, was born in 1423. He succeeded his father on the throne of Naples in 1458, but Pope Calixtus III. declared the line of Aragon extinct and the kingdom a fief of the church. The new pope, Pius II., recognized Ferdinand, but John of Anjou decided to try to regain the throne conquered by his ancestors, and invaded Naples. Ferdinand was severely defeated by the Angevins and the rebels at Sarno in July 1460, but with the help of Alessandro Sforza and of the Albanian chief, Skanderbeg, he re-established (1464) his authority in the kingdom. In 1480 the Turks captured and sacked Otranto, but in the following year it was retaken by Ferdinand's son Alphonso, duke of Calabria. An attempt at revolt on the part of the nobles in 1485 was crushed; many of the nobles, notwithstanding Ferdinand's promise of a general amnesty, were afterwards treacherously murdered at his express command. He died in Jan. 1494.

Villari, *Machiavelli,* pp. 60–64 (Eng. transl., 1892); for the revolt of the nobles in 1485 *see* Camillo Porzio, *La Congiura dei Baroni* (first published Rome, 1565; many subsequent editions), written in the Royalist interest.

FERDINAND II. (1469–1496), king of Naples, was the grandson of the preceding, and son of Alphonso II. Alphonso abdicated in his son's favour in 1495, on the approach of Charles

VIII. of France. Ferdinand was unable to defend the city, where there was a strong party hostile to the dynasty. He fled to Ischia; but when the French king left Naples with most of his army, in consequence of the formation of an Italian league against him, he returned and defeated the French garrisons; and the Neapolitans, irritated by the conduct of the French occupation, received him back with enthusiasm. With the aid of the great Spanish general, Gonzalo de Cordova, he drove out the invaders. He died on Sept. 7, 1496.

For authorities *see* under FERDINAND *I.* of Naples; for the exploits of Gonzalo de Cordova *see* H. P. del Pulgar, *Crónica del gran capitano don Gonzalo de Cordoba* (new ed., Madrid, 1834).

FERDINAND IV. (III. of Sicily, and I. of the Two Sicilies) (1751–1825), king of Naples, third son of Don Carlos of Bourbon (afterwards Charles III. of Spain), king of Naples and Sicily, was born in Naples on Jan. 12, 1751. When his father ascended the Spanish throne in 1759, Ferdinand, in accordance with the treaties forbidding the union of the two crowns, succeeded him as king of n'aples, under a regency presided over by the Tuscan Bernardo Tanucci, who neglected the young king's education, and left him to indulge in his liking for low life. Ferdinand's minority ended in 1767, and his first act was the expulsion of the Jesuits. In 1768 he married Maria Carolina, daughter of the empress Maria Theresa. The queen secured the dismissal of Tanucci, and with the help of Sir John Acton (*q.v.*), who eventually became prime minister, sought independence of the Spanish connection and a *rapprochement* with England and Austria. From the day of the execution of her sister Marie Antoinette, the queen lived in terror of revolution and Naples joined the coalition against France in 1793. For the history of Ferdinand's intervention in the revolutionary war, the establishment of the Parthenopean republic at Naples, and the savage reaction after the recapture of Naples by the army of brigands and gaol-birds under Cardinal Ruffo, see NAPLES. KINGDOM OF. Ferdinand had to flee to Sicily in 1806, where he reigned under British protection while Joseph Bonaparte ruled in Naples. Lord Bentinck, the British resident in Sicily, procured the queen's exile to Austria, and Ferdinand allowed his son Francis (afterwards Francis I. of the Two Sicilies) to act as regent in Sicily.

He returned to Naples after the fall of Napoleon, and proclaimed the kingdom of the Two Sicilies. He was now completely subservient to Italy. Ruthless repression of all Liberal opinion favoured the spread of the secret society of the Carbonari (*q.v.*). After the revolt of Gen. Pepe (1820) Ferdinand granted a paper constitution, thus securing the help of his Neapolitan subjects in quelling an insurrection in Sicily. The success of the military revolution in Naples alarmed the Powers of the Holy Alliance. Ferdinand was invited to the congress of Laibach (*q.v.*) to explain the situation. His cynical repudiation at Laibach of the constitution he had granted made conciliation in Naples hopeless. An Austrian army occupied Naples, and Pepe was defeated. The parliament was now dismissed, and Ferdinand inaugurated an era of savage persecution, supported by spies and informers, against the Liberals and Carbonari, the Austrian commandant in vain protesting against the savagery which his presence alone rendered possible.

Ferdinand died on Jan. 4, 1825. Few sovereigns have left behind so odious a memory. His whole career is one long record of perjury, vengeance and meanness, unredeemed by a single generous act, and his wife was a worthy helpmeet and actively co-operated in his tyranny.

Conforti, *Napoli nel 1799* (Naples, 1886); G. Pepe, *Memorie* (1847), a most valuable book; C. Auriol, *La France, l'Angleterre, et Naples* (1906); for the Sicilian period and the British occupation, G. Bianco, *La Sicilia durante l'occupazione Inglese* (Palermo, 1902), which contains many new documents of importance; Freiherr A, von Helfert has attempted the impossible task of whitewashing Queen Carolina in his *Königin Karolina von Neapel und Sicilien* (Vienna, 1878) and *Maria Karolina von Oesterreich* (Vienna, 1884); he has also written a useful life of *Fabrizio Ruffo* (Italian ed., Florence, 1885); for the Sicilian revolution of 1820 see G. Bianco's *La Rivoluzione in Sicilia del 1820* (Florence, 1905) and M. Amari's *Carteggio* (Turin, 1896). *Lettere di Ferdinando IV.* (1914).

FERDINAND I. (1345–1383), king of Portugal, sometimes referred to as el *Gentil* (the Gentleman), son of Pedro I. of Portugal, was born on Oct. 31, 1345, at Coimbra and succeeded his father in 1367. On the death of Pedro of Castile in 1369, Ferdinand, as great-grandson of Sancho IV. by the female line, became one of the claimants for the throne of Castile (see SPAIN: *History*), thus involving himself in disastrous wars between 1370 and 1382, when peace was made at Badajoz, it being stipulated that Beatrix, the heiress of Ferdinand, should marry King John of Castile, and thus secure the ultimate union of the crowns. Ferdinand left no male issue when he died at Lisbon on Oct. 22, 1383, and the direct Burgundian line, which had been in possession of the throne since Count Henry (about 1112), became extinct.

FERDINAND I. (1865–1927), KING OF RUMANIA, was born Aug. 24, 1865 at Sigmaringen, Prussia, the second son of Prince Leopold of Hohenzollern-Sigmaringen. As Charles I. had no son it was decided that the succession should be continued in the family of Prince Leopold, and Prince Ferdinand, Charles's nephew, became Crown Prince of Rumania and heir presumptive to the Rumanian throne in March, 1889. Prince Ferdinand took a great interest in military questions and organized the Rumanian Army on modern lines. He was commander-in-chief of the Rumanian armies during the Bulgarian campaign of 1913. On Jan. 10, 1893 he married Princess Marie, eldest daughter of the duke of Edinburgh, duke of Saxe-Coburg-Gotha. Six children were born of the marriage.

When Ferdinand ascended the throne on Oct. 11, 1914, he realized that an armed intervention in the cause of Rumania's national unity was unavoidable. A Hohenzollern by birth, he in due course declared war on his native country. As a consequence he was disowned by the Hohenzollern family. When Bucharest was occupied by General Mackensen, King Ferdinand and the Royal family withdrew with the Government and the army into Moldavia. There he endured with the rest of the population a most appalling period of anxiety, sickness and want. The Bolshevist revolution and the collapse of the Russian armies came as a crowning misery. But the Rumanian Army, headed by King Ferdinand, repulsed the German attack at Mărășești, thus saving the rest of the country from invasion. In 1918 the provinces of Bessarabia, Bucowina, Transylvania and the Banat had become united with Rumania, and on Oct. 15, 1922 King Ferdinand was crowned, at Alba Julia, king of all Rumanians.

Two most important reforms, the agrarian reform and the inauguration of universal suffrage, were enacted under Ferdinand's reign. The expropriation of large estates and their conversion into small holdings did much to guarantee the peaceful development of an agricultural country such as Rumania King Ferdinand was the first landlord to hand over his estates to his peasant-soldiers. It was also due to his initiative that the thorny Jewish question was solved by the grant of full civil and military rights to the Rumanian-born Jews. In Dec. 1925 Ferdinand's eldest son, Charles, renounced his claims to the throne, and Charles's son, Michael, became heir apparent. Ferdinand died on July 20, 1927 (see also RUMANIA).

FERDINAND I. (d. 1065), El *Magno* or "the Great," king of Castile, son of Sancho III. of Navarre, was put in possession of Castile in 1028, on the murder of the last count, as the heir of his mother Elvira, daughter of a previous count of Castile. He married Sancha, sister and heiress of Bermudo, king of Leon, and on the latter's death in battle at Tamaron (1038) took possession of Leon by right of his wife. He was recognized in Spain as emperor in 1056. The use of the title was resented by the emperor Henry IV. and by Pope Victor II., as implying a claim to the headship of Christendom, and as a usurpation on the Holy Roman empire. It did not, however, mean more than that Spain was independent of the empire, and that the sovereign of Leon was the chief of the princes of the peninsula. Although Ferdinand had grown in power by a fratricidal strife with Bermudo of Leon, and though in 1054 he defeated and killed his brother Garcia of Navarre at Atapuerca, he was counted a pious king. on account of his victories over the Mohammedans, with which he began the period of the great reconquest. Ferdlnand died on June 24, 1065, in Leon,—having laid aside his crown and royal mantle, dressed in the frock of a monk and lying on a bier, covered with ashes, which was placed before the altar of the church of Saint Isidore He left three sons, Sancho, Alphonso and Garcia, who divided the kingdom until the murder of Sancho and the imprisonment of Garcia, when Alphonso reigned over the uhole as Alphonso VI.

FERDINAND II., king of Leon only (d. 1188), was the second son of Alphonso VII. and of Berenguela, of the house of the counts of Barcelona. On the division of the kingdoms which had obeyed his father (1157), he received Leon, which he ruled for 30 years. During the minority of his nephew Alphonso VIII. of Castile he endeavoured to impose himself on the kingdom as regent On the west he was in more or less constant strife with Portugal, which was in process of becoming an independent kingdom. He extended his dominions southward in Estremadura at the expense of the Moors.

FERDINAND III. (1199–1252), El *Santo,* or "the Saint," king of Castile, son of Alphonso IX. of Leon, and of Berengaria, daughter of Alphonso VIII. of Castile, ranks among the greatest of the Spanish kings. The marriage of his parents, who were second cousins, was dissolved as unlawful by the pope, but the legitimacy of the children was recognized Till 1217 he lived with his father in Leon. In that year the young king of Castile, Henry, was killed by accident. Berengaria renounced the crown in her son's favour. Alphonso of Leon considered himself tricked, and the young king had to begin his reign by a war against his father and a faction of the Castilian nobles. His own ability and the remarkable capacity of his mother proved too much for the king of Leon and his Castilian allies. Ferdinand married Beatrice, daughter of the emperor Philip (of Hohenstaufen), and followed her advice both in prosecuting the war against the Moors and in the steps which she took to secure his peaceful succession to Leon on the death of his father in 1231. After the union of Castile and Leon by law in that year he began the series of campaigns which ended by reducing the Mohammedan dominions in Spain to Granada. Cordova fell in 1236, and Seville in 1248. The king of Granada did homage to Ferdinand, and undertook to attend the cortes when summoned. The king was a severe persecutor of the Albigenses, and his formal canonization by Pope Clement X in 1671 was due as much to his orthodoxy as to his crusading. He revived the university first founded by his grandfather Xlphonso VIII., and placed it at Salamanca. By his second marriage with Joan (d. 1279), daughter of Simon, of Dammartin, count of Ponthieu, by right of his wife Marie, Ferdinand was the father of Eleanor, the uife of Edward I. of England.

FERDINAND IV., EL *Emplazado* or "the Summoned," king of Castile (d. 1312), son of Sancho IV., El Bravo, and his wife Maria de Molina, succeeded to the throne when a boy of six. His minority was a time of anarchy. He owed his escape from the violence of competitors and nobles, partly to the tact and courage of his mother, and partly to the citizens of Avila, who gave him refuge within their walls. He died suddenly in his tent at Jaen when preparing for a raid into the Moorish territory of Granada, on Sept 7, 1312. His only son succeeded him as Alphonso XI.

FERDINAND V. of Castile and Leon, and II. of Aragon ("the Catholic") (1452–1516), was the son of John II. of Aragon by his second marriage with Joanna Henriquez, of the family of the hereditary grand admirals of Castile, and was born at Sos in Aragon on March 10, 1452. His marriage in 1469 to his cousin Isabella of Castile (heiress of Henry IV. of Castile) was dictated by the desire to unite his own claims to the crown with hers. When the king died in 1474 he made an attempt to procure his own proclamation as king without recognition of the rights of his wife. Isabella asserted her claims firmly, and at all times insisted on a voice in the government of Castile. But though Ferdlnand had sought a selfish political advantage at his wife's expense, he was well aware of her ability and high character, and their views in government were identical. The king cared for nothing but dominion and political power, and he played a great part in Europe. His share in establishing the royal authority in all parts of Spain, in expelling the Moors from Granada, in the conquest of Navarre, in forwarding the voyages of Columbus, and in contending with France for the supremacy in Italy, is dealt with elsewhere (*see* SPAIN: *History).* His character explains the most ungracious acts of his life, such as his breach of his promises to Columbus, his distrust of Ximenez and of the Great Captain He feared that Ximenez and the Great Captain would become too independent, and watched them in the interest of the royal authority. He is said to have boasted that he had deceived Louis XII. of France twelve times; it is, in any case, certain that wnen Ferdinand made a treaty, or came to an understanding with any one, the contract was generally found to contain implied meanings favourable to himself which the other contracting party had not expected. The worst of his character was prominently shown after the death of Isabella in 1504. He claimed the regency of Castile in the name of his insane daughter Joanna, without regard to the claims of her husband Philip of Habsburg. The hostility of the Castilian nobles baffled him for a time, but on Philip's death (1506) he reasserted his authority. His second marriage with Germaine of Foix in 1joj had apparently keen contracted in the hope that by securing an heir male he might punish his Hahsburg son-in-law. Aragon did not recognize the right of women to reign, and would have been detached together with Catalonia, Valencia and the Italian states if he had had a son. On this occasion Ferdinand alloued passion to obscure his political sense, and lead him into acts which tended to undo his work of national unification. As king of Aragon he abstained from inroads on the liberties of his subjects which might have provoked rebellion. A few acts of illegal violence are recorded of him—as when he caused a notorious demagogue of Saragossa to be executed without form of trial. His arrangement of the convention of Guadalupe, which ended the fierce Agrarian conflicts of Catalonia, was wise and profitable to the country, though it was probably dictated by a wish to weaken the landowners by taking away their feudal rights. Ferdinand died at Madrigalejo in Estremaclura on Feb 23, 1516.

The lives of the kings of this name before Ferdinand V. are contained in the chronicles, and in the *Anales de Aragon* of Zurita, and the *History of Spazn by* Mariana. Both deal at length with the life of Ferdlnand V.

See W H. Prescott, *History of the Reign of Ferdinand and Isabella* (1887); J. H. Mariéjol, *L'Espagne sous Ferdznand et Isabelle* (Paris, 1892).

FERDINAND VI., king of Spain (1713–1759), second son of Philip V., founder of the Bourbon dynasty, by his first marriage with Maria Luisa of Savoy, was born at Madrid on Sept. 23, 1713, and succeeded his father in 1746. His father's second wife, Elizabeth Farnese, looked upon her stepson as an obstacle to the fortunes of her own children. The hypochondria of his father left Elizabeth mistress of the palace. Ferdinand was married in 1729 to Maria hlagdalena Barbara, daughter of John V. of Portugal. For the events of his reign see SPAIN: *History,* and ENSENADA CENON DE SOMODEVILLA The death of his wife Barbara broke his heart. Betneen the date of her death in 1758 and his own on Aug. 10, 1759, he fell into a state of melancholy bordering on madness.

See William Coxe, *Memoirs of the Kings of Spain of the House of Bourbon,* vol iv. (1815); Count of Fernan Nuñez, *Vida de Carlos III.* ed. Morel Fatio and Don A. Paz y Melia (1898).

FERDINAND VII., king of Spain (1784–1833), eldest son of Charles IV., king of Spain, and of his wife Maria Luisa of Parma, was born at the palace of San Ildefonso near Balsain in the Somosierra hills, on Oct. 14, 1784. On March 17, 1808 he succeeded to the throne by the forced abdication of his father, but was shortly afterwards taken prisoner by Napoleon. He was released in 1814 (see SPAIN: *History*) and returned to find that while Spain was fighting for independence in his name a new world had been born of foreign invasion and domestic revolution. He came back to assert the ancient doctrine that the sovereign authority resided in his person only, and repudiated the impracticable constitution made by the cortes in 1814 without his consent. He proved himself, however, incapable of governing or of choosing reliable advisers, and was influenced by the lowest intriguers. The autocratic powers of the Grand Alliance, though forced to support him as the representative of legitimacy in Spain. watched his proceedings with disgust and alarm. When the inevitable revolt came in 1820 he grovelled to the insurgents as he had done to his parents and was imprisoned by them until 1823 On the invasion by France in that year the revolutionary party carried Ferdinand to Cadiz, and he continued to make promises of amendment till he was free. Then, in violation of his oath to grant an amnesty, he revenged himself for three years of coercion by killing on a scale which revolted his "rescuers" and against which the duke of Angoulême, powerless to interfere. protested by refusing the Spanish decorations offered him for his services. During his declining years Ferdinand's energy abated After his fourth marriage in 1829 with Maria Christina of Naples by whom he had two daughters, he was persuaded by his wife to confirm Charles IV.'s revocation of the Salic Law of Philip V., which gave a preference to all the males of the family in Spain When Ferdinand died at Madrid on Sept. 29, 1833, his daughter Isabella II. was proclaimed queen, and her mother acted as regent.

Ring Ferdinand VII. kept a diary during the troubled years 1820–23, which has been published by the count de Casa Valencia

See D E. de K. Vays, *Historia de la vida y reinado de Ferdinand VII.* 3 vols. (1842) Miñano, *Histoire de la Révolution d'Espagne, 1820–23* (2 vols., 1824); P. Zancada, *El Sentido Social de la revolución de 1820. Revista contemporénea* (1903).

FERDINAND II. (1810–1859), nicknamed King Bomba, king of the Two Sicilies, son of Francis I., was born at Palermo on Jan. 12, 1810. In 1832 he married Cristina, daughter of Victor Emmanuel I., king of Sardinia, and shortly after her death in 1836 he took for a second wife Maria Theresa, daughter of the archduke Charles of Austria. After his Austrian alliance the bonds of despotism were more closely tightened; there were various abortive attempts at insurrection; in 1837 there was a rising in Sicily in consequence of the outbreak of cholera, and in 1843 the Young Italy Society organized a series of isolated outbreaks. The expedition of the Bandiera brothers (*q.v*) in 1844, was followed by cruel sentences on the rebels. In Jan. 1848 a rising in Sicily was the signal for revolutions all over Italy and Europe; it was followed by a movement in Naples, and the king granted a constitution which he swore to observe. Serious disturbances broke out in the streets of Naples on May 15; the king withdrew his promise and dissolved the national parliament on March 13, 1849. He retired to Gaeta to confer with various deposed despots. and the Austrian victory at Novara (March 1849) strengthened his determination to return to a reactionary policy. Sicily was subjugated by General Filangieri, and the chief cities were bombarded. an expedient which won for Ferdinand the epithet of "King Bomba." In 1851 the political prisoners of Naples were calculated by Mr. Gladstone in his letters to Lord Aberdeen (1851) to number 15,000 (probably the real figure was nearer 40,000), and the scandalous reign of terror, and the abominable treatment of the prisoners led France and England to make diplomatic representations to the king, but without success. An attempt was made by a soldier to assassinate Ferdinand in 1856. He died on May 22, 1859, just after the declaration of war by France and Piedmont against Austria, which was to result in the collapse of his kingdom and his dynasty. He was bigoted, cruel, mean, treacherous, though not without a certain bonhomie.

(Città di Castello, 1900), which contains a great deal of fresh information, but is badly arranged and not always reliable. *See* also M. Schipa, *Il regno di Napoli al tempo di Carlo di Borbone* (1904).

FERDINAND III. (1769-1824), grand duke of Tuscany, and archduke of Austria, second son of the emperor Leopold II., was born on May 6, 1769. On his father becoming emperor in 1790, he succeeded him as grand duke of Tuscany. Ferdinand was one of the first sovereigns to enter into diplomatic relations with the French republic (1793); and although, a few months later, he was compelled by England and Russia to join the coalition against France, he concluded peace with that power in 1795, and by observing a strict neutrality saved his dominions from invasion by the French, except for a temporary occupation of Livorno, till 1799, when he was compelled to vacate his throne, and a provisional Republican government was established at Florence. Shortly afterwards the French arms suffered severe reverses in Italy, and Ferdinand was restored to his territories; but in 1801, by the peace of Lunéville, Tuscany was converted into the kingdom of Etruria, and he retired to Vienna. He obtained in 1802 the electorship of Salzburg, which he exchanged by the peace of Pressburg in 1805 for that of Würzburg. In 1806 he was admitted as grand duke of Würzburg to the confederation of the Rhine. He was restored to the throne of Tuscany after the abdication of Napoleon in 1814, but had again to vacate his capital for a short time in 181j, when Murat proclaimed war against Austria. After Waterloo he remained in undisturbed possession of his grand duchy. The restoration in Tuscany was not accompanied by the reactionary excesses which characterized it elsewhere, and a large part of the French legislation was retained. His prime minister was Count V. Fossombroni (*q.v.*). The mild rule of Ferdinand, his solicitude for the welfare of his subjects, his enlightened patronage of art and science, his encouragement of commerce, and his toleration render him an honourable exception to the generality of Italian princes of his time. He died in June 1824, and was succeeded by his son Leopold II. (*q.v.*).

(in the *Archivo Storico Italiano*, 1877); Emmer, *Erzherzog Ferdinand III., Grossherzog von Toskana* (Salzburg, 1871); C. Tivaroni, *L'Italia durante il dominio francese*, ii. 1–44 (Turin, 1889), and *L'Italia durante il dominio austriaco*, ii. 1–18 (Turin, 1893).

FERDINAND, duke of Brunswick (1721–1792), Prussian general field marshal, was the fourth son of Ferdinand Albert, duke of Brunswick, and was born at Wolfenbüttel on Jan. 12. 1721. In his twentieth year he was made chief of a newly-raised Brunswick regiment in the Pruscian service. He was present in the battles of Mollwitz and Chotusitz. In succession to Margrave Wilhelm of Brandenburg, killed at Prague (1744), Ferdinand received the command of Frederick the Great's Leibgarde battalion, and distinguished himself at Sohr (1745). During the ten years' peace he was in the closest touch with the military work of Frederick the Great, who sought to make the guards battalion a model of the whole Prussian army. Ferdinand became one of the king's most intimate friends. In the first campaign of the Seven Years' War Ferdinand commanded one of the Prussian columns which converged upon Dresden, and in the operations which led up to the surrender of the Saxon army at Pirna (1756), and at the battle of Lobositz. he led the right wing of the Prussian infantry. In 1757 he distinguished himself at Prague, and he served also in the campaign of Rossbach. Shortly after this he was appointed to command the allied forces which were being organized for the war in western Germany. He found this army dejected by a reverse and a capitulation, yet within a week of his taking up the command he assumed the offensive, and thus began the career of victory which made his European reputation as a soldier. His conduct-of the five campaigns which followed (see SEVEN YEARS' WAR) was naturally influenced by the teachings of Frederick, whose pupil the duke had been for so many years. Ferdinand, indeed, approximated more closely to Frederick in his method of making war than any other general of the time. Yet his task was in many respects far more difficult than that of the king. Frederick was the absolute master of his own homogeneous army, Ferdinand merely the commander of a group of contingents, and answerable to several princes for the troops placed under his control. In 1758 he fought and won the battle of Crefeld, several marches beyond the Rhine, but so advanced a position he could not well maintain, and he fell back to the

Lippe. He resumed a bold offensive in 1759, only to be repulsed at Bergen (near Frankfort-on-Main). On Aug. 1 of this year Ferdinand won the brilliant victory of Minden (*q.v.*). Vellinghausen, Wilhelmsthal, Warburg and other victories followed, and Frederick, hard pressed in the eastern theatre of war, owed much of his success in an almost hopeless task to the continued pressure exerted by Ferdinand in the west. He was promoted field marshal in November 1758.

Ferdinand exerted himself to compensate those who had suffered by the Seven Years' War, devoting to this purpose most of the small income he received from his various offices and the rewards given to him by the allied princes. The estrangement of Frederick and Ferdinand in 1766 led to the duke's retirement from Prussian service, but there was no open breach between the old friends, and Ferdinand visited the king in 1772, 1777, 1779 and 1782. After 1766 he passed the remainder of his life at his castle of Veschelde, where he became a patron of learning and art, and a great benefactor of the poor. He died on July 3, 1792.

See Von Westphalen, *Geschichte der Feldzüge des Herzogs Ferdinands von Braunschweig-Lüneburg* (5 vols., Berlin, 1859–1872); also authorities for SEVEN YEARS' WAR.

FERENTINO, a town and episcopal see of Italy, province of Frosinone (anc. *Ferentinum*, to be distinguished from Ferentum or Ferentinum in Etruria), 48 m. E.S.E. by rail from it. Pop. (1951) 7,522. It is picturesquely situated on a hill 1,290 ft. above sea-level, and still possesses considerable remains of ancient fortifications. The lower portion of the outer walls is built of roughly hewn blocks of limestone; above this in places is walling of rectangular blocks of tufa.

Two gates, the Porta Sanguinaria (with an arch with tufa voussoirs), and the Porta S. Maria, a double gate constructed entirely of rectangular blocks of tufa, are preserved. Outside this gate is the tomb of A. Quinctilius Priscus, a citizen of Ferentinum, with a long inscription cut in the rock.

The acropolis has massive retaining walls similar to those of the lower town. At the eastern corner, under the present episcopal palace, a projecting rectangular terrace is supported by walls of quadrilateral blocks of limestone arranged almost horizontally; while upon the level thus formed a building of rectangular blocks of local travertine was raised. A projecting cornice bears two inscriptions of the period of Sulla, recording its construction by two censors (local officials); and in the interior there is an inscription of the same censors over one of the doors, and another over a smaller external side door. The windows lighting these chambers come immediately above the cornice, and the wall continues above them again. The whole of this construction probably belongs to one period. The cathedral occupies a part of the level top of the ancient acropolis; it was reconstructed on the site of an older church in 1099–1118; the interior was restored to its original form in 1902. It contains a fine canopy in the "Cosmatesque" style. The Gothic church of S. Maria Maggiore, in the lower town (13th–14th century), has a very fine exterior. The Romans captured Ferentinum, the chief city of the Hernici, in 364 B.C. It took no part in the rising of 306 B.C. The inhabitants became Roman citizens after 195 B.C. It lay just above the Via Latina and, being a strong place, served for the detention of hostages. Horace praises its quietness, and it does not appear much in later history. (T. A.)

FERENTUM or FERENTIS, an ancient town of Etruria, about 6 mi. N. of Viterbo and $3\frac{1}{2}$ mi. E. of the Via Cassia. It was the birthplace (A.D. 32) of the emperor Salvius Otho, was destroyed in the 11th century, and is now entirely deserted. It occupied a ridge running from east to west, with deep ravines on three sides. There are some remains of the city walls, and of various Roman structures, including some baths, of which the most important is the theatre. The stage front is still standing; it is pierced by seven openings with flat arches. It has recently been well restored, and fitted for use for theatrical representation. The necropolis was on the hill called Talone on the north-east. A tomb of the Republican period with several sarcophagi of the gens Salvia, no doubt ancestors of the emperor Otho, has been found there.

FERGHANA (FERGANA), (1) A range of mountains in Asiatic Russia, branching off about lat. 41° N. and long. 75° E. from the Tien-Shan range, rising to altitudes of 13,000 ft. or more.

(2) The name given to the rich and fertile valley lying south of this range and north of the Alai mountains, and opening out toward the southwest. The climate is dry and warm, with an average temperature of 68° F. in March, rising rapidly to 95° through June, July and August. Snow and frost occur in December and January, when the temperature may fall to −4° F. No rain falls during the five months following April. and the valley owes its fertility to irrigation from the rivers Naryn and Kara-darya, which unite near Namangan to form the Syr-darya or Jaxartes river. On the right bank of the Syr-darya, from Namangan to Khojent, are vast expanses of barren shifting river sand, a menace to the fertile, irrigated areas, upon which they encroach under the influence of the southwest wind. The crops include cotton, wheat, millet. maize and rice. Fruits, especially apricots. are widely cultivated and there are numerous vineyards. Other industries include silkworm breeding, manufacturing, and food- and textile-processing industries. The extension of the Transcaspian railway into Ferghana (1899), and the opening of the Orenburg–Tashkent railway (1906) gave a great impetus to trade and helped to develop the cotton growing industry. In northern Ferghana a rubber-producing euphorbia and other medicinal and aromatic herbs are found. The Ferghana valley has had an eventful history; its fertility has always proved attractive and the Khojent pass made it vulnerable to invaders. It was overrun by Arabs in A.D. 719. In the 9th and 10th centuries it was ruled by the Persian Samanid dynasty. while in the 12th century, it became subject to Kara-Kitai, the fore-runner of Jenghiz Khan, who later conquered it. Tamerlane conquered it later on. In 1513 the Uzbeks expelled Baber, the last descendant of Tamerlane, and until about 1770 the separate cities and clans had each its own Bek. or ruler. From that time until its conquest by Russia. it was ruled by the Khans of Khokand. In 1876 it became part of a much larger unit called Ferghana, which was created as a province of Russian Turkistan, with New Marghelan (Ferghana) as its administrative centre. After the fall of the tsarist regime. the valley became part of the Uzbek S.S.R.. though for a time it was an independent Soviet province. *See* UZBEKISTAN.

(3) A town formerly known as New Marghelan or Skobelev (after the Russian general M. D. Skobelev *q.v.*). It is the administrative centre of an *Oblast* of the same name, in the Uzbek S.S.R., in lat. 40° 32' N. long. 71° 48' E.. in the south central Ferghana valley. It was built by the Russians, after their conquest of the Khanate of Khokand, ten miles southeast of the old town of Marghelan, and became the administrative centre for the Ferghana province of the former Russian Turkistan. A branch line links it with the Khokand-Andijan railway. Pop. (1959) 80.000.

FERGUSON, ADAM (1723–1816), Scottish man of letters respected as a philosopher. as a historian and as a patriot, was born the son of a Presbyterian minister at Logierait in Perthshire on June 20, 1723, and educated at St. Andrews university. Appointed deputy chaplain to the Black Watch regiment in 1745, he charged sword in hand with it at Fontenoy. Abandoning the clerical profession, he succeeded his friend David Hume as advocates' librarian at Edinburgh (1757) and eventually became professor at Edinburgh, first of natural philosophy (1759), then of mental and moral philosophy (1764). He interrupted his professorial work in 1774, when he went to Europe to supervise the young earl of Chesterfield, and in 1778. when he went to Philadelphia with a commission sent to negotiate with the Americans. Resigning his chair in 1785, he spent a few months in Germany and Italy in 1793. but thereafter lived in retirement till his death. at St. Andrews, on Feb. 22, 1816. Walter Scott composed his epitaph.

Ferguson's works include *The Morality of Stage Plays Seriously Considered* (1757), an anonymous pamphlet in defense of his friend John Home's *Douglas*; *The History of the Proceedings in the Case of Margaret, Commonly Called Peg, Only Lawful Sister of John Bull, Esq.* (1761), remonstrating for the establishment of a Scottish militia: *Essay on the History of Civil Society* (1767; 7th ed. 1814), largely inspired by Montesquieu; *Institutes of*

Moral Philosophy (1769); *Remarks* (1776) on Richard Price's *Observations on . . . Civil Liberty*, in which Ferguson proposed peace terms for the Americans; *History of the Progress and Termination of the Roman Republic*, 3 vol. (1783; new ed.. 5 vol., 1813); and *Principles of Moral and Political Science*, 2 vol. (1792).

FERGUSON, ROBERT (*c.* 1637–1714), British conspirator and pamphleteer, called the "Plotter," was a son of William Ferguson (d. 1699) of Badifurrow, Aberdeenshire. He became vicar of Godmersham, Kent, from which living he was expelled by the Act of Uniformity in 1662. In 1680 he wrote "A letter to a Person of Honour concerning the 'Black Box,' " in which he supported the claim of the duke of Monmouth to the crown against that of the duke of York; he also claimed the authorship of the pamphlet "No Protestant Plot" (1681), parts of which are usually ascribed to Shaftesbury. Ferguson was deeply implicated in the Rye House plot, and fled to Holland with Shaftesbury in 1682, returning to England early in 1683. For his share in another plot against Charles II he was outlawed. Ferguson took a leading part in organizing Monniouth's rising of 1685. He drew up the manifesto against James II, escaping to Holland after the battle of Sedgemoor. He landed in England with William of Orange in 1688, and received a sinecure appointment in the excise. Ferguson was soon in correspondence with the exiled Jacobites. He shared in all the plots against the life of William, but although he was several times arrested on suspicion, he was never brought to trial. He died in great poverty in 1714, leaving behind him a great and deserved reputation for treachery. It has been suggested that Ferguson was a spy. and that his frequent escapes from justice were due to official connivance.

See James Ferguson, *Robert Ferguson, the Plotter* (Edinburgh, 1887), which gives a favourable account of Ferpuson.

FERGUSON, SIR SAMUEL (1810–1886), Irish poet and antiquary, who was well known for such contributions to *Blackwood's Magazine* as "The Forging of the Anchor." a fine ballad, and the humorous prose extravaganza of "Father Tom and the Pope." He was born in Belfast and educated at Trinity college, Dublin, was called to the Irish bar in 1838 and was made Q.C. in 1859, but in 1867 retired from practice upon his appointment as deputy keeper of the lrish records. He was knighted in 1878. He published *Lays of the Western Gael* in 1865, *Poems* in 1880 and in 1872 *Congal,* an attempt to revivify the heroic age of Ireland in an epic poem. He died at Howth on Aug. 9, 1886. His most important antiquarian work, *Ogham Inscriptions in Ireland, Wales, and Scotland*, was published in 1887.

FERGUSSON, ROBERT (1750–1774), Scottish poet, one of the leading figures of the 18th-century revival of Scots vernacular Writing, and the chief forerunner of Robert Burns, was born in Edinburgh on Sept. 5, 1750. He was educated at Dundee grammar school and at St. Andrew's university, and became a copying clerk in a lawyer's office in Edinburgh. In 1771 he began to contribute poems to Ruddiman's *Weekly Magazine*. He was a member of the Cape club. which met at a tavern in Craig's Close) and was noted for the vivacity of temperament that is reflected in his verse. From 1773, however, his good spirits were encroached upon by fits of depression and religious guilt, and after being severely injured in the head by a fall he became insane, and died in the Edinburgh Bedlam on Oct. 1;, 1774.

Fergusson's poems were popular from their first appearance, and a collected volume came out in 1773. He wrote in both Scots and English, but the English verse has little value. His Scots poems, racy, realistic, wittily descriptive and humorous, had a stimulating effect on Burns, whose "Holy Fair" and "Cotter's Saturday Night" stein from Fergusson's "Leith Races" and "The Farmer's Ingle"; but vigorous poems like "The Daft-Days." "To the Tron-Kirk Bell" and the famous "Auld Reikie" prove how well Fergusson can stand as a poet in his own right.

Smith (1952). (E. G. M.)

FERINGHI or FERINGHEE, an Asiatic term for a European originally used in a purely geographical sense (Arabic and Persian, *Farangi,* "Frank") but now generally carrying a hostile significance. The combatants on either side during the Indian mutiny called each other Feringhis and Pandies.

FERISHTAH (FIRISHTA), **MOHAMMED KASIM** (c. 1560–*c.* 1620), Indo-Persian historiographer. was the author of the famous *Tarikh-i-Firishta* ("Ferishtah's History"), an account of the Moslems in India from the 10th century. When captain of the guard to Murtaza Nizam Shah, ruler of Ahmadnagar (1565–1588), Ferishtah conceived the idea of writing a history of Indo-Moslem rulers and saints and he fulfilled his intention when he compiled the *Tarikh-i-Fiuishta* under the patronage of Ibrahim 'Adil Shah, ruler of Bijapur, whose service he entered in 1589. With the passage of time the *Tarikh-i-Firishta* has gradually lost its status as an authority for Indo-Moslem history before Ferishtah's own day, especially since independent copies of the Indo-Persian histories, on which it was based, have become available and historical criticism has developed. It is, however, a valuable source for the history of the Moslem Deccan where he served and a remarkable example of the Indo-Moslem genius for historical writing. (P. H.)

FERMANAGH, a county of Northern Ireland, bounded on the northeast by County Tyrone and west, south and east by the frontier of the Irish republic. Area, including water, 71j sq.mi. or 6j3 sq.mi. excluding water. Pop. (1951) 53,044. The county lies chiefly in the basin of the Erne river which divides it into two nearly equal sections. The surface is hilly and, especially round Lough Erne, picturesque. Upper and Lower Lough Erne stretch from southeast to northwest. These lakes are expansions of the Erne river. which enters the county from Cavan. flows through Upper Lough Erne. past Enniskillen and through Lower Lough Erne on its way to the Atlantic. At Belleek it forms a considerable waterfall and is notable there for good salmon fishing. Trout are taken in most of the loughs, and pike of great size in both Upper and Lower Lough Erne.

The southwest boundary of the county, which is also the frontier of Northern Ireland. takes in a small portion of Lough Melvin and of Lough Macnean Upper and most of Lough Macnean Lower. An area of high ground lies between Lower Lough Erne and Lough Macnean Upper, including Belmore mountain (1.316 ft.). On the southern frontier of Fermanagh there are hills of greater height. including Cuilcagh (2,188 ft.) and Tiltinbane (1,881 ft.).

The county includes in the north an area of gneiss extending from Donegal and an area of metamorphic rock extending from Tyrone. A fault divides the latter from the Old Red Sandstone which spreads south. Limestone forms fine scarps on the southern side of Lower Lough Erne. The scenery about Lough Macnean Upper and Lower rises in siniilarly scarped hills to the summit of Cuilcagh. The Marble Arch cave near Belcoo, with its emerging river, is a characteristic subterranean waterway in the limestone. Higher Carboniferous strata form highlands on both sides of Lower Lough Erne. As well as Marble Arch there are other caves, including those at Boho near Enniskillen and at Knockmore near Derrygonnelly. The fact that Fermanagh is a predominantly limestone county makes it hard to obtain water supplies in some areas in spite of its containing the lake district of Ulster.

There is evidence of prehistoric occupation, there being "horned cairns" at Aghanaglack (Giant's Grave) and Ballyreagh, as well as stone cairns. Fermanagh became in historic times the country of the Maguires. There are many monuments of early Celtic Christianity, particularly on islands in the loughs. On Devenish Island, Lower Lough Erne, is the site of an ancient abbey, and substantial ruins there date from the 6th century, with a round tower standing 81 ft. high and a standing cross. On White Island and Innismacsaint are other ecclesiastical antiquities. There are ancient carvings in Killadeas graveyard, north of Enniskillen.

The county was included in the scheme for the plantation of Ulster in the reign of James I. At Newtownbutler in 1689, the Enniskillen men severely defeated a superior army of James II and began the victorious tradition of the "Inniskillings," now represented in the British army by the Royal Inniskilling Fusiliers. Enniskillen (pop.: 1951, 6,322), strategically situated between

Upper and Lower Lough Erne, has long been the county town. It was once the site of a Maguire stronghold.

Ferrnanagh is chiefly a pastoral and agricultural county, but there are industries in a number of towns. At Enniskillen, nylon stockings and clothing are manufactured; pottery is made at Belleek and cotton thread at Lisnaskea.

As a result of agreement between the governments of Ireland and of Northern Ireland, the hydroelectric capacities of the Erne were being developed in the mid-1950s for use by consumers on both sides of the frontier.

Fermanagh sends three members to the Northern Ireland parliament and unites with South Tyrone to send one member to the United Kingdom parliament. (HU. S.)

FERMAT, PIERRE DE (1601?–1665), French mathematician, was the greatest number theorist between Diophantus and Leonhard Euler. He is reported to have been born at Beaumont-de-Lomagne on Aug. 17, 1601, and he died at Castres on Jan. 12, 1665; but his age at death is given on his tombstone as 57.

For Fermat, a punctilious counselor of the parliament of Toulouse and a lover of classical learning, mathematics was but an avocation. About the year 1629 he made, but did not publish. the remarkable discovery that an equation $f(x,y) = 0$ represents a curve in the xy-plane—the fundamental principle of analytic geometry, which first appeared in print in 1637 in the *Géométrie* of Descartes. At this time he also showed that relative maxima and minima of $f(x)$ are found from $\frac{f(x+h)-f(x)}{h}=0$ by allowing h to vanish. This is equivalent to the modern equation $f'(x)=0$, and Fermat has been acclaimed as the inventor of the differential calculus. (*See* CALCULUS, DIFFERENTIAL AND INTEGRAL: *History.*) By 1636 he had used this device to find tangents as limits of secants, a procedure that led Newton to the method of fluxions. Fermat also noted that the area under the curve $y = x^n$ from $x = 0$ to $x = a$ is $\frac{a^{n+1}}{n+1}$, but he failed to remark the fundamental inversion theorem relating areas and tangencies.

From correspondence. in 1654, between Fermat and B. Pascal the theory of probability largely arose (though developed earlier by G. Cardano, *q.v.*); and Fermat was one of several mathematicians who independently disclosed (1659) the rectification of an algebraic curve, $ay^2 = x^3$. But it was in the theory of numbers that the genius of Fermat was most apparent, and here two theorems bear his name: (1) the "lesser Fermat theorem," that if p is prime, then $a^p - a$ is divisible by p; and (2) "Fermat's last theorem," that no positive integers x,y,z satisfy $x^n+y^n = z^n$, where n is an integer greater than two. The "lesser theorem," first given in a letter of 1640, was proved by Leibniz before 1683 and a proof was published by Euler in 1738; the "last theorem" remains a celebrated unsolved problem (see FERMAT'S LAST THEOREM). For some of his theorems Fermat gave demonstrations by his method of "infinite descent"; but one conjecture—that $2^2 +1$ is prime if n is a positive integer—was shown to be false when Euler found $2^{2^3}+1$ to be composite.

Fermat was the greatest mathematician of his day, but his influence was circumscribed by a reluctance to publish. The two volumes of his *Opera mathematica*, edited by his son, appeared belatedly in 1670–79. The definitive edition of his work is the *Oeuvres* (4 vol. and supp., 1891–1922) ed. by Paul Tannery and Charles Henry. *See* also L'Abbé Genty, *L'Influence de Fermat sur son siècle* (1784); E. Brassine, *Précis des oeuvres mathématiques de Pierre Fermat* (1853); E. T. Bell, *Men of Mathematics* (1937). (C. B. BR.)

FERMAT'S LAST THEOREM, a statement which is famous in the history of mathematics, namely that there do not exist integers x, y and z, none of which being zero, which satisfy

$$x^n+y^n=z^n \qquad (1)$$

n being a given integer >2. It was first given by Pierre de Fermat who wrote, about the year 1637, upon the margin of his copy of the works of Diophantus, "I have discovered a truly remarkable proof which this margin is too small to contain." He did not publish his proof, however, and no complete demonstration has been discovered.

The theorem was proved by Fermat for $n=4$ and, in the year 1770 by Leonhard Euler for $n=3$. The latter proof was incomplete at one point, but the missing steps were supplied by later writers.

To prove it in general, it is then not difficult to see that it is sufficient to demonstrate the impossibility of

$$x^l+y^l+z^l=0 \qquad (2)$$

in nonzero integers x, y and z for any odd prime $l>3$. This was proved by Adrien M. Legendre in 1823 for $l=5$, and later by Henri L. Lebesgue for I= 7. These proofs excited great interest among the mathematicians of the time and many efforts were made to extend them to other values of I, a number of them resulting in errors. For example. the celebrated mathematicians Gabriel Lamé and Augustin L. Cauchy published many results concerning (2) which were based on assumptions later proved false. The discussion and study of these mistakes led to the formulation, by Ernst E. Kummer, of one of the most powerful and fruitful concepts which has ever been introduced into mathematics; *i.e.,* the notion of ideal numbers. By means of this idea Kummer was able to prove (in 1850) that (2) is impossible in integers 2, y and z, none zero, for all primes l for which none of the numerators of the Bernoulli numbers (*q.v.*) B„ $a=1, 2, \ldots, (l-3)/2$, is divisible by I, where $B_1=1/6$, $B_2=1/30$, etc. Primes 1 of this character are called regular. By extensive numerical computations he found that the only primes less than 100 which are not regular are 37, 59 and 67, and in a later article published in 1874 he obtained results from which it may be inferred that the only primes which are not regular between the limits 100 and 166 are 101, 103, 131, 149 and 157. In the year 1857 Kummer published another memoir in which he concluded after a long and complicated procedure that (2) is impossible under three assumptions concerning the nature of the algebraic field defined by ζ where $\zeta=e^{2i\pi/l}$. He finds, again by the use of extensive numerical computations, that these three assumptions are satisfied for $l=37$, 59 and 67, and hence that (2) is impossible for all primes $1<100$.

Using, in the main, extensions of methods due to Kummer, Harry S. Vandiver, in the year 1929, obtained a number of conditions that must hold in case the relation (2) is satisfied. These conditions were applied by several of his collaborators, principally M. M. Abernathy, Derrick H. Lehmer and M. E. Tittle, who carried out the necessary computations and found that (2) is impossible for all primes $l<619$. These results were contained in several papers published by Vandiver between 1929 and 1939.

For the statement of later results the discussion is divided into two cases. If in (2), x, y and z are prime to each other and to 1, this condition will be referred to as case I of Fermat's last theorem; if x, y and z are prime to each other and one of them is divisible by I, the condition will be called case II of the theorem. All further statements in this article concerning (2) will refer to case I only unless otherwise noted, and only those criteria which do not involve in their enunciation the theory of algebraic numbers will be mentioned.

Legendre published in 1823 the following theorem due to Germain: If there exists an odd prime p such that the congruence

$$u^l+v^l+w^l\equiv 0 \pmod{p} \qquad (3)$$

has no set of integral solutions u, v and w, each not divisible by p, and such that l is not the residue of the lth power of any integer modulo p, then (2) has no solutions x, y and z, each prime to l. By means of this result, Sophie Germain proved that (2) is impossible in case I for all primes $l<100$.

In 1857, Kummer proved that certain congruences had to hold in order that (2) be satisfied. D. Mirimanoff in the year 1905 showed that these congruences could be reduced to the following form:

$$B, \ f_i\ (t)\equiv 0 \pmod{l}$$
$$n=(l-i)/2;$$

where the B's are the Bernoulli numbers as before:

$$i=3, 5, \dots, l-2; \quad -t=x/y, y/x, x/z, z/x, y/z, z/y;$$

$$f_i(t)=\sum_{k=1}^{l-1} k^{i-1}\, t^k \qquad (4)$$

He also added the criterion

$$f_{l-1}(t) \equiv 0 \pmod{l} \qquad (4a)$$

for the solution of (2) in case I. The criteria (4) and (4a) are generally referred to as the Kummer criteria.

In 1908 Leonard E. Dickson, using Germain's theorem, proved that (2) is impossible in case I for all primes $l<7{,}000$. A. Wieferich, in 1909, by the use of (4) and (4a) proved that, if (2) is possible in case I, then $2^{l-1}\equiv 1 \pmod{l^2}$, and in 1910, Mirimanoff obtained on the same assumption, $3^{l-1}\equiv 1 \pmod{l^2}$. The criterion, $5^{l-1}\equiv 1 \pmod{l^2}$, was derived by Vandiver in 1912 for case I. P. Furtwangler, in 1912, proved that, if (2) is satisfied in case I and r is a factor of x or of $x^2-y^2\equiv 0 \pmod{l}$, then $r^{l-1}\equiv 1 \pmod{l^2}$. This result includes those of Wieferich and Mirimanoff just referred to. In the year 1925, N. G. W. H. Beeger found that the only primes $l<14{,}000$ for which $2^{l-1}\equiv 1 \pmod{l^2}$ are $l=1{,}093$ and $l=3{,}511$, the case $l=1{,}093$ having been previously noted by Meissner. Using these results with those of Dickson, he concludes that (2) is impossible in integers x, y and z prime to l, for all primes $l<14{,}000$. He later extended this limit to 16,000. Vandiver obtained, in 1926, the theorem that if there exists an odd prime $p=1+ml$, such that $m<10l$ and

$$u^l+v^l+w^l\equiv 0 \pmod{p}$$

has no set of integral solutions u, v, w, each not divisible by p, then (2) has no solution in case I. He also proved (1925) that if (2) is satisfied in case I, then

$$f_i(t)\, f_{l-i}(1-t)\equiv 0 \pmod{l}$$

F. Pollaczek, using the Kummer criteria, proved, in 1917, that if (2) is satisfied in case I then

$$m^{p-1}\equiv 1 \pmod{p^2}$$

holds for $m\leqq 31$ except for a finite number of primes p. T. Morishima removed the exception in this statement in 1931. B. Rosser in 1939–41 pushed the limit to $m\leqq 43$ and interpreting these results by means of a new analytic method, showed that (2) does not hold for any $l<41{,}000{,}000$ in case I. Derrick H. and Emma Lehmer carried this result to $l<253{,}747{,}889$.

Based mainly on an idea due to Howard H. Mitchell, Vandiver proved, in 1944, that if c is a given even integer not divisible by 3 and it is possible to define two primes l and p such that $p=1+cl$; $l>c$; and $p>3^{\varphi(c)}$; then (2) is impossible in integers with x, y and z prime to l. Here $\varphi(c)$ is the number of positive integers $<c$ and prime to it.

As may be inferred from the above account, little has been discovered concerning case II of the theorem. Some mathematicians think that (2) may be satisfied when one of the integers x, y or z is divisible by l.

In case I, however, everything indicates that Fermat's Last Theorem is true, although it has not been proved. That it has not been proved for this case is one of the most amazing facts in mathematics; and for this reason alone, the great celebrity of the theorem is perhaps justified. Also the many attempts to solve it by competent mathematicians have led to a number of remarkable developments in number theory, including very abstract conceptions and profound results, arrived at only after long chains of reasoning.

(H. S. V.)

FERMENTATION. In industrial practice the word fermentation refers to processes by which raw materials (usually agricultural products such as grain, or industrial by-products such as molasses) are transformed by the controlled action of carefully selected strains of microorganisms (fungi, yeasts or bacteria) into definite products. Fermentation, in this connection, denotes the key operation in manufacturing processes which, by virtue of their increasing importance and specialized techniques, can fairly claim consideration as a separate branch of applied science. Louis Pasteur used the term in a narrower sense to describe changes brought about by microorganisms growing in the absence of air. In the modern biochemical laboratory, general terms such as "fermentation" tend to be replaced by a scientific terminology describing the individual enzymes or associated groups of them (see ENZYMES).

The great advances in understanding of living organisms achieved by the century-old sciences of bacteriology and biochemistry have created the newer fermentation industries. Side by side with these exist the old-established industries of brewing, wine making, tobacco curing and so on, from which science increasingly eliminates the factor of chance, if not that of art. It is recorded that when Michael Combrune, in 1762, wished to control the temperature at which grain was mashed, he was forced to hide his thermometer from his father, who objected to experimental innovations. On the other hand, among the first specialized technical journals to appear were those devoted to brewing; while many fundamental biochemical discoveries have come from laboratories supported by the industry. (See also BREWING.)

Early History of Fermentation.—Fermentations involving (as is now known) one of the many strains of yeast—*e.g.*, brewing of beer, wine making, raising of dough in breadmaking—were practised long before the beginning of recorded history. The word fermentation itself (Lat. fervere, "to boil") is a reminder of a time when chemical knowledge was so meagre that the bubbling and foaming of fermenting liquors could only be compared with boiling. That this appearance was due to the evolution of a gas (carbon dioxide) could not, of course, be understood until the existence of gases was recognized in the 17th century. Alcohol, which had been prepared long before, was the first pure organic compound known, and the process of distillation by which it was obtained from wine played an important role in the development of chemistry. Acetic acid (vinegar, *q.v.*), made by the souring of wine (a fermentation process dependent on the action of the bacterium Acetobacter), was the first acid to be made. From early times it was widely used, not only in preparing food but also in medicine and industrial arts, such as the manufacture of lead pigments.

When yeast (*q.v.*) grows in sugary solutions in the virtual absence of air, most of the sugar is converted into alcohol and carbon dioxide. Only a fraction is used by the yeast to build up new cell material. It was therefore possible, without great error, to disregard the part played by the yeast and to study the over-all change by purely chemical methods. This was done notably by Antoine Lavoisier who, after establishing that organic compounds contain carbon, hydrogen and oxygen, applied his new technique of analysis to the products of alcoholic fermentation. His figures showed that the alcohol and carbon dioxide formed equaled, in total weight and in amount of carbon, oxygen and hydrogen, the sugar consumed. Fermentation therefore obeyed the law of the conservation of matter as did more conventional chemical reactions. The sugar, he considered, split into two parts, one of which oxidized the other to carbon dioxide and was itself reduced to alcohol. Ironically, Lavoisier's analytical figures (*e.g.*, for the composition of sugar) were grossly in error, though his conclusions were nearly correct, as shown by J. L. Gay-Lussac (1810) who summarized the process of fermentation by the equation

$$\underset{\text{sugar}}{C_6H_{12}O_6} \longrightarrow \underset{\text{carbon dioxide}}{2CO_2} + \underset{\text{alcohol}}{2C_2H_6O}$$

Fermentation was thus to be considered as a chemical reaction. Yeast, which was not even classified as a definite substance (let alone an organism with remarkable powers of chemical synthesis and degradation), was thought to play a physical rather than a chemical part, an idea dating back to the time of Georg Stahl

(1697). The molecular vibrations of decomposing complex organic matter, it was held, could initiate the chemical reaction of fermentation in much the same way as a spark could cause the combination of hydrogen and oxygen. This attitude gained powerful reinforcement as new examples came to light of catalysis (*q.v.*), the name given to the action of certain substances of diverse character—*e.g.*, finely divided metals, acids and bases—which were found to accelerate the rate of a chemical reaction without themselves being materially altered. In 1817 it was found possible to oxidize a mixture of alcohol vapour and air to acetic acid by catalysis, using platinum as the catalyst. This apparently duplicated the action of the acetic acid ferment upon wine.

Moreover, about this time complex organic catalysts (then called ferments, now enzymes) began to be prepared from plants and from animal tissues and secretions: the starting material admittedly living, the enzyme preparations themselves equally obviously not. Among these were some which played a role in alcoholic fermentation. Yeast will not ferment starch, the molecule of which is made up of a large number of units of the simple sugar glucose linked together, because the large molecule cannot pass through the cell wall of yeast. Malt (sprouted barley) contains enzymes that split starch to the sugar maltose, made up of only two glucose units. which is fermentable. The conversion occurs during the mashing process of brewing. The agent responsible for this process, diastase (now known to be a mixture of enzymes), was prepared in 1833 by A. Payen and J. F. Persoz. Later, in 1860, P. E. M. Berthelot was to prepare from yeast itself the enzyme invertase, that splits sucrose (ordinary domestic sugar) into the simple sugars glucose and fructose.

Could not yeast, then, be simply considered as a catalyst? This is so close to the modern position as to make one wonder, at first, at the bitterness and fury with which the controversy over the mechanism of fermentation was conducted in the last half of the 19th century. It is now considered that the complex chemical changes of life are brought about by enzymes, each highly specialized in its catalytic action and responsible for one small step in such apparently simple reactions as the transformation of sugar to alcohol. However, enzymes themselves are produced only by living organisms, and if these marvelously active and specialized catalysts are to be used in a controlled way, it is the organism that must first be controlled. It was in insisting upon the importance, the primacy. of the living organism that Pasteur was right and his opponents wrong.

Pasteur: Fermentation as *La vie sans air* ("Life Without Air").—Establishing fermentation as a vital activity was not an exercise in experimental skill and logic; it was a triumph of the human spirit. And the 50-year-long fight to prove that it was the activity of a living organism was to lead to the germ theory of disease with its immeasurable consequences. Patient experimentation and intuition, rational argument and rhetoric, personal, national and professional pride. sheer chance. all played their part. Evidence of the living nature of yeast existed before Pasteur commenced work on the problem (1855). In 1837–38 three publications appeared, by C. Cagniard de la Tour, T. Schwann and F. Kiitzing respectively. all of whom as a result of microscopic observations concluded that yeast was a living organism that reproduced by budding. Schwann gave to it the name *Zuckerpilz* ("sugar fungus," whence comes the generic name *Saccharomyces* applied to types of yeast commonly used in baking and brewing) and explained alcoholic fermentation as "the decomposition brought about by this sugar fungus removing from the sugar and a nitrogenous substance the materials necessary for its growth and nourishment."

These views immediately aroused savage resentment and bitter scorn. Scientific innovators, for example Galileo, have often had to meet attacks from entrenched interests outside science; this time the attack came from organized science itself. with J. J. Berzelius. F. Wöhler, J. von Liebig (*qq.v.*) and other leaders of the chemical norld in the van. It is worthwhile to consider why this should have been so. For science, the 19th century was a period of transition. Shortly before its outset. Lavoisier had gone to the guillotine: "the Republic has no need of scientists." At its close, science had become the fount of industrial power, the scientist no longer an eccentric amateur but a dignified professional. Karl Marx's famous remark "the philosophers have only interpreted the world in various ways: the point, however, is to change it" would have found an echo in the hearts of many men of science of the time. Organic chemistry, in particular, had discarded the idea that substances of natural origin had anything essentially mysterious about them and was becoming established as the chemistry of carbon compounds. To reintroduce any concept which smacked of vitalism must have appeared as a dangerous and retrograde step.

In the succeeding 20 years the recognition of yeast as a living organism became more widespread, but its exact function in alcoholic fermentation remained a matter of controversy. It was still maintained that fermentation was due to catalytic action at the surface of the yeast cell, or to the transmission of molecular vibration from decomposing organic matter arising from the death of the cells. Nevertheless, when Pasteur was asked to investigate the difficulties a manufacturer was having with his fermentation process, he was already predisposed to take up a biological point of view. This was not apparently due to the publications of Cagniard de la Tour and others, but arose from his own researches in a purely chemical field.

In studying the optical activity of organic ccmpounds, which he correctly related to their molecular asymmetry, Pasteur had become convinced that optically active substances could not be synthesized by chemical methods. This is actually not the case, since the optical inactivity of synthetic products is sometimes due to their being mixtures of two forms of equal and opposite rotation. Nevertheless, his assertion that molecular asymmetry was correlated with life is, broadly speaking, correct. In alcoholic fermentation a certain amount of an optically active amyl alcohol was known to be produced. and this appeared to Pasteur to be possible only through some vital process.

In 1857 Pasteur showed that the malfunctioning of the fermentation process he was investigating was due to a new "ferment"—a minute organism which converted sugar into lactic acid. At this time there was no suspicion that lactic acid fermentation. for example of milk, involved anything other than a chemical change. Pasteur went on to study alcoholic fermentation itself and completely disproved the views of Liebig. His crucial experiment was to produce yeast by growing it in a liquid medium containing simple substances of known composition, sugar, ammonium tartrate and inorganic salts. Fermentation paralleled multiplication of the yeast. In this experiment he was to some extent fortunate for, as was shown later, yeast will not grow in such a simple medium from a very small seeding if the materials have been carefully purified, a finding which was to lead to the discovery that yeast and many other microorganisms require traces of vitamins for growth, as do higher forms of life. In a famous passage in *Études sur la bière* (1876), Pasteur was to summarize fermentation as *la vie sans air.* An abundant supply of air was found to suppress alcohol formation by yeast. Under such conditions, however, the organism grew more rapidly and was able to incorporate into its cell substance a far greater proportion of the sugar which had been transformed, a discovery which forms the basis of the modern pressed-yeast industry.

Buchner: Cell-Free Fermentation.—Fermentation was now established as a chemical change that occurred inside the cells of microorganisms, which were then called organized ferments, to distinguish them from unorganized ferments, of which diastase of malt had provided an early example. A relation between the two types of ferment was suspected by many. and in 1858 M. Traube had put forward the theory that all fermentations were due to ferments, definite chemical substances he regarded as related to the proteins and produced in the cells of the organism. Confusion between the two sorts of ferment was later to lead W. Kiihne to give the name enzymes to the substances then known as "unformed ferments."

Many investigators, including Pasteur, made unsuccessful attempts to liberate the fermentation enzyme from yeast. Success was not to come until 1897, and then almost fortuitously. Four years before, H. and E. Buchner had found that the cells of micro-organisms were disrupted when they were ground with sand. After yeast had been treated in this way, a yellow viscous liquid, free from cells, could be squeezed out with a hydraulic press. This was not intended for use in experiments on fermentation, but for pharmaceutical studies. As it kept badly, antiseptics were added; these proved unsuitable as the juice was being used in experiments with animals. Sugar was then tried as a preservative. The changes which occurred were recognized as fermentative — a feat of scientific imagination — by E. Buchner, who named the fermentation enzyme of yeast zymase. Zymase, it nas observed. differed in some respects from invertase, an enzyme from yeast known since 1860. It was less stable to heat. and catalyzed a reaction of greater complexity. That Buchner succeeded where so many others had failed seems to have been due partly to his fortunate choice of yeast, only a few types of which are suitable.

The Complexity of Zymase. — The complexity of alcoholic fermentation by living yeast was almost an article of faith with Pasteur, and in consequence it was realized from the outset that the production of alcohol and carbon dioxide from sugar by yeast juice probably occurred in a stepwise fashion, and that zymase was merely a convenient term for a mixture of an unknown number of enzymes. Cnraveling the whole story was to take nearly 40 years.

Three general methods were used in the attack on the zymase problem: (1) Suspected intermediates were added to yeast juice to see if they could be fermented. (2) The fermentation system was altered, either by removing some essential factor (such as a coenzyme, see below) or by interfering with certain steps by the addition of selective poisons (now called enzyme inhibitors). and the nature of the products of the modified process investigated. The use of inhibitors may be understood by considering a complex of enzymes which first convert a substance A to B then B to C and so on. If the conversion of B to C is interfered with. then B will accumulate instead of the usual end product and this increase in the concentration of B enormously facilitates its isolation and identification. (3) Individual enzymes themselves were separated from zymase and purified, and the intermediate reactions studied in isolation.

Of these methods, the second proved initially the most powerful. The first method often had value merely as confirmation, since it proved difficult. from a knowledge of synthetic organic chemistry. to predict the nature of the chemical intermediates involved in biochemical transformations. The third method, in essence the most decisive: had to wait until the technical problems of enzyme purification were solved. Enzymes, it must be realized. are chemically so complex that they can even now only be recognized by their action and not by chemical analysis. In the early days of enzymology chemists had no means of knowing how pure their preparations were. The unrecognized enormous potency of enzymes often led them to underestimate the degree of impurity of their preparation; in consequence, there was considerable controversy about the chemical nature of enzymes. The problem was further bedeviled by the fact that invertase, with which much early work was done, was in many ways atypical in its chemical properties. Finally, in 1926, J. B. Sumner succeeded in preparing an enzyme (from jack bean) in crystalline form, a cogent argument for its purity, and showed it to be a protein. This enzyme, urease. was extremely active and decomposed its own weight of urea in just over one second. It is now generally accepted that enzymes are proteins, and techniques for their isolation are well established. Many of those concerned in fermentation have been crystallized. Some are even available, in small quantities, commercially. One fermentation enzyme has found application in forensic medicine to estimate alcohol in the blood of motorists suspected of drunkenness.

Zymase itself in a sense constitutes an altered enzyme system. As shown by Sir A. Harden and W. J. Young in 1905, fermentation by yeast juice proceeds rapidly only when salts of phosphoric acid are added. For each molecule of sugar split to alcohol, one is esterified to form a sugar phosphate, fructose diphosphate, called the "Harden-Young ester." (In the living cell, other reactions outside the fermentation system reform free phosphate and prevent the accumulation of sugar phosphates.) Harden and Young made another fundamental advance when they found that the fermentative action of yeast juice depended not only upon enzymes, which have large complex molecules, but also upon a simpler substance which could be separated by ultrafiltration and which was to be classified as a coenzyme. (Coenzymes are agents not themselves enzymes, but necessary for the action of enzymes.)

At first the role of phosphorylation in the initial steps of the fermentation process gave rise to much controversy. Meanwhile a clue as to the nature of one of the later steps was provided by C. Neuberg's discovery (1911) of carboxylase in yeast and yeast juice. This enzyme splits pyruvic acid (*q.v.*) into acetaldehyde and 'carbon dioxide, and is now known to be responsible for the evolution of gas in alcoholic fermentation. A further important advance was made by G. Embden three years later, when he showed that fructose diphosphate was transformed to lactic acid by enzymes present in muscle preparations. It soon became evident that the characteristic fermentation process of animal tissue, glycolysis, the splitting of sugar into two molecules of lactic acid, showed striking similarities to alcoholic fermentation. From this time on, the nature of the intermediate steps in sugar breakdown was worked out sometimes with one system, sometimes with the other. The differences between the fermentation systems of different types of organism, which Pasteur found so striking, are less impressive than the similarities, when these systems have been analyzed into their component enzyme-catalyzed steps.

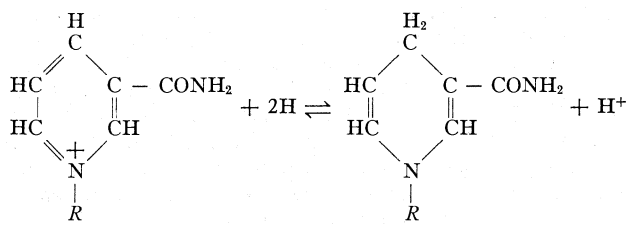
The Modern Position. — By 1939, as a result of the work of Embden. O. Meyerhof and others. knowledge of the intermediate steps in alcoholic fermentation and glycolysis was complete. In the course of its breakdown. the sugar molecule goes through about a dozen intermediate stages. The same number of enzymes, each highly specialized in the catalysis of a single step, is involved. As forecast by Lavoisier, Schwann and others, an oxidation-reduction process occurs, hydrogen being taken from one of the intermediates in an early step and transferred to one of the later intermediates. This is not a direct process. Hydrogen is first transferred to a carrier substance (diphosphopyridine nucleotide or cozymase), which is an example of a coenzyme (the one discovered by Harden and Young).. Another carrier molecule, or coenzyme. is involved in phosphate transfer. These coenzymes may be likened to the conveyer belts linking the machines (enzymes) in a factory assembly line. They are not so specialized as are the enzymes themselves, and they interact with many different enzymes concerned with processes other than fermentation. In so doing, they provide one means by which fermentation is integrated into the life of the cell as a whole.

In the 1930s cozymase was shown to contain nicotinamide, shortly afterward found to be the vitamin whose deficiency in human beings induces pellagra. Another fermentation coenzyme (cocarboxylase. concerned in the splitting of the intermediate pyruvic acid) was found to be related to thiamine: also a B group vitamin. This elucidation of the biochemical function of vitamins exemplifies the repercussions, in all fields of biochemical research, of the nork on fermentation.

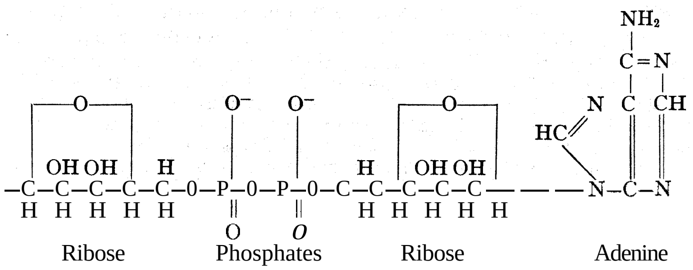
Diphosphopyridine nucleotide, the hydrogen-transferring coenzyme, has a complicated structure. It may be degraded chemically into a number of less complex substances, so that the coenzyme may be represented in terms of these units as

nicotinamide — ribose — phosphate — phosphate — ribose — adenine

Oxidation and reduction during fermentation affect only the nicotinamide part of the molecule, as shown by the equation:



Here R stands for the remainder of the molecule, namely:



The phosphate-transferring coenzyme; adenosine triphosphate, has the structure

adenine—ribose—phosphate—phosphate—phosphate

and the biochemical reaction of transfer involves only the terminal phosphate grouping. The function of the complex nonactive part of these molecules is to ensure that the coenzymes combine with the appropriate enzyme, with the active groups of atoms correctly positioned. It is generally found that biologically active molecules contain only a small "active centre." the remainder of the molecule conferring specificity in much the same way as the wards of a key adapt it to open one lock, or at most only a few. Different "keys" are constructed from simple units, such as adenine and other purine bases, sugars such as ribose, or amino acids, and the arrangement as well as the nature of these units determines the specificity of the biologically important molecule.

Yeast will ferment any one of three simple sugars: glucose, fructose and mannose. They differ only slightly in the arrangement of atoms in the molecule and can be converted one to the other by the action of dilute alkalies. The first step in fermentation is the addition to the sugar molecule of a phosphate group (transferred from a coenzyme). The three sugar monophosphates are interconvertible by enzymes which thus reproduce the catalytic action of alkali on the free sugars. From the trio of monophosphates one, fructose monophosphate, is selected for further transformation. A second phosphate group is accepted from the coenzyme to give fructose diphosphate. This molecule is split into halves. each retaining one phosphate group. The two substances so formed also belong to the class of (phosphorylated) sugars known as trioses. since the molecule contains only three carbon atoms; sugars such as glucose are termed hexoses, as their molecules have six carbon atoms. The two triose phosphates differ in the structure of their molecules in the same way as glucose monophosphate differs from fructose monophosphate, and are likewise interconvertible by a specialized enzyme. The action of the splitting enzyme, in reverse. can be imitated in the chemical laboratory; the free triose sugars can be made to combine to give fructose. by the catalytic action of alkalies.

In the next stage, the key to the whole process, one of the triose phosphates is oxidized, hydrogen being transferred to the carrier cozymase. The product remains attached to the enzyme, however, until a molecule of free inorganic phosphate (not phosphate bound to the phosphate-transferring coenzyme) is encountered, when the final step occurs by which phosphate is incorporated to form an intermediate containing two phosphate groups per molecule (diphosphoglyceric acid). This then undergoes, several intramolecular rearrangements, each catalyzed by its specific enzyme. The two phosphate groups are split off and bound to the phosphate-transferring coenzyme, and eventually pyruvic acid is formed. The net result is

$$\left\{\begin{array}{l}\text{glucose} \longrightarrow 2 \text{ pyruvic acid}\\ 2 \text{ cozymase} \longrightarrow 2 \text{ reduced cozymase}\\ 2 \text{ phosphoric acid} \longrightarrow \text{bound to coenzyme}\end{array}\right.$$

This series of enzyme reactions is common to sugar transformation in muscle and yeast. as well as some bacteria and plants. It is only the subsequent fate of the pyruvic acid that is different. In muscle, hydrogen is taken from reduced cozymase (which is thus restored to its original form) to give lactic acid. In yeast, pyruvate is first split to carbon dioxide and acetaldehyde; the latter accepts hydrogen to form alcohol. (Alcohol, however, is not formed when the yeast cell is abundantly supplied with air; in this case another complex system of enzymes converts pyruvic acid to carbon dioxide and water).

Especially as a result of studies of the bacterium Pseudomonas *fluorescens*, it has been realized that modifications of this scheme of carbohydrate breakdown occur in different organisms. In the one mentioned, glucose is first oxidized to gluconic acid. The similarities are. however, still more striking than the differences.

In the living yeast cell, the enzymes of the zymase system are enclosed within a membrane through which the phosphorylated intermediates cannot diffuse; as, normally, the cells occupy only a small proportion of the total volume, very little of the total sugar fermented is at any time present in the form of these intermediates. For this reason they escaped detection until the Buchners succeeded in liberating the enzyme complex from the cell.

The importance of phosphate, in its various forms, is clear from this summary of the chemical changes of alcoholic fermentation. In seeking further understanding of this point, it is necessary to refer to one of the most fruitful concepts of modern biochemistry, that combined phosphate is the form in which energy released by the degradation of the sugar molecule is preserved and subsequently transferred to all parts of the living cell. This energy is available for chemical synthesis, as in growth. In muscle it is converted to mechanical work, or it may appear in other forms, for example light, as in fireflies and luminescent bacteria, such as those responsible for the phosphorescent glow of rotting fish. The complexity of the fermentation process therefore becomes understandable if it is remembered that' its function is to enable the yeast cell to grow, *i.e.*, to synthesize new cell material. Zymase may be likened to an oil refinery producing both fuel oil (phosphorylated coenzyme) and raw materials for chemical processing (the intermediates of fermentation). The growth process of the yeast cell finds a counterpart in the manufacturer specializing, for example. in plastics production who requires a particular raw material and also oil to drive his machines. Also, he may require raw materials from other sources. in the same way as the yeast cell requires ammonium salts, for example, before it can construct protein molecules.

When yeast grows in the absence of air, part of the sugar transformed is incorporated as new cell substance, but a far greater part is excreted as alcohol. This apparent waste may be a means of rendering the sugar unavailable to other organisms and therefore valuable to the survival of the species. In air, more phosphorylated coenzyme is formed by enzymes outside the fermentation system and a greater proportion of the sugar can be used in building cell material.

Modern research on the biochemistry of fermentation falls into three broad classes: (1) the enzymes and reactions described are being studied in an increasing variety of organisms; (2) the individual enzymes are being examined in fine detail, in an effort to understand catalysis in terms of the molecular forces involved; (3) enzymes and their action are being investigated in situ in the living cell.

Industrial Fermentation Processes.—These start with the selection of a suitable microorganism. Each main type (*e.g.*, yeast or lactic acid bacteria) exists in a bewildering number of strains, and selection of the best one is of key importance. Fermentation conditions such as acidity, air supply and concentration of nutrients must be carefully adjusted in the light of the result aimed at.

Products may be of many types. In some cases. a major part of the raw material (usually sugar in some form) is transformed into the desired product. Examples are: alcohol. glycerol, carbon dioxide (marketed as dry ice) from yeast fermentations; butyl alcohol and acetone, lactic acid. acetic acid from fermentation by one or another type of bacterium; citric acid, gluconic acid from mold fermentations. Fermentation alcohol and acetone are being partially displaced by cheaper synthetic products. A notable product of bacterial fermentation is dextran. a gummy material. The bacteria responsible for this are well-known troublemakers in sugar refineries, but the product of their action under controlled conditions finds occasional application as a blood extender, to replace blood plasma transfusions.

A later development is the manufacture by fermentation of amino acids. an advantage over chemical synthesis being that only one of two possible optically active forms is produced. Japanese scientists devised a bacterial fermentation process to make L-glutamic acid. a widely used flavouring agent. L-lysine, a substance of great importance in human and animal nutrition, is manufactured in the U.S. The fermentation process is ingenious, in that it uses a mutant strain of a coliform organism; *i* e., an organism "created" in the laboratory by the action of ultra-violet radiation on the natural strain. This mutant is incapable of making the lysine it needs for its own growth and has to be supplied with this amino acid before it can be cultivated. But in exchange it forms in the course of fermentation a much greater amount of a precursor substance. which is then converted into lysine itself in a second stage of the process.

Other substances are produced in relatively small amount, so that their extraction and purification are more complicated. Predominant among these are the various antibiotics. These are made by mold fermentation, as are the antianemia factor vitamin B_{12} and the vitamin riboflavin. Antibiotics. and vitamin B_{12}. find increasing use outside medicine as supplements to poultry and animal foodstuffs.

In the manufacture of baker's yeast the organism itself is .the desired product. Enzymes extracted irom various microorganisms. usually in rather crude form. are also valuable. Invertase, from yeast, is used to prevent the crystalization of sugar in the manufacture of soft-centred chocolates. In the textile industry. bacterial and fungal amylases find application in removing starch sizing from cloth. Among other enzymes. an interesting one is glucose oxidase, used to destroy glucose which otherwise would cause browning and deterioration of dried eggs. Yeast fermentation has been employed as an adjunct to synthetic methods in pharmaceutical manufacture. Here what is sought is not a product of the fermentation itself, but a change (usually reduction) of some chemical added to the fermentation. Benzaldehyde in this way yields a product which can be further converted, by purely chemical methods, to ephedrine. Phytochemical reduction is also being applied in the synthesis of steroids related to cortisone. These methods have the advantage of producing only one of two possible optically active forms, an interesting echo of Pasteur's insistence on the connection between molecular asymmetry and life. FERMI, ENRICO (1901–1954), Italian-U.S. physicist. Nobel prize winner (1938) for research on artificial radioactive substances. directed the first controlled nuclear chain reaction (*see* ATOMIC ENERGY: *Achievement of a Chain Reaction*) at The University of Chicago, Dec. 2, 1942. and was first winner of the special award, which now bears his name, of $50.000 for work on the atom. Born in Rome, Sept. 29, 1901. he received a doctorate irom the University oi Pisa in 1922. He was lecturer at the University of Florence, 1924–26, and professor of theoretical physics at the University oi Rome, 1927–38. In 1934 Fermi demonstrated that nuclear transformation occurs in nearly every element subjected to neutron bombardment (*see* NEUTRON). To escape Mussolini's iascist decrees, Fermi went to the U.S., where he became professor of physics at Columbia university in 1939; he was later associated with The University oi Chicago and Los Alamos, N.M., atomic energy research programs. In 1945 he became a U.S. citizen and was appointed proiessor in the Institute ior Nuclear Studies of The University of Chicago, where he remained until his death on Nov. 28, 1954.

See Laura Fermi, *Atoms in the Family—My Life With Enrico Fermi* (1954).

FERMIUM. The synthetic element fermium has the chemical symbol Fm and the atomic number 100. It occupies a position in the periodic system of the elements as the 11th member of a rare-earthlike transition series. the actinide series. which includes the heaviest known elements and in which an inner electronic shell (the 5f shell) is being filled. The eighth transuranium element to be discovered. it was first identified by A. Ghiorso and coworkers. For a discussion of its discovery, see TRANSURANIUM ELEMENTS.

As in the case of a number of the other actinide elements, there is no completely logical assignment of atomic weight because the isotopic composition is variable, depending on the source. If there is a formal requirement for this quantity the use of the mass number of the longest-lived isotope might be considered. Since the longest-lived fermium isotope known in the early 1960s was Fm^{253}. it seemed unlikely that this element could be isolated in weighable amount. Its chemical properties have been studied on a tracer scale. and in aqueous solution only the III oxidation state appears to exist. Most of the chemical studies have been concerned with the determination of its ion exchange properties.

Isotopes of Fermium

Isotope	Half life	Type* and energy of radiation (Mev)	Isotope	Half life	Type* and energy of radiation (Mev)
$Fm^{248, 249}$	short	a	Fm^{253}	4.5 days	EC, a 6.94
Fm^{250}	—0.5 hr.	a 7.43	Fm^{254}	3.24 hr.	α 7.20
Fm^{251}	7 hr.	EC a (1%) 6.89	Fm^{255}	22 hr.	a 7.1
Fm^{252}	23 hr.	α 7.04	Fm^{256}	3 hr.	SF

*EC = electron capture; a = alpha particle; SF = spontaneous fission.

Fermium can be separated from the other tripositive actinide elements by adsorption and elution from columns packed with ion exchange resins. Separation from the rare-earth elements can be effected by the use of eluting agents such as concentrated hydrochloric acid, which forms complex ions with the actinide elements which are much more stable than the corresponding ions formed with the rare-earth elements. Since fermium is the 11th member of the actinide transition series it seemed probable that the chemistry of the tripositive ion would be similar to that of the corresponding ions of other members of the series.

The isotope Fm^{254} and heavier fermium isotopes can be produced by intense neutron bombardment of elements of lower atomic number. such as plutonium, by a process of successive neutron capture reactions interspersed with beta particle decays until atomic number 100 and these mass numbers are attained.

See J. J. Katz and G. T. Seaborg, *The Chemistry of the Actinide Elements* (1957); G. T. Seaborg, *The Transuranium Elements* (1958). (G. T. SG.)

FERMO, a town and archiepiscopal see of the Marches, Italy (anc. Firmum Picenum), province of Ascoli Piceno, on a hill 1.046 ft. above sea level. Pop. (1957 est.) 28.267 (commune). The summit of the hill was occupied by the citadel until 1446. It is crowned by the cathedral. reconstructed in 1227. Against the side of the hill was built the Roman theatre; scanty traces of an amphitheatre also exist. Remains of the city wall may be seen.

The church of S. Francesco has a tower and choir in brickwork of 1240. Under the Dominican monastery is a large Roman reservoir in two stories. The piazza contains the Palazzo Comunale, restored in 1446, with a statue of Pope Sixtus V in front. Porto S. Giorgio has a fine castle of 1269, blocking the valley which leads to Fermo.

The ancient Firmum Picenum was founded as a Latin colony in 264 B.C., after the conquest of the Picenes, as the local headquarters of the Roman power, to which it remained faithful. It was originally governed by five quaestors. It was made a colony with full rights after the battle of Philippi, the 4th legion being settled there. It lay at the junction of roads to Pausulae, Urbs Salvia and Asculum, being connected with the coast road by a short branch road from Castellum Firmanum (Porto S. Giorgio). In the 10th century it became the capital of the Marchia Firmana. In 1199 it became a free city and remained independent until 1550, when it became subject to the papacy

FERN, a name often used to denote the whole botanical class of Pteridophyta, including both the true ferns, Filicales, by far the largest group of this class in the existing flora, and the fern allies, Equisetales, Lycopodiales, etc. *(see* BRYOPHYTA; PTERIDOPHYTA).

FERNALD, MERRITT LYNDON (1873–1950), U.S. botanist noted for his publications in plant systematics and plant geography. was born in Orono, Me., Oct. j, 1873. Fernald published works extending over a 60-year period beginning with his first published paper in 1890. He was educated and spent his entire professional career at Harvard university, ultimately becoming (191j) Fisher professor of natural history and director of the Gray herbarium (1937). He was the recognized authority on the vegetation of eastern North America and propounded the so-called nunatak hypothesis to explain the persistence of plants through the ice age in areas largely covered by glaciers. His principal books are. the 7th edition of *Gray's Manual of Botany;* (with Benjamin L Robinson), (1908); *Persistence of Plants in L'nglaciated Areas of Boreal America* (1925); and *Edible Wild Plants of Eastern North America* (aith Alfred C. Rinsey) (1943); 8th (centennial) edition of Gray's *Manual of Botany* (1950). (R. C. R.)

FERNANDES, ÁLVARO (fl. 15th cent.), the most successful Portuguese captain of the earlier 1jth century, was sent southward by Prince Henry the Navigator to explore the west African coast. Most of the Portuguese made little progress beyond Arguin, and were only concerned uith slave raiding. When Prince Henry's expedition of 1445 sailed for Arguin, Fernandes was entrusted by his uncle, Gonçalves Zarco, discoverer of Madeira, with a caravel, under injunctions to devote himself to discovery. After visiting the mouth of the Senegal and rounding Cape Verde he continued to the "Cape of the Masts," 50 leagues beyond Cape Verde. In 1446 he returned to west Africa and coasted on to a bay 110 leagues beyond Cape Verde, little short of Sierra Leone. This was the farthest reached by Portuguese exploration during Prince Henry's lifetime and was not surpassed until 1462. A wound from a poisoned arrow compelled Fernandes to return to Portugal. He made no further effort to explore the African coast, as Prince Henry was content to establish trade in slaves, ivory and gold dust with Guinea (the region of the Senegal and Gambia). (A. Ds.)

FERNANDES, JOÃO (fl. 1446), Portuguese traveler who stayed seven months with the nomads of Rio de Oro, played an important part in Portuguese expansion in Africa. In 1445 he went with a Portuguese trading ship to the Río de Oro, at a latitude of about 23° N. An elderly Moorish trader wished to go back in the ship to investigate trade possibilities in Portugal; and Fernandes, then a young squire, volunteered to stay with the Moorish family as hostage, having already learned Arabic when a captive in Morocco before this date. Jews, French and Italians had earlier accompanied trade caravans into the Sahara. and Fernandes was nelcomed by the nomads with their customary hospitality. The nomads had horses and lived by herding sheep, having to move every eight days in search of fresh pasture. They lived mainly on milk, mutton and dates, while grain from Morocco was exchanged for slaves and gold dust from the Sudan. They were Moslem but did not speak Arabic. Fernandes was taken south across the desert to visit an old patriarch who from time to time went to the Sudan to trade for slaves and gold dust. He found that the nomads got their slaves from Negro kings who raided other tribes. Fernandes re-embarked at about 19° N. and was able to give Prince Henry the Navigator detailed information of the western Sahara and the trade with Guinea. Until then the Portuguese had raided the coasts for slaves as far south as the Senegal, but this roused hostility, and the Negroes repelled Portuguese attacks with poisoned arrows. From 1448 Prince Henry stopped slave raiding and made exchange treaties with Moorish and Negro chiefs, a vastly more profitable policy that made further exploration along the coast unnecessary. In 1446 and 1447 Fernandes again visited Río de Oro to arrange trade agreements.

See Gomez Eannes de Azurara, *Chronica . . . de Guiné.* (A. Ds.)

FERNÁNDEZ, GREGORIO: *see* HERNÁNDEZ, GREGORIO.

FERNÁNDEZ, JUAN (1536?–1604?), a navigator in the service of Spain, in 1563 made a celebrated voyage from Callao to Chile which won him the title of *brujo* ("wizard"). By sailing out to the westward he avoided the southerly offshore winds and reached Valparaiso in only 30 days. He discovered the islands San Félix and San Ambrosio in 1574 (according to Sarmiento de Gamboa and Leonardo de Argensola); and at an uncertain date (probably sometime between 1563 and 1574) discovered the group of islands which bear his name, establishing a settlement there which included goats. On the failure of this settlement (1580) he resumed his work as a pilot and died in about 1604. The tradition that he had discovered the southern continent in latitude 40° S., to the west of Chile, originated in a memorial by Juan Luis Arias, written after 1614.

M. Ws.)

FERNÁNDEZ, LUCAS (1474?–1542), Spanish dramatist and musician, whose plays are notable for their effective dialogue. simple humour and skillful use of interpolated songs and music. was born and educated at Salamanca. He was professor of music there from 1522. His six plays (1514) show clearly the influence of Encina *(q.v.)*, his rival as a musician. His most impressive work is the *Auto de la Pasión,* the others being short homely Christmas pieces and comic shepherd plays. His *Diálogo para cantar* (1514) is a shepherd duologue set to a popular tune and is the first example of a rudimentary zarzuela (a Spanish form of musical comedy). (J. Gs.)

FERNÁNDEZ NAVARRETE, JUAN (c. 1526–1579). Spanish painter of the Spanish Mannerist school, called EL MUDO (because he was mute), was born in Logroño. He is said by José de Sigiienza *(Historia de la Orden de San Jerónimo,* 1605) to have studied in Italy under Titian and others and to have been summoned back to Spain by Philip II. In 1568 he was appointed painter to the king. who chose him to play a major role in the decoration of the Escorial. near Madrid (1576), though he did not live to fulfill it; of the 32 altarpieces commissioned for the church only 8 were completed at the time of his death in Toledo on March 28, 1579.

El Mudo's eclectic style was based on that of the Italian Mannerists working in the Escorial; and he was strongly influenced by Titian, though there is no evidence that he was his pupil. In the "Burial of St. Lawrence" (Escorial), unfinished at his death, naturalism and chiaroscuro foreshadow later developments of the Spanish school. (E. Hs.; X.)

FERNANDO DE NORONHA, a Brazilian island in the South Atlantic ocean located some 225 mi. N.E. of Cape São Roque. The main island is 7 mi. long by $1\frac{1}{2}$ mi. wide. A neighbouring island has an area of $3\frac{1}{2}$ sq.mi., and there are several rocky islets. The islands are of volcanic origin and have steep, unprotected shore lines. The highest peak on the main island rises 1,089 ft. above sea level. The temperatures are always mild because of the island's latitude 3° 49' S. of the equator and its exposure to the full sweep of the southeast trade winds. The temperature ranges from an average of 78.8° F. in March to 75.2° in August. The rainy season is from February to June. During the long dry season there is often a serious shortage of water, although the average annual rainfall is 42.6 in. The population, (1950) 648, fluctuates considerably because most of the inhabitants are in the military garrison. The population in 1940 was 1,065. In the 18th century it was a penal colony, and some prisoners are still sent to the island.

The island was given to Fernando de Noronha, its discoverer, in 1504. Later it became a dependency of Pernambuco. In the 17th and 18th centuries it was attacked several times by naval powers, but the Portuguese successfully defended it. In 1942 the island was made a federal territory. Of little importance economically, its main products are salt and guano. However, Fernando de Noronha has considerable strategic importance because of its position off the bulge of Brazil. The island lies in the 5,500-mi. rocket-firing corridor between Cape Canaveral, Fla., and Ascension Island. An agreement was concluded on Jan. 21, 1957, between the U.S. and Brazil whereby a guided-missile tracking station was established under a five-year concession. (P. E. J.)

FERNANDO PO (or Poo), a Spanish island lying some 20 mi. off the Cameroon coast of west Africa. It is fi9 sq.mi. in area, volcanic and precipitous, but more fertile than most of west Africa. With the island of Annobón it constitutes an African province of Spain. *See* SPANISH GUINEA. (R. J. H. C.)

FERNDALE, a city of Oakland county, in southeastern Michigan, U.S., is one of Detroit's northern suburbs, about 2 mi. N. of Highland Park (*q.v.*). The Eight Mile road forms its southern boundary and the Ten Mile road its northern. Ferndale became a village in 1918. The increase in Ford car production along with the war industries of World War I brought many people to the area. The open farm lands in the north Woodward area provided homesites for these workers. It was incorporated as a village in 1919 and during the 1920s the area built up rapidly. In 1927 Ferndale was incorporated as a city. A council-manager form of government has been in effect since 1924. Ferndale is both residential and industrial. For comparative population figures *see* table in MICHIGAN: *Population.* (F. E. LE.)

FEROZEPUR (FIROZPUR), a municipal town, *tehsil* and district in the Punjab state. India. The town is about 4 mi. from the Sutlej. Population (1951) 40.703 (excluding the cantonment area with a population of 38,784).

British rule was first established at Ferozepur in 1835, when, on the failure of heirs to the Sikh family who possessed it, a small territory 86 mi. in extent became an escheat to the British government; the district was gradually formed around this nucleus. The strategic importance of Ferozepur was at that time very great: and when. in 1839, Capt. (afterward Sir) Henry Lawrence took charge of the station as political officer. it was the outpost of British India in the direction of the Sikh power. Ferozepur accordingly became the scene of operations during the first Sikh War. The Sikhs crossed the Sutlej in Dec. 1845 and were defeated successively at Mudki. Ferozeshah. Aliwal and Sobraon, after which they withdrew into their own territory, and peace was concluded at Lahore.

Ferozepur rapidly advanced in material prosperity to become a seat of commerce, trade being mainly in grain. It is the site of three colleges affiliated to the Panjab (India) university. Ferozepur *tehsil* (pop., 1951, 255,342) covers an area of 680 sq.mi.

FEROZEPUR DISTRICT comprises an area of 4,107 sq.mi. and had in 1961 a population of 1,620,389. The surface is level, with the exception of a few sand hills in the south and southeast. The country consists of two distinct tracts, that liable to annual fertilizing inundations from the Sutlej, and the upland tract. The only river is the Sutlej, which runs along the northwestern boundary. The principal crops are wheat, barley, millet, gram, pulses, oilseeds, cotton. tobacco, etc. The other important towns and seats of commerce are Moga (pop., 1951, 36,598), Fazilka (25,-934). Abohar (25.476) and Muktsar (22,097). The district is watered by the Sirhind canal and by canals from the Sutlej, the Bikaner. the Eastern and the Dipalpur canals.

FERRABOSCO or FERABOSCO, the name of a family of musicians of Italian origin who settled in England in the 16th century. The father, DOMENICO MARIA (1513–1574), was choirmaster at Bologna and at the Basilica Vaticana, Rome, and then a singer in the papal chapel. He wrote madrigals and motets.

His son ALFONSO (d. 1588), madrigalist, settled in England before 1567, when he received a pension from the queen and became intimate with William Byrd. He returned to Italy in later life and died at Turin. His madrigals were printed at Venice in 1587. He was highly esteemed in England, and Henry Peacham, in his *Compleat Gentleman,* says that "in judgment and depth of skill he was inferior unto none." Many of his madrigals and motets found their way into English collections, such as Yonge's *Musica Transalpina,* Leighton's *Teares or Lamentations.*

His son ALFONSO (d. 1628), lutanist and composer. was born and died at Greenwich. He was one of the king's musicians for the violin under James I. He wrote the music for five masques by his friend Ben Jonson between 1605 and 1609. He was music master to Prince Henry and then to Prince Charles (Charles I) and, mhen Charles came to the throne, became "composer of the king's music." He published a book of *Ayres* (1609). containing songs written for Jonson's masques, and *Lessons for 1, 2 and 3 Viols* (1609).

His son, also named ALFONSO (d. *c.* 1660), succeeded (1628) his father as a viol player in the king's band. He and his brother Henry jointly held the post of musician in ordinary to the king. Both the brothers died before July 4, 1661. John Ferrabosco. organist at Ely cathedral, who died in 1682, belonged to the same family.

FERRAR, NICHOLAS (1592–1637), English theologian, was born in London in 1592 and educated at Clare Hall. Cambridge. graduating in 1610. In 1618 he became actively connected with the Virginia company. When in 1623 it was deprived of its patent, he entered parliament; but, soon deciding to devote himself to a religious life, he purchased the manor of Little Gidding. Huntingdonshire, where he organized a small religious community. There. in 1626. Ferrar was ordained a deacon by Laud. and declining preferment, he lived an austere, almost monastic life of study and good works. He died on Dec. 4, 1637. and the house was despoiled and the community broken up ten years later. There are extant a number of "harmonies" of the Gospel. printed and bound by the community. two of them by Ferrar himself. One of the latter was made for Charles I on his request, after a visit in 1633 to see the "Arminian Nunnery at Little Gidding." Little Gidding is described in Shorthouse's *John Inglesant.*

FERRAR, ROBERT (*c.* 1500–1555), bishop of St. David's and martyr. born of a Yorkshire family, is said to have studied both at Cambridge and Oxford before he became a canon regular of St. Xugustine. As soon as the heresy laws were re-established under Mary, Ferrar was sent down to be tried by his successor at St. David's. He was burnt at the stake at Carmarthen on March 30. 1555.

See the article by T. F. Tout in the *Dict. Nat. Biog.*

FERRARA, a city and archiepiscopal see of Emilia–Romagna, Italy, capital of the province of Ferrara, 30 mi. S.N.E. of Bologna, situated on the Po di Vomano, a branch channel of the main stream of the Po. Pop. (1957 est.) 144,801 (commune). The town has broad streets and numerous palaces, which date from the 16th century, when it was the seat of the court of the house of Este.

The most prominent building is the square castle of the house of Este, a brick building surrounded by a moat, with four towers. It was built after 1385 and partly restored in 1554–70. The Palazzo del Municipio, rebuilt in the 18th century, was the earlier residence of the Este family. Close by is the cathedral of S. Giorgio, consecrated in 1135. It was built by Guglielmo degli Adelardi (d. 1146). Opposite the cathedral is the Gothic Palazzo della Ragione, in brick (1315–1326), now the law courts. A little nay off is the free university. It has faculties of law, medicine and natural science. The Palazzo de' Diamanti, contains the municipal picture gallery, with a large number of pictures of artists of the school of Ferrara.

The origin of Ferrara is uncertain, and probabilities are against the supposition that it occupies the site of the ancient Forum Alieni. It mas probably a settlement formed by the inhabitants of the lagoons at the mouth of the Po. It appears first in a document of Aistulf of 753 or 754 as a city in the exarchate of Ravenna. After 984 we find it a fief of Tedaldo, count of Modena and Canossa, nephew of the emperor Otho I. It afterward made itself independent, and in 1101 was taken by siege by the countess Matilda. At this time it was mainly dominated by several great families, among them the Adelardi. In 1146 the property of Guglielmo Adelardi passed, as the dowry of his niece Marchesella, to Azzolino d'Este. After considerable struggles Azzo Novello was nominated perpetual podestà in 1242; in 1259 he took Ezzelino of Verona prisoner in battle. His grandson, Obizzo II (1264–1293), succeeded him, and the pope nominated him captain-general and deiender of the states of the church; and the house of Este mas from henceforth settled in Ferrara. Rorso received the fiefs of Modena and Reggio irom the emperor Frederick III as first duke in 1452 (in which year Girolamo Savonarola was born there), and in 1470 mas made duke of Ferrara by Pope Paul II. Ercole I (1471–1505) and his son Alfonso I (m. Lucrezia Borgia) carried on war with Venice. In 1509 he was excommunicated by Julius II, and attacked the pontifical army in 1512 outside Ravenna, which he took. Gaston de Foix fell in the battle. With the succeeding popes Alfonso was able to make peace. He was the patron of Ariosto from 1518 onwards. His son Ercole II (duke, 1534–59) married Renata, daughter of Louis XII of France. His son Alfonso II married Barbara, sister of the emperor Maximilian II. He raised the glory of Ferrara to its highest point, and was the patron of Tasso and Guarini, iavouring, as the princes of his house had always done, the arts and sciences. For its majolica *see* POTTERY AND PORCELAIN. He had no legitimate male heir, and in 1597 Ferrara was claimed as a vacant fief by Pope Clement VIII. The town remained a part of the states of the church, the fortress being occupied by an Austrian garrison from 1832 until 1859, when it became part of the kingdom of Italy.

A considerable area within the walls of Ferrara is unoccupied by buildings, especially on the north, where the handsome Renaissance church of S. Cristoforo, with the cemetery, stands; but modern times have brought a renewal oi industrial activity. Knitted goods and shawls are made. Ferrara is on the main line from Bologna to Padua and Venice, and has branches to Ravenna, Poggio Rusco (fcr Suzzara), Cento and Comacchio. At Pontelagoscuro, which is within the commune of Ferrara, is a railway bridge over the Po and a large soap and candle factory.

See G. Agnelli, *Ferrara e Pomposa* (1902); E. G. Gardner, *Dukes and Poets oj Ferrara* (1904); K. Chledowski, *Der Hof von Fevrara* (1919); Arti Grafiche; G. Facchini, *La Storia di Ferrara* (1933).

FERRARA-FLORENCE, COUNCIL OF. The council of Ferrara and Florence was the culmination of a series of futile mediaeval attempts to reunite the Greek and Roman churches. The emperor, John VII Palaeologus, had been advised by his experienced father to avoid all serious negotiations, as they had invariably resulted in increased bitterness; but John, in view of the rapid dismemberment of his empire by the Turks, felt constrained to seek a union. The situation was, however, complicated by the strife which broke out between the pope (Eugenius IV) and the oecumenical council of Basel. Both sides sent embassies to the emperor at Constantinople, as both saw the importance of gaining the recognition and support of the east, for on this practically depended the victory in the struggle between papacy and council for the supreme jurisdiction over the church (*see* BASEL, COUNCIL OF). The Greeks, fearing the domination of the papacy, were at first more favourably inclined toward the conciliar party; but the astute diplomacy of the Roman representatives, who have been charged by certain Greek writers with the skilful use of money and of lies, won over the emperor. With a retinue of about 700 persons, entertained in Italy at the pope's expense, he reached Ferrara early in March 1438, and in the following month the Union Synod was solemnly inaugurated on April 9, 1438. After several months of negotiation, it seemed for several reasons advisable to transfer the council to Florence. There ensued long debates and negotiations on the *filioque*, in which Markos Eugenikos, archbishop of Ephesus, spoke for the irreconcilables; but the Greeks under the leadership of Bessarion, archbishop of Nicaea, and Isidor, metropolitan of Kiev, at length made a declaration on the *filioque* (June 4), to which all save Markos Eugenikos subscribed. On the next topic of importance, the primacy of the pope, the project of union nearly suffered shipwreck; but here a vague formula was finally constructed which, while acknowledging the pope's right to govern the church, attempted to safeguard as well the rights of the patriarchs. On the basis of the abovementioned agreements, as well as of minor discussions concerning purgatory and the Eucharist, the decree of union was drawn up in Latin and in Greek, and signed on July 5 by the pope. the Greek emperor and all the members of the synod save Eugenikos and one Greek bishop who had fled; and on the following day it was solemnly published in the cathedral of Florence.

The council, however, desirous of negotiating unions with the minor churches of the east, remained in session for several years, and seems never to have reached a formal adjournment. The decree for the Armenians was published on Nov. 22, 1439; they accepted the *filioque* and the Athanasian creed, rejected Monophysitism and Monothelitism, agreed to the developed scholastic doctrine concerning the seven sacraments and conformed their calendar to the western in certain points. On April 26, 1441, the pope announced that the synod would be transferred to the Lateran; but before leaving Florence a union was negotiated with the oriental Christians known as Jacobites. The *Decretum pro Jacobitis,* published on Feb. 4, 1442, is, like that for the Armenians, of high dogmatic interest, as it summarizes the doctrine of the great mediaeval scholastics on the points in controversy. The decree for the Syrians, published at the Lateran on Sept. 30, 1444, and those for the Chaldeans (Nestorians) and the. Maronites (Monothelites), published at the last known session of the council on Aug. 7, 1445, added nothing of doctrinal importance. Though the direct results of these unions were the restoration of prestige to the absolutist papacy and the bringing of Byzantine men of letters, like Bessarion, to the west, the outcome was on the whole disappointing. Of the complicated history of the "Uniate" churches of the east it suffices to say that Rome succeeded in securing but fragments, though important fragments, of the greater organizations. As for the Greeks, the union met with much opposition, particularly from the monks, and was rejected by three oriental patriarchs at a synod of Jerusalem in 1443; and after various ineffective attempts to enforce it, the fall of Constantinople in 1453 put an end to the endeavour. As Turkish interests demanded the isolation of the oriental Christians from their western brethren, and as the orthodox Greek nationalists feared Latinization more than Mohammedan rule, a patriarch hostile to the union was chosen, and a synod of Constantinople in 1472 formally rejected the decisions of Florence.

Creighton, *History of the Papacy during the Period of the Reformation,* vol. ii, 173 *sqq.* and the general church histories under reference to the Greek Church.

FERRARI, GAUDENZIO (1470/80–1546), Italian artist of the Lombard school and a painter of frescoes and altarpieces, was born at Valduggia in Piedmont. He was stated to be *annorum circa 75* when he died in Milan on Jan. 31, 1546, but he probably was born between 1475 and 1480. His earliest dated work is of 1507. The painter and writer G. P. Lomazzo, who was a pupil of one of Gaudenzio's pupils, says that he studied first under the obscure Stefano Scotto and then under Bernardino Luini; the latter's influence is visible in Gaudenzio's works, as is also that of the Milanese B. Suardi, called Bramantino. On the whole, however· Gaudenzio seems to belong to the older Lombard school, relatively little influenced by Leonardo da Vinci. He is perhaps not ranked as highly as he might be, largely because his major works are in remote churches, but Lomazzo placed him seventh among the painters of Italy.

His earliest works were done at Varallo (near the Swiss border), where he painted the frescoes in the chapel of S. Margherita in S. Maria delle Grazie in 1507, as well as an altarpiece (probably now in Turin, Galleria Sabauda) which was contracted for in 1508, and some frescoes in 1513. His major work, however, was the decoration of some of the chapels on the Sacro Monte at Varallo, a task that occupied many years. In this work he made an ambitious attempt to secure extreme realism by setting coloured terracotta figures against a frescoed background, but it is arguable that this waxworks effect defeats its own ends.

In 1510 and 1511 he painted an altarpiece for S. Maria at Arona; in 1514 he worked on the S. Gaudenzio altar at Novara, which established his fame and secured further commissions in the region. From 1jag to 1535 he is documented as living and working at Vercelli, but between 1534 and 1536 he painted the "Angelic Choir" in the dome of S. Maria dei Miracoli at Saronno. In 1539 he moved to Milan, where he spent the rest of his life and where he painted several frescoes in churches. There are other works by him in European galleries and in Sarasota, Fla.

See G. P. Lomazzo, *Trattato dell'Arte* (1584), *Idea del Tempio* (1590); E. Halsey, *Gaudenzio Ferrari* (1904) and the catalogue of the Vercelli exhibition, *Mostra di Gaudenzio Ferrari* (1956) with full bibliography. (P. J. My.)

FERRARI, GIUSEPPE (1812–1876), Italian philosopher, historian and politician, was born at Milan on March 7, 1812, and died in Rome on July 2, 1876. After studying law at Pavia, he edited the works of Vico, prefaced by an appreciation (1835). He then went to France and, in 1839, produced his *Vico et l'Italie,* followed by *La Nouvelle Religion de Campanella* and *La Theorie de l'erreur.* In 1840 he was made professor of philosophy at Rochefort, and in 1842 was transferred to Strasbourg. Owing to trouble with the clergy, he returned to Paris and published *Idées sur la politique de Platon et d'Aristote,* a defense of his theories. From 1849 to 1858 he devoted himself exclusively to writing, publishing *Les Philosophes Salariés, Mackiavel juge des révolutions de notre temps* (1849), *La Federazione repubblicana* (1851), *La Filosofia della rivoluzione* (1851), *L'Italia dopo il colpo di Stato* (1852), *Histoire des révolutions, ou Guelfes et Gibelins* (1858; Ital. trans., 1871–73). In 1859 he returned to Italy, opposed Cavour, and upheld federalism against the policy of a single Italian monarchy. He held chairs of philosophy at Turin, Milan and Rome, and was made senator in May 1876. His other works include *Histoire de la raison d'état, La China e l'Europa, Corso d' istoria degli scrittori politici italiuni.* A sceptic and phenomenalist in philosophy, a revolutionist in politics, Ferrari was admired as an orator and as a writer.

See Marro Macchi, *Annuario istorico italiano* (Milan, 1877); A. Mazzoleni, *Giuseppe Ferrari* (Milan, 1877); C. Werner, *Die ital. Philosophie des 19. Jahrh.* vol. 3 (Vienna, 1885), P. Nicoli, *La Mente di G. Ferrari* (1902); *Le Pid Belle Pagine di G. Ferrari* (Milan, 1927).

FERRARI, LODOVICO (1522–1565), Italian mathematician, is chiefly known for his solution of the biquadratic equation (an equation which contains the iourth power of the unknown quantity but no higher power). He was born in Bologna. Feb. 2, 1522. As a lad of 1j he came into the service of Girolamo Cardano (*q.v.*) in Milan, and most of the information about him can be found in Cardano's writings. He reputedly had a fiendish temper; when 17 he lost most of the fingers on the left hand in a brawl. Cardano taught him Latin, Greek and mathematics. In 1540 he became Cardano's successor as public mathematics lecturer in Milan after deieating Zuan da Coi, Brescian mathematician. At this time he iound the solution of the quartic equation, later published in Cardano's *Ars Magna.* He invented a mechanism for transforming circular into rectilinear motion, and considered geometric constructions with a fixed compass opening. The publication of the *Ars Magna* brought Ferrari into a celebrated scientific controversy with Niccolò Tartaglia in regard to the solution of the cubic equation. After six printed cartels and countercartels Ferrari was declared the winner in a public dispute in Milan on Aug. 10, 1548. Subsequently Ferrari was deluged with offers—from Rome, Venice. from Charles de Brissac. the French commander in chief, and even from the emperor Charles V to he tutor for his son. He accepted an offer from Ercole Cardinal Gonzaga, regent of Mantua, to become supervisor of tax assessments, a position which in a short time made him a wealthy man. Later. ill-health and a quarrel with the cardinal made him take a professorship in mathematics at the University of Bologna. He died shortly afterward, in Oct. 1565; Cardano suspected that Ferrari had been poisoned for the sake of his money by his sister Magdalena and her lover.

See E. Giordani. *I sei cartelli di matematica disfida di Lodovico Ferrari (1876);* O. Ore, *Cardano, the Gambling Scholar* (1953). (O. Oe.)

FERRE, CHARLES THEOPHILE (1845–1871), chief of police of the Paris commune, was until March 1871 one of the lesser known followers of L. A. Blanqui (*q.v.*). He was elected to the commune for the 18th arrondissement, polling the very. high figure of 13.784 votes. Together with Raoul Rigault, a man as young as himself, he was placed in charge of the police. Like Marat of the French Revolution, Ferré of the commune has been invested with the reputation of a monster of terrorism. The department of the police was not., indeed, very wisely run; arrests were made widely, haphazardly and clumsily. but the commune mas at least protected from internal trouble. Ferré always supported the most violent motions, in particular (after the shooting of Duval) a motion declaring that the hostages in the hands of the commune mould be executed if the government troops killed any more communard prisoners. This decree was not carried out until after the government troops had broken into Paris. when. ascertaining that they were again shooting communard prisoners: Ferré ordered the execution of the hostages. including Archbishop Darboy. At his trial before the court-martial he defended hi's action and defied the court. He was shot at Satory on Nov. 28, 1871.

See P. Larousse, *Dictionnaire du XIXe siècle, s.v.* "Ferré" (1872); G. Da Costa, *La Commune Vécue* (1901); R. W. Postgate, *Out of the Past* (1922); A. Dayct, *La Guerre, La Siège, La Commune d'après les peintures, gravures, photographies, sculptures, médailles, autographes, et objets du temps* (1901). (*See* also COMMUNE.)

FERREIRA, ANTONIO (1528–1569), Portuguese poet, was a native of Lisbon; his father was employed in the house of the duke of Coimbra at Setubal, and the poet was educated at the University of Coimbra, where he eventually became a professor. The sonnets forming the First Book in his collected works date from 1552 and contain the history of his early love for an unknown lady. The sonnets in the Second Book were inspired by D. Maria Pimentel, whom he afterwards married, and they are marked by that chastity of sentiment, seriousness and ardent patriotism which characterized the man and the writer. He was intimate with princes, nobles and the most distinguished literary men of the time, and became the foremost representative of the classical school. In Oct. 14, 1567, he became *Disembargador da Casa do Civel,* and had to leave the quiet of Coimbra for Lisbon. His verses tell how he disliked the change, and how the bustle of the capital, then a great commercial emporium, made him sad and almost tongue-tied for poetry. He died of plague in Lisbon on Nov. 29, 1569, having stayed there doing his duty when others fled.

Horace was his favourite poet and his admiration of the classics made him disdain the popular poetry of the Old School (*Escola Velha*) represented by Gil Vicente. His national feeling would not allow him to write in Latin or Spanish, like most of his contemporaries, but his Portuguese is as Latinized as he could make it, and he even calls his poetical works *Poemas Lusitanos.* Ferreira wrote the Terentian prose comedy. *Bristo,* at the age of 2j(1553), and dedicated it to Prince John in the name of the university. It is neither a comedy of character nor manners, but its *vis comica* lies in its plot and situations. The *Cioso,* a later product. may almost be called a comedy of character. *Castro* is Ferreira's most considerable work, and, in date, is the first tragedy in Portuguese, and the second in modern European literature.

The *Castro* was first printed in Lisbon in 1587, and it is included in Ferreira's *Poemas*, published in 1598 by his son. It has been translated by Musgrave (1825), and the chorus of Act I appeared again in English in the *Savoy* for July 1896. It has been done into French and German. The *Bristo* and *Cioso* first appeared with the comedies of Sá de Miranda in 1622. There is a good modem edition of the Complete Works of Ferreira (2 vols., Paris, 1865). *See* Castilho, *Antonio Ferreira* (3 vols., Rio, 1865), which contains a full biographical and critical study with extracts.

FERRERO, GUGLIELMO (1871–1942), Italian journalist and author, was born at Portici, near Naples, on July 31, 1871. At an early age he joined the staff of the Radical semi-republican *Secolo* of Milan. He travelled abroad considerably, and made a reputation by his books *L'Europa giovane* (1897) and *Il Militarismo* (1898; Engl. tr., 1902). Later he studied Roman history, and in 1902 published his *Grandezza e decadenza di Roma,* which established his fame as historian among the general public rather than among scholars. He was an ardent advocate of Italian intervention on the Allied side in World War I. After the war he published numerous articles and several books prophesying imminent catastrophe for Italy and the world. Among these are *Da Fiume a Roma* (1923), also published in English under the title *Four Years of Fascism* (1924), and *La Fin des Aventures* (Eng. ed., *War and Peace,* 1933). His Italian works were seized by the Italian government in 1935. Ferrero died in Geneva in 1942.

FERRERS, the nanie of a great Norman-English feudal house, derived from Ferrikres-St.-Hilaire, to the south of Bernay, in Normandy. Its ancestor Walkelin was slain in a feud during the Conqueror's minority, leaving a son Henry, who took part in the Conquest and held a great fief in the midlands. He established his chief seat at Tutbury Castle, Staffordshire, on the Derbyshire border, and founded there a Cluniac priory. His eldest son succeeded to Ferrikres, and, according to Stapleton, he was ancestor of the Oakham house of Ferrers, whose memory is preserved by the horseshoes hanging in the hall of their castle. Robert, a younger son of Henry, inherited his vast English fief, and, for his services at the battle of the Standard (1138), was created earl of Derby by Stephen. He appears to have died the next year.

The earls seem to have been styled indifferently earls of Derby or Nottingham (both counties then forming one shrievalty) or of Tutbury, or simply (de) Ferrers.

William, the 3rd earl, joined in the great revolt of 1173, when he fortified his castles of Tutbury and Duffield and plundered Nottingham, which was held for the king. On his subsequent submission his castles were razed. He died at the siege of Acre, 1190. His son William, the 4th earl, attacked Nottingham on Richard's behalf in 1194. He was confirmed by king John in the earldom of Derby, 1199. With his brother-in-law the earl of Chester, and with William Marshal, earl of Pembroke, whose daughter married his son, he acted in securing the succession of the young Henry, joining in the siege of Mountsorrel and the battle of Lincoln. In 1227 he was one of the earls who rose against Henry III. on behalf of his brother Richard and made him restore the forest charters, and in 1237 he was one of the three counsellors forced on the king by the barons. He died in 1247.

Robert, 6th and last earl, his grandson, succeeded as a minor in 1254. He was one of the five earls summoned to Simon de Montfort's parliament, though, on taking the earl of Gloucester's part, he was arrested by Simon. On the king's triumph, he was compelled to forfeit his castles and seven years' revenues. In 1266 he revolted on his own estates in Derbyshire, but was defeated at Chesterfield by Henry "of Almain," deprived of his earldom and lands and imprisoned. In 1269, he agreed to pay £50,000 for restoration, and to pledge all his lands save Chartley and Holbrook for its payment. As he was not able to find the money, the lands passed to the king's son, Edmund.

The earl's son John succeeded to Chartley, a Staffordshire estate long famous for the wild cattle in its chase, and was summoned as a baron in 1299, though he had joined the baronial opposition in 1297. On the death, in 1450, of the last Ferrers lord of Chartley, the barony passed with his daughter to the Devereux family and then to the Shirleys, one of whom was created Earl Ferrers in 1711. The barony has been in abeyance since 1855.

The line of Ferrers of Groby was founded by William, younger brother of the last earl, who inherited from his mother Margaret de Quinci her estate of Groby in Leicestershire, and some Ferrers manors from his father. On the death of William, Lord Ferrers of Groby, in 1445, the barony passed with his granddaughter to the Grey family and was forfeited with the dukedom of Suffolk in 1554. A younger son of William, the last lord, married the heiress of Tamworth Castle, and his line was seated at Tamworth till 1680, when an heiress carried it to a son of the first Earl Ferrers. From Sir Henry, a younger son of the first Ferrers of Tamworth, descended Ferrers of Baddesley Clinton, seated there in the male line till towards the end of the 19th century. The line of Ferrers of Wemme was founded by a younger son of Lord Ferrers of Chartley, who married the heiress of Wemme, Co. Salop, and was summoned as a baron in her right; but it ended with their son.

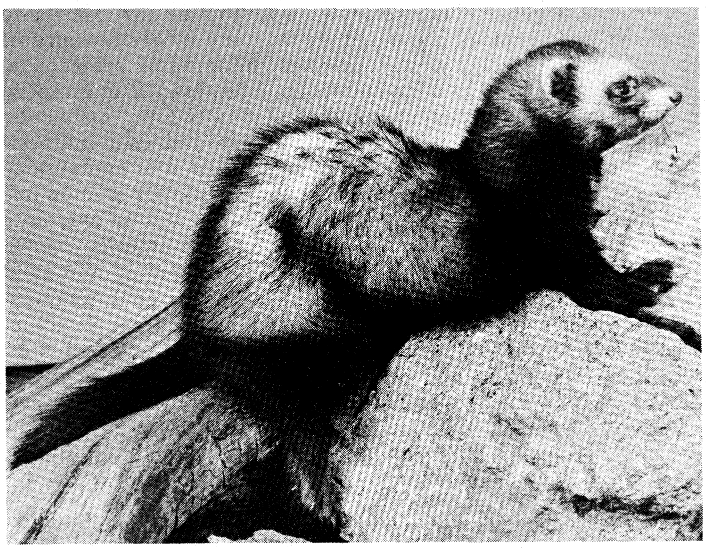
Higham Ferrers, Northants, and Woodham Ferrers, Essex, take their names from this family. It has been alleged that they bore horseshoes for their arms in allusion to Ferrikres (*i.e.,* iron-works); but when and why they were added to their coat is a moot point.

See Dugdale's *Baronage;* J. R. Planche's *The Conqueror and his Companions;* G. E. C(okayne)'s *Complete Peerage; Chronicles and Memorials* (Rolls Series); T. Stapleton's *Rotuli Scaccarii Normannie;* H. Norris, *Baddesley Clinton, with account of the family of Ferrers* (1897).

FERRERS, LAURENCE SHIRLEY, 4TH EARL (1720–1760), the last nobleman in England to suffer a felon's death, was born on Aug. 18, 1720. In 1758 his wife obtai'ed a separation from him for cruelty. The Ferrers estates were then vested in trustees, an old family steward, Johnson, being appointed receiver of rents. On Jan. 18, 1760, Johnson called at the earl's mansion at Staunton Harold, Leicestershire, when Lord Ferrers shot him. Ferrers was tried for murder by his peers in Westminster Hall. He pleaded insanity, but was found guilty. On May 5, 1760, dressed in a light-coloured suit, embroidered with silver, he was taken in his own carriage from the Tower of London to Tyburn and there hanged. It has been said that as a concession to his order the rope used was of silk.

See Peter Burke, *Celebrated Trials connected with the Aristocracy in the Relations of Private Life* (London, 1849); Edward Walford, *Tales of our Great Families* (London, 1877); Howell's *State Trials* (1816), xix. 885–980.

FERRET, a domesticated breed of the wild polecat (*Mustela putorius*), which it resembles in size, form and habits, and with which it interbreeds. It differs in the colour of its fur, which is usually yellowish-white, and of its eyes. which are pinky-red. The "polecat-ferret" is a brown breed, apparently the product of the above-mentioned cross. The ferret attains a length of about 14 in.. exclusive of the tail, which measures j in. It is employed in destroying rats and other vermin, and in driving rabbits from their burrows. The ferret is remarkably prolific, the female bringing forth two broods annually, each numbering from six to nine young. Pliny states it was employed in his time in rabbit hunting.



YLLA FROM RAPHO-GUILLUMETTE

THE COMMON FERRET

The ferret should be kept in dry, clean, well-ventilated hutches, and fed twice daily on bread, milk, and meat, such as rabbits' and fowls' livers. When used to hunt rabbits it is provided with a muzzle or with a cope. made by looping and knotting twine about the head and snout, in order to prevent it killing its quarry. As the ferret enters the hole, the rabbits flee before it. and are shot as they break ground. A ferret's hold on its quarry is as obstinate as that of a bulldog, but can easily be broken by pressure of the thumb just above the eyes. Only full-grown ferrets are "worked to" rats. Several are used at a time and without copes, as rats are fierce fighters.

See N Eveiitt. *Ferrets* (1897).

FERRI, CIRO (1634–1689), Roman painter. the chief disciple and successor of the painter and architect Pietro da Cortona, was born in Rome. When he was a little past 30 he completed the painting of the ceilings and other internal decorations begun by his instructor in the Pitti palace, Florence. He also co-operated in or finished several other works by Pietro, both in Florence and in Rome.

Of his own independent productions the chief is an extensive series of scriptural frescoes in the church of S. Maria Maggiore in Bergarno; also a painting (rated as Ferri's best work) of St. Ambrose healing an invalid. the principal altarpiece in the church of S. Ambrogio in Rome. He executed a large number of etchings and frontispieces for books.

Ferri was appointed-to direct the Florentine students in Rome: where Antonio Gabbiani was one of his leading pupils. He died in Rome on Sept. 13, 1689.

FERRIER, JAMES FREDERICK (1808–1864), Scottish metaphysician distinguished for his agnoiology or theory of ignorance, was born in Edinburgh on June 16, 1808. Educated at Edinburgh and Oxford, he qualified as a barrister in 1832, but came under the influence of Sir William Hamilton (who may have inspired his visit to Heidelberg in 1834 to study German idealist philosophy) and was appointed professor of civil history at Edinburgh (1842) and then of moral philosophy and political economy at St. Andrews (1845). He died at St. Andrews on June 11. 1864.

Ferrier's publications include a number of articles in *Blackwood's Magazine* (from 1838 onward). mainly on metaphysics though one dealt with "Some Plagiarisms of S. T. Coleridge" (1840); *Institutes of Metaphysic, the Theory of Knowing and Being* (1854), his major work; an edition of the works of John Wilson ("Christopher North"), his uncle and father-in-law, 12 vol. (1855–58); and *Scottish Philosophy, the Old and the* Yew (1856), in which he defended his *Institutes* and denounced the "philosophy of common-sense" that Hamilton had tried to combine with Kantianism. His *Lectures on Greek Philosophy and Other Philosophical Remains,* 2 vol. (1866), and *Philosophical Works,* 3 vol. (1875), appeared posthumously.

Ferrier's Hegelian epistemology (a word that he introduced into English) and ontology are based on the concept of the unity of the act of knowledge, which combines the knowing subject and the object known. The mind cannot apprehend anything except in conjunction with an apprehension of itself, and the distinction of subject and object is a source of error. Only minds in synthesis with what they know can be said to exist. and it is nonsense to speak of the mind's "ignorance" of what is allegedly unknowable (as the Kantian "thing-in-itself" was said to be), since ignorance must refer to what is still knowable though not actually known.

See E. S. Haldane, *James Frederick Ferrier (1899).*

FERRIER, PAUL (1843–1920), French dramatist, was born at Montpellier on March 29, 1843, and he died at Nouan-le-Fuzelier on Sept. 11, 1920. One of Ferrier's greatest triumphs was the produdtion with Fabrice Carré of *Joséphine vendue par ses soeurs* (1886). an *opéra bouffe* with music by Victor Roger. His opera libretti include *La Marocaine* (1879), music of J. Offenbach; *Le Chevalier d'Harmental* (1896) after the play of Dumas père, for the music of A. Messager; La *Fille de Tabarin* (1901), with Victorien Sardou, music of Gabriel Pierné.

FERRIER, SUSAN EDMONSTONE (1782–1854), Scottish novelist, born in Edinburgh on Sept. 7, 1782, was the daughter of James Ferrier, at one time one of the clerks of the court of session with Sir Walter Scott.

Susan Ferrier's first novel, *Marriage* (1818), was begun in concert with a friend, Miss Clavering, but this lady wrote only a few pages. It was followed in 1824 by *The Inheritance,* a better constructed and more mature work; and the last and perhaps best of her novels, *Destiny,* appeared in 1831. All these novels were published anonymously. With their clever portraiture of contemporary Scottish life and manners, and even recognizable caricatures of some social celebrities of the day, they could not fail to become popular north of the Tweed. Many were the conjectures as to the authorship of the novels. In the *Noctes Ambrosianae* (Nov. 1826) James Hogg is made to mention *The Inheritance,* and adds. "which I aye thought was written by Sir Walter, as weel's *Marriage,* till it spunked out that it was written by a leddy."

Scott himself gave Susan Ferrier a very high place indeed among the novelists of the day. In his *Tales of* My *Landlord* he calls her his "sister shadow," the still anonymous author of "the very lively work entitled *Marriage.*" Lively, indeed, all her works are, written in clear, brisk English, and with an inexhaustible fund of humour. Her books portray the society in which she lived, caricaturing with terrible exactness its hypocrisy, boastfulness, greed, affection and undue subservience to public opinion. Yet she wrote less to reform than to amuse. In this she is less like Maria Edgeworth than Jane Austen. Maria Edgeworth was more of a moralist; her wit is not so involuntary, her caricatures not always so good-natured. But Jane Xusten and Susan Ferrier were genuine humorists, and with the latter especially a keen sense of the ludicrous was always dominant. Her humorous characters are always her best. But if she was not a moralist, neither was she a cynic; and her wit, even where it is most caustic. is never uncharitable.

Susan Ferrier lived at Morningside House and in Edinburgh for more than 20 years after the publication of her last work. Lockhart describes her visit to Scott in May 1531. She died on Nov. 5, 1854, in Edinburgh.

She left among her papers a short unpublished article, entitled "Recollections of Visits to Ashestiel and Abbotsford." This is her own very interesting account of her long friendship with Sir Walter Scott. It contains some impromptu verses written by Scott in her album at Ashestiel.

See Sir G. B. S. Douglas, *The Blackwood Group,* "Famous Scots series," (1897).: *Memoir and Correspondence of Susan Ferrier,* collected by John Ferrier, ed. J. A. Doyle (1898).

FERROCONCRETE: *see* CONCRETE.

FERROL, EL (known as EL FERROL DEL CAUDILLO. since it was the birthplace of Gen. Francisco Franco Bahamonde), a city of northwestern Spain, in the province of Corunna; 41 mi. N.E. of the city of Corunna by rail. Pop. (1950) 56.332. Ferrol ranks with Cartagena and San Fernando, near Cadiz, as one of the principal Spanish naval stations. The town is on a north shore headland of the Bay of Ferrol and is concealed by rocky hills from view from the sea. Its natural harbour, the largest in Spain, except those of Vigo and Cartagena, is deep and safe; but the entrance is a narrow strait about 2 mi. long, which admits only one vessel at a time and is commanded by powerful modern batteries and forts on either side. Ferrol has shipbuilding yards and a large arsenal basin, with workshops and foundries, and two dry docks. Across a broad inlet west of the headland lies the submarine base of La Grana.

After the 1908 decree for bringing the Spanish navy up to date, much constructional work went on in the dockyards. Local industries are mainly connected with the building or refitting of naval vessels. Because of the competition of Corunna and also because of the lack, until 1904, of railway communication, El Ferrol is not a first-class commercial port. It is now connected by rail with Betanzos on the line from Corunna; but the exports are insignificant, consisting mainly of pit props, and the chief imports ordinarily are coal, cement, timber, iron and machinery, for use in the shipping industries.

El Ferrol was a mere fishing village until, in 1726, Philip V chose it as the site for a naval base, and Ferdinand VI (1746–1759) later set up shipbuilding yards there. Charles III developed it as a naval arsenal and erected strong fortifications between 1769 and 1774. In 1799 the British made a fruitless attempt to capture it, but on Nov. 4, 1805, they defeated the French fleet in front of the town, which they compelled to surrender. Delivered by treachery to the French on Jan. 27, 1809, it was vacated by them on July 22. When the French invaded Spain in 1823, the port withstood a month's blockade before surrendering on Aug. 27. Nationalists captured it early in the civil war of 1936–39.

FERROMAGNETISM is the kind of magnetism associated with iron. cobalt and nickel and some alloys and compounds containing one or more of these elements or manganese. It is characterized by the strong attraction of one magnetized body to another, a phenomenon known to the ancient world.

In contrast to other substances, ferromagnetic materials are magnetized easily. and in strong magnetic fields the magnetization approaches a definite limit called saturation. When a field is applied. and then removed. the magnetization does not return to its original value — this behaviour is referred to as hysteresis (*q.v.*). When heated to a certain temperature called the Curie point, different for each substance, ferromagnetic materials lose their characteristic properties and cease to be ferromagnetic; however, they become ferromagnetic again on cooling.

Ferromagnetic materials are essential parts of the machines of modern civilization, *e.g.*, electric motors and generators, transformers, telephones, loud-speakers and many others. Useful materials consist of two classes: those which are magnetized in weak fields and lose their magnetism easily (high permeability materials) and those requiring rather strong fields for magnetization but retaining their magnetism with tenacity (permanent magnets). *See* MAGNETISM. (R. M. B.)

FERRUCCIO or FERRUCCI, **FRANCESCO** (1489–1530), Florentine captain, who served in the *Bande Nere* in various parts of Italy, earning a reputation as a daring fighter and somewhat of a swashbuckler. When Pope Clement VII and the emperor Charles V decided to reinstate the Medici in Florence, they made war on the Florentine republic, and Ferruccio was appointed Florentine military commissioner at Empoli, where he showed great daring and resource by his rapid marches and sudden attacks on the Imperialists. Early in 1530 Volterra had thrown off Florentine allegiance and had been occupied by an Imperialist garrison. but Ferruccio surprised and recaptured the city. During his absence, however, the Imperialists captured Empoli by treachery, thus cutting off one of the chief avenues of approach to Florence. Ferruccio then attempted a diversion by attacking the Imperialists in the rear and started from Volterra for the Apennines. But at Pisa he was laid up for a month with a fever —a misfortune which enabled the enemy to get wind of his plan and to prepare for his attack. At the end of July Ferruccio left Pisa at the head of about 4,000 men, and although the besieged in Florence, knowing that a large part of the Imperialists under the prince of Orange had gone to meet Ferruccio, wished to cooperate with the latter by means of a sortie, they were prevented from doing so by their own traitorous commander in chief Malatesta Baglioni. Ferruccio was defeated on Aug. 3 at Gavinana; he himself was wounded and captured. Maramaldo out of personal spite dispatched the wounded man with his own hand. Nine days later Florence surrendered. Ferruccio was one of the great soldiers of the age, and his enterprise is the finest episode of the last days of the Florentine republic.

Aloisi, *La Battaglia di Gavinana* (1881); *cf.* P. Villari's criticism of the latter work, "Ferruccio e Maramaldo," in his *Arte, storia, e filosofia* (1884); Gino Capponi, *Storia della repubblica di Firenze,* vol. ii (1875).

FERRY, JULES FRANÇOIS CAMILLE (1832–1893), French statesman, was born at Saint Dié (Vosges) on April 5, 1832. He studied law, was called to the bar at Paris, and contributed to the *Temps.* He attacked the empire with great violence, directing his opposition especially against Baron Haussmann, prefect of the Seine. Elected republican deputy for Paris in 1869, he protested against the declaration of war with Germany, and on Sept. 6, 1870 was appointed prefect of the Seine by the government of national defence. He administered Paris during the siege, and after the Commune was obliged to resign (June 5, 1871). From 1872–1873 he was minister in Athens, but returned to the chamber as deputy for the Vosges, and became one of the leaders of the republican party. He was a member of the first republican ministry formed under W. H. Waddington on Feb. 4, 1879, and continued in the ministry until March 30, 1885, except for two short interruptions, first as minister of education and then as minister of foreign affairs. He was twice premier (1880–81 and 1883–1885). Two important works are associated with his administration, the non-clerical organization of public education, and the beginning of the colonial expansion of France. He reorganized the committee of public education (law of Feb. 27, 1880), and proposed a regulation for the conferring of university degrees, which, though rejected, aroused violent polemics because the 7th article took away from the unauthorized religious orders the right to teach. He finally succeeded in passing the great law of March 28, 1882, which made primary education in France free, non-clerical and obligatory. In higher education the number of teachers doubled under his ministry. After the military defeat of France by Germany in 1870, he formed the idea of acquiring a great colonial empire, not to colonize it, but for the sake of economic exploitation. He directed the negotiations which led to the establishment of a French protectorate in Tunis (1881), prepared the treaty of Dec. 17, 1885 for the occupation of Madagascar; directed the exploration of the Congo and of the Niger region; and above all he organized the conquest of Indo-China. The excitement caused at Paris by an unimportant reverse of the French troops at Lang-son caused his downfall (March 30, 1885), but the treaty of peace with China (June 9, 1885) was his work. After the resignation of President Grévy (Dec. 2, 1887), he was a candidate for the presidency of the republic, but the radicals refused to support him, and he withdrew in favour of Sadi Carnot. The violent polemics directed against him caused a madman to attack him with a revolver, and he died from the wound on March 17, 1893. The chamber of deputies voted him a state funeral.

See Edg. Zevort, *Histoire de la troisième République; A.* Rambaud, *Jules Ferry* (Paris, 1903).

FERRY, a place where passengers, freight or vehicles are carried by boat across a river, lake, arm of the sea or other body of water. The term applies both to the place where the crossing is made and to the boat used for the purpose. By an extension of the original meaning, ferry also denotes short overwater fights by airplanes carrying passengers or freight. or the flying of planes from one point to another as a means of delivering them.

The term has a long history extending back to Greek mythology. It includes a wide variety of vessels, from the most primitive canoes or rafts to large motor-driven ferries capable of carrying large motor trucks and railway cars across many miles of water. It is frequently used in combination with other words, as in the expressions train ferry, car ierrv and channel ferry.

Ferries were of great importance in ancient and medieval history, and their importance continued well into the period of modern history. Before engineers learned to build permanent bridges over large bodies of water or construct tunnels under them. ferries offered the only means of crossing. In the early history of the United States the colonists found that the coasts of the new world n-ere broken by great bays and rivers, and that the interior of the continent was divided by rivers that defied bridging for many generations. Yet crossing these rivers and bays was a necessity. At first, small boats propelled by oars or poles were the most common form of ferry. They mere replaced later by large flatboats propelled by a form of long oar called a sweep. Sails were used when conditions were favourable and in some rivers the current itself provided the means of propulsion.

Horses mere used on some ferries to walk a treadmill geared to paddle wheels; in others, horses were driven in a circle around a capstan that hauled in ropes and towed the ferry along its route.

The first steam ferryboat in the United States was operated by John Fitch (*q.v.*) on the Delaware river in 1790 but it was not financially successful. The advent of steam power greatly improved ferryboats: they became larger, faster and more reliable, and began to take on a design different from other steamers. At cities which spanned a river and where hundreds of people and many horse-drawn wagons had to cross the river daily, the typical U.S. ferryboat took shape. It was a double-ended vessel with side paddle wheels and a rudder and pilothouse on both ends. The pilothouses n-ere on an upper deck. and the lower deck was arranged to hold as many vehicles as possible. A narrow passageway ran along each side of the lower deck with stairways to give passengers access to the upper deck. A narrow casing on the centre line housed the engine space. The engine was of the walking-beam type with the walking beam mounted on a pedestal so high that it was visible above the upper deck.

Terminals to accommodate such ferries were built at each end of their routes. In order to dock promptly and permit wheeled vehicles to move on and off quickly a floating bridge was sometimes provided. This was a platform with one end supported by a pivot on land and the other end supported by floats in the water. Such an arrangement adjusted for changes in the tide, and the bridge was always nearly flush with the deck of the ferry.

As roads improved and the use of automobiles and large motor trucks increased. ferries became larger and faster, but the hull arrangement remained the same. High-speed steam engines with propellers on both ends of the ferry were used. Steam engines gave way to diesel engines and to diesel-electric drive. Several states organized commissions which took over ferries from private ownership and operated them for the public; these commissions frequently also operated bridges, public roads and vehicular tunnels. Increase in the use of motor vehicles so overtaxed many ferries that they could not handle the load. As a result, more bridges and tunnels were built, and ferries began to disappear from U.S. coasts, but their use on some inland rivers and lakes still continues. A modern type of ferry service transports large motor trucks between the United States and islands of the West Indies. Big truck-trailer combinations are driven onto a wharf from which the loaded trailers (disconnected from the truck engines) are hoisted aboard ship and secured for sea travel. Ships large enough to carry more than two hundred 35-ft. trailers are engaged in this trade. On arrival at their destination the trailers are hoisted ashore so they can complete their journey on land.

(M. R. D.)

Channel **Ferries.**—A special type of cross-channel ferry between England and France was designed to meet the urgent need to supply the British armies in France and Belgium during World War I. A cross-channel barge route was started from Richborough, Kent. to Calais, where the barges continued up the canals to Vendroux Audruicq, Zeneghem and other points. The 255 steel barges so employed, each carrying about 200 tons of stores, ammunition. etc . were towed across the channel by tugs, of which 67 were available, and provided a reliable service; no barge was ever reported lost on the channel crossing.

However, this method did not suffice for all needs and was from 1917 to 1918 supplemented by three specially built train ferries which sailed from Richborough to Calais and Dunkirk, and from Southampton to Dieppe. Railway vehicles were propelled into the ferry at the stern. the two entry tracks spreading into four tracks on the deck of the vessel itself; the capacity in terms of four-wheeled freight cars was 54 per ferry. Rail-mounted guns and locomotives could be carried on the two centre tracks. About 1.000 locomotives were thus dispatched from Richborough to Audruicq shops, almost ready for instant service.

Nearly all these locomotives were returned to England in 1919 by these same train ferries, together with passenger coaches which had been employed on ambulance trains or leave and demobilization trains in France, Belgium, Germany and Italy. In 1919 the train ferries were adjusted to take motor vehicles instead of freight cars, if required.

After World War I the ferry services were discontinued but, after a few special voyages carrying British-built rolling stock for export to the continent, they were acquired by Great Eastern Train Ferries, Ltd., and placed in service between Harwich and Zeebrugge, where suitable aprons (in effect, hinged lifting bridges) uere constructed for loading and unloading purposes. The tidal range at Harwich is only 124 ft. and therefore the necessity of passing through locks was obviated at that port. This service was inaugurated in April 1924 and required the close co-operation of the London and North Eastern railway. The service acquired traffic in vegetables, cheese, eggs, fruit, machinery, silk and rolling stock.

In conjunction with Great Eastern Train Ferries was the Anglo-Belge Ferry Boat company, which owned many of the freight cars employed on the train ferry service. Later the three former wartime train ferries. operating between Harwich and Zeebrugge, became part of the London and North Eastern railway fleet.

Further train ferry developments across the channel were delayed by the proposal to build a channel tunnel, but that project was turned down by the British government in 1930.

The Harwich-Zeebrugge freight service permitted traffic to move without transshipment between all parts of England. Scotland and Wales and any station served by the standard-gauge railways of continental Europe, stretching from Narvik to Sicily and from the Spanish frontier to Istanbul. The success of the Harwich-Zeebrugge freight service led the Southern railway to start in Oct. 1936, in conjunction with the then Nord railway of France, a train ferry service from Dover to Dunkirk.

Three vessels. nith a gross tonnage of 2,989 each. mere specially built in Great Britain. the "Tnickenham Ferry." the ' Hampton Ferry" and the "Shepperton Ferry"; they mere designed to carry passenger coaches and sleeping cars as well as freight cars across the English channel.

Difficulties were experienced in the construction of the train ferry dock at Dover. because of faults in the chalk formation. but on completion a night ferry service for passengers nas started between London (Victoria) and Paris (Nord). as well as other services for freight traffic.

As a consequence of World War II the London and North Eastern railway train ferry was reduced. but the tno fleets, Harwich-Zeebrugge and Dover-Dunkirk, received nen vessels, a French one being employed on the latter.

The Dover-Dunkirk night ferry passenger service between London and Paris proved exceedingly popular. The Harwich route continued to cater for freight traffic only.

Other Train Ferry Services.—A famous example is the train ferry across the Great Belt in the Baltic sea, operated by the Danish State railways, which carries diesel trains, sleeping cars and passenger coaches on the Copenhagen-Paris and other international services.

In conjunction with the Swedish State railways, a ferry route is operated betneen Malmö and Copenhagen; another route is between Helsingør and Halsingborg. Before World War II a joint German-Swedish service ran between Sassnitz and Trelleborg and a Danish service between Gjedser and Warnemünde. Ger Developments after 1948 included a new route from Grossenbrode, Ger., to Gjedser Italian State railways operate fine motor vessels as train ferries across the strait between Reggio di Calabria and Messina in Sicily.

Outside Europe, Japanese National railways has a number of train ferries in service between the several islands. and in North America the Canadian National operates a train ferry to Prince Edward Island as does the Canadian Pacific to Vancouver Island. Train ferries provide services across Lake Michigan, betneen Ludington and Frankfort in Michigan and Milwaukee. Manitowoc and Kewaunee in Wisconsin; they are operated by the Chesapeake and Ohio and other railways including the Ann Arbor, controlled by the Wabash railway.

Railway equipment is regularly ferried across the harbours of New York and San Francisco, and a regular service of train ferries links Cuba to the United States. (C. E R S)

FERSEN, FREDRIK AXEL, COUNT VON (1719–1794), Swedish politician, entered the Swedish Life Guards in 1740, and from 1743 to 1748 was in the French service (*Royal-Suédois*), where he rose to the rank of brigadier. At the diet of 1755–56 he was elected *landtmarskalk,* or marshal of the diet, and from henceforth, till the revolution of 1772, led the Hat party (see SWEDEN: Hzstory). In 1756 he defeated the projects of the court for increasing the royal power; but. after the disasters of the Seven Years' War, gravitated toward the court again and contributed, by his energy and eloquence, to uphold the tottering Hats for several years. On the accession of the Caps to poner in 1766, Fersen assisted the court in its struggle with them by refusing to employ the Guards to keep order in the capital when King Adolphus Frederick, driven to desperation by the demands of the Caps, publicly abdicated, and a seven days' interregnum ensued.

At the ensuing diet of 1769, when the Hats returned to power, Fersen was again elected marshal of the diet; but he made no attempt to redeem his pledges to the crown prince Gustavus, as to a very necessary reform of the constitution, nhich he had made before the elections, and thus involuntarily contributed to the subsequent establishment of absolutism.

When Gustavus III ascended the throne in 1772, and attempted to reconcile the two factions by a composition which aimed at dividing all political power between them, Fersen consented to open negotiations with the Caps, and was the principal Hat representative on the abortive composition committee. During the revolution of Aug. 1772, Fersen remained a passive spectator of the overthrow of the constitution, and was one of the first whom Gustavus summoned to his side after his triumph. Yet his relations with the king were never cordial. There was a slight collision between them as early as the diet of 1778; but at the diet of 1786 Fersen boldly led the opposition against the king's financial measures *(see* GUSTAVUS III.) which were consequently rejected. At the diet of 1789 Fersen marshalled the nobility around him for a combat *à outrance* against the throne and that, too, at a time when Sweden was involved in two dangerous foreign wars, and national unity was absolutely indispensable. This tactical blunder materially assisted the secret operations of the king. He and 20 of his friends of the nobility were arrested (Feb. 17, 1789) and the opposition collapsed. Fersen was speedily released, but henceforth kept aloof from politics, surviving the king two years. His *Historiska Skrifter*, a record of Swedish history, mainly autobiographical, during the greater part of the 18th century, is excellent as literature, but somewhat unreliable as an historical document.

See C. G. Malmström, *Sveriges politiska Historia* (Stockholm, 1855-65); R. N. Bain, *Gustavus III.* (1895); C. T. Odhner, *Sveriges politiska Historia under Gustaf III.'s Regering* (Stockholm, 1885, etc.); F. A. Fersen, *Historiska Skrifter* (Stockholm, 1867–72).

FERSEN, HANS AXEL, COUNT VON (1755–1810), Swedish statesman, was educated at home, and at the military schools of Brunswick, Turin and Strasbourg. In 1779 he entered the French military service *(Royal-Bavière)*, accompanied General Rochambeau to America as his adjutant, distinguished himself during the war with England, notably at the siege of Yorktown, 1781, and in 1785 was promoted to be *colonel propriétaire* of the regiment *Royal-Suédois*. The queen, Marie Antoinette, was especially attracted by his grace and wit and it is possible that he would have passed his life at Versailles, but for a hint from his own sovereign, then at Pisa, that he desired him to join his suite. He accompanied Gustavus III. in his Italian tour and returned home with him in 1784. Fersen went with his regiment to Finland in 1788, but in the autumn of the same year returned to France, where Gustavus required an agent thoroughly in the confidence of the French royal family, and sufficiently able and audacious to help them in their desperate straits. Before the end of 1790 Fersen had to admit that the cause of the French monarchy was hopeless so long as the king and queen of France were captives in their own capital. Finding the requisite funds he made the arrangements for their flight to Varennes, and was the coachman of the *fiacre* which drove the royal family from the Carrousel to the Porte Saint-Martin.

In 1791, Fersen was sent to Vienna to induce the emperor Leopold to accede to a new coalition against revolutionary France, but he soon realized that the Austrian court meant to do nothing, and was transferred to Brussels, where he could be of more service. In Feb. 1792, he reached Paris with counterfeit credentials as minister plenipotentiary to Portugal. On Feb. 13, he had three interviews with the royal family, but returned to Brussels on the 27th, having accomplished nothing. In 1797 Fersen was sent to the congress of Rastatt as the Swedish delegate, but in consequence of a protest from the French government, was not permitted to take part in it.

During the regency of the duke of Sudermania (1792–96) Fersen, like all the other Gustavians, was in disgrace; but, on Gustavus IV. attaining his majority in 1796, he was reinstated in all his offices and dignities. In 1801 he was appointed *Riksmarskalk* (=earl-marshal). On the outbreak of the war with Napoleon, Fersen accompanied Gustavus IV. to Germany to assist him in gaining fresh allies. He prevented Gustavus from invading Prussia in revenge for the refusal of the king of Prussia to declare war against France, and during the rest of the reign was in semidisgrace, though generally a member of the government when the king was abroad.

Fersen stood aloof from the revolution of 1809. *(See* SWEDEN: *History.)* His sympathies were entirely with Prince Gustavus, son of the unfortunate Gustavus IV., and when the newly elected successor to the throne, prince Christian Augustus of Augustenburg, died suddenly in Skåne in May 1810, the report spread that he had been poisoned, and that Fersen and his sister, the countess Piper, were accessories. When the prince's body was conveyed to Stockholm on June 20, 1810, and Fersen, in his official capacity as *Riksmarskalk*, received it at the barrier and led the funeral cortège into the city, he was attacked by the mob. In order to save him, two officers volunteered to conduct him to the senate house and there place him in arrest. But when he appeared on the steps, the crowd rushed on him and kicked and trampled him to death, while the troops, drawn up in the Riddarhus Square, made no effort to rescue the Riksmarskalk.

FERTILITY AND FECUNDITY. Fertility is the power to beget living offspring; fecundity that of the individual to produce functional gametes (marrying cells, sex cells, in the higher animals' ova and sperms). The reproductive rate of a mating or of a generation is determined both by the fecundity of the individuals composing it and by the fertility of their matings.

There is some meaning in viewing fecundity as what a species can do in terms of maximal reproduction, and fertility, as what a species actually does. Animals that live more exposed to rigorous environmental conditions usually have a high fecundity and those in more protected environments, frequently in part of their own making, a lower fecundity. This can be said differently: In a general way, fecundity is in direct relation to the chances of death; those species which have many enemies and face many hazards produce many eggs. There are numerous exceptions to this rule, however. It has been estimated that the Pacific herring of the Strait of Georgia has a population on four spawning grounds of 1,000,000 to 9,000,000 fishes. These produce annually something in the order of 8,000,000,000 to 75,000,000,000 eggs of which about 0.1% may reach maturity even though 95% may hatch. On the other hand, a mammal such as the human species has a low fecundity but a high degree of reproductive success in terms of reproductive effort.

Fecundity potentials can assume startlingly high proportions. An individual oyster can produce 55,000,000 to 114,000,000 eggs during its lifetime. It is estimated that the blue crab of the western Atlantic carries as many as 1,750,000 eggs at one time. A fish, the shad, is reputed to lay from 30,000 to 100,000 eggs per season; an adult cod about 4,400,000 eggs per year, and the carp from 2,000,000 to 4,000,000 eggs a year. An old speculation suggests that the tapeworm *Taenia* produces at least 8,800 eggs in a single proglottis and liberates as many as 13 or 14 proglottids each 24 hours.

Fecundity is affected by factors which determine or influence:

(1) *The number of gametes available at the time of fertilization.* In certain forms the female is monotocous (producing one young at a birth), only one ovum being extruded from the ovary and becoming available for fertilization at each period of "heat." In others she is polytocous, several or many extruded ova being available for synchronous fertilization by the abundant sperm. In both forms the ripening of the ova and the number extruded are conditioned by environmental factors. As a general rule, the average number of offspring in a litter in any species of mammals is inversely proportional to the average size of the animals of that species. In ungulates, twins are exceptional. The sow, however, is remarkable in having very large litters. In small mammals and rodents large litters are the rule, but the bats are exceptional, only one young ordinarily being produced at a time, doubtless to avoid extra weight when flying. Broadly speaking those species in which the gestation period exceeds six months produce but one young at a time and the number of teats is an approximate indication of the average size of the litter. The initial fecundity gradually waxes to a climax and thereafter gradually wanes. In polytocous animals the first litter as a rule is relatively smaller as are those which are born towards the end of the reproductive life of

the individual. In the fowl the greatest fecundity is exhibited during the first year and diminishes rapidly and progressively thereafter. It is probable that artificial selection is the cause of this antedating of the peak of fecundity in the fowl. Increased nourishment is followed by an increase in the number of ova shed in the polytocous forms, *e.g.*, the effects of "flushing" (special feeding) in sheep. Insufficient food and especially a deficiency of the accessory food substances, vitamins B and E (*see* VITAMMS) lead to an imperfect production or to the nonproduction of gametes by both male and female. The number of sperms is an important factor in efficient fertilization, for a certain concentration is required in the rabbit. Ordinarily, spermatozoa are present in amply sufficient numbers in the male ejaculate. Hammond (1925) found that in the case of the male rabbit repeated intercourse was followed by no reduction in fertility, though the periods between copulations became increased. Lloyd Jones and Haqs (1918), however, found that excessive intercourse led to a reduction both in pregnancies and in litter size.

(2) *The frequency of ovulation.* There are monoestrous forms in nhich the female has but a single oestrous cycle within one sexual season, and polyoestrous in which she has two or more. Since fertilization can only occur during the oestrous cycle the reproductive rate is limited by the frequency of these cycles. In most wild mammals the male experiences a sexual season as well as the female and generative activity is entirely restricted to such times. In man and most domesticated animals, however, the male is capable of sexual intercourse at all seasons, though an increased sexual activity may be evidenced at certain times of the year. Since in the human female there is no restricted sexual season fertilization can occur at all times throughout the year. Long continued lactation would seem commonly to exert an inhibitory influence on the oestrous cycle. In the pig, early weaning leads to a more frequent recurrence of oestrous cycles and an increased number of litters.

(3) *The length of life of tlze individual and tlze length of its reproductive phase.* Longevity is an hereditary character. Fecundity is exhibited during the period of life between puberty and senescence. The total number of opportunities for fertilization is influenced by hereditary and environmental factors which affect the time of attainment of puberty, the time of the onset of the climacteric, and the length of life. The protection and sanitation of domestication and civilization can prolong life and delay the decline of reproductive vigour.

(4) *The functional ability of the gametes.* The gametes of the mule and of other interspecific hybrids are in the great majority of cases inherently imperfect and incapable of fusing in proper fertilization. Commonly the sterility in these cases is due to irregularities in the mechanism of division of the germ cells and in some to the fact that the chromosome number and form of the two parental forms are widely different (*see* CYTOLOGY). Poisons, toxins and X-rays can render the gametes imperfect. The intra-abdominal undescended testis (*e.g.*, in so-called "rigs" in horses) cannot proceed to the elaboration of functional sperm for this cannot occur at a temperature as high as that within the body. Certain wild animals when removed from their natural habitat and kept in captivity become partially or completely sterile even though kept in a healthy condition and in their native countries. For reasons as yet unknown the generative system fails to discharge its functions: there is either an absence of sexual desire or an inability to elaborate functional gametes. Some normal stimulus to sexual activity, possibly a psychological one, is lacking.

Fertility.—The union of the gametes and the proper development of the resulting individual is embarrassed or prevented by factors which affect:

(1) *The act of sexual congress, e.g.*, homosexuality, intersexuality, and other structural, physiological and psychological anomalies.

(2) *The actual union of the ganzetes after efficient congress.* For reasons as yet unknown, certain individuals are infertile *inter se* but when mated with other individuals beget offspring. In human societies a differential fertility rate distinguishes the social grades. The average size of the family among the relatively socially unsuccessful is on the whole greater than that of the successful. Much of this difference is due to differences in the exercise of control, abstinence, and the use of contraceptives. It has not yet been demonstrated that any of it is due to a differential fecundity distinguishing the social grades.

(3) *The antenatal nurture of the offspring.* Hereditary and environmental factors can bring about the death of the embryo and foetus *in utero*. In polytocous forms the number of fertilized ova is frequently in excess of the nutrition available for them with the result that atrophy and absorption of the surplus embryos and foetuses occur. In other cases the death of the offspring is due to the action of hereditary *lethal* factors (*see* HEREDITY). An instance of such lethal factors is that which eliminates the homozygous yellow mouse. The mating yellow×yellow invariably yields yellows and grays in the ratio 2:1. Such yellows are constitutionally heterozygous: the homozygous yellow dies *in utero* as the result of the action of the hereditary factor for yellow present in duplicate. Haemophilic (bleeder) female children are comparatively rare: it is thought that the homozygous haemophilic usually dies early in pregnancy; only the female can carry the factor for this sex-linked character in duplicate (*see* HEREDITY). An examination of the sex ratio among new-born children, still-births and abortions, reveals the fact that during intrauterine life and parturition more males than females succumb. The male is constitutionally less able to withstand unfavourable conditions.

(4) *The postnatal viability of the individual.* The same hereditary and environmental factors as those which operate antenatally arc responsible for the fact that more males than females succumb during the antepubertal period. During the age group 10–15 years more females than males die, a reflection of the dangers that beset the onset of puberty in the female.

FERTILIZATION. A new organism, animal or plant, usually arises from a fertilized egg. Fertilization is the union of an egg cell (ovum) from the female, with a sperm cell (spermatozoon) from the male. In the process of fertilization, two main functions are served: (1) the egg is activated to development by the spermatozoon and (2) the hereditary characters of both mother and father are combined in the new organism. The activation of the egg by the spermatozoon is in the nature of a chemical reaction and results in a change in the surface and in the substance (cytoplasm) of the egg cell. The combination of the hereditary characters is accomplished by the nuclei, small bodies within the cells, or more specifically by the chromosomes within the nuclei.

Egg cells are formed in the ovary and are typically large cells rather simple in appearance, each consisting of cytoplasm and a nucleus. The cytoplasm is enclosed in a cell membrane and consists of a liquid matrix or "ground substance" in which are embedded yolk and other granules of different sizes, weights and chemical composition. The nucleus is a small spherical body within the cytoplasm enclosed by a nuclear membrane and consisting of a liquid matrix (nucleoplasm) and the chromatin material which in certain stages is in the form of very definite bodies or chromosomes in which lie the genes which determine the hereditary characters. Each species of animals and plants has a definite number of chromosomes. In the fruit fly, *Drosophila melanogaster*, on which so much genetic work has been done, there are eight chromosomes in the body cells and early egg and sperm cells. The chromosome number in man, long thought to be 48, is now placed at 46.

The spermatozoa are very specialized small cells adapted to their function of finding and attaching themselves to the egg. The spermatozoa develop in the testes from cells originally much like primitive egg cells. Whereas the egg cell increases greatly

FIG. 2.— DIAGRAM OF SEA URCHIN TYPE OF FERTILIZATION (MAGNIFICATION 200 X)

in size without much change in form as it matures, the sperm cell actually becomes smaller and very complicated in structure. They differ in shape in different animals (*see* fig. 1). The most common type is a free-swimming form consisting of: (1) a head containing the chromosomes, now massed together. but of the same number as those in the mature egg cell; (2) a middle piece in which lie certain bodies, centrosomes, which probably function in the subsequent division of the egg; and (3) a long tail which is very motile and enables the sperm to swim.

The spermatozoa of some animals (*e.g.*, crabs and lobsters) have no tails. but several spinelike processes by which they move slowly to the egg.

Since, in fertilization. the chromosomes which come from both the male and the female are added together and would double in number in each generation, there is a special mechanism by nhich this is prevented. Just before the egg cell becomes mature' and ready for fertilization, the chromosomes become associated in pairs, so that apparently only half the number is present. Now the cell (oöcyte) divides twice, very unequally, into one large and one very small cell. These two small cells, known as polar bodies (fig. 2), are discarded. But in the process of throwing off the polar bodies, one-half of each paired chromosome is discarded also, so that the mature egg is left with one-half the number of chromosomes (haploid number) that are present in each of the body cells and early germ cells (diploid number). Likewise the sperm cell (spermatocyte), in maturing, divides twice but into equal cells, each with half the original number of chromosomes (now haploid number), and all four of these cells form spermatozoa. Thus when the egg and sperm unite in fertilization, the somatic (diploid) number characteristic of the species is restored.

Since all the cells of the body, including the germ cells, arise by division of the original fertilized egg cell. each cell has the same number of chromosomes.

The sex of an individual is determined at fertilization by the sperm in man and many other animals because half of the spermatozoa differ from the other half in one of the chromosomes In butterflies, moths and birds, the sperm are all alike but the eggs are of two slightly different types with regard to one chromosome and here the female determines the sex of the next generation at fertilization. (*See* CYTOLOGY; HEREDITY; GENE.)

Fertilization in the Sea **Urchin.**—Whereas it is difficult to obtain human eggs, certain marine eggs can be obtained in abundance and the actual process of fertilization, that is, the union of the egg and sperm, can be best studied here (see fig. 2). One can put the eggs of a sea urchin, Arbacia *punctulata,* in sea water in a small glass dish and add some sperm. Under a microscope one can watch the sperm cells collect around each egg. The meeting of the egg and sperm is generally believed to be by chance in animals, not by chemical attraction, but having reached the egg, the sperm are held there by the surrounding jelly (see EMBRYOLOGY, CHEMICAL). Though there may be thousands of sperm present, only one sperm enters the egg, and, in Arbacia (also in mammals), at any point on the surface. In some animals several sperm normally enter but only one takes part in the union with the egg nucleus (*e.g.,* in the hen's egg). Within two minutes, in Arbacia, a membrane, the fertilization membrane, is thrown off a small distance from the surface of the egg; it removes the unsuccessful sperm from the surface of the egg and probably protects the egg as it develops.

Some of the details of the succeeding events can be seen in the living egg but they are better seen in stained sections, that is, thin slices of the eggs which have been killed and stained and mounted on a glass slide. About five minutes after fertilization the sperm head is seen inside the egg, accompanied by a small star-shaped figure, the sperm aster. This is generally believed to arise from the centrosome brought in by the middle piece. In this case the tail of the sperm is left outside, though in some eggs (*e.g.,* the guinea pig) the tail also enters the egg. The head of the sperm becomes the male pronucleus, enlarging somewhat as it approaches the egg nucleus (female pronucleus), which itself moves slightly toward the male pronucleus.

The two pronuclei unite near the centre of the egg and the astral radiations extend throughout the cell; this is the monaster, readily visible in the living egg. In the fusion nucleus of Arbacia the male and female components become indistinguishable. Soon (about 30 min. after fertilization) the nuclear membrane breaks and a typical division figure, the mitotic figure, then forms. The chromatin material from the nucleus forms into definite bodies, the chromosomes, which become arranged at the equator of a spindle. at each of whose poles is an aster; this figure is called the amphiaster. The chromosomes in this egg are small andnumerous: probably there are 38 (diploid number). The chromosomes then divide. half of each chromosome going to each pole; then they reform into new nuclei. The two asters are readily visible in the living egg, and one can watch the indentation of the cytoplasm between the two asters forming the cleavage furrow, which deepens and soon separates the egg into two halves or blastomeres, each with a nucleus formed by the daughter chromosomes.

The first cleavage takes place in this egg in about 50 min. after fertilization at 23° C. In this division, as in all subsequent divisions, the chromatin material, which is a combination of maternal and paternal, is equally distributed to the two daughter cells. By subsequent divisions, 4, 8, 16, etc., cells are formed with clock-like regularity. (See CYTOLOGY; EMBRYOLOGY.)

Number and Size of Eggs.—The simplest form of fertilization takes place in marine animals such as the sea urchin, as described above, mollusks and worms. The eggs and sperm are shed, when ripe. into the sea water. Since the union of egg and sperm is almost entirely by chance, each animal produces millions of eggs and sperm. In the frog, the male clasps the female as the eggs are being laid, and sheds his sperm over them. There are in this case many fewer eggs. In the higher animals, including the mammals, the eggs are fertilized inside the body of the female, on their way down from the ovary to the outside. There are still fewer eggs provided in this case. The eggs of some animals (*e.g.,* birds) are laid soon after fertilization, and since they must develop to a free-living form before hatching, they are supplied with a large amount of nourishment in the form of yolk. In the hen's egg. the young embryo is a small white disc on the surface of the yolk and all the rest of the egg, yolk and white. is nutrient material In most mammals, including man, the young embryo is nourished within the mother by her tissues. so that the egg requires no reserve material and is relatively small and simple.

Fertilization in Man and Other Mammals.—The mature human egg, as well as that of a dog and cow, is approximately 100μ in diameter ($=0.1$ mm. or 1/250 in.), excluding the zona pellucida; it is the largest cell in the body, about the size of a very fine grain of sand, just visible to the naked eye. It is essentially like the sea urchin egg, consisting of a mass of granular cytoplasm with a nucleus which cannot be seen in the living egg, but can be readily seen in stained and sectioned material; in the clearer rabbit egg, the nucleus can be seen in the living cell. There is a clear translucent zone, the zona pellucida, just outside the real cell membrane, about 20μ thick (function unknown. probably protective). It has been estimated that there are about 400.000 eggs, mostly immature: in the two ovaries of a young woman. It is believed by most authorities that all the eggs which will function in life are already present in the new-born girl, though some anatomists think new eggs are formed continuously in the ovary of the adult and that these are the functional ones. Since a woman usually sheds only one egg a month (none during pregnancy) from about 12 to 48 years of age. she needs only about 430 eggs during her lifetime. so that she has, potentially, nearly 1,000 times more than are necessary.

As the egg ripens in the ovary, cells multiply around it to form a follicle. The follicle (about 12 mm. diameter when mature) pushes its way to the surface of the ovary, bursts and releases its contents including the egg; this is ovulation. The egg now leaves the ovary, probably after the first polar body has been formed, and is received by the open end of one of the two oviducts or Fallopian tubes, usually the one on the same side of the body. It passes through the Fallopian tube which is about 11.5 cm. long (= $4\frac{1}{2}$ in.), probably both by means of the current made by the little hairs or cilia lining the tubes and by contraction of the muscle fibres in its walls. The egg takes four days to travel through the Fallopian tube on its way to the uterus.

The mature human spermatozoon is much like that of a rat or a rabbit or even a sea urchin (fig. 1). It has an over-a11 length of about 60μ (= 0.06 mm. or $\frac{1}{400}$ in.). The head. which contains the nucleus. is rounded and asymmetrical. being somewhat flattened; it is about 5μ long, 3μ wide and 1.5μ thick. The tail is about 50μ long and 0.3μ in diameter. It is among ihe smallest cells in the body. The volume of the human sperm is about $\frac{1}{50.000}$ that of the egg. It h a been estimated that all the spermatozoa necessary to produce the next generation in North America could be contained in the space of an ordinary pinhead. The eggs necessary for the next generation could be put in a pint jar. The sperm cells are formed continuously after puberty throughout life. It is estimated that there are 300,000,000 sperm in each ejaculation (4 cc.). and since it takes only one sperm to fertilize an egg, the waste is enormous.

Sperm cells deposited in the vagina by the male make their way in a few hours through the uterus. probably by muscular contraction of the wall. and up into the Fallopian tubes. They swim at the rate of about 2.7 mm. per minute which is near the rate of a good swimmer. length for length. It is in the upper part of the Fallopian tubes that fertilization takes place, that is, if there happens to be a ripe egg present. Fertilization prohahly takes place within a day after ovulation; if not fertilized. the egg clegenerntes after a day. Ovulation usually occurs about 14 days before the onset of the next menstruation. On the third or fourth day after fertilization, probably when in the four or eight cell stage, the developing egg passes into the uterus. It becomes attached to the uterine wall on about the seventh day after fertilization. The empty follicle in the ovary has meanwhile been transformed into the corpus luteum, an organ which produces the important hormone progesterone. (*See* REPRODUCTION; REPRODUCTIVE SYSTEM.)

Sperm can be introduced into the mammalian body artificially, with a pipette, and are functional in fertilizing the eggs. This has been done with horses. dogs and sheep, and was practised by the Arabs in the 14th century. It is now a common practice to trike the sperm from a particularly good bull and send it (with a small amount of glycerine) packed in dry ice to hreeders to fertilize their cows. Some bull sperm has been kept frozen in this manner for four years and has retained its fertilizing capacity. Human sperm, likewise frozen, may be kept in dry ice for three months and still retain its fertilizing power.

Fertilized mammalian eggs (rabbit and monkey) have been recovered from the Fallopian tubes, and motion pictures have been taken of their development for several days after fertilization. Development of the human egg outside the body (in vitro) is much more difficult to obtain, but there is no fundamental reason why this should not be done. The very complicated later development of any mammalian egg, including the human, will be almost impossible to obtain in vitro.

Hybrids. — In most cases the female of one species cannot be fertilized by the male of another. Well-known hybrids. however, do occur, but are usually sterile, *e.g.*, the mule (see HYBRIDISM).

Parthenogenesis. — There are a few animals in which the egg develops naturally without fertilization; such is the case in the plant lice (aphids) and the male bees (drones). There are a number of eggs, notably those of the sea urchin and starfish, which can be made to develop to normal larvae by artificial means instead of by fertilization. Heat. cold, various salts, hypotonic and hypertonic sea water have all been used to cause parthenogenesis in eggs of various animals. In the case of the frog, the eggs can be activated by pricking with a needle. Even mammalian (rabbit) eggs have been reported to develop parthenogenetically, by cooling the unfertilized eggs and then incubating them (G. Pincus and H. Shapiro, 1940). In artificial parthenogenesis, there is, of course, only one set of chromosomes, derived from the mother (see PARTHENOGENESIS).

Merogony.—This is the term applied to the fertilization of a nonnucleate egg or egg fragment. It is possible to shake apart or cut certain marine eggs, so that one part contains the nucleus and the other part has none; eggs can also be broken into two parts by rapid centrifuging. On fertilization, both these fragments, the nonnucleate as well as the nucleate, may develop into larvae. These merogonic eggs have, like the parthenogenetic eggs, only one set of chromosomes, but in this case it is the paternal set.

Parthenogenetic **Merogony.**—A combination of parthenogenesis and merogony can be made by treating nonnucleate fragments with a parthenogenetic agent. These completely nonnucleate egg fragments (of *Arbacia*) have passed through successive cleavages in a fairly normal fashion to the blastula stage (E. B. Harvey. 1956). The very early development of an egg can. therefore, take place without fertilization and without any nucleus.

Fertilization in Plants. — In plants as in animals. a union of male and female cells takes place in fertilization; but only among the lower plants such as the algae, and in the mosses and ferns, is a large cell fertilized by a small free-swimming sperm cell.

In the flowering plants. fertilization takes place in the pistil (often a vase-shaped structure present in the centre of the flower'), within which lies the ovule. and in it the egg cell. The pollen grains are carried by the wind or insects to the pistil; there they elongate into pollen tubes which grow down into the ovule. One of the nuclei of the pollen tube combines with the nucleus of the egg. thus ensuring inheritance from both parents. The fertilization process, as thus simplified: is somewhat complicated by an alternation of generations, a nonsexual generation alternating with the sexual generation. (See **PLANTS** AND **PLANT** SCIENCE; ANGIOSPERMS.)

Investigations After 1950. — Knowledge of the process of fertilization increased considerably after the main facts were established as outlined above. This was largely the result of the development of the electron microscope. Of special interest was the observation of acrosomal filaments of many sperm cells.

In many eggs the cortex, a layer just beneath the surface of the egg. contains special granules which disappear at fertilization and help form the fertilization membrane. In the sea urchin, about 15 to 20 seconds after the attachment of the acrosome filament of the sperm to the egg surface these cortical granules begin to explode in a wave which encompasses the egg surface. The vitelline membrane lifts off the surface because of the colloid osmotic pressure of the substances released by the cortical granules. The remaining material from these granules becomes incorporated into the fertilization membrane when it hardens, and into the hyaline layer which soon appears over the egg surface. There seems to he no doubt that the fertilization membrane is of dual origin, and is a combination of the vitelline membrane and material from the cortical granules.

Studies continued on the method of sperm entry into the egg, the movement of the nuclei within the egg, the fertilization cone and fertilization membrane and polyspermy, and special emphasis was placed upon the chemical changes, probably due to enzymes, that occur during and after fertilization. Since much of this work remains unsettled, definite conclusions cannot be drawn on many of the details of fertilization, especially from the chemical standpoint. See also references under "Fertilization" in the Index volume.

FERTILIZERS AND MANURES. Fertilizers include both natural and artificial substances that increase the productiveness of plants. In many countries of the world, including the United States and all of Europe, fertilizers stand in the way of widespread starvation. In areas such as China and India where famines have been commonplace, extensive use of fertilizer where needed could significantly reduce the incidence of food shortages. It was estimated that by the second half of the 20th century at least 20% of the food produced in the United States was due directly to commercial fertilizers.

It had become clear that the rapidly growing population of the world must depend increasingly upon commercial fertilizers for its food and fibre.

This article is divided into 14 broad sections dealing with the history and use of fertilizers and manures and providing detailed information about the various kinds of fertilizers. Fertilizer applicators and manure spreaders are described in the article TILLAGE MACHINERY.

In addition to the related articles referred to in the following sections of this article see also AGRICULTURAL EDUCATION AND RESEARCH; PLANTS AND PLANT SCIENCE.

The following are the main divisions of this article:

I. History
II. Essential Elements
III. Determining Fertilizer Needs

XI. Mixed Fertilizers
XII. Secondary Elements
XIII. Manures
XIV. Compost

I. HISTORY

When there were large areas of unused frontier land in the world it was often more economical for farmers to move onto new, unfarmed land than to invest additional money in fertilizers for the land they were then farming, a practice continued into the second half of the 20th century in some underdeveloped areas of the world (see TROPICAL AGRICULTURE). However, some use of manure and composts is probably almost as old as agriculture itself and many other materials, such as ground bones, wood ash from burning the felled trees, dried blood, saltpetre, guano and fish were employed long before the chemistry of soils and crops was understood (see AGRICULTURE, PRIMITIVE) The disappearance of the frontiers combined with improvements in the technology of fertilizer manufacture and more effective transportation led to a growing role of fertilizers for producing the needed food and fibre.

The first prerequisite to the use of fertilizers was an understanding of the function of plant nutrients in plant growth. In the light of present knowledge of plant growth, it is difficult to understand some of the concepts that were set forth by the scientists of a few hundred years ago. The milestones in the development of understanding of plant growth and nutrition rank in significance to mankind with the greatest achievements in chemistry, physics. mathematics, astronomy and other disciplines. The Romans, beginning with Cato about 200 B.C. through Columella in the first century A.D., knew enough about soil fertility to recommend crop rotations. liming acid soils, adding manure and growing legumes which fix atmospheric nitrogen. Jan Baptiste van Helmont (1577–1644) conducted a classic experiment with a willow tree as one of the earliest attempts to find the principle underlying plant growth. He planted a 5-lb. tree in 200 lb. of soil. Five years later the tree had grown to 169 lb. but the soil had lost only 2 oz. He concluded that water was the sole nutrient utilized.

A German, J. R. Glauber (1604–68), found large crop responses to saltpetre (potassium nitrate) and believed it to be the principle of life. In 1699, John Woodward grew plants in (a) rain water, (b) water from the Thames river, (c) effluent from the Hyde Park (London) conduit and (d) the effluent plus garden mold. The amount of plant growth increased with greater sediment in the water. He concluded that the soil contained the long-sought principle. About 1750 to 1800, trained chemists began to study plant nutrition. In 1804, Théodore de Saussure introduced quantitative methods and established several important principles. In 1834, Jean Baptiste Boussingault established the first field experiments.

In 1840, Justus von Liebig (*q.v.*) drew wide attention to agricultural fertility investigations with several striking theories contradicting the old notion that plants derive their nourishment from humus. He also proved that strong acid treatment increased the availability to plants of nutrients in bones (see Processing Phosphate Rock, below). In 1886. Hellriegel and Wilfarth determined that certain microorganisms in combination with leguminous plants obtained nitrogen from the air. From the late 1880s research continued at an accelerated rate on the determination of additional essential elements, on the best time, rate and method to apply fertilizers, and on fertilizer formulations.

II. ESSENTIAL ELEMENTS

Of the slightly over go chemical elements that occur naturally in the earth's crust or atmosphere at least 15 are known to be essential for normal plant growth. Another element is added to

TABLE I.—Elements Essential for Normal Plant Growth

Used in large amounts	Symbol	Source	Used in small amounts	Symbol	Source
Carbon. . .	(C)	From air	Boron	(B)	From soil solids
Hydrogen . .	(H)	" "	Copper	(Cu)	" "
Oxygen. . .	(O)	" "	Iron	(Fe)	" " "

Potassium . .	(K)	" " "	Molybde-num	(Mo)	" " "
Calcium . .	(Ca)	" " "			
Magnesium. .	(Mg)	" " "	Chlorine	(Cl)	" " "
Sulfur . . .	(S)	"			

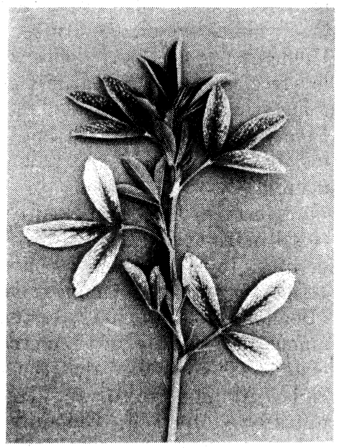
the list on an average of about every 10 or 20 years as new techniques are devised for producing more nearly chemically pure sources of nutrients for plant nutrition studies. The identification of several elements which are needed in almost infinitesimal amounts was long overlooked because the elements were contained as traces of impurities in the chemicals used to supply other nutrients known to be needed. or were dissolved in adequate quantities from the glass containers.

The essential elements and their sources are indicated in Table I. Each element has a specific biological role to play in normal plant growth. Some nutrients become part of the structure of the plant; others are required for normal growth but do not become a structural part of the plant. Several of the minor elements appear to be needed for proper functioning of the enzyme systems which regulate plant growth.

III. DETERMINING FERTILIZER NEEDS

The determination of the fertility needs of economic plants has received more attention from soil and plant scientists than any other aspect of plant growth. Several approaches are used.

Nutrient Deficiency Symptoms. — Many plants exhibit easily recognized symptoms of certain nutrient deficiencies. To the trained person these symptoms are helpful in indicating nutrients to be applied. Relying heavily upon deficiency symptoms has, however, three weaknesses: a profitable response to fertilizer is often possible before the plant shows the symptom; by the time the symptom is recognized it is frequently too late in the growth of the crop to prevent a serious loss of yield; many crops never exhibit identifiable symptoms.



BY COURTESY OF SAMUEL R. ALDRICH

ALFALFA PLANT EXHIBITING CHARACTERISTIC POTASSIUM DEFICIENCY

Soil Tests. — Soil tests carefully made on representative samples and interpreted by a trained soils expert are an important tool in planning a sound soil fertility plan. Soil tests measure the general fertility level and, when made systematically over a period of years, show whether fertility is being maintained, increased or is declining. (See also SOIL TESTING AND ANALYSIS.)

Plant Tissue Tests.—Chemical tests of the tissues of growing plants are sometimes helpful in diagnosing deficiencies, but the interpretation must be made by a trained person because of the complex interplay of soil moisture! temperature and fertility and the effect of one nutrient on another.

Soil Classification. — Soil maps are available for many important soils of the world. The description of the soils frequently gives valuable information on the inherent nutrient status.

Field Experiments and Farm Trials. — In the final analysis actual field experiments are the best guide to fertilizer response. Other techniques are mostly substitutes that are used because they are less costly than widespread field experiments. Many farmers and gardeners can conduct small trials on their own situations.

IV. INFLUENCE OF FERTILIZERS ON LIVESTOCK AND HUMAN FOOD

Fertilizers influence plants that are consumed by livestock and humans in several ways: (1) by increasing the yield and thus the amount of plant available; (2) by making it possible to grow different species of plants on a soil; and (3) by changing the chemical composition of the individual species with respect to minerals, vitamins, proteins or hormones. When a nutrient that is extremely deficient in a soil is added in small amounts the plant usually responds first in increased growth; as the nutrient is added in greater amounts it is likely to accumulate in the plant, frequently in excess of the amount required for optimum growth. Wide variations in inherent soil fertility or fertilizer applications often change yield but do not markedly affect the chemical composition of fruits and seeds although an abundant supply of nitrogen raises the protein content of grains. Data on the effect of fertilizers on vitamins, protein quality and hormones are much less extensive than for mineral composition. Research indicates that climatic factors are more influential than soil factors.

Since grazing livestock obtain all of their food directly from the soil, the nutritional deficiencies related to soil fertility and fertilizers are more common in such livestock. According to Kenneth Beeson: "An abnormally low level of phosphorus in the soil and in forage crops is the most nidespread and economically important factor in nutritional troubles in grazing animals" (American Plant Food Journal, 5:6–11, National Plant Food Institute, Washington. D.C., 1951).

The "styfsiekte disease" common in the Union of South Africa is due to a deficiency of the herbage in phosphorus and calcium. Phosphorus deficient forage has been found in Alabama, Florida, Michigan, Minnesota. Montana, Tennessee. Texas and Wisconsin in the United States. Cobalt deficiencies for livestock are knoun to exist in several areas of the world. The effect of fertilizers and soil fertility on the quality of livestock products is an important consideration because meat, milk and other livestock products contribute a substantial part to human food. Further research is needed but it appears that when enough fertilizers are used to grow desirable species and adequate quantities of plants the nutritive quality of the foods is generally acceptable. Livestock are more directly affected by fertilizer and soil fertility than humans because humans eat mostly the fruits and grains of plants, which are less influenced by soil fertility than the leaves and stems which make up a large part of livestock feed; the diet of humans includes foods brought in from other geographical areas, and many humans eat livestock products which are little affected in quality by changes in the diet of the animal. A notable example of a direct relationship between soil and human health is goitre, caused by a deficiency of iodine. There have also been reported cases of selenium toxicity in some areas of Mexico.

Organic and Inorganic Fertilizers. — Some persons have advanced the claim that chemical fertilizers jeopardize the health of animals and humans. A comprehensive study by the house of representatives of the United States led to the following committee report: "No reliable evidence was presented that the use of chemical fertilizers has had a harmful or detrimental effect on the health of man or animals." Scientific evidence indicates that nutrients actually enter living plants in the same chemical form nhether the nutrients are from organic or inorganic sources. It is possible to add certain harmful elements to the soil and have them absorbed by plants with a subsequent deleterious effect on animals. Selenium, for example, occurs in such abundance in some soils in the great plains region of the United States from Montana to New Mexico that grazing animals develop alkali disease. The effects of using chemical fertilizers should not be confused with the effects of certain chemical insecticides and fungicides which may be retained as residues on harvested crops and eventually be consumed by humans as plant or animal products.

The effect of fertilizers on bacteria, earthworms and other forms of life within the soil is of considerable importance. The consensus of soil scientists is that fertilizers judiciously used are not harmful and in fact may benefit soil life through an increase in the amount of plant residues returned. (See also FEEDS, ANIMAL; NUTRITION.)

Nutrients Removed in Crops. — The number of pounds of some important nutrients that are contained in the above-ground parts of selected crops are shown in Table II.

V. ANALYSES, GRADES AND RATIOS

The standard order to list the nutrients in a mixed fertilizer is nitrogen, phosphorus and potassium. The analysis or grade commonly refers to the percentage composition of the fertilizer in total N (nitrogen). available P_2O_5 (phosphorus anhydride) and water soluble K_2O (potassium oxide); for example, a 12–12–12. In fertilizer terminology P_2O_5 is called phosphoric acid and K_2O is called potash. These terms have been used since the mid-1880s. Some European countries use the elemental system, N, P and K, and it is likely that the rest of the world will adopt this system. Fertilizer recommendations for specific soils and crops are frequently given in terms of the desirable ratio. The ratio of a fertilizer expresses the relationship among the three major nutrients. nitrogen, phosphoric acid and potash, N-P_2O_5-K_2O, and in some cases additional nutrients. A 12–12–12 fertilizer has a 1–1–1 ratio. A mixed fertilizer is one that contains more than one of the three principal nutrients, N, P and K. Fertiliser materials are considered to be the basic materials which may either be applied directly to the soil or be combined with other materials to produce a mixed fertilizer.

Table II.—*Some Plant Nutrients Contained in Crops*

Crop	Nutrients in above-ground parts (in lb.)					
	Nitrogen	Phosphorus anhydride (phosphoric acid)	Potassium oxide (potash)	Calcium oxide	Magnesium oxide	Sulfur
Barley*, roo bu.	120	50	100	26	16	16
Cabbage, 1 ton.	6	2	8	1	1½	1½
Corn*, 100 bu.	160	66	110	42	18	18
Cotton, 1,500 lb. seed, lint; 2,joo lb. stalks, leaves, etc.	81	29	47	51	25	2
Oats*, 100 bu.	88	34	78	26	12	14
Onions, 100 bu. bulbs	15	7	14	2	5	2
Peanuts. 1.000 lb. nuts plus ''inks	73	12	50	30	10	15
Potatoes, 100 bu. tubers	31	9	30	2	4	2

Clover hay†, 1 ton	41	8	33	40	9	5

*Grain crops cannot be rompared on a bushel basis because the weight per bushel varies among crops.
†Composition, especially nitrogen, varies with the maturity of the crop.
Source: Our *Land and Its* **Care,** American Plant Food Council (1955).

Throughout most of the first 100 years of the use of commercial fertilizers. they were manufactured and sold only in the dry solid form. In the mid-1940s anhydrous ammonia gas. NH_3, was first used and in the mid-19 jos liquid mixed fertilizers were introduced. This period was noted for especially rapid changes in fertilizer manufacturing technology and agricultural use.

VI. FERTILIZER INJURY TO CROPS

Persons who are inexperienced in the use of fertilizers frequently observe brown or "burned" spots nhen they fertilize their lawns. and poor stands of vegetables nhen they fertilize their gardens. Fertilizer nutrients are, chemically speaking, supplied as soluble salts. A high concentration of soluble salts in contact with succulent plant tissues. leaves or roots kills the tissue by removing water from it. Injury may be reduced or avoided by applying less fertilizer, by mixing it through the soil surface or applying it in bands not in contact with seeds, by sprinkling a lawn immediately after fertilizing in order to nash the fertilizer off the leaves or by utilizing more costly but safer organic forms of nitrogen.

VII. FOLIAR APPLICATIONS

Plants can absorb nutrients through tiny openings (stomata) in the leaves and in some cases through the stems also. This fact led to speculation that perhaps feeding plants through leaf applications could replace soil applications. Extensive research showed that this was possible but that, with few exceptions, it is economically practical only in the case of minor elements which are required in very small amounts. Often foliar applications of minor elements are more efficient than soil applications because certain soils render the elements unavailable through chemical action.

VIII. NITROGEN FERTILIZERS

A. Natural Organics

The most important natural organic materials used in fertilizers are tankage (meat or garbage waste products), sewage sludge, castor pomace. cottonseed meal, fish scraps and dried animal manures including guano. Prior to 1850, nearly all nitrogen fertilizer came from such organic sources. By the second half of the 20th century natural organics had declined to a minor place in supplying the nitrogen fertilizer of the world. (See also Nitrogen, Fixation of.)

B. Naturally Occurring Chemical Nitrogen Fertilizers

Sodium and Potassium Nitrates.— Sodium nitrate. soda nitre or Chile saltpetre, $NaNO_3$, and potassium nitrate, nitre or saltpetre, KNO_3, were the first sources of chemical nitrogen fertilizer to be developed. They were discovered in 1809 by Thaddeus Haenke between the coastal range and the Andes mountains in Chile. Spaniards began to mine the deposits about 1813. The sodium nitrate layer, known as *caliche*, ranges from a few inches to 14 ft. in thickness. The Guggenheim process used in refining the ore can economically utilize ore as low as 8% in $NaNO_3$ and can extract 75% of the sodium nitrate. Potassium nitrate is produced as well as some iodates, borates, chlorides and sulfates of commercial value.

Coke Oven Ammonia.— Coke is extensively used by the steel industry. Coke is made by heating coal to 1,800° F. in the absence of oxygen. In this process ammonia gas, NH_3, is driven off and reacted with sulfuric acid to produce ammonium sulfate, a dry crystalline fertilizer containing 20.5% nitrogen.

C. Synthetic Nitrogen Fertilizers

Since about 80% of the air is nitrogen, there is a reserve of approximately 2 000,000 tons over each square mile of earth surface. Although this was utilized in a small way through atmospheric fixation by lightning discharges. by symbiotic bacteria mainly associated nith the roots of leguminous plants and by nonsymbiotic bacteria, the vast reserve was essentially denied to man until techniques were developed to fix nitrogen from the air. In the arc process an electric spark is passed through a mixture of nitrogen and oxygen gases to combine the two elements In the cyanamide process the final step involves combining nitrogen with calcium carbide at high temperature to yield calcium cyanamide. $CaCN_2$, containing 22 0% nitrogen. The third and by far the most important method is the Claude-Haber process for producing synthetic ammonia (NH_3).

Developed by Fritz Haber, Walter Nernst and others in Germany folloning the first laboratory production in 1910, and later modified by a Frenchman, Georges Claude, the process is represented by the equation:

$$3H_2 + N_2 \xrightarrow[+\ \text{catalyst}]{400°\text{-}500°\,C.} 2NH_3$$

In 1947 patents were assigned to the Wisconsin Alumni Research foundation for a process involving direct oxidation of nitrogen in gas-fired furnaces.

The most common sources of chemical nitrogen fertilizer are listed in Table III.

Table III.—*Chemical Nitrogen Fertilizers*

Fertilizer	Per cent Nitrogen	Form	Equivalent acidity (A) or basicity (B)*
Ammonium nitrate	33.5	Solid	180 (A)
Ammonium sulfate	20.5	Solid	535 (A)
Anhydrous ammonia	82.0	Gas	180 (A)
Calcium cyanamide	22.0	Solid	285 (B)
Calcium nitrate	15.5	Solid	135 (B)
Potassium nitrate.	13.0	Solid	200 (B)
Sodium nitrate	16.0	Solid	180 (B)
Crea	42.0–46.0	Solid	180 (A)

*Equivalent acidity is the amount of calcium carbonate required to offset the acidity caused by 100 lb. of nitrogen supplied in the fertilizer. Basicity indicates a basic rather than acidic effect.

Ammonium Nitrate.--Ammonium nitrate, NH_4NO_3, with 33.5% nitrogen is produced by reacting ammonia gas with nitric acid. It may be used for direct application or as an ingredient in either liquid or dry mixed fertilizers.

Ammonium Sulfate.— Ammonium sulfate. $(NH_4)_2SO_4$, with 20.5% nitrogen can be produced from by-product ammonia from the coking process or with synthetic ammonia, and reacted with sulfuric acid. In Europe ammonium sulfate is produced by reacting aqueous ammonium carbonate. $(NH_4)_2CO_3$, with gypsum, $CaSO_4$, to yield ammonium sulfate and calcium carbonate ($CaCO_3$). It is used for direct applications, as an ingredient in mixed fertilizers, and in bulk blends which are physically mixed immediately before applying.

Anhydrous Ammonia. — Anhydrous ammonia, NH_3, has 82% nitrogen. The synthetic fixation of ammonia has been previously described. W. B. Andrews initiated research in Mississippi in 1947 which quickly led to widespread use of ammonia in the United States for direct application to the soil. Since anhydrous ammonia is a gas with 211 lb. per square inch pressure at 104° F. and is also highly irritating, it is necessary to use special handling equipment and to insert the gas under several inches of moist soil in order to prevent extensive loss. The principal advantages are that it is the most concentrated source and thus can be transported most cheaply. and it requires no further processing before being applied. It may be metered into irrigation water for rill, that is, surface, but not overhead irrigation.

Anhydrous ammonia is widely used in the manufacture of other nitrogen fertilizers. It is also reacted with phosphoric acid to produce monoammonium phosphate (11% nitrogen and 48% phosphoric acid, or P_2O_5) and diammonium phosphate (21% nitrogen and 54% phosphoric acid).

Calcium Cyanamide. — The production of calcium cyanamide, $CaCN_2$, has been previously described. It is extensively used in Europe. The only producing plant on the North American continent is that of the American Cyanamid company in the province of Ontario. Can., near Niagara falls. When added to the soil, calcium cyanamide undergoes a series of chemical changes not all understood. but finally resulting in urea. A very dry soil or a high pH in the soil is conducive to the formation of a chemically stable, toxic compound, dicyanamide. $(H_2CN_2)_2$. The toxicity of intermediate breakdown compounds is utilized in weed control and in defoliating certain crops prior to harvesting. Because of these toxic compounds cyanamide must be applied to soil a minimum of two to three weeks before a crop is to be planted.

Calcium Nitrate. — Calcium nitrate. $Ca(NO_3)_2$, is produced by neutralizing nitric acid with limestone. It is manufactured mainly in Europe.

Sodium Nitrate. — The mining and processing of naturally occurring sodium nitrate, $NaNO_3$, has been described. Synthetic sodium nitrate production in which sodium carbonate is reacted with nitric acid began in 1929. It is used mainly for direct application as a side dressing or top dressing.

Urea. — Urea. $CO(NH_2)_2$, is prepared by reacting anhydrous ammonia with carbon dioxide gas under high pressure in the presence of a suitable catalyst. Rapidly converted in the soil by the enzyme urease into ammonium carbonate. $(NH_4)_2CO_3$, it is used for direct application and mixed fertilizers including liquids.

Nitrogen Solutions and Aqua Ammonia. — Several combinations of water, ammonia, ammonium nitrate and urea are prepared mainly as nitrogen sources in the preparation of mixed fertilizers, either dry or liquid, but are used to some extent for direct application.

Urea-formaldehyde. — About 1950 research workers in the United States department of agriculture produced urea-formaldehyde combinations in varying ratios of the two ingredients in order to produce a chemical nitrogen fertilizer that would react slowly in the soil and thus be resistant to leaching and available over a longer period of time than earlier sources.

IX. PHOSPHORUS-SUPPLYING FERTILIZERS

A. Reserves and Production

World Reserves. — The estimated world reserves of phosphate rock and apatite are given in Table IV. Additional extensive reserves not yet accurately estimated occur in Chile. China, Ireland, French West Africa, Indonesia, Korea, Nigeria. Rhodesia. Uganda, Union of South Africa and Venezuela. The principal supply of commercially used phosphates is the calcium phosphate mineral apatite (*q.v.*), of which the most common crystalline form is fluorapatite, $Ca_{10}(PO_4)_6F_2$. Iron ore is a minor source of phosphorus-carrying fertilizers, and animal bones supply smaller amounts.

Production and Consumption. — The leading countries in the production of phosphate rock are the United States, Morocco, the U.S.S.R., Tunisia, Nauru Island, Algeria, Egypt, the Christmas Islands, Makatea Island and Japan. The principal consuming areas are the United States, the U.S.S.R., Great Britain, France, Australia, Italy. Germany. Japan, Holland and Canada.

Geological Formations. — Igneous apatite occurs as an intrusive sheet on the Kola peninsula of the U.S.S.R., in eastern Uganda and in eastern Transvaal. The predominant mineral is fluorapatite, which may contain up to 30% phosphoric acid, P_2O_5, equivalent. Marine phosphorites are sometimes deposited on continental shelves when cold water, rising from great depths, warms as it nears the surface and becomes less acid as it loses carbon dioxide, CO_2; phosphates are then precipitated. The large deposits in Montana, Idaho, Utah and Wyoming represent a formation called geosynclinal; the Tennessee blue rock phosphate is a platform deposit. Residual phosphorites arise from the weathering of marine-deposited phosphatic limestones. The phosphoric acid ranges from 15% to 35%. Tennessee brown rock deposits are of this type. River pebble deposits occur on stream bottoms where they accumulate from runoff from weathering phosphatic limestone. These usually are too low in phosphorus to be mined competitively. Phosphatized rock deposits are formed when phosphate that is being leached in acid water comes into contact with limestone or with rocks rich in iron or aluminum and is precipitated as crusts on the surface of joints and cavities. Tennessee white rock and Florida hard rock deposits are of this type and may contain up to 35% phosphoric acid.

Table IV.—*World Reserves of Phosphate Rock and Apatite (4)* (in 000,000 metric tons)

Country	Reserves
French Morocco	21,000
United States	13,526
U.S.S.R.	7,568
Tunisia	2,000
Algeria	1,000
Brazil	572
Islands of Pacific and Indian oceans	182
Egypt	179
23 other countries	670
Total	46,697

Guano is a source of both phosphorus (up to 20% phosphoric acid) and nitrogen (10% to 13%). (See Guano.)

Mining. — Strip mining is practised on most phosphate deposits although there is some shaft mining. Mining started on the North American continent in the provinces of Ontario and Quebec in Canada in 1863. Phosphates had been previously discovered in South Carolina in 1837 but the first mining company in the United States was not formed until 1867. In 1882 phosphate rock was discovered in Florida and from then until World War I the principal market was in Europe, South Africa, Australia and New Zealand. In 1893 and 1896 blue rock and brown rock deposits were found in Tennessee. Smaller deposits occur in Alabama, Arkansas. Kentucky. North Carolina, Pennsylvania! Virginia and other states. Following World War I, production developed in the Pacific and Indian ocean islands and in North Africa.

B. Processing Phosphate Rock

The mineral apatite is relatively unavailable to plants until changed chemically. In fertilizer terminology available phosphoric acid, or P_2O_5 (43.7% phosphorus), is that nhich is water soluble plus that which is soluble in a neutral one normal ammonium citrate solution (citrate soluble). Justus von Liebig demonstrated in 1840 that the availability to plants of the phosphorus in bones was greatly increased by treatment with acid. In 1842 John B. Lawes, co-founder of Rothamsted Experimental station (*q.v.*) near London, patented a process for sulfuric acid treatment of phosphate rock to produce superphosphate, and essentially the same process was still used over 100 years later to produce most of the available P_2O_5 in fertilizers. The findings of Liebig and Lawes marked the beginning of the phosphate fertilizer industry.

There are two general procedures for breaking the apatite structure and making the phosphorus more available: treating the rock uith strong mineral acids and subjecting it to high temperatures.

Acid Processes. — Strong acids break the apatite bond and remove 30% to 40% of the fluorine. Phosphate rock plus sulfuric acid produces ordinary superphosphate with 16% to 20% available phosphoric acid, or P_2O_5. This is the most important supply of phosphorus-carrying fertilizer, used both for direct application and for manufacturing relatively low-analysis mixed fertilizers. Phosphate rock plus orthophosphoric acid, H_3PO_4, produces triple or treble superphosphate with 44% to 48% available P_2O_5, used for direct application and to an increasing extent in high-analysis mixed fertilizers and bulk blends.

Prompted by the shortage of sulfuric acid during World War II, the Tennessee Valley authority developed two processes: Process I uses nitric and phosphoric acid to yield phosphoric acid. monocalcium phosphate. $CaH_4(PO_4)_2$, and calcium nitrate. $Ca(NO_3)_2$. This is ammoniated to convert the highly deliquescent calcium nitrate to dicalcium phosphate, $Ca_2H_2(PO_4)_2$, and ammonium nitrate NH_4NO_3. Process II uses a nitric-sulfuric acid combination and yields phosphoric acid. gypsum and calcium nitrate. As in Process I it is ammoniated and yields similar products plus gypsum.

Heat Processes.—Subjecting phosphate rock to high temperature breaks the apatite bond and drives off nearly all fluorine. Coronet phosphate is named for the company that developed the process. A slurry of ground rock, silica and water is fed into a rotary kiln at 1 500° C. After 20 min the mass is quenched with water jets. The product contains 21% phosphoric acid, P_2O_5, with 18% available. Fused tricalcium phosphate, developed by TVA, contains 22.3% available P_2O_5 but is not used commercially. Phosphate rock-magnesium silicate glass involves heating to fusion temperature phosphate rock with olivine or serpentine. It contains 19% available P_2O_5. Rhenania phosphate, developed in Germany. has been used since 1917. Phosphate rock, soda ash, Na_2CO_3, and silica are calcined at 1,100° C. to 1,200° C. for two hours, quenched nith water before being discharged from the kiln, and ground to 180 mesh. The product carries 27.5% available P_2O_5. Calcium metaphosphate. $Ca(PO_3)_2$, was patented in Germany in 1929. TVA began production in the United States less than ten years later. It is of particular significance because of the extremely high concentration of available P_2O_5 (60% to 65%) which makes it economical to transport long distances. To make it, elemental phosphorus is burned in the presence of finely ground rock. The P_2O_5 produced from the burning phosphorus reacts with the rock. Potassium metaphosphate. KPO_3, was developed and carried to pilot-plant stage by TVA. The fertilizer contains 35% to 38% potash, K_2O, and 55% to 58% P_2O_5. Disposition of the hydrochloric acid used in the process is a problem.

Raw Rock Phosphate.—As previously mentioned, untreated phosphate rock is low in available phosphorus for plants, one-sixth to one-twentieth being citrate soluble. Given adequate time, soil acids accomplish the same purpose as mineral acids, namely to break the apatite bond. The rate of reaction is increased by fine grinding (100 mesh or finer), by moderate soil acidity and by large amounts of decaying plant residues which produce organic acids. Where it is favourably priced, rock phosphate is economically utilized to build the basic soil supply of phosphorus. More readily available sources are used to meet crop needs during the first few years. Long-season forage legumes utilize rock phosphate best. Rock phosphate is not suited to alkaline soils because of inadequate soil acids. The best grades of rock phosphate contain 30% to 36% tofal phosphoric acid. P_2O_5, and 3% to 6% citrate-soluble P_2O_5. The very fine material that settles out in waste ponds is sometimes marketed as colloidal phosphate containing 20% to 24% total P_2O_5.

Other Sources.—Basic slag, a by-product of the steel industry, usually from the Thomas and Gilchrist process. is rich in soluble calcium phosphates and is of commercial importance as a source of phosphorus mainly in Germany. France, Great Britain and other European countries where the slag often carries 17% to 20% phosphoric acid, or P_2O_5. In the United States only the slag from the open-hearth furnaces at Birmingham. Ala., is rich enough in phosphorus (9% to 10% P_2O_5, with 60% to 90% of this being available) to be competitive with other sources. Bone meal was once an important source of phosphorus fertilizer but now is used mainly by the feed industry. Liquid phosphoric acid. wet-process. is produced by treating rock with sulfuric acid. Calcium sulfate results as a precipitate and is separated out, leaving acid with 20% to 54% P_2O_5 depending upon the method used. Thermally produced acid comes from the reduction of phosphate rock in an electric furnace to produce elemental phosphorus which is burned to P_2O_5 and dissolved in water to make orthophosphoric acid, H_3PO_4. Liquid orthophosphoric acid is used on alkaline soils of the western United States mainly in irrigation water.

When orthophosphoric acid is neutralized with ammonia, monoammonium phosphate forms. Fertilizer grades contain 11% nitrogen and 48% P_2O_5. Sometimes this is mixed with ammonium sulfate to produce a nitrogen. phosphoric acid, potash ratio of 16–20–0. When the ammoniation of phosphoric acid is continued and the slurry kept at pH, or acidity, of 5.8 to 6.0, diammonium phosphate is formed. It has 21% nitrogen and 54% P_2O_5.

X. POTASSIUM FERTILIZERS

A. World Reserves

Major Producing Countries.—The potassium reserves of the world are very large but they are not precisely estimated. In the second half of the 20th century estimated world reserves of potash in lake brines and soluble salt deposits in millions of metric tons of K_2O were: Germany, 2,500 to 438,000; the U.S.S.R., 700 to 18.400; Israel, 1,200; the United States, 325; France 300; and Spain, 270. Additional good quality reserves are also found in Japan, Australia, South Africa, India, and in the more recently discovered deposits in Saskatchewan, Can. Vast mineral reserves of lower quality may be utilized when new processes are developed. The ash of giant kelp, a seaweed along the western coast of North America from lower California to Alaska, contains 30% potash or K_2O. The greatest reserve outside the soil itself is sea water, which contains about 2,000,000 tons of potash per cubic mile.

Germany.—The largest known reserves in the world, covering an area of about 24,000 sq.mi., lie in the area from Thuringia to Mecklenburg and westward to Hanover. The potassium-bearing strata are 1,200 to 4.000 ft. below the surface. The deposits are largely carnallite, sylvite, kainite and kieserite, and average 13% potash. K_2O, equivalent.

U.S.S.R.—The second largest reserves mere discovered in Perm on the west side of the Ural mountains. Information on the size of reserves and their commercial development is meagre.

Israel.—The resource is in the high salt concentration of the Dead sea.

United States.—The main potassium supply is in the Carlsbad deposits of the Permian basin area along the Texas-New Mexico border and extending north across Oklahoma and into Colorado and Kansas. The basin was an old inland sea in which potassium salts were concentrated and later buried under sand and shale to a depth of 800 to 1,000 ft. This area supplies 85% or more of the potassium produced in the country. Other reserves include beds in eastern Utah and brine from salt flats at Bonneville, Utah, brine wells at Midland, Mich., and Searles lake brines in California.

France.—The reserves are located in Alsace along the Rhine river about 25 mi. north of the Swiss border. These are among the highest quality ores in the world. The predominant mineral is sylvite. An extensive deposit has been discovered near Dax.

Spain.—Deposits are northwest of Barcelona and about 18 by 75 mi. in area. Strata vary from 8 to 70 ft. in thickness and occur at depths of 70 to 200 ft. below the surface. They are mainly carnallite and sylvite.

Poland.—The deposits are north of the Carpathian range from Kahurz to Stebine. The potassium is in four horizons in beds to 20 ft. thick and consist mainly of kainite, langbeinite, sylvite and carnallite. Rich deposits have been found in the Kujawy district of western Poland.

Canada.—Deposits were discovered in Saskatchewan in 1947. They occur at 4,000 to 12,000 ft. and may cover an area up to 500 sq.mi. when exploration is completed.

Italy.—There are large areas of leucite lava ranging from 7.5% to 10.0% potash equivalent.

Great *Britain.*—Deposits of sylvite and polyhalite in Yorkshire at a depth of 3,600 to 4,800 ft. appear to be a continuation of the salt basin of the German and French beds.

B. History of Potassium Fertilizers

Potassium fertilizer in the form of manure, potassium nitrate and ashes was reported in 300 B.C. The name potash comes from "pot ashes." The settlers in North America found Indians applying wood ashes as fertilizer. The production of potash from wood ashes was common in New Hampshire by 1632 and potash was exported to England for 100 years, reaching a peak in 1825. Potassium salts were discovered in well brine in Germany in 1839 and by 1861 commercial production mas well established. Potassium was found in 1912 in a well drilled for water at Spur. Tex. Exploration for potassium in the United States was greatly stimulated by the loss of the German supply during World War I. The first significant discovery in the great Permian basin deposit was made in an oil-well drilling in 1921 and sylvite was identified in 1925. The first commercial shipment from Carlsbad was in 1931 by the United States Potash company. In 1934 and 1940 two more companies began production and by 1950 the United States had become one of the morld's leading producers.

C. Mining and Processing

The operations at Carlsbad, N.M.. illustrate mining and processing techniques. Langbeinite, a sulfate of potassium and magnesium. $K_2SO_4.2MgSO_4$, is mined at 800 and 850 ft.; sylvinite. a mixture of potassium and sodium chlorides, at 900 ft.; beds are 5 to 12 ft. thick. The ore is drilled, blasted, loaded and hoisted above ground. The principal impurity is sodium chloride from nhich it is separated by selective dissolving nith water. The mass is centrifuged, kiln dried and sold under the trade name Sul-Po-Mag, which contains sulfur. potassium and magnesium. Sylvinite is ground and sized (the coarse fraction being treated on an agglomerating table), deslimed to remove clay, subjected to a flotation process and concentrated on gravity tables. The potassium chloride is removed from the brine by centrifuging, then kiln dried and sold as 50% K_2O granular muriate of potash. The fine fraction is also deslimed. then incorporated with flotation reagents and processed in a series of flotation cells. The concentrate is centrifuged, kiln dried and marketed as 60% muriate of potash.

D. Potassium-Supplying Fertilizers

Potassium content in fertilizers is commonly expressed as water soluble K_2O, or potash (83% potassium), although some European countries express it on an elemental basis.

Muriate of Potash.—The term muriate comes from muriatic acid, the common name for hydrochloric acid of which muriate of potash, KCl, is a salt. Muriate, 50% or 60% potash. K_2O, is used for direct application and to make mixed fertilizers, both liquid and dry. It is readily soluble in water.

Potassium Sulfate.—Composed of K_2SO_4 and containing 48% to 50% potash. or K_2O, equivalent, it is prepared by dissolving langbeinite in water and adding a concentrated muriate of potash (KCl) solution or by treating muriate of potash with sulfuric acid.

Sulfate of Potash-Magnesia.—It is prepared from langbeinite as previously described. The German product differs from the U.S. product in having one molecule of magnesium sulfate, $MgSO_4$, rather than two for each molecule of potassium sulfate, K_2SO_4. It is made by dissolving kieserite in hot water and adding KCl.

Manure Salts.—This is the fertilizer trade name for crude potassium salts that are crushed, screened and bagged with no attempt being made to remove sodium chloride and other salts.

Kainite is a term often applied to low-grade potassium salts ranging from 14% to 20% potash, but technically kainite is a mineral consisting of a hydrated sulfate and chloride of potassium and magnesium. $KCl.MgSO_4.3H_2O$.

Potassium Nitrate, having the formula KNO,, is from the Chilean nitrate deposits described in the section on nitrogen. It is little used as a fertilizer but is of interest agronomically because of the unique balance of nitrogen and potassium (13% nitrogen-~%phosphoric acid-44% potash).

Potassium metaphosphate was previously discussed under phosphorus-supplying fertilizers.

XI. MIXED FERTILIZERS

The term mixed fertilizer indicates more than one of the three major nutrients. nitrogen, phosphorus and potassium. Mixed fertilizers are formulated in hundreds of ways and there is no single typical technique. Of the many chemical reactions that take place, the most significant by iar is the ammoniation of phosphates with anhydrous ammonia or ammoniating solutions. The chemical reactions affect both the availability of certain nutrients and the physical condition of the fertilizer. There is a strong trend toward higher concentrations of nutrients in mixed fertilizers in order to save costs in handling and transporting. Prior to 1950 most mixed fertilizer was pulverized or powdered, but since then an increasing proportion has been made into pellets or granules. which are less dusty and less likely to cake. Home mixing of fertilizers was widely practised until the 1940s but has since rapidly declined. In European countries fertilizers are generally applied as individual materials but in the United States mixed fertilizers are more popular. Bulk blending of fertilizer materials increased in the second half of the 20th century.

XII. SECONDARY ELEMENTS

Calcium, magnesium and sulfur are commonly referred to as secondary nutrient elements but this does not mean they are less essential.

Calcium.—The main importance of calcium (Ca) in humid regions is its role in regulating soil acidity. In subhumid and arid regions with between 15 and 25 in. annual rainfall, calcium accumulates within the soil profile; in humid regions it tends to leach from the surface. Within humid regions there is great variation in the calcium supply of the surface and subsoil depending upon the amount of limestone or other calcium-bearing rock in the soil parent material and the extent of weathering and leaching Deficiencies are corrected by applying liming materials.

Magnesium.—Magnesium (Mg), like calcium, is related to soil pH or acidity. It is a basic part of chlorophyll, which imparts to green plants the ability to utilize sunlight in the photosynthetic process. Deficiencies are most likely to occur on acid soils. It may be supplied in the form of dolomitic limestone or for more immediate effect in the soluble forms such as Sul-Po-Mag and magnesium sulfate (Epsom salts).

Sulfur.—Sulfur (S) is added to the soil in plant residues and manures, in precipitation that carries down sulfur exhausted into the air in smoke from many industries, in commercial fertilizers in ahich sulfuric acid is involved and by soil organisms that utilize sulfur dioxide gas. Sulfur is used to acidify soils for acid-loving plants including rhododendrons and azaleas.

Minor or Trace Elements.—Some elements, though absolutely essential to plant growth, are utilized in minute quantities. Research on deficient areas and plant responses is much less complete than for the major nutrients.

Boron is important for cell division in the actively growing portions of plants. Boron (B) deficiencies cause stunting, discoloration and dying of the growing tips; are most likely to occur on sandy soils; and are aggravated by liming because the solubility of boron compounds decreases with increasing pH. Borax, $Na_2B_4O_7.10H_2O$, with 11% boron, is commonly used to correct deficiencies and is applied in amounts from 25 to about 80 lb. per acre. Water-soluble types are sometimes applied as foliar sprays. Boron is found in Chilean nitrate, in the Searles lake brine in California and in other southwestern states.

Copper, as needed by plants, is deficient in only a few scattered areas of the norld. It is supplied mainly as copper sulfate, $CuSO_4.5H_2O$, and to some extent as cupric oxide, CuO, and in other copper compounds.

Iron is one of the most common elements in the earth's crust and is deficient usually only under alkaline conditions where its solubility is low. It is applied as ferrous sulfate, often in foliar spray. It is especially needed by acid-loving plants.

Manganese is most often deficient on alkaline soils because of low solubility of manganese (Mn) compounds. Foliar sprays are therefore often more effective than soil applications. Manganese sulfate, $MnSO_4$, is the main salt applied.

Molybdenum is one of the most recent elements to be proved essential. Soil molybdenum (Mo) supplies become more available as soil acidity increases. It is nidely used in New Zealand and Australia on legumes. Cauliflower is especially sensitive to deficiency as are the related species, broccoli and brussels sprouts. Sodium molybdate. $NaMoO_4.2H_2O$, and ammonium molybdate are common sources. Deficiencies occur in citrus in Florida.

Zinc is commonly deficient for certain tree fruits in Florida and for corn in a few small areas in the United States. It is usually supplied in fertilizers as the sulfate $ZnSO_4.7H_2O$ and is most effective as a foliar application.

Chelates and Frits.—Minor or trace element deficiencies are frequently caused not by a lack of the element in the soil but rather by a low availability because the nutrient is tied up in insoluble compounds. Minor elements have been formulated as frits (glass) and chelates (organic materials), in which forms they are not subject to soil fixation and are slowly available over a long period.

XIII. MANURES

Farm manure usually consists of animal feces and urine plus bedding materials. Of the nutrients consumed by farm animals about 75% of the nitrogen, 80% of the phosphorus and 90% of the potassium is voided and this constitutes an enormous fertility resource, although in comparison with chemical fertilizers it is low in concentration and subject to large nutrient losses when improperly handled. Approximately half the nitrogen and nearly all of the potassium is leachable if the manure is exposed to rainfall before being applied to the field. Part of the nitrogen in urine readily converts to ammonia and is lost by volatilization. Much of the organic matter may be oxidized and lost when the manure is stacked for several months. Effective techniques for reducing losses include the use of adequate bedding in the stable to absorb the urine; stacking the manure under cover or in pits to prevent leaching; spreading it on fields and incorporating it into the soil as soon as is feasible; and spreading preservative materials in the stable. The most widely used preservative is ordinary superphosphate which contains gypsum, $CaSO_4$, that reacts with ammonium carbonate, $(NH_4)_2CO_3$, to form ammonium sulfate from which the ammonium is not volatilized.

Home gardeners like to use well-rotted manure. It is less odorous, more easily spread and less likely to "burn" plants. The production of rotted manure is wasteful of the organic matter and also results in great losses of soluble nitrogen and potassium unless it takes place under cover. Manure is a highly variable product depending upon kind of livestock as well as handling and storage methods. Widely used figures are 10 lb. of nitrogen, j lb. of phosphoric acid. P_2O_5, and 10 lb. of potash. K_2O, per ton of average stable manure including bedding. Sheep, goat and poultry manures average higher in all nutrients than these figures and these manures are often further concentrated by drying and sometimes by enriching with chemical fertilizers. Animal manures are lowest in phosphorus and this is the first element to consider adding. Typical rates to apply fresh stable manures are 8 to 20 tons per acre. (*See* also GUANO.)

In some of the most densely populated areas of the world. human excrement is an important source of fertilizer nutrients. A typical example is the "night soil" of China which has been used for centuries. Human excrement also makes up part of the sewage of large cities which is sometimes processed and sold as selvage sludge.

XIV. COMPOST

Home owners often have leaves, lawn clippings and garden refuse which may be effectively converted to compost, a product similar to well-rotted animal manure. Compost is made with plant residues, soil, fertilizer and sometimes limestone. The first three materials should be placed in alternate layers of four to six inches of residues, two to four inches of soil and one pound of a complete fertilizer for each eight to ten pounds of plant residues. One-half pound of limestone per pound of fertilizer will maintain a favourable pH for the microorganisms that decay the residues. The compost pile should be straight-sided, located preferably in a damp, shady place and kept moist but not saturated enough to leach soluble nutrients. Several months of summer weather are needed to fully decay the compost heap. The rate of decay may be accelerated by turning and mixing the pile at two-month intervals. Compost of this type is excellent for fertilizing or mulching shrubs and gardens.

FESCENNINE VERSES (Lat. *Fescennini versus,* also called *carmina Fescennina*), a native Italian form of poetry. At vintage and harvest. according to Vergil and Horace, and probably at other rustic festivals,.according to Tibullus, masked dancers sang jocular dialogues in verse. Festus and Symmachus state that similar songs were in use at weddings. Horace states that they became so abusive that a law was passed to check them; apparently the provision of the Twelve Tables which forbade a *malum carmen* (evil song; *i.e.,* charm intended to hurt) was stretched to include libelous verses. Macrobius refers to *Fescennini* written by Augustus attacking Asinius Pollio. It is also clear from the literary imitations by Catullus (in lxi) and Claudian (xi–xiv) that they were very free, even obscene, in language. Festus says that they averted the evil eye and that therefore some connected the name with *fascinum.* This derivation is supported by G. Michaut in *Histoire de la Comédie romaine: sur les tréteaux latins* and by other scholars, but they suppose *fascinum* to have the sense of "phallus," not "evil eye."

The true derivation may be from Fescennia, an Etruscan city, but it may reasonably be supposed that in their origin they had a magico-religious intent, abuse, buffoonery and obscenity being well-known fertility or luck charms. That they developed into the dramatic satura and thus gave birth to the beginnings of a native drama is implied by Livy but has been seriously doubted in modern times.

See E. Paratore, *Storia del teatro Latino,* pp. 11–14 (1957). (WM. BE.)

FESCH, JOSEPH (1763–1839), cardinal, was born at Ajaccio, Corsica, on Jan. 3, 1763. He was connected with the Bonaparte family by his father's second marriage to the widowed mother of Laetitia Bonaparte. At the outbreak of the French Revolution. he was archdeacon of Ajaccio; he protested against the application to Corsica of the act known as the "civil constitution of the clergy" (July 1790). On the suppression of religious orders and corporations, he had to retire into private life.

He was drawn by the Bonaparte family into espousing the French cause against Paoli and the Anglophiles. and accompanied Laetitia and her son to Toulon, in the early part of the autumn of 1793. His fortunes rose rapidly when Napoleon became First Consul (Nov. 1799). He resumed his clerical vocation, and took an active part in the complex negotiations which led to the signing of the Concordat with the Holy See on July 1j, 1801. He was then made archbishop of Lyons (1802), and cardinal 1803).

In 1804 he succeeded Cacault as French ambassador at Rome. He was assisted by Chbteaubriand. but soon sharply differed with him on many questions. His tact in overcoming the reluctance of the pope to be present at the coronation of Napoleon in Notre Dame. Paris (it was only eight months after the execution of the duc d'Enghien) was rewarded with further honours. Finally. in 1806 Karl von Dalberg, then prince bishop of Regensburg. chose him as coadjutor and designated him as his successor. Before the succession fell vacant, however, Regensburg had been incorporated in Bavaria.

By this time Napoleon mas in sharp collision with the pope on various matters both political and religious. Fesch, who was still ambassador in Rome, went as far as possible in counselling the submission of the spiritual to the civil power. For a time he was not on speaking terms with the pope; but Napoleon was dissatisfied, and recalled him.

Affairs came to a crisis when Napoleon decreed (May 17, 1809) the annexation of the papal states to the French empire. In that year Napoleon conferred on Fesch the archbishopric of Paris, but he refused the honour. In 1811 Fesch presided over a Gallican church council convened by the emperor, but failed to satisfy Napoleon, and was dismissed to his diocese. Next year Napoleon intercepted a letter from Fesch to Pius VII., who was then detained at Fontainebleau, and there was a serious breach. The tension between Fesch and the emperor was less in 1812–13. During the Hundred Days Fesch resumed his archiepiscopal duties at Lyons and became a member of the senate. On the second abdication Fesch retired to Rome. He left many works of art to the city of Lyons. He died at Rome on May 13, 1839.

See Ricard, *Le Cardinal Fesch* (1893); H. Welschinger, *Le Pape et Pempereur* (1905); F. Masson, *Napoléon et sa famille* (4 vols., 1897–1900), this correspondence with Napoleon was edited by Ducasse (1855).

FESCUE, the name given to the numerous and widely distributed perennial grasses of the botanical genus *Festuca,* found chiefly in temperate and cold regions, among which are several pasture and fodder grasses of agricultural importance. The most important of these is the tall or meadow fescue (*F. elatior*) common throughout Europe and in parts of Asia and widely cultivated and naturalized in the United States and Canada. It grows to a height of from two to five feet, and is regarded as one of the most valuable grasses for both fodder and permanent pasture. The red fescue (*F. rubra*), found throughout cool north temperate regions, is sometimes grown in meadows. The sheep's fescue (F. *ovina*), native to the Himalayas and certain mountainous districts of North America and Europe, and widely naturalized in north temperate regions. is sometimes used in dry pastures. A form called the blue fescue (var. *glauca*), with silvery-glaucous leaves, is grown for ornament.

The closely allied genus *Bromus,* which includes the brome grasses, is abundantly represented in north temperate regions, and various species are grown for forage and for ornamental purposes. Among those important agriculturally are the erect brome (B. erectus). useful as a forage grass on dry, chalky soil, and the awnless or Hungarian brome (*B. inermis*), grown for pastures and meadows. See GRASSES.

FESSA (FASA. originally Basa Sir), a town 90 mi. S.E. of Shiraz, on a fertile plain in the province of Fars, Iran. A walled city. it was famous for its large cypress-wood houses, and the manufacturing of rich textiles. For centuries good dates, oranges and nuts have grown there and it also produces other fruits, grain, tobacco and opium. The population (1956) is 11,706 and in the surrounding district of the same name are some 40 villages.

FESSE, one of the ordinaries in heraldry. *See* HERALDRY.

FESSENDEN, WILLIAM PITT (1806–1869), American statesman and financier, was born in Boscawen, N.H., on Oct. 16, 1806. After graduating at Bowdoin college in 1823, he studied law, and in 1827 was admitted to the bar, eventually settling in Portland, Me., where for two years he was associated in practice with his father, Samuel Fessenden (1784–1869), a prominent lawyer and anti-slavery leader. In 1832 and in 1840 Fessenden was a representative in the Maine legislature, and in 1841–43 a Whig member of the national House of Representatives. When his term in this capacity was over, he devoted himself with great success to the law. He became well known, also, as an eloquent advocate of slavery restriction. In 1854 he was chosen by the combined votes of Whigs and' Anti-Slavery Democrats to the United States Senate, where he delivered a speech in opposition to the Kansas-Nebraska bill which made him a force in the congressional anti-slavery contest. He was re-elected to the Senate as a member of the Republican party. As chairman of the Senate committee on finance, his services were second in value only to those of President Lincoln and Secretary Salmon P. Chase in efforts to provide funds for the defence of the Union; in 1864 Fessenden succeeded Chase as secretary of the Treasury. The finances of the country in the early summer of 1864 were in a critical condition; a few days before leaving office Chase had been compelled to withdraw from the market $32,000,000 of 6% bonds. on account of the lack of acceptable bids; gold had reached 285, while the value of the paper dollar had sunk as low as 34 cents. It was Fessenden's policy to avoid a further increase of the circulating medium, and in spite of powerful pressure the paper currency was not increased during his tenure of office. As the sales of bonds and treasury notes were not sufficient for the needs of the Treasury, interest-bearing certificates of indebtedness were issued to cover the deficits. When these began to depreciate Fessenden engaged the services of the Philadelphia banker Jay Cooke (*q.v.*) and secured the consent of Congress to raise the balance of the $400,000,000 loan authorized in 1864 by the sale of the so-called "seven-thirty" Treasury notes (*i.e.,* notes bearing interest at 7·3% payable in currency in three years or convertible at the option of the holder into 6% 5–20 year gold bonds). Through Cooke's activities the sales were enormous; the notes, issued in denominations as low as $50, appealed to the patriotic impulses of the people who could not subscribe for bonds of a higher denomination. In the spring of 1865 Congress authorized an additional loan of $600,000,000 to be raised in the same manner, and for the first time in four years the Treasury was able to meet all its obligations. After thus securing ample funds for the enormous expenditures of the war, Fessenden resigned the Treasury portfolio in March 1865, and again took his seat in the Senate, serving till his death. He was not, however, entirely in accord with the more radical members of his own party, and this difference was exemplified in his opposition to the impeachment of President Johnson and subsequently in his voting for Johnson's acquittal. He died at Portland, Me., on Sept. 6, 1869.

See Francis Fessenden, *Life and Public Services of William Pitt Fessenden* (Boston, 1907).

FESSLER, IGNAZ AURELIUS (1756–1839), Hungarian scholar, was born on May 18, 1756, at Zurány, Hungary. He became a capuchin, and made many enemies by exposing the abuses of the monasteries to the emperor, Joseph II., who ordered a searching examination in consequence. He held a chair at Lemberg university for a short time, but had to leave Hungary after the publication of his tragedy *Sidney* (1788), attacking the English Roman Catholics. He was converted to Lutheranism, and wandered from place to place. In 1796, in Berlin, he was commissioned. with Fichte, to reform the statutes of the free-masons' lodge there. In 1809 Alexander I. offered him a chair at St. Petersburg (now Leningrad), of which he was soon deprived on account of his heterodox opinions. In Nov. 1820 he was appointed consistorial president of the evangelical communities at Saratov, and later became superintendent of the Lutheran communities in St. Petersburg. He died at St. Petersburg Dec. 15, 1839.

Among his numerous works are *Die Geschichten der Ungarn und ihrer Landsassen* (10 vols., Leipzig, 1815–25); *Mathias Corvinus* (2 vols., Breslau, 1793–94); *Die drei grossen Könige der Ungarn aus dem Arpadischen Stamme* (Breslau, 1808); and the autobiographical *Rückblicke auf seine siebzigjährige Pilgerschaft* (Breslau, 1824; 2nd ed, Leipzig, 1851). See J. Koszó, *A. I. Fessler* (1923).

FESTA, CONSTANZO (c. 1495–1545), Italian singer and musical composer, became a member of the Pontifical choir in Rome in 1517, and soon afterwards *maestro* at the Vatican. His motets and madrigals (the first book of which appeared in 1537) excited Dr. Burney's warm praise in his *History of* Music; and among other church music, his *Te* Deum (published in 1596) is still sung at important services in Rome. His madrigal, called in English "Down in a flow'ry vale," is well known.

FESTIVALS, MUSIC. Music festivals, which have had a long continued period of development, generally adopted a basic form—a combination of orchestra and chorus with solo artists, interpreting large and important works.

Successive church services with choral singing and instrumental playing were of the nature of music festivals since the earliest times of Christianity. The oldest church festival in England was the Festival of the Sons of the Clergy, organized in 165j. and held at St. Paul's cathedral in London. The earliest English church festival still preserving its traditions in the second half of the 20th century was founded in 1724 under the name of Three Choirs festival, with concerts presented in Gloucester, Worcester and Hereford in turn, and with choral groups from the three communities taking part.

The once renouned Birmingham festival, founded in 1768, discontinued its activities in 1914. The Norwich festival, inaugurated in 1770, continued irregular meetings, mostly at triennial intervals. The Leeds Musical festival was established in 1858, on the occasion of the opening of the tonn hall by Queen Victoria; it became a triennial event in 1874. The Sheffield festival began in 1896. All suffered interruption during World Wars I and II.

The inception of many provincial festivals in England was motivated by charity. whether for indigent clergy or the poor of the district. But soon purely musical considerations asserted themselves, and many great works of classical music, as well as compositions by English musicians, were heard at these festivals. The movement spread to other cities and towns in Britain (Edinburgh, Liverpool, Cheltenham), culminating in a sumptuous national gathering in London during the Festival of Britain of 1951, when 22 concerts were presented.

One of the features of music festivals in Britain has been a long succession of performances devoted to Handel. The first was held in 1784 as a commemorative function in Westminster abbey. This was a project built on a large scale—525 players and singers—destined to great augmentation in later years. The most important of succeeding festivals were the triennial three-day Handel concerts founded at the Crystal palace, London, in 1857. and presented in gargantuan fashion. By 1923 the orchestra and chorus numbered 4,000. When the Crystal palace was totally destroyed by fire in 1936, the Handel festivals ended, for there was no other building large enough to accommodate so vast a body of performers, or the virtually unlimited public wishing to attend them.

A unique example of such eventful occasions, with, however, more varied programs, was the Musical Festival of the British Empire in 1911, the coronation year of George V. The zoo members of the Sheffield choir, under the direction of Sir Henry Coward, circled the world, giving performances of choral and orchestral works during a period of six months.

In the United States. the oldest music festival was the Peace jubilee. held on Feb 22, 181j, in Boston, Mass., to commemorate the cessation of hostilities between England and the United States. Subsequent peace jubilees took place in Boston in 1869 and 1872; a huge orchestra of 2,000 musicians and a chorus of 20,000 participated at the second of these events.

The triennial festivals of the Handel and Haydn Society of Boston were established in 1868.

A festival concert under the direction of Theodore Thomas, with an orchestra of 150 players, was held at the Centennial exhibition in Philadelphia, Pa., in 1876.

Among other periodic U.S. music festivals the following, with the dates of their formal opening, were of importance: Worcester, Mass.. festival (1858); Oberlin, O., Spring festival (1860); Biennial May festival of Cincinnati, O. (1873); Ann Arbor, Mich., May festival (1893); Bethlehem, Pa., Bach festival (1900); Evanston. Ill., North Shore festival (1908); Westchester County festival, N.Y. (1925); and Aspen, Colo., festival (1949). Elizabeth Sprague Coolidge established an annual Chamber Music festival in Pittsfield, Mass.. in 1918; these festivals were transferred in 1925 to the Library of Congress, Washington, D.C. The prime object of the Coolidge festivals is to promote chamber music by contemporary composers through special commissions of works.

The Eastman School Festival of American Music was started in Rochester, N.Y.. in 1925, by Howard Hanson. The Berkshire festival of the Boston Symphony orchestra was established by Serge Koussevitzky in 1937.

In Europe, the earliest music festival was a series of concerts undertaken in 1673 at Liibeck by Dietrich Buxtehude, under the name "Xbendmusiken." The Tonkiinstler-Societat of Vienna (1772) was active in presenting annual performances of Austrian and German music. The famous Bayreuth festival was inaugurated by Richard Wagner in 1876 to present his music dramas in an appropriate setting. After several years of interruption during World War II, the performances of Wagner's music were resumed in Bayreuth in 1951 under the direction of his grandsons.

Among 20th-century festivals, the most important is that of the International Society for Contemporary Music founded in Salzburg, Aus., in 1922, and held thereafter (except in 1940 and 1943–45) each summer in various European and American cities. Many first performances of modern works were given at these festivals.

In 1933, the annual spring festival, Maggio Musicale, was inaugurated in Florence, It. The Holland Music festival opened an annual series at The Hague in 1948 Music festivals were organized in quick succession in virtually all European centres during the 20th century.

In Germany festivals rapidly developed in the 19th century. Of particular significance were the Lower Rhenish festivals established in 1817 at Elberfeld, but which moved occasionally to Düsseldorf, Aix-la-Chapelle and Cologne. Felix Mendelssohn conducted seven of these festivals and other eminent directors were Anton Rubinstein, Johannes Brahms, Hans Richter, Richard Strauss, etc. The performances lapsed in 191j. Those of the Allgemeiner deutscher Musik-Verein, the concerts of which were known as the *Tonkünstversammlung,* were founded by Karl Franz Brendel, with powerful support from Franz Liszt. The first of these was held at Leipzig in 1859 and others followed, mostly in yearly succession in various German cities. The performances, which lasted several days, featured new works by contemporary composers. They were only interrupted by World War I, but failed to survive World War II.

European festivals became so numerous that, in order to avoid confusion and repetition of programs, a number of the festivals—including those at Berlin. Florence, Venice, It., Bayreuth, Aix-en-Provence, Fr., Vienna, Aus., Munich, Ger., and Ziirich, Switz.,—were amalgamated under the general title. European Association of Music Festivals. A number of cities include opera in their programs, and in some chamber as well as symphonic music is provided.

Competition Festivals.—These festivals date back to ancient times, with prizes awarded for best performances. The Eisteddfod (*q.v.*) in Wales, a national gathering of Welsh bards, held contests as early as the 6th century. Wagner's opera *Tannhauser* depicts the song contest of the German minnesingers of the 13th century.

While competition festivals may be said to have begun with the troubadours. minnesinger, minstrels, etc., in France and Germany in the 13th century, their groath in modem times was particularly marked in Great Britain. This was due in large part to the teaching in the 19th century of amateur sightsinging by the tonic-sol-fa method (movable doe), made popular by John Cunven (1816–1880) and by his son John Spencer Curwen. The latter, who began competitive festivals at London in 1860, offered prizes for the best singing of choral pieces and solos. Eventually the competitions included brass band and other instrumental performances, and spread throughout Britain. To bring order and better methods to the contests. the British Federation of Musical Competition Festivals was founded in 1921. One of its primary functions was the establishment of panels of competent adjudicators whose decisions would satisfy contestants and listeners alike.

In the United States most competition festivals are limited to individual or adjacent states, and in the majority of cases are connected with the music departments of secondary schools, particularly in the matter of bands, orchestras and choruses. In Ireland the principal competition festival is that of Feis Ceoil, founded in 1897, and usually held in Dublin. (N. Sy.; F. Bi.)

FESTOON, an ornament developed from the representation of a garland of leaves, fruit or floaers, cloth or ribbon, supported at two or more points and hanging in curves between. The festoon appears occasionally in late Greek work, particularly as a decoration for Hellenistic altars, but it was the Romans who gave it definite form. Roman festoons are usually made of fruit, grain, leaves and flowers, treated with extreme naturalism, although in wall paintings and stucco decoration simpler and more conventional types are found. The festoon was a favourite motive of the early Italian Renaissance. In Baroque work through Europe many fantastic treatments of the cloth festoon exist.

FESTUS, SEXTUS POMPEIUS (2nd or 3rd century A.D.), Latin grammarian, probably born at Narbo in Gaul, who made an abridgement in 20 books of Marcus Verrius Flaccus' De *verborum significatu.* In this work Festus made a few insertions and comments of his own. The first half of it is lost but a further abridgement of it, made by Paulus Diaconus in the 8th century, survives. Latin words which had long been obsolete he removed with the intention of including them in a separate work (*Priscorum verborum cum exemplis*), but whether this was ever written is doubtful. The remains of Festus' abridgement exist in only one manuscript, the Codex Festi *Farnesianus* at Naples, of which a facsimile was published at Budapest in 1893 by A. Thewrewk de Ponor.

FET (FOETH), **AFANASI AFANASIEVICH** (1820–1892), who assumed by decree in 1876 the name of Shenshin, Russian poet, was born at Novoselki, Orel, on Dec. 5, 1820, the illegitimate son of a landowner named Shenshin. He was still a student at Moscow university when, in 1842, he published some admirable lyrics in the *Moskvityanin.* In 1850 a volume of his Poems appeared, followed by another in 1856. He then served for several years in the army, retiring with the grade of captain in 1856. In 1860 he settled on an estate at Stepanovka, where he was often visited by Turgenev and Tolstoy. Fet's sincere and passionate lyric poetry strongly influenced later Russian poets, but during his lifetime he was decried because of his reactionary political views and somewhat unattractive personality. He published very little after 1863, but he continued to write nature poetry and love lyrics which were published in a collected edition (4 vol., 1894).

Fet also made some fine translations from Horace, Catullus and Tibullus, of Goethe's Faust and *Hermann und Dorothea.* He died in Moscow on Dec. 3, 1892.

See a paper on Fet in Oliver Elton's *Sheaf of Papers* (1922), which includes some translations.

FETAL DISORDERS, or disorders affecting the unborn human fetus. may be responsible for premature delivery, for the birth of a sick or malformed infant, or may cause death before birth. depending on the severity and variety of the disturbance.

Abortion, Stillbirth, Premature Birth.—The expulsion of a dead fetus in the first half of pregnancy is generally called an abortion; in the latter half of pregnancy it is designated a stillbirth or a late fetal death. The distinction between abortions and stillbirths has never been definitely settled and is based largely on state requirements for reporting, often 20 to 22 weeks. These subjects are discussed in separate articles ABORTION; STILLBIRTH; and PREMATURE BIRTH.

Postmature Birth.—On rare occasions pregnancy may be prolonged sufficiently to damage the child. If pregnancy does not end within three or four weeks of the normal time, the placenta may begin to degenerate and may not be able to supply the fetus with the materials it needs for survival and growth; in such cases death may occur before or during labour. The fetus is ordinarily not unusually large, but its skin may be dry and wrinkled, its fingernails and hair unusually long, and it may seem to be unusually mature. In some instances of prolonged pregnancy, however, the fetus becomes unusually large; this is a hazard to the fetus because delivery is often difficult, and the likelihood of injury is greater than when it is of normal size.

Growth of the fetus to an excessive size (over 4,500 grams or 10 lb.) during the normal length of pregnancy is rare except when the mother suffers from diabetes mellitus or is prediabetic. It has been shown that symptoms of diabetes generally appear within a few months or years following the delivery of an excessively large child, in a woman previously apparently nondiabetic. Any woman giving birth to an unusually large infant should be examined to determine whether or not she may be developing diabetes.

Erythroblastosis **Fetalis.**—Erythroblastosis fetalis is a disorder which has its origin during intra-uterine life as a result of incompatibility of the blood of the mother and the fetus. This is most often on the basis of the Rh factor, although the XB blood group is sometimes responsible.

Fetal blood cells are thought to escape from the placenta into the maternal circulation during any pregnancy. If the blood groups of the mother and the fetus are compatible, no harm results. If the mother is Rh-negative and the fetus is Rh-positive (by inheritance from its father), the mother may be stimulated to produce antibodies against the Rh-positive cells. Since Rh-positive blood cells are not normally present in her body, the response is the same as it mould be to bacteria or any other foreign substance, and antibodies are produced for the specific purpose of destroying Rh-positive cells. These antibodies against Rh-positive cells are so minute that they are able to penetrate the placenta and get into the blood of the fetus. Since their function is to destroy Rh-positive cells, they destroy varying amounts of fetal blood. This may result in anemia. If the fetus is able to produce enough blood cells to compensate for the destruction, anemia will not develop or will be mild. If the fetus cannot produce enough blood to keep pace with the destruction, it will be anemic at birth and will require immediate blood transfusions if it is to survive. Blood destruction continues after birth, producing excessive bilirubin, nhich gives the skin a yellow colour known as jaundice or icterus; parts of the brain may be injured if jaundice is severe and prolonged A form of treatment designated "exchange transfusion," in which the Rh-positive blood of the infant is removed and Rh-negative blood substituted, removes the bilirubin from the circulation and prevents brain damage. Only 5% of Rh-negative women give birth to infants affected by erythroblastosis. A fen fetuses are so severely affected that they die before birth and are stillborn, but the majority are born alive and most of these can be saved by modern treatment; a short time after birth they are entirely normal infants.

Pneumonia.—A fetus may develop pneumonia before birth. Throughout intra-uterine life the fetus normally inspires small amounts of the amniotic fluid by which it is surrounded. This is ordinarily sterile until labour begins or until the sac containing the fluid ruptures. Then bacteria enter, and if labour is very prolonged or if the bag of waters breaks before labour begins, enough bacteria may be inhaled by the fetus to cause pneumonia. Although this may be responsible for death before birth, more often the infant is ill when it is born but does not die for several hours, or may recover.

Malformations.—Malformations may be the cause of late fetal deaths or stillbirths, just as they may be responsible for early fetal deaths or abortions. The agents responsible for malformations in the human infant are almost entirely unknown. although many of the conditions that may be responsible for abortions are thought also to cause malformations

FETISHISM, a term used in many different senses: (1) the worship of inanimate objects, often regarded as peculiarly African; (2) the worship of inanimate objects conceived as the residence of spirits not inseparably bound up with nor originally connected with such objects; (3) the doctrine of spirits embodied in, or attached to, or conveying influence through certain material objects (Tylor); (4) the use of charms, which are not worshipped but derive their magical power from a god or spirit; (5) the use as charms of objects regarded as magically potent in themselves; (6) loosely, including the worship of inanimate objects, such as the sun. moon and stars, and such phases of primitive philosophy as totemism and animism.

The term may also be understood to mean the worship of or respect for inanimate objects, conceived as inherently magical.

The fetish may be regarded as a mascot or object carried for luck.

In the sense in which Sir Edward Burnett Tylor uses the term, the fetish is (1) a "god house"; or (2) a charm derived from a tutelary deity or spirit, and magically active in virtue of its association with such deity or spirit. In the first of these senses the word is applied to objects ranging from the unworked stone to the pot or the wooden figure, and is thus hardly distinguishable from idolatry. *(a)* The *bohsum* or tutelary deity of a particular section of the community is derived from the local gods through the priests by the performance of a certain series of rites. A *bohsum* may also be procured through a dream, but in this case, too, it is necessary to apply to the priest to decide whether the dream was veridical. *(b)* The *suman* is "an object which is the potential dwelling place of a spirit or spirits of an inferior status, generally belonging to the vegetable kingdom: this object is closely associated with the control of the powers of evil or black magic, for personal ends, but not necessarily to assist the owner to work evil, since it is used as much for defensive as for offensive purposes."

On the Guinea coast the spirit in the object is usually, if not invariably, nonhuman. Farther south on the Congo the fetish is inhabited by human souls also. The priest goes into the forest and cuts an image; when a party enters a wood for this purpose they may not mention the name of any living being unless they wish him to die and his soul to enter the fetish. The right person having been selected, his name is mentioned; and he is believed to die within ten days, his soul passing into the *nkissi*. Nails are driven into these figures in order to procure the vengeance of the indwelling spirit on some enemy. *See* also ANIMAL WORSHIP; ANIMISM; TOTEMISM.

FETTERS AND HANDCUFFS: *see* HANDCUFFS AND FETTERS

FETTI (FETI), **DOMENICO** (1588/89–1624), Italian painter of the Baroque period, was born in Rome and died in Venice, apparently as the result of dissipation. In Rome he was a pupil of Lodovico Cigoli but was principally influenced by the followers of Michelangelo Merisi da Caravaggio and also by Adam Elsheimer. Through Cigoli he attracted the attention of Cardinal Ferdinando Gonzaga: when the cardinal went to Mantua to become Duke Ferdinando II, Fetti became his court painter at about the end of 1613. At Mantua he saw the works of Rubens as well as those of Giulio Romano, and his style was considerably modified. Later, the influence of Venetian art was even more marked although he probably first visited the city about 1621 to buy works of art for his patron. At the end of Aug. 1622 Fetti left Mantua, apparently very hurriedly, and went to Venice, refusing to return in spite of the duke's efforts.

Fetti's best-known works are small, with small-scale figures, and painted in bright, rich colours, many of the most popular being representations of the biblical parables as scenes from everyday life. There are examples in Hampton court, Dresden, Mantua, Venice and Vienna of these and of other works.

See Baglione, *Vite de' Pittori . . .* (1642); M. Endres-Soltmann, D. F. (1914); R. Oldenbourg, D. F., mainly pictures (1921). (P. J. MY.)

FETUS, the unborn young of any vertebrate animal, particularly of a mammal. Biologists arbitrarily speak of the earliest stages of development of the fertilized egg (ovum) as the embryonic period. This period ends when the external form of the embryo begins to resemble clearly the newborn of the group to which it belongs. The next period, culminating in birth, is spoken of as the fetal period. Likewise a distinction is made between the embryo and the fetus. In human development this transition occurs at approximately the end of the ninth week after fertilization. At this time the embryonic clefts (harelip) of the face disappear, the paddlelike embryonic limb buds develop free fingers and toes and so take on the form of the human limbs, and the relatively long embryonic tail has nearly disappeared. After these changes and until birth the distinctly human-appearing embryo is technically a fetus.

See EMBRYOLOGY; EMBRYOLOGY, HUMAN; FETAL DISORDERS; etc. (H. W. MN.)

FEU, in Scotland, the common mode of land tenure. The word is the Scots variant of "fee" (*q.v.*). The feudal system still dominates Scots conveyancing, but its forms are now extensively modified by the Titles to Land (Consolidation) (Scotland) Act 1868, the Conveyancing (Scotland) Act 1874, the Conveyancing (Scotland) Act 1924, and some other statutes. It now contains three variants of holding.

Burgage holding is the system by which land in royal burghs is held, Blench holding is by a nominal payment, as of a penny Scots to be rendered upon demand only. In feu holding proper there is a substantial annual payment in money in return for the enjoyment of the land. The crown is the first overlord or superior, and land is held of it by crown vassals, but they in their turn may "feu" their land, as it is called, to others who become *their* vassals, while they themselves become mediate overlords or superiors. This process of subinfeudation may be repeated to an indefinite extent, except in cases where subinfeudation has been conventionally prohibited prior to the year 1874. If the vassal does not pay the annual feu duty for two years, the superior, among other remedies, may obtain by legal process a decree of irritancy, whereupon *tinsel* or forfeiture of the feu follows. Casualties, which are a feature of land held in feu, are additional payments to the superior, contingent on the happening of certain events.

By the Feudal Casualties (Scotland) Act 1914 all such casualties as may not have been redeemed or commuted by Jan. 1, 1930, shall be extinguished and discharged.

See Erskine's *Principles;* Bell's *Principles;* Rankine, *Law of Land-ownership in Scotland.*

FEUCHERES, SOPHIE, BARONNE DE (1795–1840), Anglo-French adventuress, was born at St. Helens, Isle of Wight, in 1795, the daughter of a drunken fisherman named Dawes. She grew up in the workhouse. went up to London as a servant, and became the mistress of the duc de Bourbon, afterward prince de Condé, who gave her a good education in modern and ancient languages. He arranged her marriage to Adrien Victor de Feuchères, and the baroness, pretty and clever, became a person of consequence at the court of Louis XVIII. De Feuchères discovered the relations between his wife and Condé, whom he had been assured was her father, obtained a legal separation in 1827, and the king forbade her appearance at court. Thanks to her influence, however, Condé was induced in 1829 to sign a will bequeathing more than 66,000,000 fr. to the duc d'Aumale, fourth son of Louis Philippe.

Again the baroness was in high favour. Charles X received her at court, Talleyrand visited her, her niece married a marquis and her nephew was made a baron. Condé, wearied by his mistress's importunities, and but half pleased by the advances made him by the government of July, had made up his mind to leave France secretly. However, he was found hanging dead from his window (Aug. 27, 1830). The baroness returned to London, where she died in Dec. 1840.

FEUCHTERSLEBEN, ERNST, FREIHERR VON (1806–1849), Austrian physician, poet and philosopher, was born in Vienna on April 29. 1806, of an old Saxon noble family. He was educated at the University of Vienna, and in 1844 was appointed dean of the faculty of medicine. In 1848, while refusing the presidency of the ministry of education, he accepted the appointment of undersecretary of state in that department. He died in Vienna on Sept. 3, 1849. He was not only a clever physician, but a poet of fine aesthetical taste and a philosopher. Among his medical works may be mentioned: *Über das Hippokratische erste Buch von der Diat* (Vienna, 1835), *Ärzte und Publicum* (Vienna, 1848) and *Lehrbuch der ärztlichen Seelenkunde* (1845). His poetical works include *Gedichte* (Stutt, 1836), among which is the well-known beautiful hymn, which Felix Mendelssohn set to music, "Es ist bestimmt in Gottes Rat." As a philosopher he is best known by his *zur Diätetik der Seele* [Dietetics of the Soul] (Vienna, 1838).

See M. Necker, "Ernst von Feuchtersleben, der Freund Grillparzers," in the *Jahrbuch der Grillparzer Gesellschaft,* vol. iii (1893).

FEUCHTWANGER, LION (1884–1958), German writer, best known for his historical novels, was born in Munich on July 7, 1884, of a Jewish family, his father being a manufacturer. He studied philosophy in Berlin and Munich and early devoted himself to literature. His first works were dramatic pieces, original or translations: *Die Perser* (Aeschylus) (1915); *Vasantasena* (1915); *Friede* (Aristophanes) (1916); *Kriegsgefangenen* (1916); *Thomas Wendt* (dramatic novel, 1919); *Der hollandische Kaufmann* (1921). He broke new ground in 1923 with a noteworthy historical novel of Margarete Maultasch, duchess of Tirol *(Die hässliche Herzogin;* English trans., *The Ugly Duchess,* 1927), in which the life of 14th-century Tirol was reproduced with great dramatic force. *Jud Suss* (1925, English trans., *Jew Suss,* 1927), a novel of 18th-century Germany, was even more notable. Feuchtwanger's later works included *Angelsächsische Trilogie* (1927); a translation of Christopher Marlowe's *Edward 11* (1925); *Power* (1926); *Success* (1930); the historical trilogy of *Josephus* (1932), *The Jew of Rome* (1935) and *Josephus and the Emperor* (1942); *The Pretender* (1937); and *Proud Destiny* (1947). In 1933 Feuchtwanger was expelled from Germany and later settled in the U.S., where he died in Los Angeles on Dec. 21, 1958.

FEUD, animosity, hatred, especially a permanent condition of hostilities between persons, and hence applied to a state of private warfare between tribes, clans or families, a "vendetta," (*q.v.*).

FEUDALISM (from Late Lat. *feodum* or *feudum,* a fee or fief; *see* FEE). In every case of institutional growth in history two things are to be distinguished from the beginning for an understanding of the process and its results. One of these is the change of conditions in the political or social environment which made growth necessary. The other is the already existing institutions which began to be transformed to meet the new needs. In studying the origin and growth of political feudalism, the distinction is easy to make.

The prevailing need of the later Roman and early mediaeval society was protection — protection against the sudden attacks of invaders or revolted peasants, against the unwarranted demands of government officers, or even against the legai but too heavy exactions of the government. The protection which the government normally furnished, the weak freeman and the small landowner could no longer obtain. He must seek protection wherever he could get it, and pay the price demanded for it.

These are the great social facts — the failure of government to perform one of its most primary duties, the necessity of finding some substitute in private life — extending through the whole formative period of feudalism.

Roman Origins. — The institutions which the need of protection seized upon had both long existed in the private, not public, relations of the Romans. One of them related to the person, the other related to land. There are thus distinguished at the beginning those two great sides of feudalism which remained to the end more or less distinct.

The personal institution needs little description. It was the Roman patron and client relationship which had remained in the days of the empire, in later times less important perhaps legally than socially. This institution. the *patrocinium,* was firmly enough entrenched to survive the German conquest, and to be continued by the conquerors. In its new use, alike in the later Roman and the early German state, the landless freeman who could not support himself offered his services, those proper to a freeman, to some powerful man in return for shelter and support.

This transaction, called commendation, gave rise in the German state to a written contract which related the facts and provided a penalty for its violation. It created a relationship of protection and support on one side, and of free service on the other.

The other institution, relating to land, was that known to the Roman law as the *precarium,* because of the prayer of the suppliant by which the relationship was begun. The *precarium* was a form of renting land not intended primarily for income, but for use when the lease was made from friendship, for example, or as a reward, or to secure a debt. Legally its characteristic feature was that the lessee had no right of any kind against the grantor. The owner could terminate the relation at any time, for any reason, or for none at all, and the heirs of neither party were bound by it.[1] The legal character of this transaction is summed up in a well-known passage in the *Digest* (xliii. 26. 12) which may be paraphrased as follows: — The *precarium* tenant may employ the interdict against a third party, because he cannot use the ordinary civil action, his holding being not a matter of business but rather of favour and kindness.

As used for protection in later Roman days the *precarium* gave rise to what was called the commendation of lands, *patrocinium fundorum.* The poor landowner surrendered to his powerful neighbour the ownership of his lands, which he then received back as a *precarium* — gaining protection during his lifetime at the cost of his children, who were left without legal claim and compelled to make the best terms they could.[2] Applied to this use the *precarium* found extensive employment in the last age of the empire. The government looked on the practice with disfavour, because it transferred large areas from the easy access of the state to an ownership beyond its reach. The laws repeatedly forbade it under increasing penalties, but it could not be stopped.

Frankish Development. — These practices the Frankish conquerors of Gaul found in full possession of society, and they seem to have made them their own without material change. The *patrocinium* they could understand by the existence of a somewhat similar institution among themselves, the *comitatus,* described by Tacitus. The *comitatus* made contributions of its own to future feudalism, to some extent to its institutional side, largely to the ideas and spirit which ruled in it. Probably the ceremony which grew into feudal homage, and the oath of fealty, certainly the honourable position of the vassal and his pride in the relationship, the strong tie which bound lord and man, and the idea that faith and service were due on both sides in equal measure, may be traced to German sources. But we must not forget that the origin of the vassal relationship, as an institution, is to be found on Roman soil.

To the *precarium* German institutions offered no close parallel. The advantages which it afforded were obvious, and this side of feudalism developed as rapidly after the conquest as the personal. The new German noble was as eager to extend his lands and to increase the numbers of his dependants as the Romans had been. The new German government furnished no better protection from local violence, nor was it able any more effectively to check the practices which were creating feudalism. *Precarium* and *patrocinium* easily passed from the Roman empire to the Frankish kingdom, and became firmly rooted in the new society. Up to this point we have seen only the small landowner and the landless man entering into these relations. Feudalism could not be established, however, until the great of the land had begun to enter the clientage of others and to hold lands by the *precarium* tenure. The first step was quickly taken. The same class continued to furnish the king's men, and to form his household and body-guard whether the relation was that of the *patrocinium* or the *comitatus,* and to be made noble by entering into it. It was later that they became clients of one another, and in part at least as a result of their adoption of the *precarium* tenure. In this latter step the influence of the Church rather than of the king seems to have been effective. The large estates which pious intentions had bestowed on the Church it was not allowed to alienate. It could most easily make them useful by employing the *precarium* tenure. On the other side, the great men were ready without persuasion to annex portions of these estates for their own on the easy terms of this tenure, not always indeed observed by the holder, or able to be enforced by the Church. The employment of the

precarium by the Church seems to have been one of the surest means by which this form of landholding was carried over from the Romans to the Frankish period and developed into new forms. It came to be made by degrees the subject of written contract, by which the rights of the holder were more definitely defined and protected than had been the case in Roman law. The length of time for which the holding should last came to be specified, at first for a term of years and then for life, and some payment to the grantor was provided for, not pretending to represent the economic value of the land, but only to serve as a mark of his continued ownership.

The Carolingian Age.—These changes characterize the Merovingian age, which had practically ended, however, before these two institutions showed any tendency to join. Nor had the king up to that time exerted any apparent influence on the processes that were going forward. It was the advent of the Carolingian princes that carried these institutions a stage further forward. Making their way up from a position among the nobility to be the rulers of the land, and finally to supplant the kings, the Carolingians had especial need of resources from which to purchase and reward faithful support. The fundamental principle of the Frankish military system, that the man served at his own expense, was still unchanged. It had indeed begun to break down under the strain of frequent and distant campaigns; but it was long before it was changed as the recognized rule of mediaeval service. If now, in addition to his own expenses, the soldier must provide a horse and its keeping, the system was likely to break down. To solve this problem the early Carolingian princes, especially Charles Martel, grasped at the land of the Church. The means devised to permit its use were found in the *precarium* tenure. Keeping alive, as it did, the fact of the grantor's ownership, it did not in form deprive the Church of the land. Recognizing that ownership by a small payment not corresponding to the value of the land, it left the larger part of the income to meet the need which had arisen. At the same time undoubtedly the new holder of the land, if not already the vassal of the prince, was obliged to assume an obligation of service with a mounted force when called upon. This expedient gave rise to the numerous *precariae verbo regis,* of the Church records, and to the condemnation of Charles Martel in the visions of the clergy to worse difficulties in the future life than he had overcome in this. The most important consequences of the expedient, however, was the bringing together of the two sides of feudalism, vassalage and benefice, as they were now commonly called. It emphasized military service as an essential obligation of the vassal; and it spread the vassal relation between individual proprietors and the sovereign.

During the reign of Charlemagne and the later Carolingian age continued necessities, military and civil, forced the kings to recognize these new institutions more fully, even when standing between the government and the subject, intercepting the public duties of the latter. The incipient feudal baron had not been slow to take advantage of the break-down of the old German military system. The poor Frank could escape the ruinous demands of military service only by submitting himself and his lands to the count, who did not hesitate on his side to force such submission. Charlemagne legislated against this tendency, trying to make it easier for the poor freeman to fulfil his military duties directly to the state, and to forbid the misuse of power by the rich. Finally the king was compelled to recognize existing facts, to lay upon the lord the duty of producing his men in the field and to allow him to appear as their commander. This completed the transformation of the army into a vassal army: it completed the recognition of feudalism by the state, as a legitimate relation between different ranks of the people; and it recognized the transformation in a great number of cases of a public duty into a private obligation.

In the meantime another institution had grown up in this Franco-Roman society, which probably began and certainly assisted in another transformation of the same kind. This is the immunity. Suggested probably by Roman practices, it received a great extension in the Merovingian period, at first and especially in the interest of the Church, but soon of lay land-holders By the grant of an immunity to a proprietor the royal officers, the count and his representatives, were forbidden to enter his lands to exercise any public function there The duties which the count should perform passed to the proprietor, who now represented the government for all his tenants free and unfree. Apparently no modification of the royal rights was intended by this arrangement, but the beginning of a great change had really been made. The king might still receive the same revenues and the same services from the district held by the lord as formerly, but for their payment a private person in his capacity as overlord was now responsible In the course of a long period characterized by a weak central government, it was not difficult to enlarge the rights which the lord thus obtained, to exclude even the king's personal authority from the immunity, and to translate the duties and payments which the tenant had once owed to the state into obligations which he owed to his lord. even finally into incidents of his tenure. The most important public function whose transformation into a private possession was assisted by the growth of the immunity was the judicial. The lord's court gradually took the place of the public court in civil, and even by degrees in criminal cases. The plaintiff, even if he were under another lord, was obliged to sue in the court of the defendant's lord, and the portion of the fine for a breach of the peace which should have gone to the state went in the end to the lord

The transfer of the judicial process, and of the financial and administrative sides of the government as well. into private possession, was not, however, accomplished entirely by the road of the immunity. As government weakened after the strong days of Charlemagne, and disorder, invasion, and the difficulty of intercommunication tended to throw the locality more and more upon its own resources, the officer who had once been the means of centralization. the count, was able to exercise the powers which had been committed to him as an agent of the king, as if they were his own private possession Nor was the king's aid lacking to this method of dividing up the royal authority, any more than to the immunity, for it became a frequent practice to make the administrative office into a fief. and to grant it to be held in that form of property by the count In this way the feudal county. or duchy, formed itself, corresponding in most cases only roughly to the old administrative divisions of the state.

DIFFERENT STAGES OF GROWTH

In its earliest stage of growth the feudal system was that of the private possession only. For protection the great landowner forced his smaller neighbours to become his dependants in return under a great variety of forms, but especially developing thereby the *precarium* land tenure and the *patrocinium* personal service, and organizing a private jurisdiction over his tenants. and a private army for defence. Finally he secured from the king an immunity which excluded the royal officers from his lands and made him a quasi-representative of the state In the meantime his neighbour the count had been following a similar process. His right to exact military, financial and judicial duties for the state he had used to force men to become his dependants, and then he had stood between them and the state, freeing them from burdens which he threw with increased weight upon those who still stood outside his personal protection. The kings first adopted for themselves some of the forms and practices which had thus grown up, and by degrees recognized them as legally proper for all classes. It proved to be easier to hold the lord responsible for the public duties of all his dependants because he was the king's vassal and by attaching them as conditions to the benefices which he held, than to enforce them directly upon every subject When this stage was reached the formative ape of feudalism may be considered at an end When the government of the state had entered into feudalism, and the king was as much lord as king; when the vassal relationship was recognized as a proper and legal foundation of public duties; when the two separate sides of early feudalism were united as the almost universal rule, so that a man received a fief because he owed a vassal's duties, or looked at in the other and finally prevailing way, that he owed a vassal's duties because he had received a fief; and finally, when the old idea of the temporary character of the *precarium* tenure was lost sight of, and the right of the vassal's heir to receive his father's holding was recognized as the general rule—then the feudal system may be called full grown. We shall not be far wrong if we place the end of its formative age near the beginning of the 10th century.

Results in England.— The growth which we have traced took place within the Frankish Empire. In Anglo-Saxon England *precarium* and *patrocinium* were lacking. Certain forms of personal commendation did develop, certain forms of dependent land tenure came into use, but these were not characteristic of the actual line of feudal descent. Scholars are not yet agreed as to what would have been their result if their natural development had not been cut off by the violent introduction of Frankish feudalism with the Norman conquest, whether the historical feudal system, or a feudal system in the general sense. To the writer it seems clear that the latter is the most that can be asserted. They were forms which may rightly be called feudal, but only in the wider meaning in which we speak of the feudalism of Japan, or of Central Africa, not in the sense of 12th-century European feudalism; Saxon commendation may rightly be called vassalage, but only as looking back to the early Frankish use of the term for many varying forms of practice, not as looking forward to the later and more definite usage of completed feudalism; and such use of the terms feudal and vassalage is sure to be misleading. There is no trace of the distinctive marks of Frankish feudalism in Saxon England, not where military service may be thought to rest upon the land, nor even in the rare cases where the tenant seems to some to be made responsible for it, for between these cases as they are described in the original accounts, legally interpreted, and the feudal conception of the vassal's military service, there is a great gulf.

The Completed System.—The temptation to use the larger part of any space allotted to the history of feudalism for a discussion of origins does not arise alone from greater interest in that phase of the subject. It is almost impossible even with the most discriminating care to give a brief account of completed feudalism and convey no wrong impression. We use the term "feudal system" for convenience sake, but with a degree of impropriety if it conveys the meaning "systematic." Feudalism in its most flourishing age was anything but systematic. Great diversity prevailed everywhere, and different facts or customs are found in every lordship But underlying all the apparent confusion of fact and practice were certain fundamental principles and relationships, which were alike everywhere. The chief of these are: the relation of vassal and lord; the principle that every holder of land is a tenant and not an owner, until the highest rank is reached, sometimes even the conception rules in that rank; that the tenure by which a thing of value is held is one of honourable service, not intended to be economic, but moral and political in character; the principle of mutual obligations of loyalty, protection and service binding together all the ranks of this society from the highest to the lowest; and the principle of contract between lord and tenant, as determining all rights, controlling their modification, and forming the foundation of all law.

The foundation of the feudal relationship proper was the fief, which was usually land, but might be any desirable thing, as an office, a revenue in money or kind. the right to collect a toll, or operate a mill. In return for the fief, the man became the vassal of his lord; he knelt before him, and, with his hands between his lord's hands, promised him fealty and service; he rose to his feet and took the oath of fealty which bound him to the obligations he had assumed in homage; he received from his lord ceremonial investiture with the fief. The faithful performance of all the duties he had assumed in homage constituted the vassal's right and title to his fief. So long as they were fulfilled, he, and his heir after him, held the fief as his property, practically and in relation to all under tenants as if he were the owner. In the ceremony of homage and investiture, which is the creative contract of feudalism, the obligations assumed by the two parties were determined, as a rule, by local custom. In detail the vassal's services differed widely, but they fall into two classes, general and specific. The general included all that might come under the idea of loyalty, seeking the lord's interests, keeping his secrets, betraying the plans of his enemies, protecting his family, etc. The specific services covered military service, which included appearance in the field on summons with a certain force, often armed in a specified way, and remaining a specified time. It often covered also the duty of guarding the lord's castle. and of holding one's own castle subject to the plans of the lord for the defence of his fief. Hardly less characteristic was court service, which included the duty of helping to form the court on summons, of taking one's own cases to that court instead of to some other, and of submitting to its judgments. The duty of giving the lord advice was often fulfilled in sessions of the court, and in these feudal courts the obligations of lord and vassal were enforced, with an ultimate appeal to war. Under this head may be enumerated the financial duties of the vassal, which were either intended to mark the vassal's tenant relation, like the relief, or to be a part of his service, like the aid, that is, he was held to come to the aid of his lord in a case of financial as of military necessity. The relief was a sum paid by the heir for the lord's recognition of his succession. The aids were paid on a few occasions, determined by custom, where the lord was put to unusual expense, as for his ransom when captured by the enemy, or for the knighting of his eldest son. The most lucrative of the lord's rights were wardship and marriage.

Ideally regarded, feudalism covered Europe with a network of these fiefs, rising gradually from the smallest, the knight's fee, at the bottom, to the king at the'top, who was the supreme landowner, or who held the kingdom from God. Actually not even in the most regular of feudal countries, like England or Germany, was there any fixed gradation. A knight might hold directly of the king, a count of a viscount, a bishop of an abbot, or the king himself of one of his own vassals, or even of a vassal's vassal, and in return his vassal's vassal might hold another fief directly of him.

The Government of Feudal Countries.—It is now possible perhaps to get some idea of the way in which the government of a feudal country was operated. The early German governments whose chief functions, military, judicial. financial. legislative, were carried on by the freemen of the nation, and were performed as duties owed to the community for its defence and sustenance, had given way to new forms of organization in which these conceptions had not entirely disappeared but in which the vast majority of cases a wholly different idea of the ground of service and obligation prevailed The members of the feudal court met, not to fulfil a duty owed to the community, but a private obligation which they had assumed in return for the fiefs. The feudal state was one in which, as it has been said, private law had usurped the place of public law. Public duty had become private obligation. To understand the feudal state it is essential to realize that all sorts of services, which men ordinarily owe to the public or to one another, were translated into a form of rent paid for the use of land. and defined and enforced by a private contract. In every feudal country, however, something of the earlier conception survived A general military levy was occasionally made. Something like taxation occasionally occurred, though the government was usually sustained by the scanty feudal payments, by the proceeds of justice and by the income of domain manors. About the office of king more of this earlier conception gathered than elsewhere in the state. and gradually grew, aided not merely by traditional ideas, but by the active influence of the Bible, and soon of the Roman law. The kingship formed the nucleus of new governments as the feudal system passed away.

Actual government in the feudal age was primitive and undifferentiated. Its chief and almost only organ, for kingdom and barony alike, was the curia—a court formed of the vassals This acted at once and without any consciousness of difference of function, as judiciary, as legislature, and as council, and it exercised final supervision and control over revenue and administration. Almost all the institutions of modern states go back to the *curia regis,* branching off from it as the growing complexity of business forced differentiation of function and personnel. In action it was an assembly court, deciding all questions by discussion and the weight of opinion, though its decisions obtained their legal validity by the formal pronunciation of the presiding member, *i.e.,* of the lord whose court it was. In a government of this kind the essential operative element was the baron. So long as the government remained dependent on the baron, it remained feudal in its character. Feudalism disappeared as the organization of society. when a professional class arose to form the judiciary, nhen the increased circulation of money made regular taxation possible and enabled the government to buy military and other services, and when better means of intercommunication and the growth of common ideas made a wide centralization possible and likely to be permanent. In nearly all the states of Europe the end of the feudal age was reached about the close of the 13th century.

Decline and Survivals.— As feudalism passed into decline, its customs tended to crystallize into fixed forms. At the same time a class of men arose interested in these forms for their own sake. professional lawyers or judges. who wrote down for their onn and others' use the feudal usages with which they were familiar. The great age of these codes was especially the second half of the 13th century. The codes in their turn tended still further to harden these usages into fixed forms, and we may date from the end of the 13th century an age of feudal law regulating especially the holding and transfer of land, and much more uniform in character than the law of the feudal age proper. This was particularly the case in parts of France and Germany where feudalism continued to regulate the property relations of lords and vassals longer than elsewhere. and where the underlying economic feudalism remained in large part unchanged.

Feudalism formed the starting-point also of the later social nobilities of Europe. They drew from it their titles and ranks and many of their regulative ideas. though these were formed into more definite and regular systems than ever existed in feudalism proper. It was often the policy of kings to increase the social privileges and legal exemptions of the nobility while taking anay all political poner, so that it is necessary in the history of institutions to distinguish sharply between these nobilities and the feudal baronage proper. It is only in certain backward parts of Europe that the terms feudal and baronage in any technical sense can be used of the nobility of the 15th century.

FEUERBACH, ANSELM (1829–1880), German painter, who was, apart from Arnold Böcklin, the most important representative of late classicism in Germany. Nephew of the philosopher, L. Feuerbach, he was born at Speyer. Bavaria. on Sept. 12, 1829. He began to study art in 1845 at the Diisseldorf academy under F. W. Schadow (*q.v.*). From 1848 to 1850 he worked under Karl Rahl in Munich and during 1851–54 twice stayed for some time in Paris. There Thomas Couture exerted a great influence on him, one which was to be decisive in his subsequent development. Two early works painted in Paris show his dependence on Couture: "Hafiz at the Well" (1852) and the "Death of Aretino" (1854). Idealistic, philosophical figure compositions, the intrinsic values of which were lyrical and elegiac, later became his main interest. During a stay of many years in Italy (1855–73), first in Venice, then in Florence and Rome, Feuerbach came under the influence of the Renaissance painters, chief among them Titian—whose "Assumption" he copied in Venice—and Paolo Veronese.

The principal aorks of the Italian years of his maturity are "Dante Walking nith the Noble Ladies of Ravenna" (1858), the two pictures representing "Iphigeneia" (1862, 1871), "Paolo and Francesca" (1864), "Plato's Symposium" (1869. second composition 1873), the "Judgment of Paris" (1870) the "Battle of the Amazons" (1869–73), and various compositions on the "Medea" theme (1866–70). A uniform dark tone with little contrast in colour matches the lyrical, secretly tragic basis of these works. Feuerbach's gifts were not suited to dramatic action and consequently the "Fall of the Titans," the ceiling piece in the hall of the Vienna Academy of Fine Arts (where he became a professor in 1873), is one of his weaker and more derivative compositions. The work was strongly criticized by contemporary critics. This failure in addition to illness caused Feuerbach finally to leave Vienna and return to Italy in 1876. He died in Vienna on Jan. 4, 1880. His greatest and most original accomplishments are his formal, statuesque portraits, including the various ones of his model, Nanna Risi and his stepmother, Henriette Feuerbach, a few individual "heroic" landscapes and numerous drawings. With his painting may be considered his literary work: *Vermächtnis,* published in 1882. which told the story of his struggles, and his letters to his stepmother, which appeared in 1911.

(F. Ny.)

FEUERBACH, LUDWIG ANDREAS (1804–1872), German philosopher, fourth son of the eminent jurist *(see* Feuerbach, Paul Johann Anselm), was born at Landshut, Bavaria, on July 28, 1804. His influence was greatest upon the anti-Christian theologians such as D. F. Strauss, author of *Das Leben Jesu,* and Bruno Bauer, who like Feuerbach had passed from Hegelianism to a form of naturalism. After two years in Berlin, under Hegel, Feuerbach studied natural science at Erlangen in 1828. His first book, published anonymously, *Gedanken über Tod und Unsterblichkeit* (1830), attacks personal immortality and advocates the Spinozistic immortality of reabsorption in nature. He then published *Darstellung der Geschichte der neuern Philosophie* (2 vol., 1833–37), *Abalard und Heloise* (1834), *Pierre Bayle* (1838) and *Uber Philosophie und Christentum* (1839), in which he claimed "that Christianity has in fact long vanished not only from the reason but from the life of mankind, that it is nothing more than a fixed idea." This attack is followed up in his most important work, *Das Wesen des Christentums* (1841; Eng. trans. by George Eliot, 1853), which aims to humanize theology. He lays it down that man is to himself his own object of thought. Religion is consciousness of the infinite. Religion therefore is "nothing else than the consciousness of the infinity of the consciousness; or, in the consciousness of the infinite, the conscious subject has for his object the infinity of his own nature." Thus God is, so to speak, the outward projection of man's inward nature. In the first part of the book Feuerbach develops the "true or anthropological essence of religion." Treating of God in his various aspects "as a being of the understanding." "as a moral being or law." "as love" and so on, he shows that these aspects correspond to some need of human nature. In the second part he discusses the "false or theological essence of religion," contending that the view which regards God as having a separate existence leads to a belief in revelation and in sacraments, which are pieces of religious materialism. Feuerbach denied that he was rightly called an atheist. but the denial is merely verbal. During the troubles of 1848–49 Feuerbach's attack upon orthodoxy made him something of a hero with the revolutionary party. His *Theogonie* (1857) was followed by

Gottheit, Freiheit und Unsterblichkeit (1866). He died on Sept. 13, 1872.

Some of Feuerbach's ideas were taken up by those engaged in the struggle between church and state in Germany and by those who, like F. Engels and Karl Marx, were leaders in the revolt of labour against capital.

Feuerbach's *Werke* were published in 10 vol. (1846–66; 1903–11); and the correspondence, ed. by K. Griin, in 2 vol. (1874).

FEUERBACH, PAUL JOHANN ANSELM, RITTER VON (1775–1833), the German jurist, chiefly remembered for his work in the field of criminal law reform, was born at Hainichen, near Jena, on Nov. 14, 1775, and brought up at Frankfurt am Main. At 16, he ran away from home to study at Jena where, despite ill-health and poverty, he took his doctorate in philosophy in 1795. With the birth of a son in 1796, he was forced to turn from philosophy and history to law, which offered better prospects. In 1796 he published *Kritik des natürlichen Rechts* . . . ("Critique of Natural Rights") followed by *Anti-Hobbes*, . . . (1798), a dissertation on the limits of the civil power. Feuerbach, as the founder of a new theory of penal law, the so-called "psychological-coercive or intimidation theory," gave to the rigorous Kantian doctrine that punishment ought only to be given for its own sake, a secular purpose, namely to enforce the threat of the law which deters the would-be law breaker. In this he was a fierce adversary of the idea of individual prevention put forward by Karl Grolmann, who was his life-long friend.

Feuerbach's famous *Lehrbuch des gemeinen in Deutschland geltenden peinlichen Rechts* ("Textbook of Common Law generally applied in Germany"; 1801) remained the leading textbook in Germany for half a century. This, and his earlier works, were a powerful protest against vindictive punishment and furthered the reform of the' German criminal law. The administration of justice was, before Feuerbach's time, distinguished by two characteristics: the superiority of the judge to all law, and the blending of the judicial and executive offices. Feuerbach, using as his chief weapon the *Revision der Grundbegriffe* ("Revision of the basic assumption"; 1799) achieved the recognition of the formula, *nullum crimen, nulla poena sine lege* ("no crime and no punishment unless provided by statutory law").

In 1805 he was given a post in the ministry of justice and commanded to draft a penal code for Bavaria (*Strafgesetzbuch für das Konigreich Bayern*). Practical reform was begun in Bavaria under his influence with the abolition of torture in 1806. In 1808 appeared the first volume of his *Merkwiirdige Criminalfalle* ("Remarkable Criminal Cases"), completed in 1811. In his *Betrachtungen über das Geschworenengericht* ("Remarks on the Jury Principle"; 1812) Feuerbach criticized, from a legal point of view, the defects of the jury, at that time recommended in accordance with the French code, but he was prepared to accept the jury as a political safeguard of civil rights, provided that it fitted into a wider framework of constitutional guarantees and the rule of law. The Bavarian criminal code was promulgated in 1813; distinguished by the clarity of its definitions and its careful classifications, it remained, together with the French *code pénal,* a model for European states until the Prussian criminal code of 1861.

During the war of liberation (1813–14) Feuerbach published several political brochures which, owing to the writer's position, had almost the weight of state manifestoes. In 1814 he was appointed second president of the court of appeal at Bamberg, and three years later he became first president of the court of appeal at Anspach. In the two treatises which he subsequently published in 1821 and 182j, he strongly urged publicity in all legal proceedings and showed himself a forerunner of modern efforts in the field of comparative law.

As one of his last activities he championed the cause of the mysterious foundling Kaspar Hauser. He died suddenly at Frankfurt on May 29, 1833.

See *Leben und Wirkens Ans. von Feuerbachs,* 2 vol. (1853) with its occasional notes by his fourth son Ludwig, a distinguished philosopher. *See* also M. Gruenhut, *A. von F. und das Problem der strafrechtlichen* (1922); G. Radbruch, *P. J. A. Feuerbach* (1934, 2nd ed. 1957); E. Wolf, *Grosse Rechtsdenker der deutschen Geistesgeschichte,* 3rd ed., pp. 536–583 (1951). (J. F. LR.)

FEUILLANTS, CLUB OF THE, a political association which played a prominent part during the French Revolution. It was founded on July 16, 1791, by several members of the Jacobin club who refused to sign a petition presented by this body, demanding the deposition of Louis XVI. Among them were B. Barère and E. J. Sieyès, who were later joined by other politicians, Dupont de Nemours being among them. The name of Feuillants was popularly given to this group because they met in the house in the rue Saint-Honor6 which had been occupied by the religious order bearing this name. The official name of the club was *Société des amis de la Constitution,* the title being a sufficient indication of the line they intended to pursue. This consisted of opposing everything not contained in the constitution of 1791; in their opinion, the latter was in no need of modification, and they hated all those who were opposed to it, whether *émigrés* or Jacobins. They affected to avoid all political discussion, and called themselves merely a "conservative assembly." This attitude they maintained after the constituent assembly had been succeeded by the legislative, but not many of the new deputies became members of the club.

With the rapid growth of extreme democratic ideas the Feuillants soon began to be looked upon as reactionaries, and to be classed with aristocrats. They did, indeed, represent the aristocracy of wealth, for they had to pay for attendance a subscription which was at that time a large sum. Moreover, the luxury with which they had surrounded themselves, and the restaurant which they had annexed to their club, seemed to mock the misery of the half-starved proletariat and added to the suspicion with which they were viewed, especially after the popular triumphs of June 20 and Aug. 10, 1792. A few days after the insurrection of Aug. 10 their papers were seized, and 841 members were proclaimed as suspects. This was the deathblow of the club. It had made an attempt, though a weak one, to oppose the forward march of the revolution, but, unlike the Jacobins, had never sent out branches into the provinces. The name of Feuillants, as a party designation, survived. It was applied to those who advocated a policy of cowardly moderation, and *feuillantisme* was associated with *aristocratie* in the mouths of the sans-culottes.

FEUILLETON, originally a kind of supplement attached to the political portion of French newspapers. Its inventor was Bertin the elder, editor of the *Débats.* It was usually separated from the political part of the newspaper by a line, and printed in smaller type. In French newspapers it consists chiefly of nonpolitical news and gossip, literature and art criticism, a chronicle of fashions, epigrams, charades, etc. The term came into English use to indicate the installment of a serial story printed in one part of a newspaper.

FEUQUIERES, ISAAC MANASSÈS DE PAS, MARQUIS DE (1590–1640), French soldier and diplomatist, born at Saumur on June 1, 1590, came of a distinguished family of which many members held high command in the civil wars of the 16th century. He entered the royal army at the age of 30, and soon achieved distinction.

In 1626 Feuquières served in the Valtelline, and in 1628–29 at the siege of La Rochelle, where he was taken prisoner. He was made *maréchal de camp* in 1629, serving in the fighting on the southern frontiers of France and occupying various military positions in Lorraine. Richelieu repeatedly employed him on diplomatic missions. He was sent as an ambassador into Germany where he rendered important services in negotiations with Wallenstein; he renewed at Heilbronn (April 19, 1633), the treaty of alliance with Sweden; and he was also employed in the tortuous negotiations at Frankfurt in 1634. In 1636 he commanded the French corps operating with the duke of Weimar's forces. With these troops he served in the campaigns of 1637 (in which he became lieutenant general), 1638 and 1639, At the siege of Thionville (Diedenhofen) he was mortally wounded

His *Lettres inédites* appeared (ed. by Gallois) in Paris in 1845.

His grandson ANTOINE MANASSÈS DE PAS, MARQUIS DE FEUQUIÈRES (1648–1711), who entered the army at the age of 18, won a promotion to the rank of captain for his conduct at the siege of Lille in 1667. In the campaigns of 1672 and 1673 he served on the staff of Luxemburg, and at the siege of Oudenarde in the following year the king gave him command of the royal marine regiment, which he held until he obtained his own regiment in 1676. Promoted to *maréchal de camp,* he served under Catinat against the Waldenses, and in the course of the war won the nickname of the "Wizard."

In 1692 he made a brilliant defense of Speierbach against greatly superior forces. and was rewarded with the rank of lieutenant general. Marshal Villeroi impressed him less favourably than his old commander Luxemburg, and the resumption of the war in 1701 found him in disfavour in consequence. The rest of his life. embittered by the refusal of the marshal's baton he spent in compiling his celebrated memoirs. which, coloured as they were by the personal animosities of the writer, mere yet considered by Frederick the Great and the soldiers of the 18th century as the standard work on the art of nar as a whole.

The *Mémoires de la guerre* (1701, 1711, 1725, 1735, etc., London 1736, Amsterdam subsequently) mere translated into English (1737) and German (1732). They deal in detail with every branch of the art of nar and of military service.

FÉVAL, PAUL HENRI CORENTIN (1817–1887), French author of sensational novels and dramatist, was born at Rennes on Sept 27. 1817. His *Mystères de Londres* (1844) was published under the pseudonym "Sir Francis Trolopp." Other novels include *Le Fils du diable* (1846); *Les Compagnons du silence* (1857); *Le Bossu* (1858); *Le Poisson d'or* (1863); *Les Habits noirs* (1863): *Jean le diable* (1868), and *Les Compagnons du trésor* (1872). Féval later considered his chronicles of crime an evil influence, and he revised his earlier works and wrote religious pamphlets. He died in Paris on March 8, 1887. His *Oeuvres* (38 vol) appeared in 1895.

FEVER is a manifestation of disease, characterized by elevation of the body temperature. Although most often associated with infection, it is also observed in other pathologic states, such as cancer, coronary artery occlusion and disorders of the blood.

Under normal conditions the temperature of deeper portions of the head and trunk does not vary by more than 1°–2° F. in a day, and does not exceed 99° in the mouth or 99.6" in the rectum. There is a small rhythmic diurnal variation, highest in the late afternoon, lowest in the early hours of the morning. In persons with fever the temperature may rise to 106°, and daily fluctuations of 5°–9° may occur. with peak levels tending to occur in the late afternoon. Transient elevations to 112°–113° have been recorded, but are very rare

During fever the blood and urine volumes become reduced as a result of loss of water through increased vaporization. Body protein is rapidly broken down, leading to increased excretion of nitrogenous products in the urine.

At a time when the body temperature is rising rapidly the affected person may feel chilly, or even have a shaking chill; conversely, when the temperature is declining rapidly he may feel warm and have a flushed moist skin. Drugs such as aspirin, nhich reduce fever, seem to exert their effect on the temperature-regulating areas of the brain; they do not influence body temperature in health.

The mechanism of fever appears to involve a disturbance in the brain's control of various processes affecting heat production and heat loss; *i.e.,* muscle tone, flushing. sweating, etc. The generally accepted hypothesis is that in febrile diseases certain products of tissue injury are carried by the blood to the brain, where they disturb the function of the heat-control centres. A material capable of such an effect has been demonstrated in white blood cells. The liberation of products of this type from injured cells may be the cause of fever in disease. *See* also ANIMAL HEAT.

See George W. Pickering, "Regulation of Body Temperature in Health and Disease," Lancet, vol. i, pp. 1–9 and 59–64 (Jan. 1958). (P. B. B.)

FEYDEAU, ERNEST-AIME (1821–1873), French author, mas born in Paris. He gained a great success with his novel *Fanny* (1858), followed in rapid succession by a series of similar stories. Besides his novels Feydeau wrote several plays. He died in Paris on Oct. 27, 1873.

FEZ (*Fās*), city in northern Morocco. Its historical importance, the wealth of its population, its many craftsmen and its famous university entitle Fez to be called the real centre—religious, political and economic—of the Shereefian empire. It lies in 34° 6' 3″ N., 4° 38' 15″ W., about 230 mi. N.E. of Marrakesh, 100 mi. E. from the Atlantic and 85 mi. S. of the Mediterranean on the main line of communication between the Atlantic coast and Algiers. It is in a deep valley on the Wad Fas, an affluent of the Wad Sebu, which divides the town into two parts—the ancient tonn, Fas el Bali, on the right bank, and the new, Fas el Jadid, on the left. Pop. (1952) 179,372.

Fez stretches out between low hills, crowned by the ruins of ancient fortresses. The city is surrounded except on the south by hills, interspersed with groves of orange, pomegranate and other fruit trees. and large olive gardens.

From its peculiar situation Fez has a drainage superior to that of most Moorish towns. When the town becomes dirty, water is allowed to run down the streets by opening lids for the purpose in the conduits and closing the ordinary exits, so that it overflows and cleanses the pavements.

Streets and Trade.—Most of the streets are exceedingly narrow, and as the houses are high, and built in many cases over the thoroughiares, these are often very dark and gloomy; but since wooden beams, rough stones and mortar are used in building, there is less of that ruined, half-decayed appearance so common in other Moorish towns where mud concrete is used.

Fez is the principal native industrial and commercial centre of Morocco. It lies at the crossing of the east-west route, from Algeria and the Atlantic cities of Morocco. and the north-south caravan route between Tangier and the Sahara. Manufactures include yellow slippers of the famous Morocco leather, fine white woolen and silk haiks, silk embroidery, woolen cloths and blankets. cotton and silk handkerchiefs, silk cords and braids, leather bookbinding, swords and guns, saddlery, brass trays, Moorish musical instruments, rude painted pottery and coloured tiles.

Schools and Mosques.—In the early days of Moslem rule in Morocco. Fez was the seat of learning and the pride of Islam. Its schools of religion, philosophy and astronomy enjoyed a great reputation in Africa and also in southern Europe, and were even attended by Christians. On the expulsion of the Moors from Spain, refugees of all kinds flocked to Fez, and brought with them some knowledge of arts. sciences and manufactures, and thither flocked students to make use of its extensive libraries. But its glories were brief, and though still the university town of Morocco, it retains but a shadow of its greatness. A number of students read at the Karueein. They pay no rent, but buy room keys from the last occupants, selling them again on leaving.

The Karueein (Karuwiyin) is celebrated as the largest mosque in Africa. On account of the vast area covered, the roof, supported by 366 pillars of stone, appears very low. The side chapel for services for the dead contains 24 pillars. All of these columns support horseshoe arches, on which the roof is built, long vistas of arches being seen from each of the 18 doors of the mosque. The number of lights in the mosque is given as 1,700. The mosque of Mulai Idris, built by the founder of Fez about A.D. 810, is considered so sacred that the streets which approach its entrance are forbidden to Jews, Christians or four-footed beasts.

A new city, begun in 1916. grew up three miles to the west of the old town, leaving the picturesque charm of the latter unspoilt. This new town. with modern buildings and tree-lined streets, lies between the old city and the station of the railway which connects Fez with Rabat. Casablanca and Tangier and continues as far as Taza. Oujda and Algiers.

According to Moslem historians Fez was founded in 807 by Idris II, although a settlement is now known to have existed in

801. The original town was in two sections, that of the people of Quairan and that of 8,000 Berber families expelled from Spain.

In the 13th century Fez. Jadid and many other beautiful colleges were built to house the foreign students; some are still standing, and are the purest examples of Spanish-Moorish art in Morocco.

On May 21, 1911, the French entered Fez at the request of the sultan, Mulai Hafid, who sought their aid in quelling a local rebellion. It was at Fez that M. Regnault signed the treaty of March 30, 1912, establishing the French protectorate over Morocco. A riot broke out, and Fez was besieged by the Berbers, but order was restored by General Lyautey. (P. W. I.)

FEZZAN, the ancient Phazania, or country of the Garamantes, became one of the three provinces of the United Kingdom of Libya in 1951. It is a region covering about 220,000 sq.mi. of desert south of Tripolitania. Four-fifths of its population of 54,438 (1954) live in scattered oases and the rest are nomadic. The Fezzan's international boundaries with Algeria and French West Africa follow those established by the former Italian colonial government of Tripolitania in the Franco-Italian convention of Sept. 1919. Its boundary in the east with Cyrenaica follows roughly the 19th meridian east and in the north with Tripolitania a line in the region of the 29th parallel.

Physical Geography. — The political area of the Fezzan has no clear relationship to natural boundaries. But among the physical features of the area are Jebel el-Soda (the Black mountain) in the north and the Tummo mountains in the extreme south. Between them are areas of sand dunes, stony desert, hilly outcrops of rock and two main depressions in which subterranean water permits settled habitation.

These depressions run in a northeasterly direction from the Ahaggar mountains of southern Algeria and support the principal oases of the province, Murzuk, Sebha and Brak. Hon and Waddan are to the north of Jebel el-Soda and in the southern part of the region are small settlements based on isolated water holes. Only in the north is there sufficient rainfall to provide sparse grazing. Elsewhere rain seldom falls except in the form of isolated storms which may occur only once in several years. The climate is Saharan, marked by low humidity, a wide range of daily temperature, extreme summer heat and temperatures sometimes falling below freezing point in the winter.

Flora and Fauna. — The date palm flourishes in the oases, where cereals and fruit can also be successfully cultivated on irrigated land. Outside the oases such vegetation as may be found is characteristic of the Sahara but most of the region is naked desert.

In the uninhabited oases, gazelle and desert antelopes are found in small and decreasing numbers. Camels and goats can find sufficient grazing for their meagre needs in the north together with jackals and hyenas. Among birds are ostriches, falcons, vultures, swallows and ravens; in summer wild duck are numerous but in winter they seek a warmer climate. There are no remarkable insects or snakes. A species of Artemia or brine shrimp, about a quarter of an inch in length, of a colour resembling goldfish, is caught with cotton nets in the saline Bahr el-Dud in the Wadi el-Gharbi. These are mixed with dates into a paste having the taste and smell of salt herring which is considered a delicacy by the people of the Fezzan.

History. — The country formed part of the territory of the Garamantes, described by Herodotus as a very powerful people. Attempts have been made to identify the Garamantes with the Berauna of the Arabs of the 7th century, and to the period of the Garamantes, H. Duveyrier, a French archaeologist who travelled in Fezzan during 1859–61, assigns the remains of remarkable hydraulic works and certain tombs and rock sculptures — indications, it is held, of a Negro civilization of ancient date which existed in the northern Sahara. The Garamantes, whether of Libyan or Negro origin, certainly had a considerable degree of civilization when in the year 19 B.C. they were conquered by the proconsul L. Cornelius Balbus Minor and their country added to the Roman empire. By the Romans it was called Phazania, whence the name Fezzan. After the Vandal invasion Phazania appears to have regained independence and to have been ruled by a Berauna dynasty. At this time the people were Christians, but in 666 the Arabs conquered the country and all traces of Christianity seem speedily to have disappeared. At first the area was subject to the caliphs, but early in the 10th century an independent Arab dynasty was established, with its capital at Zaila.

In 1174 Fezzan was conquered by an expedition sent by Saladin (*q.v.*), but it seems to have reasserted itself. In the 13th century the country became part of the Born empire (see BORNU), but it is probable that it was governed by a native tribe of hereditary rulers, who were dethroned in the 14th century by the Khorman, an Arab tribe which reduced Fezzan to slavery. It was rescued in about the middle of the 16th century by a sherif of Morocco, Montasir-b.-Mohammed, who founded the dynasty of Beni Mohammed. This dynasty, which came into frequent conflict with the Turks in Tripoli, gradually extended its borders as far as Sokna in the north. It was the Beni Mohammed who chose Murzuk as their capital. They became intermittently tributary to the pasha of Tripoli, but within Fezzan the power of the sultans was absolute. The last of the Beni Mohammed sultans was killed in 1811 by El-Mukkeni, one of the lieutenants of Yusef Pasha, the last sovereign but one of the independent Karamanli dynasty of Tripoli. El-Mukkeni then made himself sultan of Fezzan. and became notorious by his slaving expeditions into the central Sudan, in which he advanced as far as Bagirmi. In 1831, Xbd-el-Jelil, a chief of the Aulad-Sliman Arabs, usurped the sovereign authority. After a troublous reign of ten years he was slain in battle by a Turkish force under Bakir Bey, and Fezzan was added to the Turkish empire in 1842.

After the founding of the White monastery at Beida, Cyrenaica, by the Senussi (*q.v.*) order (tariqa) in 1843, emissaries following the Saharan caravan routes founded lodges (*zawaya*) in the Fezzan. The Senussi order became the dominant influence under the Abid branch of the Senussi family. But the expansion of French rule from equatorial Africa began to weaken Senussi authority at the beginning of the century and the Italian invasion of Tripolitania and Cyrenaica in 1911 led to its eclipse. The treaty of Ouchy in 1912 which ended the Italo-Turkish War (*q.v.*) was quickly followed by the occupation of the Fezzan although it was abandoned again after the reverses suffered by the Italians in 1915 at the hands of the Senussi-inspired tribes. The subsequent defeat of the Senussi army by British forces in the western desert of Egypt led to anarchy in the Fezzan when Sayyid Mohammed Abid was obliged to withdraw to Kufra. Gen. Rodolfo Graziani reoccupied the whole area in 1930 and the Fezzan became part of the Italian military territory of Southern Tripolitania.

During World War II the Fezzan was occupied by French forces under Gen. J. Leclerc in the winter of 1942–43 and was administered as an occupied enemy territory until the formation of the United Kingdom of Libya in Dec. 1951. (See also LIBYA.)

Population. — The total population in 1954 was 54.438. The inhabitants are mixed people who have settled in oases along desert routes between the Mediterranean and equatorial Africa. They include Arabs and Berbers from the north, Tuareg from the west, Teda and Bornu from the south. The principal languages are Arabic, Kanuri and Hausa.

The capital of the Fezzan is at Hon, 280 mi. S.W. of Tripoli and nearly 500 mi. from the southern extremity of the province.

Constitution. — The status of the Fezzan as a province in the United Kingdom of Libya stems from a resolution of the general assembly of the United Nations on Nov. 21, 1949. The French military occupation administration, the successors of the Italian colonial regime, transferred its powers to a Libyan governor (*wali*) on Dec. 24, 1951.

The governor is appointed by the king of Libya whom he represents with full royal powers and prerogatives. Provincial executive authority is exercised by an executive council under a president appointed by the king in consultation with the governor, and each member (nazir) is responsible for an administrative department. There is also a provincial legislative council to which three-quarters of the members are elected. The Fezzan sends eight members to the senate of the kingdom of Libya, half nominated by the king and half elected by the legislative council, and five elected members to the house of representatives. The first elections were held on Feb. 19, 1952.

Resources. — Apart from the dates exported to Tripoli, the Fezzan is singularly lacking in economic resources. In 1956 concessions to prospect for oil were given to British, French and United States companies and the discovery in 1955 of oil resources in unconfirmed quantities close to the Algerian frontier of the Fezzan raised hopes that they might meet with success. (D. C. CG.)

FFESTINIOG, an urban district of Merionethshire, Wales, 19 mi. N. of Dolgelley by road. Pop. (1951) 6,920. Area 25.5 sq.mi. It includes the town of Blaenau Ffestiniog and the village of Ffestiniog. The urban district, beautifully situated at the head of the vale of Ffestiniog in the Snowdonia National park, is 600 ft. above sea level.

The slate mines of Blaenau Ffestiniog are famous. Roman remains have been found in the vicinity. Nearby are the Beddau Gwyr Ardudwy (the graves of the men of Ardudwy), half-legendary memorials of early warfare, and Hafod Ysbyty farm, an old stone-staired monastic hospital or sanatorium. A large pumped storage hydroelectric scheme, the first of its kind in Great Britain, was being developed in the mid-1950s.

FIACRE (FIACHRACH), **SAINT** (d. *c.* 670), Irish anchorite of noble descent. His *Acta,* which have little historical value, relate that he went to France and with the permission of St. Faro, the bishop of Meaux, built a monastery at Prodilus, the modern Breuil, in the province of Brie. There he received St. Chillen (? Kilian), who was returning from a pilgrimage to Rome, and there he remained until his death. In 1568, at the time of the religious troubles, his remains were transferred to a shrine in the cathedral of Meaux. St. Fiacre is the patron of Brie, and gardeners invoke him as their protector; his feast is kept on Aug. 30.

See O'Hanlon, *Lives of the Irish Saints,* vol. viii, pp. 421–447 (1875–1904).

FIARS PRICES, in the law of Scotland, the average prices of each of the different sorts of grain grown in each county, as fixed annually by the sheriff, usually after the verdict of a jury. They serve as a rule for ascertaining the value of the grain due to feudal superiors, to the clergy, or to lay proprietors of teinds, to landlords as a part or the whole of their rents, and in all cases where the price of grain has not been fixed by the parties. It is not known when or how the practice of striking the fiars, as it is called, originated. It probably was first used to determine the value of the grain rents and duties payable to the crown.

FIAT MONEY, irredeemable money issued and made legal by government order (fiat) but not secured by a gold or silver or other adequate reserve. It is usually paper but may also consist of coins of baser metals whose metallic content is worth far less than their face value.

The issue of fiat money tends to cause the withdrawal from circulation of sound money and a great inflation of prices in terms of the unsecured currency. Fiat money was issued freely in the United States during the Revolutionary War and the Civil War periods.

FIBIGER, JOHANNES ANDREAS GRIB (1867–1928), Danish pathologist and professor at the University of Copenhagen, whose experiments on the production of gastric tumours in rats led to the first experimental production of cancer, and who was awarded the Nobel prize for medicine and physiology for 1926, was born at Silkeborg, Den.. on April 23, 1867, and died at Copenhagen on Jan. 30. 1928. While examining tuberculous rats, Fibiger found three with cancer of the stomach. The tumours contained a parasite (afterward named *Gongylonema neoplasticum)* which he was able to trace to a tropical type of cockroach that had come in sugar from the West Indies. When the cockroaches were eaten by rats infesting the particular sugar refinery, the larvae coiled up in their muscles developed into the adult nematodes in the stomachs of the rats. By feeding rats and mice similarly Fibiger was able to produce stomach tumours of which one in a mouse proved transplantable.

Fibiger's experiments — rightly considered a pattern of methodical research — encouraged K. Yamagiwa to begin tar-painting of animals to produce cancer, a method at once adopted by Fibiger as superior to his own, and leading into modern chemical cancer research.

It was later shown that Fibiger's animals must have been lacking in the then unknown vitamin A, which deficiency is now known to produce lung lesions corresponding to those interpreted by Fibiger and contemporaries as cancer metastases. Also gastric proliferations similar to those interpreted in Fibiger's time as fully developed cancer will occur under vitamin A deficiency in the presence of the *Gongylonema,* although they will be reduced in degree in the absence of either of those two factors. Thus, most of Fibiger's tumours would not fulfill modern criteria for fully developed cancer. It is true that his thesis of a carcinogenic effect of some parasites has been supported in other ways. However, no detailed analysis nor any final proof of its validity has yet been produced.

See K. Secher, *Johannes Fibiger* (1947); C. R. Hitchcock and E. T. Bell, "Studies on the Nematode Parasite, *Gongylonema neoplasticum* . . . ," *J. Nat. Cancer Inst.,* 12:1345–87 (June 1952). (Js. C.)

FIBONACCI, LEONARDO: *see* LEONARDO OF PISA.

FIBRE PLANTS. Plants that have long slender threadlike thick-walled cells or groups of cells growing through the leaves, stems or fruits are fibre-yielding plants. More than 2,000 species of such plants have been catalogued in various parts of the world. Of this number, less than fifty are of commercial importance. For a selected list of widely used commercial vegetable fibres *see* table in the article FIBRES.

Abaci (manila or manila hemp), sisal (sisal hemp) and similar plants yielding leaf fibres are native to the tropics, while flax, cotton, hemp and other fibre-yielding plants grow better in the temperate zone. Although the United States uses large quantities of vegetable fibres, with the exception of cotton and some palm fibres, none are grown in commercial quantities within its borders. India and Pakistan supply jute and like fibres from which hessians (coarse textiles) and twine are made. Mexico, Cuba and Africa produce henequen and sisal used in the manufacture of rope and twine. Abacá, from which the better grades of cordage are made, comes mostly from the Philippines. Flax and hemp are produced in Russia and other European countries.

Most plant fibres are readily grouped according to their structure, to their origin in the plant, or according to their use. A simple classification that includes all vegetable fibres follows: (1) seed and fruit hair fibres, sometimes called surface fibres; (2) structural or leaf fibres frequently referred to as hard fibres; (3) bast or soft fibres, often referred to as stem fibres; (4) miscellaneous fibres, including root and stem fibres; and (5) pulp fibres from tree trunks, bamboo and similar sources used in the manufacture of paper.

Uses. — The principal uses made of vegetable fibres in industry may be grouped under seven major headings which can in turn be subdivided to include all products made of fibres. The major uses are: (1) textiles; (2) cordage; (3) brush; (4) filling and padding; (5) paper; (6) plaited and felted fibres; and (7) raw materials for the chemical industry, particularly cellulose.

Many fibre-yielding plants produce other products that may be of equal or greater value than the fibre. Cottonseed yielding linters (fibres and fuzz not removed in ginning and used for batting, etc.), oil and meal; flaxseed yielding linseed oil and meal; the coconut yielding oil; and the yuccas (of the lily family) and lechuguilla (of the same family as the century plants, agave [*q.v.*]) yielding saponin *(see* SAPONINS AND SAPOGENINS), from which drugs and other products are made, are examples of the importance of by-products in the fibre industry.

Seed and Fruit Hair Fibres. — Seed and fruit hair fibres grow as short single-celled seed hairs in cotton, as pod fibres in kapok and as husk or hull fibres in the coconut. Cotton is by far the most important vegetable fibre grown, as to quantity and uses made of the fibre. The improvement in quality and yield of fibre resulting from breeding and selection, the progress in completely mechanizing production and the improvement in spinning and weaving and the manufacturing of cotton-made products, all contribute to its universal use.

Kapok, pachote, samohu and several similar fibres grow in seed pods on trees. The properties of these fibres make them useful as filler, as insulation and in life preservers and cushions on boats.

Coir. the fibre from the coconut, is used in door mats, coarse twine, rope and brushes.

Leaf Fibres. — Structural or leaf fibres are hard and stiff in texture and extend lengthwise through the pulpy tissue of long leaves or leaf stems of monocotyledonous or endogenous plants. They impart rigidity and stability to the plant and help protect it from injury by wind and weather Most of these plants are native to the western hemisphere. With the exception of phormium (New Zealand flax, or flax lily), native to New Zealand, and the istles (various agaves) native to northern Mexico, the leaf fibres are all grown in tropical or subtropical climates. Plants like henequen and lechuguilla thrive in the arid climate and rocky soils of Yucatan and northern Mexico, while abaci grows best in a fertile, well-drained soil having an ample supply of moisture.

Sisal is native to Yucatan but grows better in Africa and other areas where more fertile soils and more moisture are available. Leaf fibres come from perennial plants that produce fibre over a period of 5 to 20 years or more, depending on soil, climate and harvesting procedures. The leaves of the agaves, including the genus and *Furcraea,* are harvested for fibre as they mature. When mature, the entire abaci stalk is harvested.

Most of the leaf fibres are extracted by mechanical methods involving macerating and scraping. Machines ranging from a crude dull knife and a block of wood with which 10 to 15 lb. of fibre can be scraped daily, to the large powerful raspador type decorticators, which are capable of producing up to 3.000 lb. of dry fibre per hour, are in use.

Many leaf fibres, as the istles in Mexico and caroa in Brazil, are harvested from the wild state and are processed by hand scraping. Others, as sisal and henequen (see SISAL FIBRE), and abaci are grown under cultivation on large plantations where decorticating. which is the process of extracting the fibre from the leaves. is highly mechanized. All other operations use large amounts of hand labor. The raspador type decorticator as used on most plantations consists of two large rotating drums equipped with dull knives operating against curved surfaces and disposed adjacent to offset gripping devices which carry the plant material through the machine.

Cantala, sisal, pita floja (a wild pineapple) and others are occasionally retted, or soaked, for local use, but the fibre is inferior in strength and colour.

Bast or Stem Fibres. — Bast fibres are secured from dicotyledonous or exogenous plants groan mostly as annuals planted from seed each year. In order to produce long slender stalks free from leaves and branches, the plants must be grown in a dense stand. The fibres are soft and flexible in character and extend through the inner bark of the stalk or stem of the plant. The stalks average one-half inch in diameter and are from 5 to 15 ft. tall. The best quality of the bast fibre is produced by water retting or by chemically treating the fibre. The retting process for jute and similar fibres is accomplished by submerging bundles of stalks in the back waters of rivers or in ponds or artificial pools where bacteria consume the nonfibrous material. leaving a slimy substance that is readily washed from the remaining fibre ribbon or strand. The time of retting varies from 5 to 20 days or more, depending on the age of the stalk and the temperature and kind of water.

Retting is usually considered complete when the bark and fibre slip easily from the woody part of the stalk. The fibre is cleaned and washed by workers who wade waist deep into the water. Drying is done in the open air.

Flax fibre contains more cellulose and is finer and stronger than jute. It brings a higher price on the market. More care is used in the handling and in the retting procedure. Under-retted fibre does not clean well and if over-retted it loses strength and luster thus lowering its value. In the United States and Canada and in some European countries the retting is done in large tanks under controlled conditions. The washing is done by draining off the retting media and flushing several times with fresh water. The retted stalks are spread out on the grass or are stood up in shocks and completely dried before breaking, scutching, or separating, and hackling, or combing. The flax industry has been mechanized to a large degree but many operations are still done by hand in European countries.

The name hemp has been applied to many fibres that are in no way related to true hemp (*Cannabis sativa*). True hemp is one of the strongest vegetable fibres. comparing well with flax, ramie and others. Before the advent of abaci it was used for most of the marine rope and for other high-grade cordage. The better grades of fibre are produced by water retting. A large part of the crop is cut and spread on the stubble nhere it remains until retting is completed by dews, rains and snows.

Hemp production has been mechanized in the United States; but much hand labour and many of the old hand-operated brakes and scutchers are still in use in the countries where most of the fibre is grown.

Ramie (Rheas China Grass) is one of the few bast fibre plants grown as a perennial. It is of the Urticaceae or nettle family, but is free of stinging hairs typical of most nettles. Plantings are established from root pieces planted in rows. The young plants soon spread out over the entire area and grow in a crowded condition much like other bast fibres. Once established, a plantation should produce fibre for ten years or more before replanting is necessary. Ramie is native to China but grows well in many other countries where soil and climate are favourable. The better grades of ramie fibre are produced by decorticating or ribboning the stalk and treating the resulting crude product chemically to purify the fibre. When degummed, ramie filasse (fibre prepared for manufacture) is white in colour with a soft luster that is much like silk in appearance. It contains a high percentage of cellulose which accounts for many of its unique properties.

Miscellaneous Fibres. — Miscellaneous fibres include the stiff roots of some grasses and stem fibres as Spanish moss. The principal root fibre is known as zacaton in Mexico where most of it is produced. It is also known as broomroot, rice root, etc. The root fibres are coarse, crinkled and stiff when properly treated. They are used mostly in brushes. Cheaper palm fibres are replacing this fibre and its demand is decreasing. Spanish moss is an air plant of the pineapple family. It has been produced in Louisiana, Mississippi, Florida and other states along the Atlantic seaboard. At one time it ranked next to horsehair as an upholstery material, and for mattress and cushion filler. Foam rubber and other rubberized products have largely replaced it.

For additional information the reader is referred to the articles on specific plants, as ABACÁ FIBRE; COIR; HEMP; etc. For uses see BRUSH; CELLULOSE; PAPER: *Manufacture;* ROPE AND ROPEMAKING; TEXTILES; etc. For production see articles on countries and states.

FIBRES, the general term for certain structural components of animal and vegetable tissue utilized in manufactures, and in respect of such uses, divided for the sake of classification into textile, paper-making, brush and miscellaneous fibres.

Textile Fibres. — Textile fibres are mostly products of the organic world, elaborated in their elongated form to subserve protective functions in animal life (as wool and epidermal hairs, etc.) or as structural components of vegetable tissues (flax, hemp and wood cells). It may be noted that the inorganic world provides an exception to this general statement in the fibrous mineral asbestos (*q.v.*), which is spun or twisted into coarse textiles. Other silicates are also transformed by artificial processes into fibrous forms, such as "glass," which is fused and drawn or spun to a continuous fibre, and various "slags" which, in the fused state, are transformed into "slag wool." Lastly, we note that a number of metals are drawn down to the finest dimensions, in continuous lengths, and these are woven into cloth or gauze, such metallic cloths finding valuable applications in the arts. Certain metals in the form of fine wire are woven into textile fabrics used as dress materials. Such exceptional applications are of insignificant importance, and will not be further considered in this article.

The common characteristics of the various forms of matter comprised in the widely diversified groups of textile fibres are those of the colloids. Colloidal matter is intrinsically devoid of structure, and in the mass may be regarded as homogeneous; whereas crystalline matter in its proximate forms assumes definite and specific shapes which express a complex oi internal stresses. The properties of matter which condition its adaptation to structural functions, first as a constituent of a living individual, and afterwards as a textile fibre, are homogeneous continuity of substance, with a high degree of interior cohesion, and associated with an irreducible minimum of elasticity or extensibility. The colloids show an infinite diversity of variations in these essential properties: certain of them, and notably cellulose (*q.v.*), maintain these characteristics throughout a cycle of transformations such as permit of their being brought into a soluble plastic form, in which condition they may be drawn into filaments in continuous length. The artificial silks or lustra-celluloses or rayons are produced in this way, and have already taken an established position as staple textiles. For a more detailed account of these products see CELLULOSE and SYNTHETIC FIBRES.

The animal fibres are composed of nitrogenous colloids of which the typical representatives are the albumens. fibrines and gelatines. They are of highly complex constitution and their characteristics have only been generally investigated. The vegetable fibre substances are celluloses and derivatives of celluloses, also typically colloidal bodies. The broad distinction between the two groups is chiefly evident in their relationship to alkalis. The former group are attacked, resolved and finally dissolved, under conditions of action by no means severe. The celluloses, on the other hand, and therefore the vegetable fibres, are extraordinarily resistant to the action of alkalis.

The animal fibres are relatively few in number but of great industrial importance. They occur as detached units and are of varying dimensions; sheep's wool having lengths up to 36in., the fleeces being shorn for textile uses at lengths of 2 to 16in.; horse hair is used in lengths of 4 to 24in., whereas the silks may be considered as being produced in continuous length, "reeled silks" having lengths measured in hundreds of yards, but "spun silks" are composed of silk fibres purposely broken up into short lengths.

The vegetable fibres are extremely numerous and of very diversified characteristics. They are individualized units only in the case of seed hairs, of which cotton is by far the most important; with this exception they are elaborated as more or less complex aggregates. The bast tissues of dicotyledonous annuals furnish such staple materials as flax, hemp, rhea or ramie and jute. The bast occurs in a peripheral zone, external to the wood and beneath the cortex, and is mechanically separated from the stem, usually after steeping, followed by drying.

The commercial forms of these fibres are elongated filaments composed of the elementary bast cells (ultimate fibres) aggregated into bundles. The number of these bundles, of any part of the filament may vary from 3 to 20. In the processes of refinement preparatory to the spinning (hackling, scutching) and in the spinning process itself, the fibre-bundles are more or less subdivided, and the divisibility of the bundles is an element in the textile value of the raw material. But the value of the material is rather determined by the length of the ultimate fibres (for, although not the spinning unit, the tensile strength of the yarn is ultimately limited by the cohesion of these fibres), qualified by the important factor of uniformity.

Thus, the ultimate fibre of flax has a length of 25 to 35mm.; jute, on the other hand, 2 to 3mm.; and this disparity is an essential condition of the difference of values of these fibres. Rhea or ramie, to cite another typical instance, has an ultimate fibre of extraordinary length, but' of equally conspicuous variability, viz., from 50 to 200mm. The variability is a serious impediment in the preparation of the material for spinning and this defect, together with low drawing or spinning quality, limits the applications of this fibre to the lower counts or grades of yarn.

The monocotyledons yield still more complex fibre aggregates, which are the fibro-vascular bundles of leaves and stems. These complex structures as a class do not yield to the mechanical treatment by which the bast fibres are subdivided, nor is there any true spinning quality such as is conditioned by bringing the ultimate fibres into play under the drawing process, which immediately precedes the twisting into yarn. Such materials are therefore only used for the coarsest textiles, such as string or rope. An exception to be noted in passing is to be found in the pineapple (*Ananas comosus*) the fibres of which are worked into yarns and cloth of the finest quality. The more important fibres of this class are manila, sisal, phormium. A heterogeneous mass of still more complex fibre aggregates; in many cases the entire stem (cereal straws, esparto), in addition to being used in plaited form, *e.g.,* in hats, chairs, mats: constitute the staple raw material for paper manufacturers., requiring a severe chemical treatment for the separation of the ultimate fibres.

In this class we must include the woods which furnish wood pulps of various classes and grades. Chemical processes of two types (a) acid and (*b*) alkaline, are also employed in resolving the wood, and the resolution not only effects a complete isolation of the wood cells, but, by attacking the hydrolpsable constituents of the wood substance (lignocellulose), the cells are obtained in the form of cellulose. These cellulose pulps are known in commerce as "sulphite pulps" and "soda pulps" respectively. In addition to these raw materials or "half stuffs" the paper-maker employs the rejecta of the vegetable and textile industries, scutching, spinning and cloth wastes of all kinds. which are treated by chemical (boiling) and mechanical means (beating) to separate the ultimate fibres and reduce them to the suitable dimensions (0·5–2·0mm.). These paper-making fibres have also to be reckoned with as textile raw materials! in view of a new and growing industry in "pulp yarns" (*Papierstoffgarn*), a coarse textile obtained by treating paper as delivered in narrow strips from the paper machine; the strips are reeled. dried to retain 30–40% moisture, and in this condition subjected to the twisting operation. which confers the cylindrical form and adds considerably to the strength of the fibrous strip. The following are the essential characteristics of the economicallv important fibres.

Animal Fibres.—A. Silk. (*a*) The true silks are produced by the *Bombyx mori,* the worm feeding on the leaves of the mulberry. The fibre is extruded as a viscous liquid from the glands of the worm, and solidifies to a cylindrical thread. The cohesion of these threads in pairs gives to raw silk the form of a dual cylinder. If they are used for textile purposes the thread is reeled from the cocoon, and several units. five and upwards. are brought together and suitably twisted. (b) The "Wild" silks are produced by a large variety of insects, of which the most important are the various species of Antherea. which yield the Tussore silks. These silks differ in form and composition from the true silks. While they consist of a "dual" thread. each unit of these is complex, being made up of a number of fibrillae. This unit thread is quadrangular in section, and of larger diameter than the true silk, the mean breadth being 0·052mm., as compared with 0·018, the mean diameter of the true silks. The variations in structure as well as in dimensions are, however, very considerable.

B. Epidermal hairs. Of these (a) wool. the epidermal protective covering of sheep, is the most important. The varying species of the animal produce wools of characteristic qualities, varying considerably in fineness, in length of staple, in composition and in spinning quality. Hence the classing of the fleeces or raw wool followed by the elaborate processes of selection, *i.e.,* "sorting" and preparation, which precede the actual spinning or twisting of the yarn. These consist in entirely freeing the fibres and sorting them mechanically (combing, etc.), thereafter forming them into continuous lengths of parallelized units. This is followed by the spinning process which consists in a simultaneous drawing and twisting, and a continuous production of the yarn with the structural characteristics of *worsted* yarns. The shorter staple—from 5 to 25% of average fleeces—is prepared by the "carding" process for the spinning operation, in which drawing and twisting are simultaneous, the length spun being then wound up, and the process being consequently intermittent. This section of the industry is known as "woollen spinning" in contrast to the former or "worsted spinning." (b) An important group of raw material closely allied to the wools are the epidermal hairs of the Angora goat (mohair), the llama, alpaca. Owing to their form and the nature of the substance of which they are composed, they possess more lustre than the wools. They present structural differences from sheep wools which influence the processes by which they are prepared or spun, and the character of the yarns; but the differences are only of subordinate moment. (c) Various animal hairs, such as those of the cow, camel and rabbit, are also employed; the latter is largely worked into the class of fabrics known as felts. In these the hairs are compacted together by taking advantage of the peculiarity of structure which causes the imbrications of the surface. (d) Horse hair is employed in its natural form as an individual filament or monofil.

Vegetable Fibres.—The subjoined scheme of classification sets out the morphological structural characteristics of the vegetable fibres:—

Produced from	
Dicotyledons.	*Monocotyledons.*
A. Seed hairs.	D. Fibro-vascular bundles.
B. Bast fibres.	E. Entire leaves and stems.
C. Bast aggregates.	

In the list of the more important fibrous raw materials subjoined, the capital letter immediately following the name refers the individual to its position in this classification. In reference to the important question of chemical composition and the actual nature of the fibre substance, it may be premised that the vegetable fibres are composed of cellulose, an important representative of the group of carbohydrates, of which the cotton fibre substance is the chemical prototype, mixed and combined with various derivatives belonging to the subgroups. (a) Carbohydrates. (b) Unsaturated compounds of benzenoid and furfuroid constitutions. (c) "Fat and wax" derivatives, *i.e.*, groups belonging to the fatty series, and of higher molecular dimensions—of such compound celluloses the following are the prototypes:—

(*a*) Cellulose combined and mixed with "pectic" bodies (*i.e.*, pecto-celluloses), flax, rhea.

(*b*) Cellulose combined with unsaturated groups or ligno-celluloses, jute and the woods.

(*c*) Cellulose combined and mixed with higher fatty acids, alcohols, ethers, cuto-celluloses, protective epidermal covering of leaves.

The letters a, b, *c* in the table below and following the capitals, which have reference to the structural basis of classification, indicate the main characteristics of the fibre substances. (See also CELLULOSE.)

Miscellaneous Fibres.—Various species of the family Palmaceae yield fibrous products of value, of which mention must be

	Botanical identity. Genus and order.	Country of origin.	Dimensions of ultimate.	Textile uses.
