Cotton, A.*a* .	Gossypium hfalvaceae	Subtropical and tropical countries	12–40mm. 0·019–0·025. Av. 28mm.	Universal. Also as a raw material in chemical industries, notably explosives, celluloid.
Flax, B.a . .	Linum Linaceae	Temperate countries, chiefly European	6–60mm. 0·011–0·025. Av. 28mm.	General. Special effects in lustre damasks. In India and America plants grown for seed (linseed).
Hemp, B.a . .	Cannabis Cannabineae	Temperate countries, chiefly Europe	5–55mm. 0·016–0·050. Av. 22mm. Av. 0·022	Coarser textiles, sail-cloth, rope and twine.
Ramie, B.a . .	Boehmeria Urticaceae	Warm temperate, China	60–200mm. 0·03–0·08. Av. 120mm. Av. 0·050	Clothing in China: "grass cloth:" gas mantels.
Jute, B.b . .	Corchorus Tiliaceae	Tropical countries, chiefly India	1·5–5mm. 0·020–0·025. Av. 2·5mm. Av. 0·022	Coarse textiles, chiefly "Hessians" and sacking. "Line" spun yarns used in cretonne and furniture textiles.
Sunn-hemp, B.b .	Crotalaria Leguminosae	India	4·0–12·0. 0·025–0·050. Av. 7.5. Av. 0·022	Twine and rope. Coarse textiles.
Ambari, B.b . .	Hibiscus	Persia, Russia, India	2–6mm. 0·014–0·033. Av. 4mm. Av. 0·021	Coarse textiles. H. *Elams* has been extensively used in making mats.
Sida, B.b . .	Sida Malvaceae	Tropical and subtropical	1·5–4mm. 0·013–0·02. Av. 2mm. Av. 0·015	Coarse textiles. Appears capable of substituting jute.
Chingma, B.b	Abutilon Malvaceae	China Manchuria Japan		Coarse fabrics, twines.
Lime or Linden, C.b . . .	Tilia Tiliaceae	European countries, chiefly Russia	1·5mm. 0·014–0·020. Av. 2mm. Av. 0·016	Matting and binder twine.
Mulberry, C	Broussonetia Moraceae	Far East	5–31mm. 0·02–0·04. Av. 15mm. Av. 0·03	Paper and paper cloths.
Manila, D	Musa Musaceae	Tropical countries, chiefly Philippine Islands	3–12mm. 0·016–0·032. Av. 6mm. Av. 0·024	Twine and ropes. Produces papers of special quality.
Sisal, D .	Agave Amaryllideae	Tropical countries	1·5–4mm. 0·020–0·032. Av. 2·5. Av. 0·024	Twine and ropes.
Yucca . . .	Yucca Liliaceae	do.	0·5–6mm. 0·01–0·02.	do.
Bow-string hemp.	Sansevieria Liliaceae	East Indies, Ceylon, East Africa	1·5–6mm. 0·015–0·026. Av. 3mm. Av. 0·020	do.
Phormium, D .	Phormium tenax Liliaceae	New Zealand	5·0–1 jmm. 0·010–0·020. Av. 9mm. Av. 0·016	Twine and ropes. Distinguished by high yield of fibre from green leaf.
Pineapple, D .	Ananas Bromeliaceae	Tropical East and West Indies	3·0–9·0mm. 0·004–0·008. Av. 5. Av. 0·006	Textiles of remarkable fineness. Exceptional fineness of ultimate fibre.
Henequén, D .	Agave Amaryllidaceae	Yucatan, Cuba	1·5–4 mm. 0·02–0·03	Binder twine, rope.
Cantala, D . .	Agave Amaryllidaceae	Java, Philippines		Twines and ropes.
Tula ixtle, D .	Agave Amaryllidaceae	Mexico		Twines, "Tampico," brushes.
Jaumave ixtle, D.	Agave Amaryllidaceae	Mexico		Twines, "Tampico," brushes.
Palma, D. . .	Samuela Yucceae	Mexico		Twines.
Piteira, D. .	Furcraea Amaryllidaceae	Brazil, Mauritius	1·3–3·7 mm. 0·015–0·24	Ropes, sacks.

made of the following. *Raffia,* epidermal strips of the leaves of *Raphia ruffia* (Madagascar), R. taedigera (Japan), largely employed as binder twine in horticulture, replacing the "bast" (linden) formerly employed. Coir, the fibrous envelope of the fruit of the *Cocos* nucifera, extensively used for matting and other coarse textiles. Carludovica *palmata* (Central America) yields the raw material for Panama hats, the *Corypha australis* (Australia) yields a similar product. The leaves of the date palm, Phoenix dactylifera, are employed in making baskets and mats, and the fibro-vascular bundles are isolated for working up into coarse twine and rope; similarly, the leaves of the Elaeis *guineensis,* the fruit of which yields the "palm oil" of commerce, yield a fibre which finds employment locally for special purposes. *Chamaerops humilis,* the dwarf palm, yields the well-known "Crin d'Afrique." Locally (Algiers) it is twisted into ropes, but its more general use, in Europe, is in upholstery as a stuffing material. The cereal straws are used in the form of plait in the making of hats and mats. Esparto grass is also used in the making of coarse mats.

The processes by which the fibres are transformed into textile fabrics are in the main determined by their structural features. The following are the distinctive types of treatment:

A. The fibre is in virtually continuous lengths. The textile yarn is produced by assembling together the unit threads, which are wound together and suitably twisted (silk; artificial silk).

B. The fibres in the form of units of variable short dimensions are treated by more or less elaborate processes of scutching, hackling, combing, with the aim of producing a mass of free parallelized units of uniform dimensions; these are then laid together and drawn into continuous bands of sliver and roving, which are finally drawn and twisted into yarns. In this group are comprised the larger number of textile products, such as cotton, wool, flax and jute, and it also includes at the other extreme the production of coarse textiles, such as twine and rope.

C. The fibres of still shorter dimensions are treated in various ways for the production of a fabric in continuous length.

The distinction of type of manufacturing processes in which the relatively short fibres are utilized, either as disintegrated units or comminuted long fibres, follows the lines of division into long and short fibres; the long fibres are worked into yarns by various processes, whereas the shorter fibres are agglomerated by both dry and wet processes to felted tissues or felts. It is obvious, however, that these distinctions do not constitute rigid dividing lines. Thus the principles involved in felting are also applied in the manipulation of long fibre fabrics. For instance, woollen goods are closed or shrunk by milling, the web being subjected to a beating or hammering treatment in an apparatus known as "the stocks," or is continuously run through squeezing rollers, in weak alkaline liquids. Flax goods are "closed" by the process of beetling, a long-continued process of hammering, under which the ultimate fibres are more or less subdivided, and at the same time welded or incorporated together. As already indicated, paper, which is a web composed of units of short dimensions produced by deposition from suspension in water and agglomerated by the interlacing of the component fibres in all planes within the mass, is a species of textile. Further, whereas the silks are mostly worked up in the extreme lengths of the cocoon, there are various systems of spinning silk wastes of variable short lengths, which are similar to those required for spinning the fibres which occur naturally in the shorter lengths.

The fibres thus enumerated as commercially and industrially important have established themselves as the result of a struggle for survival, and each embodies typical features of utility. There are innumerable vegetable fibres, many of which are utilized in the locality or region of their production, but are not available for the highly specialized applications of modern competitive industry to qualify for which a very complex range of requirements has to be met. These include primarily the factors of production and transport summed up in cost of production, together with the question of regularity of supply; structural characteristics, form and dimensions, including uniformity of ultimate unit and adaptability to standard methods of preparing and spinning, together with tenacity and elasticity, lustre. Lastly, composition, which determines the degree of resistance to chemical disintegrating influences as well as subsidiary questions of colour and relationship to colouring matters. The quest for new fibres, as well as modified methods of production of those already known, require critical investigation from the point of view of established practice. The present perspective outline of the group will be found to contain the elements of a grammar of the subject. But those who wish to pursue the matter will require to amplify this outlined picture by a study of the special treatises which deal with general principles, as well as the separate articles on the various fibres.

Analysis and Identification.—For the analysis of textile fabrics and the identification of component fibre, a special treatise must be consulted. The following general facts are to be noted as of importance.

All animal fibres are effectively dissolved by 10% solution of caustic potash or soda. The fabric or material is boiled in this solution for ten minutes and exhaustively washed. Any residue will be vegetable or cellulose fibre. It must not be forgotten that the chemical properties of the fibre substances are modified more or less by association in combination with colouring matters and mordants. These may, in many cases, be removed by treatments which do not seriously modify the fibre substances.

Wool is distinguished from silk by its relative resistance to the action of sulphuric acid. The cold concentrated acid rapidly dissolves silk as well as the vegetable fibres. The attack on wool is slow, and the epidermal scales of wool make their appearance. The true silks are distinguished from the wild silks by the action of concentrated hydrochloric acid in the cold, which reagent dissolves the former, but has only a slight effect on Tussore silk. After preliminary resolution by these group reagents, the fabric is subjected to microscopical analysis for the final identification of its component fibres (see H. Schlichter, Journal *Soc.* Chem. Ind., 1890, p. 241).

A scheme for the commercial analysis or assay of vegetable fibres, originally proposed by the author (Col. Ind. Exhibition, 1886, Miscellaneous Reports) and now generally adopted, includes the following operations:—

1. Determination of moisture.
2. Determination of ash left after complete ignition.
3. Hydrolysis:
   (a) loss of weight after boiling the raw fibre with a 1% caustic soda solution for five minutes;
   (b) loss after boiling for one hour.
4. Determination of cellulose: the white residue after
   (a) boiling for five minutes with 1% caustic soda,
   (b) exposure to chlorine gas for one hour,
   (c) boiling with basic sodium sulphite solution.
5. Mercerizing: the loss of weight after digestion with a 20% solution of sodium hydrate for one hour in the cold.
6. Nitration: the weight of the product obtained after digestion with a mixture of equal volumes of sulphuric and nitric acids for one hour in the cold.
7. Acid purification: treatment of the raw fibre with 20% acetic acid for one minute, the product being washed with water and alcohol, and then dried.
8. Determination of the total carbon by combustion.

Paper-making.—The paper-making industry (see PAPER MANUFACTURE; PAPER MATERIALS) employs as raw materials a large proportion of the vegetable fibre products already enumerated, and, for the reasons incidentally mentioned, they may be, and are, employed in a large variety of forms; in fact any fibrous material containing over 30% "cellulose" and yielding ultimate fibres of a length exceqding 1 mm. can be used in this industry. Most important staples are cotton and flax; these are known to the paper-maker as "rag" fibres, rags, *i.e.,* cuttings of textile fabrics, new and old, being their main source of supply. These are used for writing and drawing papers. In the class of "printings" two of the most important staples are wood pulp, prepared by chemical treatment from both pine and foliage woods, and in England esparto cellulose, the cellulose obtained from esparto grass by alkali treatment; the cereal straws are also used and are resolved into cellulose by alkaline boiling followed by bleaching. In the class of "wrappings" and miscellaneous papers a large number of other materials find use, such as various residues of manufacturing and preparing processes, scutching nastes, ends of rovings and yarns. flax, hemp and manila rope waste, adansonia bast and jute wastes, raw (cuttings) and manufactured (bagging).

Brush Fibres, **Etc.**—The fibres in brushes are mainly drawn from the badger, hog, bear, sable. squirrel and horse. Brushes required for cleansing purposes are composed of fibres of a more or less hard and resilient character, such as horse hairs, and other tail hairs and bristles. For painting work brushes of soft quality are employed, graduating for fine work into the extreme softness of the "camel hair" pencil. Of vegetable fibres the following are used in this industry. The *Caryota urens* furnishes the Kittul fibre, obtained from the base of the leaf stalks. Piassava is obtained from the *Attalea funifera*, also from the *Leopoldina piassaba* (Brazil). Palmyra fibre is obtained from the *Borassus flabellifer*. These are all members of the natural order of the Palmaceae. Mexican fibre. or Istle, is obtained from the agave. The fibre known as Whisk, largely used for dusting brushes, is obtained from various species of the Gramineae; the "Mexican Whisk" from *Epicampes macroura;* and "Italian Whisk" from *Andropogon*. The *coir* fibre mentioned above in connection with coarse textiles is also extensively used in brush-making. Aloe and agave fibres in their softer forms are also used for plasterers' brushes. Many of the whitewashes and cleansing solutions used in house decoration are alkaline in character, and for such uses advantage is taken of the specially resistant character of the cellulose group of materials.

Stuffing **and** Upholstery. — Another important use for fibrous materials is for filling or stuffing seats and cushions in upholstery. One of the most important is the floss or seed-hair of the *Ceiba pentandra,* known as Kapok. The fibre is soft, silky and resilient, and maintains its resiliency in use. Horse hair is extensively used in this industry, as are also wool flocks and other short animal hairs and uastes.

For hat and matting manufactures a large range of the fibrous products above described are employed, chiefly in their natural or ram state.

See also ALPACA; COTTON AND THE COTTON INDUSTRY; FELT; FLAX; HEMP; JUTE; MOHAIR; WOOL; CELLULOSE; SYNTHETIC FIBRES; SHODDY; SILK AND SCRICULTURE; RAMIE; KAPOK; FUR; etc. (C. F. C.)

FIBRIN is the essential part of the blood clot, a substance that connects the edges of a wound and prevents passage of the blood corpuscles. It results from a chemical process in the plasma that causes dissolved fibrinogen to separate out. *See* BLOOD.

FICHTE, IMMANUEL HERMANN (originally HARTMANN) **VON** (1796–1879), German philosopher: son of Johann Gottlieb Fichte (*q.v.*) was born at Jena on July 18, 1796. Having held educational posts at Saarbrucken and Dusseldorf, he became professor of philosophy at Bonn in 1836 and at Tübingen in 1842. He died at Stuttgart on hug. 8, 1879.

Fichte's most important writings are: *System der Ethik* (1850–53), *Anthropologie* (1856), *Psychologie* (1864–73), *Die theistische Weltansicht und ihre Berechtigung* (1873). His general views on philosophy are marked by an eclecticism, a predominantly historical treatment of problems and a conciliatory tone. He edited the works and correspondence of his father.

See R. Mehlich, *I. H. Fichtes Seelenlehre und ihre Beziehung zur Gegenwart* (1935); J. Ebert, *Sein und Sollen bei Immanuel Hermann Fichte* (1938).

FICHTE, JOHANN GBTTLIEB (1762–1814), German philosopher and patriot, who was recognized, together with Friedrich Schelling and Hegel, as one of the three immediate claimants to the Kantian succession, was born at Rammenau in Upper Lusatia on May 19, 1762, the son of a ribbon weaver. Educated at the Pforta school (1774–80) and at the universities of Jena (1780) and of Leipzig (1781–84), he started work as a tutor. In this capacity he went to Zurich in 1788 and to Warsaw in 1791, but left after two weeks' probation. Meanwhile, at Leipzig in 1790, he had composed his "Aphorismen iiber Religion und Deismus" (1st ed. in the *Sämmtliche Werke,* i; see *Bibliography* below), reminiscent of Spinoza's determinism. The major influence on his thought at this time, however, was that of Kant, whose doctrine of the inherent moral worth of man harmonized with his character; and he resolved to devote himself to perfecting a true philosophy, the principles of which should be practical maxims. Having already begun an abridgment (never completed) of the *Critique of Judgment,* he went from Warsaw to see Kant himself at Königsberg. The first interview was disappointing, but when Fichte submitted his *Versuch einer Kritik aller Offenbarung* ("Essay Toward a Critique of all Revelation") to Kant, the latter was favourably impressed by it and helped to find a publisher (1792). Fichte's name and preface were accidentally omitted from the first edition and the work was ascribed by its earliest readers to Kant himself; when Kant corrected the mistake while commending the essay, Fichte's reputation was made.

From the *Critique of Pure Reason* it was clear that for Kant speculative theology must be purely negative, while the *Critique of Practical Reason* as clearly indicated the view that the moral law is the absolute content or substance of any religion. A critical investigation of the conditions under which religious belief was possible was still wanting; and this it was that Fichte sought to supply in the *Versuch.* His exposition of the conditions under which revealed religion is possible turns upon the absolute requirements of the moral law. Religion itself is the belief in this moral law as divine, and such belief is a practical postulate, necessary in order to add force to the law. The revelation of this divine character of morality is possible only to a being in whom the lower impulses have been, or are, successful in overcoming reverence for the law. In such a case it is conceivable that a revelation might be given in order to add strength to the moral law. Religion ultimately then rests upon the practical reason and satisfies the needs of man, insofar as he stands under the moral law. In this conclusion we see the prominence assigned by Fichte to the practical element and the tendency to make the moral requirements of the ego the ground for all judgment on reality. Having reached this point he had to press forward and leave the Kantian position.

In 1793 Fichte married Johanna Maria Rahn, whom he had met during his stay in Zurich. In the same year he published anonymously two remarkable political works, *Zurückforderung der Denkfreiheit von den Fürsten Europens* and *Beitrag zur Berichtigung der Urteile des Publikums iiber die franzosische Revolution.* Of these the latter, which is much the more important, was intended to explain the true nature of the French Revolution, to demonstrate how inextricably the right of liberty is interwoven with the very existence of man as an intelligent agent and to point out the inherent progressiveness of state arrangements and the consequent necessity of reform or amendment.

As in the *Versuch,* the rational nature of man and the conditions necessary for its realization are made the standard for political philosophy.

When K. L. Reinhold vacated the chair of philosophy at Jena (1793), Fichte was called to succeed him. To the ensuing period belongs his most important philosophical work *(see* below). In this period he published *Einige Vorlesungen iiber die Bestimmung des Gelehrten* (1794; Eng. trans., *The Vocation of the Scholar,* 1847), being lectures on the importance of the highest intellectual culture and on the duties that it imposed, delivered not merely to his own pupils but to all students of the university; the introductory *Über den Begriff der Wissenschaftslehre* and the theoretical *Grundlage der gesamten Wissenschaftslehre* (both also 1794), supplemented by *Grundriss des Eigentümlichen der Wissenschaftslehre* (179j); the practical *Grundlage des Naturrechts* (1796; Eng. trans., *The Science of Rights,* 1869 and 1889); *Erste Einleitung . . . , Zweite Einleitung in die Wissenschaftslehre* and *Versuch einer neuen Darstellung der Wissenschaftslehre* (all three 1797); and *System der Sittenlehre nach den Principien der Wissenschaftslehre* (1798; Eng. trans., *The Science of Ethics as Based on the Science of Knowledge,* 1897). To the theme of his *Wissen-*

schaftslehre ("doctrine of knowledge" or "science") he was to recur continually throughout his life.

In 1795, however, Fichte had become one of the editors of the *Philosophisches Journal;* and in 1798 his friend F. K. Forberg sent him an essay on the development of the idea of religion. Before printing this, Fichte, to prevent misunderstanding, composed a short preface, "On the Grounds of Our Belief in a Divine Government of the Universe," in which God is defined as the moral order of the universe, the eternal law of right which is the foundation of all our being. The cry of atheism was raised, and the electoral government of Saxony, followed by all the German states except Prussia, suppressed the *Journal* and demanded Fichte's expulsion from Jena. After publishing two defenses *(Appellation an das Publikum uber die . . . ihm beigemessenen atheistischen Äusserungen* and *Der Herausgeber des philosophischen Journals gerichtliche Verantwortung gegen die Anklage des Atheismus,* both 1799), Fichte threatened to resign in case of reprimand. Much to his discomfort, his threat was taken as an offer to resign and was duly accepted.

Except for the summer of 1805 (which he spent at Erlangen, delivering the lectures published in 1806 as *Uber das Wesen des Gelehrten,* a longer version of his Jena lectures of 1794), Fichte resided in Berlin from 1799 to 1806. Among his friends were the leaders of German romanticism, A. W. and F. Schlegel and F. Schleiermacher. His works of this period include *Die Bestimmung des Menschen* (1800; Eng. trans., *The Vocation of Man,* 1848); *Der geschlossene Haudelsstaat* (also 1800), an intensely socialistic treatise m favour of tariff protection; *Sonnenklarer Bericht an das grössere Publikum uber die neueste Philosophie* (1801; Fr. trans., *L'Essence de la théorie de la science,* 1916) ; two new versions of the *Wissenschaftslehre* (composed in 1801 and in 1804; published posthumously), marking a great change in the character of the doctrine; *Grundzüge des gegenwartigen Zeitalters* (1806; lectures delivered 1804–05; Eng. trans., *Characteristics of the Present Age,* 1849), analyzing "the Enlightenment" and defining its place in the historical evolution of the general human consciousness, but also indicating its defects and looking forward to belief in the divine order of the universe as the highest aspect of the life of reason; and *Die Anweisung zum seligen Leben, oder Religionslehre* (1806; Eng. trans., *The Way Towards the Blessed Life,* 1849). In this last-named work the union between the finite self-consciousness and the infinite ego or God is handled in a deeply religious fashion reminiscent of the Gospel of St. John. The knowledge and love of God is declared to be the end of life. God is the All; the world of independent objects is the result of reflection or self-consciousness, by which the infinite unity is broken up. God is thus over and above the distinction of subject and object; our knowledge is but a reflex or picture of the infinite essence.

The French victories over the Prussians in 1806 drove Fichte from Berlin to Konigsberg (where he lectured for a time), then to Copenhagen, whence he returned to Berlin in Aug. 1807. From this time his published writings are practical in character; not till after the appearance of the *Nachgelassene* and of the *Sämmtliche Werke* was the shape of his final speculations known. We may here note the order of these posthumously published writings as important for tracing the development of Fichte's thought. From 1806 we have the remarkable *Bericht uber die Wissenschaftslehre* (*Sämmtl. Werke,* viii), with its sharp critique of Schelling, and from 1810 the *Thatsachen des Bewusstseyns* (published 1817), of which another treatment is given in lectures of 1813 (*Nach. Werke,* i). Of the *Wissenschaftslehre* we have, in 1812–13, four separate treatments contained in the *Nachgelassene Werke.* Perhaps the most interesting are the lectures of 1812 on transcendental logic *(Nach. Werke,* i). From 1812 we have notes of two courses on practical philosophy, *Rechtslehre* (*Nach. Werke,* ii) and *Sittenlehre (ibid.,* iii). A finished work in the same department is the *Staatslehre* (published 1820), which gives the Fichtean utopia organized on principles of pure reason; in many cases what it proposes amounts to despotism.

From 1807, however, Fichte was mainly occupied with public affairs. In 1807 he drew up a plan for the proposed new university of Berlin. In 1807–08 he delivered at Berlin his noble addresses to the German nation *(Reden an die deutsche Nation),* full of practical views on the only true foundation for national recovery and glory. From 1810 to 1812 he was rector of the new Berlin university. During the great effort of Germany for national independence in 1813. he lectured on the idea of a true war (*Über den Begriff eines wahrhaften Kriegs,* forming part of the *Staatslehre)*.

At the beginning of 1814, Fichte caught a virulent hospital fever from his nife, who had volunteered for work as a hospital nurse. He died on Jan. 27, 1814.

Philosophy. — The philosophy of Fichte falls chronologically into the periods of Jena and of Berlin, which are also different in their fundamental philosophic conceptions. The former period is marked by its ethical emphasis, the latter by the emergence of a mystical and theological metaph'ysic of being. Fichte was prompted to change his original position because he came to appreciate that religious faith surpasses moral reason. He was also influenced by the general trend which the development of thought took. It cannot be denied that his own turn coincided with, and resembled, the direction in which romanticism and the speculation of Schleiermacher, Schelling and Hegel moved.

But the system of 1794 was the historically most original and also the most characteristic work that Fichte produced. It was incited by Kant's critical philosophy and especially by the *Critique of Practical Reason.* From the outset it was less critical, precisely because it was more systematical, aiming at a self-sufficient, well-rounded doctrine in which epistemology and ethics were intimately united. Fichte's ambition was to demonstrate that practical (moral) reason is really (as Kant had only intimated) the root of reason in its entirety, the absolute ground of all knowledge as well as of humanity altogether. To prove this, he started from a supreme principle which was supposed to be independent and sovereign so that all other knowledge was deduced from it. Fichte did not assert that this supreme principle was self-evident, but rather that it had to be postulated by pure thought. He followed thereby Kant's doctrine that pure practical reason postulates the existence of God, but he tried to transform Kant's rational faith into a speculative knowledge, on which he based both his theory of science and his ethics.

The supreme principle is therefore at the same time a theoretical thesis and a practical act, and it is the practical act that prevails and dominates the meaning of the whole system. The supreme act concerns the origin of the ego itself. Insofar as the ego is the ego of a moral agent it does not originate from any source outside itself, since in that case it would not be responsible for its actions. It can be responsible only if its actions are rooted in the supreme act by which it "posits" itself. Fichte used this new term in order to indicate that the supreme act unites thinking and doing in originating both the highest speculative thesis and the highest ethical reality.

In one of the introductions to his *Wissenschaftslehre* we find an illuminating sentence: "What a philosophy a man embraces depends upon the kind of man he is." This does not mean that philosophy is an outcome of a man's individual nature or that he may choose his philosophy according to his temper or mood, as the existentialists of the 20th century would allow. On the contrary, it means that there is only one true philosophy, namely that which is in agreement with moral reason. A man by choosing his philosophy makes his character manifest. If he is what he ought to be, he has no choice but to obey the moral law. This is the same in thinking as in doing. The moral law governs the will as well as the thinking mind and therefore dictates the true philosophy. It is not merely a matter of science, but it is also and even primarily a matter of conscience when a man decides about the supreme principle of his philosophy. Only by obeying the moral law and the dictate of moral reason can he reach the truth in speculation and become truly free.

Whereas in all other things reality and thought are separable, a man as a moral being can be real only if he brings forth himself; he is not an ego if he does not act as such; and he cannot act as an ego if he is not aware of such action. Ego and self-consciousness are bound together, and only by virtue of this intrinsic bond is he a self. The philosopher has to be moral reason incarnate. Consequently he has to make the absolute ego the Archimedean point from which his system departs and on which it relies. The term "absolute ego" is however not free from a certain ambiguity.

Historians differ in their interpretations of this term. The absolute ego, Fichte says, posits itself. What is this absolute ego? Is it that of an empirical and finite man, inasmuch as he is a moral agent and only thereby an ego? Or is it absolute because it is no longer finite but infinite and therefore the ego not of man but of God? It is difficult to give a precise answer. But the supreme principle certainly points to an ideal ego; *i.e.,* to an ego which is in no way determined by any finite conditions but which determines itself and only thereby posits itself as a self. Yet this ideal self is not merely an ideal or an idea in the mind of finite man. On the contrary, it is even more truly real than any merely finite self; it is more truly a self, precisely because it is not finite and not restricted in its freedom. One might say that Fichte's "absolute ego" resembles the idea of God in Archbishop Anselm's ontological proof; if it were merely an idea, it would not be as absolute as it is supposed to be.

The absolute ego is absolute, Fichte says, in form as well as in content. It is absolute in positing itself by itself and it is absolute in positing itself as an ego. There is no higher reason that could be adduced to prove that it posits itself as an ego; if such a reason could be given, the absolute ego would no longer be absolute and an ego. Out of the same unconditional sovereignty the absolute ego posits over against itself its own opposite. This second act is absolute only as to its form (negation), but not with respect to its content, since there is no content that could be negated except the absolute ego itself. Since the act of self-negating is as independent as the act of self-positing, we cannot ask why the absolute ego brings forth its own opposite and thereby somehow restricts itself and even contradicts itself. Only later when the system unfolds do we learn why a supreme antithesis had to be put as a second supreme principle. The reason is again purely moral; the absolute ego restricts itself in order to originate that sphere in which morality can work; for morality cannot work and the will cannot operate without a certain resistance. Although morality depends upon the absolute freedom of the will, still this freedom itself has a moral significance and dignity only if it overcomes temptation and remains victorious in its struggle with desire and impulse.

Here again Fichte is the disciple of Kant transforming his teacher's doctrine in the direction of ethical speculation. "The world is nothing but the material of our duties"; these words illuminate Fichte's deepest intentions and reveal the very soul of his system. The absolute ego creates its own counterpart to make possible the finite moral person and the finite moral life of man. It is the religious mystery of creation that Fichte in his bold antithesis tries to expound philosophically. The moral will of the human being is both absolute and conditioned, infinite and finite and only thereby the will of an ever-striving, ever-fighting, ever-longing human person. Fichte sought the ultimate foundation of this contradiction inherent in our own existence and in the world in which we have to live and to act. And from this supreme antithesis Fichte develops in the course of his system the peculiarity of world and self in an utterly abstract dialectical procedure.

The dynamic of the system is set in motion by the contradiction of the two highest principles. They have to be reconciled to each other. The solution of this task is directed by the superiority of the thesis in which the absolute ego posits itself. Even the act of self-negation is still an act of the absolute ego and, as such, within the domain of its creative activity, which is indestructible and in the end victorious. How can the absolute ego defeat its opponent? The answer is given by means of the first synthesis in the system, which combines both thesis and antithesis on the ground of the thesis. The absolute ego posits itself according to this synthesis as both determined by its negative counterpart (called the nonego) and determining it; in the first case the world of sense perception and ultimately of scientific knowledge arises; in the second case the practical world of persons and of their purposes emerges. In each case new contradictions obstruct a final solution and new solutions have to be sought.

In the process of this dialectical deduction Fichte demonstrates that the world of sense is necessarily a world in space and time, ordered by causality and subject to general laws; and that the practical world is necessarily built on impulse and desire, inclination and longing, yet ultimately under the legislation of pure practical reason. Man can overcome the obstacles of his nature only by approximating to the goal of a community regulated by the moral conscience of its members. This goal, however, is infinitely remote. The finite ego can never restore within itself the original absolute ego. In this respect no final solution of the supreme contradiction can be attained.

A grandiose ethical intuition underlies the *Wissenschaftslehre* of the Jena period. But it is also evident that the system suffers from an incurable ill; though it claims to be perfect and self-sufficient, it never arrives at its own end. The beginning could be justified only if the end were attainable, but the tension between the contrasting poles of the infinite and the finite ego, between the ideal and the real self, is never completely solved. Ethical speculation defeats itself. The ambiguity of the absolute ego proves fatal to the system. Fichte himself was aware of this defect. This was the reason why he changed again and again the foundations of his *Wissenschaftslehre* and, especially, why he transformed it into a religious metaphysic in which the ethical speculation was not completely given up but was subordinated to a philosophic theology. These later drafts, however, he did not publish, probably because he felt that his day in the development of German idealism had passed.

The popular writings which Fichte did publish disclose in what direction his mind moved. Already in the *Bestimmung des Menschen* he had defined the absolute ego as the infinite moral will of the universe, God, in whom are all the individual egos, from whom they have sprung. More precise utterances are given in the *Thatsachen des Bewusstseyns* and in the later lectures. In them God is the absolute Life, the absolute One, who becomes conscious of himself by self-division and translation into the individual egos. The individual ego is only possible as opposed to a nonego, to a world of the senses; thus God, the infinite will, manifests himself in the individual and the individual has over against him the nonego or thing. "The individuals do not make part of the being of the one life, but are a pure form of its absolute freedom." "The individual is not conscious of himself, but the Life is conscious of itself in individual form and as an individual." In order that the Life may act, though it is not necessary that it *should act,* individualization is necessary. "Knowledge is not mere knowledge of itself, but of being, and of the one being that truly is, namely God. . . . This one possible object of knowledge is never known in its purity, but ever broken into the various forms of knowledge which are and can be shown to be necessary. The demonstration of the necessity of these forms is philosophy or *Wissenschaftslehre" (Thatsachen des Bewusstseyns).* The idea and the method of the *Wissenschaftslehre* prepare the way for Hegelian dialectic; while Schopenhauer's philosophy is very largely contained in the later writings of Fichte. *(See* also HEGEL, GEORG WILHELM FRIEDRICH, and SCHOPENHAUER, ARTHUR.)

FICHTELGEBIRGE, a mountain group of Bavaria, forming the centre from which various mountain ranges radiate—the Elstergebirge, linking it to the Erzgebirge, in a northeast, the Frankenwald in a northwest and the Böhmer Wald in a southeast direction. The streams which rise there are the Eger and the Saale, both flowing into the Elbe; the Weisser Main into the Rhine and the Naab into the Danube. The chief peaks of the group are the Schneeberg (3,448 ft.) and the Ochsenkopf (3,360 ft.). The district is thickly wooded and is rich in mineral wealth, producing iron, vitriol, sulfur, copper, lead and many kinds of marble. A large population is supported by the iron mines, forges and blast furnaces: and by charcoal burning. Although surrounded b~ railways and crossed b~ the several lines, the Fichtelgebirge, because of its raw climate and bleakness, is not much visited. Of interest are Alexandersbad and Luisenburg.

FICINO, MARSILIO (1433–1499), Italian philosopher and scholar, one of the leaders of Renaissance Platonism, was born on Oct. 19, 1433, at Figline near Florence. His father, a physician, was acquainted with Cosimo de' Medici and with St. Antoninus (archbishop of Florence from 1446 to 1459). After the customary training in Latin language and literature, Ficino studied Aristotelian philosophy and medicine, probably at Florence, but his early interests included also the thought of Epicurus, of Plato and the Neoplatonists, of Augustine and of Thomas Aquinas. After having studied the sources available in Latin, he acquired a thorough knowledge of Greek and devoted the greater part of his life to the translation and interpretation of Plato and of his ancient followers. as well as to the formulation and diffusion of his own Christianized and modernized version of Platonic philosophy. Encouraged and supported by Cosimo de' Medici and his successors. Ficino began his formal activity as a translator and teacher and as the head of the so-called Platonic Academy of Florence in 1462. His numerous translations from Greek into Latin include, besides some Neoplatonic and early Christian writings, the so-called Hermetic corpus (1463; printed in 1471) and, above all, the complete works of Plato and of Plotinus. Whereas several Platonic writings had been translated before, this was the first complete translation of Plato into any western language (begun in 1463, completed *c.* 1470, printed in 1484) and hence a major event in the intellectual history of Europe. In the case of Plotinus, it was the first translation of significance (1484–86; printed 1492). Both versions are excellent and were in general use until the 18th century.

Among Ficino's commentaries, those on Plato's *Symposium* (1469; printed 1484, translated into Italian by Ficino) and on Plotinus (printed 1492) were especially important and influential. Ficino's original works include the *Theologia Platonica* (1482), his chief philosophical work; *Epistolae* (1495), his collected letters, among which many of his shorter philosophical treatises are inserted; and works on medicine and astrology (*De vita libri tres,* 1489) and on theology (*Liber de Christiana religione,* 1474). Ficino's letters and prefaces show that he was engaged in more or less informal teaching, holding courses, orations and discussions, and that his personal and scholarly connections gradually extended from Florence to the rest of Italy and of Europe. Ficino was ordained as a priest in 1473, received several ecclesiastic benefices and became a canon of Florence cathedral. Having been closely identified with the Medici and particularly with Lorenzo, who was his pupil, Ficino retired after the expulsion of the Medici in 1494 and died on Oct. 1, 1499.

Whereas Ficino's role as a scholar, that is, as a translator and commentator of ancient Platonism, has always been recognized, his place as a philosopher in his own right is more difficult to assess. In an age which took pride in a revival of everything ancient, Ficino assumed the task of reviving ancient Platonism. In doing so, he felt free to add medieval and modern ideas to the authentic heritage. Citing the testimony of St. Augustine, he believed that there was a basic agreement between Christian religion and Platonic philosophy and that each of them had its own venerable tradition which remained fundamentally stable in spite of surface variations. In conceiving the universe as a hierarchy of substances that descends from God to matter, he was strongly influenced by Neoplatonic and medieval views. Yet in assigning to the human soul a privileged, central place in this hierarchy and in stressing that the soul through its universal, infinite aspirations and thoughts links the highest with the lowest beings and acts as a bond and knot of the universe, Ficino reveals his originality and his affinity with the thought of Renaissance humanism which had given special emphasis to man and his dignity. His notion of the world as an animated being held together by a dynamic unity was to dominate much speculation on nature during the 16th century and afterward. In accordance with the Neoplatonists and with the medieval mystics, he conceives the task of human existence as an inner ascent of the soul through higher and higher degrees of knowledge and of love, a process which culminates in the immediate contemplation and enjoyment of God. Since this ultimate end cannot be attained during our present life, Ficino postulates the immortality of the soul and assigns to the proofs for this immortality a prominent place in the *Theologia Platonica.* Elaborating on classical and Christian notions, he explains the human relations of love and of friendship in their highest form through a common share in God and in the contemplative life; and in his commentary on Plato's *Symposium* he laid the ground for the theory of spiritual or "Platonic" love that was to become dominant in the poetry and literature of the 16th century. His notion that religion is natural to all men and that every form of religion has a measure of truth whereas Christianity is the most perfect of all seems to have inspired Lord Herbert of Cherbury and later deists. In many other ways, the direct and explicit influence of Ficino's ideas can be traced through the 16th century, whereas his anonymous influence, disguised under the name of Plato or Plotinus, persisted to the end of the 18th.

The *Marsilii Ficini opera* were published (2 vol. 1576), and a *Supplementum Ficinianum,* ed. by P. O. Kristeller, (2 vol. 1937).

FICK, AUGUST (1833–1916), German philologist, a pioneer in Indo-European etymological research, was born on May 5, 1833, at Petershagen, Westphalia, and was educated at the university of Gottingen, where he became a professor in 1876. His second professorship, at the university of Breslau (1888–91), was relinquished for ill-health, but his research continued. His most enduring contributions fall under two headings. (1) He was the first to undertake a comprehensive study of the common vocabulary of the Indo-European languages. The first edition, *Wörterbuch der indogermanischen Grundsprache in ihrem Bestande vor der Völkertrennung* (1868) reconstructed a "parent" language of remote prehistoric times. In subsequent editions the title was more reserved! *Vergleichendes Wörterbuch der indogermanischen Sprachen;* while giving more emphasis to comparison of the recorded ancient languages, Fick did not discard reconstruction of the prehistoric source. (2) In *Die griechischen Personennamen nach ihrer Bildung erklärt* (1874; 2d. ed. with F. Bechtel, 1894), Fick showed how the formation of many proper names in Greek corresponded exactly to the manner of forming names in most other Indo-European languages (except Latin). This demonstration favoured the conception of the original Indo-European community as a stable aristocracy whose descendants became rulers of the Greek. Hindu, Iranian, Celtic, Germanic and other great nations of antiquity. Fick's method contained some features which were already outdated in his lifetime. Yet his lucid presentation and his orderly grasp of an immense repertory of facts made his writings useful for more than a generation. and much of his research has been incorporated rather than superseded by recent scholars. He died on March 24, 1916, at Hildesheim, Germany. (S. Ln.)

FICTION: *see* Novel; Romance; *see* also separate articles on various national literatures.

FICTIONS, or legal fictions, in law, the term used for false averments, the truth of which is not pennitted to be called in question. English law as well as Roman law abounds in fictions. Sometimes they are merely the condensed expression of a rule of law; *e.g.,* the fiction of English law that husband and wife were one person, and the fiction of Roman law that the wife was the daughter of the husband. Sometimes they must be regarded as reasons invented in order to justify a rule of law according to an implied ethical standard. Of this sort seems to be the fiction or presumption that everyone knows the law, which reconciles the rule that ignorance is no excuse for crime with the moral commonplace that it is unfair to punish a man for violating a law of whose existence he was unaware. Again, some fictions are deliberate falsehoods, adopted as true for the purpose of establishing a remedy not otherwise attainable. Of this sort are the numerous fictions of English law by which the different courts obtained jurisdiction in private business, removed inconvenient restrictions in the law relating to land, etc.

What to the scientific jurist is a stumbling block is to the older writers on English law a beautiful device for reconciling the strict letter of the law with common sense and justice. Blackstone, in noticing the well-known fiction by which the court of king's bench established its jurisdiction in common pleas (viz., that the defendant was in custody of the marshal of the court), says, "These fictions of law, though at first they may startle the student, he will find upon further consideration to be highly beneficial and useful; especially as this maxim is ever invariably observed, that no fiction shall extend to work an injury; its proper operation being to prevent a mischief or remedy an inconvenience that might result from the general rule of law. So true it is that in *fictione* juris semper *subsistit aequitas"* ("in a fiction of law equity must always exist").

Fictions form one of the agencies by which, in progressive societies, positive law is brought into harmony with public opinion. The others are equity and statutes. Fictions in this sense include. not merely the obvious falsities of the English and Roman systems, but any assumption which conceals a change of law by retaining the old formula after the change has been made. It thus includes both the case law of the English and the Responsa Prudentum of the Romans. "At a particular stage of social progress they are invaluable expedients for overcoming the rigidity of law; and, indeed, without one of them, the fiction of adoption, which permits the family tie to be artificially created, it is difficult to understand how society would ever have escaped from its swaddling clothes, and taken its first steps towards civilization." (Sir H. Maine, Ancient Law.)

The bolder remedial fictions of English law have been to a large extent removed by legislation. Thus in ejectment cases the mysterious sham litigants have disappeared. The bond of entail can be broken without having recourse to the collusive proceedings of fine and recovery. Many fictions must have begun their career as metaphors concealing principles. The conception that a man-of-war is a floating island, or that an ambassador's house is beyond the territorial limits of the country in which he resides, was originally a figure of speech designed to set a rule of law in a striking light. It is then gravely accepted as true in fact, and other rules of law are deduced from it. On the other hand, obsolete principles may be classed as fictions when they are quoted as having a present existence. Thus the legal attributes of the king, and even of the house of lords, are fictions. Again, many would hold that the assertion that any elective government really represents the people is hardly more than a fiction.

Bentham notices the comparative rarity of fictions in Scots law. As to fiction in particular, compared with the work done by it in English law, the use made of it by the Scottish lawyers is next to nothing. No need have they had of any such clumsy instrument. They have two others "of their own making, by which things of the same sort have been done with much less trouble. *Nobile officium* gives them the creative power of legislation; this and the word desuetude together the annihilative." And he notices aptly enough that, while the English lawyers declared that James II had abdicated the throne (which everybody knew to be false), the Scottish lawyers boldly said he had forfeited it. (Historical Preface to the second edition of the Fragment on Government.)

FICUS, a very large genus of the Moraceae (*q.v.*) family, comprising trees, shrubs and woody root-climbing vines, with milky sap, minute flowers and seeds inside an ovoid, a globose or pyriform receptacle (or fig) that has a small opening at the apex. Well-known examples are the cultivated figs (*q.v.*), the banyan (*q.v.*), the bo tree and the rubber plant (*F. elastica*). (J. M. BL.)

FIDEICOMMISSION, the name given in Roman law to a provision made by a testator directing his heir or legatee to enter on the inheritance and subsequently denude wholly or partially in favour of a third party. It was introduced formally in the time of Augustus, previously having had no legal force. As cases arose of a legatee failing to comply with this request a court was instituted, the praetor *commissarius*, with special powers of adjudication. *See* SETTLEMENT.

FIDELITY AND SURETY BONDS. A fidelity bond usually provides protection against loss from dishonest acts of persons covered by the bond. It may also protect against losses discovered while the bond is in effect even though they were sustained earlier. A surety bond usually provides that the party furnishing the surety will make good any default by the person covered by the bond (the obligor or principal) in performance of an obligation.

Suretyship is a relationship whereby one party, the surety, promises to reimburse the obligee of a principal for default in the performance of the principal's duty. According to the narrow view, the prevailing view in U.S. jurisdictions, the surety is allied with the principal and has a primary obligation to pay the principal's debt. This is distinguished from guaranty, whereby the guarantor's obligation is conditioned upon nonpayment by the principal, and hence is a secondary obligation. Unless the duty is primary, under the narrow view, the relationship is one of guaranty. According to the broad or British view, followed in a minority of U.S. courts, guaranty is included within the suretyship meaning. In such case, the surety's obligation may be either primary or secondary. The surety upon making payment, usually has a right to be reimbursed.

The principal types of fidelity bonds are individual, schedule, position and blanket bonds. An individual bond protects against loss up to a stated amount resulting from dishonest or fraudulent acts of the named individual employee. There are two types of schedule bonds: a name schedule bond covers the employees named in the bond, each for a specified amount; a position schedule bond is similar but specifies the amount of coverage for each position rather than for each person, and an employee is covered so long as he occupies the position stated. A blanket fidelity bond covers all employees, and names, schedules or positions are not specified. Rates for fidelity bonds depend partly upon the classification of the insured, such as importer, exporter, manufacturer, distributor, wholesaler or retailer. Public officials and employees are under fidelity protection through bonds written especially for such purpose in meeting statutory requirements. Their dishonest acts are covered and guarantees of faithful performance of duties are given.

The principal types of surety bonds are contract bonds, judicial proceedings court bonds, fiduciary court bonds and miscellaneous bonds.

A contract bond guarantees the surety will make good the obligation of principal or obligor should he default on the contract in relation, for example, to construction, maintenance or repairs of a building. The principal or obligor may default in performance, may be unable to meet time limitations for completion of a project, or may default in payment of labour or material costs. Special types of contract bonds include bid or proposal bonds, performance bonds, payment of labour and materials bonds, and maintenance bonds. A bid or proposal bond guarantees the bidder will enter into the contract and provide a performance bond, should his bid be accepted within a specified time period. Labour and materials bonds guarantee payment for labour and materials used in completion of the project. Maintenance bonds guarantee against defective workmanship and materials.

A court bond guarantees the preservation of the opposing litigant's rights and assures the solvency of the principal and his willingness to fulfill his obligations to such party. These bonds, which include appeal and attachment bonds, cover many forms of actions in civil, criminal and admiralty proceedings. The filing of court bonds and their coverage are governed by statute.

A court fiduciary bond, usually required by law, guarantees a court fiduciary will faithfully perform his duties as guardian, receiver, trustee, administrator or executor of property.

Miscellaneous bonds may be required by governmental bodies, individuals, corporations or other legal entities. They include auctioneers' bonds, convict lease bonds for the lease and hiring of state convicts, and depository and indemnity bonds.

Various other types of bonds are written by surety companies. Forgery bonds indemnify the insured against loss for having paid money, given. value, extended credit or delivered property upon the faith of instruments or documents on which the signature has been forged, the amount raised or other alterations made. Checks, drafts, promissory notes or trade acceptances and securities may be covered. See also GUARANTEE. (V. G.)

FIDES, a Roman goddess, deified "good faith." Her cult was traditionally founded by Numa. She was closely connected with Jupiter, and her temple at Rome, dating from 254 B.C., was located on the Capitol near his. Sacrifices were made to her with covered hands symbolic of secret inviolable trust. On coins her symbol is often a pair of clasped hands. (R. B. LD.)

FIDUCIARY, a term derived from Roman law and used in those foreign codes which have been chiefly influenced thereby. The idea, but hardly the law, corresponds with the English trustee. (See TRUST AND TRUSTEES.) Many relations give rise to fiduciary obligations, and are even treated as occasioning trust obligations; *e.g.,* parent and child, guardian and ward, principal and agent, etc. (See CHILDREN: LAWS CONCERNING; INFANT; AGENCY.) Such obligations exist, however, independently of the true notion of trusteeship and are to be found where this notion is but rudimentary. They may rather be said, being in relation to property, to arise from auasi-contract. where not statutory.

FIDUCIARY ACCOUNTING is the branch of accounting pertaining to the records and reports rendered by a fiduciary—one who is in a position of unusual trust and confidence. Because of the requirement for good faith, fiduciary accounting is largely prescribed by courts and emphasizes that the fundamental equation for double entry is assets (properties) equal responsibilities. Whether acting under court jurisdiction or private trust instruments. the fiduciary will charge himself with asset values assumed and with increases in asset values; he will credit himself for decreases in value, values turned over to beneficiaries and for approved expenses. Fiduciary accounting includes accounting for decedents' estates, for trust arrangements and for firms in financial difficulty. With the separation of corporate ownership and control there is some inclination to treat managers as fiduciaries and general corporate accounting as fiduciary accounting. Both are governed by the objectives of general accounting. (C. T. D.)

FIDUCIARY ISSUE, that portion of a note issue. whether that of a government or of a bank, which is not protected by a specific backing of metal or coin or assets capable of being converted into coin or bullion on demand. Thus, where no metallic reserve or other assets capable of automatic conversion into metal is kept, the whole issue is of a fiduciary character. The term does not imply that there are no assets of any kind maintained against the note, but only that such assets as are kept are of a nonmetallic character—commercial bills of exchange, government securities or floating debt due by government. In the modern world where many central banks keep part of their "metallic reserves" not in their own vaults but in the shape of deposits with other central banks or in the shape of short-dated bills payable in other gold-using countries, it is no longer possible to draw a sharp line of distinction between the fiduciary and the nonfiduciary portion of the total circulation, and what is regarded as "gold cover" has in such cases to be defined carefully by the legislation governing the issue. Strictly, the fiduciary circulation consists of all that part of the total issue which is not directly covered by gold coin or bullion in vault or such metal "earmarked" (*i.e.,* held specifically segregated) on account of the issue in some other institution.

It does not follow that the mere maintenance of a cash reserve adds to the safety of a note issue. To do so the whole of the note issue must be convertible; *i.e.,* the reserve against the notes must be used in case holders desire them to be redeemed. Unless the note is effectively convertible, an increase in the total note issue accompanied by an increase in the total reserve will not necessarily prevent "over issue," *i.e.,* a total of notes so large that its value falls in terms of the standard of value.

The fiduciary amount may be fixed absolutely in amount: *i.e.,* the issuer may be prohibited from issuing more than a certain volume of uncovered notes. Or the note issue may be based upon the principle of a fixed absolute amount, the proportion of covered to uncovered notes being left to the discretion of the issuing authority. Or the note issue may be based upon the idea of a proportionate reserve without any absolute limit to the total, a minimum proportion of cash indirectly fixing the amount bf the fiduciary issue. The system of proportional reserves and of a fixed fiduciary amount may be partly combined by providing that if the total issue exceeds the sum of the fully covered notes and the fixed fiduciary amount (the so-called tax-free contingent) the excess shall be taxable. The reserve proportion is allowed to vary (thus varying the fiduciary portion), subject to provisions by which the tendency to over-issue is checked by a scale of taxation rising as the reserve proportion falls. (See GOLD RESERVES.) (T. E. G.; X.)

FIEF, a feudal estate in land, land held from a superior (see FEUDALISM). The word is the French form, which is represented in medieval Latin as jeudum or *feodum,* and in English as "fee" or "feu" (see FEE). The A.Fr. *feoffer,* to invest with a fief or fee has given the English law terms "feoffee" and "feoffment."

FIELD, CYRUS WEST (1819–1892), U.S. capitalist and promoter of the first trans-Atlantic telegraphic cable, was born in Stockbridge, Mass.. Nov. 30, 1819. At the age of 15 he went to New York city and worked as an errand boy in a dry goods store. He was employed briefly as an assistant by his brother Matthew, a paper manufacturer. In 1841 he organized the firm of Cyrus W. Field and Co. of New York city, wholesale paper dealers. He was one of the founders (1854) of the New York, Newfoundland and London Telegraph Co., formed to lay a trans-Atlantic cable, and helped to organize a similar company, the Atlantic Telegraph Co., in Great Britain (1856). Unsuccessful attempts to lay a cable mere made in Aug. 1857 and in June 1858. A complete cable was laid between July 7 and Aug. 5, 1858, and operated successfully for three weeks, but the insulation failed. In July 1866, a successful cable was finally laid. For this achievement Field received many honours at home and abroad.

In 1877 he bought a controlling interest in the New York Elevated Railroad company. of which he served as president (1877–80). He developed the Wabash railroad with Jay Gould. and later owned the *Mail* and Express. He suffered heavy financial losses in later years. Field died July 12, 1892, in New York city. He was buried at Stockbridge, Mass.

See Isabella Field Judson, Cyrus W. *Field, His Life and Work* (1896); Charles Bright, *The Story of the Atlantic Cable* (1903). (J. R. LT.)

FIELD, DAVID DUDLEY (1805–1894), father of U.S. legal reform, was born in Haddam, Conn., on Feb. 13, 1805. He studied at Williams college, but did not graduate. Thereafter he studied law in Albany and New York city, being admitted to the bar in 1828. He entered vigorously upon the practice of law, and became an acknowledged expert in both common law and equity pleading. Subsequently he began a campaign to bring about a codification of common law procedure in New York, which campaign was ultimately to spread over the United States and abroad. The movement began in 1837 with a letter to Gulian G. Verplanck, a member of the New York state legislature, in which Field urged the reform of the judicial system. When a constitutional convention was called, to meet in 1846, Field, a master of propaganda, reorganized the arguments of 1837 which now appeared in a series of articles in the *New* York Evening Post, being later reprinted in pamphlet form as *The Reorganization of the Judiciary;* it was instrumental in persuading the convention to report in favour of a codification of the law. The legislature in 1847 appointed a commission on pleading and practice for both procedural and substantive law of which Field became a member. After several preliminary reports to the legislature, a code of civil procedure was reported and enacted in 1848. A code of criminal procedure was completed. but not adopted until later. Within a quarter of a century after 1848, the New York code of procedure. in some form, was adopted in 24 states, two territories, the district court, and in the federal courts. The Civil Code of Procedure was adopted in England and Ireland in 1873, and later by several British overseas possessions. including India. Xlthough Field became chairman of a state commission for the reduction of the whole body of state law into a systematic code, the resulting codification was only partially adopted in New York; these codes were more extensively adopted in such other states, as California, where Field's brother, Stephen (*q.v.*) was a distinguished judge. He died in New York city on April 13, 1894. (A. RY.)

FIELD, EUGENE (1850–1895), U.S. poet and journalist, known as the "poet of childhood," mas born in St. Louis, Mo., Sept. 2, 1850 (or Sept. 3; Field himself confused the date). After his mother died when he was six, Field was sent to relatives in Amherst. Mass. He entered Williams college, soon transferring to Knox college and then to the University of Missouri. but took no degree. At the university he was less a student than a prankster, a role he was to play all his life. For the local newspaper he wrote humorous verse which marked the beginning of his career in journalism.

After his marriage in 1873 Field did editorial work on the *St. Louis Journal,* the *St. Joseph Gazette,* the *Kansas City Times* and the *Denver Tribune.* From his *Tribune* column, "Odds and Ends," he gathered comic paragraphs to make his first small volume, *The Tribune Primer* (1882), journalistic joking in the tradition of Artemus Ward, Bill Nye and Josh Billings. These squibs served as apprentice work for his major literary achievement, his "Sharps and Flats" column in the *Chicago Morning News* (renamed the *Record* in 1890). This column (1883–95) did much to establish the daily personal column as a newspaper feature. In it Field satirized the cultural pretensions of the newly rich Chicago meat barons. Some of these paragraphs were later collected and entitled *Culture's Garland* (1887). In the column also appeared some delicate stories and verses. The best of his verse was collected in *A Little Book of Western Verse* (1889), drawn in part from his column—poems in Pike county dialect. after the manner of Bret Harte and John Hay, verses for children in an affected Old English dialect, translations of Horace and the much-loved "Little Boy Blue" and the "Dutch Lullaby" ("Wynken, Blynken, and Nod"). His last work included *Echoes From the Sabine Farm* (1892), rhymed translations of Horace by Field and his brother Roswell (18j1–1919), and *The Love Affairs of a Bibliomaniac* (1896), an amusing discussion of book collecting. His collected works in ten volumes were published the year after his death, and two more volumes were added in 1901.

Eugene Field was a gay, high-spirited person, whose ebullience and wit, often taking the form of elaborate practical joking, charmed his friends. Xlthough some felt that indulging his fondness for the whimsical and eccentric led him to squander his very real literary talent, all were attracted by his rare and lovable nature, which his friends Slason Thompson and Charles Dennis sought to perpetuate in their volumes of personal reminiscence. A later age, however, has had to judge the man by his writing alone. Together with the characters in his fanciful lullabies, Field is memorialized in a bronze monument in Lincoln park, Chicago.

FIELD, JOHN (1782–1837), Irish composer and pianist, was born at Dublin on July 26, 1782. He came of a musical family, his father being a violinist and his grandfather the organist in one of the Dublin churches. From the latter the boy received his first musical education. He appeared at the Rotunda in Dublin at the age of ten. In 1794, when the family had settled in London. he made his debut there. He became the favourite pupil of Muzio Clementi, whom he accompanied to Paris to show off the Clementi pianos. and later, in 1802, on his great concert tour through France, Germany and Russia. Field appeared in most of the European capitals, and remained in St. Petersburg as a music teacher when Clementi returned to England. Field made frequent concert tours in Russia and in 1822 settled in Moscow. In 1831 he visited England for a short time. and for the next four years led a wandering life in France: Germany and Italy. He died in Moscow on Jan. 23, 1837. His nocturnes for the pianoforte still live because of their continuous flow of beautiful melody, They were Chopin's models,

FIELD, MARSHALL (1835–1906), U.S. merchant, was born at Conway, Mass., on Aug. 19, 183j. At the age of 17 he became a clerk in a dry goods store at Pittsfield, Mass. In 1856 he moved to Chicago, where he became a clerk in the large mercantile establishment of Cooley, Wadsworth and company. In 1860 he was admitted to a junior partnership. In 1865, with Potter Palmer (1826–1902) and Levi Z. Leiter (1834–1904), he organized the firm of Field, Palmer and Leiter, which subsequently became Marshall Field and company. Under Field's management the annual business of the firm increased to more than $40,000,000 in 1895. He died in New York city on Jan. 16, 1906. Field's public benefactions were numerous: notable among them being his gifts to The University of Chicago and to the Field Columbian Museum of Natural History.

FIELD, NATHAN (1587–1619?), English actor and playwright, son of John Field, Puritan divine, was baptized at St. Giles, Cripplegate, Oct. 17, 1587. He attended St. Paul's school. In 1600 he a-as impressed for the Children of the Queen's Chapel. His biography is largely the story of his connection with this and other dramatic companies; various Queen's Revels troupes, 1604–13; the Lady Elizabeth's Men, 1614–16; and the King's Men, 1616 (161)-I. He had probably died by Aug. 1619, when his successor at King's was named in an actor list; his administratrix was commissioned on Aug. 2, 1620.

Field was famed for such adult male roles as Bussy in *Bussy D'Ambois* and Littlewit in *Bartholomeu Fair.* He wrote two comedies, *A Woman Is a Weathercock* (acted 1609, printed 1612) and *Amends for Ladies* (acted by 1611, printed 1618), and collaborated with Philip Massinger in *The Fatal Dowry* (printed 1632) and with others in some of the Beaumont-Fletcher plays. In 1928 R. Florence Brinkley showed that the bachelor Nathan was distinct from his married stationer brother Nathaniel (1 581–1633), with whom he had often been confused since 1679.

FIELD, STEPHEN JOHNSON (1816–1899), U.S. jurist and supreme court justice from 1863 to 1897, was born at Haddam, Conn., on Nov. 4, 1816. the son of a Congregational minister. Like his brother, David Dudley Field (*q.v.*) he attended Williams college. nhere he graduated as valedictorian in 1837. He was admitted to the bar in 1841, and practised with his brother in New York until 1848. In 1849 he went to California and settled in Marysville. His eventful career is recounted in his *Personal Reminzscences of Early Days ın Calzfornia,* privately printed in 1878. As a legislator, he carried to enactment the civil and criminal practice acts of 1851. The former provided "the most liberal exemptions from forced sale of the personal property of the debtor," and gave effect in law to the customs and regulations established by miners. Field sat on the California supreme court from 1857 until his appointment, on March 10. 1863, to a newly created tenth seat on the U.S. supreme court. There he served—perhaps too long—until Dec. 1897, surpassing even Chief Justice John Marshall's record.

A war Democrat, Field tended to read small the powers resulting from rebellion. He spoke for the court in holding invalid state and congressional test oaths; he struggled, unsuccessfully in the end, to invalidate the legal tender act. In the slaughterhouse cases, in 1873, he wrote a memorable dissent arguing that economic *laissez faire* was a part of the "privileges and immunities" secured by the 14th amendment. Dissenting in *Munn* v. *Illinois* and companion cases! in 1877, he contended that the regulation of rates of railroads and grain elevators was beyond the powers of government. The spirit of these dissents came to prevail in the early decades of the 20th century. In 1895 he entered whole-heartedly into overturning the income tax law, warning against "a war of the poor against the rich." Field had a syllogistic mind, and went ever-confidently wherever first principles seemed to lead.

In 1880 and 1884 Field aspired to the Democratic nomination for the presidency. and in the latter year concluded, "had I received the cordial support, instead of opposition of (California) my candidacy. according to the judgment of my friends, would have stood great chances of success." He died in Washington. D.C. on April 9, 1899.

FIELD ARTILLERY: see ARTILLERY.

FIELD EMISSION is a physical effect consisting of the emission of electrically charged particles from a conductor under the action of a strong electric field. Particularly field emission of electrons from cold metals into a vacuum is an elementary effect comparable with thermionic, photoelectric or secondary emission. The effect is also called field electron emission, cold emission or autoelectronic emission.

The field emitter is the most effective of all cathodes for releasing electrons from the structure of a metal. Investigations conducted with it have made significant contributions to basic science, and provided early evidence in support of the wave mechanical theory. Technical application of field cathodes is still very difficult.

Field emission of either electrons or positive ions is applied in the field emission microscope. It was this most powerful of microscopes. in which helium ions from a cold emitter point produce an image, that made the atoms of a metal surface visible for the first time (E. W. Müller, 1956).

Historical Development. — Field electron emission from cold metals requires a field strength of order of magnitude 30,000,000 v. per centimetre. Because electrical breakdown in gases occurs at much lower field, the effect can be observed only in highly evacuated tubes. To produce such a high field with a reasonably low voltage, usually in the kilovolt range, the emitting electrode must have a small radius of curvature. as provided by a fine wire, a sharp edge or a needle point. It was in tubes containing such electrodes that field emission was first observed by R. W. Wood (1897) In the early 1920s J. E. Lilienfeld attempted to use field emission cathodes in high-voltage rectifiers and X-ray tubes. but high-vacuum techniques as well as theoretical understanding were not yet sufficiently advanced. Application of the then new quantum mechanics to the electron theory of metals in the late 1920s brought forward the theory of R. H. Fowler and L. Sordheim, describing field emission as "tunneling" of electrons through the metal's surface potential barrier. Experimental advances were made possible with the introduction of the field emission microscope and a cathode point polished to atomic smoothness by E. W. Müller in 1937. Subsequently, the field emission microscope was widely used for the investigation of field emission itself and for the study of adsorption phenomena and other problems of surface chemistry. A modified version led to the discovery of field ion emission. When the field emission microscope was operated with helium ions and the emitter cooled to the temperature of liquid hydrogen, the resolution of the best electron microscopes was surpassed by far and it became possible to see the atoms constituting a metal surface. The adaptation of radar microsecond pulse techniques to field emission studies by W. P. Dyke and co-workers (1953) had great technical significance. Very high-current densities became accessible, and the emitter could also be operated at elevated temperatures (T-F emission) to secure better stability and lifetime for technical applications.

Theory of Field Emission. — Classical electron theory failed to explain the experimental facts of field emission. In their quantum mechanical theory Fowler and Nordheim use the following assumptions: The conduction electrons in a metal form a gas of free particles obeying Fermi-Dirac statistics. The metal surface is assumed to be an ideal plane. causing a classical image force acting on an electron outside the metal. The basic concept of wave mechanics is that conduction electrons arriving at the inside of the metal surface are not totally reflected but can rather penetrate or tunnel through the potential barrier, which is sufficiently thinned by the applied field (fig. 1). The number of electrons

FIG. 1. — FIELD ELECTRON EMISSION OCCURS BY PENETRATION OF ELECTRONS NEAR FERMI LEVELTHROUGH POTENTIAL BARRIER AT METAL SURFACE. EXAMPLE SHOWN IS FOR A FIELD OF 40,000,000 VOLTS PER CENTIMETRE, AND A WORK FUNCTION OF $\phi = 4.5$ EV

emitted per unit area from each energy level ε (measured here from the Fermi level) is then the product of the number of incident electrons, called the supply function, N (E), and the transmission coefficient, D (ε), at this level. The total current density is the integral of this product taken over all energies ε and multiplied by the electron charge. Using Fermi-Dirac statistics one obtains for the supply function

$$N(\epsilon) = \frac{4\pi mkT}{h^3} \log \left(1 + e^{-\frac{\epsilon}{kT}}\right)$$

where m = mass of electron, k = Boltzmann constant, T = absolute temperature. and h = Planck's constant. The transmission coefficient is found from a solution of the Schrodinger equation written for the assumed potential, which gives in the WKB approximation

$$D(\epsilon) = e^{-\frac{8\pi\sqrt{2m(\phi-\epsilon)^3}}{3heF}v(y)} \qquad (2)$$

where ϕ = thermionic work function, F = field strength, and $v(y)$ is an elliptic function of the variable

$$y = \frac{\sqrt{e^3F}}{\phi - \epsilon}$$

which describes the image force effect and for which some data are given in Table I.

TABLE I

y	v(y)
0	1.000
0.2	0.937
0.4	0.789
0.6	0.577
0.8	0.312
1	0.000

The total current density as obtained by an approximated integration for the case of negligible temperature is then

$$i = \frac{e^3F^2}{8\pi h\phi} e^{-\frac{8\pi\sqrt{2m}\phi^{3/2}}{3heF} v\left(\frac{\sqrt{e^3F}}{\phi}\right)} \qquad (3)$$

and with ϕ measured in e-volts (electron volts) and F in volts/cm., one obtains

$$i = \frac{1.54\times10^{-6}F^2}{\phi} e^{-\frac{6.83\times10^7\phi^{3/2}}{F} v\left(\frac{3.79\times10^{-4}F^{1/2}}{\phi}\right)} \text{ amp./cm.}^2 \qquad (4)$$

(A more detailed discussion of the possibilities of integrating the product of eq. (1) and (2) for finite temperatures is given in the *Bibliography:* Good and Müller.) Computed current densities for a typical tungsten emitter ($\phi = 4.5$ ev) are shown in fig. 2. Emitter temperature is not of great influence below 1,000° K. Here, the majority of the electrons comes from the conduction band below the Fermi level, shown as region I in fig. 1. At higher temperatures and at high fields most of the emitted electrons are thermally excited and tunnel through the barrier in region II. This kind of emission has been called temperature-and-field emission or T-F emission. At high temperatures and also at low fields barrier penetration is negligible compared to the number of electrons spilling over the hump in region III, which is thermionic emission.

Field emission of positive ions can be understood as the evaporation of ions over the potential barrier. The height of this barrier is the binding energy of the ion (without field) reduced through the image force by the Schottky effect. The emitted positive ions come either from an adsorption layer or from the atoms of the emitter itself, so that the supply is rather limited. A continuous-field ion emission can be obtained however, by supplying atoms or molecules from gas surrounding the emitter. At a field of more than 250,000,000 v. per centimetre in the case of hydrogen, and more than 400,000,000 v. per centimetre for helium, all incident gas molecules are ionized very close to the tip when one electron tunnels out of each molecule and enters the metal surface. while the ions are ejected by the field. This complex mechanism can be treated quantitatively (see *Bibliography:* Good and Muller).

Experimental Work in Field Emission. — Together with radioactive alpha-decay. field emission provides the experimentally most easily accessible example of the quantum mechanical tunnel effect. A number of experiments have therefore been carried out to prove the validity of the Fowler-Nordheim theory and its consequences. Difficulties arise from the fact that only the applied voltage and the resulting current can be measured directly, while the theory provides the dependence of the current density upon field strength and work function. For a given atomically clean metal tip as a cathode, neither the field nor the work function is homogeneous over the entire emitting surface. Laborious experimental techniques have been applied to determine the exact shape of the emitter needle point by electron microscopy, to ensure cleanliness of the surface by ultra high-vacuum techniques and to find the work function of the various crystal planes of the tip metal. The dependence upon electrical field of eq. (4) has been confirmed within the possible errors of 5% up to current densities of 6 × 10^6 amp/cm.^{2} At higher fields slight deviations in the direction of smaller currents have been observed which may be due to space charge, the effect of atomic surface structure upon the image force or details of the electron band structure of the metal. Tungsten tips have been operated with microsecond pulses up to field strengths of 70 × 10^6 v./cm., where at current densities of about 10^8 amp./cm.^{2} a destructive vacuum arc is initiated by heat development in the tip (see *Bibliography:* Dyke and Dolan).

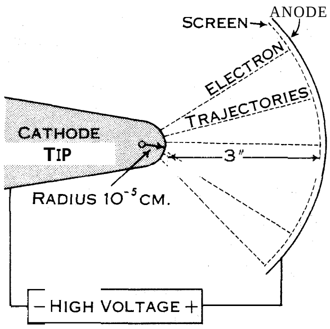
FIG 2 —COMPUTED CURRENT DENSITY OF FIELD EMISSION FROM TUNGSTEN ($\phi = 4.5$ EV) AT VARIOUS TEMPERATURES, PLOTTED AS A FUNCTION OF RECIPROCAL FIELD

Field Emission Microscopy. — The specimen is a needle-shaped field emitter, with an approximately hemispherical tip of radius 10^{-5} to 10^{-4} cm., arranged in a vacuum tube opposite to a fluorescent screen at anode potential (fig. 3). The emitted electrons move to the screen along nearly radial trajectories, there producing an enlarged pattern of the emission details of the tip surface The magnification equals approximately the ratio of tip-screen distance to tip radius and can easily be 1,000,000 diameters. The resolution is limited by the inherent tangential velocity component of the field electrons, amounting to a few tenths of an electron volt, and by diffraction caused by the wave nature of the electrons, or, equivalent to it, the Heisenberg uncertainty principle. Under the usual condition the resolution is 20–30 Å.

The image depicts the distribution of current density which is determined by the local field strength due to tip geometry and local arrangement of surface atoms, and by the work function. The latter may again depend upon the atomic structure of the involved crystal planes, various kinds of disorder in the atomic arrangement, and the presence of adsorbed matter. The proper interpretation of the pattern in view of these features is the objective of field emission microscopy. Clean or presumably clean surfaces have been studied with a number of metals such as tungsten, tantalum. molybdenum. iridium. platinum, titanium, nickel, iron, silicon and copper, and some alloys such as stainless steel. Surface migration. details of crystal groath, phase transformation and motion of grain boundaries have been investigated.



PREPARED FOR ENCYCLOPAEDIA BRITANNICA INC BY E W MULLER

FIG. 3.—SCHEMATIC DIAGRAM OF FIELD EMISSION MICROSCOPE

The potential barrier at a metal surface may be considerably influenced by adsorption. The presence of a small fraction of a monomolecular layer or even of some individual molecules can be detected in the field emission microscope, making it a versatile tool for research in surface chemistry and catalysis The behaviour of oxygen. hydrogen and other gases on the surface of various metals has been studied in a range from liquid helium temperatures (by immersing the entire microscope in liquid helium) to 2,000° K. Skillful interpretation of the patterns allows conclusions to be made about the electron exchange betueen adsorbate and substrate and the resulting binding forces. (For detailed results of the investigations of adsorption by field emission microscopy it is necessary to refer to the works listed in the *Bibliography.)*

If the tip of a field emission microscope is operated at sufficiently high positive voltages, surface atoms of an adsorption layer or from the tip metal itself are emitted as positive ions. The ion current, however. is usually too small to produce a visible pattern on the screen. Therefore the tip must be made negative again in order to inspect the changes in the electron emission pattern. Field desorption can be observed continuously when the microscope is operated with alternating current of adjustable half waves, the positive half causing field desorption and the negative one electron emission for viewing the surface. Quantitative study of field desorption provides a new way of investigating binding energies in surface chemistry. Field desorption is also a means of perfectly cleaning and smoothening the surface of the specimen in the microscope without the application of heat. For instance, at room temperature tungsten evaporates at a rate of one monolayer per second under the influence of an electrical field of 500,000,000 v. per centimetre.

Field Ion Microscope. — This modification of the field emission microscope was introduced by E W. Muller (1951) in order to improve the resolving power. Compared mith electron emission, in the case of field ion emission the tangential velocity components of the image forming particles can be greatly reduced by lowering the tip temperature, and diffraction effects are negligible because of the much shorter de Broglie wave length of the ions. By cooling the tip mith liquid hydrogen to 21° K., filling the microscope with helium at about 1 micron pressure and operating the positive tip at a field strength of 400,000,000 v. per centimetre, a resolution of 2.7 Å, has been obtained (fig. 4, Muller. 1956). The field ion microscope is the first microscopic device to depict the individual atoms that constitute a surface. Although the extremely high field limits its application to the refractory metals, and some other metals with high melting points, it is a most promising tool for some problems of metallurgy, such as the study of dislocations of fatigue under cycling stress or radiation damage.

Technical Applications.— From the report above it appears that field emission is mainly a subject of and a tool for basic research. The unique properties of field electron emission, such as instantaneous emission from a cold cathode, the extremely high-current density of up to 10^8 amp. per square centimetre, and the minute size of the point emitter have for a long time encouraged physicists and electrical engineers to design devices for practical use. As a result of all the experience of many researchers and particularly the successful work of Dyke and collaborators, technical application can be expected. A direct-current bias method has been found for stabilizing the electrical performance of the microsecond-pulsed T-F emission cathode during long periods of operation at useful power levels. Needle cathodes have been operated in parallel to yield a peak power of 3 megawatts. for instance, as a cathode in an X-ray flash tube. The minute dimensions of the electron source suggest further application in cathode ray tubes, X-ray microscopes and traveling-nave amplifiers.

FIELDFARE, *Turdus pilaris,* one of the thrushes and a common winter visitor to the British Isles. In spring it nests in north European and Siberian birch forests, migrating to southern Europe, India and northern Africa in winter. It is gregarious in habit and somewhat resembles the mistle thrush (*T. viscivorus)* in appearance. The nest, placed high in a tree, is similar to that of the blackbird *(T. merula)*, as are the eggs. The song is low and poor, the call note harsh and loud. It feeds upon worms, slugs and insect larvae, adding, in hard weather, hips, haws and other berries. It is accidental in Greenland and at Foxe basin, arctic America. Structurally very like the fieldfare, but differing in appearance and habits is the North American *Turdus migratorius,* called the robin (*q.v.*), because of its ruddy breast and familiar habits. It is essentially a migrant, ranging from Greenland to Guatemala and almost everywhere an abundant species. It has a pleasant song and is of great service as a destroyer of insects.

FIELD GLASSES: *see* BINOCULAR INSTRUMENT.

FIELDING, HENRY (1707–1754), English novelist and playwright. was born at Sharpham Park, near Glastonbury, Somerset, on April 22, 1707. The family moved later to East Stour. Dorset. His father, Lieut. Edmund Fielding, was a grandson of the earl of Desmond, who belonged to the younger branch of the Denbigh family. Sarah Fielding was Henry's sister. Up to the time of his mother's death Fielding was educated by a clergyman named Oliver, and then went to Eton, probably as an oppidan. If we may believe his first biographer, Arthur Murphy, he left Eton "uncommonly versed in the Greek authors. and an early master of the Latin classics"––a statement which should perhaps be qualified by Fielding's own uords to Sir Robert Walpole in 1730:

Tuscan and French are in my head ;
Latin I write, and Greek—I read

Thomas Winnington and Sir Charles Hanbury Williams were among his friends at Eton. The chief, however, was George, later Baron. Lyttelton, of Frankley.

When Fielding left Eton is unknown. But in Nov. 172j he was staying at Lyme and apparently bent on carrying off, if necessary by force, a local heiress, Miss Sarah Andrew, whose fluttered guardians promptly hurried her away, and married her to someone else *(Athenaeum,* June 2, 1883). He consoled himself by translating part of Juvenal's sixth satire into verse as "All the Revenge taken by an injured Lover.'! After this he must have lived the usual life of a young man about town, and probably at this date improved the acquaintance of his second cousin. Lady Mary Wortley Montagu, to whom he inscribed his first comedy, *Love in Several Masques* (Drury lane, Feb. 1728). Almost immediately afterward (March 16), Fielding entered himself as "Stud. Lit." at Leyden university. He had apparently left before the annual registration of Feb. 1730; and in Jan. 1730 he brought out a second comedy at the newly opened theatre in Goodman's Fields. Like its predecessor, the *Temple Beau* was an essay in the vein of William Congreve and William Wycherley. His chief dramatic successes. from a critical point of view, the *Author's Farce* (1730) and *Tom Thumb* (1730, 1731), were burlesques; and he was also fortunate in two translations from Molière, the *Mock Doctor* (1732) and the *Miser* (1733). Other plays which might be recorded were *The Coffee-House Politician,* a comedy (1730); *The Letter Writers,* a farce (1731); *The Grztb-Street Opera,* a burlesque (1731); *The Lottery,* a farce (1732); *The Modern Husband,* a comedy (1732); *The Covent Garden Tragedy,* a burlesque (1732); *The Old Debauchees,* a comedy (1732); *Deborah; or, a Wife for you all,* an afterpiece (1733); *The Intriguing Chambermaid* (from Jean François Regnard). a two-act comedy (1734); and *Don Quixote in England,* a comedy (1734), which had been partly sketched at Leyden.

On Nov. 28, 1734, he married Charlotte Cradock of Salisbury, at St. Mary Charlcombe, near Bath (see *Macmillan's Magazine,* April 1907), and early in 1735, he seems for a time to have retired with his bride to his old home at East Stour.

Early in March. 1736. he was back again managing the Haymarket theatre with a so-called "*Great Mogul's* Company of *English* Comedians." This new enterprise opened well. The first piece (produced on March j) was *Pasquin, a Dramatick Satire on the Times.* Its success was unmistakable; and its author followed it up by the *Historical Register for the Year 1736,* of which the effrontery was even more daring. But the Licensing act of 1737, which restricted the number of theatres, rendered the lord chamberlain's licence an indispensable preliminary to stage representation, and—in a word—effectually put an end to Fielding's career as a dramatist. *Tumble-Down Dick; or, Phaeton in the Suds, Eurydice* and *Eurydice Hissed* are the names of three occasional pieces which belong to the last months of Fielding's career as a Haymarket manager.

As a means of support he reverted to the profession of the law and. in Kov. 1737, he entered the Middle Temple. He also did a good deal of literary work, the best known of which is contained in the *Champion,* a news journal of the *Spectator* type, undertaken with James Ralph, whose poem of "Night" is made notorious in the *Dunciad.* On June 20, 1740, Fielding was called to the bar, and occupied chambers in Pump Court. He travelled the western circuit, and attended the Wiltshire sessions. Although, with the *Champion,* he professed, for the time, to have relinquished periodical literature, he still wrote at intervals, but whether he actually wrote the famous *Apology for the Life of Mrs. Shamela Andrews* (1741), a parody of *Pamela,* as Samuel Richardson certainly thought, is quite uncertain.

In any case it is certain that the reading of *Pamela* was the point of departure of Fielding's first novel. *Joseph Andrews,* which made its appearance in Feb. 1742. Professing, on his title page, to imitate Cervantes. Fielding set out to cover *Pamela* with Homeric ridicule by transferring the heroine's embarrassments to a hero. supposed to be her brother. Fielding saw in Pamela's virtue a certain interested quality, and he set out to parody her in the person of Joseph. But the element of parody fell speedily into the background as its author warmed to his theme. His secondary speedily became his primary characters, and Lady Booby and Joseph Andrews do not interest us now as much as Mrs. Slipslop and Parson Adams—the latter a personage who ranks in literature with Laurence Sterne's "Uncle Toby" and Oliver Goldsmith's "Vicar." By the time he had reached his second volume, he had convinced himself that he had inaugurated a new fashion of fiction; and in a remarkable preface he announced his discovery. Postulating that the epic might be "comic" or "tragic" prose or verse, he claimed to have achieved what he termed the "Comic Epos in Prose." of nhich the action was "ludicrous" rather than "sublime," and the personages selected from society at large, rather than the restricted ranks of conventional high life. His plan was happily adapted to his gifts of humour, satire and, above all. irony. That it was matured when it began may perhaps be doubted, but it was certainly matured when it ended. Indeed, except for the plot. which, in his picaresque first idea. had not preceded the conception, *Joseph Andrews* has all the characteristics of *Tom Jones.*

A minor work was a *Vindication of the Dowager Duchess of Marlborough* (1742), then much before the public by reason of the *Account of her Life* which she had recently put forth. Later in the same year, David Garrick applied to Fielding for a play; and an early effort, *The Wedding Day,* was hastily patched together and produced at Drury Lane in Feb. 1743 with no great success. It was, however, included in Fielding's next important publication, the three volumes of *Miscellanies* issued by subscription in April 1743. These comprised some early poems, some essays, a Lucianic fragment entitled a *Journey from this World to the Next,* and last but not least, occupying the entire final volume, the *History of the Life of the late Mr. Jonathan Wild tlze Great.* It is probable that *Jonathan Wild* was actually written before *Joseph Andrews.* Taking for his ostensible hero a well-known thieftaker, who had been hanged in 1725, Fielding proceeds to illustrate, by a mock-heroic account of his progress to Tyburn, the general proposition that greatness without goodness is no better than badness. He will not go so far as to say that all "Human Nature is Newgate with the Mask on"; but he evidently regards the description as fairly applicable to a good many so-called great people. Irony (and especially irony neat) is not a popular form of literary art; and the remorseless pertinacity with which Fielding pursues his demonstration is to many readers discomforting and even distasteful. Yet—in spite of *Scott*— *Jonathan Wild* has its softer pages; and as a purely intellectual conception it is not surpassed by any of the author's works. It will always remain a masterpiece of that irony which is based on understatement.

The events of Fielding's life, both before and after the publication of *Jonathan Wild,* are obscure. He had become early a martyr to gout, and his wife died of fever in his arms, leaving him for the time so stunned and bewildered by grief that his friends feared for his reason. For some years his published productions were unimportant. He wrote prefaces to the *David Simple* of his sister Sarah in 1744 and 1747; and, in 1745–46 and 1747–48, produced two newspapers in the ministerial interest, the *True Patriot* and the *Jacobite's Journal,* both of which were connected with, or derived from, the rebellion of 1745. In Nov. 1747 he married his wife's maid, Mary Daniel, at St. Benet's, Paul's Wharf; and in Dec. 1748 he was made a principal justice of peace for Middlesex and Westminster, an office which put him in possession of a house in Bow street, and £300 per annum "of the dirtiest money upon earth."

Meanwhile he had intermittently occupied himself in composing his second great novel, *Tom Jones; or, the History of a Foundling,* published in Feb. 1749, with a dedication to Lyttelton. In *Tom Jones* Fielding systematically developed the "new Province of Writing," in which he had made a beginning in *Joseph Andrews.* He paid closer attention to the construction and evolution of the plot; he elaborated the initial essays to each book. which provide part of its unending interest, and he compressed into his work the flower and fruit of his forty years' experience of life. He has, indeed, no character quite up to the level of Parson Adams, but his Westerns and Partridges, his Allworthys and Blifils, his parson Thwackum and his philosopher Square have the inestimable gift of life. He drew pictures of ordinary humanity with absolute truthfulness neither extenuating nor disguising defects and shortcomings The bill of fare he provided for his readers he himself describes in the introduction of Book I as "human nature" pure and simple. As for his purpose and method he says in the Dedication: "I have employed all the wit and humour of which I am master. in the folloning history; wherein I have endeavoured to laugh mankind out of their favourite follies and vices." Incidentally he produced a "document" of unrivalled excellence on the social life of the England of his time. *Tom Jones* follows the picaresque method of *Joseph Andrews,* but its plot, in spite of great diversity of its characters, the amazing variety of its incidents and its vast canvas, has a unity and coherence which is new.

Much of *Tom Jones* has become classic. Take the dispute betueen Thwackum and Square on the definition of honour. "Honour." says Thwackum, "is not therefore manifold, because there are many absurd opinions about it; nor is religion manifold, because there are various sects and heresies in the world. When I mention religion, I mean the Christian religion; and not only the Christian religion, but the Protestant religion; and not only the Protestant religion, but the Church of England. And when I mention honour, I mean that mode of Divine grace nhich is not only consistent with, but dependent upon, this religion; and is consistent with and dependent upon no other. . . ." Square in his reply says: "I have asserted that true honour and true virtue are almost synonymous terms, and they are both founded on the unalterable rule of right, and the eternal fitness of things; to which an untruth being absolutely repugnant and contrary, it is certain that true honour cannot support an untruth."

Meanwhile Fielding was taking his duties as a magistrate seriously. His novels provide abundant evidence of his view of the unsatisfactory state of penal law and administration. In May 1749 he became chairman of quarter sessions at Westminster, and in 1751 he wrote an *Enquiry into the Causes of the Late Increase of Robbers, etc.* These preoccupations left their mark on his next novel, *Amelia* (1752), which is more concerned with social problems and popular grievances than its forerunners. Amelia herself, in whom, as in the Sophia Western of *Tom Jones,* he reproduced the traits of his first wife, is certainly, as Johnson admitted, "the most pleasing heroine of all the romances," and the drawing of Dr. Harrison and Col. Bath is admirable. But in 1749 he had been dangerously ill, and his health was visibly breaking. The £1,000 which Millar is said to have given for *Amelia* must have been painfully earned. Pamphlets and an unsuccessful newspaper adventure, the *Covent Garden Journal* (1752) followed. He resigned his post as magistrate and tried various specifics to restore his health. Finally he tried change to a warmer climate. On June 26, 1754, he accordingly left for Lisbon, in the "Queen of Portugal." The protracted discomforts of the sick man and his family on this voyage are narrated at length in the posthumous tract entitled *Journal of a Voyage to Lisbon,* which, with a fragment of a comment on Bolingbroke's then recently-issued essays, was published in Feb. 1755 "for the Benefit of his (Fielding's) Wife and Children" Reaching Lisbon at last in Aug. 1754, he died there two months later (Oct. 8) and was buried in the English cemetery, where a monument was erected to him in 1830. *Luget Britannia gremio non dari fovere natum* is inscribed upon it.

There is but one absolutely authentic portrait of Fielding, a familiar outline by Hogarth, executed from memory for Andrew Millar's edition of his works in 1762. It is the likeness of a man broken by ill-health and affords but faint indication of the handsome Harry Fielding. who in his salad days "warmed both hands before the fire of life."

Fielding has a great place in the history of the English novel. If the *Spectator* is to be credited with foreshadowing the characters of the novel, Defoe with its earliest form, and Richardson with its experiments in sentimental analysis, it is to Henry Fielding that we owe its first accurate delineation of contemporary manners. He owed much to *Don Quixote,* something to the best of the French picaresque novels. but his own creation was different from that of any of his predecessors Fielding drew a large and varied picture of life, of people neither good nor bad, but human, with a tolerance and a humour and penetrating insight which are rare enough. Fielding is the master from whom Dickens and Thackeray and the great school of the English Victorian novelists descend.

Among the many editions of Fielding's works may be mentioned those edited by A. Murphy (1762), G. Saintsbury (1893), E. Gosse (1899); the Harvard University edition (1903), etc. For Fielding's lifework *see* A. Dobson, *Fielding* (1907); G. M. Godden, *Henry Fielding* (1910); W. L. Cross, *The History of Henry Fielding* (Yale, 1918); F. T. Blanchard, *The Novels of Fielding* (Yale, 1926).

FIELDING, SIR JOHN (1722–1780), English police magistrate (justice of the peace) in London, younger stepbrother of Henry Fielding, and his worthy successor in the arduous task of suppressing professional crime and of establishing reformed methods in London's administration of criminal justice. He was appointed a justice of the peace, at first as his brother's assistant, about 1750; and though already blinded (probably by an accident, at the age of 19) he became locally famous as "the Blind Beak," and was reputed to be able to recognize by their voices some 3,000 thieves. He was a pioneer in the treatment of juvenile offenders and in numerous details of police administration. He was knighted in 1761 for his services, and his name stands in the honour roll in the history of the modern police system. His only authentic published writings are *A Plan for Preventing Robberies within 20 Miles of London* (1775), *An Account of the Origin and Effects of a Police*, etc. (1758) and *Extracts from Such of the Penal Laws as Relate to the Peace and Good Order of the Metropolis* (1768).

There is an impressive portrait of Fielding in judicial robes by N. Hone, showing the massive head, lion locks and close-lidded eye sockets.

(J. H. Wi.)

FIELDING, WILLIAM STEVENS (1848–1929), Canadian journalist and statesman, was born in Halifax, Nova Scotia, on Nov. 24. 1848. From 1364 to 1884 he was on the staff of the *Morning Chronicle*, the chief Liberal paper of the province, and worked at all departments of newspaper life. In 1882 he entered the local legislature as Liberal member for Halifax; and from 1884 to 1896 was premier and provincial secretary of the province, but in the latter year became finance minister in the dominion administration of Sir Wilfrid Laurier and was elected to the house of commons for Shelburne and Queen's county. He opposed confederation in 1864–67, and as late as 1866 won a provincial election on the promise to advocate the repeal of the British North America act. His .administration as finance minister of Canada was important, since in 1897 he introduced a new tariff, granting to the manufactures of Great Britain a preference, subsequently increased; and later he imposed a special surtax on German imports owing to unfriendly tariff legislation by that country. In 1902 he represented Canada at the colonial conference in London. He was a plenipotentiary for the negotiations of the Franco-Canada commercial treaties in Paris (1907, 1909 and 1922); served on several royal commissions; and negotiated various other commercial agreements. He was one of the Canadian delegates to the assembly of the League of Nations in 1922. From 1917–25 he was M.P. for Shelburne and Queen's county, and from 1921–2j held office as minister of finance. In 1923 he was made privy councilor.

He died at Ottawa on June 23, 1929.

FIELD IONIZATION: *see* FIELD EMISSION.

FIELD MOUSE, the designation of such mouselike rodents as are not house mice, more strictly, *Apodemus*, the long-tailed field mouse of Europe and Asia. *See* MOUSE.

FIELD OF CLOTH OF GOLD, often erroneously called Field of the Cloth of Gold, is the name given to the place between Guines and Ardres where Henry VIII of England met Francis I of France in June 1520. Before the castle of Guînes a temporary palace, covering an area of nearly 12,000 sq.yd., had been erected for Henry. It was decorated sumptuously and furnished with a profusion of golden ornaments. For less distinguished visitors 2,800 tents were erected. The size of Henry's following may be gathered from the fact that in one month 2,200 sheep were consumed. The two monarchs met at the Val Doré, a spot midway between the two camps. on June 7. The subsequent tournaments, banquets and entertainments lasted until the 24th. The meeting made a great impression on contemporaries, but its political results were very small. Henry shortly after enjoyed an equally friendly meeting with Francis' rival, the emperor Charles V.

The *Ordonnance* for the Field is printed by J. S. Brewer in the *Calendar of State Papers, Henry VIII*, vol. iii (1867). *See* also J. S. Brewer, *Reign of Henry VIII* (1884); A. F. Pollard, *Henry VIII*, new ed. (1905).

FIELDS, JAMES THOMAS (1817–1881), U.S. publisher and author, was born in Portsmouth, N.H., Dec. 31, 1817, the son of a shipmaster who died when Fields was a child. At the age of 14 he went to Boston as clerk in a bookseller's shop. While working there he began to write for the local newspapers. In 1829 he became junior partner in the bookselling firm of Ticknor, Reed and Fields. which became Ticknor and Fields in 1854 and Fields, Osgood and Co. in 1868. He was the publisher of the foremost contemporary U.S. writers, with most of whom he was on terms of close personal friendship; Whittier, for instance, depicted him in *The Tent on the Beach*. He was also the U.S. publisher of some of the best-known British writers of his time.

In 1862–70, as the successor of James Russell Lowell, he edited the *Atlantic Monthly*. His writings include: *Poems* (1849); *Yesterdays With Authors* (1872) and *Hawthorne* (1876). He died in Boston on April 24, 1881. His second wife, Annie Xdams Fields, whom he married in 1854, was the author, among other works, of *Under the Olive* (1880), a book of verses.

FIELDS, number systems whose elements behave like the numbers of elementary algebra. The usual textbook for college algebra contains a list of what are called the properties of real numbers. These are really the postulates defining a *general field*. Thus a field F is any set consisting of at least two elements a, b, . . . such that the sum $a+b$ and product ab of any two elements of F is in F and the following seven laws hold:

I. Commutative law for addition. If a and b are in F then $a+b=b+a$; that is, a sum is independent of the order of its summands.

II. Associative law for addition. If a, b and c are in F then $a+(b+c)=(a+b)+c$; that is, a sum is independent of the grouping of its summands.

III. Subtraction law. If a and b are in F there are elements x and y in F such that $a+x=b$, $y+a=b$.

IV. Distributive law. If a, b, c are in F then $a(b+c)=ab+ac$ and $(b+c)a=ba+ca$.

V. Commutative law for multiplication. If a and b are in F then $ab=ba$; that is, a product is independent of the order of its factors.

VI. Associative law for multiplication. If a, b and c are in F then $a(bc)=(ab)c$; that is, a product is independent of the grouping of its factors.

VII. Division law. If a and b are in F and a is not zero there are elements x and y in F such that $ax=b$ and $ya=b$.

The set of postulates as we have given them are formulated so as to be *independent*. They can then be used in other topics. (*See* ALGEBRAS (LINEAR].) If I and II hold, the numbers x and y of III are equal and unique and we write $x=b-a$ and call x the *difference* of b and a. The number $0=a-a$ is the unique *zero* element of F and the concept occurs in VII.

If V and VI hold, the numbers x and y of VII are unique and we write $x=ba^{-1}$ (read b, a inversej and call x the quotient of b by a. In particular $1=aa^{-1}$ is the unique *unity element* of a field.

The most elementary types of fields are fields whose elements are ordinary complex numbers. Indeed, a set F of complex numbers is a field if the sum, product, difference and quotient with nonzero denominator of any two members of F is in F.

A subset H of a field F is called a subfield of F providing H is a field relative to the addition and multiplication operations of F. Thus we have defined subfields of the field of all complex numbers above. Every field of complex numbers contains the field of all rational numbers as a subfield.

Fields which contain a subfield mathematically equivalent to the field of all rational numbers are called nonmodular fields. In the contrary case the field is called modular and there exists an integer p which is always a prime number such that the sum $1+1+ \ldots +1$ with p terms is equal to zero. where 1 is the unity element defined above. The unity element 1 then generates a field of p elements 0, 1, 2, . . ., $p-1$ which can be thought of as a field of remainder classes of all integers on division by p. If $p=2$, the classes are the class of all odd integers and the class of all even integers. The integer p is called the characteristic of the modular field.

Extensions of Fields.—A field K is called an extension of a field F if F is a subfield of K. If x is in K the set of all rational functions of x with coefficients in F forms a subfield of K usually designated by $F(x)$ (read F of x). This field is called a simple transcendental or a simple algebraic extension of F according as x is not or is a root of an equation. $f(x)=x^n+c_1 x^{n-1}+ \ldots +c_n=0$, with coefficients $c_1, \ldots, c_n$ in F. In the latter case we can always select a polynomial $f(x)$ of least possible degree; this polynomial will always have the property that it is not the product of two factors with coefficients in F; every element of $F(x)$ will be a polynomial $a_0+a_1x+ \ldots +a_{n-1}x^{n-1}$ with coefficients $a_0, \ldots, a_{n-1}$ in F.

We may also consider fields $Y=F(y_1, \ldots, y_t)$ consisting of all rational functions with coefficients in F of t quantities $y_1, \ldots, y_t$ in an extension field K of F. Then if all of the simple extensions $F(y_1)$, $F(y_2)$, . . ., $F(y_t)$ are algebraic, every element y in Y will generate a simple algebraic extension of F. There will then be an integer n and n quantities $u_1, \ldots, u_n$ in Y such that every quantity of x is uniquely expressible in the form $a_1u_1+ \ldots +a_nu_n$ for $a_1, \ldots, a_n$ in F. We call such a field Y an algebraic extension of degree n over F.

Ii every element y of an algebraic extension Y of finite degree n over F is a root of some corresponding equation which has coefficients in F and no multiple roots, the field Y is said to be separable. Then it can be shown that there exists a quantity x in Y such that Y is the simple algebraic extension $F(x)$. Every algebraic extension of finite degree n over a nonmodular field F is separable.

A separable field Y over F is said to be normal if every element of Y is the root of an equation with its coefficients in F and its roots in Y. Then $Y=F(x)$ where $x=P_1(x)$ is a root of $f(x)=0$ whose other roots are polynomials $P_2(x)$, $P_3(x)$, . . ., $P_n(x)$. It can be shown that $P_i[P_j(x)]=P_k(x)$ for some integer k. Every separable field is contained in a normal field. The theory of normal fields is usually called the Galois Theory.

It may happen that the roots of $f(x)=0$ are the iteratives $P(x)$, $P^2(x)=P[P(x)]$, . . ., $P^n(x)=P[P^{n-1}(x)]=P^0(x)=x$ of a single polynomial $P(x)$. Then $F(x)$ is called a cyclic field over F. Cyclic and normal fields are of great importance in linear algebras and other branches of algebra.

An algebraic number field is an algebraic extension of finite degree over the field of all rational numbers. A Galois or finite field is a field consisting of a finite number of elements. It is a modular field of characteristic p and can be shown to be a normal field over its subfield of p elements.

MacDuffee, An Introduction to Abstract Algebra (1940); E. Artin, Galois Theory (1942). For the theory of algebraic numbers see H. Weyl, Algebraic Theory of *Numbers* (1940). (A. A. AT.)

FIENNES, NATHANIEL (c. 1608–1669), English politician, second son of William, first Viscount Saye and Sele, was educated at Winchester and at New College, Oxford, where as founder's kin he was admitted a perpetual fellow in 1624. After some time spent on the continent, where he came into touch with Calvinist leaders he returned to Scotland in 1639, and established communications with the Ccvenanters and the Opposition in England, and as member for Banbury in both the Short and Long Parliaments he took a leading part in the attacks upon the Church of England. He was one of the commissioners appointed to attend the king to Scotland in Aug. 1641; and was nominated one of the committee of safety in July 1642. In the Civil War he commanded a troop of horses in Essex's army, was present at the relief of Coventry in August, at Worcester and at Edgehill. In Feb. 1643 Fiennes was sent down to Bristol, arrested Colonel Essex the governor, executed the two leaders of a plot to deliver up the city, and received a commission himself as governor on May 1, 1643. On the arrival of Prince Rupert (July 22) Fiennes capitulated. He was tried at St. Albans by the council of war in December, was pronounced guilty of having surrendered the place improperly. and sentenced to death. He was, however, pardoned, and subsequently exonerated. He held various appointments under the Commonwealth. He took no part in the Restoration, and died at Newton Tony in Wiltshire on Dec. 16, 1669. Fiennes married (1), Elizabeth, daughter of Sir John Eliot, by whom he had one son, afterward 3rd Viscount Saye and Sele; and (2), Frances, daughter of Richard Whitehead of Tuderley, Hants, by whom he had three daughters. Fiennes was the author of a large number of pamphlets. some of which have been reprinted in the series of Thomason and Somers tracts.

FIERI FACIAS: see PRACTICE AND PROCEDURE.

FLESCHI, GIUSEPPE MARCO (1790–1836), Corsican adventurer. was born at Murato, Corsica on Dec. 13, 1790. He served under Murat, then returned to Corsica, where he was condemned to ten years' imprisonment and perpetual surveillance by the police for theft and forgery. He eluded the police, obtained a small post in Paris, and took lodgings on the boulevard du Temple. There, with two members of the Société des Droits de l'Homme, Morey and Pépin by name, contrived an "infernal machine." On July 28, 1835, as Louis Philippe was passing along the boulevard to the Bastille, accompanied by his three sons and a numerous staff, the machine exploded. Marshal Mortier was killed, with 17 other persons, and many were wounded; but the king and the princes escaped. Fieschi himself was severely wounded. He was condemned to death, and was guillotined on Feb. 19, 1836. Morey and Pépin were also executed, another accomplice was sentenced to 20 years' imprisonment and one was acquitted.

See *Procès* de Fieschi (2 vols., 1836); also P. Thureau-Dangin, *Hist.* de la monarchie de *Juillet* (vol. iv, ch. xii, 1884).

FIESCO (DE' FIESCHI), **GIOVANNI LUIGI** (*c.* 1523–1547), count of Lavagna was descended from one of the greatest families of Liguria, first mentioned in the 10th century. He married Eleonora Cibb, marchioness of Massa, in 1540, a woman of great beauty and family influence. The Fiesco belonged to the French or popular party, while the Doria were aristocrats and Imperialists. When Fiesco determined to conspire against Doria he found friends in many quarters. Pope Paul III was the first to encourage him, while both Pierluigi Farnese, duke of Parma, and Francis I of France encouraged him. Among his associates in Genoa were his brothers Girolamo and Ottobuono, Verrina and R. Sacco. A number of armed men from the Fiesco fiefs were secretly brought to Genoa, and it was agreed that on Jan. 2, 1547, during the interregnum before the election of the new doge, the galleys in the port should be seized and the city gates held. The first part of the program was easily carried out, and Giannettino Doria, aroused by the tumult, rushed down to the port and was killed, but Andrea escaped from the city in time. Giovanni Luigi, while crossing a plank from the quay to one of the galleys, fell into the water and was drowned. The news spread consternation among the Fiesco faction, and Girolamo Fiesco found few adherents. They came to terms with the senate and were granted a general amnesty. Doria returned to Genoa on the 4th thirsting for revenge, and in spite of the amnesty he confiscated the Fiesco estates. Girolamo Fiesco and Verrina were captured, tried, tortured and executed. Ottobuono Fiesco, who had escaped, was captured eight years afterward and put to death by Doria's orders.

There are many accounts of the conspiracy, of which perhaps the best is in E. Petit's *André Doria*, ch. xi and xii (1887). *See* also E. Callegari, *La Congiura del Fiesco* (1892) and A. Gavazzo, *Nuovi documenti sulla congiura del conte Fiesco* (1886); E. Rernabb-Brea, in his *Sulla congiura di Giovanni Luigi Fieschi* (1865) publishes many important documents, while L. Capelloni's *Congiura del Fiesco*, edited by A. Olivieri (1858) and A. Mascardi's *Congiura del conte Giovanni Luigi de' Fieschi* (1629) may be commended among the earlier works. The Fiesco conspiracy has been the subject of many poems and dramas, of which the most famous is *Fiesco* by Johann Schiller. *See* also under DORIA, ANDREA; FARNESE.

FIESOLE, GIOVANNI DA: *see* ANGELICO, FRA.

FIESOLE, MINO DA (1430–1484), Italian sculptor, was born at Poppi in the Casentino. Trained in Florence, supposedly in the studio of Desiderio da Settignano, he worked in this town and in Rome, where he was active in 1454, 1463 and from about 1473 to 1480. He died in Florence in 1484. In Florence Mino executed the monuments of Giovanni Salutati, bishop of Fiesole (d. 1466), in Fiesole cathedral, and of Bernardo Giugni (d. 1466) and Count Hugo of Andersburg in the Badia. The latter was begun in 1471 and completed after Mino's return from Rome in 1482. In 1473 he carved two reliefs for the pulpit by Antonio Rossellino in Prato cathedral, and in 1481 a tabernacle for S. Ambrogio, Florence. Mino's work in Rome has been confused with that of the sculptor Mino del Reame. In Rome he worked in association with Giovanni Dalmata on the tomb of Pope Paul II for St. Peter's (Grotte Vaticane), and executed, among many other works, the monuments of Niccolo Forteguerri (Sta. Cecilia in Trastevere), Pietro Riario (SS. Apostoli), Cristoforo della Rovere (Sta. Maria del Popolo) and Francesco Tornabuoni (Sta. Maria sopra Minerva). Much of Mino's work in Rome was undertaken in conjunction with Andrea Bregno and others.

Mino enjoyed popularity as a portrait sculptor. His earliest portrait bust, that of Niccolo Strozzi (Kaiser Friedrich museum, Berlin), was carved in Rome in 1454. Other notable portrait busts by Mino are those of Astorgio Manfredi (National Gallery of Art, Washington), R. della Luna (Museo Nazionale, Florence) and D. Neroni (1464; Louvre, Paris). These well-characterized busts are among the earliest Renaissance portrait sculptures.

Though much admired in the 19th century, Mino's sculptures came to occupy a place below those of Desiderio da Settignano and Antonio Rossellino. In his larger works the treatment of form is frigid and mannered, and he appears, perhaps as a result of long absence from Florence, to have lacked the ready invention and technical proficiency of his great contemporaries.

See W. R. Valentiner, "Mino da Fiesole," in *Studies of Italian Renaissance Sculpture* (1950). (J. W. P.-H.)

FIESOLE (anc. *Faesulae*), a town and Episcopal see of Toscana, Italy, province of Firenze; it is 3 mi. N.E. of the city of Florence by electric tramway. Pop. (1951) 4,194. It is on a hill with two summits 970 ft. above sea level. and commands a fine view. The cathedral of S. Romolo is an early and simple Tuscan Romanesque basilica, begun 1028 and restored 1256. The picturesque battlemented campanile belongs to 1213. The 13th-century Palazzo Pretorio contains a small museum of antiquities. The inhabitants of Fiesole are largely engaged in straw-plaiting.

Below Fiesole, between it and Florence, lies San Domenico di Fiesole (485 ft.). In the Dominican monastery the painter, Fra Giovanni Angelico da Fiesole (1387–1455), lived until he went to S. Marco at Florence. Here, too, is the Badia di Fiesole, re-erected about 1456–1466 by a follower of Brunelleschi. It is an irregular pile of buildings, in fine and simple early Renaissance style; a small part of the original façade of 1028 in black and white marble is preserved. The slopes of Fiesole are covered with beautiful villas, the Villa Medici and the Villa Palmieri are among the finest. To the southeast lies Monte Ceceri (1,358 ft.), with quarries of gray *pietra serena*, largely used in Florence for building. To the east of this lies the 14th-century castle of Vincigliata restored and fitted up in the mediaeval style.

FIFE, an eastern county of Scotland, bounded north by the Firth of Tay, east by the North sea, south by the Firth of Forth and west by the shires of Perth, Kinross and Clackmannan. The Isles of May, Inchkeith, Inchcolm, and the islet of Oxcar belong to the shire. The land area is 504.5 sq.mi.; its population was 306,778 in 1951. Its coast line measures 108 mi.

The Lomond hills to the south and southwest of Falkland reach a height of 1,712 ft.; their summits show intrusive sheets of dolerite and basalt penetrating the Lower Carboniferous rocks, as does that of Benarty, on the confines of Kinross. Volcanic structures of various ages occur widely; in the north they are of Old Red Sandstone age and form the higher ground bordering the Firth of Tay, the Howe (or Hollow) of Fife; south of this tract, and watered in part by the river Eden, is a lowland underlain by soft Upper Old Red Sandstones; the quarries in these rocks in Dura Den are famous for their fossil fishes. The Carboniferous formations occupy the rest of the county southward. Many necks of volcanoes of the Permian period are traced in east Fife, as at Largo Law, and in the example of columnar basalt at Kincraig point on the coast. Of the rivers the Eden is the longest; formed on the borders of Kinross-shire by the confluence of Beatie burn and Carmore bum, it pursues a wandering course for 30 mi. northeastward, partly through the Howe of Fife, to the North sea. There is good trout fishing in its upper waters, but weirs prevent salmon from ascending it. The Leven and its tributary the Ore, and the Motray water, are the other streams. The only large valley is the fertile Stratheden.

The term Fife was once applied to the peninsula lying between the estuaries of the Tay and Forth and separated from the rest of the mainland by the Ochil hills. Its inhabitants were Picts of the northern branch, and their country was long known as Pictavia. Doubtless it was because of the long continuance of an independent king that Fife itself came to be called distinctively the Kingdom. The Romans, probably only temporarily, occupied a few points, and left no impression on the civilization of the natives. Christian missionaries—especially St. Serf, St. Kenneth, St. Rule, St. Adrian, St. Monan and St. Fillan—have left memorials in the numerous coastal caves between Dysart and St. Andrews, and in crosses and sculptured stones, some doubtless of pre-Christian origin, at various places. The word Fife, according to W. F. Skene, seems to be identical with the Jutland *Fibh* (pronounced Fife) meaning "forest" and was probably first used by the Frisians to describe the country behind the coasts of the Forth and Tay, where Frisian tribes are supposed to have settled at the close of the 4th century. The next immigration was Danish, which left lasting traces in many place names (such as the frequent use of *law* for hill). In 1426 the first shire of Kinross was formed, consisting of Kinross and Orwell, and was enlarged to its present dimensions by the transference from Fife of the parishes of Portmoak, Cleish and Tulliebole. Although the county has lain outside the main stream of Scottish history, Dunfermline, Falkland and St. Andrews were often the scene of pageantry and romantic episodes during the reigns of the earlier Stuarts. Of the 66 royal burghs in Scotland 14 are in the shire. Notwithstanding the marked preference of the Stuarts, the Kingdom played the leading part in the dramas of the Reformation and the Covenant, and by the 18th century the people had ceased to regard the old royal line with any but sentimental interest, and the Jacobite risings of 1715 and 1745 evoked only lukewarm support.

Many notable buildings are to be found in St. Andrews (*q.v.*); these include the cathedral, St. Rule's tower and church, the castle and the United college, principal centre of university life. Dunfermline abbey is distinguished as being the burial place of seven kings of Scotland, the last being Robert the Bruce. Culross contains many fine examples of Scottish domestic architecture dating from the town's prosperity during the 17th and 18th centuries, and Falkland palace, dating from the early 16th century, was one of the favourite retreats of the royal family of Scotland.

About 10% of the total area of 249,738 ac. devoted to farming is rough grazing, including hill pastures. Farming gave employment to 4,895 workers in 1951. The principal crops grown, in order of importance judged by acreage figures, are oats, hay, potatoes, barley, turnips, wheat and sugar beets. Cattle numbers are fairly divided between cattle kept for beef production and cattle kept for milk production. Sheep breeding and feeding are important branches of farming. East Fife, which is favoured by its soil and a low rainfall (about 30 in.), is mostly devoted to arable farming with cattleand sheep feeding. West Fife, less favoured by climate and soil but having a large industrial population, is mostly concerned with milk production. The whole of the coastal belt from Kincardine on Forth to Newburgh on Tay and in the valleys formed by the rivers Motray, Eden, Leven and Ore is very fertile and produces early crops. Elsewhere the soil is naturally poor but has been much improved by liming and other treatment. The poorest soils are mostly under afforestation.

Fife possesses large reserves of coal and is an area of expanding production. The coal fields comprise roughly three areas: the western field of Saline, Oakley, Blairhall and Valleyfield; the central basin, centred on Cowdenbeath, stretching from Dunfermline on the west to Cardenden and Kinglassie on the east; and the eastern field of Dysart-Markinch-Leven with known extensions under the Firth of Forth. From these reserves are produced first-class house coals and a wide range of industrial fuels for general purposes. Beds of limestone and sandstone lying near to coal seams are quarried, as also are exposures of basaltic whinstone of unusual hardness and durability.

The manufacture of linen ranks with agriculture as the county's oldest industry and continues to flourish in Dunfermline and Kirkcaldy as well as at Falkland, Cupar, Leven and Strathmiglo. The weaving of pure silk and artificial fibres has also been introduced. Kirkcaldy. Newburgh and Falkland are famous for the manufacture of linoleum, and paper is made at Guardbridge, Inverkeithing, Markinch and Leslie. There are engineering works and iron foundries at Kirkcaldy, Dunfermline and Leven; shipbuilding is carried on at Burntisland, boatbuilding at Anstruther and St. Monance, and shipbreaking at Inverkeithing. The distillery at Cameron Bridge produces whisky which is blended at Markinch. The white fishing industry is centred on Pittenweem and salmon fishing occurs in the river Tay. Other industries include furniture and carpetmaking, and the manufacture of bobbins, plastics, scales, oilskins, blankets and golf clubs.

From the Forth bridge the main railway line follows the coast as far as Dysart and then turns northward to Ladybank, where it diverges to the northeast for Cupar and the Tay bridge. From Thornton junction a branch runs to Dunfermline and there begins also the coast line for Leven, Crail and St. Andrews which touches the main line again at Leuchars junction.

The population at the 1951 census was 306,778, and both Gaelic and English were spoken by 623 persons. The chief towns are the large burghs of Kirkcaldy (pop., 1951, 49,050) and Dunfermline (44,719); and of the 23 small burghs the largest are Buckhaven and Methil (20,152), Burntisland (5,668), Cowdenbeath (13,151), Cupar (5,530), Leven (8,868), Lochgelly (9,103) and St. Andrews (9,457). The county council meets in Cupar and there are seven county districts. For parliamentary purposes Fife is divided into the county constituencies of East Fife and West Fife, and the burgh constituencies of Dunfermline Burghs (Dunfermline, Cowdenbeath, Inverkeithing and Lochgelly) and Kirkcaldy Burghs (Kirkcaldy, Buckhaven and Methil, Burntisland and Kinghorn).

G. Snoddy, *Afoot in Fife* (Edinburgh, 1950); W. Ballingall, *The Shores of Fife* (Edinburgh, 1872).

FIFE, originally the small primitive cylindrical transverse flute, now the small B♭ military flute, usually conoidal in bore, used in a drum and fife band. The pitch of the fife lies between that of the concert flute and piccolo. The words *fife* and the Fr. *fifre* were undoubtedly derived from the Ger. *Pfeiff*. The O.E. spelling was *phife*, *phiphe* or *ffyffe*. The fife was in use in England in the middle of the 16th century. At the battle of St. Quentin (1557) the list of the English army employed states that one trumpet was allowed to each cavalry troop of 100 men, and a drum and fife to each 100 of foot. *A drumme* and *phife* were also employed at one shilling per diem for the "Trayne of Artillery." This was the nucleus of the modem military band.

FIFTH COLUMN, a term of modern origin denoting the existence within a potential or actual enemy state of a group of hidden and unsuspected activists who promote the cause of the enemy and undermine national solidarity by whatever means at their disposal. It is the near-synonymous equivalent of disloyalty, subversion and treason. The term generally is credited to Gen. Queipo de Llano, a participant in the Spanish Civil War (1936–39) on the rebel side. When four rebel army columns were moving on Madrid, the general referred to his militant supporters within the capital as his "fifth column," intent on undermining the resistance of the Loyalist government from within. The term thus connotes a modern parallel to the ruse of the Trojan horse.

Next to espionage and sabotage, the main technique of the fifth column is infiltration of sympathizers into the entire fabric of the nation under attack, and particularly into positions of policy decision and national defense. Fifth-column activities find a conspicuous field of operation in psychological and actual warfare between the rival ideological camps of totalitarianism and democratic constitutionalism. The techniques of infiltration and subversion, in preparation for subsequent military attack, were utilized with striking success by Adolf Hitler against neighbouring democratic nations, partly in literal imitation of the Trojan horse (hiding troops in the holds of vessels peacefully anchoring in the harbours of the land to be victimized), partly by availing himself of the support of local sympathizers, for whom Vidkun Quisling (*q.v.*), minister of defense of Nor–ray, has provided a generic name.

The technique of the fifth column in all its disguises is also assumed to be standard practice of international communism. In most cases, however, Communist practice differed from that of the Nazis, an openly operating Communist party taking the place of the clandestine fifth column. Occupancy by Communists of the ministries of the interior and of defense, in control of the police and the armed forces, respectively, together with the establishment of communist militia or action squads; proved the most effective methods of the fifth column, as illustrated by the fall of Czechoslovakia in 1948.

The defense of democratic states against totalitarian infiltration was handicapped by observance of the principle of freedom of political expression accorded to all; further, such states were accustomed to repress only overt criminal acts. However, realizing their danger, many European democracies passed legislation before World War II for the defense of the constitutional state, aiming primarily at preventing subversion from within and disloyalty of public officials and armed forces. The ideological "cold war" after the war resulted in the adoption of similar measures by most western states against Communist infiltration. In particular, in the United States a vast body of legislation was enacted, and supplementary activity undertaken, including the loyalty review of the entire public service of the federal government and the states. In this context the term fifth column as such found access to a legal document, the Internal Security (McCarran) act of 1950 (64 Stat. 987), section 2. Whether the danger of fifth-column penetration was such as to warrant the infringement of traditional civil liberties that resulted from the precautionary policy was a matter of dispute. *See also* ESPIONAGE; SABOTAGE.

FIFTH MONARCHY MEN were an extreme Puritan sect which came into prominence in England during the Commonwealth and Protectorate. They were so called from their belief that the time of the fifth monarchy uas at hand, that is. of the monarchy which should succeed the Assyrian, Persian, Greek and Roman and during which Christ should reign on earth with His saints for 1,000 years. After the fall of the Commonwealth they at first supported Oliver Cromwell; and the Nominated or Barebone's Parliament of 1653, chosen from nominees of the Independent Churches, raised their hopes of bringing in speedily the rule of the saints. The establishment of the Protectorate, however, dashed these hopes and turned the sect against Cromwell. The violence of their agitation led to the arrest of their leaders—Maj. Gen. Thomas Harrison, Maj. Gen. Robert Overton, Christopher Feake. John Rogers and others—and an attempt at an armed rising, led by Thomas Venner in April 1657, was easily suppressed. Venner attempted another. and equally abortive, rising in Jan. **1661.** He and a number of others were executed and the special doctrines of the sect died out.

See S. R. Gardiner. *History of the Commonwealth and Protectorate, 1649–1656* (London, 1903); Sir C. Firth, *The Last Years of the Protectorate* (London, 1909). (R. B. WM.)

FIG, the popular name given to various plants of the genus *Ficus,* of the mulberry family (Moraceae), comprising more than 1,800 species, the flowers being borne on the inner surface of a hollow receptacle or syconium which matures into a spherical or pear-shaped multiple fruit. The species vary greatly in habit—some being low trailing shrubs. others gigantic trees. among the most striking forms of the tropical forests to which they are chiefly indigenous. They have alternate or sometimes opposite leaves and abound in a milky, usually acrid. juice. This juice contains caoutchouc in considerable quantity.

Ficus carica, which yields the well-known figs of commerce, is a bush or small tree—from a few feet to 30 or **40** ft. high—with broad, rough, deciduous leaves. deeply lobed or sometimes nearly entire. The fig is indigenous to an area extending from Asiatic Turkey to north India, but natural seedlings grow in most Mediterranean countries. It was undoubtedly one of the earliest fruit trees cultivated by primitive man, and spread in remote ages over all the districts around the Aegean and Levant. The Greeks are said to have received it from Caria (hence the specific name); Attic figs became celebrated throughout the east, and special laws mere made to regulate their exportation. The fig was one of the principal articles of sustenance among the Greeks; the Spartans especially used it at their public tables. Pliny enumerates many varieties, and alludes to those from Ebusus (the modern Iviza) as most esteemed by Roman epicures; he describes those of home growth as furnishing a large portion of the food of the slaves, particularly those employed in agriculture, by whom great quantities were eaten in the fresh state at the periods of fig harvest. In Latin myths the plant plays an important part. Held sacred to Bacchus. it was employed in religious ceremonies; and the fig tree that overshadowed the twin founders of Rome in the wolf's cave, as an emblem of the future prosperity of the race, testified to the high value set upon the fruit by the nations of antiquity.

In the old world, figs are grown commercially in the following countries in order of usual importance: Italy, Turkey. Algeria, Greece, Portugal and Spain. In Spain the most important fig provinces are Málaga, nhere figs are grown in regular orchards as well as mixed plantings with other fruit trees; Huelva, the centre of the industry being at Lepe, where a fig variety of the same name is grown; Murcia, reported to have the largest number of trees and the greatest production of any of the provinces; Huesca, where the Fraga fig grown near Lérida has a good market reputation; and Majorca. the largest of the Balearic Islands. Spanish figs are mostly of the common type, although the Turon fig grown in southern Granada is a variety of the Smyrna type. In Algeria figs are gronn commercially in the mountainous coastal districts, principally in the vicinity of Tizi Ouzou and Bougie. The unirrigated orchards are on rolling hills or steep mountain sides and consist mostly of Smyrna-type varieties with Kabylian names.

The commercial production of figs in Italy is mostly south of Naples, the principal producing centres being Lecce in the south, Cosenza in the interior and Agropoli on the coast. Dottato is the principal commercial variety, but numerous other figs are widely planted for the production of fresh and dried fruit. The famous Smyrna figs of Turkey are produced mainly in the Meander valley, but the dried product is largely packed and marketed in Izmir. Sari Lop is the variety gromn for drying while Bardajic is consumed in the fresh state. Both are of the Smyrna type. The commercial production of figs in Portugal is mostly confined to the province of Algarve, and Faro is the principal centre of growing and packing. In Greece figs of the Smyrna type comprise the bulk of the dried figs entering into commerce. Messenia is the variety most widely gromn in the province of the same name, and

Kalamata is the city where the fig-packing industry is centralized. Greek string figs are so called from the fact that the figs are flattened out, then strung on reeds about **1.5** lb. to each string before shipment to market.

Commercial fig culture in the United States is largely confined to California and Texas, although fig trees are very common in yards throughout the south and with winter protection thrive as far north as New Tork city. The varieties grown in California in order of importance are Calimyrna. Adriatic, Mission, Kadota and Brown Turkey. California fig orchards are practically all grown under irrigation.

The Texas fig industry is centered in the vicinity of Houston and is devoted mainly to the production of fresh figs for canning and preserving, mostly in glass containers. Because of summer rains and high humidity, figs are not dried commercially. Almost all the commercial plantings are of the Brunswick fig known in Texas as the Magnolia. The smaller Celeste is grown a few trees in a place from Texas to Florida and is used in Louisiana for preserving on a small commercial scale.

The varieties of figs grown in various parts of the world run into the hundreds. Their nomenclature is very much confused, since the same fig is often grown in neighbouring provinces under entirely different names. When introduced into other countries a new name is commonly coined. Thus Lob Injir of Smyrna became Calimyrna in California, and Dottato of Italy became Kadota. The Italian San Piero is known in England as Negro Largo, in France as Aubique Noire and in California as San Pedro Black, Brown Turkey or Black Spanish. There are four general horticultural types of the fig. The most primitive is the caprifig, commonly regarded as the wild type from which edible figs have evolved. Trees of the caprifig characteristically produce three series of fruit buds each growing season; the first gives rise to the profichi or spring crop, the second to the mammoni or summer crop and the third to the mamme or winter crop. Most caprifigs are inedible, but all three crops harbour the larvae; pupae or temporarily the adults of the fig wasp.

The other three types of fig are Smyrna, White San Pedro and Common. Smyrna-type figs develop only when fertile seeds are present, and these seeds account for the generally excellent quality and nutty flavour of the fruit. Figs of the White San Pedro type combine the characteristics of both the Smyrna and the Common type on one tree. First-crop figs develop without flower pollination while second-crop figs in axils of leaves require it. Common figs such as the Dottato. Fraga and Brown Turkey do not require pollination of flowers of either crop, the seeds in the mature fruit usually being hollow. The flowers of such figs were once regarded as incapable of fecundation and were therefore designated as mule flowers; but this is incorrect; it has been proved that all common figs can produce fertile seeds if the flowers are pollinated.

Fig fruits are borne singly or in pairs above the scars of fallen leaves or in axils of leaves of the present season. The flowers are of two kinds, female and male. Long-styled female flowers are characteristic of the fruits produced on most garden and orchard fig trees. Short-styled female flowers are found only in fruits of the caprifig tree and are adapted to the egg-laying habits of the fig insect or *Blastophaga.* Male flowers, which produce pollen, are found in caprifigs, usually near the apex. Young receptacles of Smyrna-type figs drop from the tree owing to lack of fecundation. which circumstance has led from ancient times to the practice of caprification or the placing of caprifigs containing mature *Blastophagas* in the cultivated trees. The insects as they issue from the caprifigs become dusted with pollen; they enter the Smyrna-type figs and crawl over the long-styled flowers in a vain attempt to find a suitable place to deposit their eggs. The flowers thus become pollinated and the resulting fecundation causes the fruit to set and eventually to mature. Hormone sprays will induce Smyrna-type figs to set and mature into seedless or even "seeded" edible fruit.

In most districts figs partially dry on the tree and drop naturally to the ground from which they are picked up and placed on trays in the sun. Turning and manipulating during the drying process improves the texture and quality of the product. The packing of dried figs in boxes, mats, baskets, cartons, bricks, etc., gives employment to thousands of men, women and children during the fall and winter seasons.

In Mediterranean countries, the fig is so widely used both fresh and dried that it is called "the poor man's food." Figs are known to possess in an unusual degree two important food qualities, a definite laxative effect and a high excess alkalinity of ash. The laxative effect is probably due to the bulk of seeds and fibre combined with some specific solvent present in the juice. The chief nutritive element in dried figs is sugar, the content of reducing sugar running as high as 64%. The vitamin content of figs depends somewhat upon the variety. For example: in California, fresh Mission figs contain about twice as much vitamin A precursor as Kadotas and considerably more than Calimyrnas. Vitamin B appears to be unfavourably affected by sulfuring preceding sun drying. In the fig districts of the old world both fresh and dried figs are commonly used for stock feed. Even the leaves are harvested when they are mature and stored or sold for fodder.

Fig trees are so readily propagated from woody cuttings that no other method of propagation is considered in a commercial way. Cuttings of dormant wood taken in February and planted in nursery rows should grow in one season to a height of 4 ft. and be ready to transplant at the end of the growing season. The trees thrive in a wide range of soil types and in most Mediterranean countries receive water only from the natural rainfall. Some varieties produce one crop only in summer or fall. Some bear two crops, the first maturing in June or July on wood of the previous season's growth. the second ripening in summer and fall in the axils of leaves of the same season. In cool climates such as England and central France most varieties mature only the first crop. Pot culture of figs in greenhouses has long been practised in England and some other countries.

Species of the genus *Ficus* are classified by botanists into groups depending upon the kind and distribution of flowers which on the inside of the receptacle are either male, pseudohermaphrodite. or female with long- or short-styled pistils. Classification may also be made on the fruiting habit or method of producing receptacles. Some fig trees produce fruit singly or doubly in the axils of leaves. Some bear single fruits,on the large branches or on the trunk; some bear clusters of fruit on woody knobs or leafless twigs while others have strings of figs on drooping branches. In a few species the figs are borne below ground on leafless runners, such figs being designated as geocarpic or earth figs. How these figs are pollinated underground or whether they are uprooted by animals is not apparent.

Some fig trees, for example: *Ficus religiosa* and *F. benghalensis,* commonly start life from seeds deposited by birds. squirrels, monkeys, or fruit-eating bats. high up on a palm or other native tree. The roots grow downward, attached to the trunk of the supporting plant, but are not parasitic. Such figs are known as epiphytes or more accurately as hemi-epiphytes, as they pass their early life on the trunks of trees but subsequently become connected with the ground by their own root system. The name "strangler" has become attached to fig trees which grow in this way, since their descending and encircling roots become at length largely or entirely confluent! forming a pseudo trunk hollow at the centre through which the dead or dying host plant passes. These fig trunks are roots and not stems, a fact which should be taken into account in studying their anatomy. Roots of fig trees often enter cracks and crevices, thus causing serious injury to buildings and walls on which they are growing. In a vivid description of an old ruin in Ceylon one writer states that a fig tree forms one of the most remarkable objects of the place, its roots streaming downward over the walls as if their wood had once been fluid, following every sinuosity of the building and terraces till they reach the earth.

The Sycomore fig, *F. sycomorus,* is a tree of large size, with heart-shaped leaves. The deep shade cast by its spreading branches makes it a favourite tree in Egypt and Syria, where it is often planted along roads and near houses. The fruit is borne in clusters on specialized leafless shoots attached to the older branches. Sycomore figs become edible only if the apex is cut open to prevent the development of the insect which normally inhabits the fruit. The prophet Amos was thus a "fig dresser."

The Sacred fig: peepul or bo *(F. religiosa),* a large tree with heart-shaped, long-pointed leaves on slender stalks, is much grown in southern Asia. The leaves, bark and fruit are used in native medicine, and a gum resembling caoutchouc is obtained from the juice; but in India it is chiefly planted with a religious object, being regarded as sacred by both Brahmans and Buddhists. A gigantic bo, growing near Anarajapoora, in Ceylon. is said to have been a branch of the tree under which Gautama Buddha became endued with his divine powers, and has always been held in the greatest veneration. Planted in 288 B.C., it (or suckers from it) is probably the oldest historical tree in the world.

Ficus elastica, the India rubber tree, the large, oblong-shaped glossy leaves and pink buds of which are familiar in U.S. greenhouses, furnished most of the caoutchouc obtained from the East Indies, previous to the cultivation of Brazilian rubber trees in the orient. It grows to a large size, and is remarkable for the snakelike roots that extend in contorted masses around the base of the trunk. The small fruit is unfit for food.

Ficus benghalensis, the banyan, of India, has heart-shaped leaves commonly used as elephant fodder. The branches send out numerous aerial roots that grow down to the soil and form props or additional trunks eventually developing the broadest crown of any plant. Some have as many as 300 trunks and a circumference of 2,000 ft. The fruits, fresh or dried, are eaten in various parts of India especially in times of food scarcity.

In southern Florida, two native species occur, the Golden fig *(F. aurea)* and the Short-leaved fig *(F. brevifolia)*, both stranglers.

Many species are native to Mexico and Central America. The Common fig (*F. carica)* is sparingly naturalized in old fields and along roadsides from Virginia to Florida and Texas. Numerous species are grown as greenhouse ornamentals and as standard trees out of doors in Florida and California. No species of *Ficus* is native to the Hawaiian Islands, but several have been introduced and widely distributed for reforestation purposes. F. *macrophylla,* the Moreton Bay fig of Australia, is well suited to this project. Previous to 1921 fertile seeds of this fig had to be imported from its native home. During that year, however, the wasp. essential to pollination of Moreton Bay figs,, was introduced into Hawaii and ripe figs containing fertile seeds secured. This was the second case on record where the wasp of a wild fig tree had been established outside its natural habitat, the first being the colonization of the *Blastophaga* on caprifigs in California A single tree of *F. macrophylla* in Honolulu produced in 1922 fruits from which 224 lb of dry seeds were secured. These seeds, if properly sown, might have yielded 6,558,720 seedlings which, advantageously placed, would reforest all the watersheds on the islands of this group.

FIGEAC, a town of southwestern France, capital of an *arrondissement* in the *département* of Lot, 47 mi. E.N.E. of Cahors on the Orléans railway. Pop. (1954) 5,636 It stands on the right bank of the Célé, here crossed by an old bridge. Figeac grew up round an abbey founded by Pippin the Short in the 8th century, and throughout the middle ages it belonged to the monks. At the end of the 16th century the lordship was acquired by the duke of Sully, who sold it to Louis XIII in 1622.

The town is very rich in medieval houses, notably the Hôtel de Balène, of the 14th century. Another house. dating from the 15th century, was the birthplace of the Egyptologist J. F Champollion. The church of St. Sauveur, once belonging to the abbey of Figeac, is 12th century restored. Notre-Dame du Puy belongs to the 12th and 13th centuries. The altar-screen is a fine example of carved woodwork of the end of the 17th century. Of the four obelisks which used to mark the limits of the authority of the abbots of Figeac. two to the south and the west of the town remain.

Figeac is the seat of a subprefect and has a communal college. Trade is in cattle, leather, wool. plums. chestnuts, walnuts and grain, and there are zinc mines in the neighbourhood.

FIGG, JAMES (*c.* 1695–1734), generally acknowledged the first champion of England at fighting with bare fists. was born at Thame, Oxfordshire. about 1695. For years he was the leading pugilist and master of the "noble art" of self-defense. He was also famous for his swordsmanship, and for cudgeling and wrestling. He was only beaten once. and then he is said to have been ill.

Figg opened a boxing academy, called Figg's amphitheatre, and, a magnificent and resolute figure, he was ready at all times to accept a challenge to fight. Figg died on Dec. 7, 1734. *See* also BOXING.

FIGNER, VERA NIKOLAEVNA (1852–1942), Russian revolutionist and martyr, was born on June 24, 1852, in the province of Kazan, the eldest of six children in an aristocratic family. Her father, Kikolai Figner, was a government forester; her mother, Ekaterina Kupriyanov, was a daughter of the district judge in Tetyushy. From 1863 to 1869 Vera Figner attended a finishing school for the daughters of Russian nobility in the city of Kazan. During the year following her graduation, her uncle Kupriyanov, a "liberal democrat," awakened in her a wish to find some useful activity. In the summer of 1870 she decided, as did many Russian women of her class and generation, to study medicine and become a doctor among the peasants. Her parents opposed the plan and with the hope of discouraging her design introduced her to a season of polite-society in the capital of the province. There she met Alexei Filipov, a magistrate, who shared her views; they were married on Oct. 18, 1870. In the spring of 1872 Vera Filipov, her husband, who resigned his post in order to accompany her, and younger sister Lydia, went abroad and matriculated at the University of Zurich. Through her contact with Russian men and women student refugees then in Switzerland, she became familiar with the literature of socialism, and within the year joined with her sister a secret society called the "Frichi" club. By 1873 she was conversant with a new revolutionary doctrine which later received the name of "Populism," favouring Mikhail Bakunin's active optimism that aimed at inducing revolt against the ruling power. That summer the students were ordered to return to Russia by a government decree; the Zurich group disbanded, some obeying the summons. others staying in Europe. Vera Filipov continued abroad, determined to complete her studies, for she believed that once she was licensed to practise medicine among the people, she would also be in a position to impart the new doctrine which she had accepted. By Dec. 1875, however, many of those who had gone back to Russia had been arrested or exiled for their political activities. At the urgent request of former members of the secret circle who remained free, and six months before the end of her medical course, Vera Filipov went back to Moscow to assist in carrying on the program they had begun. In 1876 she obtained a divorce from her husband, who did not sympathize with her political interests, and resumed her maiden name. From that time on, her life was linked with the destinies of the Russian revolutionary movement.

In the autumn of 1876 she joined with Mark Nathanson and others in founding the secret society "Land and Liberty" which hoped to provoke a mass uprising among the people. Between 1877 and 1879 she established herself as an able surgeon, and combined the practice of medicine with that of revolutionary propagandist in the provinces of Samara and Saratov. With the assistance of a younger sister, Evgenia, also a doctor, she conducted a free school for peasant children. But the warfare waged against them by the police and village officials, who were suspicious of their purpose, brought Vera Figner to the conviction that the only course by which the existing order would be changed was the course of violence. Her certainty was strengthened by a discussion with Alexander Solovyev, who visited her prior to his unsuccessful attempt to kill the tsar in April 1879, in which he argued convincingly for the course he was to pursue.

In 1879 "Land and Liberty" split up over the question of the place of political terror in its program, and Vera Figner became a member of the executive committee of the more radical division called "the People's Will." Plans were put in motion for a series of terrorist acts, including the assassination of the tsar. In September Vera Figner was sent to Odessa with dynamite for the bombing of the railroad over which he was expected to pass when returning from the Crimea. This venture failed, and she resumed her underground work in St. Petersburg (Leningrad). In 1881 she assisted Sophie Perovskaya and others in organizing the conspiracy, and took part in making the bombs that brought about the death of Alexander II on March 1 (13). Immediately afterward she was sent to Odessa to manage the local affairs of the party. By June of 1882 the executive committee had been annihilated, due to the successful manoeuvres of the police in ferreting out the leaders, and Vera Figner was its only representative still free in Russia. In Kharkov she strived to create a centre which should compensate in some degree for its absence, and managed to form a military group; but within a few weeks Vera Figner, the army men and those who still were left in the ranks of the party, were betrayed to the police by Sergy Dagayev, a former trusted member of the organization. Arrested on Feb. 10, 1883, she was imprisoned in the Peter Paul fortress in St. Petersburg. Following her trial 20 months later, Sept. 22, 1884, she was condemned to death but the sentence was commuted to penal servitude for life. On Oct. 12, 1884 she was removed to Schlusselburg fortress where she was kept in solitary confinement for the greater part of the next 20 years. On Sept. 20, 1904 she was exiled to Archangel, then to Kazan province, and later to Nijni-Novgorod. In 1906 she was permitted to go abroad and while living in Switzerland, France and England, she engaged in winning support for Russian prison reform. At the outbreak of World War I she returned to Russia but was arrested at the frontier and detained in Nijni-Novgorod until the end of 1916 when she was allowed to go to St. Petersburg. After the February revolution, which she witnessed, she was made chairman of an amnesty committee that helped the political prisoners freed from tsarist prisons.

For some years after the Russian Revolution she was occupied in writing and publishing her memoirs (7 vol.), which afford a major clue to the terrorist methods employed by the Russian military police at the time, and magazine articles which describe the revolutionists and movements with which she had been associated. Between 1928 and 1929 a collection of her works, including some of her poems, was issued. Many of the productions that came from the pen of Vera Figner, which aside from their historical content contain artistic literary value, were translated into foreign languages.. In later years she lived in Moscow where she died June 16, 1942, at the age of 90. An old revolutionist, E. Yaroslavsky, writing her obituary in the Russian newspaper *Pravda,* June 1942, declared that "the name of Yera Figner will live in the history of Russia as one of the first women to declare war on tsarism."

FIGUEIRA DA FOZ, a seaport of central Portugal. in the district of Coimbra. Pop. (1950) 10,486. Figueira da Foz is an important fishing-station. and one of the headquarters of the coasting trade in grain. fruit, wine. olive oil, cork and coal. Glass is manufactured. and the city attracts many visitors by its excellent climate and sea-bathing. A residential suburb, the Bairro Novo, exists chiefly for their accommodation, to the northwest of the old town. Figueira da Foz received the title and privileges of a city in 1882.

FIGUEROA, FRANCISCO DE (1536–1617?), Spanish poet, of whose life little is known, was born at Alcalá. Although Figueroa ordered that his poems should be burnt at his death, the order does not seem to have been carried out for Luis Tribaldos de Toledo in 1625 edited over 60 of Figueroa's poems which exhibit his mastery over blank verse and his inclination to the pastoral tradition. A facsimile of this edition was published by A. M. Huntingdon (1903).

(1911); *Varias composiciones inéditas,* edit. A. Lacalle Fernandez in *Rivista crítica hispano-americana* (1919). *See* also J. Fitzmaurice-Kelly, *A New Hist. of Span. Literature* (1926).

FIGULUS, PUBLIUS NIGIDIUS (not later than 98–45 B.C.), Roman savant and writer, next to Yarro the most learned Roman of the age. He was a friend of Cicero, to whom he gave his support at the time of the Catilinarian conspiracy (*see* CATILISE). He was praetor in j8, sided with Pompey in the Civil War, was afterward banished and died in exile. He sought to revive Pythagorean doctrines and combine them with Etruscan and oriental beliefs, notably a belief in astrology, and apparently gathered some adherents. Suetonius and Apuleius tell of Figulus' supernatural powers. Jerome calls him *Pythagoricus et magus.* The indifference of the Romans to such abstruse and mystical subjects caused his works to be soon forgotten. They included *De* dis ("Concerning the gods"), in at least 19 books, the earliest comprehensive work on Roman religion, but soon superseded by Varro's *Res divinae; Commentarii grammatici,* in at least 29 books. a loose collection of notes concerned among other matters with synonyms, inflexion, orthography, word formation, syntax and etymology; *De extis* ("Concerning sacrificial meats"); *Augurium privatum; De ventis* ("Concerning winds"), in at least four books; De *animalibus,* in at least four books, used by the elder Pliny; De *hominum natura,* in at least four books; *Sphaera graecanica et sphaera barbarica;* and a rhetorical treatise *De gestu* ("Concerning gesture").

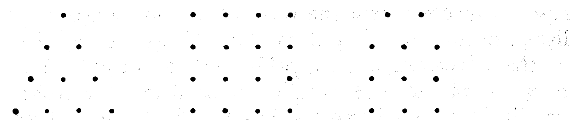
FIGURATE NUMBERS. The early Greek mathematicians found that if groups of dots were used to represent numbers, they could be arranged so as to form geometric figures, examples of which are as follows:



Of these, the first represents a triangular number; since there are 10 dots, 10 is a triangular number. It is also seen from the upper portions of the configuration that 3 and 6 are triangular numbers. The second figure is a square, and from it one sees that 4, 9 and 16 are square numbers. From the third it is seen that 12 is a pentagonal number; for if the perimeter is traced a five-sided figure results. The triangular numbers may be represented by $\frac{1}{2}n\ (n+1)$, where n is any positive integer. The square numbers are represented algebraically by n^2, and the pentagonal numbers by $n^2+\frac{1}{2}n\ (n-1)$. The Greeks also considered oblong (heteromecic) numbers, the sides (or factors) of which differ by unity. Thus. 3×4. $4\times$ j. . . . are oblong numbers. There were also prolate (promecic) numbers. the factors differing by two or more, as in the case of 2×5; but these were often included under oblong numbers. Besides various other types of plane numbers there are solid numbers. For example, 8 is a cubic number, and j is a pyramidal one. Numbers which are related to geometric figures in such ways are called figurate numbers or figured numbers. Plane figurate numbers are also called polygonal numbers, the solid figurate numbers being designated as polyhedral. The theory probably goes back to Pythagoras (*c.* 530 B.C.). Such numbers were studied and described by Nicomachus (c. A.D. 100), Theon of Smyrna (*c.* 125). Boëthius (*c.* 480–524) and many later writers.

FIGURED BASS (also known as THOROUGH-BASS. GENERAL BASS and BASSO CONTINUO) is a kind of musical shorthand, whereby the harmonies of a composition are indicated by means of figures above or belon the bass part, instead of in the ordinary notation. It came into existence early in the 17th century in Italy, being introduced in the first place for the use of the organist or cembalist accompanying a choral composition, and thereafter was very aidely and generally employed for a long period, but nowadays it is retained in use only in harmony textbooks and similar technical norks. The principle of the system is quite simple, the figures indicating the interval of the note to be played. reckoning from the bass upward. Thus a 3 represents a third, a 5 a fifth, a 6 a sixth, and so on. *e.g.,* $\begin{smallmatrix} & 6 & \\ 5, & 6, & 5 \\ 3 & 4 & 3 \end{smallmatrix}$ and the like. chromatic signs being added when necessary to indicate the inflection of a given interval, *e.g.,* $\begin{smallmatrix} \sharp 6, & \flat 9, & \natural 4 \\ 5 & 4 & 3 \end{smallmatrix}$. Much skill and taste were none the less required for the proper interpretation of a figured bass. more especially as in course of time the signs used were still further abbreviated and simplified. leaving more and more to the knowledge and understanding of the performer, who was required further, not merely to provide the bare harmonies indicated but to place and connect them in accordance nith the laws of correct part-writing, to embellish them with runs. ornaments and so on. and generally to provide. on the strength of the mere indication of the essential harmonies, a complete and satisfying accompaniment.

FIGUREHEADS, SHIPS', ornamental symbols or figures formerly placed on some prominent part of a ship, usually at the bow. A figurehead could be a religious symbol, an emblem indicating nationality, or a figure to symbolize the ship's name. Figureheads have been discontinued on most ships since World War I.

The custom of decorating a vessel apparently began in ancient Egypt or India, nhere an eye was painted on either side of the prow. The Chinese followed this custom nith their river junks. The ancients are supposed to have believed that the eyes or *oculi* could help a vessel find its way safely over the water. The first prominent navigators and traders of the western world, the Phoenicians. probably spread this custom throughout the Mediterranean and handed it down to the Greeks and Romans.

As early as 1000 B C. the stem and sternpost were carved and painted to distinguish one ship from another, and at least one class of vessel used an identifying symbol: a falcon or a falcon's eye generally appeared on the bows of funeral barges of the Nile. Although the *oculi* were the most popular symbols used by early sailors. some figureheads were fashioned for the purpose of terrorizing less civilized tribes. The Egyptians probably originated the practice of using religious symbols; other Mediterranean peoples extended this practice by using carvings and paintings of their principal deity to identify the vessel with its city-state. The Carthaginians, for example, often used a carving of Xmmon while the Athenians used a statue of Xthena.

THE COILED-SNAKE FIGUREHEAD FROM THE OSEBERG SHIP, *c.* 800 A.D.

The ships of the ancient Egyptians. Phoenicians. Greeks and early Romans were constructed with heavy vertical timbers at the bow and stern to which the side planking was attached. These stem and sternposts protruded well above the hull and their prominent and semierect position and form created a focal point of interest and a shape obviously suited for decoration. When the ram type of prow was developed as a weapon of warfare, the stem lost its prominence and the ram was decorated instead. One Athenian vessel of about 500 B.C. had the entire ram carved in the shape of a boar's head. After the ram type of prow lowered the prominent bow features of the ship, greater emphasis was placed on decorating the stern. This trend was carried to an extreme by the Romans at the height of their naval power when their ships were distinguished by a very high sternpost carved to sweep up and around in graceful curves which terminated in the gilded head of a swan or other figures. Even in the Roman merchantman of about 200 A.D., when the bowsprit first was used. the chief emphasis in decorating the vessel continued to be at the stern; but the trend was changing. for some paintings reappeared on the bow.

Along the more blustery northwest coast of Europe, good seamen such as the Vikings. Danes and Normans continued to build their ships with high bows and a projecting stem. The figurehead of the Oseburg ship of about 800 A.D. was a coiled snake with head upreared. In 1004 A.D. a Danish ship bore a dragon's head at the bow. and obtained the effect of a huge sea serpent by having the graceful sweep of the bulwarks terminate aft in a high-coiled tail. The ships of William the Conqueror are represented in the Bayeux tapestry as similar to those of his Korse ancestors, but the decorative symbols (except for the lion's head on the stern) reflect the spread of the Christian church.

In the 13th and 14th centuries a boarding platform was attached forward and projected out over the stem. With this type of construction the figurehead practically disappeared. Gradually the boarding platform was moved back until it formed the forecastle and the beakhead of the 16th century was added to become the natural place for a figurehead. Gradually the beakhead was reduced in size and moved back under the bowsprit until just the figurehead remained. During this period the fashions in figureheads varied from the popular carvings of the saints, to national emblems such as the lion and the unicorn, then to the simple scroll and the billethead, and finally to the carving representing the person for nhom the vessel mas named.

It is interesting to note that figureheads were carved from oak or elm in England, while pine was used almost exclusively in America. The cost of a figurehead in the United States about 1816 ranged from $700 for a 74-gun vessel, $600 for a 44-gun craft, $200 for a sloop, to $46 for the "head" on the revenue cutter "Eagle."

The "Sovereign of the Seas," a galleon built in 1637, was the most highly decorated vessel in the history of shipbuilding. Her carving and gilding cost about £7,000, while the comparative total cost of the ship was £41,000. Figureheads varied in size from 18 in. for small heads and busts to 8 or g ft. for full-length figures.

(M. H. I.)

FIGURES OF SPEECH is a broad term for a large variety of uses of words, phrases, clauses and sentences to achieve desired effects in meaning, sound and style. Traditionally it is defined as deviation in the use of words from the literal sense or from simple and common practice, and includes figures of rhetoric, syntax, etymology and orthography.

METAPHOR, SIMILE AND KINDRED FIGURES

Figures of Resemblance. — The most basic of all figures is the metaphor (Gr. *metaphora,* from *meta*, "over," and *pherein,* "to carry"), which states an analogy, similarity or relation betneen tno things. The difference between metaphor and synonym is that the metaphor does not mean that the two things are the same, only that they are similar in their relations to something else. For example. calling the first observed robin the "herald of spring" means that the robin is to the beginning of spring weather as the herald (announcer) is to his prince. A like set of relations is conveyed by the metaphorical use of the verb in "the ship plows the sea." Thus in a metaphor one thing is said to be another only as a fiction or useful analogy. A literal description is not figurative, *i.e.*, symbolical. "Blue" or "green" ocean is literal, but "sky-blue ocean," which compares the colour of the ocean to the colour of the sky, is metaphorical.

As Aristotle pointed out in his *Rhetoric,* the difference between a simile and a metaphor is slight, the simile being only a metaphor nith an explanation: "Thus when Homer says of Achilles that 'he rushed on, a very lion,' it is a metaphor. for here. as valour is an attribute to both. he transfers to Achilles the metaphorical appellation of 'a lion'" In general, the metaphor is more compact, forceful and suggestive. The simile requires a phrase beginning with "like." "as." "as if," etc., which makes it not only more prolix than a metaphor but also labels the thought as make-believe. Severtheless. the simile can be effective in prose or poetry. The extended comparison is often called the "epic simile" from Homer's frequent use of it in his poems, as in the *Iliad,* Book VIII, 5jj–j60 (reprinted from *The Iliad of Homer,* translated by Richmond Lattimore by permission of The University of Chicago Press. Copyright 1951 by The University of Chicago).

As when in the sky the stars about the moon's shining
are seen in all their glory, when the air has fallen to stillness,
and all the high places of the hills are clear, and the shoulders out-jutting,
and the deep ravines, as endless bright air spills from the heavens
and all the stars are seen, to make glad the heart of the shepherd.
such in their numbers blazed the watchfires the Trojans were burning
between the waters of Xanthos and the ships, before Ilion.

Here the comparison, beginning with literal description, conveys spaciousness, multiplicity and implies cosmic significance. The "epic simile," in fact, often takes on the exaggeration of hyperbole to magnify the miraculous strength and courage of mythical heroes. The pseudo-epic James Macpherson's *Ossian* is full of examples: "As autumn's dark storms pour from the echoing hills. so towards each other approached the heroes. As two dark streams from high rocks meet and mix. and roar on the plain: loud, rough, and dark in battle meet Lochlin and Innisfail."

Figures of Relationship. — The synecdoche (Gr. *synekdochē,* from *synekdechestkai,* "to receive jointly") is a variety of metaphor whereby a part stands for the whole, such as a "sail" for a ship, or ten "head" of cattle for that number of animals. or "motor" for automobile. The part must be characteristic, important and conspicuous. A ship is not referred to as a "rudder," or an automobile as a "taillight."

Closely akin to synecdoche is the metaphor called metonymy (Gr. *metōnymia,* from *meta,* "change," and *onoma* or *onyma,* "name"), by which a name closely associated with an object is used instead of the usual name of the object, as "crown" or "scepter" for king; "White House" for president (or presidential staff) of the United States, sometimes even personified. "The White House announces . . ." Other variations of metonymy are cause for effect, or vice versa, such as "gray hair" for old age, or "shade" for trees, the latter very common in 18th-century "poetic diction," which overused both synecdoche and metonymy. The Anglo-Saxon kenning also used a part for the whole; in *Beowulf* the ocean is called "swan's-bath," "whale-road," etc.

A kindred metaphor is the antonomasia (L. *anti,* "instead of," and *onoma,* "name"), in which the surname of an individual becomes a generic term for persons of similar activity, condition or characteristic; or for a noun associated with the proper name. For the latter, note "Venus" for love, "Bacchus" for wine, "Mars" for war. etc. Recent history has contributed "quisling" for traitor, "McCarthy" and "McCarthyism" for demagogue and demagoguery. If the use of a name becomes so widespread that its origin is commonly forgotten, it is then a part of the language and is not usually regarded as a figure of speech. Examples are "macadam," small broken stones for paving a road, a process developed by John L. McAdam, and "mackintosh," a waterproof coat invented by Charles Macintosh.

Play Upon Words. — Etymology is one source for the pun (It. *puntiglio,* "fine point" or "verbal quibble"), a humorous play upon two or more meanings for one sound (homophone or homonym). Thoreau, no less than Shakespeare, was a master of such quibbles Three roads leading to a village, he said, make it "trivial." In Shakespeare's time "raskall" was a lean deer out of hunting season; when applied to a person, therefore, the word nas an abusive metaphor (called by the Greeks *catachresis),* but only the abusive connotation remains in "rascal" today. What is most often called a pun, however. is actually paronomasia (Gr. *para,* "beside." and *ononza,* "name"), a play on similar but not identical sounds. O. W. Holmes illustrates it in pretending to condemn the pun in *Autocrat of the Breakfast Table:* "Homocide and verbicide — that is, violent treatment of a word with fatal results to its legitimate meaning, which is its life — are alike forbidden. Manslaughter, which is the meaning of the one, is the same as man's laughter, which is the end of the other." Prosonomasia involves a nickname created by a play on the sound of the person's name. An opponent of Erasmus called him "Errans Mus" (wandering mouse). Hostility breeds such coinages as "Dr. Fraud" for Dr. Sigmund Freud, founder of psychoanalysis.

Enlarged Metaphors. — When the pun is used seriously, it may become a symbol, as when Thoreau finds "concord" (harmony, peace) in the discordant cries of the mild goose and the onl. A symbol begins in a metaphor but acquires additional and more pervasive meaning each time it is used. If the meaning accumulates through a whole literary composition, the symbols merge into allegory. Myth is also an extension of metaphor, dramatizing syinbolical fictions on the origin and purpose of man and nature.

The parable is allegory on a limited scale, being a story nith both a literal and a figurative meaning, such as Christ's parable of the mustard seed; as is the fable, which instructs by making animals act like men. From proverbs such as "wise as serpents" or "harmless as the dove" are derived symbols of wisdom, peace, etc. The legend makes a symbol of heroic action, and uses the lives of great men as paradigms (L. *paradigma,* "example").

The Decay of Metaphor and the Cliché. — As noted above the common noun "mackintosh" illustrates one process of language formation in the decay of metaphor, and the cliché illustrates another. The former has ceased to be a figure of speech; the latter is still figurative, but lacks the impact of newly coined or unfamiliar metaphors. When Emily Dickinson described the flight of a hummingbird as

> A route of evanescence
> With a revolving wheel . . .

she created metaphor, fresh, accurate and thrilling in sense-appeal. But if many people began referring to the flight of a hummingbird as "route of evanescence" or "revolving wheel" the phrases would cease to astonish and become clichés. Though pedagogues frequently condemn the use of clichés, their brevity, simplicity and conciseness keep them alive. "Jack-of-all-trades" is simpler and more vivid than "One who can turn his hand to any (or to many kinds of) work." Phrases such as "eat like a horse," "dead as a doornail," "sly as a fox" — implied also in "foxy" — are idiomatic figures. When the cliché is objectionable it is not because it is familiar but because it is used inappropriately. such as "allergic to" for all situations of dislike or incompatibility. The mixed cliché, like mixed metaphors of all kinds, is inept because it is confused and contradictory, often unintentionally ludicrous, *e.g.,* "The hand that rocked the cradle has kicked the bucket," for a solemn subject, the death of a mother.

The cliché is an obvious example of a basic linguistic process. Max Müller said in *Science of Language* that "under the microscope of the etymologist almost every word discloses traces of its first metaphorical conception." Emerson expressed the same idea in "The Poet": "Language is fossil poetry." Owen Barfield summarizes this doctrine (with which he does not entirely agree) in *Poetic Diction* when he writes: "every modern language, with its thousands of abstract terms and its nuances of meaning and associations, is *apparently* nothing, from beginning to end, but an unconscionable tissue of dead, or petrified, metaphors." (London, Faber & Faber Ltd., 1952). These decayed and petrified metaphors are the fossils of mythology ("jovial" from Jove) ; folklore ("lunatic," moon-struck, *i.e.,* made insane by exposure to moonlight) ; social custom ("jubilee," from Hebrew *jobil,* "ram's horn," used as a trumpet to announce a celebration) ; and every field (another metaphor) of human activity. Taboos and the desire to avoid unpleasant subjects also give rise to euphemisms, like "go west" for dying. *i.e.,* follow the setting sun:

FIGURES FOR EMPHASIS

Figures of Degree of Emphasis. — One of the most vigorous of all figures for emphasis is hyperbole, mentioned above under metaphor, which magnifies things beyond their natural bounds or attributes miraculous powers and qualities to persons. Emily Dickinson. to convince her lover of the steadfastness of her devotion, asks rhetorically and answers hyperbolically:

> Alter? When the hills do.
> Falter? When the sun
> Question if his glory
> Be the perfect one.

Humour. — American especially — often employs hyperbole. Mark Twain: "Noise proves nothing. Often a hen who has merely laid an egg cackles as if she [had] laid an asteroid."

Emphasis can be secured by the reverse of hyperbole: by litotes (Gr. *litotes* from *litos,* "plain, simple"), or understatement. Litotes asserts by the use of a negative: "He is not an ordinary man." meaning he is really a remarkable man. The understatement emphasizes by diminishing. Usually to be fully appreciated it must be taken in context. When Henry James has one of his characters say. "This is my little point," he means that he thinks his point is very important indeed.

The psychological origin of understatement may be either false modesty or a deeper sense of irony. Irony (Gr. *eirōneia,* from *eirōn,* "dissembler in speech") is one of the most emphatic of all figures and the most subtle and insinuating. It states the opposite of the intended or true meaning in such a way that the truth is underscored. In dramatic irony the speaker is unaware of the true import of his words, as when silly Dogberry in *Much Ado* says as a joke, "Write me down an ass!" But serious irony can be profoundly pathetic or even tragic. as when Oedipus sets out to find the guilty person and ends by bringing himself to justice, arising from a sense of human frailty (especially prominent in Greek tragedy), or in protest against overwhelming odds, stupidity, arrogance, etc. Mark Antony in his oration at Caesar's funeral casts doubt on Brutus's motives by repeating "But Brutus is an honourable man." To his pretended consolers Job replies, "No doubt ye are the people, and wisdom shall die with you." Irony resembles, and often makes use of, paradox, antithesis, understatement, anticlimax.

Other Rhetorical Figures. — Of other figures that promote or express emphasis, one of the most obvious is the exclamation, expressing sudden or strong feeling. The exclamation may be a single word ("oh!", "alas!"), a phrase ("For shame!"—which is also a figure of syntax, ellipsis; *see* below), a sentence or whole passage: "What a piece of work is a man! how noble in reason! how infinite in faculties! . . ."

Another common figure is the interrogation or rhetorical question, *i.e.,* a question asked only for effect, the answer being obvious. The Greek Sophists were fond of this figure, and it has always been a favourite with orators, lawyers and special pleaders. The apostrophe is also much used by orators, though found often, too, in older poetry. especially heroic. Here the speaker interrupts his discourse to address directly the thing or subject discussed—if a thing, this likewise involves personification, as when Milton begins *Lycidas* by begging the indulgence of literary fame ("laurel") and invoking the symbol of elegy ("myrtle"):

> Yet once more, O ye laurel, and once more,
> Ye myrtles brown, with ivy never sere, . . .

Figures of Syntax. — Although most figures of speech are some variety or combination of metaphor, the term figure of speech is also applied to variations from normal usage in syntax. word-form, and spelling. Of these the most important are figures of syntax, which include omissions, repetitions and unnecessary addition of words. Ellipsis is the omission of words, phrases or clauses, as in the command, "Go home!" (subject understood but not expressed). Ellipsis is used for pithiness and economy. In asyndeton connectives are omitted for the same reasons: Julius Caesar's "I came, I saw, I conquered." The opposite is polysyndeton, in which connectives are repeated, like the famous "and's" of the Bible. The usual effect is, again, to increase emphasis: "Day after day the wind blew, and the snow melted, and the ground appeared, and thawed, and clucked like a hen . . ." (Sylvia Townsend Warner, *Summer Will Show,* New York, Viking Press, Inc., 1936, p. 25). These repetitions likewise affect the rhythm of the sentence or passage, as do anaphora, repetition of the beginning word or phrase; and anadiplosis, repetition of the last word or phrase.

Faulty or needless repetition is called pleonasm, tautology or redundancy. Primitive folk ballads sometimes employ ungrammatical repetition for metrical purposes: "Mary, she said," for "Mary said." Wasteful use of words is called circumlocution, verbosity, prolixity, and is an error of syntax and style rather than true figures of speech.

OTHER FIGURES

Etymological Figures. — Etymological figures include aphaeresis, omission or elision of a syllable ("'neath" for "beneath"; "'twas" for "it was"); syncope, elision of middle letter ("ne'er" for "never"); apocope, dropping or elision of a final letter or sound ("mo'" for "more"; "mos'" for "most"); prothesis, prefixing of a syllable — sometimes reverting to a more archaic form of the word — for emphasis or rhythm ("arunning" for "running"; "beloved" for "loved"); paragoge, adding a syllable at the end of a word ("deary" for "dear"; illiterate "drunken" for "drunk"); diaeresis, the separation of a diphthong into two vowels — or resisting elision of two vowels —, indicated by two dots over the second vowel (coöperate, Thaïs); synaeresis, the opposite of diaeresis (Harvard students call their "Coop. Store" the "Coop." rhyming with "dupe"); tmesis, inserting a word between compounds ("which thing soever" for "whichsoever thing").

Orthographic Figures. — Figures of orthography include mimesis, which is deliberate misspelling for comic effect or mimicry of dialect, as when Josh Billings claimed that "Hamericans speak Hinglish"; metathesis, displacing of a letter or syllable ("Fastolph" for "Falstaff"); and archaism, the resurrection of a word or expression no longer in common usage ("fain" for "glad"; "forsooth" for "in truth"). But none of these are especially important in modern literature. In fact, the linguistic study of figures of speech has been largely superseded by psychological and esthetic analysis of imagery, which includes any use of words for sense-appeal.

LITERARY STUDY OF FIGURES OF SPEECH

The Literature of Figures of Speech. — The Greeks and Romans of classical antiquity and both medieval and Renaissance scholars of Europe elaborately classified, defined and rationalized the use of figures of speech. Such a list is found in Quintillan's *Institutio Oratoria* in the 1st century A.D. In the 16th century George Puttenham translated the classical names into English. Aristotle's observations in his *Rhetoric* (4th century B.C.) on the use of metaphors are still sound. To adorn, he says, borrow metaphors from things superior; to disparage, from things inferior. "It is proper to derive metaphors . . . from objects which are closely related to the thing itself but which are not immediately obvious." Metaphors should suggest things beautiful in sound, in association, or have a strong sense-appeal. Note the epithet (another classical figure much used by Homer) in "rosy-fingered dawn." Observe the difference in literal "purple," "red" or even figurative "purple-fingered" or "red-fingered."

The unintentional degrading of a subject by using metaphors of low or repulsive associations has been definitively treated by Alexander Pope in "The Art of Sinking in Poetry." This can be illustrated by a passage in Shakespeare's *Henry V* when the King boasts (IV, iii):

> And those that leave their valiant bones in France,
> Dying like men, though buried in your dunghills,
> They shall be fam'd; for there the sun shall greet them,
> And draw their honours reeking up to heaven,
> Leaving their earthly parts to choke your clime,
> The smell whereof shall breed a plague in France.

Hugh Blair, an 18th-century Scottish rhetorician, calls this "a gross transgression. . . having mentioned a dunghill, [Shakespeare] presently raises a metaphor from the steam of it; and on a subject, too, that naturally led to much nobler ideas."

The Function of Figures of Speech. — Figures of speech have often been regarded as mere decoration, or even as deceptive or insincere. Because in classical Greece they were cultivated and taught by the Sophists, Plato distrusted the trickery of professional rhetoricians, though he himself was a master of figurative language; and Aristotle, as has been seen, rationalized the use of metaphor. If intelligently employed, all the figures of speech promote clarity and vigour of thought and expression. Far from being useless decoration, figures may be an essential part of the thought — or *the* thought, as when Isaiah says "All flesh is grass." In the case of onomatopoeia, the word imitates the sound made by the subject, and all good figures are a kind of intellectual onomatopoeia. *See* also ALLITERATION; ONOMATOPOEIA.

FIJI, a British colony consisting of an archipelago in the Pacific ocean. betaeen 15° and 22° S. and on or about the meridian of 180°. There are more than 300 islands, varying greatly in size, with a total area of 7.055 sq.mi. Suva, the capital, is situated in the southeast of Viti Levu (4,114 sq.mi.), the principal island of the group. Suva has a population (1956) of 37,371 (metro.). The island is mountainous in the interior, and the Rewa river is navigable by small craft for 70 mi. Vanua Levu (2,393 sq mi.) is the second island in size and lies 40 mi. N.E. of Viti Levu. Other islands of some importance are Taveuni (168 sqmi.), which has highly developed plantations; Kandavu (158 sq mi.). the first landfall for ships and planes approaching Suva from the south; Ovalau, rich in historical associations centred round Levuka, the early capital of the colony; and Makongai, known for its leprosy hospital, which serves a large area of the South Pacific. The dependency of Rotuma (18 sq.mi.) lies about 400 mi. to the north.

Physical Features. — The larger islands are of volcanic origin and are mountainous, with peaks of over 3.000 ft., the highest being Mt. Victoria (4,341 ft.) on Viti Levu. The surface of these islands is rugged and the vegetation is tropical in its luxuriance. The smaller islands are of the low coral reef type, and the larger islands are surrounded by coral reefs. The southern islands contain dense forests on the windward side, with many valuable woods, while the leeuard slopes are open grassland. The flora resembles that of New Guinea (*q.v.*).

The climate. for the tropics, is temperate, the temperature seldom falling below 60° F. or rising above 90°. The prevailing minds are the trades, but in this area they are easterly rather than southeasterly. At Suva, which has the climatic conditions of the windward coasts. the annual rainfall is 120.8 in., distributed throughout the year, whereas on the leeward coasts annual averages range from 70 to 90 in., but most of this rain falls during the four months of the hot season, from December to March, when there are northerly monsoonal winds. Tropical cyclones are of occasional occurrence, some part of the colony being affected by one almost every year.

History — The Dutch navigator Abel Tasman sighted a few islands in the northeastern part of the archipelago in 1643; Capt. James Cook visited the isolated southern island of Vatoa in 1774, and Capt. James Wilson of the missionary ship "Duff" discovered islands in northern Lau in 1797. Capt. William Bligh of H.M.S. "Bounty" recorded most of the islands when, after the mutiny, he went through the group in the track of the trade wind. J. S. C. Dumont d'Urville in the "Astrolabe" carried out a more accurate survey in 1827, but it was a U.S. exploring expedition that made the first thorough survey in 1840.

The trade in sandalwood attracted United States ships and East Indiarnen at the beginning of the 19th century, and for nearly 30 years the only Europeans known to the Fijians mere beachcombers and the crens of visiting ships. Firearms salvaged from wrecks were used in native wars and were largely the monopoly of the chiefs of the small island of Mbau, who. using muskets against clubs and spears, raised themselves to a dominant position. Traders and missionaries came to settle, the first missionaries (Wesleyans) arriving from Tonga in 1835; but the native wars continued and reached a climax in the 1850s when Thakombau, the most powerful chief, was driven back on Mbau. He renounced his ancient gods and became the champion of the missionaries. The issue then became a struggle between the old ways and the new. It was decided when the king of Tonga with 2,000 warriors came to the help of Thakombau and was completely successful. Thakombau then became paramount chief of western Fiji. In 1857 a British consul was appointed at Levuka. Shortly afterward the Americans demanded of Thakombau the payment of indemnities fixed three years previously for outrages suffered by United States citizens. The chief sought relief by offering to cede his territories to Great Britain. offering 200,000 ac. of land on condition that the United States claims were paid. The offer was turned down and the British consul was recalled. Finally, however, after the near ruin of the islands by a government of settlers who had set themselves up to administer under Thakombau, a deed ceding Fiji unconditionally was drawn up and completed on Oct. 10, 1874, and Fiji was proclaimed a possession and dependency of the British crown.

The outbreak of war in the Pacific in Dec. 1941 gave the Fiji archipelago an unexpected military significance. It became an important supply station on the route from the American west coast and Honolulu to Australia and New Zealand, and extensive installations mere constructed rapidly to facilitate air and naval warfare. It served as an advanced training area for the and New Zealand expeditionary force, and later it was a forward base for the United States military, air and naval forces.

Population. — The population in 1946 was 259.638; at the census of 1956 it was 345,737. comprising 148,134 Fijians, 169,403 Indians, 6,402 Europeans, 4,155 Chinese. 7.810 part-Europeans and 9,833 other Pacific races. At the time of the cession of Fiji in 1874 the population, composed almost entirely of Fijians, numbered about 200,000. Epidemics reduced the numbers, and the population reached its lowest point. 83,000, in 1919.

The development of the colony demanded more labour than could be found locally, and in 1879 the immigration of indentured labourers from India was started. By 1911 there were 43,000 Indians, in 1936 there were 85,000, and by 1956 the number was 169,403. This immigration was stopped in 1919. The hard-working Indians have gradually improved their economic status; from poorly paid indentured labourers they have mostly evolved into the position of leaseholders. Besides sugar cane, the Indians also cultivate rice, cotton and corn. (W. H. Is.)

The Fijian People. — The Fijians are of mixed ,Melanesian and Polynesian stock, Polynesian influence being most noticeable in the eastern islands where contact with Tongans and to a less extent with Samoans is evident in a lighter skin colour, straight rather than frizzy hair, and the more prominent position taken by the womenfolk in many customs. The social structure of the Fijians has predominantly Polynesian characteristics except in western Viti Levu. nhere the institution under which a chief holds office hereditarily subject to acceptability of his leadership by the people is not found. The physical features of the highlanders of Viti Levu are similar to those of other Melanesians, and they maintain that they are the autochthonous people of Fiji, in contrast with the large majority of Fijians, who trace their origin to an arrival by sea from the west. The dialects spoken by the Fijians belong to the Malayo-Polynesian group of languages, but the dialect of Mbau is understood, spoken and written throughout the archipelago.

Most Fijians live a communal life in villages on land they themselves own. With the gradual spread of industrial activities, however, the tendency has become marked for many Fijians to take up work in one of the several centres of population, where their traditional way of life is appreciably affected. Their houses in the villages are built with a timber framework and thatched walls and roof, but an increasing use is made of corrugated iron for roofs even in the remotest villages. The work of housebuilding is undertaken by the members of the social unit to which the householder belongs. The family house is usually about 2j or 30 ft. long by 18 or 2j ft. wide and is divided by screens of reeds or plaited bamboo or bark cloth into living and sleeping quarters. Kitchens are built separately near by. Many Fijians, however, have built themselves houses of timber and corrugated iron on a European plan. Fijians no longer build the tall, steep-roofed houses nor the huge double-hulled sailing canoes for which they are justly known as master craftsmen, but in some areas they continue to practise other crafts with consummate skill. Pottery is made without the use of a wheel; large cooking vessels, bowls and water containers are expertly made from clay and sand with wooden patting tools. Bark cloth is made from beaten-out lengths of the bast of a mulberry tree which are joined to make large sheets and then covered with intricate patterns in reddish brown and black. Mats are plaited from the leaves of a screw pine cultivated for the purpose and are used mostly for floor coverings or as bedding. All these three crafts are practised by women, and the products of their work are sold or bartered as well as being used for domestic purposes by the people themselves. Many of these products are decorated with stylized designs, the detail of which depends on the nature of the material used.

Elaborate ceremonial dress and personal decoration were worn on the numerous occasions when ritual was practised. Men wore a fringed kilt and arm and leg bands of coloured leaves, their faces were blacked and their hair was dusted with powdered yellow turmeric; women wore white or decorated bark cloth; and both sexes oiled their skins with scented coconut oil. A modified version of this customary dress is still worn on special occasions.

Some of the old customs were cruel, yet they were practised as an integral part of the Fijian way of living. They were gradually dropped during the second half of the 19th century under the influence of Christian missionaries; the leading Fijian chiefs agreed to abandon the worship of the spirits of their ancestors, usually performed through the medium of a priest who affected to determine the fate of such activities as warfare or fishing expeditions.

Certain ceremonies embodying a modicum of ritual little changed since pre-cession days are still carried out in all parts of Fiji. One which all Fijians regard as of much importance is the formal presentation of a tambua; that is, a sperm whale's tooth to the ends of which a plaited coconut fibre cord is attached for convenience in handling. This is offered as a token of good will on the occurrence of births, marriages and deaths, or on other special occasions, as, for example, council meetings. In each instance the party making the presentation accompanies it with a request, perhaps for nothing more than a reciprocal expression of good will or perhaps for something more tangible, such as permission to plant on a piece of communal land or help in time of trouble. The recipient is expected to carry out the request if he accepts the whale's tooth; if he cannot do so, he should not accept it. A kava plant is sometimes offered as a mark of good will on a less formal occasion instead of a whale's tooth, but as a preliminary to a council meeting both whale's tooth and kava plant are presented, and then follows the preparation of the kava drink, the first cup being offered with ritual to the senior chief present. Kava is a species of pepper plant, and the drink consists of a solution of the pounded root in cold water, strained of all bits of fibre; it is drunk as soon as it has been made. It is not alcoholic but it has a slight diuretic effect when large quantities are consumed. When prepared for ceremonial purposes kava used to be drunk in small quantities but in a strong solution;. the latent narcotic properties found in the root of this plant may then have caused slight temporary'muscular weakness, but it does not appear to have affected the mental powers.

TYPICAL THATCHED-ROOF HOUSES OF FIJI

Meetings that are of sufficient importance for these ceremonies to be performed are usually attended by large numbers of persons, who reciprocate the hospitality of the hosts by gifts of food, mats or bark cloth as well as by vigorous communal gesture-dances in which the precision of movement in unison is assisted by an orchestra using wooden gongs or bamboo stamping tubes.

An important aspect of the social organization of the Fijians is the inseparable connection between the social unit to which a person belongs and the land that all the members of the unit, chiefs and people alike, own in common. This common o nership by related groups of peoples of their family lands and of their customary fishing rights over the shore reefs is the basis of Fijian economic activities today, just as the principles of Fijian social organization have been successfully used, with modifications, as the foundation for the present system of native administration.

(G. K. R.)

Religion. — Out of a total population of 345.737. the 1956 census recorded 138,147, mostly Fijians. as Methodists and 137.206, all Indians, as Hindus. The total number of Christians nas 178,161 Roman Catholics numbering 27,542 and Anglicans 5,130. Indian Moslems numbered 25,394.

Education. — —In 1957 there were 508 primary schools with an enrolment of 65,645. There nere 32 secondary and postprimary schools with 3.480 and five postsecondary institutions with 216 The enrolment of girls is not far short of that of boys except in the case of Indians. where the difference is greater. Apart from government and a number of mission schools. village school committees, Indian organizations and two commercial concerns also maintain schools. In general the government trains and supplies moat teachers and administers the educational system. Voluntary bodies provide buildings for nongovernment schools and 25*s*. a year for each pupil. There are three technical centres and there is also at Suva a central medical school with 200 students training as assistant medical oractitioners. A number of students are maintained in higher educational institutions in New Zealand. Evening classes for adults in a number of professional and technical subjects are well developed at Suva. The literacy rate for Fijians is 87.62% and of Indians 35.62%.

Welfare. — Medical services are for the most part provided by the government. In 1956 there nere 2.160 beds and 23,120 hospital admissions. Outpatients numbered 347,039. Health is generally good. Tuberculosis is the most serious disease. Malaria does not occur. A government housing scheme for workers in Suva is in operation.

There is no provision for unemployment relief or social insurance or pensions. but indoor and outdoor relief is provided for the infirm, aged and destitute.

Administration. — Government is provided for under letters patent, 1937, and royal instructions. These provide for an executive council presided over by the governor and consisting of 3 ex

officio members and 6 nominated, and a legislative council with 16 official and 1j unofficial members, of whom 5 are European. 5 Indian and 5 Fijian. Roth the European and Indian representation is made up of three elected and two nominated members. There is also a Fijian administration which constitutes a local government system with jurisdiction over all Fijians in the colony. In order to protect them from exploitation Fijians are not permitted to alienate their land.

Production. — The economy of Fiji is primarily dependent on agriculture. The total area of land under cultivation is estimated at 350,000 ac. The principal export crops are sugar cane, coconuts and bananas, nith pineapples and miscellaneous fruits and vegetables as minor export crops. The colony produces most of its requirements of staple foods: rice, dalo (taro), yams, tapioca, pulses, fruits and vegetables.

Apart from gold mining, which is an important industry at Vatukoula near the north coast of Viti Levu, industrial production is limited to the processing of sugar cane, the dehydration of coconut meat in the preparation of copra, and the production of coconut oil, coconut meal and margarine.

Communications. — There are 798 mi. of all-weather surface roads and about 400 mi. of narron-gauge light railway operated by the Colonial Sugar Refining company. There are an airport and a flying boat base and four airstrips on the main islands. The main ports of call are Suva and Lautoka but shipping calls also at Levuka, Savusavu and Rotuma. *See* also PACIFIC ISLANDS.

FIKRET, TEVFIK (1867–191j), Turkish poet, who. continuing the work of Xbdiilhak Hâmid (*q.v.*), succeeded in freeing Turkish poetry from the rules of Persian literary composition and established the forms and themes of western poetry. Born in Istanbul of a central Anatolian family, the son of a government official, he was educated at the Galatasaray *lycée* where he later .became principal. Tradition bound in his early years. he soon came under the influence of French literature and in 1896 became the editor of the avant-garde periodical *Servetifünum* that gave its name to the literary school of the 1890s. Early sentimental poems about the humble and poor and simple descriptive pieces gave place to a series of powerful poems included in the *Rübabi Shikeste* and the *Haluk' un Defteri* in which the poet gave expression to his hatred of tyranny and fanaticism, his love of liberty and his faith in mankind's advancement. (F. I.)

FILAMENT is the cathode in one of the common types of vacuum tube for radio receiving sets. The filament may be the source of the electron (*q.v.*) emission which constitutes the current flowing through the vacuous space. (*See* CATHODE RAYS; ELECTRON TUBE; THERMIONICS.)

FILANGIERI, CARLO (1784–1867), PRINCE OF SATRIANO, Neapolitan soldier and statesman, was the son of Gaetano Filangieri (*q.v.*). At the age of 15 he decided on a military career and, having obtained an introduction to Napoleon Bonaparte, then first consul. was admitted to the military academy at Paris. He received a commission in an infantry regiment in 1803 and took part in the campaign of 1805 under Louis Nicolas Davout, first in the Low Countries and later at Ulm, Mariazell and Austerlitz, where he fought with distinction. He returned to Naples as captain on Masséna's staff to fight the Bourbons and the Austrians in 1806 and subsequently went to Spain, where he followed Joseph Bonaparte in his retreat from Madrid. In consequence of a fatal duel in 1810, he was sent back to Naples; there he served under Joachim Rlurat with the rank of general and fought against the Anglo-Sicilian forces in Calabria and at Messina. On the fall of Napoleon he took part in Murat's campaign against Austria and was severely wounded at the battle of the Panaro (1815). On the restoration of the Bourbon king, Ferdinand IV (I). Filangieri retained his rank and command, but found the army utterly disorganized and impregnated n·ith Carbonarism. In the disturbances of 1820 he adhered to the Constitutionalist party and fought under Gen. Guglielmo Pepe (*q.v.*) against the Austrians. On the re-establishment of the autocracy he was dismissed from the service and retired to Calabria. where in 1819 he had inherited the princely title and estates of Satriano.

In 1831 he was recalled by Ferdinand II and entrusted with various military reforms. On the outbreak of the troubles of 1848 Filangieri advised the king to grant the constitution. n·hich he did in Feh. 1848, but when the Sicilians formally seceded from the Neapolitan kingdom Filangieri was given the command of an armed force with which to reduce the island to obedience. In September he began the bombardment of Messina, which he captured (Sept. ?) after very severe fighting. He then advanced southward, besiege? and took Catania, where his troops committed many atrocities, and by May 1849 he had conquered the whole of Sicily, though not without much bloodshed. He remained in Sicily as governor until 18jj, when he retired into private life, since the hostility of Giovanni Cassisi. the minister for Sicily, prevented his carrying out the reforms that he desired. On the death of Ferdinand II (May 22, 1859) the new king, Francis II, appointed Filangieri premier and minister of war. He promoted good relations with France, then fighting with Piedmont against the Austrians in Lombardy, and strongly urged on the king the necessity of an alliance with Piedmont and a constitution as the only means whereby the dynasty might be saved. These proposals being rejected, Filangieri resigned his office. In June 1860 Francis at last promised a constitution, but it was too late, for Giuseppe Garibaldi was in Sicily and Naples was seething with rebellion. On the advice of Liborio Romano, the new prefect of police, Filangieri was ordered to leave Naples. He went to Marseilles with his nife and subsequently to Florence, where at the instance of Gen. A. F. La Marmora he undertook to write an account of the Italian army. Although he adhered to the new government he refused to accept any dignity at its hands. and died at his villa of San Giorgio a Cremano. near Naples. on Nov. 2, 1867. *See* also NAPLES, KINGDOM OF.

His biography was written by his daughter, Teresa Filangieri Fieschi Ravaschieri, *Il Generale Carlo Filangieri* (1902), an interesting although somewhat too laudatory volume based on the general's own unpublished memoirs. *See* also P. Cala Ulloa, *Di Carlo Filangievi nella storia de' nostri tempi* (1871) ; V. Finocchiaro, *La Rivoluzione siciliana del 1848–49,* with bibliography (1906).

FILANGIERI, GAETANO (1752–1788), Italian lawyer, author of an influential work on legislation in which he advocated economic, legal and religious reforms, was born at Naples on Aug. 18. 1752. His father planned a military career for him. but he soon abandoned it for the study of law. At the bar his knowledge and eloquence early secured his success, while his defense of a royal decree reforming abuses in the administration of justice gained him the favour of the king, Charles, afterward Charles III of Spain, and led to several honourable appointments at court. The first two books of his great work, *La Scienza della legislazione,* appeared in 1780. The first book contained an exposition of the rules on which legislation in general ought to proceed, while the second was devoted to economic questions. These two books showed him to be an ardent reformer and vehement in denouncing the abuses of his time. He insisted on unlimited free trade and the abolition of the medieval institutions which impeded production and national well being. Their success was great and immediate not only in Italy but throughout Europe at large. In 1783 he married, resigned his appointments at court and, retiring to Cava. devoted himself steadily to the completion of his work. In the same year appeared the third book, devoted entirely to the principles of criminal jurisprudence. The suggestion which he made in it as to the need for reform in the Roman Catholic Church brought upon him the censure of the ecclesiastical authorities. and it was condemned by the Congregation of the Index in 1784 In 178j he published three additional volumes, making the fourth book of the projected work and dealing with education and morals. In 1787 he mas appointed a member of the supreme treasury council by Ferdinand IV, but his health, impaired by close study and overwork in his new office. compelled his withdrawal to the country at Vico Equense. He died on July 21, 1788, having just completed the first part of the fifth book of his *Scienza.* He left an outline of the remainder of the work, which was to have been completed in six books.

The best edition of the *Scienza* is that by Villari, 3 vol. (1864–76) ; the book was translated into most of the European languages, Eng. trans. by R. Clayton, *The Science of Legislation* (1806).

FILARETE (ANTONIO DI PIETRO AVERLINO or AVERULINO) (*c.* 1400–1469), Italian sculptor and architect, who from 1433 until 1445 was employed in Rome on the bronze door of St. Peter's, is thought to have been born in Florence and trained under Ghiberti. In 1448 he fled from Rome back to Florence, entering in 1451 the service of Francesco Sforza, duke of Milan. In Milan he was active principally as an architect, and designed the Ospedale Maggiore (1457–65), the first Renaissance building in Lombardy. Between 1460 and 1464 Filarete wrote his *Trattato d'architettura.* Inspired by Leone Battista Alberti's *De re aedificatoria,* this describes a model city called Sforzinda, and was dedicated to Piero de' Medici, for whom Filarete made a bronze reduction of the equestrian statue of Marcus Aurelius, now in the Albertinum, Dresden (1465). According to Giorgio Vasari, he returned in 1465 to Rome, where he died.

The two wings of the famous door at St. Peter's are divided into unequal rectangular areas, with figures of God the Father and the Virgin Mary, St. Peter and St. Paul, and representations of the martyrdoms of these saints. Between them are historical scenes, and in the foliated borders are figures from classical mythology. By comparison with the bronze doors of Lorenzo Ghiberti and Donatello in Florence, Filarete's door is ill-planned and crudely executed, and its importance derives from its hieratic classicizing style. The first Renaissance monument of a specifically Roman type, it influenced the work of Isaia da Pisa and later Roman sculptors. (J. W. P.-H.)

FILARIASIS. This group of infections is caused by slender, threadlike roundworms called filariae (*see* NEMATODA). Filariae are parasitic in blood, tissues and body cavities of a great variety of animals, including man.

The principal human filariae are *Wuchereria bancrofti, W. malayi, Onchocerca volvulus* and *Loa loa.* The resulting infections are Bancroftian filariasis, Malayan filariasis, onchocerciasis and loaiasis, respectively. Filarial worms of lesser medical importance include *Acanthocheilonema perstans,* A. *streptocerca* and *Mansonella ozzardi.*

Many characteristics are shared by the four principal human filariae. Adult female worms living in body tissues give birth to large numbers of microscopic, motile embryos called microfilariae, which appear either constantly or periodically in blood or lymph vessels of the skin of an infected person. Unless ingested by suitable insect hosts (mosquitoes for *W. bancrofti* and *W. malayi,* black flies for *O. volvulus* and deer flies for *L. loa),* microfilariae cannot develop further and are destroyed by the human body. However, once in their particular insect host, microfilariae migrate quickly from the digestive tract to selected tissues, where, after about two weeks, they complete a series of growth stages. Then, as infective larvae, they move to the mouth parts of the insect to await transfer to a new human host. As the insect takes another blood meal, the larval worms escape onto or into the person's skin and penetrate to subcutaneous tissues or lymph vessels. Little is known of the development of larvae in man, except that the worms mature in about a year.

SHEATHED EMBRYO (MICROFILARIA) OF WUCHERERIA BANCROFTI, THE CAUSATIVE ORGANISM OF BANCROFT'S FILARIASIS. AS SEEN IN THE BLOOD OF A PATIENT AT MIDNIGHT. ORIGINAL X 300

Bancroftian Filariasis.—Adult *W. bancrofti* live in lymphatic vessels and lymphoid tissues, especially in the pelvic region. Microfilariae usually show nocturnal periodicity, swarming into cutaneous blood vessels at night and migrating to internal organs, especially the lungs, during the day. In inhabitants of certain South Pacific islands, however, microfilariae are present continuously in peripheral blood. Some authorities regard this nonperiodic form as a separate species, *W. pacifica.*

Bancroftian' filariasis is widely but unevenly distributed in the tropics. It occurs along the coasts and watercourses of tropical Africa and of Asia from Arabia to China, along the northeastern coasts of Australia and South America, and on many tropical islands in the Pacific and Indian oceans and the Caribbean sea.

The principal mosquito vectors are *Culex fatigans,* C. *pipiens* and *Aedes polynesiensis.* Several species of *Anoplzeles* are of local importance.

Many infected persons have no symptoms of disease. When symptoms do occur, they may appear as early as $3\frac{1}{2}$ months after infection. Lymphangitis (inflammation of lymph vessels) and lymphadenitis (swelling of lymph nodes) near the worms are early symptoms. Acute attacks last a week or less, then subside, only to recur at irregular intervals of time. Between attacks the affected lymphatics remain swollen but not painful. These reactions probably result from sensitization of tissues to filariae. Severity of symptoms is intensified by secondary bacterial infections.

After repeated attacks, chronic disease causes blockage of lymph channels. The arms. legs. scrotum or breast may become permanently swollen (elephantiasis). Deeper lymphatic channels of the body may rupture into the bladder, body cavity or tunica vaginalis.

Effects of medicinal treatment on filariasis are not consistent. Diethylcarbamazine, arsenicals and antimonial compounds are valuable in eliminating microfilariae and perhaps adult worms, but their effectiveness against filarial disease is unproved. Surgical treatment offers relief from chronic forms of the disease (elephantiasis. etc.). but these conditions tend to relapse.

Prevention of Bancroftian filariasis consists of antimosquito measures, protection from mosquito bite and use of antifilarial drugs (especially diethylcarbamazine) to reduce microfilarial infections in the human population.

Malayan **Filariasis.**—Infections with *W. malayi* generally resemble those with *W. bancrofti.* However, both adult worms and microfilariae of the two species can be differentiated. Other distinctive characteristics of *W. malayi* are its distribution and its mosquito vectors. *W. malayi* is found in river valleys of southeastern Asia from India to southern Korea and on adjacent islands. Several species of *Mansonia* mosquitoes are the principal vectors. Control of Malayan filariasis was complicated by discovery of microfilariae that appear to be *Ti'. malayi* in Malayan monkeys.

Onchocerciasis.—Adult *O. vulvulus* are found either free or in tumours in subcutaneous tissues. Related species of *Onchocerca* occur in other animals. Onchocerciasis is prevalent in equatorial Africa and in coffee-growing areas of Mexico, Guatemala and Venezuela. Several species of black flies transmit *O. volvulus (see* BLACK *FLY).*

Early in the infection, adult filariae wander freely in subcutaneous tissues, but eventually they are trapped by growth of fibrous tumours around them. Microfilariae are found in nodules and the skin. Few appear in peripheral blood. In Africa, nodules are most abundant on the trunk, thighs and arms. but in Central America they occur most commonly on the head and shoulders. The nodules vary in size and firmness and may provoke intense itching but are otherwise painless. Wandering microfilariae may enter the eyes through small lymphatic vessels, become trapped and eventually cause blindness. Impaired vision is found in 30% of infected persons in Guatemala and up to 85% in Belgian Congo.

Surgical removal of tumours is recommended, since this eliminates the source of microfilariae. Suramin sodium and diethylcarbamazine rapidly destroy microfilariae but also may precipitate severe allergic reactions. Application of DDT as an emulsion to rivers in Africa effectively controlled black fly populations. In Guatemala. however, these flies breed in tiny mountain streams that are difficult to locate and control. *See* also BLINDNESS

Loaiasis.—Adult *Lou loa* lives freely in subcutaneous tissues. Microfilariae. usually with diurnal periodicity, are found in peripheral blood. Loaiasis is found in equatorial rain forests of Africa, and several species of *Chrysops* (deer flies) act as vectors. *Loa* produces a chronic disease characterized by itching, irritation and fugitive snellings. The latter, known as Calabar swellings, are temporary inflammatory reactions appearing suddenly and disappearing in about three days. They probably result from sensitivity to the parasite or its products. In their wanderings adult worms may pass through the anterior chamber of the eye, hence the name "eye worm." They do not materially affect vision.

Diethylcarbamazine destroys microfilariae and, in recently acquired infections, adult worms as well. Long-established infections are more resistant to chemotherapy. Adult worms can be removed surgically when they move close to the surface of the skin.

Prevention of loaiasis includes use of antifilarial drugs to reduce human sources of infection and vector control measures. In some areas, control is seriously complicated by loaiasis in monkeys. *See* also PARASITIC DISEASES.

FILBERT, the name applied to plants and nuts of the genus *Corylus (see* HAZEL). This genus includes at least 11 known species of deciduous, catkin-bearing plants which together nearly encircle the land portion of the globe in the north temperate zone. The filberts C. *americana* and the beaked filbert, C. *cornuta,* attain heights of 10 to 15 ft.; the California filbert: C. *californica,* sometimes grows to 30 ft. The other species are the Chinese filbert, *C. chinensis;* the European filbert. C. *avellana;* the giant filbert. *C. maxima;* the Himalaya filbert, C. *ferox;* the Japanese filbert, *C. sieboldiana;* the Siberian filbert. C, *heterophylla;* the Tibetan filbert. *C. tibetica;* and the Turkish filbert. C. *colurna.* Hybrids between several of the species have occurred naturally or under cultivation. The American and beaked filberts have been used as pistillate parents in crossing with choice varieties of the European filbert to breed hardy varieties for use in the northern states and British Columbia. Breeding filberts by making backcrosses on the chance-hybrid Rush variety was begun in 1919 by J. F. Jones of Lancaster, Pa. Later breeding by J. U. Gellatly, Westbank, B. C., utilized the beaked filbert from the Peace river valley. The U.S. department of agriculture and the New York Experiment

J. HORACE MCFARLAND CO

AMERICAN FILBERT (CORYLUS AMERICANA)

station introduced some hybrid varieties after 1950.

The European and giant filberts, together with some of their natural hybrids, furnish the commercial varieties under cultivation in Europe, Turkey and the United States. The plants range from shrubs to trees 25 ft. in height. In various parts of Asia, varietal selections for local use have been made from the Himalaya and Siberian species. The Chinese and Turkish filberts are free growing species, the former reaching heights of 120 ft. and the latter of 60 ft. or more. As known in western Europe and the United States, the nuts of both are rather small, thick-shelled and of mild flavour. Nevertheless, both are important food producers in their respective habitats. Ornamental shrubby filberts include the Japanese with its red catkin flowers, the Winkler American variety with its red fall colour and the well-known purple foliaged variety of giant filbert. One variety has contorted limbs.

Culturally, the European filbert requires a cool to cold, but not rigorous climate, a definite period of winter chilling, a deep, medium rich soil. freedom from dense shade, an abundance of one-year wood for fruiting and pollen from other varieties. Wherever it grows, it is likely to be vulnerable to winter injury; the staminate flowers may be killed for part or all of their length. or the branches may be frozen back. Flower injury, which is more common in most varieties, may occur during midwinter or while the pollen is being shed. It is most frequent when the flowers are open, when daily minimum temperatures suddenly drop from above freezing to several degrees below and when there are strong accompanying winds. Actually the damage is more largely due to desiccation by wind than to low temperatures, and it may be prevented to a great extent by windbreaks.

Filbert roots penetrate deeply into the soil; where hardpans are less than ten ft. below the surface, the trees do not perform well after the first few years. All species tolerate considerable shade, but when this becomes too great, fruiting falls off sharply. By English systems of pruning, the trees are appreciably dwarfed as they are hard-pruned in late winter after the pollinating period is over and again in summer by merely nipping off certain new shoots. In Oregon and Washington valleys pruning is mostly limited to opening up the branches to permit the sun to reach all of the fruiting spurs, and to controlling the suckers which, with most varieties, tend to spring up thickly about the base of the tree. Also in the Lnited States, all new plantings include trees of pollinizer varieties at regular intervals throughout the orchard. The usual ratio of pollinizers to the principal varieties is 1 to j or 8.

In England and the U.S. many varieties are grown. In England. Kentish Cob, the favourite, bears a large. attractive appearing nut u-hich is oblong, wide and thick, and of excellent eating quality. Of the United States varieties, the first and a second in popularity are Barcelona and Du Chilly. The former bears a nut of irregularly rounded form, but of large size. The tree is a stronger grower and a more fruitful bearer than Du Chilly, though the nut is not its equal in fine flavour. Du Chilly resembles Kentish Cob so closely as to seem to be identical with it. Royal is a giant fruited variety of Oregon origin. Germany has produced hardy varieties. Turkey, Italy and Spain were leading producers in the second half of the 20th century. The U.S. was a relatively small producer, mostly in Oregon and Washington. (J. C. McD.)

FILCHNER, WILHELM (1877–1957), German scientist and explorer who led the German antarctic expedition of 1911–12, was born at Munich on Sept. 13. 1877, and was educated at the Prussian militafy academy. A journey across the Pamirs in 1900 aroused his scientific curiosity and was followed by an expedition to Tibet in 1903–05. In 1911–12 he took a German expedition to Antarctica in the "Deutschland," having previously visited Spitsbergen (1910) to test equipment. In Antarctica Filchner discovered the southwestern continuation of Coats land and made observations of ice drift in the Weddell sea. War frustrated plans for a second expedition. In 1926–28 he led a further expedition to Tibet carrying out cartographic surveys and magnetic observations. In 1939–40 he made a magnetic survey of Nepal. The period of World War II he spent in India. He died in Zurich on May 7. 19j7.

His published accounts of his travels include *Ein Ritt über den Pamir* (1903); *Das Ratsel des Matschu* (1907); *Zum sechsten Erdteil* (1922); Om *mani padme hum* (1929); *Bismillah* (1938); *Ein Forscherleben* (1950). (H. G. KG.)

FILE-FISH or **TRIGGER-FISH,** the name given to fishes of the genus *Balistes* of the family Balistidae and sub-order Balistiformes, inhabiting all tropical and subtropica! seas. The body is compressed and not covered with ordinary scales, but with small juxtaposed scutes. The first of the three dorsal spines is very strong, roughened in front like a file and hollowed out behind to receive the second much smaller spine, which, besides, has a projection in front, at its base, fitting into a notch of the first. Thus these two spines can only be raised or depressed simultaneously, in such a manner that the first cannot be forced down unless the second, which has been compared to a trigger, has been previously depressed. Both jaws are armed with eight strong incisor-like and sometimes pointed teeth, by which these fishes are enabled to break off pieces of madrepores and other corals on which they feed, and to chisel a hole into the hard shells of Mollusca in order to extract the soft parts. In this way they do much injury to pearl-fisheries. The related file-fish (*Monacanthus*) has only one dorsal spine and a velvety skin. Some 30 different species are sometimes referred to as *Balistes*. About coral reefs of the Indian and Pacific oceans there are brightly coloured, boldly patterned trigger-fishes (*Balistapus rectangulus* and *B. aculeatus)* with the Hawaiian name "humuhumu-nukunuku-apua'a," which are reputed to be poisonous to eat.

FILELFO, FRANCESCO (1398–1481), Italian humanist whose life and works illustrate the power acquired by men of letters in 1 jth-century Italy. He was born at Tolentino, July 25, 1398 In 1421 he went to Constantinople, returning to Italy in 1427, and from then until his death (July 31, 1481, at Florence) he moved from one city to another as a teacher of classical languages and literature. Exceptionally productive was the period spent in the service of the dukes of Milan, from about 1440 until 1471. His literary output, in Latin. Greek and Italian, was, like his culture, unusually extensive. including epic and lyric poetry, erudite classical works and treatises on philosophy. His most interesting achievement was his large collection of letters, an invaluable source of information on the period.

Filelfo's work is relatively unimportant as a contribution to philology or the history of poetry, but his life and writings together are of significance in the social history of his time since they show the influence letters had acquired. His services were eagerly sought by nearly all the Italian princes, who offered him the money and power for which he was ambitious in return for the subjection of his personality and principles.

In Filelfo is epitomized the division of literature as a profession from moral considerations and personal feelings which was to constitute one of the main features of Italian history until the Risorgimento.

FILIBUSTER, a name originally given to the buccaneers (*q.v.*). The term is probably derived from the Dutch *vry buiter,* "freebooter"; it was revived in the L.S. to designate those adventurers who, after the termination of the war between Mexico and the United States, organized expeditions within the United States to take part in West Indian and Central American revolutions. The modern use of the word in this sense denotes one who engages in private warfare against any state.

With the passage of time, the term has taken on another meaning applicable to legislative bodies and especially to the United States senate. It refers to the practice of using delaying tactics or engaging in prolonged discussion for the purpose of preventing a vote. It is consequently a device whereby a determined minority by delay and interminable debate seeks to prevent the majority from expressing its will in legislation. The intent is to wear out the majority so that from fatigue or under the pressure of other business, it will give up and either lay aside the pending measure or alter it significantly to induce the minority to lay aside the filibuster. It is thus a stratagem to make the minority — rather than the majority—will prevail.

In the C.S. house of representatives a minor form of filibustering is sometimes carried through by frequent quorum calls. But the power of the rules committee to prescribe limits on debate normally assures the house of the ability to come to a vote. It is in the U.S. senate that the practice of filibustering has found its fullest development. Its effectiveness is greater near the end of a session when pressure to adjourn is great, the time is short and there tends to be a mass of other legislation to pass upon.

In most deliberative bodies attempts at filibustering can be prevented by the parliamentary action of moving the previous question. This motion, like those to adjourn and to lay on the table. is not debatable. If this motion carries. then the vote on the pending business must immediately take place. The United States senate had such a previous question rule from 1789 and 1806, and it mas widely used in the British parliament in the 17th and 18th centuries. From 1789 to 1828 the presiding officer of the senate also had, in practice, the unappealable power to stop superfluous motions and tedious speeches, and evidence seems to indicate that this power was used by vice-presidents John Adams. Thomas Jefferson and Aaron Burr.

In 1825 John Randolph of Virginia was elected to the senate and proceeded to make irrelevant and tedious speeches which Vice-Pres. John C. Calhoun refused to rule out of order. In 1828, apparently in order to check such devices, the senate not only specifically provided that the presiding officer had such powers, but also made his rulings appealable to the senate itself. Apparently the purpose was to strengthen rather than weaken senate discipline by adding the weight of the majority to questions of order. A rule of relevancy was also available to limit debate.

But in 1872, Vice-Pres. Schuyler Colfax ruled that "under the practice of the Senate the presiding officer could not restrain a Senator in remarks which the Senator considers pertinent to the pending issue." With this ruling, the heyday of the filibusters arrived.

During the so-called Progressive era, from 1907 to 1917, the filibuster was used a number of times on ideological grounds, notably by Sen. Robert M. La Follette, Sr. and others against the Aldrich-Vreeland Banking bill of 1908, the Canadian Reciprocity bill of 1911, the Ship Purchase bill of 191j and finally Pres. Woodrow Wilson's Armed Merchant Ship bill of March 1917.

Rule 22.—This last filibuster by the so-called "willful 11" during the closing days of the 64th congress, as relations with Germany reached a crisis, led to the adoption of cloture provisions in the opening days of the 6jth congress. Under pressure from Sen. Thomas J. Walsh of Montana. rule xxii was amended so that a petition of 16 senators to close debate on "any pending measure" should, after two days' delay. be brought before the senate for a vote and could be passed by the affirmative votes of two-thirds of those present and voting. If this motion carried, then each senator was entitled to speak for not more than one hour on all motions, and dilatory motions or amendments were to be ruled out of order.

In the entire history of this version of rule xxii (1917–49), the closing of debate was successfully invoked on the treaty of Versailles in 1919, the World court in 1926 and on two other occasions. Though frequently tried, it was never affirmatively voted for the so-called civil rights bill of the 1930s and 1940s; *e.g.*, federal bills against lynching and use of the poll tax as a prerequisite to voting and bills for fair employment practices.

In 1949, a determined effort was made to modify rule xxii so that cloture would not be so difficult. But the move backfired when a coalition of the conservative, southern uing of the Democratic party and the middle western and western wing of the Republican party under the guise of broadening the rule to cover "motions or other matters" as well as "measures," made it more, rather than less, difficult to limit debate. This was done by requiring for passage of a cloture motion an affirmative vote of two-thirds of the members "duly chosen and sworn." A second change, although little noticed at the time, was even more important. namely. that there could be no limitation of debate on a motion to bring up a change in the rules. This new rule xxii, added to the historic underrepresentation of the populous states in the senate. was designed to give the senators of a small fraction of the people—from just 17 states—an unchangeable veto power over legislation.

Rules for the Senate.—A group of senators, however, believed that there was a crack in the filibuster defenses and that under the express constitutional provision that "each House may determine the Rules of its Proceedings" (art. i, sec. 5), it was possible for the senate. like the house, to change its rules at the beginning of a new congress without being inhibited by rule xxii itself. The opponents of this theory argued that the senate, as a "continuing body," carried over its rules from congress to congress and was, therefore, bound by rule xxii from the very beginning of a new congress.

A motion was therefore made by the proponents of a change at the beginning of the 83rd congress on Jan. 3, 1953 to proceed to the consideration of rules for the senate. After a brief debate, the Republican leader, Sen. Robert A. Taft, moved to table this motion, and this was done by a vote of 70 to 21. In Jan. 1957, this effort was renewed and again tabled. But this time there were 38 votes (and 3 others absent) against tabling the motion. During the discussion an opinion generally favourable to the motion was handed down by Vice-Pres. Richard M. Nixon.

Immediately following this vote! two main resolutions were presented for changing rule xxii. The majority and minority leaders. senators Lyndon Johnson and William Knowland, sponsored one which merely called for the re-establishment of the 1917 rule calling for cloture by a two-thirds vote of those present and voting, but also provided that senate rules should continue from one congress to the next and could only be changed in accordance with their own terms.

Sen. Paul H. Douglas of Illinois with 13 other senators presented an alternative resolution providing that after two days' notice on motion of 16 senators debate could be limited by two-thirds of those "present and voting," and after 15 days by an affirmative vote of a majority of those "duly chosen and sworn." The sponsors of this resolution pointed out that they wanted to provide for full and free debate, but that after a due period of discussion a majority was entitled to obtain a vote.

These resolutions were referred to the rules committee which. after full hearings by a subcommittee, in 1958 reported out the Douglas resolution by a majority vote. It was not called up for action by the senate leadership, and the proponents of a change in rule xxii announced that the battle to restrict filibustering would be a continuing one until successful.

FILICAIA, VINCENZO DA (1642–1707), Italian poet once highly esteemed for a wealth of sonorous verse on political and religious themes, was born at Florence, Dec. 30, 1642. He was educated by the Jesuits and studied law at Pisa university. He then returned to Florence where he devoted himself to literary studies. He secured the patronage of Christina of Sweden, entered the Arcadia (see ITALIAN LITERATURE), and was later appointed governor of Volterra (1696) and Pisa (1700) by Cdsimo III, grand duke of Tuscany. Filicaia won fame with six spirited *canzoni* (1684) on the relief of Vienna from the Turkish siege by John Sobieski and the Poles. His sonnets lamenting the fate of Italy (*e.g.*, "Dovè, Italia, il tuo braccio?") were also admired until well into the 19th century; and for Lord Macaulay he was a major poet. Yet to modern taste—except for a few religious lyrics. such as the lines "Alla beata Vergine"—Filicaia's verses seem bombastic and pretentious. He died at Florence, Sept. 24. 1707. His Poesie Toscane was published in 1707 and Poesie e lettere in 1864.

(D. M. WE.)

FILIGREE, jewel work of a delicate kind made with twisted threads usually of gold and silver. Though filigree has become a special branch of jewel work it was originally part of the ordinary work of the jeweler. A. Castellani states, in his *Memoir on the Jewellery of the Ancients* (1861), that the jewelry of the Etruscans and Greeks was made by soldering together and so building up the gold, rather than by chiseling or engraving the material. The art may be said to consist in curling, twisting and plaiting fine, pliable threads of metal, and uniting them at their points of contact with each other, and with the ground, by means of gold or silver solder and borax, by the help of the blowpipe. Small grains or beads of the same metals are often set in the eyes of volutes, on the junctions or at intervals at which they will set off the wirework effectively. The more delicate work is generally protected by framework of stouter wire. Brooches, crosses, earrings and other personal ornaments of modern filigree are generally surrounded and subdivided by bands of square or flat metal giving consistency to the filling up.

The Egyptian jewelers employed wire, both to lay down on a background and to plait or otherwise arrange *à jour*. But, with the exception of chains, it cannot be said that filigree work was much practised by them. Their strength lay rather in their cloisonné work and their molded ornaments. Many examples, however, remain of round plaited gold chains of fine wire, such as are still made by the filigree workers of India, and known as Trichinopoli chains. In ornaments derived from Phoenician sites such as Cyprus and Sardinia, patterns of gold wire are laid down with great delicacy on a gold ground, but the art mas advanced to its highest perfection in the Greek and Etruscan filigree of the 6th to the 3rd century B.C.

It is probable that in India and various parts of central Asia filigree has been worked from the most remote period without any change in the designs. Indian filigree workers retain the same patterns as those of the ancient Greeks, and work them in the same way. Very fine grains or beads and spines of gold, scarcely thicker than coarse hair, projecting from plates of gold are methods of ornamentation still used.

Passing to later times we may notice in many collections of medieval jewel work reliquaries, covers for the gospels, etc., made either in Constantinople from the 6th to the 12th century, or in monasteries in Europe, in which Byzantine goldsmiths' work was studied and imitated. These objects, besides being enriched with precious stones, polished, but not cut into facets, and with enamel, are often decorated with filigree. In the north of Europe the Saxons, Britons and Celts were, from an early period, skillful in several kinds of goldsmiths' work.

The Irish filigree work is more thoughtful in design and more varied in pattern than that of any period or country that could be named. Its highest perfection must be placed in the 10th and 11th centuries. The Irish National museum in Dublin contains a number of reliquaries and personal jewels, of which filigree is the general and most remarkable ornament. The "Tara" brooch has been copied and imitated, and the shape and decoration of it are well known. Instead of fine curls or volutes of gold thread, the Irish filigree is varied by numerous designs in which one thread can be traced through curious knots and complications, which, disposed over large surfaces, balance one another, but always with special varieties and arrangements difficult to trace with the eye. The long thread appears and disappears without breach of continuity, the two ends being generally worked into the head and the tail of a serpent or a monster. The reliquary containing the "Bell of St. Patrick" is covered with knotted work in many varieties. A two-handled chalice, called the Ardagh cup, found near Limerick in 1868, is ornamented with work of this kind of extraordinary fineness.

Much of the medieval jewel work all over Europe down to the 15th century. on reliquaries. crosses, croziers and other ecclesiastical goldsmiths' work, is set off with bosses and borders of filigree. Filigree work in silver was practised by the Moors of Spain during the middle ages. The Spanish filigree work of the 17th and 18th centuries is of extraordinary complexity, and silver filigree jewelry of delicate and artistic design is still made throughout the country. The manufacture spread over the Balearic Islands and among the populations that border the Mediterranean. It is still made all over Italy and in Malta, Albania, the Ionian islands and many other parts of Greece. That of the Greeks is sometimes on a large scale, with several thicknesses of wires alternating with larger and smaller bosses and beads, sometimes set with turquoises, etc., and mounted on convex plates, making rich ornamental headpieces, belts and breast ornaments. Silver filigree brooches and buttons are also made in Denmark, Norway and Sweden. Some very curious filigree work was brought from Abyssinia after the capture of Magdala — arm guards, slippers, cups, etc. *See* also SILVERSMITHS' AND GOLDSMITHS' WORK; JEWELLERY.

FILIPPI, FILIPPO DE (1869–1938), Italian scientist and explorer who led an important scientific expedition to the Karakoram range in central Asia, was born in Turin on April 6, 1869. He graduated in medicine at Turin university, and published a number of papers on physiological and biological chemistry. In 1897 De Filippi went to Alaska as scientific observer with the duke of the Abruzzi (*q.v.*) and climbed Mt. St. Elias. Although he did not accompany the expedition to the Ruwenzori in central Africa in 1906, he wrote the report. In 1909 he joined the duke's expedition to the western Himalaya and Karakoram mountains and in 1913–14 organized and led his own scientific expedition to the Karakoram under the auspices of the Indian government. De Filippi died at Florence on Sept. 23, 1938.

FILLAN (FAELAN), SAINT, the name of two saints of Irish origin; Fillan is the Scottish form of the name, Faelan the Irish. Very little is known about either of them.

A St. Faelan of Cluain Moescna (unidentified place name. somewhere in County Westmeath, Ire.) is entered in 8th-century calendars with a feast on Jan. 9. This was the date of several Fillan's fairs in medieval Scotland, showing the same patron. His crozier, still in existence (at the National museum, Edinburgh), was present at Bannockburn, with a relic of his arm. as one of the sacred battle ensigns of Scotland. His biography, as found in the medieval Breviary of Aberdeen, is unreliable.

The other St. Fillan, whose feast has been kept on June 20 from the 8th century onward, had churches dedicated to him at Kilwhelan (in the parish of Ballyroan, County Leix, Ire.) and in the district of Strathearn (in Perthshire, Scot.).

(PL. GN.)

FILLMORE, MILLARD (1800–1874), 13th president of the United States, came of a family of English stock which had early settled in New England. He was born on Jan. 7, 1800, in a log cabin built by his father and an uncle in a clearing made by them in the heart of the forest in the township of Locke, Cayuga county. in central New York. At 15 he was apprenticed to a wool carder and. except for intermittent brief attendances in a local one-room school, he had no formal education until he was 18 years of age. He then managed to secure six consecutive months of schooling and shortly after obtained his release as an indentured apprentice and started work in a law office. He was admitted to the bar in 1823 and, after a short time in Buffalo, practised law in and near the village of East Aurora until 1830 when he settled permanently in Buffalo.

Within 15 years he became one of the recognized political leaders of New York state; within 20 years he rose to the stature of a national figure and at the end of 30 years Fillmore became the president of the United States upon whom rested the burden of what proved to be one of the most fateful decisions in the history of the nation. In 1828 he was elected to the state assembly where he served three terms and secured the passage of a law abolishing imprisonment for debt. In 1833 he was elected to the U.S. congress as an anti-Jackson (antiadministration) man; he served 1837–43 as a Whig. During this period he had become one of the outstanding leaders of the northern wing of the Whig party and in his last term he was chairman of the all-powerful ways and means committee. In 1844 he was nominated as the Whig candidate for governor of New York. He was defeated by a narrow margin, but in 1847 was elected by a large plurality as the first comptroller of the state.

In 1848 the Whig national convention, which nominated Zachary Taylor for president, nith the strong support of Henry Clay nominated Fillmore for vice-president On the death of President Taylor (July 9, 1850) Fillmore became president.

Throughout the preceding decade agitation over the threatened extension of slavery into new territory had been steadily growing in intensity and reached its climax after the Mexican War when congress was confronted with the proposed admission of California to statehood. In his last speech, the dying Sen. John Calhoun sternly demanded recognition of the southern point of view favouring the extension of slavery into California and the southwest. His warning that the southern states might not remain in the union if these demands were denied, together with equally extreme demands by antislavery leaders. precipitated a crisis in the affairs of the Whig party as well as in the nation at large. To meet this, Senator Clay proposed a set of resolutions subsequently substantially embodied in legislative measures known as the Compromise of 1850.

President Taylor strongly opposed the adoption of these measures but Fillmore, becoming president upon his death, approved them. He reorganized the cabinet making Daniel Webster secretary of state, Thomas Corwin secretary of the treasury and John J. Crittenden attorney general. Fillmore had had nothing to do with the framing of the controversial measures and, while presiding over the senate, had scrupulously refrained from expressing any opinion. At heart, as he wrote to Webster, he detested slavery but viewed it as an evil which must be endured and given the protection of the constitution until it could be gotten rid of "without destroying the last hope of free government in the world." The alarm caused by the violent expressions of conflicting opinion, together with threats of secession, aroused his lifelong devotion to the cause of preserving the union. Joining with Webster, he exerted his influence openly in favour of Clay's proposals.

One of these measures was the Fugitive Slave law, introduced by Sen. James Mason of Virginia. making it the affirmative duty of the federal government to aid in the capture and return of slaves to their lawful owners. The attorney general advised that this statute was constitutional and, together with Webster, urged Fillmore to sign it, which he did. Fillmore publicly announced that if occasion required he would call upon the military to aid in the enforcement of the statute. In a real sense it was the enactment of this law, together with Fillmore's announcement, which disintegrated the Whig party. Throughout its history the party had been handicapped by the intrigue of ponerful discordant factions, the most extreme of which had been the radical abolitionists in the north and the equally radical leaders in the south seeking the extension of slavery.

For a year or more after the adoption of the compromise. agitation died down somewhat but the attempts as well as the failures of the federal government to enforce the Fugitive Slave law soon made slavery the one dominant political issue. In 1852, Webster became a candidate for the presidency along with Fillmore and Gen. Winfield Scott, with the result that the vote of the northern Whigs was split. Scott was nominated and defeated; Clay and Webster both died. Fillmore retired as president on March 4, 1853. In the next presidential contest of 1856, while traveling abroad, he was nominated by the new American party which sought to capitalize upon maintaining nativism and was nicknamed the "Know Nothing" party. Overnhelmingly defeated he never again sought public office but retired to Buffalo.

Several times in his career Fillmore had shown egregiously poor judgment: first, at its outset, in identifying himself with the political use of the anti-Masonic issue and later in accepting the nomination of the American party. both of these groups being saturated nith intolerance and prejudice. When the Republican party emerged in 1856 he viewed it as an insignificant group of northern extremists; but when the war came, consistent with his lifelong devotion to the union. he loyally supported Lincoln until 1864 nhen, discouraged by the failure to achieve victory. he voted for George McClellan.

In a very real sense Fillmore's support and defense of the Fugitive Slave law proved to be his political death warrant. At heart a consistent opponent of the extension of slavery, it is reasonably clear that in supporting the Compromise of 1850 he was dominated solely by his conscientious desire to preserve the union. His policies and decisions delayed for a decade the outbreak of the Civil War.

Throughout his career he was a constant advocate of expanding the internal development of the country, seeking particularly to unite the east with the far west. Equally important, he was one of the first national leaders to appreciate the importance of extending U.S influence in the Pacific. As president he sent Commodore Matthew C. Perry with a fleet to Japan in 1853, which resulted in the Japanese government altering its attitude and entering into trade and diplomatic relationships with the U.S.

Fillmore's successes in public life resulted from qualities of personal character. Although he mas not a dramatic or spectacular figure and throughout his public career he was handicapped by the jealousies and divisions in the Whig party, he consistently maintained an attitude of dignity, magnanimity, high-minded integrity and intense earnestness. In Buffalo he was a leader in founding the university, the general hospital. the Society of Natural Sciences, the Fine Arts academy, the Historical society and many other cultural institutions.

In domestic life he married (1826) the friend and counselor of his youth. Abigail Powers, by whom he had a daughter and a son. His first wife died in March 1853. and in 1858 he married Caroline C. McIntosh. Fillmore died at Buffalo on March 8. 1874. Most of his official papers were destroyed at the direction of his son.

See William E Griffis, *Millard Fillnzore* (1915); *Millard Fillnzore Papers,* Buffalo Historical Society, vol. x, xi (1908); Robert J. Rayback, *Millard Fillmore* (1959) (J L. O'B)

FILMER, SIR ROBERT (d. 1653), English political writer, champion of the divine right of kings, was born at East Sutton, Kent, and studied at Trinity college, Cambridge. where he matriculated in 1604. Knighted by Charles I at the beginning of his reign, he was an ardent supporter of the king's cause, and his house is said to have been plundered by parliamentarians ten times during the Civil War and he himself to have been imprisoned at Leeds castle in Rent. He died on May 26, 1653.

Filmer mas already a middle-aged man uhen the great controversy between the king and the commons roused him into literary activity. His writings afford an exceedingly curious example of the doctrines held by the most extreme section of the divine right party. His theory is founded upon the statement that the government of a family by the father is the true original and model of all government. In the beginning of the world God gave authority to Adam, with control over his descendants, even as to life and death From Adam this authority was inherited by Noah, and Filmer quotes as not unlikely the tradition that Noah sailed up the Mediterranean and allotted the three continents of the old world to the rule of his three sons. From Shem, Ham and Japheth the patriarchs inherited the absolute power which they exercised over their families and servants; and from the patriarchs all kings and governors derive their authority.

The difficulty that a man "by the secret will of God may unjustly" attain to power which he has not inherited appeared to Filmer in no way to alter the nature of the power so obtained, for "there is, and always shall be continued to the end of the world, a natural right of a supreme father over every multitude." The king is perfectly free from all human control. He cannot be bound by the acts of his predecessors, for which he is not responsible; nor by his own, for "impossible it is in nature that a man should give a law unto himself"—a law must be imposed by another than the person bound by it.

With regard to the English constitution, he asserted. in his *Freeholder's Grand Inquest touching our Sovereign Lord the King and his Parlianzent* (1648), that the lords only give counsel to the king; the commons only "perform and consent to the ordinances of parliament." and the king alone is the maker of laws, which proceed purely from his will.

The most complete expression of Filmer's opinions is given in the *Patriarcha,* which was published in 1680, many years after his death. His position, however. was sufficiently indicated by other works uhich he published during his lifetime.

Because of the circumstances of the time, Filmer's theory obtained a recognition which it is now difficult to understand. Nine years after the publication of the *Patriarcha,* at the time of the revolution uhich banished the Stuarts from the throne. Locke singled out Filmer as the most remarkable of the advocates of divine right, and thought it worth while to attack him expressly in the first part of the Treatise on Government, going into all of his arguments in order. He pointed out especially that even if the first steps of Filmer's argument are granted. the rights of the eldest born have been set aside so often that modern kings can claim no such inheritance of authority as he asserted.

FILMY FERN: see FERNS AND FERN ALLIES.

FILTERABLE VIRUSES: see VIRUSES.

FILTERS, LIGHT. Light filters are used in optics and photography to change the light which passes through them by absorbing some part of it. If they absorb the same fraction of all wave lengths, they are known as neutral density filters, and they change the intensity of the light, but not its colour. Most filters are coloured, because they absorb some parts of the spectrum selectively, and their uses are determined by the nature of this absorption.

Filters are made in several forms: (1) liquid filters in which solutions of dyes or coloured salts are held in shallow glass troughs with parallel sides; (2) solid filters of coloured glass; (3) dyed films of gelatin, cellulose esters and other plastics — these are frequently cemented between flat plates of optical glass; (4) gaseous filters. Still another type, the Christensen filter, consists of a liquid in which is a suspension of small transparent particles having the same refractive index as the medium but different dispersion. The greatest variety of filters, of high reproducibility and precise transmission characteristics, are in the form of gelatin film. They are prepared by coating a previously determined thickness of gelatin containing the necessary dyes upon plate glass, and after drying, stripping the gelatin film off the glass.

The colour of a filter is determined by the light it absorbs. Thus, a filter which absorbs blue from white light is yellow; a red filter absorbs blue and green; a green filter, blue and red; and a blue filter, green and red. The spectral absorption characteristics of a filter are best expressed by absorption or transmission curves (see figs. 1 and 2). They are measured on an instrument known as a spectrophotometer, which combines the properties of a spectroscope and a photometer

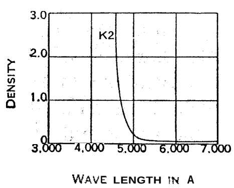

FIG. 1.—ABSORPTION CURVE OF YELLOW K2 FILTER

Filters are classified into several types according to their uses: (1) selective filters, which absorb much of the spectrum and transmit a narrow spectral region; (2) subtractive filters, which transmit most of the spectrum and absorb only a narrow spectral region (for every selective filter there can clearly be theoretically a subtractive filter of complementary colour); (3) compensating filters which transmit in greater or less intensity most of the spectrum, and which have gradual absorption characteristics.

Application of Light Filters. — Filters used in optics or photography may be classified according to their use as:

1. Compensating or correction filters. These are used to alter the response of a film to a particular light source so that the photograph appears more nearly in the relative tone values as perceived by the eye. For black and white photography they are yellow or pale green in colour, while for colour photography they may be pale blue, yellow, magenta or cyan. When colour film intended for use with daylight is used with tungsten filament lamps, or vice versa, a special blue or orange filter respectively must be used. Photometric filters are designed to change the effective quality of a light source and are used for visual photometry and photography.

2. Contrast filters. These are used to modify the brightness of a particular colour visually or in a photograph. If the colour is to appear lighter in a black and white photograph than in the original it is photographed through a filter of its own colour; if it is to appear darker, a filter of complementary colour is used.

3. Selective or separation filters are used for making two- or three-colour separation negatives for colour photography, and for projection in the additive colour processes (see fig. 2, and PHOTOGRAPHY: *Colour* Photography).

4. Haze filters are used to reduce or eliminate the effects of atmospheric haze in photography. They absorb ultraviolet and violet light, which are preferentially scattered by haze, and they are generally yellow. As greater haze penetration is desired, the filters shift to deeper yellow or red. Orange filters are used to increase visibility of distant objects through telescopes, binoculars, etc.

5. Monochromatic filters have sharp transmission bands, and are used to isolate particular lines from the spectra of gaseous-discharge lamps, such as the mercury arc.

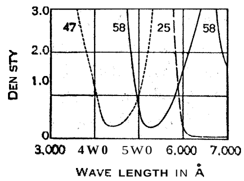

FIG. 2.—ABSORPTION CURVES FOR BLUE (47), GREEN (58), AND RED (25) FILTERS FOR THREE-COLOUR PHOTOGRAPHY

6. Ultraviolet and infrared filters are concerned with the invisible spectrum. Ultraviolet filters are generally made of glass, and usually have a narrow transmission band about the mercury line at 3,650A., and are opaque to visual light. Infrared filters are made to absorb most or all of the visual spectrum and to transmit the near infrared freely.

7. Safelights embody special filters designed to illuminate photographic darkrooms when used in conjunction with tungsten filament lamps. They are made for use with films, plates and papers of different spectral sensitivities, so that they may be handled in the safelight without being fogged in a reasonable time of exposure.

8. Polarizing filters polarize light very efficiently in the visual spectrum, and are used for producing polarized light effects, and reducing glare and reflections in photography.

9. Neutral density filters are gray in colour, and are made to absorb all visual wave lengths sensibly to the same extent. In photography they are used for reducing light intensity without changing its quality.

Filters which are made of dyes may be unstable, although the majority of the most commonly used filters are made of quite stable dyes. The manufacturer's specifications should be consulted. Gelatin filters cemented in glass, or solid glass filters, to be of the best quality, should have flat surfaces which are parallel. They are usually available in two degrees of quality: those which are useful in general photography with short focus lenses, and those for use with long focus lenses or in making separation negatives in photomechanical reproduction. In the case of the latter, a very high degree of optical quality is required.

(W. CK.; X.)

FILTRATION. In many industrial processes it is necessary to separate finely divided solid materials from liquids. The process of filtration consists in passing the liquid through a porous medium, which retains the solid particles. In some cases the recovery of the solid material is the main object; in others the filtration is done for the sake of purifying the liquid. Many types of filter are in use, differing in respect to (1) the various porous materials which are available for filtration; and (2) the construction of the apparatus in which these are applied.

Filter Materials. — The following are the main types of material which are in use:

1. Sheets of woven or felted material. These comprise porous filter paper, cotton, woolen or linen cloth, felt and woven metal.
2. Unwoven fibrous material, such as cotton, wool, linen fibre, cellulose pulp, metal fibres, sponge.
3. Granular or powdered materials, such as gravel, sand, earth, coke, sawdust, cork.
4. Porous plates of stone, porcelain, carbon, silica, etc.

The choice of material depends upon (a) the fineness of the substances to be filtered, (b) the chemical nature of the liquid, (c) convenience in collecting the solid material after filtration.

Laboratory Filtration. — Porous paper is generally used as the filter medium, being resistant to most of the liquids which require filtration. The commonest method of filtration is to fold a circular filter paper twice at right angles, and open it out to a cone with three thicknesses of paper at one side and one at the other. This is placed in a conical glass funnel. and the liquid is poured into it. In some cases. the filter funnel is provided with a hot-water jacket to keep the liquid warm during filtration. Filter paper is also manufactured in the form of thimbles, for extractions with solvents, such as alcohol and ether, in special apparatus. The Buchner funnel is made of porcelain and has a flat, perforated bottom on which a circular filter paper is placed. This form of filter has the advantage that the filtration may be assisted by the application of suction below the filter. The Gooch crucible is a porcelain cup with a perforated bottom. A thin layer of asbestos serves as the filter, and the crucible can be ueighed, after drying, to ascertain the weight of solid material collected. Filters are now made for laboratory use in which the porous material consists of a fritted mass of hard glass, which has been ground and sieved to a definite degree of fineness. This is made into disks, which are fused into various types of glass apparatus, and are resistant to almost all chemical reagents.

Filtration of Drinking Water. — Domestic filters are usually supplied in the form of earthenware vessels with filter beds of charcoal; in some cases filters of paper, asbestos or stone are used. It was originally thought that charcoal filters would unfadingly remove microorganisms, but the action was subsequently found to be less complete than had been believed. Indeed, if the filter material be not removed at intervals, it may become the seat of organic growths.

Large-scale filtration of town supplies of water is generally effected in sand filters.

Industrial Filtration — When possible, it is advantageous to allow the solid precipitate to settle in the liquor for some time, and to run off as much as possible of the clear liquid. The sediment may then be stirred up with water, allowed to settle and the liquid again decanted, so as to minimize the bulk of liquor to be filtered, and to facilitate the subsequent washing. The design of industrial filters varies according to the requirements. The chief considerations are that the filter shall present a maximum available surface without occupying too much factory space, that it shall withstand the required pressures, that it shall not be easily clogged, but shall be readily cleaned and easily controlled at all points. In some cases filters are designed to work continuously. Simplicity and economy of construction often outweigh all other considerations; thus for many purposes it is sufficient to filter through a bed of sand, or through a simple sheet of cloth resting on a flat, perforated support. Suspended bags of cloth are also frequently used, and have the advantage that the bag can be squeezed or wrung out after filtration to remove as much liquor as possible from the solid material.

Vacuum and Pressure Filters. — As in laboratory filtration, suction is frequently applied to accelerate the flow of liquid. A filter cloth is spread on a perforated plate of earthenware or other material, and the receiver into which the filtrate flows is connected with a vacuum pump. Conversely, pressure may be applied to the surface of the liquid in the filter. In place of cloth filters, porous plates are sometimes used; these may be either flat plates or cylindrical candles of porous material, presenting an increased filter area. Leaf filters may be used either for suction or pressure. A typical form of leaf consists of a rectangular frame of perforated pipes to which is attached a stiff, corrugated coating of coconut matting or other material, and the whole enveloped by a cloth bag. The liquid passes from the exterior to the interior of the leaf, and is assisted either by external pressure or by internal suction. A filtering unit consists of a number of parallel leaves, thus presenting a large filtering surface.

Filter presses are somewhat similar in principle. In one form, recessed plates are supported on a framework, so that they can be firmly pressed together by a screw press. Sheets of cloth are placed between the plates, and thus. when the filter press is assembled, it forms a series of narrow partitions separated by cloth filters. Channels are provided so that the sludge to be filtered can be forced under pressure between the cloth sheets, and the filtered liquid is collected from taps at the bottom of the plates. After filtration and washing, if necessary, the plates are separated. and the cake of solid material is removed. In place of recessed plates. some filter presses have alternate plates and distance frames. In centrifuges the filtration is assisted by the rapid rotation of a circular pan. The periphery of the pan is perforated, and covered on its inner side with a filter cloth, supported by a basket of metal. The rapid rotation (up to about 1,000 r.p.m.) uhizzes the liquid through the filter, with a force several hundred times greater than in gravity filtration.

Continuous Filters. — In the above-mentioned filters. the solid material has to be collected at intervals. and this necessitates interrupting the filtering operation. Continuous filtration can be effected by rotary filters. A hollow drum is supported in such a way that it can be rotated on a horizontal axis. The periphery of the drum is perforated and is covered with a filter cloth, and the drum dips into the liquid to be filtered. By suction, the liquid is drawn through the filter cloth to the interior of the drum, and the solid remains on the outside. The drum rotates slowly, and a scraper is fixed in such a position that it scrapes off the solid material continuously. In some cases, rotating discs are similarly used. A recent advance in filtration methods is the streamline filter, which permits the separation of very finely divided solid matter, which would pass through ordinary filter cloths. The liquid is forced through the edge of a pack of sheets of paper pressed tightly together. The channels between the sheets are so minute that the finest precipitates are retained. The filter is made in various forms to permit of continuous filtration, etc.

Coagulation as an Aid to Filtration. — The greatest difficulties in filtration are presented by slimy substances, which clog the filter. Increased pressure only accentuates the difficulty, and considerable importance attaches to methods whereby the slimy material may be caused to clot together and settle out. This can be effected by the addition of kieselguhr, fuller's earth, clay, talc, silica gel and various carbonates. Another procedure is to coat the filter with a layer of finely divided kieselguhr. boneblack, sawdust or some other finely porous material, which retains the slime and prevents it from penetrating into the filter material.

(R. C. F.)

FIMBRIA, GAIUS FLAVIUS (d. 84 B.C.), Roman soldier, partisan of Marius. He was sent to Asia in 86 B.C. as legate to L. Valerius Flaccus, but quarreled with him and was dismissed. Taking advantage of the absence of Flaccus at Chalcedon Fimbria revolted and slew Flaccus at Nicomedia. He then took command of the army and obtained several successes against Mithridates, whom he shut up in Pitane on the coast of Aeolis, and would undoubtedly have captured him had Lucullus cooperated with the fleet. Fimbria treated most cruelly all people of Asia who had revolted against Rome or sided with Sulla. Having gained admission to Ilium by declaring that, as a Roman, he was friendly, he massacred the inhabitants and burnt the place to the ground. But in 84 Sulla crossed over from Greece to Asia, made peace with Mithridates, and turned his arms against Fimbria, who committed suicide.

Fimbria's troops were made to serve in Asia until the end of the third Mithridatic War.

See MARIUS, GAIUS; ROME: Ancient History; SULLA, LUCIUS CORNELIUS.

FINALE, a term in music for the concluding movement in an instrumental composition, whether symphony, concerto or sonata, and in opera of the older type the concluding section of each act. Among instrumental examples the great choral finale to Beethoven's Ninth Symphony, and, among operatic finales, that of Mozart's *Nozze di Figaro*, to the second act, are famous.

FINANCE is that part of practical affairs which is concerned with money taken in a broad sense, to include not only that which is legally money (such as coin and paper money) but also bank credit or "credit money." Without suggesting that a word of such extensive practical application can be adequately defined by any simple formula. we may indicate its significance by saying that finance is "the art of providing the means of payment." The immediate aim thereby assigned to finance in any business is simply that of maintaining at all times an adequate cash balance (in money or bank credit). But the means employed include all the multifarious methods of borrowing money and of exchanging one sort of pecuniary right against another.

Subdivisions of Finance. — The following are the principal categories of finance in commercial enterprise:

(1) *Banking.* Banks create credit money by lending, and supply their customers with the means of payment.

(2) *The Money Market.* Closely associated with the banks, but distinguishable from them: is the money market, an organization for dealing competitively with short-term lending in the form of bills of exchange or day-to-day loans.

(3) *The Investment Market,* viz.:

(a) *The Stock Exchange,* where stocks, shares, bonds and debentures are bought and sold,

(b) *New Capital Issues,* or the raising of funds from investors for the promotion of new capital enterprises.

(4) The Foreign Exchange Market, where the means of payment in one country are exchanged for the means of payment in another.

(5) *Insurance,* including life insurance, which is a form of investment, and insurance against risks (such as fire or shipwreck).

Public Finance. — This is in a class by itself. Governments raise the means of payment:

(a) by taxation,
(b) by borrowing.

Taxation means compulsory contributions of money taken by authority of law from members of the community.

Governments have other resources. On the one hand they obtain money from state-owned enterprises, such as posts, telegraphs, telephones, railways or from state-owned property, such as forests or mines. On the other hand they exact services in kind, such as compulsory military service. But in any highly developed community taxation is the principal resource.

If revenue fails to meet expenditure, the deficiency has to be made good by borrowing.

Financial policy has to decide (1) how much revenue is to be raised and by what taxes, (2) how much public expenditure there is to be, and in what directions it is to be limited, (3) whether any of the expenditure is to be met by borrowing, and, if so, how much, and on what terms the money is to be borrowed.

The generally accepted principle is that revenue ought to meet expenditure, except

(1) expenditure of a clearly capital character, such as public buildings or income-yielding plant;

(2) emergency expenditure, so large in amount that to cover it by taxation would be unduly burdensome or even entirely impracticable; *e.g.,* war expenditure.

Control of Public Expenditure. — In order to secure a balance between revenue and expenditure outside these exceptional cases, some control over expenditure is needed.

This control takes several forms:

(1) *Parliamentary Control.* Parliaments are given the right of voting the public expenditure under a number of separate categories (sometimes elaborately and minutely classified), and the executive government is required to keep within the vote under every head.

(2) *Executive Control.* Every department is required to conform to the directions of the ministry of finance in regard to its expenditure. (A particularly drastic and searching control is exercised by the treasury in Great Britain).

(3) *Accountability.* To be effective, all forms of control require some system which will bring to light any cases in which the directions given have been contravened. There must be a thorough system of audit devised for this purpose.

In limiting expenditure it is necessary to weigh in the balance the advantages of the expenditure which is in question, against the disadvantages of the taxation which would have to be imposed to meet it. The ministry of finance, in exercising control over the various heads of expenditure and in determining what taxes are to be imposed, retained or remitted, should constantly keep that comparison in view.

It is also the function of the ministry of finance to consider what items of expenditure may be met from borrowing, what form the borrowing should take, what provision should be made for sinking fund to pay off debt, and what arrangements should be made for dealing with debt maturities and conversions. In all these matters, while it is for the ministry of finance to make proposals, the measures actually taken are usually regulated by statutory enactments.

A minister of finance also requires authority for temporary borrowing. Primarily temporary borrowing is needed to meet a temporary lag of revenue behind expenditure, or to meet emergency expenditure in the interval before a permanent loan can be issued. But there is a danger that it may extend beyond these limits. Temporary borrowing can be effected through banks, which create the credit money which they lend. An excessive floating debt is a great danger because it may lead on to inflation of the currency. Inflation may be regarded as a breakdown of public finance. The government, having failed to provide the means of payment by means of taxation and genuine borrowing, has resort to the creation of bank credit to fill the gap.

Governments and legislatures take responsibility for the provision of currency for the community. But sound principle generally requires this function to be kept as separate as possible from the finance of the public service. The administration of the currency is (or ought to be) directed to the provision of the means of payment for the community generally and not for the government in particular.

Public finance includes, besides the finances of governments, the finances of local authorities (municipalities, county councils, communes, etc.). Local authorities are usually given limited taxing powers by statute and their borrowing powers are also restricted and supervised. Sometimes they receive subsidies from the government out of the national tax revenue. (R. G. H.)

FINANCE, ARTICLES ON. The subject of finance is treated in so many articles that the suggestions listed here cannot be considered exhaustive. Thus in addition to the articles indicated here the index should be used as a guide also.

Basic to the problems of finance is the treatment of monetary problems. In the most general terms monetary problems are discussed in the following articles: MONEY; CAPITAL AND INTEREST; CURRENCY; INFLATION AND DEFLATION. The latter article is concerned with the value of money and different aspects of this same problem are discussed in the articles QUANTITY THEORY OF MONEY and INDEX NUMBERS. The historical development of currencies is discussed in the articles MONEY, MEDIAEVAL; CURRENCY. PRIMITIVE; and GOLD STANDARD. The last named of these articles also treats some aspects of international monetary relations. Special articles are devoted to the main currencies; *e.g.,* DOLLAR; POUND STERLING; FRANC; MARK; KRONE; PESO; and others. Problems of coinage and the genuineness of money are treated in the articles MINT; ASSAY OFFICE; SEIGNIORAGE; and COUNTERFEIT MONEY.

Next in importance to money, as concerns private financing, are the articles on banking. Chief among this group are BANKING; MONEY MARKET; CEKTRAL BAKK; SAVINGS BANKS; CLEARING HOUSE; MERCHANT BANKERS; DISCOUNT; DISCOUNT HOUSE; INVESTMENT BANKING; and TRUST COMPANY. Banking instruments are discussed in many articles, the most important of which are CHECK; BILL OF EXCHANGE; and COMMERCIAL PAPER. Some historical aspects of banking are discussed in the articles BANKING; MONEY-LENDING; and PAWNBROKING. There is also a series of articles on several important banking institutions of national importance; *e.g.,* FEDERAL RESERVE SYSTEM, THE; BANK OF ENGLAND; BANQUE DE FRANCE; and of international standing; *e.g.,* EXPORT-IMPORT BANK OF WASHINGTON; BASK FOR INTERNATIONAL SETTLEMENTS, and BANK FOR RECONSTRUCTION AND DEVELOPMENT, INTERNATIONAL.

On the subjects of the stock market and financial investment consult: STOCK EXCHANGE (BOURSE); INVESTMENTS: INDIVIDUAL; ARBITRAGE; FUTURES; and CURB MARKET.

On persons engaged in handling stock exchange business consult the articles: STOCKBROKER; JOBBER (STOCK EXCHANGE); and BROKER. On securities traded on stock exchanges or related to the exchange consult: STOCK; SHARE; CONSOLS; BEARER SECURITIES.

International monetary problems are discussed in the following articles: INTERNATIONAL PAYMENTS; EXCHANGE, FOREIGN; EXCHANGE CONTROL; CAPITAL. EXPORT OF.

The taxation of international transactions is discussed in the articles CORN LAWS; TARIFFS; COUNTERVAILING DUTIES. Some discussion of the exchange value of various currencies is contained in the articles on individual currencies (POUND STERLING; DOLLAR, etc) mentioned above.

Articles on insurance will be found listed in a special article entitled INSURANCE.

Articles in the field of public finance may be classed under three headings. Those dealing with general budgetary controls are under BUDGET, GOVERNMENTAL; EXCHEQUER; FINANCE; and SUPPLY.

Articles on public revenues embrace, among others, the following: TAXATION; TAXATION, LOCAL; REVENUE; TARIFFS; INCOME TAX; ESTATE AND INHERITANCE TAXES; EXCISE TAX; INHERITANCE; LAND TAXES; SALES TAXES; LUXURY TAXES; EXCESS-PROFITS TAX; and CAPITAL LEVY. Some historical aspects of taxation are treated in the articles GABELLE; and WINDOW TAX.

Finally, on the public debt, the following articles are most important: DEBT. PUBLIC: and INTER-ALLIED DEBTS.

(B. F. H.)

FINANCE ACT: see BUDGET, GOVERNMENTAL.

FINANCIAL STATEMENTS, broadly speaking, are any statements that report the financial condition or the operations of a business, a government, or a not-for-profit organization devoted to some charitable, religious or educational purpose. The term is commonly used, however. in a more limited sense in trade and financial circles to refer to the balance sheet. statement of income, and statement of retained earnings of a business. The balance sheet shows the amount and kinds of assets (properties), liabilities (debts), and the owners' investment (excess of assets over liabilities) as of a certain date. The reader examines the balance sheet to discover the liquidity of the concern and probable solvency. Liquidity is a matter of convertibility of the assets into cash; solvency, of ability to meet debts when due.

Comparative balance sheets showing the financial condition of a business for two or more years reveal financial tendencies, changes in response to varying business conditions, and policies on such matters as debt retirement and expansion of the ownership investment by retained earnings.

The earnings statement summarizes those transactions which have brought gain or loss to the owners during a period of time, usually a year, between two successive balance sheets. Accountants ordinarily divide this statement, which serves as an explanatory link between the amounts of the ownership interest in succeeding balance sheets, into a statement of income or profit and loss statement and a statement of retained earnings or earned surplus. The latter recounts items that are not strictly profit or loss, such as dividends which distribute net income to the stockholders, or arbitrary reductions in the valuation of fixed property, or sometimes items that relate to the earnings of an earlier period, such as the revision of the tax liability of an earlier year. Some accountants regard it as improper to place these latter adjustments of prior years' gains or losses in this surplus section lest the unskilful reader overlook them in studying the earnings over a period of years; they prefer to show such adjustments in the regular income statement suitably segregated.

Earnings statements are useful in portraying the elements of profitability when details are given on sales or gross revenues, cost of goods sold, and certain expenses such as depreciation, maintenance, taxes, interest and rents. Good form calls for the separation of income and expenses derived from the main operations, such as the trading activities of a merchant, from similar data related to sidelines. Extraordinary and nonrecurring gains and losses together with any related income taxes should be separately stated. Where the total earnings are summed up in the single figure of "earnings per share of stock," many prefer a figure that excludes extraordinary terms. They want a representative or "normal" measure of earnings. Good practice requires the reporting of figures that both include and exclude such items. Whether a particular unusual item is likely to recur in the future may depend upon whether a short or long run point of view is taken.

The earnings statement is ostensibly a mere record of the past. But, as in other fields, the reader projects this historical experience in judging the probable future. Debates over proper form often hinge upon the debaters' ideas as to the probable way in which the reader is likely to think or react. Because statements are read for a variety of purposes, no single form can satisfy all persons. Adequate disclosure of material details enables informed and competent persons to derive the kinds of information that will serve their various needs. The past record of earnings has the greatest utility in gauging the future where the business offers goods or services that are bought frequently and habitually. Demand and earnings fluctuate most where technology changes, style alters frequently, raw materials vary greatly in cost, or durability or luxury character causes irregular buying.

Users of Statements. — The more important users of financial statements are (1) short-term creditors, (2) investors, (3) business management, and (4) government agencies. Commercial banks and trade creditors extend short-term credit. They may rely heavily upon a personal estimate of the ability and character of the prospective debtor and his previous record of paying his bills rather than upon precise financial information. Experience has shown. however, that such credit can be extended more freely and with less risk, especially to small businesses when statements are available. Attention of the short-term creditor centres on the balance sheet, especially on the current assets, consisting of cash and liquid investments, stocks of merchandise (inventories), and amounts owing by customers (accounts receivable) as they relate to short-term debts.

Investors in bonds or stocks tend to place primary emphasis upon the earnings statements and less upon the balance sheet, save as the latter suggests risk because of unliquidity and insolvency. When commercial banks extend term loans that are to be repaid systematically over a period of years, they too have an interest in the statement of income because they depend for repayment more upon future earnings and less upon existing current assets. A widening ownership of large business corporations makes fuller disclosure through financial statements a natural development.

Business management finds detailed statements valuable. Comparison with the statements of other members of the industry is used to discover conformity to customary practice and to study relative operating achievement.

Standardized financial statements are the essential basis for many phases of governmental regulation and the taxation of business. When prices are regulated. especially as for public utilities, financial statements disclose the level of earnings and how they conform to the standard set by policy. Statements permit the study of a corporation's finances to determine the suitability of its securities for acquisition by regulated investment institutions, such as insurance companies and banks. Where securities are widely owned by individuals who are not in a position to enforce adequate statement information, the government may set up requirements for the disclosure of material financial information.

Differences Related to Function. — Figures compiled under rules for meeting one need may be inadequate to meet other needs. Merchandise inventories shown in a balance sheet at a very low cost figure of the distant past will not tell a banker how valuable they are currently for paying debts. Regulatory bodies when dealing with a financial institution like a bank, may look with favour on an understatement of asset values that increases the margin of safety of that institution in a crisis. A stockholder, however, who wishes to value his shares for sale, would prefer fuller information on current values. Income tax regulations may specify certain maximum allowances for depreciation expense, but business management may find that rapid teclinological change justifies larger allowances. Or, management may elect the highest permissible depreciation rates for income tax purposes when less would appear adequate, lest possible tax savings for shareholders be lost. Considerable changes in the price level create many problems for all classes who use conventionally prepared statements. Radical accounting adjustments were suggested by German accountants in the price inflation after World War I and in the U.S. after World War II.

Accounting Terminology.— The conditions prerequisite to the interpretation of financial statements are an understanding (1) of the information required by the particular user. (2) of the terminology and (3) of the rules or conventions employed by accountants in their preparation of financial statements. The needs of the various major groups who use statements have been suggested. As for terminology, perhaps the two areas most baffling for the ordinary reader, but essential to the understanding of the balance sheet, are the items that state the ownership interest and the "reserves."

The ownership interest of a proprietorship or partnership may be stated in amounts belonging to the one or several owners (thus, John Doe, Capital. . . . $25,000) or merely as the net worth. The total amount is the excess of the assets over the debts of the concern. When added to the debts, the sum equals the assets by definition. Custom places both items on one side of the balance sheet headed liabilities or, more correctly, liabilities and owners' capital. The latter and more precise heading recognizes the legal difference between the creditors, who have claims to fixed sums of money as of certain dates, and the owners, who are the residual claimants to assets and income.

In a corporation's balance sheet, the interest of the owner-stockholders should be broken down as between paid in investment and subsequent accretions from earnings left in the business. The former appear as so much capital stock, often at an arbitrary par or stated value, and any excess as excess paid in by stockholders, paid-in surplus or capital surplus. The other portion of the ownership equity may appear as earnings retained in the business, profit and loss, earned surplus, or. as the Bank of England terms it, the rest. Recognition that this amount is merely a balance of value and represents the residual claim of the owners, which may be represented as invested in nonliquid assets, should prevent a not unusual layman's misconception that surplus is a pot of money readily available for dividends or debt payment.

"Reserves" popularly means cash or liquid investments available to meet some specific purpose or a general emergency. The accountant may use the term quite differently. In the balance sheet it may be employed in three different ways: (1) as an allowance for loss in value of some asset (valuation "reserve"), (2) as an estimated liability, or (3) as an "appropriation" of the retained earnings or surplus.

Valuation *Reserves.*—Instead of merely showing such an asset as plant and machinery at its net book value, it is customary to show its original cost with a separately stated amount of allowances for depreciation or, more confusingly, a reserve for depreciation. Similarly, allowances for losses on customers' debts to the business may show as a deduction either for allowances for bad debt losses or a reserve for bad debts. Such "reserves" allow for possible loss of value and are not cash or funds.

Liability Reserves.–Occasionally a liability, especially where the amount is uncertain, appears as a "reserve." Thus, income tax liability may be called reserve for income taxes.

Appropriated *Surplus.*—Some accountants who wish to show that retained earnings are not available for dividend distributions transfer a portion of such surplus to a "surplus reserve." such as reserve for contingencies, sinking fund reserve. or merely general reserves. Others prefer to show this point by merely stating these amounts as appropriated surplus: for contingencies, or for bond retirements, or for plant expansion. Still others regard both forms as likely to mislead by implying that all of the remainder of the retained earnings account is available for dividend payments. Actual availability can be determined only by examining (1) the remainder of the balance sheet to see whether cash or other liquid funds exist in excess of what is required to satisfy creditors. (2) reported plans for the future that will use up existing cash, and (3) earnings prospects that will provide cash to pay dividends.

Originally, these "reserves" were sometimes grouped in the balance sheet between the liabilities and the ownership equity. As time passed, they were more commonly placed with the asset, liability, or ownership accounts to which they were more closely related. An even later tendency was to abandon the term "reserve" for more accurately descriptive account titles.

Accounting Rules.— The significance and limitations of financial statements arise in part from the rules or principles of accounting which determine their construction. These rules grew from customs found most generally useful in trade and finance. One basic principle is that assets should reflect cost rather than current market value in order to avoid showing unrealized profits from appreciation. This rule is modified by allowances for value losses where some systematic basis for estimate exists, as in the case of depreciation of machines and buildings, bad debt losses, and the depletion of oil wells and mines. This cost rule is commonly suspended when current assets have a market value below cost at the date of the balance sheet. The current assets are those assets that turn into cash in the course of ordinary operation within a year (longer in a few industries) and typically include cash, marketable securities, customers' indebtedness and inventories. Marketable securities and inventories are commonly valued at whichever is the lower, cost or market, partly as a matter of conservatism, which is itself almost an accounting principle. This practice is also a matter of recognizing a value loss that reduces current debt-paying power. The measurement of this ability is a central object of statement analysis. Fixed assets, such as plant or long-term security investments not likely to be sold to meet debt, are commonly shown at cost and ignore market value fluctuations on the assumption that such fluctuations are not important to the "going concern." Appraisal and revaluation of the fixed assets are not common practice.

Many special accounting rules arise from trade customs, governmental regulations and tax laws. They often apply only to the statements of special kinds of businesses, such as manufacturing, merchandising, railroads, public utilities, commercial banks, life, fire and casualty insurance, and holding companies.

FINANCIAL STATEMENT ANALYSIS

Balance sheets and earnings statements may be analyzed comparatively or internally. In comparative analysis, changes in successive balance sheets or earnings statements, yearly, quarterly, or monthly, are studied for tendencies and trends. These changes may reflect long-term growth or decline of the particular business or the industry of which it is a part or they may represent cyclical, seasonal, or special fortuitous factors. Correct understanding of the nature of the influences at work is as important as the facts of change.

Internal analysis examines the relationships or ratios between various items in the statements. The simplest devices are the percentage balance sheet, which compares each of the assets and liabilities as a per cent of total assets and the percentage income statement where the various operating income and expense items are shown as percentages of the gross revenues or sales Ratios are studied to discover probable liquidity or solvency and profitability or efficiency. Two common liquidity tests are the current and quick ratios. The former is the ratio of current assets to current liabilities; the latter is the ratio oi cash and equivalent plus customers' debts (receivables) to the current liabilities. Comparisons of annual sales volume to the customers' debts and to inventories give an idea as to their liquidity and also how efficiently the capital invested in those forms is being used to produce profits. Comparisons of indebtedness to the owners' investment indicates something of the risk of insolvency that is being assumed. Comparisons of the cost of goods sold and the various expenses to revenues may be studied from year to year and between companies in the industry to ascertain relative efficiency and profitability. The amount of earnings relative to the investment of creditors and owners provides another measure of profitability, which, however, requires greater care in interpretation because of changing prices and the failure of the balance sheet to reflect current property values.

Although financial statements find their most vital significance for those immediately concerned with the financial fortunes of the particular business, they are read and used by others. They are used for economic analysis; for studies of business conditions; for shaping political and legislative policies; for governmental regulation and for background information for settling labour disputes. Misinterpretation is easy here as it is in all forms of statistical abstraction. Price level changes are an especially disturbing factor. In spite of such limitations, financial statements perform a useful economic service by making possible a more intelligent assumption of business risks, directing capital into more economic channels, and improving the quality of business management and of competition. They also serve a wider social purpose in providing one more kind of information useful in evaluating political and social policies.

FINCH, a name, usually in combination, as bullfinch, chaffinch: etc., for birds of the largest avian family Fringillidae. Generally speaking finches are small songbirds with a short, stout, conical bill for crushing seeds, and are characteristic of Europe, Asia and North America, where most of the numerous species live. *See* also Brambling; Bunting; Bullfinch; Canary; Chaffinch; Crossbill; Goldfinch; Greenfikch; Grosbeak; Hawfinch; Liknet; Redpoll; Siskin; Sparrow.

FINCHLEY, a municipal borough (1933) of north Middlesex, Eng.. forming with Friern Barnet a borough constituency returning one member to parliament. It lies northwest of London, with Hampstead to the south, Hendon to the west, Barnet to the north and Hornsey to the east. Pop. (1951) 69,991. Area 5.4 sq.mi. The glacier which covered much of the British Isles in one of the ice ages came as far south as Finchley. At the time of Domesday Book Finchley was a part of the manor of Fulham which belonged to the bishop of London. The area was agricultural, producing much hay, and Finchley common. traversed by the Great North road, was later notorious for its highwaymen, Jack Sheppard being captured near there in 1724. Gen. George Monck camped on the common on his march on London in 1660 and in 1745 a force to resist Prince Charles Edward, then at Derby, encamped there and inspired William Hogarth's painting "The March of the Guards Towards Scotland . . ." also known as the "March to Finchley." The common or glebe land now occupies 46 ac. The parish church of St. Mary, largely 15th century, was restored in 1872–73 and subsequently; damage from World War II was repaired in 1953. Finchley owned about 420 ac. of open spaces and playing fields in 1956. The borough is largely residential, much of the southern part lying in Hampstead garden suburb (Golders Green).

FINCK, FRANZ NIKOLAUS (1867–1910), German philologist, whose major studies were in types of language structure; was born on June 26. 1867, in Krefeld. He concentrated more on Armenian than any other single language, publishing a grammar in 1902 and some works on Armenian literature and manuscripts in 1903 and 1907. He also published studies of the German and Armenian Gypsy languages (1903, 1907), of the noun accent in Baltic languages and Slavonic languages (1895), of the Irish dialect of the Aran Islands (1899), of the Bantu languages (1908) and of the Polynesian languages (1909).

Finck's work in structural typology, which mas in the tradition of W. von Humboldt and H. Steinthal, first appeared in a study of German in 1899, then in *Die Klassifikation dev Sprachen* in 1901 and in *Die Haupttypen des Spvachbaus* in 1910. When he died, on May 4, 1910, in Berlin, he was professor of the Oriental seminar at Berlin university. He is perhaps best remembered for *Die Sprachstämme des Erdkreises* (1909). (E. P. H.)

FINDLAY, a city of northwestern Ohio, U.S., the seat of Hancock county, lies in a rich agricultural area: and is the trading centre for the surrounding community. Industries include the manufacture of ditching machines, beet sugar, tires and rubber goods and radio and television equipment. The Blanchard river, which flows through Findlay, is the scene of "Down by the Old Mill Stream" written by Tell Taylor, who lived there. The original settlement developed out of Fort Findlay, built during the War of 1812 by Col. James Findlay, for whom it was named. The town was laid out in 1821, incorporated as a village in 1838 and chartered as a city in 1887. It is the seat of Findlay college (Church of God), chartered in 1882. For comparative population figures *see* table in Ohio: *Population.* (L. M. C.)

FINE, a pecuniary penalty imposed by a court of law upon a person convicted of a criminal offense. Fines constitute in whole or in part the punishment for many common law and statutory offenses in both the United States and Great Britain. Unless the amount of a fine is specified by statute, it may be fixed by the court in the exercise of its discretion. The U.S. constitution and many state constitutions prohibit the imposition of excessive fines.

Several methods are employed in attempting to recover unpaid fines. Under the common law and by statute in many states, an execution may be levied against the defendant's property. In many jurisdictions, statutes also enable the court to order a defendant to work out his fine by manual labour. Moreover, in most states a defendant may be imprisoned until the fine is paid or otherwise settled in accordance with law. He may be imprisoned indefinitely in some jurisdictions. but statutes commonly limit the amount of time he may be compelled to serve. Usually, imprisonment for such a fixed period does not cancel the fine itself; however, some statutes provide that the fine is discharged by imprisonment for a fixed period, and others allow a credit on the fine for each day served in prison.

The term is also applied to payments formerly made to the lord of a manor on the alienation of land by a tenant, and to a fictitious legal action, abolished in England in 1833, dealing with the conveyance of land. *See* also Criminal Law. (C. R. Se.)

FINE ARTS. In classical Greece the association of the arts, and more especially sculpture, with the temples of the gods and the great athletic festivals, gave them dignity and sanctity, though work as exquisite as any of these official commissions was produced in such arts as white-figured vase paintings and engraved gems. In the Roman empire the glorification of the emperor and the individual was added to the functions of art and when such mass industries as Arretine ware and industrial bronze casting were developed a certain distinction of status between the artist and the craftsman was achieved. In the more simply organized life of the middle ages, however, great painters were employed by their patrons to paint fine religious pictures and to stain cloths for tournaments, indifferently. and no distinction of status was made between artist and craftsman in the medieval guilds. Even in the 16th century Holbein was content to design jewels for Henry VIII and Raphael tapestries for the pope.

The conception of the fine arts as creation on a loftier level seems everynhere to have accompanied the establishment of academies of painting and sculpture. The earliest such institution was the Académie Royale de Peinture et de Sculpture founded at Paris by Louis XIV in 1648. It hardly made the scission complete, for all through his reign royal buildings, and those imitated from them, were so richly decorated with painting and sculpture that his academicians mere as much occupied with decoration as with the creation of easel pictures and free-standing sculpture.

In the 18th century a change of taste in western Europe made the division between the fine and the decorative arts more stringent. François Boucher takes an intermediate place; many of his pictures are independent of their setting, but an almost equal number are (or were) part of a larger decorative scheme, either as tapestries or as pictures built into paneling. A *dessus de porte* is not an easel picture and has not the same claim in academic eyes to an independent existence in the realm of creation. Gradually, however, the fashion changed, and by the middle of the century it was easy to put the carvers and plasterers who decorated rooms and the artists who painted creative pictures that might chance to adorn their walls into different categories. At this time verbal usage closely confirmed the association of the idea of the fine arts with academic foundations. The phrase "fine art" was, according to the Oxford English dictionary, first used in 1767; the Royal academy was founded in the following year. In France M. J. Chénier used "les Beaux Arts" in his *Charles IX* in 1789; the Académie des Beaux-Arts was refounded under that title in 1795.

The distinction between the fine arts and all other arts continued through the 19th century, the great age of academies. It was encouraged by the rise of the middle classes, who were more apt to move house than the territorial magnates, and consequently preferred mobile pictures to elaborate and immovable decorative ensembles, and liked to give an enhanced status to their possessions. Two wars have, however, begun to modify the idea, for men of taste may no longer have room to display pictures in their homes. It is significant that by the middle of the 20th century Jean Lurçat was designing tapestries and Pablo Picasso pottery. Nonetheless the public—if not the artist—is still prepared to consider as "fine," art that fulfills no other purpose than the artist's desire for creation. (J. Ev.)

FINFOOT or sun grebe, names for three species of medium-sized cootlike birds but brown above and whitish below, with lobed feet. They constitute the family Heliornithidae and suborder Heliornithes in the order Gruiformes and are related to the rails (*q.v.*) rather than the grebes (*q.v.*). The finfoot, a secretive bird, is a poor flyer which spends most of its time in shady, quiet rivers, half submerged near overhanging banks. None are more than two feet long; the olive-coloured American finfoot (*Heliornis fulica*), only half that size, with red bill and black-banded yellow toes, ranges from Veracruz to northeastern Argentina.

The African finfoot (Podica senegalensis) occurs from Senegal to the Congo and Ethiopia to the Cape. The Asiatic finfoot (*Heliopais* personata) is found in Burma, Assam, Malaya and Sumatra. (G. F. Ss.; X.)

FINGAL'S CAVE, a famous cave on the southern coast of Staffa, an island of the Inner Hebrides, Scot. Visited in 1772 and first described by Sir Joseph Banks, it can be entered only by boat. It is 227 ft. long, 42 ft. wide and lined by a series of hexagonal basaltic pillars similar to the Giant's Causeway in County Antrim, Ire. It is a haunt of sea birds and seals.

FINGER: see SKELETON, VERTEBRATE: *Appendicular* Skeleton.

FINGER-AND-TOE, CLUBROOT or ANBURY, a destructive plant disease due to fungus organism known botanically as *Plasmodiophora brassicae,* which attacks cabbages, turnips, radishes and other cultivated and wild members of the family Cruciferae. It is caused by one of the simple alga-like fungi of the order Chytridiales. The presence of the disease is indicated by nodules or warty outgrowths on the root, which sometimes becomes swollen and ultimately rots, emitting an unpleasant odour. The disease is contracted from spores present in the soil which give rise to motile spores which enter the root. The parasite develops within the living cells of the plant, forming a mass of living material known as the plasmodium, the form of which alters from time to time. The cells which have been attacked increase enormously in size and the organism spreads from cell to cell. Ultimately the plasmodium becomes resolved into numerous minute round spores which, on the decay of the root, are set free in the soil. The disease is more frequent in acid soils. Lime in various forms has been used, but a dressing of 1,500–2,000 lb. per acre of hydrated lime will give commercial control. To prevent the organism from passing in a living state into the manure, diseased plants should be burned or, if thoroughly boiled, they may be fed to animals.

More details on control practices are found in F. Heald's Manual of Plant Diseases, 2nd ed., pp. 464–466 (1933).

FINGERING, a term used to describe the methods for the use of fingers in playing keyboard, stringed and wind instruments. Research has shown that early systems of fingerings on the chamber organ, the clavichord and the harpsichord which originated in England influenced the systems of François Couperin, J. S. Bach and C. P. E. Bach, which have been generally taken to be the foundation of keyboard technique. These systems were based on the relative strength of the five fingers. The choice of fingers was also governed by considerations of sonority, touch and phrasing associated with one keyboard instrument or another. Later systems of pianoforte fingering were an expansion of these principles.

Fingering on stringed instruments is based on the principle of stopping the strings at varying lengths and on the movable positions of the hand along the finger board. In wood-wind instruments systems of fingering depend on the stretch between the fingers in regard to the uncovering of holes which, cut into the wall of the instrument, vary the size of the vibrating column of air.

See E. Halfpenny, "Fingering," in Grove's Dictionary of Music and Musicians, vol. 3 (1954).

FINGER NUMERALS, the representation of numbers by positions of the fingers, a method used by early peoples in the absence of inexpensive material upon which to write. The use of such symbols survived into modern times, particularly in international trade in the orient. In the system inherited from the Greeks and Romans small numbers were usually represented on the left hand, the right hand being used for hundreds. When Juvenal wrote (Satire X), "Happy is he indeed who has postponed the hour of his death so long and finally numbers his years upon his right hand," he referred to one who lives to be more than 100 years old. The finger numerals are related to the finger computations in use in the middle ages, referred to in various early printed books and still familiar in certain parts of the world. The operation of multiplication was the one in which they played the most important part, computation being carried as far as 10×10. For example, to multiply 8 by 6, turn down $8 - 5$ fingers on one hand and $6 - 5$ on the other. There are then 3 turned down and 2 standing on one hand and 1 turned down and 4 standing on the other. Add the fingers down $(3 + 1 = 4)$ and multiply those standing $(2 \times 4 = 8)$, and the result is 4 tens + 8 units, or 48; the operation follows the formula, $ab = [(a - 5) + (b - 5)]\,10 + (10 - a)\,(10 - b)$. Numerous variants of the plan were in use, some having been brought to Europe from the Arab schools. See also NUMERALS. (D. E. S.)

FINGERPRINTS. The use of fingerprints as a system of identification is of very ancient origin, and was known from the earliest days in the east when the impression of his thumb mas the monarch's sign manual. The permanent character of the fingerprint was first put forward scientifically in 1823 by J. E. Purkinje, professor of physiology, who read a paper before the University of Breslau, adducing nine standard types of impressions and advocating a system of classification which attracted no great attention. Sir Francis Galton, who laboured to introduce identification by fingerprints, was the founder of our present system of fingerprint identification. Sir William Herschel, who in India employed a simple form of fingerprint identification, is regarded as the first who devised a feasible method for the regular use of fingerprint identification. The Bengal police, under the administration of Sir E. R. Henry, afterwards chief commissioner of the London metropolitan police, usefully adopted fingerprints for the detection of crime. The prints depend upon the ridge formations in the bulbs of the end joints of the fingers. The skin is traversed in various directions by the depressions and friction ridges, thus forming the fingerprint patterns which continue unchanged from birth to death. The constancy of the markings of the fingerprints has been proved beyond question and this universally accepted fact has permitted the predication of the present system of identification. The fingerprint patterns lend themselves to convenient classification according to the types and patterns and the number of ridges appearing between designated points in the patterns. The patterns are catalogued according to four main types: arches, loops, whorls and composites. There are subclasses of these types, all of which are identifiable by symbol or number according to the system, which permit the expert to read each print as a distinct classification.

One of the first methods of scientific identification was the adoption of the Bertillon system which was devised by the French savant A. Bertillon. Based upon the anthropometry measurements of the body the system is obsolete in all countries with the exception of France. The first authentic record of the use of fingerprints in the United States reveals that Gilbert Thompson of the United States Geological survey utilized his thumb impression to prevent the forgery of commissary orders during his supervision of a survey in New Mexico in 1882. The Federal Bureau of Investigation (FBI), United States department of justice, maintains the world's largest collection of fingerprint records and is the chief repository for criminal fingerprint data mutually interchanged among the nation's law enforcement agencies. By 1952 it was co-operating with 81 foreign countries and territorial possessions in the international exchange of criminal identifying data. The identification division of the FBI was established in 1924, when collections previously maintained by the United States penitentiary, Leavenworth, Kan., and by the International Association of Chiefs of Police were given to the FBI. The 810,188 cards received formed the nucleus of a constantly increasing collection, which in 1958 exceeded 149,000,000 criminal and noncriminal fingerprint cards. More than 23,000,000 of the cards comprised the arrest records of more than 9,300,000 individual criminals or suspects. During the 12-month period which ended June 30, 1958, more than half of all persons whose arrests were reflected on fingerprint cards received at the FBI identification division were found to have previous criminal histories, and 15,534 fugitives from justice were identified.

Separate from the criminal records are files containing more than 100,000,000 fingerprint cards of members of the armed forces, civilian personnel of the federal government, aliens and law-abiding citizens who volunteered their fingerprints as a precautionary measure. About 70% of the more than 1,500 fingerprint cards of unknown dead persons submitted annually to the FBI have been identified through cards previously on file.

In the operation of its system the Federal Bureau of Investigation employs the Henry method, with current extensions, utilizing all ten fingers as a unit for the classification and filing of fingerprints. It also created a classification method which permits the separation of the impressions of the ten fingers into a single fingerprint system. (*See* also INVESTIGATION, CRIMINAL.) (J. E. H.)

FINIAL, in architecture, the decorative upper termination of a pinnacle, gable end, buttress, canopy or spire; especially in the Romanesque and Gothic styles. It usually consists of a vertical pointed central element surrounded by four outcurving leaves or scrolls. When the form it decorates has crockets (*q.v.*) the finial may be formed of four or more crockets surrounding the central uprights. Finials in the form of candelabrum shafts occur frequently in early Renaissance work. The term is also applied loosely to any small pinnacle, knob or other decorative feature terminating a verticle motive. *See* also SPIRE.

FINIGUERRA, MASO (i.e., *Tommaso*) (1426–1464), goldsmith, draftsman, and engraver, was born in Florence in 1426, and died there in 1464. He is recorded as the first Italian master of the early Renaissance to specialize in engravings. But owing to lack of documentation, all conclusions as to his activity remain speculative.

As a young man Maso is believed to have worked with Lorenzo Ghiberti; later he associated himself with Antonio Pollaiuolo. His own style seems grounded on theirs. None of his productions as a goldsmith is known, save perhaps the Thewalt cross of about 1464, decorated with niello plaques, in the Metropolitan museum, the design of which may be his.

Before 1450 he had been producing nielli. A niello is made by engraving a design on a flat surface of silver and filling the engraved lines with a black enamel-like substance. Before applying this substance Maso frequently made casts in sulfur of the engraved silver, and some of these are still preserved, notably the British Museum's Coronation of the Virgin of about 1459–1464. He also made niello prints, which are impressions from the silver on paper; some of these also still exist. Sulfur casts and niello prints now give us our most complete picture of Maso as niellist.

From the niello print it was only a step to the copperplate print, and shortly after 1460 Maso seems to have been busy turning these out. Perhaps most famous of the engravings attributable to him is the series of the seven Planets.

The art of copperplate engraving is, however, a German development, and Giorgio Vasari erred in hailing Finiguerra as its inventor. Even in Italy he seems not to have been the first. Pollaiuolo's Battle of the Naked Men of about 1460 may antedate any of Maso's works. But Finiguerra remained the great popularizer of the new medium.

As draftsman his name is sometimes connected with the Florentine Picture-Chronicle of about 1464 in the British Museum, a work containing more than a hundred lively drawings. He is also believed to have produced designs for the intarsia woodwork in the sacristy of the Cathedral of Florence. The extent of his contribution there also remains a matter of conjecture.

Hind, *Early Italian Engraving,* vol. I–II, part I (1938); A. Blum, *Les Nielles du quattrocento* (1950); J. G. Phillips, *Early Florentine Designers and Engravers* (1955). (J. G. Ps.)

FINISTÈRE, the most western *département* of France, formed from part of the old province of Brittany. Pop. (1954) 727,847; area: 2,714 sq.mi. It is bounded west and south by the Atlantic ocean, east by the *départements* of Côtes-du-Nord and Morbihan, and north by the English channel. (For history *see* BRITTANY.)

Finistère is the west end of the worn down ancient fold region, axes of which still emerge slightly as the Monts d'Arrée (1,282 ft.) in the north and Montagnes Noires in the south. These run east and west, with the Aulne basin between them. Small streams flow north from the Monts d'Arrée and south from the Montagnes Noires. The Aulne and Elorn, and the other streams in lesser degree, have estuaries because of coastal sinking, and these estuaries form the harbour of Brest and other navigable entries. Off the promontories prolonging the Monts d'Arrée are the Ushant Islands and off that prolonging the Montagnes Noires the Îles de Sein in the south, with Batz off the north coast and many others. Between islands and mainland are famous tide races which make navigation difficult. The coasts are often steep and rocky.

The climate is oceanic, average temperature 52° F., rainfall heavy. Though more than a third of the *département* is covered by heath, wasteland and forest, it produces oats, wheat, buckwheat, rye and barley. The neighbourhood of Roscoff and the borders of the Brest roadstead are extremely fertile and yield large quantities of asparagus, artichokes and onions, besides melons and other fruits. The cider apple is abundant. Hemp and flax are also grown. The farm and dairy produce is plentiful, and cattle and horses are largely bred. Honey and wax are produced. The great pilchard fishery makes this *département* a nursery of seamen for the French navy. Coal, though found in Finistère, is not mined; there are quarries of granite, slate, potter's clay, etc. The lead mines of Poullaouen and Huelgoat, which long yielded silver, are no longer worked. The preparation of sardines is carried on on a large scale at several coast towns. The manufactures include ropes, agricultural implements, paper, leather, earthenware, soap, candles and fertilizers and chemicals derived from seaweed. Brest has important foundries and engineering works, and shipbuilding is carried on there and at other seaports. Brest and Morlaix are the most important commercial ports. Trade is in fish, vegetables and fruit. Coal is the chief import. The *département* is served by the Orléans and Ouest-État railways. The canal from Nantes to Brest traverses the *département.*

Finistère is divided into the following *arrondissements* of Brest, Châteaulin, Morlaix and Quimper (43 cantons, 294 communes), the town of Quimper being the capital of the *département* and the seat of a bishopric. The north of the *département* belongs to the region of the 10th army corps (Rennes), and the south to the region of the 11th army corps (Nantes) and the whole to the archiepiscopal province and *académie* (educational division) of Rennes, where its court of appeal is also situated.

The more important places are the ports of Quimper, Brest, Morlaix, Quimperlé, Douarnenez, Concarneau, Roscoff and, inland, Landerneau and Châteaulin. Finistère abounds in menhirs and other megalithic monuments, of which those of Penmarc'h, Plouarzal and Crozon are most noted. The two religious structures characteristic of Brittany—calvaries and ossuaries—are frequently met with; *e.g.,* the calvaries of Plougastel-Daoulas, Pleyben, St. Thégonnec (17th century) and Guimiliau (16th century), and the ossuaries of Sizun and St. Thégonnec (16th century) and Guimiliau (17th century).

Daoulas has the remains of a Romanesque church and cloister. Locronan and St. Jean du Doigt have interesting churches and are among many centres of famous folk ceremonies called pardons. St. Pol de Léon has a fine granite Gothic cathedral. Kerjean has a 16th-century château.

FINITE DIFFERENCES: *see* CALCULUS OF DIFFERENCES.

FINK, MIKE (1770?–1823), U.S. frontiersman and legendary hero, was born at Fort Pitt, Pa. As a youth he won fame as a marksman and Indian scout around the fort. Later, when keelboats were the chief vessels of commerce on the Ohio and Mississippi Rivers, he became "the king of the keelboatmen," renowned as the best marksman, most energetic roisterer, and champion rough-and-tumble fighter in perhaps the toughest group in the west. In 1822, he joined the Ashley-Henry trapping expedition to the Rockies; the next yenr, he died a violent death at Fort Henry on the Yellowstone river. Stories about him told orally and published by writers of many sorts in greatly varied publications spread his fame widely between 1828 and the Civil War, though thereafter it declined. In tall tales, sketches, short stories, romances, plays and even poems, he was a symbol of the boastfulness, the playfulness, the might, and the violence of frontiersmen. The picturesque nature of his death had imaginative appeal, and greatly varied versions of his murder were published.

FINLAND, called in Finnish SUOMI, is an independent republic of northern Europe. Through most of the early centuries of development (A.D 1155–1809) it was dominated culturally and politically by the Swedes; from 1809 to 1917 it was a Russian grand duchy. The Finns took advantage of World War I, and the Russian revolution of 1917, to win their independence, legalized by treaty of Tartu (Dorpat) with the Soviet Union, Oct. 14, 1920.

Geography.— Finland extends from 59° 48' to 70° 6' N. lat. and 19° 2' to 31° 35' E. long. It is 700 mi. from north to south, bordering Norwegian Lapland and the Arctic ocean on the north, the U.S.S.R. on the east, the Gulf of Finland on the south, the Gulf of Bothnia and Sweden on the west. It includes the numerous rocky Ahvenanmaa (*q.v.*) or Åland Islands in the southwest, part of Lapland, and, by the treaty of Tartu and until 1940, the ice-free fjord of Petsamo (Pechenga) in the north.

The area (1920–40) was 147,799 sq.mi. of which 60% was forest, 11% lakes, 3% arable and 5% grassland, and the rest largely swamp. The area of 130,119 sq.mi. determined in 1953 included inland waters (12,206 sq.mi.) but excluded territory ceded or leased to the U.S S.R. The chief lakes are Saimaa. Kallavesi, Paijanne and Näsijärvi; there are about 55,000 other lakes, many with rapids such as the Imatra. The chief rivers (none large) are the Muonio between Finland and Sweden, the Kemi and the navigable Oulujoki. The surface of the country is tableland 400 to 600 ft. above sea level. with a few elevations to 2,000 ft., and in the northwest, in the Haltio Mount, to 4,344 ft. The coastline is low, but rising more than 3 ft. per 100 years.

Geographically Finland is like the Scandinavian peninsula, showing granite and archaean rock with glacial and postglacial deposits of both lacustrine and marine origin. The soil is largely morainic, silty gravel, but clays form the most important portion of the cultivated areas. The climate is halfway between maritime and continental, the long severe winters being moderated somewhat along the coasts by the prevailing winds from the southwest. Summer lasts only two to two and a half months.

Flora and Fauna.— The predominance of forest. chiefly coniferous. gives the Finnish flora and fauna a special character and is also economically important. The dominant trees are pine (*Pinus sylvestris*) and spruce (*Picea abies*). The undergrowth is usually scrubby and meagre. About 30% of Finland is covered with marsh and bog. Among the plants are about 1,140 species of flowering plants and ferns and more than 1,000 species of lichens. The species of fauna number about 12,000; many of the birds migrate south in winter.

The country can be divided, botanically and zoogeographically, into five zones. The narrow coast area or oak zone is the richest in plant and animal species because of its milder climate. Oak, the dominant tree, and ash and hazel grow there. The commonest mammal is the hedgehog. There are numerous birds and insects and many sea birds and seals along the coast.

North of the oak zone is the maple or south Finland zone. The maple and elm reach their northern limit there. and there are many marshes and swamps and much bare land. Only two kinds of bat, the mole and goldfinch are found there.

North again is the lime or central Finland zone. The climate is more severe and there are larger barren areas and more marshes. In this and the maple zone occur a few bears, wolves and, in winter, small herds of reindeer followed by gluttons (wolverines). Numerous seals live in the Gulf of Bothnia.

The north Finland zone is the northern limit of the alder (*Alnus glutinosa*). There are immense pine forests, swamps and bogs. In the swampy wastes lichens and the crowberry (*Empetrum nigrum*) abound and swans and wild geese nest. Bears, wolves, domestic reindeer, gluttons, the lynx and viper are all found there.

The Lapland zone is mostly barren land with huge watery swamps and bogs. In the north is an area of coniferous forest, mostly dwarf pines covered with lichen. The spruce and, still farther north, the pine find their limit there. A small belt of birch grows north of the conifers, beyond which lies the tundra. Many northern birds, reindeer, wolves and gluttons live in the Lapland zone. Mosquitoes swarm in the marshes. The rivers hold salmon and trout; in the birch belt lives the Lapland bunting and by the lakes the long-tailed duck. The tundra is the home of the arctic fox, lemming and reindeer (now dying out in the wild state), snow bunting, ptarmigan and golden plover. On the Arctic coast a variety of sea birds nest, and cod, haddock, herring and many other kinds of fish are found in the sea. (X.)

HISTORY

The first real settlements in Finland were probably made about A.D. 100 by people crossing over from the southern shores of the Gulf of Finland. These people were thus a northern offshoot from the Finno-Ugrian tribes whose story is shrouded in mystery, as is the early development of the groups in Finland. At first they wandered about, burning off the forest in order to till the soil. Weapons, implements and ornaments indicate continuing relationship with the tribes to the south. Gradually family homesteads were established, and settlement from the southwest reached Lake Ladoga about A.D. 700. Increasingly trade and cultural bonds were established with the Swedes to the west, and southeastern influence all but disappeared. The tribes increased in population, warred among themselves, and were fought over by Sweden and by the Russian principality of Novgorod.

Swedish Rule.— Crusades were stimulated by the pope to win the people from their pagan beliefs (in Ukko, god of the air; Tapio, of the forests; Ahti, of the water, etc.). King Erik IX of Sweden in such a crusade (about 1155) conquered the Finns and left the English-born Bishop Henry of Uppsala at Turku (Åbo). But the Finns relapsed into paganism, though Henry became later their patron saint. Thomas. another English bishop, resumed the missionary task in 1209, and almost separated Finland from Swedish control to establish it as a papal province. The famous Birger Jarl compelled the Tavastians, one of the subdivisions of Finns, to accept Christianity in 1249; Torkel Knutson conquered the Karelians in 1293 and built the castle of Viborg (Viipuri), which for centuries to come was the outpost of Swedes and Finns against the Russians.

The Swedes spread civilization and accorded to the Finns the same civil rights they themselves had. Swedes settled in the Åland Islands and in spots along the western and southern shores of Finland. About 1528, Gustavus Vasa introduced the Reformed religion, and King John III raised the country to the dignity of a grand duchy. Gustavus Adolphus II and his successors did much for learning, but the country suffered terribly from war, famine and pestilence. Many Finns were compelled to fight with the Swedes in Germany during the Thirty Years' War.

In 1710 Peter the Great set out to wrest Finland from Sweden, and six years later the whole country was in his power. Thousands perished in the wars of Charles XII, but by the treaty of Nystad in 1721 the Russians retained Ingermanland, the whole Lake Ladoga, Karelia and the province of Viborg. Twenty years later the Swedes attempted reconquest but suffered disaster. In 1788 war again broke out between Sweden and Russia, and was carried on for two years without result.

In Feb. 1808 Tsar Alexander's army invaded Finland without declaring war. By the treaty of Fredrikshamn, on Sept. 17, 1809, Sweden ceded Finland and the Aland Islands to Russia.

Russian Rule.— Finland did not enter Russia as a conquered province. Alexander I granted it a free constitution and fundamental laws, and it became a semi-independent grand duchy with the emperor as grand duke. A senate was created and a governor general appointed. The province of Viborg was reunited with Finland in 1811. Åbo (Turku) remained the capital till 1821, when the seat of government was transferred to Helsingfors (Helsinki). The diet, which had not met for 56 years, was convoked by Alexander II at Helsingfors in 1863; but it was only under his successor, Alexander III, that the imperialist Pan-Slav movement, with the motto "one law, one church, one tongue," acquired influence in official circles.

Politics in Finland were complicated by the rivalry between the Swedish party, hitherto the dominant minority, and the Finnish national party which was asserting itself linguistically and politically.

Nicholas II, by the "February manifesto" (Feb. 15, 1899), virtually abrogated the legislative power of the Finnish diet. A new military law, practically amalgamating the Finnish with the Russian forces, followed in July 1901; Russian officials and the Russian language were foisted on Finland wherever possible, and in April 1903 the Russian governor was invested with dictatorial powers. To the Russian system of spies, domiciliary visits; illegal arrests; banishments and the suppression of newspapers, the Finns carried on a dogged resistance which culminated in the famous "national strike" of Nov. 1905. After six days the tsarist government — already much shaken by the events in Russia and Manchuria— capitulated. An imperial manifesto of Nov. 7, 1905, restored the *status* quo anfe 1899. The new diet remodelled the constitution on the basis of universal suffrage with freedom of the press, speech, meeting and association.

After "two glorious years of peace" and internal progress, the tsar peremptorily fixed an annual contribution in lieu of military service (*ukaz* of Oct. 7. 1909). The Finnish diet, though ready to compromise. was twice dissolved. and its social reform measures already passed — prohibition, child welfare, insurance, old-age pensions. education and betterment of landless workers—were thus killed. Civil marriages, however, were instituted. better provision made for illegitimate children and the principle of "equal pay for equal work" applied in the teaching profession, in the printing trade and, in 1913, in the state service. The duma alone considered itself competent to decide the questions affecting the interests of the Russian empire. Accordingly it passed the Imperial Legislation act on June 30/17, 1910, amid shouts of "Finis Finlandiae." Two imperial laws were laid before the diet. which refused them both and was dissolved. In one, the duma affirmed the principle of an annual indemnity in lieu of service; in the other, full civil rights were accorded to temporary Russian residents in Finland. The last-named measure, apart from its injustice, caused the overlapping of two different codes of law. Judges resigned, high officials went into exile. and every provisional governor left voluntarily or under compulsion. The country was ruled by a packed senate, the diet was peremptorily dismissed. the press censored. The Russification inflicted by the duma mas as oppressive as that imposed by the tsar.

World War I and the Russian Revolution. — Finland escaped invasion, but its liberties were restricted and its merchant marine was bottled in the Gulf of Bothnia. The Allied blockade caused a 25% rise in living costs, but industries connected with military supply attained unexampled prosperity. The Russians, sporadically anxious to please, abolished the annual military indemnity and merely imposed a 5% tax on property and mortgages. Finland naturally feared that a victorious Russia would again turn oppressor. About 2,000 young Finns enlisted on the German side, ostensibly for service only on the eastern front.

Nicholas II abdicated on March 1j, 1917, and the provisional government restored representative government in Finland. The Russified senate was disbanded and a temporary body of 12 (half Social Democrats, half representing the bourgeoisie) assumed executive power. The Socialist speaker of the diet, Oskari Tokoi, was nominated president of the senate; Kullervo Manner; of the same party, speaker of the diet. The diet, resolving on July 18, 1917, that it alone could make laws relating to home affairs and finance. passed en bloc all bills previously held up by the tsar, including the eight-hour day and the total prohibition of alcohol. Yet it failed to relieve the food shortage. The intense industrial development had strengthened hooliganism, and the war had brought about 40.000 Russian refugees from food shortage and incipient riot. From March 1917 to Feb. 1918 repeated strikes threatened the existence of the nation. Meanwhile, the advent of the Bolsheviks to power in Nov. 1917 deepened the pro-Russian sympathies of the Social Democrats, while the propertied classes sought to cut adrift from the Soviet state. On Dec. 6, 1917, the diet and the now bourgeois senate drew up a declaration of independence. The soviet of people's commissars on Jan. 4, 1918, declared that the step conformed with their policy, whereupon Sweden and the other Scandinavian countries acknowledged the independence of Finland. France and other states followed. The treaty of Brest-Litovsk (March 3, 1918) confirmed Finland's independence, and four days later Finland concluded a treaty which made it Germany's ally. (See BREST-LITOVSK, TREATIES OF.)

"Red Guards," recruited from Finnish labourers and reinforced from Russia, began to overrun the country. A hurriedly organized Finnish national army, under Baron Carl Gustaf Emil Mannerheim, a former general of the tsarist army, proved insufficient to maintain order. Sweden refused to help, but at the request of the Finnish government, Germany sent about 12,000 troops under Gen. Count Rudiger von der Goltz. The Finns and Germans conquered the Reds and drove out the Russians. Mannerheim subdued Tampere on April 6 and Goltz entered Helsinki on April 14. After Mannerheim's decisive victory near Viipuri (Viborg), on April 28–29, the "White" counterterror took the lives of thousands.

The diet, which met in June 1918, was moderate, since the Socialists who formed 46% of the electorate mere excluded from the register. It authorized the Germanophile senator, Pehr Eyvind Svinhufvud, to exercise the supreme poner in so far as it had not already been conferred on the senate, which offered the crown to Prince Frederick Charles of Hesse, brother-in-law of the German emperor. Prince Charles accepted the crown, but never proceeded to Finland and the question was allowed to lapse.

The Germans demanded Finnish military co-operation against the Murmansk railway. which was guarded by a British expeditionary force. Their claims were becoming peremptory when. on July 18, the Allied offensive in the west diverted Germany's forces. Thus time nas gained *until* the Armistice of *Nov. 11, 1918*, turned Finland toward the democratic regime. On Dec. 12 Svinhufvud mas succeeded as regent by Mannerheim, who formed a coalition government composed of 6 Republicans and 6 Monarchists. In the general election of March 1. 80 Social Democrats. 42 Agrarians, 28 coalitionists, 26 Progressives, 22 Swedes and 2 Christian Labour members were returned. The Social Democrats lost 12 seats as a result of the disfranchisement of 40,000 voters for participation in the Red revolt.

The Republic, 1919–1939.—On June 17, 1919, the Finnish diet established a republic. The new constitution came into force on July 17. There is a single chamber, eduskunta, of 200 members, in which the sovereign power is embodied. The executive power is vested in a president who is chosen for a six-year term by 300 presidential electors nominated by the citizens. He ratifies new laws or withholds consent. dissolves the diet, orders new elections and conducts foreign affairs. All his powers are exercisable through the ministers and his decisions have to be taken in the council of state consisting of 10 ministers, who are responsible legally and politically. There are ten administrative districts, closely following the linguistic distribution. Both Finnish and Swedish are official languages. Amnesty bills of 1921 and 1927 freed the defeated opponents of the war years. Suffrage is universal for men and women above the age of 24.

A peace treaty was signed with Soviet Russia at Tartu (Dorpat), Estonia, on Oct. 14, 1920. Pechenga (Petsamo) was ceded to Finland, which thus obtained an outlet on the Arctic ocean. On Dec. 16, 1920, Finland was admitted to the League of Nations. As such it claimed sovereignty over the Åland Islands (see AHVENANMAA), which was disputed by Sweden. In June 1921 the League of Nations decided in favour of Finland. In Oct. 1921 the East Karelians, racially allied to the Finns, revolted against Moscow. but the rising was crushed.

In these years Finnish foreign policy remained in the hands of

R. Holsti. On March 17, 1922, Holsti signed in Warsaw a treaty which pledged Finland, along with Estonia, Latvia and Poland, to consultation in case of a Soviet aggression. The diet of Finland, however, on May 12 refused to ratify this treaty and enunciated a general policy of avoidance of military obligations.

In succeeding years all attempts to form a Baltic bloc came to nought, while Finland turned more and more toward co-operation with its Scandinavian neighbours. (W. L. B.; X.)

Internal politics between World Wars I and II had turned on the issues of townsmen v. countrymen, property owners v. wage earners and a new Finnish-speaking intelligentsia *v.* a Swedish-speaking upper class, but agreement had always been reached within the bounds of democratic procedure. The wave of extreme Rightist or Fascist movements which spread over Europe in the early 1930s got no farther in Finland than a feeble Lapua movement which was put down in 1932 without fighting.

The strongest single party had been the Social Democratic and its best-known leader was Vaino Tanner. After the war of independence of 1918 the Communist party was small at first, but its strength in a country bordering on the U.S.S.R., with a strong Finnish Communist centre there, caused such fears that the party and its newspapers were suppressed in 1923, which did not prevent the Communists from securing 18 seats in the diet elected in 1924. New difficulties led to tense situations and the passage in 1930 of anti-Communist laws.

The most important reform of the between-wars period, carried through without serious opposition, was the *Lex Kallio* (1927), which, by splitting up the big estates and bringing new areas into cultivation, turned Finland into a nation of peasant-proprietors.

World War II.—Relations with the Soviet Union were never good, but Finland did sign one of the U.S.S.R.'s network of non-aggression pacts (Moscow, Jan. 21, 1932) and also was a party to the treaty in which the Soviet Union and all its European and middle-eastern neighbours defined the aggressor (London, July 3, 1933). Neither of these treaties, however, prevented the Soviet aggression against Finland in 1939.

On Oct. 5, 1939, the U.S.S.R. invited a Finnish delegation to Moscow to discuss political questions. Finland sent Juho Kusti Paasikivi, minister to Sweden and one of the peace delegates of 1920. The Soviet government asked for a 30-year lease of the port of Hanko, for a Soviet naval base; it also asked for the cession of part of the Karelian isthmus, some islands in the Gulf of Finland and various other portions of Finnish territory, in all about 1,066 sq.mi. in strategic locations, Finland to receive as compensation about 2,135 sq.mi. north of Lake Ladoga. The Finnish fortified zone in the Karelian isthmus was to be dismantled; the two states were also to agree not to join any alliances directly or indirectly hostile to the other.

Finland agreed to the cession of most of the islands demanded and an adjustment of the frontier in the Karelian isthmus, against compensation in both cases; it undertook to supplement the non-aggression pact of 1932 with a political agreement such as requested by the U.S.S.R.; it refused, however, to dismantle its fortifications and rejected the Soviet claim to Hanko as not compatible with Finnish neutrality. No agreement was reached and the Finnish delegation left Moscow on Nov. 13.

The Soviet press and wireless now launched a violent campaign against Finland and on Nov. 30, 1939, the Soviet armed forces attacked the country by land, sea and air. Two days later it was announced from Moscow that a "people's government of Finland" had been set up in the sea resort of Terijoki, close to the Soviet border. This puppet government consisted wholly of Finnish Communists who had fled to Russia after the unsuccessful attempt to impose a Communist regime on Finland in 1918. The head of this "government" was Otto Willie Kuusinen, a member of the executive committee of the Comintern. Vyacheslav Molotov signed with Kuusinen a treaty of friendship and mutual aid in which the latter agreed to all Soviet demands presented to the legitimate Finnish government.

Once more Mannerheim, now 72 and a field marshal, took command of his country's forces. The Finns fought heroically and Soviet hopes for an internal revolution proved fruitless. Finland's able defense drew promises of aid from Great Britain and France, and on Dec. 14, 1939, the League of Nations expelled the U.S.S.R. from membership as an aggressor. Although sympathy for the Finns was widespread throughout the world, the neutrality of Sweden and Norway prevented any substantial practical help. After 105 days' fighting, superiority in manpower and material enabled the Soviet army to break through the Mannerheim line. On March 12, 1940, defeated Finland signed a peace treaty in Moscow ceding to the U.S.S.R. more than one-tenth of its territory, including the whole Karelian isthmus with the city of Viipuri (Viborg). the country's fourth largest industrial centre; Hanko became a Soviet base. Nothing was heard of the Kuusinen "government."

When the Germans invaded the U.S.S.R. on June 22, 1941, the Finnish temptation to recover the lost land was stronger than any other consideration. Risto Ryti, who in Dec. 1940 succeeded Kjosti Kalliό as president of the republic, announced on June 27 that "for the liberty of the motherland" Finland was going to war alongside Germany. For the third time Mannerheim led the Finns against the Soviet army. By the end of August all territory lost in 1940 had been recovered; to liberate the Karelian people the Finnish army invaded the region between the lakes of Ladoga and Onega and took Petrozavodsk on Sept. 30.

Since Finland, disregarding warnings by the British and the U.S. governments, persisted in clinging to its policy of fighting on the German side, Great Britain declared war on it on Dec. 6, 1941, and the United States broke off diplomatic relations on June 30, 1944. The Finns had started to discuss peace with the U.S.S.R. in Feb. 1944, Paasikivi, Finland's negotiator of 1920 and 1940, going first to Stockholm, where he met Mme. Aleksandra Kollontay, the Soviet minister, and, at the end of March, to Moscow, for talks. The U.S.S.R. insisted, however, on the re-establishment of the 1940 frontier and in addition asked for the cession of Petsamo (thus shutting off Finland from the Arctic ocean) and payment of a $600,000,000 indemnity, *i.e.*, the country's national income in 1939. Such humiliating terms were at first refused, but as the Soviet armies started an offensive in Karelia, Viipuri being captured on June 20 and Petrozavodsk on June 29, the Finns changed their mind. On Aug. 1, 1944, Ryti resigned and Mannerheim (from June 4, 1942, marshal of Finland) was elected president of the republic.

On Sept. 19 the armistice was signed. Finland agreed to the terms presented to it in February with two differences: first, the leased territory for a Soviet naval base was moved from Hanko to Porkkala, only 18 mi. from Helsinki; second, the reparations to be paid in five years were reduced to $300,000,000. A sequel to the armistice was an armed conflict between the Finns and a German army in the north under Col. Gen. Lothar Rendulic.

The Republic from 1945.—In Nov. 1944 Paasikivi formed a new government. Elections were held on March 17–18, 1945, and on the resignation of Mannerheim on March 4, 1946, Paasikivi succeeded him as president. The peace treaty between Finland and the Allied powers was signed in Paris on Feb. 10, 1947.

After the second Soviet-Finnish war the Communist party emerged again into the open. For election purposes it combined with leftist splinter groups in a Finnish Democratic People's league (S.K.D.L.). Before World War II the Social Democratic party was the strongest. but now the Agrarian (Peasant) party was equally important. Three other parties had been important throughout the history of independent Finland: the Union (Conservative) party, the Progressive (Liberal) party, which was reformed in 1951 as the People's party, and the Swedish party representing the interests of the Swedish-speaking minorities.

Between 1944 and 1952 the obligation of settling the transferred population and of paying reparations to the Soviet Union were paramount internal problems. When the U.S.S.R. annexed Finnish Karelia, the inhabitants decided to settle in what was still Finnish territory. The Finnish government was therefore faced with the task of finding homes, employment and, in most cases, land for more than 400.000 people. The reparations problem was even more difficult. Finland had to supply the U.S.S.R. with goods worth $300,000,000 at the price levels of 1938, and, accord-

*There were also 8 members of the Patriotic People's Movement (I.K.L.), a Fascist party.

ing to detailed stipulations, was to consist of about one-third each of timber and timber products, ships and cables and machinery. For the last category Finland lacked alike the materials, the plant and the skilled workers; its production involved a revolution in the national economy. Nonetheless, the total reparations bill was met by the closing date. Sept. 1952.

Finland was the only country under Soviet influence where democracy survived. Though Mauno Pekkala and Yrjo Leino, both Communists, were respectively prime minister and home secretary from 1946 to 1948, they failed to bring the army or the police under Communist influence. In 1948 the major event before the elections was the Soviet-Finnish treaty of mutual assistance (April 6), which bound Finland to fight in defense of the U.S.S.R., but only if the latter were attacked through Finland and even then only on Finnish territory. After the elections (July), K. A. Fagerholm formed a minority government comprising his own Social Democrats and some nonparty men. This, however, had the support of other non-Communist parties and survived the Communist-organized strike of Aug. 1949, which protested the government's first devaluation of the currency (July) ; but it had to resign on the presidential election of Jan. 1950 (which returned Paasikivi) and was replaced in March by a government of Agrarians, with some members from the two smallest parties, under Urho Kekkonen. The new government negotiated an advantageous five-year trade agreement with the U.S.S.R., a feature of which was the latter's promising to take quantities of Finnish industrial products (but for this, the industries created to meet the Soviet demand for reparations might have had no market after reparations were paid). In Jan. 1951 Kekkonen took seven Social Democrats into the government, to strengthen his hand for measures against the continuing inflation. The elections (July) had little effect on the representation of the parties, and Kekkonen maintained the previous coalition.

The export boom of 1951 was followed bv a trade recession which aggravated the economic problem; and-in 1953, after controversv between the parties on the means of lowering prices, the coalition government resigned (June). Kekkonen then formed a ministry of Agrarians, Swedes and nonparty economists. When this fell in November, a caretaker government under Sakari Tuomioja took office. Elections, held in March 1954, failed to clarify the situation, as neither Fagerholm nor Kekkonen could bring the other's party into a government under him; but in May an Agrarian-Social Democratic coalition was effected under Ralf Torngren, of the Swedish People's party. A law was passed to prolong the normal life of a parliament from three to four years. In October, however, the government resigned as the two major parties disagreed on the measures of reducing the cost of living; but Kekkonen formed yet another coalition between them. On Feb. 15, 1956, Kekkonen was elected president of the republic by the majority of 151 in the electoral assembly of 300.

On Sept. 19, 1955, an agreement was signed in Moscow by which the U.S.S.R. gave up its military base at Porkkala in return for a 20-year prolongation of the Soviet-Finnish treaty of mutual assistance of 1948. This abandonment had no strategic significance because from 1945 the U.S.S.R. had had other, better bases in the Gulf of Finland. Later in 1955 Finland was admitted to the United Nations and joined the Nordic council, thus taking part in international affairs for the first time after World War II.

POPULATION

The total population of Finland, reckoned to number about 421,500 in 1750 and about 1,661,000 in 1851, was returned as 3,147,600 in 1920, as 3,695,600 in 1940 and as 4,029,803 by the census of 1950—when almost all the Finnish-speaking population of the territories lost or leased to the U.S.S.R. had been transferred to Finland (423,759 persons in 1946). Racially this population is the result of a 1,000-year blending of Finno-Ugrian (*q.v.*) and Teutonic (Swedish) elements, which however are still to a considerable extent distinguishable: 8.55% of the population spoke Swedish, 91.26% spoke Finnish (see FINNO-UGRIAN LANGUAGES), and there was a small minority of Lapps. The average density of population was only 31.0 per square mile in 1950, but the distribution was uneven, as 40% inhabited the three southern provinces of Uusimaa, Turku-Pori and Häme, which constitute only one-sixth of the national territory.

The principal cities, according to the 1950 census, were Helsinki (Helsingfors), the capital, 369,380; Turku (Åbo) 101,824; Tampere (Tammerfors) 101,143; Lahti 44,652; Pori (Björneborg) 43,213; Oulu (Uleåborg) 37,910; Vaasa (Vasa) 34,999; Kuopio 33,353 and Jyväskylä 30,661.

Religion and Education.—The national church is the Evangelical Lutheran, to which 96% of the population adhere; the archbishop of Turku is its head, and it has five other bishops. The Orthodox church, which serves 1.8% of the population, has an archbishop at Kuopio. There are small communities of Baptists, Roman Catholics and Jews; and 2% of the population is described as of no religious affiliation.

Since 1921 attendance at school has been compulsory for children between the ages of 7 and 15 years. Secondary education is provided by the "middle" schools for children between the ages of 10 and 15; by other secondary schools from which pupils may pass to the universities at the age of 18; and by various types of vocational schools. Higher education is provided by degree-granting colleges which pupils enter after passing the matriculation examination at the secondary schools. Finland's first university, founded at Turku in 1640, was transferred to Helsinki in 1827. A Swedish university was opened at Turku in 1919, a second Finnish one in 1922.

In 1953–54 there were: 6,402 primary schools with 541,770 pupils and 22,817 teachers; 345 secondary schools with 114,901 pupils; 473 vocational schools with 31,054 pupils and 3,284 teachers: 179 "folk" high schools for adults with 52,374 pupils and 1,068 teachers; 14 primary teachers' colleges with 2,456 students and 201 teachers. There were 3 universities and 12 other institutions of higher education with a total of 15,355 students and a teaching staff of 1,210.

ECONOMICS AND FINANCE

Agriculture.—Agriculture is the chief occupation of the people although the arable land covers less than 8% of the country area. Arable land lies mainly on the coastal plains; hay occupies one-half and cereals one-third of the cultivated area. Oats are the dominant cereal but from 1930 quick-ripening spring wheat gained ground. Potatoes are the chief root crop. (*See* Table II.) Numbers of livestock are shown in Table III.

Industry.— Finland has few minerals. There is no coal or oil. At Outokumpu about 600,000 metric tons of sulphide ores are produced annually (4% copper. 26% sulphur, 27% iron, with some zinc, cobalt, silver and gold). Finland possesses extensive deposits of limestone, soapstone and red granite, but the country's main resources lie in its forests and water power. In the Finnish forest industry a continuous trend toward development of higher stages of manufacture was to be observed. Before World War I the greater part of output was sawn timber. The period between World Wars I and II was marked by a powerful advance in the pulp and paper industry. In the years following World War II the industry manufactured prefabricated houses; however, the greatest attention was devoted to processing wood pulp into paper, cardboard and packing material.

About one-fifth of the population is engaged in the manufacturing industry, mainly connected with forest products. In 1939 Finland had an installed capacity of electric energy amounting to 1,004,000 kw., including 492,000 kw. of hydroelectric generators. In the territories ceded to the U.S.S.R., Finland lost about one-quarter of its hydroelectric power plants. In 1938 production of electricity amounted to 3,108,000,000 kw.hr., including 2,456,000,000 kw.hr. from hydroelectric plants; after 1945 new power stations were built, and in 1954 the total production amounted to 5,643,000,000 kw.hr., mostly from hydroelectric plants.

Finance and Banking.—The Finnish markka was stabilized in relation to the U.S. dollar in 1922, and in 1925 a gold basis was adopted, the rate being 39.70 markkaa to the dollar and approximately 193.23 markkaa to the pound sterling. World depression forced the markka off gold in Oct. 1931; in 1933 it was stabilized again at 227 markkaa to the pound sterling. In Dec. 1938 its parity level with the dollar and the pound was again abandoned, and in 1939 the exchange rate was 49 markkaa to the dollar and 197 markkaa to the pound. Further devaluations followed World War II, and after Sept. 1949 the exchange rate was 231 markkaa to the dollar and 646 markkaa to the pound. The Bank of Finland, dating from 1811, is the state bank and bank of issue. There

*Actual. †Estimates.

was a currency circulation of 2,300,000,000 markkaa against gold holdings of $28,900,000 and foreign exchange holdings of $48,500,000 in Dec. 1938 (when deposit money amounted to 2,800,000,000 markkaa); and a currency circulation of 48,300,000,000 markkaa against gold holdings of $35,300,000 and foreign exchange holdings of $188,900,000 in Dec. 1955 (when deposit money amounted to 43,300,000,000 markkaa). For the national budget *see* Table IV. In Sept. 1939 the foreign debt stood at 1,040,000,000 markkaa and the internal debt at 2,810,000,000 markkaa; at the end of 1954 the figures were 62,100,000,000 markkaa and 49,700,000,000 markkaa respectively.

Foreign Trade.—Before World War I Russia was the most important buyer of Finnish goods, but after the proclamation of its independence Finland turned its foreign trade westward. Great Britain became the largest export market (45.3% in 1937), followed by Germany (13.1%); and Great Britain was also the chief source of imports (22.1% in 1937), likewise followed by Germany (19.4%). In 1946 the Soviet Union took second place as Finland's customer and supplier, Great Britain maintaining its first place. By the end of 1953, however, the U.S.S.R. was taking 25.4% of the exports and Great Britain 22%, the same countries providing 21.4% and 15.8% of the imports respectively. In 1954 Great Britain recovered first place among Finland's customers and suppliers, taking 22.5% of the exports and providing 18.8% of the imports. (*See* also Table V.)

Metals and metal manufacture, machinery and apparatus, textiles, coal, oil and cereals headed the import list; exports consisted of timber and timber products (about four-fifths of the total) and agricultural products such as butter, cheese and hides.

Table V.—*Foreign Trade*
(In millions of markkaa)

Transport and Communications.—In 1953 there were 7,476 km. of railways on which 16,343,000 tons of goods were transported. The numerous lakes are utilized freely for transport and, joined by short canals, constitute continuous waterways. These waterways are navigable at a length of about 2,700 mi. and floatable at a length of about 26,500 mi. There were 63,460 km. of roads in Dec. 1953, when the number of licensed motor vehicles comprised 59,216 cars and 49,054 commercial vehicles. The merchant navy (vessels of 100 or more gross tons) amounted in April 1955 to 588 vessels, totalling 728,805 gross tons. Finnish air lines connect Helsinki with Stockholm, Copenhagen, Hamburg, Amsterdam, Paris and London, and with the chief provincial towns. In 1954 air transport amounted to 94,512,000 passenger-kilometres and 873,600 ton-kilometres of freight; kilometres flown (1953) 3,993,000. In 1954 there were 408,531 telephones and 970,798 radio licences.

Defense.—Under the treaty of Paris (1947) Finland was permitted to maintain an army of 34,400, an air force of 3,000 officers and men and 60 aircraft (bombers being forbidden) and a navy up to 10,000 tons and 4,500 officers and men. The president of the republic is commander in chief: with the minister of defense responsible to the council of ministers for the efficiency of the armed forces; there is also a high command and general staff. All male Finnish citizens are liable for military service from the age of 19 to the age of 60. The period of peacetime service is 350 days. All men conscripted belong to the reserve up to the age of 40 and can be called to attend periodical training courses. From 40 to 60 they belong to the second reserve.

(J. H. Jn.; X.)

FINLAY, GEORGE (1799–1875), British historian. was born of Scottish parents at Faversham, Rent, on Dec. 21, 1799. He studied for the law in Glasgow, and about 1821 went to Göttingen. In 1823 he went to Greece, being interested in the struggle for Greek independence. and spent 14 months studying the country. At Missolonghi he met Byron. and for two months spent nearly every evening discussing Greek affairs with him. After a short visit to Scotland he returned to Greece, where he spent the rest of his life.

In 1827 Finlay took part in the unsuccessful operations of Lord Cochrane and Sir Richard Church for the relief of Athens. When independence was secured in 1829 he bought an estate in Attica, and tried, without much success. to introduce better methods of agriculture in Greece. He then turned to the systematic study of Greek history with which he occupied himself until his death in Athens on Jan. 26, 18;j.

The first part of his great work appeared in 1844, under the title of *Greece under the Romans*, and was followed by *History of the Byzantine and Greek Empires from 716–1453* (2 vol., 1854); *History of Greece under the Ottoman and Venetian Domination* (1856) and *History oj the Greek Revolution* (2 vol., 1861). From 1864 to 1870 he was correspondent of *The Times*.

Bibliography.—H. F. Tozer's edition of his *History of Greece from its Conquest by the Romans to the Present Time, 146 B.C.–A.D. 1864*, 7 vol. (Oxford, 1877), which includes the books mentivned above, contains also a fragmentary autobiography. Finlay's *Greece under the Romans* and *History of the Byzantine Empire from 716 to 1077* have been published in the Everyman Edition (1906).

FINLAY, ROBERT BANNATYNE FINLAY, 1ST VISCOUNT (1842–1929), British lawyer and politician, was born near Edinburgh on July 11, 1842. He was educated at Edinburgh academy and university and graduated in medicine. He was called to the bar in 1867 and became a queen's counsel and a bencher of the Middle Temple in 1882. He sat as a Conservative for Inverness Burghs from 1885 to 1892 and regained the seat and was made solicitor general in Lord Salisbury's government in 1895, when he was knighted. In 1900 he became attorney general, remaining in the government until the Conservative defeat of 1905–06.

From 1902 to 1903 he was lord rector of Edinburgh university. In 1910 he was elected M.P. for Edinburgh and St. Andrews universities, and in 1916, on the formation of David Lloyd George's government, he became lord chancellor and received a barony. He retired in 1918 and was created a viscount in 1919. In 1920 he was appointed British member of the Permanent Court of Arbitration at The Hague, and in 1921 he became a judge of the Permanent Court of International Justice.

Finlay died March 9, 1929.

FINNER, the name used by whalers to denote the rorquals (*q.v.*) (*see* also WHALE).

FINNEY, CHARLES GRANDISON (1792–1875), U.S "new measure" evangelist. theologian and college president, was born in Warren, Conn., Aug. 29, 1792, and grew to manhood in Oneida county. N Y. After teaching school for a few years he studied law privately and in 1818 entered the law office of Benjamin Wright, Adams, N Y. His religious training had been meagre, but references to Mosaic institutions in his law studies impelled him to study the Bible. With his conversion in 1821 he was convinced that he had been given a "retainer from the Lord Jesus Christ to plead His cause," so he immediately dropped his law practice to become an evangelist, and was licensed by the Presbyterians. Adopting some of the features of frontier revivals—especially the "anxious seat"—and addressing congregations as he used to plead with a jury, he fomented wild revivals in the villages of upper New York. These methods, carried into the Congregational and Presbyterian churches of the larger towns and cities, were soon dubbed "new measures" and aroused intense opposition, particularly among men trained in the New England schools and at Princeton. Such opposition lessened as Finney's methods became more polished, while his revivals carried into the larger cities continued to be spectacularly successful.

In 1832 he began an almost continuous revival in New York as the settled minister of the Second Free Presbyterian church Because he was at odds with Presbyterian theology and discipline, his supporters built the Broadway tabernacle for him in 1834. Two years later he withdrew from the presbytery, and the church became Congregational in polity. In 1835 he became professor of theology in the newly formed theological school at Oberlin. O., and for two years divided his time between that post and his New York tabernacle. In 1837 he severed his connection with the latter and became minister of the First Congregational church in Oberlin, which was closely related to Oberlin college. From 1851 to 1866, besides his other two posts, he was president of the college. He died Aug 16, 1875.

The changing modes and surroundings of Finney's career as a revivalist typify the development of revivalism during the period of his greatest activity. Beginning in raw frontier villages among lo er-class and poor people, he moved into the burgeoning urban centres of financial and social power, working among those of the rising middle class with its growing philanthropic interests. In making this change of locale, his revivals were metamorphosed from the largely unplanned fomenting of emotional outbursts leading to conversions, into rather carefully designed meetings in which he pleaded the cause of Christianity in sermons and lectures which resembled the lawyer's brief. When he settled as a minister and professor of theology his emphasis changed from concentration solely upon getting conversions to include concern for the perfection of the Christian life in the churches.

His theology was typical of all the revivalists, emphasizing common sense and man's initiative in conversion and ability to make himself a new heart by his own choice. As did other revivalists, he tended to make the test of the truth of the doctrine preached its effectiveness in getting results, namely converts. This emphasis, of course, played havoc with traditional standards of doctrine and polity in the churches, impoverishing the religious life by excessive emphasis on the conversion experience to the neglect of cultivation of the Christian life thereafter.

His life is best told in his *Memoirs* (1876), and his views expounded in his *Lectures on Revivals* (183j) and *Lectures on Systematic Theology* (1847). (S. E. MD.)

FINNISH LITERATURE. The earliest writer in the Finnish vernacular was Mikael Agricola (c. 1510–57), who published an A.B.C. book (*c.* 1542) and, as bishop of Turku (Åbo), religious and educational works. A Finnish version of the New Testament was printed by Agricola in 1548. and some books of the Old Testament in 1551–52. A complete Finnish Bible was published at Stockholm in 1642. The dominion of Sweden was unfavourable to the development of Finnish literature; not until 1835, when the Finnish epic, the *Kalevala* (*q.v.*), was published thanks to Elias Lönnrot (*q.v.*), was the Finnish language used for literary composition. A great work in the revival of interest in the Finnish language was done by Suornalaisen Rirjallisuuden Seura (the Society of Finnish Literature), founded in 1831.

Modern Finnish literature has its roots in the poetry, drama and fiction of Aleksis Kivi (1834–72), a genius whose original style inspired others to write in Finnish. *Nummisuutarit* (1864; "The Cobblers of the Heath") is one of his robust peasant comedies. His most famous work is the epic novel *Seitseman veljestä* (1870; "Seven Brothers"), in which Kivi gave full rein to his humour and rich fantasy. Realistic writing was further developed by the novelist and playwright Minna Canth (1844–97). Finnish cultural life received a vigorous impulse when Kaarlo Bergbom founded the Finnish National theatre and P. E. Cajander (1846–1913) translated the plays of Shakespeare.

The central figure in Finnish letters at the beginning of the century was Juhani Aho (1861–1921), a realist who, toward the end of his life, made big concessions to romanticism. His works include *Rautatie* (1884; "The Rail ay"). *Papin tytär* (1885; "The Clergyman's Daughter") and *Lastuja* (1891–1921; "Chips"), eight volumes of stories, memoirs, travel notes, essays, etc. A much-discussed author was the man whose pseudonym was Johannes Linnankoski (1869–1913); his best-known novel was *Laulu tulipunaisesta kukasta* (1905; "The Song of the Blood-Red Flower") and his best work stylistically *Pakolaiset* (1909; "The Fugitives"). Arvid Jarnefelt (1861–1932), after his remarkably mature first work *Isänmaa* (1893; "The Fatherland"). became strongly influenced by Tolstoy. Two skilful portrayers of peasant life are Joel Lehtonen (1881–1934) and Ilmari Kianto (1874–); their chief novels are, respectively, *Putkinotko* (1919) and *Ryysyrannan Jooseppi* (1924).

The third great master of Finnish prose after Kivi and Aho is the 1939 Nobel prizewinner F. E. Sillanpaa (*q.v.*; 1888–). Like most Finnish writers, he depicts country life, but none has caught its poetic undertones as well as he. Three of his novels are *Hurskas kurjuus* (1919; "Meek Heritage"), *Nuorena nukkunut* (1931; "Fallen Asleep While Young") and the lyrically beautiful *Ihmiset suviyössä* (1935; "People in the Summer Night"). The colourful novels of Unto Seppanen (1904–55) are a vivid portrayal of life in his native Karelia. The "proletarian" writer Toivo Pekkanen (1902–) began his career as a factory hand and became a member of the Finnish academy; *Lapsuuteni* ("My Childhood") is an uplifting account of his early years. Lauri Viita (1916–) is a gifted poet who has also written a novel, *Moreeni* ("The Moraine"). The versatile and prolific writer Mika Waltari (1908–) has great mental elasticity and artistic temperament. His historical novels are well known abroad. Pentti Haanpaa (1905–55) was a master of the short story; his pithy style was well suited to his portrayal of life in the backwoods. Oiva Paloheimo (1910–) is a polished stylist appreciated for both his poetry and prose. Two brilliant young writers of promise are Marko Tapio and Veikko Huovinen, the latter a satirist with a dry humour.

Of numerous women writers, the following deserve mention: Aino Kallas (1878–1956), Finnish by birth and Estonian by marriage, has always championed the cause of Estonia in her writings; these are mainly short stories. Maila Talvio (1871–1951) was a richly productive novelist for whom religion was the inner source of power and hope. Maria Jotuni (1880–1943) was a short-story writer with a ready humour and a piercing insight into human nature. One of the best of the younger women writers is Eeva Joenpelto.

The first great poet in Finnish was Eino Leino (1878–1926), whose most famous work was *Helkavirsia* (1916), strongly nationalist historic poems in ballad form. He also translated Dante's *Divine Comedy* into Finnish blank verse. One of the first to express the growing nationalist Finnish movement was the poet Kaarlo Kramsu (1855–95), and typically Finnish in feeling were Larin Kyosti (1873–1948) and Otto Manninen (1872–1950); the latter made excellent translations of Homer, Molière, Goethe, Ibsen and others. An outstanding poet, classical scholar and literary critic is V. A. Koskenniemi (1885–), former member of the Finnish academy, and another humanist, poet and critic is Lauri Viljanen (1900–). Lyric poets who did much to influence the development of Finnish poetry were Juhani Siljo (1888–1918), Aaro Hellaakoski (1893–1952), Uuno Kailas (1901–33), Kaarlo Sarkia (1902–45) and Saima Harmaja (1913–37). Important also are Martti Haavio (1899– ; pseudonym P. Mustapää), Yrjö Jylha (1903–1956), whose experiences as a soldier in the winter war of 1939–40 found expression in *Kiirastuli,* and the women writers Aale Tynni (1913–) and Helvi Juvonen (1919–).

Swedish-Finnish Literature.—Finland's most famous poet was Johan Ludvig Runeberg (*q.v.*; 1804–77), whose works, though written in Swedish, are truly Finnish in spirit; they not only laid the foundation for Finland's independence, but also influenced the work of later poets who wrote in Finnish. His patriotic cycle of poems, *Fanrik Ståls Sagner* (1848–60; "The Tales of Ensign Stål"), is world famous. The second great poet of this period, who also strongly influenced Finnish literature in general, was Zacharias Topelius (1818–98). Poems, essays, historical novels, fairy tales and plays poured from his pen. Of the many fine poets of the next generation—including Mikael Lybeck (1864–1925) and Hjalmar Procopé (1868–1927)—the most outstanding are Bertel Gripenberg (1878–1946), Arvid Morne (1876–1946) and Emil Zilliacus (1878–), who also translated the Greek classics into Swedish. Swedish-Finnish modernism's pioneer was Edith Sodergran (1892–1923); she had a deep influence on later writers as well as on contemporaries. Modernism's second great figure is Elmer Diktonius (1896–), followed by Rabbe Enckell (1903–), Goran Stenius (1909–), Walentin Chorell (1912–) and Ralf Parland (1914–).

One of the greatest humanists in Europe was Yrjö Hirn (1870–1952), essayist, aesthete and literary historian. Runar Schildt (1888–1925) was the most eminent writer of Swedish prose in Finland. His short stories and plays are characterized by a polished style, penetrating psychological insight and sympathy for the lonely and oppressed.

(A. L. Br.)

FINN MAC CUMHAILL (fin mă-kōōl') was probably the general to whom Cormac mac Airt, king in Tara (*fl.* c. A.D. 250) entrusted the task of organizing a standing army, whereby he sought to establish a suzerainty over the whole of Ireland. But he has attracted to himself a vast body of popular legend, and has thus become a mythological figure which dominates the folklore of the Gaelic peoples, in Ireland, Scotland and the Isle of Man. It is difficult to trace the growth of the legend, owing to a paucity of early materials. The tales told of the hero were of a popular nature, transmitted by word of mouth, and did not assume a literary form so soon as the mythologies of the Tuatha DC Danann or the sagas of Cú Chulainn. In these tales Finn is represented as being the leader of a band of braves, of strongly contrasted characters—which the story-tellers generally manage to preserve with remarkable consistency and with no little humour. They wander about with a seeming lack of aim, but they are employed in defending Ireland against foreign invaders (as in the well-known tale of the *Battle of Ventry),* and in the intervals devote themselves to the pleasures of the chase.

They are not always united; they belong to opposing families; and the best-known tale of the cycle is that of Finn's pursuit and destruction of his lieutenant Diarmait, who had eloped with his destined bride, Grainne, the daughter of Cormac mac Airt.

(R. A. S. M.)

FINNO-UGRIAN, the designation of a division of the Ural-Altaic family of languages and their speakers. The term Finn is the name given by their neighbours, though not used by themselves, to the inhabitants of the eastern shores of the Baltic. It is probably the same word as the Fenni of Tacitus and *Φίννοι* of Ptolemy, though it is not certain that those races were Finns in the modern sense. It possibly means people of the fens or marshes, and corresponds to the native word *Suomi,* which appears to be derived from *suo,* a marsh. Finn and Finnish are used of the inhabitants of Finland and of similar tribes found in Russia and sometimes called Baltic Finns and Volga Finns. In this sense the Estonian tribes (Baltic), the Lapps, the Cheremiss and Mordvins (Volga), and the Permian tribes are all Finns. The Ostiaks, Voguls and Magyars form a separate subdivision called Ugrian, from Yura or Ugra, the country on either side of the Ural Mountains.

The name Finno-Ugric is primarily linguistic. The Finno-Ugrians form, with the striking exception of the Hungarians, a moderately homogeneous whole. They are nomads, but are hardly ever warlike and have no power of political organization. Those of them who have not come under European influence live under the simplest form of patriarchal government.

In Russia the Finno-Ugric tribes are widely spread in the wooded country, especially on the banks of lakes and rivers. They form a considerable element in the population of the northern, middle and eastern provinces of Russia, but are not found much to the south of Moscow (except in the east) or in the west (except in the Baltic provinces). The Finno-Ugric (or Palaeo-Arctic) people have black or even reddish hair, sparse beards, yellowish to whitish skin, short stature, flat heads, flat faces, high cheek bones, oblique eyes and straight or concave noses. The head index varies from long to round.

The following are the principal Finnish peoples. The *Permians* and *Syryenians* (Syrjenian, Sirianian, Zyrjenian, Zirian) may be treated as one tribe. They both call themselves Komi and speak a mutually intelligible language, allied to Votiak. The name Bjarmisch is sometimes applied to this sub-group. Both Permians and Syryenians are found chiefly in the governments of Perm, Vologda and Archangel. The Syryenian headquarters are at the town of Ishma on the Pechora, whereas the name Permian is more correctly restricted to the inhabitants of the right bank of the upper Kama. The *Votiaks* dwell chiefly in the south-eastern part of the government of Viatka. They call themselves Ud-murt or Urt-murt. The Cheremiss, who call themselves Mari, inhabit the banks of the Volga, chiefly in the neighbourhood of Kazan.

The *Mordvinians,* also called Mordvá, Mordvins and Mordvs, are scattered over the provinces near the middle Volga, especially Nizhni Novgorod, Kazan, Penza, Tambov, Simbirsk, Ufa and even Orenburg. Though not continuous, their settlements are considerable both in extent and population. They are the most important of the Eastern Finns, and their traditions speak of a capital and of a king who fought with the Tatars. They are mentioned as Mordens as early as the 6th century, but now call themselves after one of their two divisions, Moksha or Erza. Their language (two dialects) is derived from Early Finnish, and has constructions peculiar to itself.

The *Lapps* are found in Norway, Sweden and Finland. They call themselves Sabme, but are called Finns by the Norwegians. They are the shortest and most roundheaded race in Europe. The majority are nomads who live by pasturing reindeer, and are known as Mountain Lapps, but others have become more or less settled and live by hunting or fishing. From ancient times the Lapps have had a great reputation among the Finns and other neighbouring nations for skill in sorcery.

The *Estonians* are the peasantry of the former Russian province Estonia and the neighbouring districts. They have reddish flaxen hair with a tall element. They are practically a branch of the Finns, and are hardly separable from the other Finnish tribes inhabiting the Baltic provinces. They call themselves Mā mēs, or country people, and their land Rahwama or Wiroma (*cf.* Finnish, Virolaiset, Estonians).

Livs, Livlanders or *Livonians* is the name given to the old Finnish-speaking population of west Livland or Livonia and north Kurland. They were a warlike and predatory pagan tribe in the middle ages, and it is possible that they were a mixed Letto-Finnish race from the beginning. They have become almost completely absorbed by Letts, and their language is only spoken in a few places on the coast of Kurland, if indeed it still exists. It is known as Livish or Livonian and is allied to Esthonian. The *Votes* (to be distinguished from the Votiaks), are also called southern Chudes and Vatjalaiset. They now occupy only a few parishes in north-west Ingria The *Vepsas* or *Vepses,* also called Northern Chudes, another tribe allied to the Esthonians, are found in the district of Tikhvinsk and other parts of the former government of Old Novgorod.

The *Finns* proper or Suomi, as they call themselves, inhabit Finland and the Olonetz, Tver and governments of Leningrad. Formerly a tribe of them called Kainulaiset was also found in Sweden, whence the Swedes call the Finns Qven. At present there are two principal subdivisions of Finns, the Tavastlanders or Hämäläiset in the south and west and the Karelians or Karjalaiset in the east and north. The Tavastlander has a round head, a broad face, concave nose, fair complexion. frequently light hair and blue or grey eyes. The Karelians have broader heads and are shorter.

History. — Most of the Finno-Ugrian tribes have no history or written records, and little in the way of traditions of their past. In their later period the Hungarians and Finns enter the course of ordinary European history. For the earlier period we have no positive information, but from archaeological and philological data an account of the ancient nanderings of these tribes may be constructed. Barrows containing skulls and ornaments may mark the advance of a special form of culture. But clearly all such deductions contain a large element of theory, and. the following hypothesis has been proposed by Peake. (*J R.A I.* xlix. 1919.) In late Palaeolithic times various types of long-headed men occupied the plain of north Europe. Then came in Solutrian times a nomadic people from Eurasia, hunters of wild horses. Then a broadheaded race of perhaps Mongol affinities pressed to the Baltic. The Nordic Steppe folk spread north and about the middle of the Bronze Age came into touch with the Mongoloids who nere reinforced by later waves. "Thor must have led his red-haired followers from the banks of the Volga while Woden brought his fair-haired warriors from the Russian Steppes."

FINNO-UGRIC LANGUAGES are a family of languages constituting much the larger of the two branches of a more comprehensive grouping, the Uralic languages. The Finno-Ugric languages are spoken by over 18 000,000 people distributed discontinuously over an area extending from Norway in the west to the environs of the Ob river in Siberia. and into the Carpathian basin In this vast territory. the Finno-Ugric peoples constitute enclaves, surrounded mostly by speakers of Germanic, Slavonic, or Turliic tongues. Formerly, their habitat was more restricted, essentially to a region between the Baltic and the Urals; it was under the pressure of their Indo-European and Turkic conquerors that they migrated, in successive waves, farther to the west and north in Europe and beyond the Urals into Asia.

The family is usually considered to comprise the following extant units.

The Ugric division. This is further subdivided into: (1) Hungarian (Magyar); and the two Ob-Ugric languages, (2) Vogul (Mansi), and (3) Ostyak (Khanty). Single Hungarian words are known from the 10th century and the first full text from the 13th, so that this is both the oldest recorded Finno-Ugric language as well as the one spoken by the largest population (about 13,000,-000). Vogul, the language of some 5,000 peasants, hunters and reindeer breeders, is spoken along the western tributaries of the Ob and the Irtysh; and Ostyak is spoken by over 20,000 fishermen, hunters and reindeer nomads along the Ob and several of its tributaries.

The two Permian languages. They are the closely related (4) Zyrian (Komi) and (5) Votyak (Udmurt). Attested since the 14th century by religious texts and inscriptions written in a specially constructed alphabet, invented by St. Stephen of Perm (1335–1396), Zyrian — also known as Syryenian — is now spoken by more than 360,000 people over an enormous territory between the Vychegda, Mezen, Pechora and Kama rivers, near the Arctic ocean, as well as in the Murmansk region and on both sides of the Crals. Zyrian has two literary forms, one of them based on the southernmost dialect, Permyak. Votyak is spoken between the Vyatka and the Kama, and smaller groups are scattered beyond both of these rivers; there are over 500,000 speakers.

There are two groups of (6) Mordvins (Mordva), the Moksha and the Erzya, who speak different dialects and possess separate literary standards. Mordvin is spoken by a population of approximately 1,500,000, in numerous enclaves south of the Volga bend, along both sides of the river.

The (7) Cheremis (Mari) divide into three dialect groups spoken, by a population of somewhat under 500,000, along the right bank of the Volga (the so-called Mountain Cheremis, of Kozmodemyansk); in the prairie region beyond the left bank (Meadow Cheremis); and in the Bashkir Republic (Ufa Cheremis).

The Finnic (or Balto-Finnic) division consists of eight more or less mutually intelligible dialects or languages: (8) Finnish (Suomi); (g) Karelian; (10) Olonets; (11) Vepse; (12) Lude; (13) Vote; (14) Estonian; and (15) Livonian. Finnish is the language of about 3,500,000 speakers in Finland (where it is the principal national tongue), and in adjacent regions of Scandinavia and the U.S.S.R. A'ritten Finnish dates from the 16th century and has been, since the middle of the 19th, the vehicle of a comprehensive literature. Karelian is a term used to designate a dialect spoken in the Karelo-Finnish Soviet Republic; Olonets is the dialect spoken on both sides of the boundary north of Ladoga. Lude is spoken farther to the east and it, in turn, shades into Vepse, spoken in small settlements along the southwestern edge of Lake Onega. Vote is spoken by a dwindling population—perhaps 500 peasants — in Ingria. Estonian is used by about 1,-250,000 speakers in the Estonian Soviet Socialist Republic and in scattered enclaves elsewhere in Russia. Its written form dates from the 16th century; modern literary Estonian is based upon the Tallin (northwest) dialect, but formerly the rather different Tartu (southeast) dialect was employed for this purpose. Livonian is almost extinct; it is spoken by perhaps 1,500 fishermen and peasants on the north promontory of Kurland.

The (16) Lapp languages, spoken by over 30,000 people, are usually divided into northern (sometimes, however, called central or western), southern and eastern groups. Northern Lapp is the language of the reindeer breeding Finnish Lapps, those of Norwegian Finnmark and Troms, and of Norrbotten, except that southern Lapp is spoken in the southernmost region of this Swedish province. Eastern Lapp is the language of the fishermen of Inari, and the Russian Lapps of Kolta and Kola.

The vocabulary of the Finno-Ugric languages contains an adequate common stock of terms to permit the reconstruction of the ancestor language. but also reflects a series of contacts with neighbouring peoples at different periods in their history. The Iranian loanwords seem to be the oldest. Finnish borrowed from Lithuanian in remote times, and later from Germanic languages and Russian. Cheremis, Votyak and the Ob-Ugric tongues are rich in Turkic loans. Hungarian has also borrowed, at different times. from several Turkic sources, as well as from Iranian, Slavonic. German, Latin and Romance.

The sound systems of the present day Finno-Ugric languages exhibit a variety of structures and practically no trait is common to them all. Vowel harmony, for instance, which is sometimes thought of as a characteristic of these tongues, is absent from Ostyak, Lapp and the Permian group. Consonant gradation — an intricate alternation between two classes of stem consonants—occurs in Lapp and the Finnic tongues, with only occasional traces in the sister languages. The grammar of Finno-Ugric languages typically operates by the addition of multifarious endings to different stem forms. The declension of some of these languages—for example, Hungarian and Finnish — includes a more or less elaborate case system. Lapp and the Ob-Ugric languages possess dual number as well as plural. The verb in the Ugric languages and Mordvin is marked by a distinction between subjective and objective conjugation, and the non-Ugric languages have a negative conjugation. A typical feature of Finno-Ugric syntax is illustrated by the contrast of these two Hungarian phrases: *a nagy* haz "the big house," and *a ház nagy* "the house is big": in the former phrase, the attribute precedes the head; in the latter, an equational sentence, the predicate comes after the subject.

FINSBURY, a metropolitan borough of London, Eng., is the second smallest of the metropolitan boroughs. Pop. (1951) 35,370. Area 0.9 sq.mi. Because of the large number of offices, factories and warehouses within its boundaries, it has been estimated that the daytime population is about 150,000. One of the 28 metropolitan boroughs formed under the London Government act of 1899, it was created from the parishes of St. James and St. John, Clerkenwell; St. Luke, Middlesex; St. Sepulchre, Middlesex; the Charterhouse; and the liberty of Glasshouse Yard. It is bounded by Islington on the north, Shoreditch on the east, the City of London on the south, and Holborn and St. Pancras on the west. One member is returned to parliament by the constituency of Shoreditch and Finsbury. The Angel, once a famous coaching inn, lies in Finsbury and not Islington as commonly supposed; from there, Goswell road, the residence of Charles Dickens' Mr. Pickwick, and St. John street radiate through the borough. Rosebery avenue runs from St. John street southwestward to Clerkenwell road, which with Old street crosses the borough from west to east. The old distinctions of Clerkenwell on the west and St. Luke's on the east are still frequently used. Local industries are many and include light engineering, manufacture of optical, surgical and scientific instruments, clothing factories, printing, bookbinding; stationery, tobacco pipe manufacture, brewing and distilling. Watch and clockmaking, once the largest industry in Finsbury, has almost disappeared, but the borough is still the centre of the repairing trade and for the supply of parts and tools. The establishment of the British Horological institute in Northampton square in 1858 showed the importance of Clerkenwell as the centre of the trade, and the Northampton Polytechnic carries on the tradition by holding special classes in horology and optical work. The large parcels depot and inland section of the general post office (built in 1934) are at Mount Pleasant, Rosebery avenue; close by are the Finsbury town hall (1895) and the head offices of the Metropolitan Water board (1920), with the former reservoirs of the New River Mead.

It is probable that the name of the borough is derived from the family name of the Fiennes (also spelled Finnes or Fennes). who were the owners of the manor of Finsbury, the manor house of which stood in Finsbury fields or Fynnysberefelde. Two ladies of this family gave some land north of the city gates for the use of the citizens of London. The nature of this ground, which mas marshy and fenlike, has led to the belief that this was the origin of the name Fensbury or Finsbury. The ground was drained in 1527 and for several centuries was used for sports and pastimes, especially for archery. Chalybeate springs were discovered in Clerkenwell in the 17th century, the most famous being Sadler's well, Islington spa and the London spa. These were quickly made into popular resorts by their enterprising owners, who added tea gardens and other entertainments to attract custom. The Fortune theatre and Red Bull theatre were erected at the end of the 16th century. After the fire of London many refugees came from the city into Moorfields, and it mas from that time that the area really became residential. By 1901 its population had risen to 101,463.

The borough includes several buildings of historical interest. In the old parish of Clerkenwell (*q.v.*) is the gatehouse of the former priory of St. John of Jerusalem. West of Aldersgate street are the buildings of Charterhouse (*q.v.*), originally a Carthusian monastery, subsequently a hospital and school. Bunhill fields, City road, is the famous burial ground used by the dissenters from the middle of the 17th century until 1852; the graves of John Bunyan, Daniel Defoe and William Blake (*qq.v.*) are there. Facing Bunhill fields is Wesley's chapel and the house of John Wesley, which is now a museum. In Bunhill row John Milton died. South of Bunhill fields lies the Artillery ground of the Honourable Artillery company, so occupied since 1641, with barracks and an armoury house, started in 1734, completed in 1735.

Sadler's Wells theatre, Rosebery avenue, preserves the name of the fashionable medicinal spring discovered in the grounds of Sadler's Musick house in 1683. A new theatre was built on the site in 1765 and rebuilt in 1931, and it is now famous for ballet and opera. The Northampton Polytechnic, St. John street, was opened in 1898. Owen's school for boys was founded in 1613, and in 1886 a girls' school was opened. St. Luke's Hospital for Lunatics, Old street, erected in 1751, is now a Bank of England printing works.

The housing programs, after World War II, of Finsbury Borough council included Spa Green estate, Priory Green estate, Holford Square estate and the Stafford Cripps estate; the three blocks of the latter are 12 stories high. The borough is provided with only 15 ac. of open spaces, but it has a large memorial sports centre at Barnet, Herts, opened by Prince Philip, duke of Edinburgh, in May 1955. This comprises football, cricket and hockey pitches, bowling green, tennis and netball courts, putting green, running track and children's playground. (M. McD.)

FINSEN, NIELS RYBERG (1860–1904j, Danish physician, originator of the Finsen lamp for treatment of skin diseases, was born Dec. 1j, 1860, at Thorshavn, in the Faroe Islands. His. parents were Icelandic, and he went to school in Reykjavik. His interest in the contrasts in the light and darkness of the north led him to study the effects of light on living organisms. Graduated in medicine from the University of Copenhagen in 1890, Finsen conducted experiments on light and published (1893) a paper on treatment of smallpox with red light (excluding blue, violet and ultra-violet rays of ordinary light), thus preventing suppuration of pustules. Later he found actinic rays to be responsible for the bactericidal property of sunlight, and this enabled him to develop a method of treatment of lupus vulgaris by ultra-violet rays. In 1895 he published his general theory of the effect of light on living organisms. *The Treatment of Lupus Vulgaris by Concentrated Chemical Rays* was published in 1837. Finsen's Light institute was founded in Copenhagen in April 1896. He was awarded the Nobel prize in medicine in 1903. From the age of 23 Finsen was practically an invalid, and during the last few years of his life he directed the work of the institute from his home. He died Sept. 24, 1904. (A. U. D.)

FIORD (FJORD), a long narrow arm of the sea commonly extending far inland, resulting from the inundation by the sea of a severely glaciated valley. Many fiords are astonishingly deep; Sogne fiord in Norway is 4,078 ft. deep: Messier channel in Chile is 4,250 ft., and Scoresby sound in Greenland is deeper than 4.000 ft. It is the great depth of these submerged valleys, extending thousands of feet below sea level, that necessitates their glacial origin. It is assumed that the huge. thick glaciers formed in these valleys were so heavy that they could erode the bottom of the valley far below sea level before they floated in the ocean water. After the glaciers melted the waters of the sea invaded the valleys and formed the fiords.

Glacial erosion produces U-shaped valleys, and fiords are characteristically so shaped. Since the lower, slanting, part of the U is underwater, the walls of fiords may arise vertically for hundreds of feet from the water's edge. Similarly, just a few yards from the shore the water may be several hundred or even thousands of feet deep. In some fiords small streams in tributary valleys plunge hundreds of feet over the steepened edge of the fiord; some of the world's highest waterfalls are of this type. Valleys are normally winding and twisting, and so fiords commonly have the same attributes — winding channels and occasional sharp corners. The U-shaped valley floored with glacial debris in many cases extends inland back into the mountains, and in a few cases still has a small glacier at the head of the valley. The river that formed the original valley commonly re-establishes itself on the upper valley floor after the disappearance of the ice and begins to build a delta (*q.v.*) where it enters the sea at the head of the fiord. In many cases this delta is the only place on the fiord nhere villages and farms are located. Fiords commonly are deeper in the middle and upper reaches than at the seaward end. This results from the greater erosive power of the glaciers closer to their source, where they are moving most actively and vigorously. All such valleys are not the result of glacial erosion, however.

See D. W. Johnson, *Shore Processes and Shoreline Development* (1919); Andre Guilcher, *Coastal and Submarine Morphology* (1958). (W. C. C.)

FIORE, PASQUALE (1837–1914), Italian jurist and leading authority on international law, was born at Terlizzi, Puglia, on April 8, 1837. He studied at Urbino, Pisa and Turin and, after a period of teaching philosophy at a school at Cremona, during which he published *Elementi di diritto pubblico constituzionale e amministrativo* ("Elements of Public Constitutional and Administrative Law," 1862), he was appointed professor of constitutional and international law at Urbino in 1863. He then occupied similar chairs at Pisa, Turin and finally, from 1881, at Naples, where he died on Dec. 17, 1914.

Although a prolific writer on a wide range of legal topics, Fiore's international reputation rests on his writings on public and private international law, which were translated into many languages. Since they reflect the spirit and political conditions of his time they have tended to become out of date, but he made a lasting contribution by realizing the need for dividing international law into new categories, in his *Trait6 de droit pénal international et de l'extradition* ("Treatise on International Criminal Law and the Law of Extradition," 1880), and by meeting the need for a more precise statement of the law in his *International Law Codified* (1890; Eng. trans., 1918).

Fiore's *Elementi di diritto internazionale privato* ("Private International Law," 1901) is one of the principal statements of the doctrines of the so-called Italian or neostatutist school which, inspired by P. S. Mancini, has exercised profound influence, especially in Latin and Latin-American countries. (J. U.)

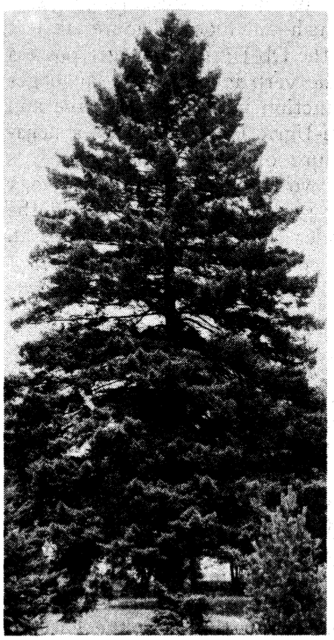
FIORELLI, GIUSEPPE (1823–1896), Italian archaeologist, was born at Baples, June 8, 1823. In 1845 he was made inspector of the Pompeiian excavations, which position he retained until 1848, when he was discharged and imprisoned for his political views. After the unification of Italy in 1860, however, he returned to favour and was chosen to fill the positions of professor of archaeology at the University of Naples and superintendent of the excavations in Pompeii and southern Italy. In 1875 he was put in charge of all excavations in Italy. He was founder of the first archaeological school in Italy, located at Pompeii.

Fiorelli published a number of works on his archaeological findings, including *Osservazioni sopra talune monete rare di città greche* (1843); *Monete inedite dell' Italia antica* (1845); *Notizia dei vasi dipinti rinvenuti a Cuma dal conte di Siracusa* (1853); *Pompeianarum Antiquitatum Historia* (1853); and *Descrizione di Pompei* (1875). He died Jan. 28, 1896, at Naples.

FIORILLO, JOHANN DOMINICUS (1748–1821), German painter and historian of art, was born at Hamburg on Oct. 13, 1748. He studied at Bayreuth, Rome and Bologna, and in 1769 was admitted to the Bologna academy. Returning to Germany, he obtained the appointment of historical painter to the court of Brunsnick. In 1784 he became keeper of the collection of prints at the university library at Gottingen. He was appointed professor extraordinary in the philosophical faculty in 1799 and ordinary professor in 1813. He died at Gottingen Sept. 10, 1821. The most notable of his paintings is perhaps the "Surrender of Briseis." His writings include *Geschichte der zeichnenden Künste* (5 vol., 1798–1808) and *Geschichte der zeichnenden Künste in Deutschland und den Vereinigten Niederlanden* (4 vol., 1815–20).

FIR, the Scandinavian name originally given to the Scotch pine (*Pinus sylvestris*), but now used to designate members of the genus *Abies* and a few other coniferous forms.

The firs are distinguished from other genera in the pine family by their sessile needles, which develop conspicuous circular leaf scars upon falling. Their cones, which are erect at maturity, are composed of many thin, rounded, closely overlapping scales, each bearing two broadly winged seeds, and enclosed by a bract carrying the ovules. The cones disintegrate soon after ripening, and leave the erect, naked central axis attached to the supporting branchlet.



J HORACE MCFARLAND COMPANY

SCOTCH PINE (*Pinus sylvestris*)

The trees usually have a straight trunk, and a tendency toward conical or pyramidal growth, throning out each year a more or less regular whorl of branches from the foot of the leading shoot. while the buds of the lateral boughs extend horizontally.

There are about 25 species of the true firs (*Abies*), widely distributed in the northern hemisphere.

The silver fir (*A. alba*), a representative of the old world, is a lofty tree, sometimes 150 ft. high. with large spreading horizontal boughs curving upward toward their extremities. The fiat leaves are two ranked, deep green above but with tuo broad white lines beneath; as the foliage in large trees has a tendency to curl upward, a silvery appearance is observed from below. The large, erect cones are cylindrical in shape, and have long bracts, the curved points of which project beyond the scales. When the tree is young the bark is of a silvery gray, but becomes roughened and darkened with age. The tree is abundant in most of the mountain ranges of southern and central Europe. but is not found in the northern parts of that continent. In Asia it occurs on the Caucasus and Urals, and in some parts of the Altaic chain. Extensive forests of this fir exist on the southern Alps. where the tree grows in elevations up to nearly 4,000 ft ; in the Rhine countries it forms a great part of the extensive forest of the Hochwald and occurs in the Black Forest and in the Vosges; it is plentiful likewise on the Pyrenees and Apennines. The wood is inferior, but, being soft and easily worked, is largely employed in the countries to which it is indigenous for all the purposes of carpentry. Deficient in resin, the wood is more perishable than that of the spruce, although it is said to stand well under water. The bark contains a large amount of a fine. highly resinous turpentine, which collects in blisters on the trunk during the heat of summer. After purification by straining, it is sold as "Strasbourg turpentine," much used in the preparation of some of the finer varnishes. Burgundy pitch is also prepared from it by a process similar to that used on the exudations of the Norway spruce. A fine oil of turpentine is distilled from the crude material; the residue forms a coarse rosin. Introduced into Great Britain at the beginning of the 17th century, the silver fir has become a common exotic, although, like the Nonvay spruce, it rarely comes up from seed scattered naturally. It is also planted as an ornamental tree in eastern North America.

Several other old world firs are successfully grown for ornamental purposes in Europe and North America. Among these are the Spanish fir (A. *pinsapo*); the Greek fir (A. *cephalonica*); the Algerian fir (A. numidica); the Cilician fir (A. *cilicica*), of Asia Minor; the Nordmann fir (A. *nordmanniana*), of the Caucasus; and the Momi fir (A. *firma*), the Nikko fir (A. *homolepis*) and the Veitch fir (A. veitchii), of Japan.

In North America there are ten native species of fir, found chiefly from the Rocky mountains westward and attaining their maximum development in the Sierra Nevada and Cascade ranges. Of the two firs occurring in the eastern states and Canada, the best known is the balsam fir (A. *balsamea*), which is found from Newfoundland to Virginia and northwestward to Labrador and the Yukon. It is a widely branching tree, 40 ft. to 60 ft. high, with fragrant resinous leaves; it is extensively used for pulpwood, sparingly for lumber, and yields the valuable oleoresin known as Canada balsam (*q.v.*). The smaller southern balsam fir or she-balsam (A. *fraseri*) is confined to the southern Appalachian mountains. Several firs of the western United States attain immense size. The white fir (A. concolor), sometimes 250 ft. high with a trunk diameter of 6 ft., ranges from Wyoming to the Sierra Nevada and southward to Mexico. The lowland white or grand fir (*A.* grandis). occasionally 300 ft. high, is a valley species found from Montana west to Vancouver Island and south near the coast to central California. The Pacific silver fir (A. amabilis). a beautiful tree native to the Cascade and Olympic ranges from Oregon to British Columbia, reaches a height of 250 ft. and a trunk diameter of 4 ft. to 6 ft. The red fir (*A. magnifica*), often zoo ft. high, is a handsome tree of the northern Sierra Nevada and the southern Cascade mountains. The noble fir (A. *nobilis*), usually 150 ft. to 200 ft. but sometimes 250 ft. high, with a trunk 6 ft. to 8 ft. in diameter, forms large forests in Washington, Oregon and northern California. The smaller alpine fir (A. lasiocarpa), commonly 80 ft. to 100 ft. high. is found in the Rocky mountains from New Mexico to Alaska, and westward to Oregon, Washington and British Columbia. With the exception of the noble fir, the wood of most western firs is inferior to that of pine or spruce, but is used for lumber and pulpwood. Noble fir is occasionally used as a substitute for spruce in aircraft fabrication. See DOUGLAS FIR; HEMLOCK; SPRUCE. (E. S. HR.)

FIRDAUSI (FIRDUSI, FIRDOUSI) (*c.* 935–*c.* 1020), Persian poet, was the author of the celebrated *Shah-Nama* ("Book of Kings") in which the Persian national epic found its final and enduring form. His real name was Abul Qasim Mansur (or Hasan or Ahmad), Firdausi being a nom de plume. He was born c. 935 in a village on the outskirts of the ancient city of Tus (near the city of Meshed in northeast Iran). In the course of the centuries many legends have been woven around the poet's name but very little is known about the real facts of his life. Something can be gathered from the personal references scattered here and there throughout his poem, but otherwise the only reliable source is the account given by Nizami-yi-'Arudi, a 12th-century poet who visited his tomb in 1116 or 1117 and collected the traditions that were current in his birthplace less than a century after his death. According to Nizami, Firdausi was a *dihkan* or landowner, deriving a coinfortable income from his estates. He had only one child, a daughter. and it was to provide her with a dowry that he set his hand to the task which, in the event, was to occupy his attention for 35 years.

The *Shah-Nama* of Firdausi, a poem of nearly 60,000 verses, is based mainly on a prose work of the same name, compiled in the poet's early manhood in his native Tus. This prose *Shah-Nama* was for the most part the translation of a Pahlavi (Middle Persian) work, the *Khwatai-Namak*, a history of the kings of Persia from mythical times down to the reign of Khosrau II (590–628), but it also contained additional material bringing the story to the overthrow of the Sassanians by the Arabs in the middle of the 7th century. The first to undertake the versification of this chronicle of pre-Islamic and legendary Persia mas Dakiki, a poet at the court of the Samanids, who came to a violent end after completing only 1,000 verses. These verses, which deal with the rise of the prophet Zoroaster, were afterward incorporated by Firdausi, with due acknowledgments, in his own poem.

The *Shah-Nama*, finally completed in 1010, was presented to the celebrated sultan Mahmud of Ghazni, who by that time had made himself master of Firdausi's homeland, Khurasan. Information on the relations between poet and patron is largely legendary. According to Nizami-yi-'Arudi, Firdausi came to Ghazni in person, and through the good offices of the minister Ahmad ibn Hasan Maimandi was able to secure the sultan's acceptance of the poem. Unfortunately Mahmud then consulted certain enemies of the minister as to the poet's reward. They suggested that Firdausi should be given 50,000 dirhems, and even this, they said, was too much, in view of his heretical Shiite tenets. Mahmud, a bigoted Sunnite, was influenced by their words and in the end Firdausi received only 20,000 dirhems. Bitterly disappointed, he went to the bath and, on coming out, bought a draft of *fuka'* (a kind of beer) and divided the whole of the money between the bath attendant and the seller of *fuka'*. Then, fearing the sultan's wrath, he fled first to Herat, where he remained in hiding for six months, and then, by way of his native Tus, to Mazanderan, where he found refuge at the court of the Sipahbad Shahriyar, whose family claimed descent from the last of the Sassanians. There Firdausi composed a satire of 100 verses on Sultan Mahmud, which he inserted in the preface of the *Shah-Nama* and read out to Shahriyar, at the same time offering to dedicate the poem to him, as a descendant of the ancient kings of Persia. instead of to Mahmud. Shahriyar, however, persuaded him to leave the dedication in Mahmud's name, bought the satire from him for 1,000 dirhems a verse and caused it to be expunged from the poem. Nizami adds that Firdausi also destroyed his rough copy of the satire and that in his day only six verses remained extant. This is of course inconsistent with the fact that the whole text, bearing every mark of authenticity, has survived to the present day.

It was long supposed that in his old age the poet had spent some time in western Persia or even in Baghdad, under the protection of the Buyids, but this assumption was based upon his presumed authorship of *Yusuf* and Zulaikha, an epic poem on the subject of Joseph and Potiphar's wife, which, it later became known, was composed more than 100 years after Firdausi's death. For an account of his last days it is necessary to fall back upon the narrative of Nizami-yi-'Arudi. Sultan Mahmud was returning from one of his campaigns in India when the minister Ahmad ibn Hasan Maimandi, by means of an apposite quotation from the *Shah-Nama*, reminded him of his shabby treatment of Firdausi. He determined to make amends and. upon returning to Ghazni, gave orders that 60.000 dinars' worth of indigo should be given to Firdausi and that it should be transported to Tus on the royal camels. The indigo reached Tus in safety; but as the camels were entering the town by one gate Firdausi's bier was being carried out through another. A fanatical preacher had denied the poet burial in the Moslem cemetery and his body was being taken to its final resting place in a garden that belonged to the poet outside the walls of the town. He was survived by his daughter, who proudly refused the sultan's gift; and in the end the money was spent on repairing a resthouse on the boundaries of Tus Nizami does not mention the date of Firdausi's death. The earliest date given by later authorities is 1020 and the latest 1026: it is certain that he lived to be over 80.

The Persians regard Firdausi as the greatest of their poets. For nearly 1,000 years they have continued to read and to listen to recitations from the *Shah-Nama*, nhich. though written before the Norman conquest, is as intelligible to the average modern Persian as is the Authorized (King James) version of the Bible to a modern Englishman. The language. based as the poem is on a Pahlavi original, is pure Persian with only the slightest admixture of Arabic. European scholars hdve criticized the monotonous metre, the constant repetitions and the stereotype similes of this enormous poem; to the Persian it is the history of his country's glorious past, preserved for all time in sonorous and majestic verse.

BIBLIOGRAPHY.—The chief editions of the *Shah-Nama* are those of T. Macan (1829), J. Mohl (1838–78) and J. A. Vullers (1877–84), the last incomplete. Beroukhim's edition (1934–3j) is based on the earlier three. There are English translations by J. Atkinson (1832), A. G. and E. Warner (1905–25) and A. Rogers (1907), a French translation by J. Mohl facing the text of his edition, also published separately (1876–78); German translations by J. Gorres (1820), A. von Schack (1851) and F. Riickert (1890–95); Italian translation by I. Pizzi (1886–88).

FIRE is so familiar that it scarcely needs definition. Its extraordinary usefulness and equally extraordinary dangers impress practically every human being from infancy onward. Ordinary fire is the rapid chemical combination of oxygen with the carbon and other elements of organic substances in such a way that heat, flame and light are produced. In a broader sense fire is the process whereby the combination of one chemical element with another, when reduced to a gaseous condition, produces heat and flame.

Among all the discoveries and inventions made by men, only a few, such as speech, writing and agriculture, have borne such momentous fruit as has the discovery of how to make and use the type of combustion commonly known as fire. The use of fire is the basis of practically all forms of modern manufacturing and transportation; it has been a powerful agent in determining the spread and present distribution of mankind and of civilization; it has perhaps been a major, although indirect agent in causing racial differences in mentality. It is the background and basis of our modern industrial life.

Universality of Fire.—Traces of fire appear among the earliest human relics, far back at the beginning of Paleolithic times. During historic times it is doubtful whether any race or tribe has ever been completely without knowledge of fire. Early travellers, to be sure, have brought back tales like that of the missionary Krapf in East Africa. He heard from a slave that a tribe in southern Shoa lived like monkeys in the bamboo jungles and were totally ignorant of fire. That was in the middle of the 19th century, but no competent observer has yet seen such a tribe. In the same way Wilkes of the famous United States Exploring Expedition in the Pacific reported that no sign of places for cooking, nor any appearance of fire was found in Bowditch Island (Fakaafo), but Hale, the ethnographer of the same expedition, reports the native word for fire. We now know that these people not only talked about fire, but have a legend as to its origin and could kindle a blaze. Since other reports of fireless people fare in the same way, Sumner and Keller seem justified in saying that "it is certain that over the whole earth no fireless tribe of men has been found. . . . Man is scarcely man till he is in possession of fire."

Original Use of Fire.—Although we have no real knowledge as to the original use of fire or as to man's discovery of the art of kindling a flame, primitive legends, the usages of primitive people and ancient religious ceremonials give some clue to the major facts. One of the most important conclusions derived in this way is that fire was used long before it could be artificially generated. Lippert even goes so far as to argue that the use of fire enabled man's ape-like progenitor to descend from the trees and walk erect because it gave him protection from other animals. Even if this idea is untenable, as it probably is, one of man's earliest discoveries must have been that he could make profitable use of the fires engendered naturally by lightning, falling meteors, the materials ejected from volcanoes, friction developed by avalanches and boulders and other natural occurrences. He probably soon realized the value of a blaze not only for warmth, but for cooking food, warding off wild beasts and driving game out of the jungle. Thus early man presumably cherished fire long before he learned how to make it.

Preservation of Fire.—Even in modem times many tribes have been observed which carefully preserve their fire year after year and suffer serious loss if it is extinguished. The people of the Andaman islands, who are said to be ignorant of the art of producing fire, take a smouldering stick with them and keep it burning if they go away from their huts for more than a few hours on a hunting or fishing expedition. Among certain Papuans who have no means of kindling a blaze, live coals of a very slow-burning wood are constantly preserved in the huts. If by chance the fire goes out, these coast dwellers have to go to the mountains where the inhabitants understand the art of fire-making, and bring thence some live coals. Even where the art of kindling a fire is understood, the technique is often so crude or the difficulties because of damp weather are so great that the fire is preserved with extraordinary care. The Australian aborigines prefer to make long journeys to get fire from another tribe rather than undertake the labour of making it themselves. Among the Herero, to cite one of the many examples given by Sumner and Keller, the difficulty of making fire by friction was formerly so great that the daughters of the household were regularly charged with the care of the flame. If the fire went out, it was regarded as an evil omen.

WAPISIANA BOYS OF SOUTHERN BRITISH GUIANA MAKING A FIRE
The device employed is that of rotating a stick in a round hole in the piece of wood lying on the ground

Fire and Religious Rites.—A great number of facts of this kind agree with some of the most widespread and primitive legends and religious practices. According to the familiar Greek legend, Prometheus brought fire to earth. Sometimes he is said to have lighted a torch at the sun's chariot, and sometimes to have gone underground. In the Cook islands near New Zealand, the Polynesian hero Maui is said to have obtained fire for man by going down to hell where he learned to generate a spark by rubbing two pieces of wood together. Perhaps the multitudinous legends of this sort are reminiscent of the period when the art of making fire was unknown. In such circumstances there must have been repeated periods when prolonged rainy spells or other accidents put out all the fires among the very scanty population of a large area. In such a case no fire may have been available for many years, and the bringer of new fire would be a hero. Perhaps a late relic of the periodic loss of fire is found in certain ceremonies of both the Roman Catholic and Greek Orthodox churches. According to the traditional method, all the lights in the churches are gradually extinguished during Passion Week. When the last light has been extinguished, "new fire" is made; formerly this was done by some primitive means, such as friction of wood, long after flint and steel were understood. From this "new fire" all the lights to be used throughout the next year are supposed to be kindled. At Jerusalem the rush of the Eastern Orthodox pilgrims to light their candles at the newly created blaze has often made it necessary to employ soldiers to preserve order. Another reminiscence of the early necessity for extreme care in preserving fire is found in the Vestal Virgins who tended the undying fire in Rome. Elsewhere, as in ancient Peru, a similar custom is reported.

Worship and Sentiment.—While ceremonies connected with fire play at least a subordinate part in almost every religion, they sometimes become dominant. In the ancient Jewish religion and many others fire is the means whereby offerings are transmitted to the deity or to departed souls as among the Greeks. In many cases fire itself is worshipped, and often the worship of the sun can scarcely be distinguished from that of fire. The ancient Mexicans had a fire-god Xiuheuctli, closely related to the sun-god; the Kamchadals and Ainus of north-eastern Asia make fire their chief deity. Among more civilized people the ancient Assyrians, Chaldaeans and Phoenicians practised fire-worship; Abraham was perhaps a reformer who refused to sacrifice his son Isaac in the consuming fire; the Israelites of later times were often scourged by their prophets for offering their children as sacrifices to Moloch, the god of fire. Among the ancient Aryans, if we may use so indefinite a term, Agni (Latin *ignis*) was the chief god. Even to-day fire-worship is a notable feature of Hinduism, which is an offshoot of the old Aryan cult, and is the dominant factor in the religion of the Zoroastrians or Parsees. Among the oppressed remnant of the Parsees who still survive in the parts of Persia near Yezd and Kirman, and among many more primitive people, it is considered most irreverent to throw into the fire anything impure or disagreeable or to spit into it. The modern Parsees do indeed regard fire as merely a symbol, but in the beginning fire itself was probably the real object of worship. This is not surprising for there is probably no agency more powerful for good and ill, and motives of both gratitude and fear must have mingled in the minds of the early worshippers.

Although the worship of fire has largely disappeared in our day, its symbolism is still widely spread. The fire of love, the fire of ambition, are common similes.

Discovery of the Art of Fire Making.—In many of the legends which centre around the origin of fire, the interesting figure of the serpent-fighter occurs. The native Australians of Victoria say that a certain Karakorok, the good daughter of the good old man Pundyil, went abroad to kill the serpents which filled the land. Before she had killed them all, her staff snapped and a flame burst out of it. According to the ancient *Shahnama* of Persia, a hero called Hushenk hurled a prodigious stone at a snake; the snake escaped, but the stone struck a rock whereupon "light shone from the dark pebble, the heart of the rock flashed out in glory, and fire was seen for the first time in the world."

A North American legend states that the buffalo gave fire to man; as he raced in great herds across the plains at night, he lighted up the darkness with sparks and set the brush ablaze as his hoofs hit the rocks. The Dakota Indians replace the buffalo by a friendly panther which struck fire from its claws as it scampered up a stone hill. In South America the Quichés claim to have received fire from Tohil who produced it by shaking his sandals. His sign, like that of the Mexican god, Quetzalcoatl, is a flint. The vital point in all these legends is that the movements of men or animals cause stones to crash together, thus producing a spark which gives rise to fire. Such occurrences, together with his own experience in breaking rocks in order to discover which make the best tools, may have led some savage genius to discover that when flint and iron pyrites are struck together they produce sparks which will ignite dry grass or leaves. That mode of making fire is especially likely to originate in regions where rocks and dry grass are abundant.

In moist regions where the soil is so deep and the vegetation so dense that rocks are rare, or in places where flinty rocks are not present, another kind of natural occurrence is more likely to have helped in the discovery of fire. Now and again in the dry season two dead branches, rubbing together in the wind, become so hot that they ignite. Such accidents are not common, but during the hundreds of thousands of years of man's early development they presumably occurred often enough to be observed by men who possessed not only the ability and vision to see their significance, but also the curiosity and energy to make experiments.

Methods **of** Making Fire.—These two methods, percussion and friction, have always been the chief ways of making fire, but concentration of the sun's rays and the electric spark have also come into use. Friction has been by far the most widespread method among primitive people. In one of the simplest frictional methods the blunt end of a stick is rubbed back and forth along another piece of wood lying on the ground. The stick makes for itself a groove, and ultimately a spark is developed. This method formerly prevailed among the savages in New Zealand, Hawaii, Tonga, Samoa and elsewhere. In Tahiti Charles Darwin saw a native produce fire thus in a few seconds, but he himself succeeded only after long effort. In a somewhat more advanced frictional method the movable stick is rotated as rapidly as possible in a stationary piece of wood that lies on the ground. Such a fire drill, as it is commonly called, is sometimes rotated by rubbing the vertical stick between the palms of the hands. This device in one form or another has been observed among the primitive people in Australia, Kamchatka, Sumatra and the Caroline islands. It is common among the Veddahs of Ceylon and in much of southern Africa as well as in large parts of both Americas. Various improvements have been devised in order to increase the speed of rotation. On the Pampas of South America the Gaucho formerly took an elastic stick about 18in. long, placed one end in a hole in a stationary piece of wood, pressed the other to his breast, leaned dcwn to bend the stick, and then rapidly turned the curved part like a carpenter's bit. A better method is to wind a string around the rotating stick or drill and pull it back and forth. In order to make it possible for one man to do this effectively, the Eskimos place the upper end of the drill in a socket of ivory or bone which can be held firmly in the teeth. Other Eskimos, as well as some Indians, fasten the two ends of the string to a bow and saw the bow back and forth. In our own day a device of this kind, with sawdust or some such material in the bottom of the hole to make the sparks catch quickly, is one of the first things taught to boy scouts. Still more ingenious than the bow drill is the pump drill of the Onandaga Indians. Here a string is fastened in such a way that when a small board is repeatedly pushed down the drill stick twirls rapidly, first one way and then the other. Many modifications of these methods are described and illustrated in the works of Tylor and Pauschmann.

In all the simpler frictional methods the two great difficulties have always been to create a spark and then to bring it into immediate contact with a sufficient amount of easily combustible tinder. In the most modern method—the match—both of these were first obviated by coating the ends of the movable stick with sulphur, which ignited at low temperature, and tipping the end with phosphorus which can be still more easily ignited by a single stroke. By the substitution of potash and non-poisonous forms of phosphorus for the earlier ingredients the modern safety match has at last been evolved as the latest successor of the two sticks rubbed together.

The method of making fire by percussion does not appear to have been of great importance until the Iron Age was so far advanced that steel was available. Its development was delayed by the difficulty in finding natural products such as pyrites which can be relied on to produce a spark when struck with a flint. After iron became common, the flint and steel became the best method of creating a fire. This method, however, was dominant for only a short time compared with the frictional method, for as soon as matches tipped with sulphur and phosphorus came into use (soon after 1830), it ceased to be of importance except in more backward regions. There it survives widely; in Central Asia flint-lock guns are still common.

Another method of making fire, namely, the concentration of the sun's rays by means of a lens or mirror, also belongs to a fairly high stage of civilization, but has never been used to any great extent. Aristophanes mentions a burning-lens in *The Clouds*; although the mirrors of Archimedes may not actually have set fire to the ships of the Roman besiegers of Syracuse, they show that the art of generating fire in this way was well understood. In Peru the sacred fire is said to have been kindled by means of a concave cup set in a great bracelet. In China the burning-glass has long been well known.

The latest important method of making fire is by means of the electric spark. According to one common device, a gas jet is arranged so that when it is opened an electric circuit is closed and then broken, and a spark passes through the escaping gas and ignites it. It should be noted in this connection that the intense heat generated by the electric current is beginning to displace fire not only in cases where an extremely high temperature is desired, but in various household appliances and elsewhere. This is only a partial displacement, however, for in most cases the electric current itself is generated by means of a fire in which coal is burned.

Fire and Material Progress.—When once the art of using and making fire became established, it must have altered human development in at least three ways. First, it must have stimulated the inventive faculty, thereby leading to material progress; second, it must have led to an increase in the density of population; third, it must have enabled primitive man to inhabit areas which had previously been too cold. These three changes must have had a profound effect upon the location of the centres of civilization and progress, and perhaps upon the mental development of the various human races.

One invention commonly leads to another. Fire must have been peculiarly important in this respect. Although no exact knowledge is possible, we can infer with considerable certainty that after people once mastered what was then the extremely difficult art of using fire, it required only a moderate degree of inventiveness to make many other important discoveries. The primitive fire-users must soon have learned that sticks which are partly burned in the fire become pointed and hardened, thereby becoming more serviceable as weapons. Even if the effect of fire on food was not previously known, bits of flesh, green fruit, edible roots or other kinds of food must inevitably have fallen accidentally into the fire and been cooked as soon as fires became common. Their improved flavour and tenderness when rescued must have led persons with the keener type of mind to make experiments. The range of opportunities thus opened is enormous, for practically every growing thing which had the least semblance of edibility must have been subjected to the process of roasting. As time went on, and it became possible to heat water in skin bags by means of hot stones or in earthen vessels, the art of boiling food must have been discovered. At some time or other an earthenware jar which boiled dry, or some other accident must have suggested the possibilities of baking food by enclosing it within non-combustible receptacles. In our own day experiments in the use of fire for cooking are perhaps more numerous and vigorous than ever before.

Food is only one of the ways wherein fire obviously stimulated experiments. During the long period when the use of fire was known but the art of generating it unknown, the desire to create a blaze must have stimulated men's inventive faculties even more persistently than we are now stimulated by the desire to secure new and better sources of power. Again, having seen that animals are so averse to a blaze, he must have asked himself: "How can I best use fire to keep away animals during the night?" Then he presumably found that a flaming torch is a most effective weapon when thrust into the face of a wild animal. Thus the stimulus to invention must have gone on so that men discovered that firebrands hurled into the huts of their enemies are a good weapon, or that when a patch of jungle is burned, the wild animals can be driven out and easily caught. In later days when civilization had advanced far higher, similar reasoning and experiment showed that flaming pitch, red hot balls of metal or explosive projectiles are effective ways of lighting fires in the midst of the enemy.

In connection with metallic ores fire has been a main agency in stimulating the inventive faculty. The first inkling as to the possibility of smelting presumably arose from the accidental melting of bits of ore in a hot fire. When once the significance of that fact was grasped by some genius, and when the highly valuable qualities of the resultant metals were realized, the stimulus toward melting all sorts of stones must have been enormous. Here, too, we see a line of experiments which has continued with increasing intensity to our own day. Thousands upon thousands of skilled inventors have worked upon the problem of making hotter and hotter fires. Thus we have melted more and more refractory stones, thereby enormously increasing the number of available metals and other valuable compounds. In this respect, as in many others, fire and its possibilities are still among the greatest agencies in stimulating human progress.

Greater perhaps than any of the preceding—or at least later and more striking in its effect—is the relation of fire to power. As soon as the first savage saw a yam or other bit of vegetation pop in the fire because steam was escaping, the principle of the development of power from fire was brought to man's attention. For hundreds of thousands of years thereafter many a boy presumably experimented by holding the lid down over a boiling vessel of water until the steam puffed it violently up. Many a man in addition to Hero, who made what was really a steam engine more rhan 2,000 years ago, must have realized that the expansive force of steam possesses energy which might be of high value. But only in modern times did progress along other lines finally make the steam engine a practical invention. Then the attempt to use the energy liberated by fire suddenly gave an almost incredible stimulus to the world's inventive faculties. Our whole modern system of manufacturing, transportation, lighting and heating is based on the utilization of fire.

Pyrotherapy **and** Sterilization.—One of the most extraordinary features of fire is the way in which its use continues to increase even in our own day. This is especially true in the field of health. The value of cauterization in preventing harm from poisonous bites like those of snakes or mad dogs, and in preventing the spread of infection from wounds or sores has long been known, and was practised by the ancients. The value of hot baths in skin disease and in those of the joints has also been appreciated, at least since rhe days of the Romans. Only in modern times, however, have two other therapeutic uses & fire become known. One is the process of baking whereby a limb or other member is kept for a while at a temperature as high as it can endure with results which are said to be highly beneficial. The other is the use of fire for sterilization. The knowledge that heat, either in the form of flame or through the medium of steam or hot water, will kill bacteria has been one of the most revolutionary discoveries of modern times. To it, perhaps, as much as to any other single factor, is due the wonderful progress of modern surgery.

Dangers of Fire.—In spite of all the benefits derived from fire, the mere word "Fire!" is one of the most dreaded expressions in every language, for fire is as dangerous as it is useful. Some of the greatest disasters in all history have been fires such as those in Rome in the time of Nero, and the one which ravaged London for four days in 1666 and gave Sir Christopher Wren a chance to plan many important improvements. Chicago suffered a similar fire in 1871 and 100,000 people were rendered homeless; San Francisco experienced a similar fate after the great earthquake of 1906. Earthquakes have been the cause of some of the most terrible fires, as in Tokyo in 1923. There the style of architecture renders fires especially dangerous, for the houses are constructed of wood with paper walls and heavy thatch of straw. At Tokyo the fire killed 60,000 or 70,000 people. burned 25 sq.m. and drove away nearly 1,000,000 persons. In all countries the annual losses by fire are enormous. In England they amount to about £12,000,000 annually. In the United States, partly because wooden houses are more common than in Europe, the losses are far greater, amounting to over half a billion dollars every year from 1922 onward, and to $560,000,000 in 1926. or approximately $5 per person. In that same year the fear of fire led the people of the United States to pay $635,000,000 in premiums to fire insurance companies, while $352,000,000 was returned to cover losses. Forest fires are amazingly frequent and some of them lay waste thousands of square miles. From 1916 to 1925 the average number of such fires in the United States alone was about 51,000. Nearly half of these devastated at least ten acres; the average damage to trees and property amounted to about $21,000,000, but the real damage was enormously greater because the fires kill the young growth, expose the soil to erosion, and alter the character and density of the new growth. In 1825 one of the greatest forest fires burned an area of 3,000,000ac. in Maine and New Brunswick, while fires that burned more than 1,000,000ac. in the United States and Canada occurred in 1853, 1871 (two totalling 3,280,000ac.), 1881 and 1910. Such fires may still occur in regions like Siberia, but are impossible in the more advanced countries because of the improved methods of fire-protection.

The Effect of Fire on Density of Population.—One of the most noteworthy facts in the history of civilization is the way in which many of the greatest inventions increase the density of population. Inventions connected with fire are pre-eminent in this respect. One of the first effects of the original discovery of the art of using fire must have been to increase the available food supply. It did this directly through the art of cooking, whereby many previously inedible or indigestible products became good articles of diet, and also by making it possible to smoke and preserve food that otherwise would have been wasted. Indirectly the use of fire still further increased the food supply by improving man's tools. It not only enabled him to use sharpened sticks as described above, but helped him to break up the stones from which he procured flint implements, and kept him warm and dry so that he could work more effectively in cool weather. It enabled him to smelt metals and ultimately to make machines of all sorts. Thus fire has been a major agent in the process whereby man has multiplied his labour so that one man with the help of fire-made and fire-driven machinery can do as much work as scores or hundreds who have only their naked hands and no help from fire. In recent centuries no factor has exceeded the use of coal in fostering the growth and concentration of population; in earlier times the use of fire in other ways produced similar although less obvious results.

Fire and the **Coldward** March **of** Civilization. — One of the most extraordinary results of the use of fire is the way in which it has enabled the centres of human progress to move from warmer to cooler regions. According to the most recent studies the best climate for primitive savages without fire, clothing or shelter, is one where the temperature averages not far from 70° at all seasons, but yet has a fair degree of variability. The nearest approach to such a climate is by no means found in equatorial regions but at a distance of 25° or more to the north or south. Even there, however, although the winters are admirable, the summers are much too long and warm for the best health and greatest efficiency. Now man is so constituted that up to a certain point he can endure too much heat more easily than too little. Among naked savages, for example, a temperature of 90° is far less uncomfortable than one of 60°. Therefore unless people possess artificial means of warming themselves they tend to live in regions that are too warm rather than too cold. This retards progress, for people usually overcome the adverse effect of high temperature by inactivity rather than activity.

The introduction of fire changed all this. In conjunction with discoveries as to clothing and shelter, it enabled people to be comfortable in cool climates. Each new discovery meant a step away from low latitudes. The invention of the hearth to replace the bare ground as a place for a fire was one of the earliest reasons for such a step. The invention of a protected opening in the roof to carry off the smoke was another. Still another was the combination of the hearth with a chimney in such a way as to give an efficient draft, eliminate smoke and throw the heat out into the room; then came the enclosed oven or stove of mud as in China; later the stove of metal; then central heating by means of furnaces supplying hot air, steam or hot water and heated first by wood, then by coal, and lately by oil or gas. Each of these improvements in the use of fire, together with the corresponding advances in clothing and architecture, reduced the difficulties due to low temperature, for they helped to create an artificial climate in which people were approximately as comfortable, healthful and energetic as in the ideal climate. Thus to-day we can live comfortably and in good health in climates so cold that people without fire would perish.

One of the greatest benefits of man's conquest of fire has been that the human race has gradually been able to migrate into the cooler and hence more healthful and energizing parts of the world. At every stage of this process of expansion there has been a definite zone of highest comfort, best health and greatest activity. Beginning not far beyond the tropics, the zone shifted to Mediterranean lands, and then to higher latitudes. To-day it is coincident with the zone of greatest progress, highest civilization and world dominance, a condition which also appears to have been true in the past. A further advance in the use of fire may possibly carry the zone of greatest progress as far north as southern Scandinavia and southern Canada, but not beyond, for there the summers as well as the winters become too cool. The ultimate location of this most favoured zone will doubtless be the regions where the following three conditions are most nearly fulfilled: (1) the summer climate is ideal for civilized people who wear clothes and live in houses; (2) the use of fire creates ideal atmospheric conditions within doors during the rest of the year; and (3.) the degree of variability arising from the weather on the one hand and the use of fire on the other produces the maximum stimulus, but does not injure health. With our present skill in the use of fire a climate like that of London comes as near as any to satisfying these three conditions, but the regions surrounding Paris, Berlin, New York and Chicago do not lag far behind.

From all this it appears that the "coldward course of progress" as GilFillan has called it, or the "northward course of empire" to use Stefansson's phrase, has depended upon the use of fire more fully than on any other factor that is yet clearly defined. It has involved a migration of the centres of power from regions where the *winter* climate is ideal but the summers debilitating, to those where the summer climate is ideal, and the disadvantages of the winter can be obviated by the use of fire together with clothing and shelter.

Fire and **Racial** Inheritance. — The possible biological effect of fire upon mankind ought not to be overlooked, although it is highly speculative. At first, and perhaps for many generations, the users of fire probably comprised only a small group of unusually intelligent, competent and progressive people. The first persons to use almost any revolutionary discovery are usually of that sort, no matter whether the discovery be the aeroplane, the electric motor, the art of weaving or the alphabet. During the long period when the technique of fire was new and crude its users must have had great need of intelligence, skill, patience and material prosperity, for otherwise they would not and could not have devoted to the art the many hours each day that must inevitably have been required. Among primitive hunters who are constantly obliged to change their abode it is by no means easy to maintain a fire that must never be allowed to go out, and the new arts of cooking and drying food and making fire-hardened weapons must also have been difficult. But the people who were sufficiently wise, active and patient to master all these difficulties must have reaped great advantages. Their food supply, as we have seen, became more abundant, more reliable and more nutritious, their improved weapons lessened the danger from both beasts and men, and their children must have enjoyed a freedom from hunger, exposure, disease and danger hitherto unknown. Such advantages, in a day when there was no such thing as birth control, must have caused the descendants of the fire-users to increase in number faster than did the people who lacked the wit, energy or resource to use the new invention. Thus, if there is any truth in the inheritance of mental traits, the inherent intelligence and progressiveness of the population must have been improved.

The degree of improvement must have differed from place to place. Near the equator the people presumably made little use of fire; the warmth of their climate not only prevented them from feeling much need of it, but made them loathe the necessary exertion. Thus in such regions fire had little effect in causing the intelligent people to increase in numbers. In the cooler parts of man's primitive habitat, on the contrary, the use of fire presumably caused the descendants of the more intelligent and progressive people to be numerous in proportion to those of the more stupid and indifferent, thus altering the average level of innate intelligence. Beyond the limits of the old inhabited area the use of fire enabled people to migrate into regions previously too cold for occupancy. Since all the migrants must have been of the intelligent fire-using class, whatever innate superiority they may have possessed must have been segregated and thereby perpetuated. Thus there must have been a gradation of innate ability from the unaltered people of the hottest regions to the selected new settlers in cooler regions. If such a differentiation occurred once, it must have occurred repeatedly when further progress in the mastery of fire enabled mankind to move into still cooler regions. The result would correspond exactly with the temperamental differences which now seem to be innate in the people of tropical as compared with temperate regions. All this is indeed speculative, but it ought not to be overlooked in considering the part played by fire in the development of mankind.

NOTABLE FIRES OF HISTORY

Of many of the early fires of history, there are only fragmentary records. In the middle ages many of the towns of Europe consisted of small buildings of wood construction, crowded closely together, which lent themselves to ready destruction by fire both in war and peace. In the accompanying list of notable fires, some are included which would be relatively unimportant compared with the destruction of cities in later conflagrations which are listed. A limited selection of later fires had to be made in preparing a representative list and only those of particular significance could be included. Fire destruction of World War II dwarfs all the rest.

Great Britain and Ireland

Year
798. London. Nearly destroyed.
982. London. Greater part of the city burned.
1137. York. Totally destroyed.
1212. London. Greater part of the city burned.
1292. Carlisle. Destroyed.
1544. Leith. Burned.
1612. Cork. Greater part burned, and again in 1622.
1614. Stratford-on-Avon. Burned.
1666. London. "The Great Fire," Sept. 2. It began in a wooden house in Pudding lane, and burned for three days, consuming 13,200 houses, with St. Paul's church, 87 parish churches, 6 chapels, the guildhall, the royal exchange, the custom-house, many hospitals and libraries, 52 companies' halls, three of the city's gates, four stone bridges, and the prisons of Newgate, the Fleet, and the Poultry and Wood street Compters. The fire swept from the Tower to Temple church, and from the northeast gate to Holborn bridge. Six persons were killed. The total loss of property was estimated at the time to be £10,730,500. The fire is credited with founding the institution of fire insurance.
1675. Northampton. Almost totally destroyed.
1694. Warwick. More than half burned; rebuilt by national contribution.
1700. Edinburgh. "The Great Fire."
1731. Blandford, Dorset. Town largely destroyed; 13 killed.
1824. Edinburgh. High street, Tron Kirk and Parliament square fires, Nov. 15 and 17; 10 killed, loss £200,000. This fire led to modernization of the Edinburgh fire engines and draft of rules for conduct of police, firemen, magistrates and property owners in event of fire.
1834. London. Houses of parliament destroyed.
1861. London. Cotton's and other wharves, Tooley street shops, steamer, boats and barges destroyed. Loss £2,000,000. This fire led to the passing of the Metropolitan Fire Brigade act of 1865, which combined the London Fire Engine establishment and the Voluntary Society for the Protection of Life from Fire into one body, and the establishment by the Fire (Insurance) Offices' committee of the London Salvage corps.
1866. London. First Crystal palace fire. Loss £150,000. Subsequent fires in 1923 (loss £5,000), 1936 (almost complete destruction) and 1950 (last building destroyed).
1915. London. Second Zeppelin raid by Germans, Sept. 8, caused 29 fires and £530,000 damage (air raids of World War I caused 224 fires in London).
1940. London. First large air attack of World War II by Germans, Sept. 7, hit docks area, causing great fires. On Dec. 29–30, 1940, area around St. Paul's destroyed; 1,472 separate fires.
1940. Coventry. Air raid fire destroyed city centre, Nov. 14. This attack is credited with revealing the destructiveness of incendiary bombs. Lesser raids April 8 and 10.
1941. London. Heaviest single German attack of war, April 16 and 17, 457 tons incendiaries and high explosive bombs dropped. May 10, house of commons destroyed.
1949. Bootle, Lanc. Gladstone dock fire, Nov. 9. Loss £2,000,000.
1950. Treorky, Rhondda. Factory fire. Loss £1,000,000.
1951. London. Broad street warehouse fire, 3 firemen killed.
1951. Bristol. Avonmouth docks oil tank fire; 12,000,000 gal. of oil destroyed.

France

59. Lyons, Lugdunum. Burned to ashes. Nero made an offer to rebuild the city.
1118. Nantes. Greater part of city destroyed.
1862. Marseilles. Destructive fire.
1871. Paris. Suppression of the Commune (*q.v.*). Property destroyed £32,000,000.
1938. Marseilles. Destruction of large part of Cannebière, 75 people killed.
1949. Landes district. 355 fires devastated 600 sq.mi. of forest and heathland.

Germany

1491. Dresden. Destroyed.
1758. Pirna. Burned by the Prussians; 260 houses destroyed.
1811. Forest fires in Tyrol destroyed 64 villages and hamlets.
1842. Hamburg. A fire raged 100 hours, May 5–7. During the fire the city was in a state of anarchy; 4,219 buildings, including 2,000 dwellings, were destroyed. One-fifth of the population was made homeless and 100 persons lost their lives. Total loss £7,000,000.
1943. Hamburg. British air force wreaked terrible havoc by a series of attacks, principally those of July 24–25, July 27–28 and July 29–30. Fires were set, respectively, over 18.5, 17 and 10 sq.mi., with 1.;, 5.1 and 2.2 sq.mi. of concentrated fire. The first attack killed 2,000, but the second produced a great mass fire or fire storm which killed 60,000–100,000 people. The thousands of fires started great air movements, similar to those in a storm or cyclone, which produced gales (fire storm) in the streets at the edge of the burning area and made raging flues in the streets in the fire area. More than 300,000 dwellings were destroyed in the series of attacks on Hamburg and 750,000 people were made homeless.
1945. Dresden. In the closing days of World War II, Dresden was subjected to air attack which probably dwarfed all previous attacks of the war on German cities. No detailed evaluation of damage was published but estimated deaths of more than 35,000, and development of fire storm conditions, suggest it was the greatest fire of World War II.

Central and Southern Europe

548 B.C. Delphi, Gr. Temple of the oracle of the Pythian Apollo destroyed by fire.
64. Rome. Burned during 8 days. Ten of the 14 wards of the city were destroyed.
1106. Venice. Greater part of the city was burned.
1379. Memel was in large part destroyed, and again in 1457, 1540, 1678 and 1854.
1883. Vienna. Loss £1,000,000.
1910. Brussels. Brussels exhibition. Loss £1,750,000.
1922. Geneva. Northern railway station destroyed. Loss £400,000.
1926. Bacau, Rum. Loss £1,000,000.
1939. Warsaw. Devastation of city by Germans, Sept. 24.
1940. Rotterdam. German air raid fires killed thousands, May 14.

Northern Europe

1624. Oslo. Nearly destroyed.
1728. Copenhagen. Nearly destroyed; 1,650 houses burned.
1794. Copenhagen. Royal palace burned.
1751. Stockholm. 1,000 houses destroyed.
1790. Karlskrona. 1,087 houses, churches, warehouses, etc., destroyed.
1858. Christiania. Loss estimated at £250,000.
1865. Carlstadt, Swed. Almost entirely destroyed, 10 lives lost.
1940. Norway. Elverum destroyed in May, and fires in a number of other cities after German bombings.

Russia and Siberia

1752. Moscow. 18,000 houses burned.
1786. Tobolsk. Nearly destroyed.
1812. Moscow. Russians fired city on Sept. 14 to drive out the army of Napoleon. The fire continued five days. Kine-tenths of the city was destroyed; 30,800 houses burned; loss £30,000,000.
1812. Riga. Partly destroyed.
1850. Cracow. Large part of city burned.
1862. St. Petersburg. Loss £1,000,000.
1879. Irkutsk. Loss £4,500,000.
1941. Russia. Many cities burned in face of German invasion; the extent of damage was very great but was not revealed.

Turkey and the Near East

1750. Constantinople. In Jan. 10,000 houses burned; in April property destroyed estimated from £1,000,000 to £3,000,000; later in year 10,000 houses were destroyed.
1756 Constantinople. 15,000 houses destroyed. During the years 1761, 1765 and 1767 great havoc was also made by fire.
1772. Smyrna. 3,000 dwellings burned; 3,000–4,000 shops, etc., consumed. Loss £4,000,000.
1782. Constantinople. Fire burned three days; 10,000 houses, 50 mosques and 100 corn mills destroyed; 100 lives lost. In Feb. 600 houses burned; in June 7,000 more.
1784 Constantinople. Fire destroyed 10,000 houses, most of which had been rebuilt since the fires of 1782. In the same year a fire in Pera destroyed two-thirds of that suburb. Loss estimated at 2,000,000 florins.
1870. Constantinople. Suburb of Pera swept by a fire which destroyed more than 7,000 buildings, including the residence of the foreign legations. Loss estimated at nearly £5,000,000.
1871 *et* seq. Constantinople. Fires of greater or lesser severity continued to be of almost annual occurrence until the 1920s, great fires being reported in 1908, 1911, 1912, 1915, 1918, 1919 and 1922.
1922. Smyma. Conflagration attributed to the war between the

Turkish and Greek armies. Loss £20,000,000.
1954. Istanbul. Fire destroyed ancient covered bazaar Nov. 27; loss $178,000,000.

India, China and the Far East

1799. Manila. Vast storehouses burned.
1803. Bombay. Loss £600,000.
1822. Canton, China. Nearly destroyed by fire.
1923. Tokyo and Yokohama, Jap. Following earthquake, about seven-tenths of Tokyo and most of Yokohama destroyed by fire; loss estimated at £200,000,000.
1924. Canton. Conflagration as a result of insurrection; loss £4,000,000.
1925. Kumagaya, Jap. Central portion of town burned out.
1932. Tokyo. Department store fire; loss £1,000,000.
1938. Canton. Great fires set by Japanese air attacks May 28 and subsequently.
1938. Changsha, China. Fire set by authorities burned five days; almost complete destruction of city.
1940. Chunking, China. Japanese air raid caused great fires, Aug. 19–20 and loss of 4,572 lives.
1944. Bombay. Explosion on steamship "Port Stikine" and resultant fires destroyed docks and spread into a residential area, April 14; more than 700 deaths; damage estimated at £20,000,000.
1945. Tokyo. Attack by U.S. bombers with incendiaries on March 9 burned over 17 sq.mi. and killed nearly 84,000. Probably more persons lost their lives by fire at Tokyo in a 6-hr. period than at any one time in the history of man.
1945. Osaka, Jap. Air attack of March 13; 8 sq.mi. burned.
1945. Tokyo and Yokohama. Attack with incendiary bombs by U.S.A.A.F., April 15, burned over 7 sq.mi.
1945. Nagoya, Jap. Air attack of May 17, nearly 4 sq.mi. destroyed.
1945. Yokohama. Air attack of May 28; approximately 9 sq.mi. burned over.
1945. Hiroshima, Jap. Atomic bomb attack, Aug. 6; 68,000 of 75,000 buildings destroyed. A fire storm which developed after the blast contributed to the large life loss of 70,000 to 80,000.
1945. Nagasaki, Jap. Atomic bomb attack, Aug. 9; 20,000 out of 52,000 buildings destroyed. Fire damage was extensive but no fire storm developed. Loss of life more than 35,000.
1948. Hong Kong. Warehouse burned, Sept. 22; about 150 died.
1952. Tottori, Jap. Conflagration destroyed 5,287 houses; loss, 19,300,000 yen.
1955. Yokohama, Jap. 100 persons killed in fire-swept home for aged.
1958. Kiem, Vietnam. Fire destroyed town; 10,000 left homeless.

Australia and New Zealand

1888. Brisbane. Loss £400,000.
1897. Melbourne. Flinders lane fire; loss £1,000,000.
1921. Kirribilli. About 32,000 bales of wool burned; loss £750,000.
1925. Melbourne. Knitting mills fire; loss £1,000,000.
1926. Adelaide. Sugar refining company fire; loss £700,000.
1943–44. Victoria. Bush fires, Dec. 1943–Feb. 1944, 51 dead; loss £5,000,000.
1947. Christchurch, N.Z. Department store destroyed, with 41 deaths, Nov 18. This fire prompted adoption of plans long discussed for a fire brigade administration covering all New Zealand.

South Africa

1902. Cape Town. City chambers; loss £250,000.
1942. East London. Loss £1,000,000.

United States

1760. Boston. Fire caused a loss estimated at $500,000.
1835. New York. Great fire of New York began in Merchant street, Dec. 16, and burned 530 buildings in the business part of the city; area burned over was 52 ac.; loss $15,000,000.
1845. Pittsburgh. Large part of the city burned April 11; 1,100 buildings destroyed.
1849. St. Louis. 23 steamboats at the wharves and whole or part of 1j blocks of the city burned, May 17.
1851. San Francisco. Fire destroyed 2,500 buildings, May 4–5; more than three-fourths of the city destroyed.
1851. St. Louis. More than three-quarters of city and 2,500 buildings burned, May 4; loss $11,000,000.
1866. Portland, Me. Great fire on July 4 involved 1,550 buildings, 200 ac.
1871. Chicago. Great fire began in a barn on the night of Oct. 8 and raged until Oct. 10. The area burned over was 2,124 ac.. or $3\frac{1}{3}$ sq mi in the heart of the city; 250 lives were lost, 98,500 persons were made homeless, and 17,450 buildings were consumed; loss estimated at $168,000,000.
1871. Peshtigo, Wis Forest fires, Oct. 8, destroyed 1,280,000 ac. and many buildings; 1,500 killed.
1872. Boston. Great fire of Nov. 9–10 destroyed richest quarter of Boston. Fire commenced at the corner of Summer and Kingston streets; 65 ac, burned over; 776 buildings burned; loss $75,000,000.
1882. Leadville, Colo. Loss $10,000,000.
1900. Hoboken, N.J. German steamships in dock fire, June 30; 326 killed.
1901. Jacksonville, Fla. Conflagration destroyed 1,700 buildings; loss $11,000,000.
1903. Chicago. Iroquois theatre fire, Dec. 30; 602 killed. This fire led to more stringent regulations for theatres all over the world.
1904. Baltimore, Md. 80 city blocks involved, Feb. 7; loss $150,000,000.
1904. New York. Excursion steamer "General Slocum" burned June 15; 1,030 killed.
1906. San Francisco. Great fire following earthquake, April 18; total loss of life about 1,000; total damage about $350,000,000.
1908. Atlanta, Ga. Conflagration of May 8; loss $11,500,000.
1908. Collinwood, O. Lakewood Grammar school fire and panic, March 4; 175 children killed.
1911. New York. Factory fire, March 25; 145 women killed.
1916. Jersey City, N.J. Warehouses and steamers, "Black Tom disaster"; loss $22,000,000.
1916. Paris, Tex. Conflagration, March 21; 1,440 buildings burned; loss $11,000,000.
1917. Atlanta. Conflagration of May 21 destroyed 1,938 buildings.
1917. Kingsland, N.J. Munitions factory; loss $12,000,000.
1918. Minnesota. Forest fires, Oct. 12; Colquet and 25 other towns involved; 559 killed.
1923. Berkeley, Calif. Fire destroyed 600 buildings; loss $12,500,000.
1929. Cleveland, O. Hospital fire, May 15; 125 killed.
1930. Columbus, O. State penitentiary fire, April 21; 320 killed.
1934. Off New Jersey coast. Steamship "Morro Castle" burned Sept. 8; 125 killed.
1937. New London, Tex. Natural gas explosion in school building, March 18; 294 killed.
1940. Natchez, Miss. Dance hall fire, April 23; 207 killed.
1942. Boston. A night club fire, Nov. 28; 493 killed.
1944. Hartford, Conn. Circus fire, July 6; 168 killed.
1946. Atlanta. Hotel fire; 119 killed.
1947. Texas City, Tex. Ship loaded with ammonium nitrate fertilizer exploded April 16; 468 killed; loss $67,000,000.
1951. West Frankfort, Ill. Coal mine explosion, Dec. 21; 119 killed.
1957. Warrenton, Mo. Fire in home for aged Feb. 17; 72 killed.
1958. Chicago. Elementary school fire, Dec. 1; 94 killed.

West Indies

1873. Havana, Cuba. Loss £600,000.
1882. Kingston, Jamaica. Loss £6,000,000.
1948. Castries, St. Lucia. Commercial section of town wiped out; loss £2,000,000.

Lanada

1825. New Brunswick. Tract of 4,000,000 ac., more than 100 mi. in length, including many towns, burned over; 160 persons killed.
1837. St. John, N.B. 115 houses and nearly all the business part of the city burned, Jan. 13.
1877. St. John. Fire extended over area of 600 ac.; loss $15,000,000.
1892. St. John's, Nfd. Loss $15,000,000.
1904. Toronto, Ont. General conflagration; loss $13,000,000.
1917. Halifax, N.S. About 75 ac. of city burned following explosion of munitions ship; 1,000 buildings levelled; 1,500 persons killed.
1923. New Brunswick. Forest fires; loss $20,000,000.
1949. Toronto, Ont. Steamer "Noronic" burned, Sept. 17; 120 killed.
1950. Rimouski, Que. Lumber yard fire destroyed 346 buildings, May 6; loss $16,000,000. (Ho. B.; X.)

FIREARMS: see PISTOL; SMALL ARMS, DEVELOPMENT OF.

FIREBACK, the ornamented slab of cast iron protecting the back of a fireplace. The date at which firebacks became common probably synchronizes with the removal of the fire from the centre to the side or end of a room. They never became universal, since the proximity of deposits of iron ore was essential to their use. In England they were confined chiefly to the iron districts of Sussex and Surrey, and appear to have ceased being made when the ore in those counties was exhausted. They are, however, occasionally found in other parts of the country, and it is reasonable to suppose that there was a certain commerce in an appliance which gradually assumed an interesting and even artistic form. The earlier examples were commonly rectangular, but a shaped or gabled top eventually became common.

English firebacks may roughly be separated into four chronological divisions: those moulded from more than one movable stamp; armorial backs; allegorical, mythological and biblical slabs with an occasional portrait; and copies of 17th- and 18th-century continental designs, chiefly Netherlandish. The fleur-de-lis, the rosette and other motives of detached ornament were much used before attempts were made to elaborate a homogeneous design, but by the middle of the 17th century firebacks of a very elaborate type were being produced. Thus there are representations of the Crucifixion: the death of Jacob. Hercules slaying the hydra, and the plague of serpents. Coats of arms were very frequent, the royal achievement being used extensively; many existing firebacks bear the arms of the Stuarts. About the time of Elizabeth the coats of private families began to be used, the earliest instances remaining bearing those of the Sackvilles, who were lords of a large portion of the forest of Anderida, which furnished the charcoal for the smelting operations in early British iron fields. To the armorial shields the date was often added, together with the initials of the owners. The method of casting firebacks was to cut the design upon a thick slab of oak, which was impressed face downward upon a bed of sand, the molten metal being ladled into the impression.

Firebacks were also common in the Netherlands and in parts of France, notably in Alsace. At Strasbourg and Metz there are several private collections, and there are also many examples in public museums. The museum of the Porte de Hal at Brussels contains one of the finest examples in existence. with an equestrian portrait of the emperor Charles V, accompanied by his arms and motto. When monarchy was first destroyed in France the possession of a *plaque* de *cheminée* bearing heraldic insignia was regarded as a mark of disloyalty to the republic, and on Oct. 13, 1793, the national convention issued a decree giving the owners and tenants of houses a month in which to turn such firebacks with their faces to the mall, pending the manufacture by the iron foundries of a sufficient number of backs less offensive to the instinct of equality. Very few of the old plaques were removed, however. and to this day the old châteaux of France contain many with their backs outward.

FIREBRAT, a wingless insect (*Thermobia domestica*) of the order Thysanura, so called because of its occurrence about fireplaces and bakehouses. It feeds on starchy material.

FIREBRICK. Another descriptive term for this product is refractory brick, which includes a variety of shapes made from nonmetallic minerals and intended for service at high temperatures. The largest consumers of firebrick are the metal and glass industries.

Ran· materials for firebrick include fire clays, of which the essential mineral components are hydrated aluminum silicates having the general formula $Al_2O_3.2SiO_2.2H_2O$; minerals of high aluminum oxide content, such a; bauxite. diaspore and kyanite; sources of silica, including sand and quartzite (commonly known as ganister); the magnesia minerals. magnesite, dolomite, forsterite and olivine; chromite, a solid solution of chromic oxide with the oxides of aluminum, iron and magnesium; carbon in the form of graphite or coke; and vermiculite mica. Minor raw materials are zirconia, zircon, thoria, beryllia, titania and ceria and other rare earths.

Manufacture. — Refractory shapes are formed by the following processes used in building brick manufacture: dry press, stiff mud and soft mud (see BRICK), as well as casting and hot pressing. The soft mud process of forming firebrick is a hand operation in which a slug of plastic clay is thrown into a steel-lined wooden mould. The casting process employs a suspension of finely ground raw material in water, which is poured into absorbent plaster moulds to form the desired shapes. Hot pressing consists in subjecting the dry mix to moderate or high pressures in a heated die, causing bonding and densification to occur more readily than would be the case without pressure application. This method has been utilized in the preparation of specialized refractories for very high temperature service.

Drying of firebrick shaped by conventional methods is commonly performed in continuous tunnel driers in which temperature and humidity are carefully controlled. In the burning of firebrick oil- or gas-fired tunnel kilns or periodic kilns are ordinarily used. Some ram materials, including magnesite and dolomite, require an additional firing in rotary kilns to bring about sintering and densification before the crushed and sized material can be fabricated into refractory shapes and refired. Grog for firebrick is also made by burning fire clay or aluminum oxide minerals in a rotary kiln. Electric furnace fusion of raw materials, followed by casting of the melt in special moulds, is important. Fused alumina, mullite and zirconia brick have no porosity and great resistance to attack by molten glasses. Silicon carbide, a widely used refractory, is formed by reaction of petroleum coke with sand in electric or resistance furnaces. The resulting crystalline product is crushed and graded. After incorporation of a bonding material it is formed into the desired shapes which are then fired in a tunnel kiln.

Properties. — Desirable properties of firebrick are: (1) refractoriness; (2) resistance to attack by such corrosive materials as glasses, metals, slags and salts; (3) high strength at ordinary temperatures and resistance to deformation under loading at high temperatures; (4) resistance to spalling (surface fracture of the brick resulting from stresses which are usually induced by uneven heating or cooling); (5) ability to withstand abrasion; and (6) thermal conductivity suitable for the conditions of use.

Firebrick may conveniently be grouped into three categories: (1) acid, (2) neutral and (3) basic. The neutral classification is not widely used, however. since some refractories, such as those made from mixtures of chrome ore and magnesite, have both acid and basic characteristics. Silica brick is typical of acid firebrick and magnesite brick of the basic group.

Refractoriness of firebrick is often evaluated in terms of pyrometric cone equivalents. These provide an index number corresponding to a given temperature at which the material undergoes marked softening and deformation. Low-duty fire-clay bricks have cone values ranging from 19 to 26 (1,520° to 1,595° C.), and superduty fire-clay bricks have values of 33 to 34 (1,745° to 1,760° C.). High-alumina firebricks have cone values that Increase from 34 to 42 (1,760° to 1,990° C.) as the aluminum oxide content is raised from 50% to 99%. For very high temperature service, graphite and other carbon refractories, as well as silicon carbide, are available. These have the disadvantage of poor resistance to oxidation, although this condition can be improved by incorporation of additives designed to form a protective glaze at operating temperatures.

In the majority of uses, firebrick must be able to resist corrosive chemical reactions, particularly those which result from contact with molten slag. It is a general rule that the refractory should be of chemical nature similar to the material with which it will come in contact; *e.g.*, a basic refractory should be used when it will come into contact with a basic slag, for example in basic open-hearth steelmaking. Silica brick might seem ideal for lining a glass tank in which a high-silica glass is to be melted. but this is not the case; such bricks are porous and would permit the melt to penetrate within the grains and destroy the bond, resulting in early failure. Therefore it is customary to use a very dense firebrick made from fire clay and ganister, or a fused cast refractory with zero porosity.

The ability of firebrick to withstand loading at high temperatures is closely related to the melting behaviour of the refractory, since the greater the amount of liquid formed within the material, the greater the deformation under load. Knowledge of the load-bearing capacity of firebricks is important in furnace design. particularly where the refractory is rather uniformly heated to a high temperature, as in well-insulated furnace roofs and interior parts of the furnace structure.

The loss of fragments of material from a fire-clay brick or from the face of a panel of fire-clay brick masonry under service conditions is known as spalling. This type of failure usually results from thermal stresses which occur when the material is subjected to rapid temperature changes. Firebricks having uniform and low coefficients of thermal expansion are least susceptible to spalling. At temperatures above 650° C., silica brick is very resistant to spalling, but below that temperature a marked volume change occurs, resulting from crystalline inversion of the cristobalite modification of silica; spalling is likely to result unless heating and cooling in this temperature range are very slow. The fact that open-hearth furnaces in steel mills have silica brick roofs is one of the reasons why interruption in operations involves considerable lost time and much expense.

Uses.—The greatest use of firebrick is in the production of iron and steel. Vast quantities of refractories are used in blast furnaces, open hearths, Bessemers, electric furnaces and ladles.

Fire-clay brick has been most commonly employed in the lining of blast furnaces. but carbon refractories are also widely used for bosh and hearth linings. It is in the open hearth. however, that the greatest variety of lining materials is employed, including magnesite, chrome, silica, fire-clay and insulating brick. The front and back walls of the furnace as well as the roof are made of silica brick, and it is usual practice to introduce a layer of chrome brick between the silica and magnesite brick. Chrome firebrick is compatible with both silica and magnesite. whereas the two latter types of firebrick, if in immediate contact, would fail through chemical reaction at high temperatures.

In the foundry industry, cupolas are used for melting gray iron. Since the charge consists of pig iron and scrap, together with limestone and steel, it is necessary to line the cupola with dense firebrick that will withstand abrasion. Sudden temperature changes require that the brick be resistant to spalling, and slag attack is also generally severe. Fire-clay brick best meets these conditions. The nonferrous metal industry is likewise a large consumer of firebrick for the production of copper, zinc, lead, nickel and melting of aluminum.

Firebrick is vital to the production of glass. Glass furnaces or tanks, as they are called, are elaborate refractory structures in which high rates of melting can be maintained. Glass may be considered as a special and extremely corrosive type of slag. Several materials used in its manufacture, such as soda ash, sodium sulphate, lime and borax. react vigorously with many refractories at high temperatures. For this reason highly siliceous, dense, fireclay bricks, known as flux blocks, are much used in the portion of the tank that is in contact with molten glass. Mullite firebricks. prepared from the mineral kyanite, have excellent durability, as do also fused alumina bricks, since these allow no penetration of the glass and are comparatively inert chemically.

Firebrick linings must be employed in lime and cement kilns. Dense fire-clay blocks give good service. hfagnesite is an excellent material for lining rotary kilns used in portland cement manufacture, since the refractory and the clinker are both highly basic and do not react with one another.

Electric power generation is heavily dependent upon the utilization of firebrick. Large quantities are employed in the furnaces of steam-generating plants. although the water cooling of furnace walls eliminated part of the need for high-temperature linings.

Industrial Trends.—The history of the firebrick industry shows a continuous change from manufacture of a few types of all-purpose materials to a high degree of specialization. Initially, iron and glass manufacture provided the impetus for firebrick development. Near the close of the 19th century the great variety of lining materials used in the steel industry, including silica, magnesite and chrome firebrick. was introduced.

For most processes where firebricks are employed as a lining material, the production rate and efficiency are augmented by increases in operating temperatures. Thus, there has been a continued incentive for the firebrick manufacturer to improve the refractoriness and general quality of his products as well as to diversify them for many new applications.

Special types of refractories are required in the construction of power plants based on the utilization of nuclear energy; the materials must have outstanding chemical and physical stability at high temperatures. These specifications resulted in intensive study and use of various high-melting oxides, carbides, sulphides and nitrides that were not previously widely employed as refractories.

FIRE CONTROL: see GUNNERY, NAVAL.

FIREDAMP, the most prevalent of the noxious and inflammable gases found in mines. The chief constituent of this gas is methane (*q.v.*), also known as marsh gas. Firedamp is commonly termed "gas" by the coal miner, and a mine in which its occurrence is common is known as a "gassy" or "fiery" mine. Firedamp is never found as pure methane in mines. Analyses in seams in the north of England made by Sir H. de la Beche and Lyon Plaqfair in 1846 showed the gas to contain:

	Per Cent
Methane	77.j to 98.2
Nitrogen	1.3 to 26.1
Carbonic acid	0.3 to 2.1
Oxygen	0.0 to 3.0
Hydrogen	0.0 to 3.0

Sometimes. besides methane. firedamp contains a small quantity of another highly inflammable gas. ethane (*q.v.*). Thus samples of mine atmospheres taken in a working place (a dip drift) at the Glückhilf colliery at Waldenburg in 1881 and analyzed by Poleck for the Prussian Firedamp commission, showed its composition to be as follows:

	1. Per Cent	2. Per Cent
Methane (CH_4)	34.93	32.65
Ethane (C_2H_6)	2.89	3.99
Carbonic acid (CO_2)	41.49	41.49
Carbon monoxide (CO)	...	1.87
Nitrogen (N) Oxygen (O)	20.69	20.00
	100.00	100.00

The considerable quantity of carbon dioxide points to the sample being the result of decomposition. The carbon monoxide was discovered by the aid of the spectroscope. Methane is odourless, colourless and tasteless. It burns with a bluish flame forming carbonic acid and water. As it is lighter than air it rises upward to the roof and is found in the higher parts of the workings. When mixed with air to the extent of 6.1%, the atmosphere becomes just ignitable. so that 6.1% is spoken of as the lower limit of inflammability; the most explosive mixture, however. is that which contains 9.47% of methane; that is, where there is present just sufficient methane to consume all the oxygen in the air. Eight to 14% may be regarded as the high explosive range. At 22% the mixture ceases to be explosive. Though firedamp is found chiefly in coal mines, where it exudes from the pores and cavities in the coal, its occurrence is not restricted thereto. In 1886 two explosions of firedamp occurred in the Mill Close Head mine 'at Darley Dale in Derbyshire. by which five persons lost their lives; its occurrence in metalliferous mines has also been reported. It probably occurs in all coal mines. though some are commonly described as exempt (*e.g.,* the coal mines of the Forest of Dean), but is probably generated in such small quantity as not to be detectable on the flame of a lamp or candle.

The usual way of determining the presence of firedamp in the mine atmosphere is by the pale violet-blue cap above the flame of the safety lamp. It is detectable by this means when present to as low as ½% (see SAFETY LAMP).

In some seams firedamp exists in a state of considerable pressure, as determined by Lindsay Rood in experiments conducted by him in 1880 for the royal commission on accidents in mines. For this purpose holes were driven into the solid coal, plugged and fitted with a pressure gauge. when pressures as high as 461 lb. per square inch were obtained after some days. The greatest volume of gas given off was equivalent to 5,927 cu.ft. per hour. These, however. are abnormal figures. Sudden outbursts of firedamp. the *dégagements instantanés* of the Belgian miner, are an infrequent occurrence in British coal mines. usually taking place in the neighbourhood of a fault. Blowers of gas, the *soufflards* of the French miner, are more common, a blower being a stream of gas frequently accompanied by water, continuing at a constant pressure sometimes for years. (See also COAL AND COAL MIXING.) (R. R.)

FIREDOG, or andiron, one of a pair of supports for wood that is burned in an open fireplace. It has an upright standard to which is attached a horizontal bar which raises the logs above the hearth level. The spreading base gives the support an appearance similar to that of a dog, hence firedog. Various materials are used, such as cast iron, wrought iron, steel, brass and cast brass. Wrought-iron firedogs, with little or no ornament, were used in the simple homes, whereas the more expensive materials, with every conceivable adornment, belonged to the élite. The 17th century was noted for its rich and elaborate andirons, some of

which stood 4 ft. high and were tipped with such decorations as bronze disks, shields of arms and statuettes.

FIRE ENGINES. The modern fire engine or pumper is a motor-driven vehicle used when fighting fires. It is specially built to (1) carry a crew of firemen and equipment that will be required for fire extinguishment and (2) to provide the required volume of water at proper pressure for the hose lines.

The equipment usually carried is fire hose, nozzles, water (100 gal. or more), ladders, pike poles, electric lanterns, axes, forcible entry tools, gas masks and portable fire extinguishers.

The power to propel the fire engine and operate the pump is provided by an internal combustion motor of heavy duty design. Fast acceleration and good hill climbing ability are essential features. The motor must have adequate power to enable the pump to deliver a rated volume of water at specified pressures for good fire streams.

Fire engines are built in several sizes to meet the operating requirements of standardized pump performance ratings.

Other types of vehicles also used by the fire service include (1) the ladder truck which carries a large assortment of ground ladders of varying lengths; (2) the combined fire engine and ladder truck, making a "quadruple" which performs the functions of both vehicles; (3) the aerial ladder truck which carries a power-operated aerial ladder to reach heights or locations not possible with ground ladders, and which is used for rescue operations, access to upper floors of buildings, and as a water tower; (4) the "quintuplet," a combination in one vehicle of the fire engine, ladder truck and aerial ladder truck.

History. — The earliest method of fighting fires consisted of throwing water on the fire from buckets or other vessels. It is not known what fire-fighting facilities were available at the time of the burning of Rome in A.D. 64. The first use of a device for applying water to a fire in the form of a stream dates back as far as the 2nd century B.C. The science of fire extinction was still in a very elementary stage in 1666, when the great fire of London occurred. The only fire engines used at this fire were those of the hand-operated type. The early squirting devices were usually in the form of a mammoth syringe. This later developed into a receptacle for holding water which was filled and replenished during the fire by a bucket brigade, the water being withdrawn and ejected by means of an early form of pump.

The pumps on the early fire engines were hand-operated and the range and force of the stream were poor. In many instances the engine was destroyed by the fire because of the fact that the short range of the stream made it necessary to take the apparatus close to the flames. This led to the development of better pumps which could squirt a much longer distance. Subsequently, the development of a flexible pipe or hose made it possible to locate the engine well away from the fire and to convey the water under pressure from the engine to the fire. A still later development was the employment of suction hose to enable the pump to feed from sources other than its own suction.

Steam Fire Engines. — The first mechanically operated fire engines appear to have been developed early in the 19th century when steam was first used for operating a fire pump — the vehicle on which the pump and steam boiler were mounted being drawn to the fire either by the firemen or by horses. About 1860 steam fire engines were being made in England and the United States. Public interest in steam fire engines was greatly stimulated by competitions held in England at the Crystal palace in 1863, in which engines from the United States took part.

Steam fire engines were used almost exclusively at the Chicago, Ill., conflagration in 1871. Toward the end of the 19th century horse-drawn steam fire engines had been brought to a state of high perfection both in Europe and in the United States, when engineers began the development of the self-propelling vehicle.

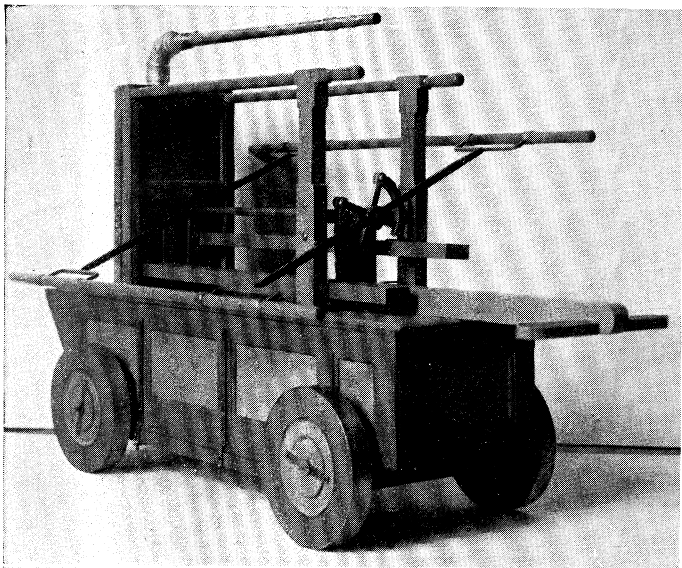
The earliest self-propelled machines were those of steam fire engines.

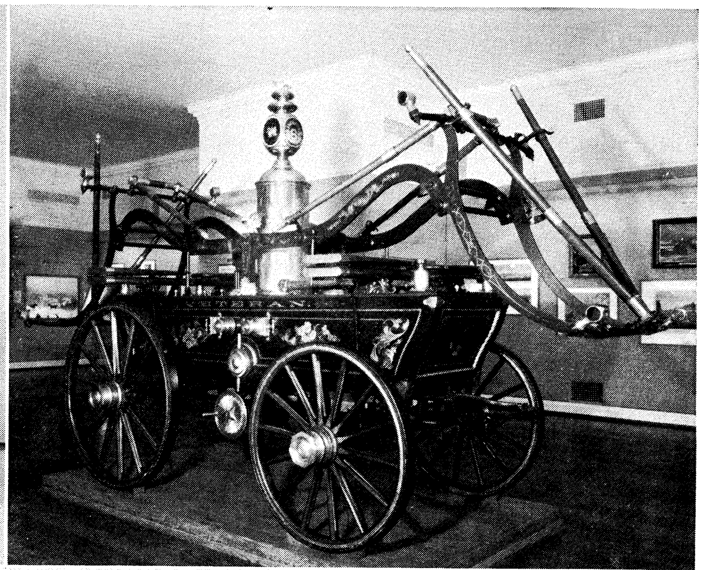
Motor Fire Engines. — The first self-propelled fire engines employing an internal combustion motor (other than as a tractor) were built about 1903. By 1910 a considerable number of motor fire engines were in successful service in various parts of the world, and by 1920 practically every large city had discarded horse-drawn and steam fire engines in favour of self-propelled engines.

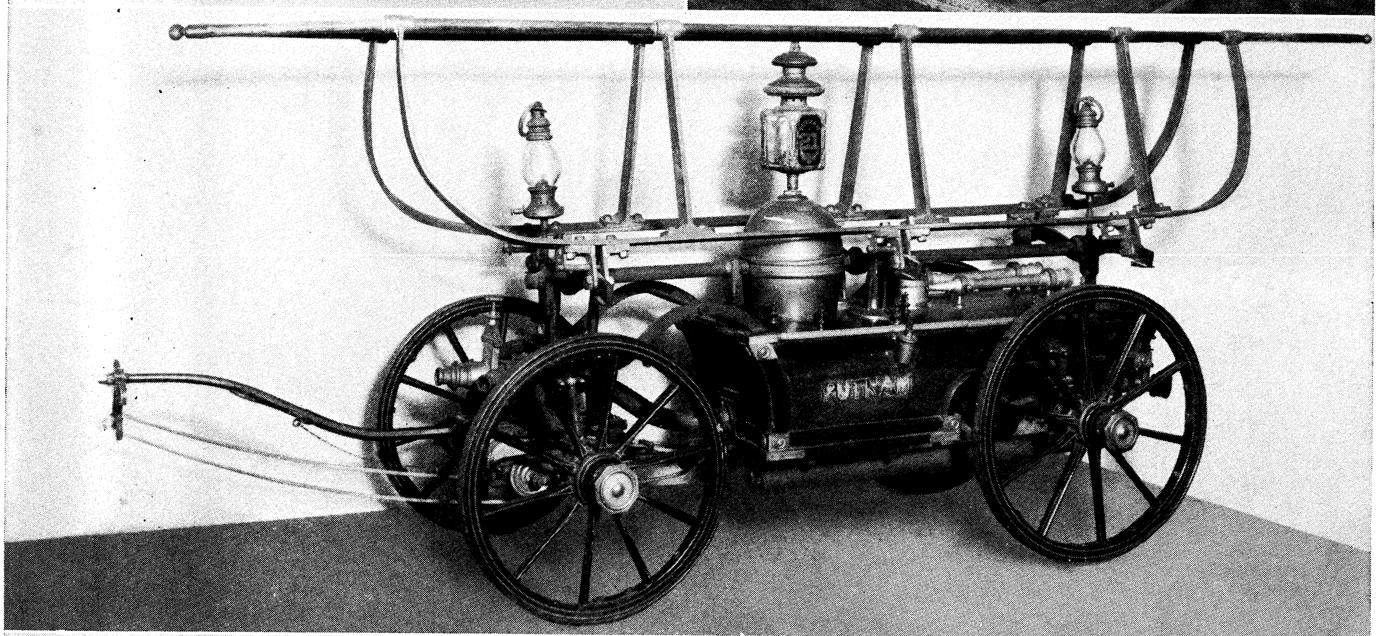
Three types of fire pumps — piston, rotary gear and centrifugal —were used in fire engines for about 30 years after fire engines were motorized. During this period, the efficiency and performance of the centrifugal pump improved so greatly that it superseded other types in the medium and larger sizes of pumps. The piston and rotary gear types came to be used only for small stream ($\frac{3}{4}$ in. and 1 in.) hose lines and nozzles. The centrifugal pump is not self-priming and requires an auxiliary device to exhaust the air from the pump and the suction lines when the pump is to operate at draft. When operating from a hydrant the use of a primer is not required.

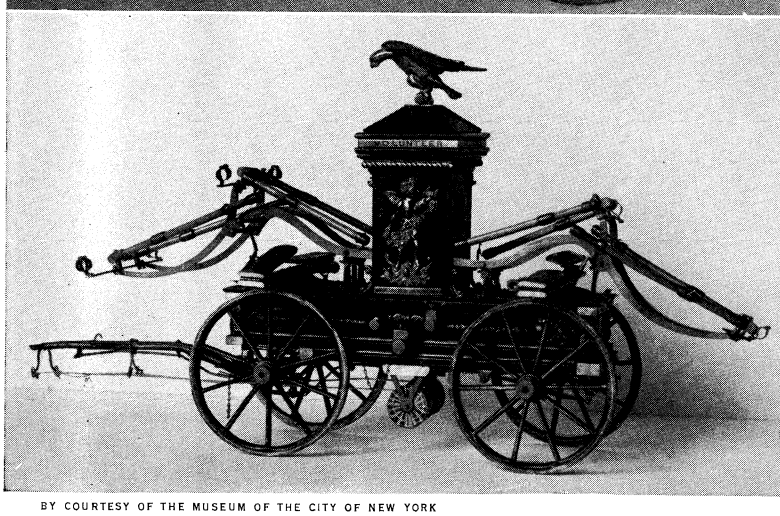
Chemical Fire Engines. — Chemical fire engines are large-capacity chemical fire extinguishers usually mounted on two wheels for portability; they are principally used in industrial organizations and at airports. These units are built in four different types: soda acid, foam, carbon dioxide and dry powder. The soda acid and foam types were mounted on fire engines and used on small fires. The mounting of these units on fire engines was discontinued by 1930 and water tanks were substituted. The types used for industrial fire protection usually have a capacity of 40 gal. for either the soda-acid or the foam type. The carbon dioxide type carries one or more cylinders of carbon dioxide. Cylinders hold 50 lb., 75 lb., or 100 lb. of carbon dioxide in liquid form. The dry powder extinguishers have 150 lb. or 350 lb. capacity. The soda-acid engine consists of one or more cylindrical vessels charged with a solution of bicarbonate of soda dissolved in water. Enclosed in this cylindrical vessel is also a receptacle for holding a quantity of sulphuric acid. A hose line generally $\frac{3}{4}$ in. or 1 in. in diameter is connected to the outlet of the cylindrical vessel, and when the chemical engine is required for use, the sulphuric acid is caused to be discharged from its receptacle into the bicarbonate of soda solution. This admixture of the acid with the soda solution within the cylindrical vessel forms carbonic acid gas under pressure, which forces the solution through the hose. In the soda-acid machines various methods for causing the acid to be discharged into the soda solution are employed: (1) inverting the acid bottle by means of an operating handle; (2) revolving the cylindrical vessel on its trunnions, thus inverting the acid receptacle.

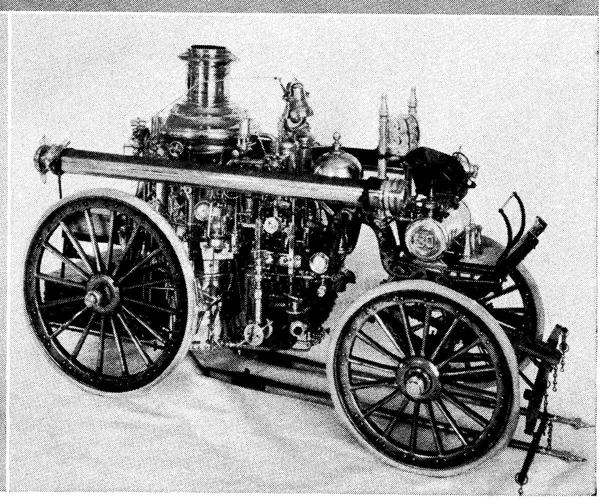
The foam type of machine is somewhat similar to the soda-acid except that the acid ingredient is a solution of aluminum sulphate dissolved in water. To make the bubbles tougher and more stable a stabilizing ingredient is added to the bicarbonate of soda solution. The discharge from a foam chemical engine is therefore a tough and tenacious foam made up of minute bubbles containing











EARLY U.S. FIRE ENGINES

Top left: Hand-operated model built in England and put into service in New York city in 1731

Top right: An engine of the 1850s. One of the largest of its day, it weighed about 4,500 lb. when loaded and required 16 men to operate its brakes

Centre: Crane neck type of engine, built about 1863, which was capable of throwing a stream of water 150 ft. into the air

Bottom left: The "Philadelphia" or "double deck" style of engine first introduced in 1840. Photograph shows a replica made in 1885 from an original engine

Bottom right: Steam fire engine first put into service about 1905. About 1913 it was converted from horse to tractor-drawn and remained in active service in New York city until 1932

carbonic acid gas. This foam has the property of adhering to any solid surface upon which it is thrown and will even adhere to a vertical wall or to a ceiling: it also floats on any flammable liquid. This foam completely excludes air from the surface which it covers and deprives the fire of the oxygen which would otherwise feed the flames, thus extinguishing the fire by sufiocation. Foam is also used in the fire service in the form of a dry powder which employs a foam generator to mix the powder with water being discharged by the fire pump. The foam powder is poured into the hopper on the generator as required for foam production. As the stream of water passes through the base of the generator, the dry foam is automatically drawn into the water stream resulting in chemical action producing foam for discharge from the nozzle.

The carbon dioxide extinguisher contains a quantity (by weight) of carbon dioxide in liquid form. The liquid changes to a gas at −39° F., and the pressure increase in the cylinder expells the gas when a seal is punctured at the outlet valve.

The dry powder type extinguisher uses bicarbonate of soda with additives to prevent caking. A nitrogen gas cylinder is used to provide an inert gas to expel the powder when required. A relief valve controls the discharge pressure.

Fire Boats.—An important feature of the fire-fighting equipment in large river, lake and sea ports is the fire boat. They are essentially large tugboats equipped with fire pumps of 3.000 to 12,000 gal. capacity. The older boats were steam-propelled and the pumps steam-driven. The newer boats are propelled by internal combustion motors. such as the efficient diesel engine, which are not only employed to propel the boat but also utilized to drive the fire pumps when required. A typical later boat has a pumping capacity of 12,000 gal. of water per minute at about 100 lb. pressure, is 123½ ft. long, 26 ft. beam and 73 ft. draught, designed to travel at a speed of about 14 knots.

Fire Extinguishers.— Fire engines usually carry two or more of the following types of small fire extinguishers: soda acid (2½ gal.); foam (23 gal.); carbon dioxide (15 Ib.); dry chemical (25 to 30 lb.); carbon tetrachloride (1 qt. to 1 gal.); water type (j gal.). The type and number of extinguishers will vary according to the hazards that exist in the area covered by a particular department, each type being particularly suited for specific risks.

(J. H. Os.; C. B. R.; Ht. W.)

FIRE ESCAPES in England refer to constructing ladders mounted on wheels which are intended to be used exclusively for the purpose of enabling people to escape from burning buildings. Abraham Wivell invented the first portable fire escape ladder of this kind about 1837. Before Wivell's time, however, various smaller fire escapes were in use. There is in existence a very interesting drawing by C. Geissler, dated 1789, showing three types employed in Geneva at that date, consisting (1) of the cloth or canvas chute, (2) the rope and basket (or sling), and (3) sectional ladders fitted with sockets so that several could be joined together to make one long length. the top section having running wheels to travel easily up the walls of a building. Sectional ladders of somewhat similar build were the first fire escapes to be used in London, when John Braidwood, the famous first chief of the London Fire Engine establishment, put them into service there in 1832. They were made in short lengths of about 6 ft. for carrying upon the fire engines of the period.

Wivell's wheeled fire escape was not officially adopted, though it was put into service in London by the Royal Society for the Protection of Life from Fire. A few years later another type of wheeled escape known as the fly-ladder was evolved and this, being an improvement upon Wivell's machine, gradually superseded it. The fly-ladder had a main ladder about 3j ft. in length mounted upon a spring carriage. with large wheels. At about 10 ft. from the top of the main ladder a folding ladder of about 20 ft. was joined by hinges, and was raised when required for use by ropes attached to projecting levers. It was possible also to detach this folding ladder when required; and in the event of greater heights having to be negotiated than the combined height of the main and fly-ladders, a separate short ladder was placed at the top of the folding ladder, and by this means a height of about 60 ft. could be reached. At the underside of the ladder was affixed a canvas chute protected externally by copper wire netting; this was used to pass persons down when it was possible to get the top of the chute upon a suitable window sill. For greater heights the persons had to be carried down the ladders in the same way as is done in the present day.

Telescopic Escapes, 1890.—The fly-ladder escape held the field in England until about 1890 when telescopic escapes were introduced embodying the sliding body principle, which enables the ladders to be carried in a horizontal position and elevated to the vertical on arrival at a fire. These ladders were arranged to slide in a framework attached to the axle, and were held in position by means of hand-driven gear arranged on the backfly. They could be pitched at any angle to the building, thus enabling a wide forecourt to be bridged. which could not be done with the older types of fire escapes; but it was found that for service of this kind it was necessary to strengthen the sides of the ladders: and in 1896 J. C. Merryweather patented a system of bowstring girder trussing which also formed a convenient handrail on each of the ladders. Other makers, notably Shand Mason & Co., introduced other forms of trussing to achieve the same object. Soon after these sliding carriage escapes were introduced the motor system began to make headway in service: and it became customary to arrange brackets at the rear of the motor vehicles to carry fire escapes, which could then be dismounted upon the arrival of the engine at a fire, and wheeled by hand to any convenient position for use. This is still the practice in most large British fire brigades. Before arriving at this stage of development. however, there had been an intermediate stage when sliding carriage fire escapes were carried upon horse vehicles, some being of the dog-cart pattern, and others being four-wheeled horse-drawn vehicles generally known in the service as tenders. Many fire brigades now carry light trussed ladders (35 to 40 ft. dismounted ladders) in an overhead position on their motor vehicles; these are very serviceable where buildings of moderate height are concerned.

Another form of escape which, although introduced many years ago, is still popular, is the pompier ladder; as its name indicates, it is of French origin. It is an exceptionally light ladder usually from 16 to 18 ft. in length. and at the end an iron or steel hook is fixed for the purpose of reaching over and holding on to window sills. In expert hands the pompier ladder is very useful, but it can only be safely worked by trained firemen. It is not always employed in the ordinary way as a fire escape. but is used for the purpose of enabling firemen to scale walls of burning buildings, and persons to be saved are lowered to the ground by ropes which the firemen carry.

Recent Methods.—In Great Britain and on the continent of Europe, the most modern type of fire escape is that known as the turntable ladder. It is mounted upon an automobile chassis, and the ladders can be slewed around to any required position. A good example is a machine built at the end of 1927 for the Leicester fire brigade. The chassis has a six-cylinder engine of 60 b.h.p., which not only provides the power for road travelling but also. through special gearing, elevates, extends and revolves the ladders, so that they can be moved into any desired position. The movements of the ladders are controlled by three levers. and a graduated quadrant shows automatically the angle of elevation, while an indicator gives the height of extension. Plumbing gear is provided to enable the ladders themselves to remain vertical even when the carriage is standing on uneven ground. At the top of the ladders is fitted a swivelling monitor nozzle, for use as a water tower, from which a jet can be sent in any direction. Upon the turntable platform is a powerful searchlight which will throw a beam up the ladders whatever their position may be, thus lighting up the man who is controlling the jet or effecting a rescue; and this man is in communication, by means of a loud speaker telephone, with his comrades on the ground. In the centre of the chassis is fixed a Hatfield fire pump. capable of delivering 250 gal. per minute, and at the top of this pump is mounted a monitor swivelling nozzle from which a jet can be thrown direct upon a fire. The delivery of the pump is also arranged in such a way that the water can pass up through hose carried up the ladders for the purpose of attacking the fire from above, by means of the water tower just mentioned. It will be seen that it is possible for this machine to be used as a water tower and fire engine simultaneously, since the pumps can be working on the main monitor which is mounted upon the pump itself, while the ladders are being used for rescue purposes.

Every possible precaution has been taken to secure safety in operation. Trussing is employed to increase the strength of the ladders, and an ingenious device insures that when either of the three controlling levers are released by the operator, no matter at what angle or extension the ladders may be, the power is cut off and the ladders remain absolutely secure. Again, if either of the levers is pulled down, or kept down too long, overelevation or overextension is automatically prevented by a device which forcibly returns the levers to the free position before the point of danger is reached. The outstanding feature of this machine is that, contrary to the practice in some of the earlier types, the one engine performs every operation. Motor turntable ladders are built in various lengths, but as they are expensive machines it is the general practice to construct them to command very considerable heights. The longest ladder of this type built up to the year 1953 was made by the Magirus company of Germany. It is 170 ft. in length. Ladders of 45-m. length (150 ft.) are also constructed by this company. The common heights made by all manufacturers are from 75 to 100 ft. (J. H. Os; X.)

United States.—The term fire escape in the United States is usually restricted to those means of escape added to an existing building and designed only for emergency use. The most common type is the open iron stairs with railed balconies extending from roof to street and usually required by a local regulation in order to bring a building up to an improved standard of egress established after the building was first designed. or where a definite standard is required because of a change in the type or number of occupants.

This type of escape has serious limitations. In areas subject to winter exposure they must be kept clean of ice and snow. Unless installed against a blank wall, smoke and fire from lower story windows may render them impassable. Many people are affected by height and are likely to be timid and descend at a much slower rate than on inside staircases. Because these fire escapes are for emergency use only their proper upkeep may be neglected.

Many escapes of this type must extend over public walkways and the lower section is a counterweighted flight, usually with some type of locking device so prowlers cannot pull it down from the street. In other cases the escape may have a fixed ladder or a balcony where ladders are added after arrival of the fire department. In spite of these limitations, however, many lives have been saved by this type of installation. the LaSalle hotel fire in Chicago, Ill., on June j 1946, being one of the outstanding examples.

Another type of escape for existing buildings is the simple iron-railed balcony which leads around a fire wall or fire exit partition. In this type a person must leave one section of a building, usually through a window, onto the balcony pass the fire wall and enter another building or another section of the same building and then use the regular means of egress.

A third type of fire escape is the slide escape—a chute which may be installed in a vertical spiral or straight and may be either open or enclosed. The straight chute may be parallel to the building or at right angles. Access to the chute is through openings at floor level, from which persons slide to ground level. They are usually approved for new industrial buildings having high hazard occupancy such as manufacture of explosives, grain elevators. etc. On existing buildings they are limited to schools, orphan asylums and hospitals. One distinct advantage of their use in hospitals is that patients may escape on a hospital pad or mattress.

The best escapes. however, are those which are planned in the design of the building—enclosed staircases, fireproof towers or other approved means of egress.

FIREFLY, a term popularly applied to luminous, winged beetles of the family Lampyridae. The family contains about 2,000 described species and is world-wide in distribution. In the temperate zone, the beetles are a familiar sight on warm summer nights. when they may be seen flashing their lights in woodlands, over meadows, lawns, marshes and along lakes and streams. The flashing. which is believed to facilitate the meeting of the sexes, is sometimes synchronized, with thousands of individuals lighting up rhythmically and in unison. The commoner North American species belong to the genera *Photinus* and *Photuris; Luciola* is a well-known European genus. In many lampyrid species, the female may be wingless, larviform and luminous, while the males are beetlelike. capable of flying and either feebly luminous or nonluminous; the females of these species are known as glowworms (*q.v.*). Click beetles (family Elateridae) of the genus *Pyrophorus* emit a brilliant greenish light from a pale spot situated on each side at the base of the pronotum; they are sometimes referred to as fireflies but are more properly called fire beetles. They range from southern United States to Argentina and Chile. Other luminous click beetles (genus *Photophorus*) occur in New Caledonia, New Hebrides and Fiji. (See BEETLE.)

(R. L. WL.)

FIRE INSURANCE as now transacted all over the world was evolved in England in the 17th century. Until then any one suffering loss of house or goods by fire was dependent upon charity or the assistance of members of his guild to recoup his loss. The charitable principle was put into effect largely through church briefs or king's letters nhich entitled the sufferer to beg. Many proposals for a more systematic provision against fire losses failed to obtain support until after the great fire of London (1666). The principles already established in marine insurance were then applied to the insurance of houses. The basic principles were that the house owner should make a fixed annual contribution as premium to the insurers or underwriters who entered into a contract with him to make good fire loss or damage. In 1680 a fire office was formed to insure houses in London at a premium calculated at $2\frac{1}{2}\%$ of the yearly rent for brick houses and 5% for frame houses. Forty years later lire insurance had become established not only for houses but for goods, merchandise, furniture and wares of every description, and over the next 100 years numerous fire offices were formed all over the country.

In its development. fire insurance in Great Britain was particularly free from restrictive legislation. Apart from an iniquitous stamp duty. which often cost the insured more than the premium, there was little interference by the legislature. and not until 1909 were fire-insurance companies made subject to special legislation designed essentially to ensure their solvency.

A sound reputation for the fulfilment of contracts was early established by the British companies, and this was due in no small measure to their co-operation in establishing adequate rates of premium, particularly in respect of hazardous risks. Some agreements of this kind existed as early as 1826 and led eventually to the formation of the Fire Offices' committee in 1868 the members of which, known as tariff companies, regulate their business in the light of their pooled experience. By penalizing features of fire hazard and allowing discounts when the property is suitably protected, the companies have done much toward the prevention of fire.

The fire-insurance companies also initiated fire brigades; the company-maintained brigades which operated in London at the beginning of the 19th century eventually formed the nucleus of the metropolitan fire brigade. When it was recognized that the protection of property and lives against fire was a public duty to be discharged by the government or local authorities. the fire-insurance companies became free to concentrate on the technical aspects of risk improvement. They also established and still maintain at their own expense salvage corps in London, Liverpool, Glasgow and Belfast, the function of which is to minimize loss nhen a fire occurs. More recently the Fire Protection association, instituted by the Fire Offices' committee. was formed to give specialized advice on all fire-prevention problems.

Fire insurance is now transacted in the United Kingdom by nearly 140 companies as well as by underwriters at Lloyd's.

World-wide operations produce more than £200,000,000 in fire premiums each year. There was a tenfold increase in the first half of the 20th century.

The essential principles of fire insurance evolved in Great Britain have been widely followed in other countries. The governments of many countries have, however. intervened in the conduct of fire insurance by stringent legislation and have thus greatly restricted freedom of development and underwriting. State monopolies or privileged state companies, state reinsurance banks, state controllers and superintendents of insurance, with intervention in investments, reserves, policy conditions, rates and loss settlements, are widely established. In some countries the law governing fire insurance forms part of the civil or commercial code.

There are certain fundamental principles which govern all fire insurance contracts:

Good Faith.—Sound underwriting requires that insurers charge a premium commensurate to the risk involved, and for this purpose they require particulars which will enable them to assess the premium. Insurance contracts are contracts *uberrimae fidei; i.e.*, of the utmost good faith. It is not sufficient that a proposer for fire insurance answers truthfully such questions as may be asked of him by the insurer; the higher duty of full disclosure of all material facts applies. Contracts of insurance are therefore different from ordinary commercial contracts to which the doctrine of *caveat emptor* (let the buyer beware) applies. If the representations made by the proposer are not true, or if he fails to disclose everything that ought to be made known to the underwriter as material for a proper assessment of the risk. then the contract is rendered either voidable or void. In general, it is sufficient if the information given by the proposer is substantially correct, but any fact that appears on the policy as a warranty must be literally correct.

Indemnity.—A policy of fire insurance is a contract of indemnity against loss and not a contract to produce gain. The insurer undertakes to make good to an insured person, either by money payment or reinstatement, the loss he has suffered within the limits and terms and conditions of the policy. The insurers are liable only for the material loss; they cannot be called upon to pay for sentimental value. The peril causing the loss must have been accidental (*i.e.*, not caused intentionally by the insured).

A corollary of the principle of indemnity is the doctrine of subrogation. It sometimes happens that the insured is in a position to recover the amount of his loss, or part of it, from a third party as well as from his insurers. The insured may proceed against either or both, but the principle of indemnity means that if he claims from his insurers he automatically transfers to them his rights to recover from the third party.

Insurable Interest.— A policy of fire insurance covers the insured person's interest in the subject matter. An insured person must stand in such a relationship to the property insured as to suffer from its damage or destruction. This interest must exist at the inception of the policy and at the time of the loss.

There are many kinds of insurable interest: (1) Absolute ownership. This is probably the commonest form of interest. The insured need not be the sole owner; he may be a joint owner or partner in a firm. (2) Limited ownership (*e.g.*, tenants for life). (3) Mortgagors and mortgagees. The insurance is usually effected in the joint names, but each party has a separate insurable interest and may insure separately. (4) Lessors and lessees. These possess a joint interest, but each party may insure separately. (5) Trustees. These are legal owners of property and may insure in their own names. (6) Bailees. These are persons holding goods of another on trust, such as carriers! innkeepers, pawnbrokers, warehousemen and wharfingers. Some classes of bailees have their liability limited by statute.

It is not essential that the insured disclose the nature of his interest or for this to be stated in the policy. An exception is made in respect of goods held in trust or on commission, which are not covered unless specially mentioned.

Who Grants Insurance.— Fire insurance in Great Britain is conducted in rhe main by joint-stock limited-liability companies, mutual associations, and underwriters at Lloyd's. In the case of the companies the insured parties' contributions are restricted to the premiums they pay; they cannot be called upon to make good a deficiency in the fund. Operations of mutual associations are usually confined to a particular trade or business, but the mutual system is not regarded as entirely satisfactory, since a proportionate contingent liability rests on each insured to make good any general excess of losses over the general premium contributions. An insurance "written" at Lloyd's is divided among members of a syndicate, and the proportionate responsibility of each member is detailed in the policy. A proposer for fire insurance has no direct approach to underwriters at Lloyd's. All business is conducted through the medium of a Lloyd's insurance broker.

The Policy.— The standard form of policy now in use by most companies in the United Kingdom provides that if the property insured is destroyed or damaged by certain means the insurers will pay to the insured the value of the property at the time of the happening of its destruction or the amount of the damage. The causes covered are:

1. Fire (whether resulting from explosion or otherwise) not occasioned by or happening through: (a) its own spontaneous fermentation or heating or its undergoing any process involving the application of heat; (b) earthquake, subterranean fire, riot, civil commotion, foreign enemy, military or usurped power, rebellion or insurrection.
2. Lightning.
3. Explosion of boilers used for domestic purposes only.
4. Explosion of gas used for domestic purposes or used for lighting or heating the building, the building not being part of any gas works.

There are certain conditions which are implied in every policy of fire insurance, irrespective of specific inclusion in the contract. They are based on common law and. in general, have reference to the principles of good faith and insurable interest. Conditions expressed in the standard form of policy are:

Misdescription. Any material misdescription of the property insured or concealment of material fact invalidates the policy.

Alteration and Removal. Increase of risk, transfer of interest or removal of the property must be notified to the insurer and his consent to the alteration endorsed on the policy The clause as to removal mar be modified by an extension clause in the household-goods policies.

Excepted Goods and Perils. Certain classes of property, such as money, stamps, securities and documents, plans and patterns are not covered by a general description but must be specially mentioned. Explosives. and goods in trust must also be specified and damage by explosion (except as stated in the policy) is not covered. (This must not be confused with fire damage caused by explosion, which is covered.)

Claims Procedure. Notice of loss must be given immediately and a detailed claim submitted within 30 days. The insured must, if required, furnish reasonable proof of loss.

Fraudulent Claims. If the claim is in any respect fraudulent, all benefit under the policy is forfeited.

Reinstatement. Should the company elect to reinstate, the insured must give them reasonable assistance in the form of plans, specifications, etc. Reinstatement need not be exact but only reasonably sufficient and is limited to the sum insured.

Right of Entry. The company may enter and take possession of premises which have been the scene of a fire likely to give rise to a claim and may take possession of and deal with insured goods in a reasonable manner.

Contribution. If there is any other insurance effected for the same interest on the property destroyed or damaged, liability under the policy is limited to its rateable proportion of such destruction or damage. The condition is based on the fundamental principle of indemnity. The methods of achieving contribution vary according to circumstances.

Subrogation. This condition sets out the rights of the company under this heading (see *Indemnity* above).

Permanence of Warranties. This emphasizes that warranties to which the policy may be subject apply throughout the whole currency of the policy. Without this requirement, it would be necessary to obtain from the insured at each renewal an agreement that the warranties applied.

Arbitration. All differences arising out of the policy must he submitted to arbitration and an award made before action in the courts is taken.

Purchaser's Interest Clause. It is provided that property which is the subject of a contract to purchase shall be covered jointly for the benefit of the vendor and purchaser up to the date of the completion of the purchase, provided that the property covered is a building. The clause gives a concession in regard to condition 2 (alteration and removal).

Individual policies are subject to special conditions designed for each particular case and mostly for the convenience and advantage of the insured. In addition to the normal fire cover, the excluded perils of earthquake, subterranean fire, riot, civil commotion can usually be insured on payment of an additional premium. Insurance against a foreign enemy, military or usurped power, rebellion or insurrection is not obtainable. A comprehensive form of policy granted to house owners or householders conveniently embodies in one form insurance against fire and many additional risks.

Reinsurance.— By a system of reinsurance the company accepting the fire risk, known as the original or ceding company, gives off so much of the sum assured as is in excess of the amount it desires to retain. The amount given off is distributed among other companies, known as the reinsuring companies. Reinsurance cover is effected (1) by treaty arrangements, or (2) facultatively, in which case, unlike the treaty method, each request for reinsurance is accompanied by sufficient information to enable the reinsuring company to judge its acceptability. The system enables insurers to limit their liability on any one risk to a figure proportionate to the funds available and is based on one of the underlying principles of insurance (*i.e.*, the distribution of loss).

Consequential Loss.—Common law has laid down that ordinary fire insurance protects the insured only in respect to material loss or damage. Loss consequent upon fire is not included, but can be made the subject of consequential loss insurance, also known as profits insurance. The protection thus afforded is now as essential as that against material loss to most business concerns. There are three items to be considered: net profit; standing charges; increased cost of working. Insurance of any one or any combination of these three can be effected.

Net profit is defined as the residual profit from which dividends and allocations to reserve are normally provided; *i.e.*, the amount remaining after all charges have been met.

Standing charges are those charges which have to be met after a fire, and of necessity vary with individual circumstances. Any desired range may be specified when the insurance is effected. but they are usually made up from rent, rates and taxes; interest on loans and debentures; directors' fees; salaries and wages; advertising contracts; auditors' fees; and insurance premiums.

Increased cost of working is intended to cover abnormal expense incurred in keeping the business going after a fire.

An important factor is the period of indemnity; *i.e.*, the period in respect of which compensation is payable after a fire. A maximum period is chosen by the proposer (not the insurer), and should represent his estimate of the time needed to restore the business to full production after a fire. The period may vary from three months to three years, the most commonly selected period being from one to two years. After a fire, the indemnity period is the time during which there is actual interruption of normal trading or production.

The usual basis for the sum insured is the net profit and standing charges for the last financial year, or for the ensuing year, should the previous year's trading not afford a reliable guide. The premium calculation is related to the rates charged for insuring the ordinary fire risk and the period of indemnity.

The method employed for adjustment of losses varies according to the nature of the trade or industry. The usual method compares trading after the fire with that of the corresponding period in the previous 12 months and is known as the turnover standard. The settlement of loss of profits claims is largely a matter for accountants, and insurers instruct assessors with specialized knowledge whenever an important claim arises.

FIRE INSURANCE IN THE UNITED STATES

The insurance of property against loss by fire was one of the first forms of insurance to be provided in the United States by purely domestic companies. The first incorporated company, in fact, was formed during the colonial period, the Philadelphia Contributorship, a mutual company patterned aiter the Amicable Contributorship of London and organized by Benjamin Franklin in 1752. The first stock company, the Insurance Company of North America, was organized in 1792 to do a marine-insurance business but was extended to include fire insurance during its first year of operation It was early recognized that the business of insurance so affected the public interest that special forms of regulation were required. Because of its prior origin, fire insurance was subject to regulation much earlier than other forms, and in no case, with the possible exception of life insurance, has regulation, historically, been quite so detailed. While control is vested in the states, there is considerable uniformity in regulatory laws and practices. The chief supervisory official in each state is termed the superintendent or commissioner of insurance. He is charged with administration of the financial requirements imposed upon new companies desiring to enter the business, or existing companies seeking admission to the state. He also receives and reviews the annual statements required by law; makes periodic examinations, determines if reserve, investment and other requirements are being met; and appoints conservators or liquidators when conditions require.

The making and promulgation of fire-insurance rates is an activity carried on in the US. by state rating and inspection bureaus supported by the companies doing business in the state. In behalf of their member companies, these bureaus file with the insurance commissioner of the state class rates by areas for dwellings and a few other types of structures In addition, schedules for the determination of rates on commercial and industrial properties are filed. By application of the schedule, specific rates for such properties are developed by the inspection bureau. Factors taken into account in schedule rating include, in addition to a rating on the community in which the property is located, construction, occupancy and exposure to possible fire from adjoining properties. State bureaus usually operate in co-operation with regional bureaus which compile statistics and perform other functions related to the measurement of the fire hazard, as well as with the National Board of Fire Underwriters. The latter, in addition to technical and statistical functions, is concerned with the establishment of standards for and the rating of towns and cities to reflect the relative community fire hazard.

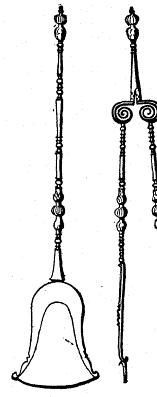
Fire insurance policies as issued in the United States consist of two parts, the agreement or contract and the stipulations or conditions. The agreement or contract is sufficiently complete so that it could stand alone as a contract of insurance. It includes space for description of the property and for the attachment of various endorsements which may be used to modify or supplement the terms of the contract. The stipulations set out certain requirements imposed on the insured both before and after a loss has occurred, circumstances which void or suspend the contract, property and perils not covered, permission for certain types of modifications, etc., and are added to make the contract more definite and specific.

The risk assumed is all direct loss by fire, lightning and removal from premises endangered by fire, of the property described in the contract, which property may be either real or personal. To be covered, loss by fire must be due to a "hostile" fire. The measure of damage is actual cash value, or replacement cost, new, less depreciation. No consequential losses, such as loss of use, are covered by the fire policy itself, but fire insurance companies insure such hazards separately under the title of business interruption insurance. Fraud or misrepresentation void the policy, and coverage is suspended if the hazard is increased by means within the knowledge or control of the insured. Intangibles such as money and securities are not covered, nor are bullion and manuscripts unless specifically described. A variety of financial interests in addition to ownership may be insured, such as those of a mortgagee, one legally liable, a lessee or a representative of the owner. Interest at the time of loss is sufficient, existence at the inception of the contract not being required.

In order to place a contract in effect, a form is usually added, containing a standard description of the type of property concerned, as well as a number of standard modifications. The form designed for dwellings and their contents, for example, permits application of 10% of the building insurance to apply to other buildings on the insured premises. A similar amount may be used to cover rental value, limited to $\frac{1}{12}$ of the amount per month. Ten per cent of the contents insurance may be used to cover personal property away from the premises. In no case, however, do these provisions increase the amount of insurance beyond that specified. In forms applying to property other than dwellings, coinsurance or reduced rate contribution clauses are sometimes used for the purpose of inducing the insured to purchase insurance more closely approaching the value of his property than might otherwise be the case. A reduced rate is charged, in return ior which the insured agrees to insure his property up to, say, 80% of its value. If he fails to do so he recovers irom the insurer, in case of a partial loss, only in the proportion which the insurance bears to the amount required by the clause.

During the 1930s, fire insurance companies began the issuance of supplementary contracts in conjunction with fire-insurance policies, covering such hazards as windstorm, smoke, riot, aircraft and vehicles, for which such companies already were offering separate insurance. Within a period of 15 to 20 years such extensions of the fire insurance policy had become well standardized under the terms of a form called the extended-coverage endorsement. This endorsement does not increase the amount of insurance but merely extends the coverage to additional hazards. In the 1950s further extensions were introduced under multiple-line insurance powers granted by the state legislatures, permitting fire companies to insure hazards formerly the exclusive province of casualty companies. At the same time, casualty companies were permitted to insure hazards formerly reserved to fire companies, and some uniformity was beginning to appear in the comprehensive policies issued by either or both types of companies. (J. E. Hs.)

FIRE IRONS, the implements for tending a fire. Usually they consist of poker, tongs and shovel, and they are most frequently of iron. steel or brass. or partly of one and partly of another. The more elegant brass examples of the early part of the 19th century are much sought after for use with the brass fenders of that date. They were sometimes hung from an ornamental brass stand. The fire irons of our own times are smaller in size and lighter in make than those of the best period. 4 typical example of the fireplace furnishings of the 18th and 19th centuries is shown in the accompanying illustration. In addition to the above, the bellows, the various cooking utensils, the hearth broom, etc, as well as the containers and receptacles about the mantel, make an interesting collection of fireplace furnishings.



BY COURTESY OF THE METROPOLITAN MUSEUM, N.Y. CITY

ENGLISH FIREPLACE SHOVEL AND TONGS OF THE 19TH CENTURY

FIRENZUOLA, AGNOLO (1493–*c.* 1545), Italian poet and littérateur, was born at Florence on Sept. 28, 1493. He studied law at Siena and afterward at Perugia, where he became the associate of the notorious Pietro Aretino, and copied his licentious way of living, though he is stated to have worn the monastic habit for a time. Firenzuola practised for some time as an advocate at Rome, and eventually settled at Prato as abbot of San Salvatore. His writings are of great importance in the history of Italian literature because they are written in Tuscan just as the literary style began to emerge from popular speech. He wrote *Discorsi degli animali,* imitations of oriental and Aesopian fables: *Dialogo delle bellezze donne* (Eng. trans., 1892); *Ragionamenti d'ainore,* a series of short tales in the manner of Boccaccio (Eng. trans.. 1889) ; *Discacciamento delle nuove lettere,* a controversial piece against Trissino's proposal to introduce new letters into the Italian alphabet; a free version of the popular *Golden Ass* of Apuleius; and two comedies, I *Lucidi,* an imitation of the *Menaechmi* of Plautus, and *La Trinuzia,* which in some points resembles the *Calandria* of Cardinal Bibbiena. His poems are chiefly satirical and burlesque.

The best edition of his collected works is that by Bianchi (Florence, 1848).

FIREPROOFING. This term is applied to methods of making normally combustible materials fireproof as far as may be, but in practice the most that can be done with them is to subdue or retard inflammability. The subject is one of great importance, especially in connection with the construction of theatres and other buildings where large numbers of people are collected together and where special illumination is required. The nature of or disposition of materials used in theatres has become the subject of public regulation in many countries and it is usual to provide that no combustible scenery shall be employed unless it has been treated with flame-retarding solutions. The London County council regulations. for instance. provide that in theatres materials such as wood. canvas, textiles, etc.. must be rendered noninflammable by impregnating them with solutions, and names the following as having been found suitable: (1) for scenery and coarse fabrics, a solution of 1 lb. of phosphate of ammonia and 2 lb. chloride of ammonia (sal ammoniac) in $1\frac{1}{2}$ gal nater; (2) for delicate fabrics and cotton wool, 10 oz. borax and 8 oz. boracic acid in 1 gal. of water. Stage woodnork must be thoroughly impregnated with phosphate of ammonia. It is. however, quite imoossible to make woodwork really fireproof and the council therefbre insists, as far as possible, upon the use of incombustible materials such as asbestos.

Such precautions have only been taken in comparatively recent times, the London County council's regulation requiring stage woodwork to be rendered noninflammable having first come into force in 1901. In 1923 special conditions were laid down with regard to the use of plywood, and by 1928 the construction of theatres was governed by a long series of safety regulations which experience had shown to be necessary. Floors. tiers and roofs. fittings in dressing rooms, all floors and linings to scene stores, workshops, etc., have to be formed of fire-resisting material; soft wood or other inflammable wall linings, decorations, partitions. screens or barriers must not be used, and cavities must not be left behind any linings or decorations. No fireplace may be used and no heating system involving use of a naked flame may be installed in any portion of the auditorium or stage; the stage and cellars below must not be congested with scenery and properties, and the regulations do not stop at fireproofing. There are stringent rules as to hydrants, fire appliances, fire drills, light installations. etc., and it is required that a competent fireman with practical experience in fire prevention and extinction should be on the staff. (A. F. H.)

United States.—The building code recommended by the National Boerd of Fire Underwriters is commonly used as a basis in the preparation of building ordinances of many cities. A solution which has been widely recognized for the fireproofing of fabrics is one made of 3 parts of ammonium phosphate. 2 parts of ammonium chlorate and 1 part of ammonium sulphate and about 40 parts of water. Lumber impregnated with fire-retardant chemicals is termed fireproof wood. The industry had its beginning in the United States in 1895. The principal market for fireproof wood has been in New Tork city. Its building code prohibits the use of wood for floors and interior trim for buildings in excess of 150 ft. in height unless fireproofed in accordance with rules prescribed by the superintendent. The treatment of the wood is commonly done by impregnating it with fire-retardant chemicals in closed cylinders under artificial pressure. *(See* TIMBER PRESERVATION.) (C. T. B.)

FIRE PROTECTION. Every fire involves a permanent and absolute loss of capital, but the loss is usually so well distributed by the existing system of insurance that its incidence is not often seriously felt. Fire losses, in reality, are borne by the community, insurance offices being merely the medium by which the loss is distributed. There are individual fires in property every day, the sum total of which adds up each year to an enormous wastage. The imagination is moved more, however, by the occasional fire in which there is great loss of life or by the conflagration which sweeps out hundreds of buildings in a city.

CONFLAGRATIONS

There is no universally accepted definition of a conflagration. Some authorities list as conflagrations all fires causing more than a specified amount of loss. irrespective of the extent of spread or the number of buildings involved. Perhaps the best practice is to apply the term only to fires extending over a considerable area and destroying numbers of buildings. A large fire in a group of buildings such as those belonging to a single industrial plant is not considered a conflagration even though the area and values involved map be considerable. Neither is a fire in a closely exposed group of mercantile or warehouse properties classified as a conflagration unless the fire crosses natural or prepared exposure barriers, such as streets and fire walls.

For certain fires the term "group fire" is more closely descriptive. These include fires within the limits of an industrial plant property even if several buildings are involved, and fires in a group of mercantile buildings, particularly within a single city block. In both cases, buildings may be so close together that a fire may spread from some of the buildings to adjoining ones, but it is unlikely to spread outside the plant area, or beyond the block or group of mercantile buildings because of fire wall barriers, streets or other open spaces.

The conditions described as "fire storms" in cities attacked with incendiaries in World War II were conflagrations in the sense of fires burning over large areas, but they differed from peacetime conflagrations in certain respects and were also different from the conflagrations which resulted from the incendiary attacks on most of the Japanese cities.

The fundamental circumstances of a fire storm occur in any fire: a column of burning gases and hot air rises over the fire and air is drawn in at the sides. This may be observed at many peacetime fires; for example, where a large oil tank is burning. In such cases there is a strong air movement in toward the centre of the fire. Natural wind tends only to incline the column of rising and burning vapours.

In a fire storm, destruction is usually complete within the area. In a conflagration, some buildings escape because of irregular convection currents, fire barriers or fire-fighting efforts.

Peacetime Conflagrations. — Peacetime conflagrations have been of four general types:

(1) Fires starting in congested sections which spread in one or more directions before effective resistance is organized to bring them under control. These fires usually spread first to near-by properties, cross streets because of radiated heat, and spread chiefly in the direction in which the wind is blowing. Failure to control such fires is due almost entirely to lack of sufficient heavy stream devices on the part of the fire department and lack of protection against fire spreading between buildings. Buildings equipped with automatic sprinklers, adequately supplied by mater, have been notably successful barriers to the spread of such fires.

(2) Fires occurring in primarily residential sections which spread beyond control because of closely built combustible construction and wooden shingle roofs. Such conflagrations are probable where fire protection forces are weak and water supplies are inadequate.

(3) Conflagrations resulting from extensive forest and brush fires entering a city over a wide frontage at a point where the water distribution system is weak and limited fire-fighting resources are overtaxed.

(4) Conflagrations caused by explosions with resulting fire over a wide area.

Wartime Conflagrations. — In World War II, great fire destruction was visited on the cities of Germany and Japan. British cities suffered severe fires in the early days of the war, but few were conflagrations in the strict definition of the word. German cities. for the most part, were so built that conflagrations in the technical sense were not possible, though the magnitude of destruction by fire far exceeded that of most conflagrations. Attacks with incendiaries, principally by the royal air forces, started thousands of fires, but they burned in individual buildings with little spread from building to building.

On the basis of incomplete assessments, at least 54 of the largest cities in Germany had their central zones destroyed, destruction varying from 10% to 70% in individual cities with a median of 40%, principally caused by fire. In Hamburg, Kassel, Darmstadt, Stuttgart, and possibly Dresden and a few other cities, fires of conflagration proportions occurred with great loss of life. These resulted from the merging of thousands of individual fires.

The U.S army air forces had practically destroyed 65 Japanese cities before the atomic bombs were dropped. Many of these fires were true conflagrations as the cities were predominantly of low wood-frame construction. Fire storms also occurred in a number of cases where incendiaries alone were used, and at Hiroshima as a result of the mass fire started by the atomic bomb. As in Germany, the centres of the Japanese cities were destroyed by fire, total destruction varying from 12% to 96% in individual cities, with a median of 50%, wholly the result of fires.

FIRE PREVENTION AND PROTECTION

Building Construction and Arrangement. — Buildings constructed of fire-resistive materials and effectively divided to avoid spread of fire are essential to adequate fire protection. The danger of fire either outside or inside a building must be considered in relation to the occupation involved, type of construction, the floor area covered and the height of buildings. In the case of large industrial structures used for hazardous manufacturing nork or containing combustible stocks, constructional details are naturally of even greater significance than they are in private houses or other buildings used for nonhazardous purposes. The fire-resistive qualities of walls, roofs, floors and steel girders then require consideration, while the number and nature of floor openings likely to aid the spread of a fire (hoists, shafts, stairways) become factors of great importance.

The study of fire prevention leads naturally from a consideration of the building itself to a survey of its supply of light, heat and power and an investigation into the use to which the building is put.

All methods of obtaining light, heat and power involve obvious dangers of fire, but special mention may be made of electricity, which, though apparently the safest source, presents perils of its own and causes many fires. Short circuits, leaks and contacts are a constant danger, unless the installation is carefully made and periodically inspected and overhauled; and by a strict observance of established rules the risks are reduced to a minimum.

The use to which a building is put is a factor which introduces a variety of potential causes of fire, and much work is done by scientists and engineers in combating the hazards inherent in particular industrial processes. Examples of such hazards are: friction in machinery, flammable vapours and dust. liquid and powdered fuels, paint spraying, static electricity and the propensity of certain products to ignite spontaneously.

Every material which will burn gives off heat, and the rate at which it develops heat is an important factor in deciding on the particular measures for fire prevention and protection. The contents of an ordinary living room in a home may be made up of ordinary combustibles which would give off an estimated 40.000 B.T.U. per square foot. In such occupancies, and a great many others, the principal combustible material is wood or similar substances. The calorific value for wood can be taken on the average at 80.000 B.T.U. per pound. By contrast, the contents of an ordinary warehouse would give off heat of the order of 240.000 B.T.U. per square foot. The amount of heat generated for materials in some storage areas might be ten times that figure or more. This factor is known as "fire loading" and must be taken into consideration in the design of buildings as well as other loads which are imposed on the structure.

It must be obvious that if a material is combustible and is all stored in one place. total loss in a fire can result. The most important fire prevention measure is to store valuable material in units no larger than one can afford to lose in a fire at one time. This can be done by providing spaces between piles of goods so that fire in one pile cannot spread to the next; or by storing parts of the supply of goods in different buildings or at completely different locations. Areas of individual buildings should be kept to a reasonable maximum to accomplish this same objective and even with elaborate measures for fire protection, such as fire brigades, automatic sprinklers and ample water supplies, it is not prudent to concentrate values unnecessarily in combustible materials or buildings.

Fire Exits. — The protection of life from fire is quite as important as the saving of property. Certain building acts provide for owner maintenance of means of escape in case of fire. Such regulations apply more particularly in connection with public buildings, which are usually treated under municipal building bylaws or under acts applying to industry such as the Factory and Workshop act in Britain. Each individual tenant or occupier of a building has, however, a duty to perform in making provision for the escape of those employed by him or under his care.

Fire departments or brigades in large towns are usually provided with fire-escape ladders, but these have much more limited use than is popularly supposed. Only a relatively few people can be taken out of a burning building over fire department ladders. Since a fire is likely to fill a single stairway with smoke or flames, it is axiomatic that at least two ways out should be provided from all areas.

In the United States, the matter of safe exits from buildings came under continuous study, beginning in 1911, by the National Fire Protection association. The problem of deciding what meas-

ures are required in individual buildings becomes very complicated, depending on the occupancy and the arrangement of the building. One factor is the rapidity mith which fire may be expected to develop and spread in a particular building; another is the travel distance to a safe place. The N.F.P.A. embodied the results of its work in a document issued on an advisory basis, The *Building Exits* Code, revised periodically.

The ordinary fire escape, a relatively flimsy, narrow and badly arranged outside stair reached through windows, is frowned upon. Rope escapes, chutes and ladders are also considered vastly inferior to proper stairs or ramps. The arrangement of stairs to be used in an emergency is particularly important to prevent jamming in panics. Stairways, corridors and other means of exit can be made safe if proper attention is given to the details of moving people along such exit ways without introducing the likelihood that they will stumble or be jammed.

FIRE EXTINCTION

Important to fire suppression is the early discovery of the outbreak and an immediate application of the means of putting it out. There are automatic appliances for the purpose but, in many cases, manual appliances must be used. A pail of water is the most primitive fire extinguisher known and is valuable if available during the first few minutes. The popular stirrup pump, familiar to millions of British wartime civil defense workers, is an effective appliance. In the home, a large and substantial metal cover is excellent for confining a fire when a pan of cooking fat takes fire on the stove in the kitchen.

Plans for dealing with fires should be made in detail beforehand. Even with primitive fire-fighting equipment many small fires can be readily extinguished, but persons must have had some training and experience in the use of fire-fighting tools. The best guarantee of efficient first measures against fire is widespread training in fire extinguishment.

Fire Extinguishing Appliances.—So-called chemical extinguishers are effective in the early stages of a fire. There are many satisfactory types and their cost is not excessive. The successful use of extinguishers depends on their accessibility. They must receive periodic attention, some kinds requiring recharging annually.

The principal chemical extinguishers are water-solution types. A chemical reaction. if any, is provided principally to expel the water solution; it is the water which cools the burning material and extinguishes the fire.

Some extinguishers, however. work on other principles than cooling. The foam type spreads a layer of tough foam over the burning material and extinguishes the fire by eliminating its contact with oxygen. Extinguishers using carbon dioxide gas or dry chemical (inert gas), and also extinguishers using various vaporizing liquids (of which carbon tetrachloride is the commonest), depend on this smothering action.

Extinguishers, such as the carbon dioxide, dry chemical and vaporizing liquid types, produce an inert stream which does not conduct electricity and so may be used on electrical equipment mith reasonable safety. When extinguishers are subject to freezing temperatures, they should be kept in heated cabinets, or in some types water solutions may be replaced with antifreeze solutions to which, for example, calcium chloride has been added. Carbon dioxide, dry chemical and vaporizing liquid types will not freeze at ordinary temperature ranges.

The principal extinguisher required in a home is one of the water-solution types because these are most effective on the ordinary combustibles, wood, paper and the like. In industry, there are many situations requiring specialized types of extinguishers. Most of the devices used, other than water, are designed primarily for manual or small-scale use. They can be used in some cases to deal with fairly large fires under controlled conditions such as can be provided at a specific location.

In buying fire extinguishers and appliances, it is alnays well to get experienced advice to avoid acquiring a type with too limited extinguishing capacity, or a type which presents toxic or other dangerous effects in the hands of an unskilled operator.

Automatic Fire Alarms.—There is a great variety of useful automatic fire-alarm devices; the simplest types ring an alarm gong fixed outside the building or convey a danger signal to a fire station.

The alarms are brought into action whenever the temperature in the room is raised to a point well above what may be regarded as the highest natural temperature to be expected or, in another variety, when the temperature increases at a dangerously rapid rate. The actuating apparatus is a thermostat of the "fixed temperature" or the "rate-of-rise" type. The thermostats are placed in parts of the rooms, such as ceilings, where they are best affected by the heat of a fire. The signal is transmitted, in simple types. to a point where a bell may be set ringing or where the position of the fire may be shown on an indicator board, or both.

In the most comprehensive automatic fire-alarm systems, signals are sent to a central station operated by a company which specializes in this work. There has been a long history of poor performance of fire-alarm systems when individual property owners depend on their own day to day interest in keeping the system operative. Where fire-alarm service is purchased on an annual basis from a company which makes the giving of such service its primary business, the performance of automatic fire alarms has been very good. The central station services include not only receiving fire alarms but furnishing a central point to which watchmen must report as they make their rounds, receiving signals when water flows in an automatic sprinkler system or when a valve in water-supply piping provided for fire purposes is opened or closed, and providing a variety of other protective services.

Automatic Sprinkler Installations.—The most effective system for automatic fire alarm and extinction is the sprinkler installation, various details of which were first developed both in Great Britain and in the United States about 1880. Sprinkler installations mere successfully applied to almost every kind of building. They averted much destruction of property and considerably reduced the cost of fire insurance in buildings so protected. Insurance companies grant substantial premium rebates for properly installed and maintained systems.

The protected building is provided with a system of pipes containing water under pressure and fixed near the ceiling of every room. Into this piping sprinkler heads or orifices are inserted at such intervals that every part of the area will be commanded and drenched. The sprinkler heads are constructed to open at a temperature of 155° F. (68° C.) and discharge water directly on the fire. While heads designed to operate at the temperature mentioned are the usual ones, the systems can be arranged to delay and not operate until higher temperatures are reached. It is always possible to greatly accelerate the discharge of water when this is desirable through installing the systems in sections, each section having heads which are normally open. Through a system similar to that used in "rate-of-rise" fire alarm devices, water may be turned into the system by remote control and the area promptly drenched. This is a special type of installation, but there are many situations in industry where it is useful.

In the ordinary sprinkler system there is an alarm bell fitted outside the building which operates simultaneously with the sprinkler head, thus giving the alarm locally. One purpose of this alarm is to keep water damage at a minimum. Water damage is a much less serious problem with automatic sprinklers, however, because the water applied to the fire is more effectively employed than when firemen have to apply large quantities of water with hose streams in what is a relatively inefficient operation.

The safety secured by sprinkler equipment for buildings fully justifies the expenditure. Without such systems it would be necessary to strictly limit the size of buildings or the total arnount of combustible material which may be brought together in one place.

Sprinkler equipment is most commonly used in industrial or mercantile buildings where the presence of piping on ceilings is not objectionable from the point of view of appearance. Sprinkler protection has also been provided for many historic shrines, churches, and other locations nhere the necessary piping and heads can be so located as to be practically unnoticeable.

Fire Departments (Brigades).—Organized fire brigades existed in civilized communities many centuries before the Christian era and were familiar to the citizens of the Roman empire. In England. fire preventive measures are traditionally associated with William the Conqueror's couvre-feu or curfew. but the custom of ringing a bell to order the extinguishment of fires and candles can be traced back to the days of Alfred the Great. References to organized fire fighting, which was probably not on efficient lines, are occasionally encountered in the history of the middle ages.

The establishment of fire insurance companies in Great Britain naturally brought about the question of minimizing loss by fire by preventing its spread. Because the public authorities had been diffident in this connection the offices set about establishing brigades of their own. Probably the first insurance office to possess fire engines was the Royal Exchange, which announced in

*TABLE I.—Fire Losses, United Kingdom and Ireland**
(War damage excluded)

*Published estimates of Fire Offices' Committee Fire Protection Association.

1722 that it had provided several engines with firemen and watermen and their implements for extinguishing fires. They were followed by many other offices who placed fire marks on the buildings they insured. and no doubt each particular brigade gave special attention to any premises insured by their own company. In 1833 the London fire engine establishment was formed by a combination of offices; this consisted of 76 officers and men who took upon themselves the fire protection of London. A year later the houses of parliament were destroyed by fire, and in 1861 the great fire in Tooley street occurred, with damage estimated at £2.000.000. In the following year a parliamentary committee was formed "to enquire into the existing state of legislation, and of any existing arrangements for the protection of life and property against fires in the metropolis." This inquiry showed a total inadequacy of appliances, and in 1865 the fire offices handed over to the metropolitan board of works the fire protection of London which for more than 30 years they had carried on at their own expense.

Various statutes were subsequently passed by parliament, not only in relation to London but to other towns throughout the country. by which parliament recognized as a public duty the maintenance of proper equipment to local authorities. the cost to be borne from the rates. The Metropolitan Fire Brigade Act of 1865 provided for the handing over of the fire stations, engines and property of the London fire engine establishment, together with the force of firemen, to the board of works and this formed the nucleus of the new metropolitan fire brigade. The insurance companies. being relieved from the burden of extinguishing fire, not only handed over their freehold and leasehold properties and valuable appliances worth many thousands of pounds, but consented to an arrangement whereby they became liable to contribute to the upkeep of the brigade.

Brigades in Great Britain apart from London exhibited considerable variety in conditions and regulations until the act of 1938 imposed a recognized standard of efficiency. Prior to 1938 there was no duty at common law for local authorities to maintain fire brigades, and the statutory authority invoked for the organization of a brigade—the Town Police Clauses act in 1847, the Burgh Police (Scotland) act in 1892 and other local government statutes—was invariably permissive only. The act of 1938 substituted compulsion for permission, repealed the enactments under which the existing brigades had been constituted and established government control. Thus, at a single stroke, the multitude of independent brigades, which had previously had little opportunity for co-ordinating their activities and experience, became in effect welded into a single body. The eventual result was an all-round improvement in fire protection.

Power of entry was safeguarded by a section of the act which authorized any member of a brigade to enter or break into any premises where a fire had or was reasonably supposed to have started. Consent of the owner or occupier was not required and obstruction or interference by any person became a punishable offense.

The senior officer present was empowered with sole charge and control of all operations and the police were given authority to divert the traffic at their discretion.

During World War II, by the act of 1941, the traditional responsibility of operating a fire brigade was taken away from local authorities and vested in the national fire service. By the Fire Services Act of 1947, the fire brigades were returned to local authorities but not, in all cases, to the same local authorities which operated them in the prewar period. Approximately 1,400 local authority fire brigades had been consolidated into one organization under home office control as a wartime measure. The 1947 act transferred these back to only 140 authorities.

The 1947 act left the determination of the local authorities to be handled on a basis of consultation between the home office and local authorities. The latter could suggest schemes for reorganization, but home office approval assured that the reorganized fire brigades be large enough so that they did not revert to the prewar position, when the average fire brigade was a small, weak organization.

The weakness of the wartime organization was perhaps principally that of a top-heavy administrative setup. For operating convenience, the fire service was broken up into approximately 30 fire forces: each of which constituted a substantial fire brigade organization.

The postwar schemes approved by the home office generally resulted in the formation of substantial fire forces also. One of the largest postwar units was, of course, that of the county of London brigade, serving an area of 117 sq.mi.

The terms of the Fire Services Act of 1947 established county boroughs, county councils and joint authorities as fire authorities in England and Wales. Scotland was divided into ten joint areas, plus Glasgow. The act did not alter responsibility for fire prevention, restricting the spread of fire, or means of escape in case of fire.

Under other provisions of the act of 1947, the home office established a fire service department and a Fire Service college near Dorking, Surrey. for advanced training of members of fire brigades. The fire service department operates an inspectorate as a means of checking on conditions in the various brigades but the administration is in the hands of the local authorities designated as fire authorities. Another important provision of the 1947 act was the system of grants by the secretary of state to local fire authorities. The act limited the grant to 25% of expenditure, with payment being conditional on the authority's fulfilling its obligations.

A number of associations were established in the United Kingdom for the furtherance of the science of fire fighting. the welfare of fire brigade personnel and kindred objects, including the Chief Fire Officers' association, Fire Brigades union, Fire Offices' committee, the Institution of Fire Engineers, Junior Fire Officers' association, National Association of Fire Officers, National Fire Service Association of Great Britain, Industrial Fire Protection Association of Great Britain, and the Society for the Protection of Life from Fire.

United States and Canada.—In the United States and Canada, and in most of the rest of the world, the operation of fire brigades is traditionally a municipal function. Usually when a fire brigade is organized it comes under the direction of a particular local authority.

From early times, when public authorities did not act to provide some sort of fire brigade, citizens organized volunteer fire departments. These were alternately encouraged and discouraged by the authorities. The Roman emperor Trajan is believed to have disapproved the proposal of one of his provincial governors to form a company of firemen for the city of Nicomedia because such bodies could be expected to engage in revolutionary activities no matter how noble the public purpose for which they were originally founded. It was perhaps not strange that the pure volunteer form of fire department became established in the British colonies in America where local government machinery was rudimentary.

The pure volunteer department is basically a volunteer association of citizens, the members of which not only are not paid for their fire-fighting services but may be expected to contribute to the general support of the brigade. This form of organization was recognized by the statutes of many of the states in the United States and became a common form of fire department organization even in cities as large as Reading and Harrisburg, Pennsylvania. The states in which this form of organization was commonest at mid-20th century were Pennsylvania, New Jersey, Delaware and Maryland, but volunteer departments were to be found in almost all the states of the U.S. and in Canada.

The history of these organizations in the United States and elsewhere is that they are sooner or later recognized by local ordinances and state statutes and they frequently become formally incorporated with power to own property and otherwise act as any incorporated body. Eventually, they become responsible to local governmental authorities. Usually the local authority is allowed

TABLE 11.—Fire Losses in the United States*
(Fires in buildings only)

Year	Property Loss	Year	Property Loss
1943	$395,600,000	1949	$672,500,000
1944	450,000,000	1950	699,600,000

1947	703,000,000	1953	889,120,000
1948	714,800,000	1954	875,450,000

*Published estimates of National Fire Protection Association.

to audit the financial operations of the volunteer fire department organization or corporation in return for money collected by taxes which may be used to buy fire apparatus. A common pattern is for the fire company or department to have a large number of dues-paying members, relatively inactive as far as the performance of fire-fighting duties are concerned. In many cities, the fire station becomes a club house for the members, providing a bar, restaurant, and recreation facilities for a neighbourhood area.

The traditional fire department unit in the United States and Canada is the individual fire company in its most rudimentary form, consisting of one piece of fire apparatus, usually a pumping engine with a few short ladders, and enough men to operate it. Even in towns which may have more than one piece of fire apparatus. each piece of equipment has organized around it a "fire company," which works for the most part on its own. Except in large cities it is rare to find an officer directing more than one piece of fire apparatus at a fire.

In larger cities a number of fire companies occasionally have to work together. U.S. and Canadian practice is to group 8 to 15 individual fire companies into a battalion. A battalion of ten companies might, for example, consist of six pumping engines, two ladder trucks and two companies performing ancillary services such as salvaging operations, providing lighting equipment, rescue or other special equipment. The battalion force of a North American fire department is essentially the same grouping of apparatus and men found in a fire company in the practice of British and continental fire brigades. Large departments have divisions made necessary by the geography of the protected area, and some have marine and forest divisions.

Except in cities where all or part of the firemen are on call, fire companies are manned 24 hours a day. This requires a system of shifts, details of which differ. In the U.S. and Canada, work weeks 56 to 72 hours are representative. All members of the department, including battalion and division commanders, work on a shift basis. Headquarters staff officers are the exception to this rule. While always on call, they work usual office hours.

The duties of the fire headquarters staff indicate some of the functions performed by a large department. In small departments the chief officer would be the only one who does not work on a shift basis. He is the "staff," as distinguished from company officers or battalion or divisional commanders on shifts.

In a large fire staff, for example, the chief fire officer has reporting directly to him a first assistant chief as executive officer of the department, a public relations officer, an officer in charge of investigations and fire reports, a finance and budget officer and a research officer.

The first assistant chief has reporting to him a personnel officer, a training officer, a staff chief officer for each division of the force which works on a shift basis, and another chief officer to be in charge of the service bureaus of the headquarters staff.

The service bureaus of the staff include the fire prevention bureau, which handles explosives and flammables and matters of building protection, a communications bureau, a water bureau responsible for regular and emergency water supplies, a maintenance bureau with facilities for caring for apparatus and buildings and a bureau for procuring, storing and issuing supplies.

The transition from the small local fire company to larger and more effective fire forces is a process of integration. For example, in Nassau county, New York, there were still a great many small fire departments in the 1950s, many of them of the volunteer type. These were being gradually integrated through the operation of a county fire commission. Usually the first step in integration is to provide a message centre at which calls for assistance are received and whose orders on dispatching are recognized by the respective fire companies in the area. Another is the administration of a program for the training of members of fire companies. A third is the operation of a fire marshal's branch to investigate fires.

The process of integration became notable in the United States and Canada. A number of strong, well-organized county fire departments arose, good examples of which are the county fire departments of Los Angeles and Kern counties in California. Integration through the state and provincial governments also proceeded. In certain states (for example, Massachusetts and Ohio) the state established a civil service system for the recruitment, admission and promotion of firemen in fire departments. In nearly all the states and the Canadian provinces. the state fire marshals were originally set up to provide means of investigating incendiary fires, but they were also given responsibility for various other functions, such as educating the public in fire safety measures

TABLE 111.—Fire Losses in Canada*
(Figures exclude forest and federal government losses)

Year	property Loss	Year	Property Loss
1943	$31,464,710	1949	$65,159,044
1944	40,562,478	1950	81,525,298
1945	41,903,020	1951	76,919,357
1946	49,413,363	1952	80,902,205
1947	57,050,461	1953	84,270,896
1948	67,144,473		

*Reports of Dominion Dept. of Insurance.

and in the supervision of fire safety conditions in schools and public buildings. Later, most of the states set up state-wide programs for the training of members of municipal fire departments. In numerous states, notably New York, Oregon and California, legislation has been passed empowering the governors to place all the fire departments under state control in emergency.

Australia and New Zealand.—The advantages of administration of fire brigades over a substantial area is well illustrated in Australia. In most of the states there is a state fire brigades' board which has certain advisory powers with respect to local fire brigades. There are also state-wide fire departments, operated by the state government rather than the municipalities, in New South Wales, South Australia and Western Australia. In Victoria there are two fire brigades' boards, one serving the metropolitan area of Melbourne and the other a country fire authority supervising fire brigades in the rest of the state. As an example, in South Australia there is a state-wide fire department and a fire staff with headquarters in Adelaide.

In New Zealand, the Fire Services Act of 1949 set up a scheme of supervising fire brigades similar to the British arrangement. This was brought about by a disastrous fire in a department store at Christchurch on Nov. 18, 1947, in which 41 persons lost their lives.

Water Supply at Fires.—The supply of water for extinguishing fires has, of course, a large bearing on the efficiency of the fire department or brigade. Pipes should be laid in such a manner as to secure the best practicable supply of water in case of fire. Where there is no mains supply, firemen necessarily look for natural supplies of the means of extinguishment. Water supplies in rural areas are frequently inadequate and fire damage to farm produce and property is heavy in consequence.

FIRE RESEARCH

United States.—Underwriters' Laboratories, Inc., in Chicago. Ill., was established in 1894 by the capital stock fire insurance companies of the United States, members of the National Board of Fire Undernriters. In 19jo, Underwriters' Laboratories of Canada was established by the stock fire insurance companies of the dominion.

There are a number of other laboratories, each making substantial contributions to fire research. The most important in the United States, other than Undenvriters' Laboratories. Inc., is the Factory Mutual laboratories. established and operated by the Associated Factory Mutual Fire Insurance companies, with a large testing station at Nornood. Massachusetts. Mention also should be made of the fire testing station of the Swedish Government Testing institute. In addition to these laboratories. with substantial test facilities, much fire research is conducted at numerous laboratories in schools and colleges throughout the world.

U.S. and British standard methods of making fire tests of building construction and materials are similar. The U.S. technique is described in *Standard Methods of Fire Tests of Building Construction and Materials,* prepared by a joint committee of the National Fire Protection association, the American Society for Testing Materials. the National Bureau of Standards, the Associated Factory Mutual Fire Insurance companies, the National Board of Fire Underwriters. and Underwriters' Laboratories, Inc., operating under procedure of the American Standards association.

One important development of fire research activities in the United States is the labelling of fire protection equipment and the reporting on hazardous devices by Underwriters' Laboratories. Inc. It has long been a recognized principle of fire protection nork that a degree of reliability should be required in connection with devices for protection against fire that goes beyond what would be provided in devices for other purposes. One method of accomplishing this has been the development of standards for extinguishers, sprinklers. fire pumps, fire doors, and other items of fire protection equipment. Standards as such are not self-policing. A method proposed to insure that purchasers get equipment which meets a specific standard is to ask for a certification from the manufacturer to that effect. This arrangement has been tried out in various places and is a practice in some European countries and in other parts of the world. Even such a certificate falls short of an ideal system of policing the devices.

It was this need for a more dependable system of policing that prompted the fire insurance companies, through Underwriters' Laboratories in the United States, to begin the practice of checking to see that certain standards were met with respect to fire-protective equipment. The Fire Offices' committee, in the United Kingdom and for its foreign activities, has a similar but less comprehensive procedure.

By the 1950s U.S. practice for many devices, labelled by Underwriters' Laboratories, was approximately as follows: a manufacturer submitted a product to conform with some general standard of fire protection service. (It may! for example, have been an extinguisher which conformed to the standards of the National Fire Protection association for first aid fire appliances.) Underwriters' Laboratories also prepared detailed standards for the construction of the commoner types of devices on which it was asked to pass. The pilot model of the item passed Underwriters' Laboratories' initial review. and a procedure was set up whereby subsequent production of the item was checked under terms convenient both to Underwriters' Laboratories and the manufacturer. This usually embodied an arrangement for the testing of the manufacturer's product in the factory or making appropriate checks at that point. Some items were further checked by purchasing them in the open market.

In return for subjecting their product to Underwriters' Laboratories' examination and supervision, the manufacturer was allowed to place on his device a label which identified the product as having met certain specified standards. This, of course, was of great practical importance to insurance men who from time to time were called upon to recognize various items of fire protection equipment as a basis for credits or rebates in insurance charges. The label of Underwriters' Laboratories, however, had an importance far beyond its use in insurance rating as it was widely used by property owners and by federal, state: and local authorities, particularly municipal fire and building departments, as a basis for identification and acceptance of the devices.

Great Britain.— Systematic studies of fire resistance were begun in England toward the end of the 19th century by the British Fire Prevention committee, the results of which were published in a series of "red books" well known in the fire world. About 260 of these reports were issued. the last one appearing in 1921. One of the results of this work was recognition of the need for a standard procedure in tests of fire resistance such as is described in the *British Standard Definitions for Fire Resistance, Incombustibility and Non-Inflammability of Building Materials and Structures,* published by the British Standards institution. In order to provide facilities for such tests. the Fire Offices' committee built and equipped a fire testing station at Boreham Wood, Elstree, opened in 1935.

At about the same time the Riverdale committee, reviewing fire brigade services in England and Wales. recommended attention to fire research. A fire-fighting research section was established at the building research station of the department of scientific and industrial research. The formation of this section practically coincided with the outbreak of World War II. At that time, there was a general expectation of severe damage by high explosive bombs and the air raid precautions department of the home office had set up a research and experiments branch. This became subsequently the research and experiments department of the ministry of home security. When it became evident that in many raids much more damage was caused by fire than by high explosive bombs, the expansion of the fire research work had to be considered. The ministry of home security carried on with the work during the war, after which responsibility was resumed by the department of scientific and industrial research. During the war, a great variety of agencies contributed to various phases of the special fire studies of the war.

At the war's close, the Fire Offices' committee proposed to extend its fire research work and it was decided to establish the Joint Fire Research organization, the cost of which would be shared equally by the Fire Offices' committee and the department of scientific and industrial research. Accordingly, a fire research board was appointed in Nov. 1946. The Fire Offices' committee placed the fire testing station at the disposal of the Joint Fire Research organization as a part of their contribution to the capital cost.

The Elstree fire testing station embodies some of the most modern furnaces for testing the structural components of buildings, a notable piece of equipment being a furnace in which building columns can be subjected to loading and fire temperatures at the same time.

Special Organizations.— Thereare a number of organizations, professional and technical, in the fire field within the United States and Canada which have kept up a steady pressure on property owners and public officials to bring natural fire hazards of the continent under control. The largest of these is the National Fire Protection association. The fire department organizations include the International Association of Fire Chiefs and the International Association of Fire Fighters (affiliated with the American Federation of Labor). National insurance organizations like the National Board of Fire Underwriters and fire insurance rating associations and organizations in each of the states and provinces are active in promoting fire prevention work.

In 1922 an important annual educational program of fire prevention education was introduced and came to be widely observed in both the United States and Canada — Fire Prevention week, held during the week each year in which the anniversary of the great Chicago fire of 1871 occurred (Oct. 8–10). The Chamber of Commerce of the United States awards prizes annually to local chambers for fire prevention activities. A home fire prevention campaign has been carried on since 1950 jointly by the National Fire Protection association and the Advertising council. "Sparky," the fire house Dalmatian, features this campaign of public education.

The complexity and technical character of fire prevention and fire protection work is illustrated by the existence of not only the technical organizations, like the Fire Offices' Committee Fire Protection association in Britain and the National Fire Protection association in the United States and Canada, but by two professional organizations. The Institution of Fire Engineers is a professional society, with many members not only in the United Kingdom but throughout the British Commonwealth. Membership in a professional grade in that organization is obtained through passing written examinations. and advancement to member is by vote of a board of senior fire brigade officers.

In the United States and Canada, interest in the professional aspects of fire protection work is not limited to members of fire departments or brigades but includes persons in the insurance business and individuals in the management of industrial enterprises who have decisions to make with respect to fire prevention and protection measures. In 1950, the Society of Fire Protection Engineers was organized as a section of the National Fire Protection association.

FIRESHIP, a vessel laden with combustibles, floated down on an enemy's ships to set them on fire. Fireships were used in antiquity and in the middle ages. The highly successful employment of one by the defenders of Antwerp when besieged by the prince of Parma in 1585 brought them into prominent notice, and they were used to drive the Spanish Armada from its anchorage at Calais roads in 1588. In 1809 fireships designed by Lord Cochrane were used against French ships anchored in the Aix roads. In the Greek War for Independence fireships employed against Turkish crews were largely responsible for giving the Greek insurgents command of the sea. In April 1862, the Confederates sent fireships against the Union fleet and mortar-boats below Fort Jackson in the Mississippi river on five successive nights, but they were towed clear and caused no damage. On April 24, however, while Farragut's fleet was passing the Confederate forts during darkness his flagship the "Hartford" was set on fire by a fireship. The excellent discipline of the officers and men of the "Hartford" enabled them to put out the fire while using their guns against the Confederates to good effect.

Fireships were made by building a fire chamber between the decks from the forecastle to a bulkhead constructed abaft the mainmast. This space was filled with resin, pitch. tallow and tar. together with gunpowder in iron vessels. The gunpowder and combustibles were connected by trains of powder and by bundles of brushwood called bavins In using a fireship, a body of picked men steered her down on the enemy and when close enough they set her alight and escaped in a boat which was towed astern. As the service nas peculiarly dangerous a reward of £100 or a gold chain with a medal (to be worn as a mark of honour) was granted in the British navy to the successful captain of a fireship. A rank of *capitaine de brûlot,* next to the full captain, existed in the French navy of Louis XIV. (J. B. Hn.)

FIRESTONE, HARVEY SAMUEL (1868–1938), U.S. rubber manufacturer, was born at Columbiana, O., Dec. 20, 1868. After selling buggies in Detroit and solid-rubber carriage tires in Chicago, he went to Akron, O., (1900) and with a $10,000 investment formed the Firestone Tire and Rubber company. He pioneered the manufacture of pneumatic tires for the Ford model-T automobile, nonskid tire treads, low-pressure balloon tires, motor truck and farm tractor tires. He early supported the ship-by-truck movement which led to long-distance trucking. To break a monopolistic grip on rubber prices held by growers in southeast Asia, he started plantations in Liberia (1926).

When Firestone died Feb. 7, 1538, at Miami Beach, Fla., his company was a leading corporation, already experimenting with synthetic rubber and producing plastics.

See Alired Lief, *Harvey Firestone: Free Man of Enterprise* (1951) and *The Firestone Story* (1951). (A. Lf.)

FIRE THORN: see Pyracantha.

FIRE WALKING, a religious ceremony common to many peoples, and widespread in all ages. The details of the ritual and its objects vary in different lands, but the essential feature of the rite, priests, fakirs and devotees passing barefoot over heated stones or smouldering ashes, is always the same. Fire walking was usually associated with the spring festivals and was believed to ensure a bountiful harvest. Such was the Chinese vernal festival of fire.

In the time of Kublai Khan the Taoist Buddhists held great festivals to the "High Emperor. of the Sombre Heavens" and walked barefoot through a great fire, preceded by their priests bearing images of their gods in their arms. Though they were severely burned, these devotees held that they would pass unscathed if they had faith.

J. G. Frazer (*Golden Bough,* vol. iii, p. 307) described the ceremony in the Chinese province of Fukien. The chief performers were labourers who had to fast for three days and observe chastity for a week. During that time they were taught in the temple how they were to perform their task. On the eve of the festival a huge brazier of charcoal, often 20 ft. wide, was prepared in front of the temple of the great god. At sunrise the next morning the brazier was lighted. A Taoist priest threw a mixture of salt and rice into the flames. The two exorcists, barefooted and followed by two peasants, traversed the fire again and again until it was somewhat beaten down. The trained performers then passed through with the image of the god.

Frazer quotes Indian fire walks, notably that of the Dosadhs, a low Indian caste in Behar and Chota Nagpur. On the fifth, tenth, and full moon days of three months in the year, the priest walked over a narrow trench filled with smouldering wood ashes.

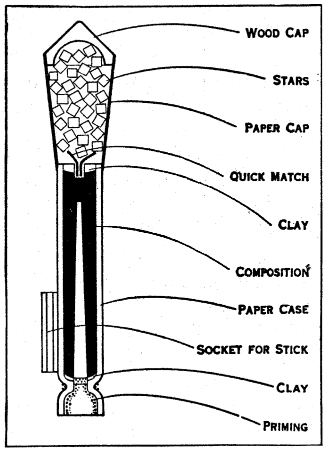
The interesting part of fire walking is the alleged immunity of the performers from burns. On this point authorities and eyewitnesses differ greatly.

FIREWEED, any of several weedy plants that spring up profusely after a forest fire, especially the great willow-herb (*Epilobium angustifolium,* family Onagraceae) which occurs throughout North America and in northern Europe and Asia. Less common are the American horseweed (*Conyza canadensis*), which is widely naturalized in Eurasia. and *Erechtites* hieracijoliu (both belonging to the family Compositae) also introduced into the Old World. All but the great willow-herb are annuals and hence difficult to eradicate on a scale sufficient to be effective, unless they are chemically destroyed. The most profuse, because of its windblown downy-tufted seeds. is the great willow-herb (*q.v.*). Spraying with 2,4-D in bright sun will kill it. (S. Tr.)

FIREWORKS. The history of pyrotechny may be said to have begun when a prehistoric firemaker first mixed saltpetre from his cooking with charcoal from his fire, to use as tinder. In subsequent ages other ingredients nere added as pyrotechnic mixtures developed. and eventually. when the principle of the gun was evolved by Berthold Schwartz in the 13th century, the pyrotechnic mixture most suitable for his needs was named gunpowder.

About the date of the introduction of artillery the military fireworker came into existence, whose business was to provide pyrotechnic engines of war, to which duty was subsequently added the provision of spectacular firenorks in celebration of victory or peace During the 17th and subsequent centuries most occasions of national rejoicing were celebrated by displays of fireworks; these were generally provided by the military fireworkers.

In earlier displays a limited number of pyrotechnic effects were eked out with others of a scenic or theatrical nature and the use of merely inflammable substances, in the form of torches and flares, which cannot, strictly speaking, be classed as pyrotechnics. It was not until the early part of the 18th century that displays of any considerable pyrotechnic merit were produced,



CROSS SECTION OF A SKYROCKET
The solid black portion represents the composition, which when ignited, produces a recoil that starts the rocket on its spectacular upward flight

During the 17th century there were two schools of pyrotechnic thought, that of northern Europe, with Nuremberg as its centre and Clarmer as its leader, and the Italian school. The former, although producing probably better results from a purely pyrotechnic point of view, could not vie with the southern school in artistic elaboration and the scenic accessories introduced. In the earlier part of the 18th century the brothers Ruggieri, Bolognese firework artists, attracted no doubt by the lavish expenditure of Louis XV., visited Paris and produced displays at Versailles and elsewhere on a hitherto unprecedented scale. One of the Ruggieris, in conjunction with one Santi, carried out the display in London which celebrated the Peace of Aix-la-Chapelle in 1749, an event which appears to have been celebrated in most of the capitals of western Europe. During the remainder of the century firework displays increased both in number and scale; in addition to official exhibitions celebrating national events, the popular places of resort, the tea gardens and bowling greens began to add fireworks to their list of attractions. Those in the London resorts, Vauxhall, Ranelagh and Marylebone gardens, are still remembered.

As yet no real advance had been made in pyrotechnic mixtures; no colour had been introduced, the art still relied on saltpetre, which had been its foundation. (The importance attached to this salt by early writers, such as Biringoccio, is reflected in the long and elaborate dissertation they give on its preparation and refinement.) Although some pyrotechnists claimed to produce various tints, there is no doubt De Frezier, in his two books published in 1707 and 1747, came nearest to the truth in describing the flame produced by his compositions as "reddish," "greenish," etc.

In the first quarter of the 19th century, however, the era of modern pyrotechny began with the introduction into the art of potassium chlorate, which had been discovered by Berthollet in 1788. Genuine colour effects were now possible and a field of research was opened which, even yet, has not fully been explored. The subsequent introduction of the two metals, magnesium (about 186;) and aluminium (in 1894) also gave a brilliancy never before attained, and added greatly to the variety of effects produced.

The famous displays at the Crystal Palace, near London, instituted in 1865, were one of the greatest factors in the development of the modern display. Old-fashioned limitations and scenic accessories were discarded and a scale and method, both in aerial and ground fireworks, were reached which had never previously been attained, eclipsing any official effort, with the exception of the "National Peace display" in Hyde park in 1919, which was probably the greatest display produced up till that time.

Firework Compositions. — The phenomenon we know as fire is produced by the combination of certain substances, which have a tendency so to do, with oxygen in so rapid a manner as to produce intense heat. When such inflammable substances are set on fire in the ordinary way they obtain the necessary oxygen from the air. The art of the pyrotechnist is in the production of mixtures of ingredients which do not depend on atmospheric oxygen for their combustion. These mixtures are known as pyrotechnic compositions. Every pyrotechnic composition contains at least one ingredient having a supply of oxygen with which it readily parts and others which receive and combine with that oxygen and in so doing produce the effect for which the particular composition has been designed. The most used oxygen-supplying ingredients are potassium nitrate (saltpetre) and potassium chlorate, Compositions may be divided into two classes, those designed to produce force and sparks and those producing flame, either white or coloured. There are also certain compositions which are designed to produce special effects such as noise, a dense cloud of smoke for military or other purposes, or a whistling sound as that produced by picrate of potash in the familiar whistling rocket.

Force and Spark Compositions. — The basis of these compositions is a mixture of potassium nitrate, sulphur and charcoal, ground to a fairly fine powder. In some cases "mealed," or finely ground gunpowder is added to give extra fierceness when required, as for sky rockets, turning cases (used to turn wheel devices) and similar fireworks. Additional ingredients are included to produce sparks of various forms. The nitrate of lead and barium are also used sometimes in these compositions; also aluminium in an extremely finely divided dust to produce a very brilliant white fire.

Flame Compositions. — In this class are included those compositions which give colour to pyrotechny, the "stars" in rockets, shells and roman candles, the decorations on revolving and stationary devices and set pieces and the outlines in pictorial, or (as they are technically called) lancework pieces. *White Fire,* which varies in its composition according to the purpose for which it is used, generally consists of the ingredients potassium nitrate, salts of antimony, or arsenic and sulphur. With the exception of white fire and a few others of little importance, such as the portfire and blue light used at sea, flame compositions rely for their combustion and their colour on the presence of potassium chlorate, or occasionally perchlorate. *Coloured Fires.* The combustion of potassium chlorate, or perchlorate, in combination with a metal salt has the effect of turning the metal present into a gaseous state and produces a coloured flame. The following are the salts used: — Red, the nitrate, carbonate or sulphate of strontium; green, the nitrate, chlorate or carbonate of barium; yellow, oxalate or carbonate of sodium, and for blue the carbonate, sulphide or arsenite of copper in combination with calomel, mercurous chloride. It is interesting that, although copper burnt in a blowpipe flame produces a green colour, in pyrotechny copper salts are only used to produce blue, as in the presence of chlorine, which must be present with potassium chlorate, the flame is blue; this is deepened by the addition of calomel, which produces still further chlorine.

Magnesium powder is used with colour compositions where extra brilliancy is aimed at. Most colour compositions have, in addition, some burnable substance which serves to increase the mass and effect without detracting from the brightness or colour. The most commonly used are shellac, sterine, sugar of milk, pitch and paraffin. Sometimes the burnable substance serves also as an agglutinant, as shellac and spirit, starch paste, gum water, linseed oil or dextrine.

Firework Cases. — The composition of each firework is enclosed in a "case" formed of paper, pasted and rolled round a cylindrical former; they are either "dry rolled," that is, only the edge of the paper is pasted, or "wet rolled" in which case the paste covers the whole surface of the paper. Generally the case used for force and spark compositions remains intact during the burning of the firework and that enclosing a flame composition is consumed as the firework burns.

Compositions are introduced into the cases in two ways, either by "charging" (when a succession of small quantities of composition are poured in from a scoop of suitable size, each scoopful being consolidated by a number of blows delivered by a mallet on a cylindrical wooden tool exactly fitting the bore of the case, known as a "drift"), or by "filling" with a small copper funnel having a spout of suitable size to fit the case and provided with metal rod of somewhat less diameter than the inside of the spout, having a knob for the hand at the upper end. Composition is placed in the funnel, the spout inserted in the case and a rapid up and down movement of the rod alternately releases a small quantity of composition and consolidates it in the case. This method is only used with cases of small diameter.

It may be as well to mention here that these manual methods have never been superseded satisfactorily by mechanical means, although many experiments have been made. In pyrotechny, as in some other crafts, hand work maintains its superiority.

Rockets.—The rocket, which is the most elaborate in construction of any single firework, also requires the highest degree of technical skill in manufacture. The sky-rocket (its most familiar form) is driven into the air by the recoil produced from a jet of fire thrown out by its burning composition. In order to make this jet as strong as possible the case, which is wet rolled, is choked, or constricted, by pulling in with a cord near one end before drying. In addition, the composition is so charged into the case that a conical cavity is left from the choke or vent, nearly to the top of the case; by so doing, when the rocket is ignited, as large an area as possible of composition is burning at the moment when it is required to give the rocket its initial impetus. This cavity is produced by charging the rocket on a tapering spindle and using drifts of varying lengths, pierced with a hole of suitable size. Above the composition in the body of the rocket is a diaphragm of compressed clay, bored with a central hole through which the fire from the top, or "heading," of the composition is communicated to the "garniture" contained in a case, usually in the form of a truncated cone, which forms an extension of the body of the rocket and is known as the "cap." The garniture consists of "stars" of colour, or other suitable composition, either contained in short cylindrical cases, when they are known as "pinched stars" from their method of manufacture, or compressed into cylindrical form without a case, when they are known as "pumped stars." *Gerbs* and *Fountains* are charged without a central cavity, the choke generally being formed by a clay diaphragm. The compositions are similar to those of the rocket, with the addition of spark-producing ingredients. The composition for gerbs (formerly known as Chinese fire) contains iron filings; for fountains (formerly known as brilliant fire) steel filings; and for flower pots, lampblack, producing remarkable sparks, which, from their form, gave to this composition the name of spur fire. *Devices and Set Pieces* consist of frameworks of wood on which are secured firework units which are connected together by quickmatch and take the form of wheels moving in the vertical or horizontal plane; stationary, or, as they are called, fixed devices, of various geometrical forms; waterfalls; tree pieces and "lancework" pieces. The outline of a lancework piece is constructed in cane on a wood lattice framework and the design picked out in appropriate colouring with lances (small cases of colour, or "bright" composition, about the size of a cigarette); by this means almost any pictorial design can be carried out. At the Crystal Palace, London, where this type of set piece has been most highly developed, pictures have been produced over 600ft. long and 50ft. high, carried out entirely in lines of fire.

See Vannuccio Biringoccio, *Pirotechnia* (Venice, 1540 and 1553); De Frezier, *Traité des Feux d'Artifice* (1707 and 1747); Ruggieri, *Elémens de Pyrotechnie* (1801 and 1821); Chertier, *Nouvelles recherches sur les feux d'artifice* (1843 and 1854); Websky, *Lustfeuerwerkkunst* (Leipzig, 1878); Kentish, *The Pyrotechnist's Treasury* (1878); Denisse, *Traitd pratique complet des feux d'artifce* (1882); A. St. H. Brock, *Pyrotechnics, The History and Art of Pyroteclzny* (containing *a* complete bibliography) (1922). (A. St. H. B.)

FIRMAMENT, the sky, the heavens. In the Vulgate the word *firmamentum,* which means in classical Latin a strengthening or support *(firmare,* to make firm or strong) was used as the equivalent of στερέωμα (στερεόειν, to make firm or solid) in the Septuagint, which translates the Heb. *rāqīya'*. The Hebrew probably signifies literally "expanse," and is thus used of the expanse or vault of the sky, the verb from which it is derived meaning "to beat out." In Syriac the verb means "to make firm," and is the direct source of the Gr. στερέωμα and the Lat. *firmamentum*. In ancient astronomy the firmament was the eighth sphere containing the fixed stars surrounding the seven spheres of the planets.

FIRMICUS, MATERNUS JULIUS, a Latin writer, who lived in the reign of Constantine. His *De erroribus profanarum religionum,* written *c.* 346 and still extant, attacks the false objects of worship among the oriental cults and discusses a number of formulae and rites connected with the mysteries. Its declamatory tone contrasts with his eight books on astronomy (Libri viii, *Matheseos)* written *c.* 336.

The best editions of the *De Erroribus* are those by C. Bursian (Leipzig, 1856); by C. Halm, in his *Minucius Felix* (*Corp. Scr. Eccl. Lat.* ii) (Vienna, 1867); and by K. Zeigler (1907). The astronomical work was first printed at Venice in 1499, the last edition being by W. Kroll and F. Skutsch (Leipzig, 1897–1913). *See* G. Ebert, *Gesch. der chr. lat. Litt.* (1889); O. Bardenhewer, *Patrologie* (1901).

FIRMINY, a town of central France in the *département* of Loire, 8 mi. S.W. of St. Etienne by rail. Pop. (1954) 17,834. It has important coal mines known since the 14th century and extensive manufactures of iron and steel goods.

FIRST AID TO THE INJURED. First aid is defined as the immediate and temporary care given the victim of an accident or sudden illness in order to avert complications, lessen suffering and sustain the person until the services of a physician can be obtained. Proper immediate care is sometimes necessary to save life, but the knowledge of what not to do as well as what to do is vitally important. The present article on first aid procedures is a compilation of instructions recommended by the American Red Cross, the Bureau of Health Education of the American Medical association, and the Detroit Industrial First Aid Advisory committee.

General instructions that apply to all first aid activity are avoidance of excitement or panic, correction of situations that might aggravate the original injury, and protection of the accident victim from unnecessary exposure to the elements or to new hazards such as accidents occurring while speeding to a first-aid station or hospital. For example, in motor accidents, the victim should be removed from the highway, if this is possible, or guards placed about the area to warn approaching traffic. Certain common conditions such as heart attack, stroke, fainting and epilepsy cannot be readily differentiated by the first aider. When these emergencies arise, they will be best cared for by applying the procedures of first aid for shock.

When the victim is prostrate he should not be moved until the proximate nature of the injury has been determined. The victim should be kept lying in a comfortable position, his head level with the body. If the victim is unconscious, he should be handled as for skull fracture or apoplexy. A smell of alcohol on the breath can be misleading.

First Aid Equipment.—A first aid kit (distinguished from a home medicine cabinet) should consist of a dust-tight durable case containing the following items: several packages of sterile gauze squares of two or more sizes, 2 in. x 2 in. to 4 in. x 4 in.; sterile gauze or muslin dressings about 1 yd. square; a roll of 1 in. adhesive tape; six bandages, 1 in., z in. and 4 in. widths; one pair bandage scissors; one package sterile cotton applicators; one pair tweezers; one package ready-made adhesive gauze compresses; one first aid bottle (1 oz.) mild antiseptic; one $2\frac{1}{2}$-in. elastic bandage; safety pins; and two ampules of aromatic spirits of ammonia that may be broken when needed. All medication and supplies should be plainly marked and labels read carefully before using.

In addition, the home and automobile should be equipped with wooden splints and the bandages to apply them, a blanket, flashlight, jackknife and a short pencil and pad for recording pertinent information.

Examination.—Look for serious bleeding, stoppage of breathing and poisoning. They must be treated immediately. Then look for evidence of wounds, fractures, dislocations and burns; feel the pulse; try to elicit response from the victim. Never try to have a patient stand or walk until you have determined there is no injury to the spine, pelvis or legs. Keep the injured person warm. He should have blankets under him, but the first aider in covering him must give consideration to the temperature of the environment. Keep the patient comfortable but not hot. Never give water or other liquids to an unconscious person. Do not let the patient see his own injury. Send someone to call a physician or ambulance.

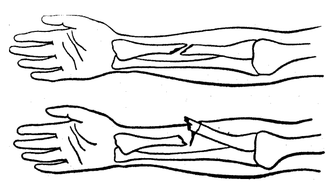
Shock.—In every severe injury shock is a serious condition and may result in death. Severe pain, loss of blood, extensive burns and accidents due to electricity cause a depressed state of all body functions, resulting in a failure of blood circulation. Shock may be more severe in the aged. The symptoms usually develop gradually. The skin is cool and clammy; perspiration is noted on the forehead, above the lips and palms of the hands; the pulse is weak and unconsciousness may occur. Shock is so serious that every effort should be made to prevent it. Elevate the lower part of the body. In chest injuries raise the head and shoulders slightly if breathing is difficult. Keep the patient comfortable but not hot. Fluids such as warm water, broth, tea or coffee may be given in small amounts unless the patient is nauseated, unconscious or has an abdominal wound. Alcoholic drinks are not advised. Avoid unnecessary moving. (See also SHOCK.)

Transportation.—In the handling of any seriously injured or prostrate person the transportation of the patient is of prime importance. Improper action might increase the damage at the site of the injury and cause harm to nerves and organs, thereby seriously complicating the original injury. Few cases require hurried or snap decisions. Determine by observation and questioning the approximate nature of the injury. Notify a physician as soon as you have essential information regarding the type of injury (head, back, limb, abdomen) and the age of victim (child, adult, aged). Request advice regarding immediate care and do not end the telephone conversation until you are sure the doctor's questions are answered and advice is given. Usually the physician will notify the hospital and call an ambulance. If this is not feasible, determine your transportation method. Exactly what is to be done? What materials are needed to move the patient? If the patient is to be carried to a vehicle, how must he be placed in it? Exactly what is the duty of each helper in carrying the patient to the vehicle? These questions should be answered by the first aider before getting started. The patient should not be bothered or worried by questions or discussion of the matter.

The stretcher is extremely valuable in short or long transportation. Stretchers may be improvised by the use of the following: (1) poles and blanket; (2) a blanket properly rolled; or (3) a door, ladder or screen covered with light board and blanket. If the patient is unconscious, his hands should be tied together with a bandage; if he is conscious, his hands may be left free. Few cases require breakneck speed; many are benefited by careful movement rather than haste. Seek advice and assistance at the hospital before moving the patient from the vehicle.

INJURY TO BONES AND JOINTS

A fracture is a break in a bone and is generally the result of violence such as a fall or a sudden blow. X-ray examination is the most positive way for determining the nature and extent of any bone injury. There are tno kinds of fractures, (1) closed (simple) where the bone is broken, but no connecting wound from the broken area through the skin; (2) open (compound) where the broken bone penetrates the skin or a crushing injury has broken the skin and muscle tissues to the depth of the broken bone (fig. 1). An open fracture, because of the entrance of germs, is much more serious than a closed fracture. A history of a fall or violence, pain on motion about the injured area, deformity, tenderness and swelling over the injured bone are characteristic of fracture.



FROM THE DETROIT INDUSTRIAL FIRST AID ADVISORY COMMITTEE UNIV OF MICHIGAN INSTITUTE OF INDUSTRIAL HEALTH, BY COURTESY OF FEBRUARY PUBLISHERS

FIG. 1—CLOSED (TOP) AND OPEN FRACTURES

For all fractures and possible fractures keep the broken ends and adjacent joints quiet. Splint the injured area when in doubt. If the fracture is open (compound) and bone or tissue protrudes through the damaged skin, special care must be exercised in the handling of the injury. (See also FRACTURES AND DISLOCATIONS; BONE, DISEASES AND INJURIES OF.)

Fracture of Long Bones (Arm, Leg) should be immobilized with a splint. In fractures of the leg, thigh or hip apply the splint before moving the victim. If it is necessary to move the injured person a short distance, someone should place his hand above and below the fracture area to keep it quiet while others support the weight of the body. Use a stretcher if one is available.

Splints should be padded and sufficiently long so that the joint on each side of the fracture is incorporated in the splint. Improvised splints can be made from thin boards of sufficient length covered with padding. Too small or unwieldy boards are likely to cause more harm than good.

Fracture of the Spine (Backbone) is caused by a fall or crushing accident. Backache, pain in the neck, paralysis of one or both lower extremities and shock are symptoms that the spinal cord may be damaged. Extreme caution is important in the handling of this type of injury because permanent paralysis or even death may result from improper first aid. Transport the victim on a rigid frame. This frame may be improvised by using boards or a door; support the head and neck carefully. If the patient is found on abdomen or side, roll him gently to the back, rotating the neck in line as the body rotates and bind him to the frame. Do not use a pillow, particularly if the injury is in the neck or upper back. Place pads on each side of the head to prevent rolling. Place a small padding under the small of the back. Do not permit the patient to sit up. Do not let the head tilt forward, sideways or backward. Do not move the patient from the frame to a stretcher or bed until he has been examined by a physician.

Fracture of the Hip is generally the result of a fall. Symptoms are usually shock, often severe; the foot is frequently turned outward; there is tenderness and pain over the hip. While on his back the patient cannot raise his heel although he can move his ankle and foot. Apply a splint on the injured side of the body from armpit to foot. If a splint is not available bandage the injured limb to the other limb. Give proper shock care. Transport on a stretcher.

Sprains.—Sprains result from a tearing and stretching of ligaments about a joint. There is pain, swelling and possible discoloration. It is often difficult to differentiate a sprain from a fracture; if there is doubt it is best to treat the injury as if it were a fracture. Rest and elevation of the affected area are desirable, as are cold applications.

WOUNDS

A wound (*q.v.*) is a break in the skin and is classified as an abrasion (scraped), incision (cut), laceration (torn) or puncture (stab) wound. The dangers that might complicate wounds are infection, hemorrhage and shock.

In the first aid treatment of wounds, cleanliness is essential. Do not touch the mound with the hands or fingers or any unsterile material. A minor abrasion or laceration should be cleansed thoroughly with bland soap and warm water, rinsed with warm water and treated with a mild antiseptic; the injury then may be dressed with a ready-made adhesive gauze bandage or sterile gauze and roller bandage. Do not use improvised bandages or dressings unless the material has been thoroughly washed with soap and hot water and freshly ironed. If the wound is of a nature that will require subsequent dressing, it is advisable to consult a physician. Wounds which cause hemorrhage have usually cut or torn a blood vessel. Most vessels close to the surface of the skin are veins and small arteries. All that is needed for control of the bleeding is direct pressure over the wound with sterile gauze from the first aid kit or a clean unused handkerchief. It is not harmful to allow fresh water to run over the bleeding wound before applying pressure with a square of gauze between the fingers and the wound. This is called digital pressure (fig. 2). Do riot apply a retaining bandage until the bleeding has been controlled. It is better to add another piece of gauze over the first section than to remove the first gauze from the mound. Contamination of the wound by contact with additional material should be avoided as much as possible. When bleeding is not severe, infection is the chief danger.

When arteries are cut or a number of large veins have been lacerated, severe bleeding ensues. Blood from the arteries is bright red and comes in spurts. The chief duty of the first aider is to stop the loss of blood; determine as quickly as possible the source of bleeding and apply digital pressure close to the wound, but not on the wound's edge. If digital pressure will not stop the flow of blood, it may be necessary to apply a tourniquet but this should be done only as a last resort. The tourniquet is a dangerous instrument. and it should be used only when profuse bleeding—such as that which occurs when a large artery or vein in one of the limbs has been cut—cannot be checked by direct pressure. In preparing the tourniquet, do not use rope, wire or any material that might cut into the flesh when drawn tight. Use flat material at least an inch wide, such as a necktie, belt or suspender. Place the tourniquet close to the wound where the skin is unbroken. but not on the wound edge. Wrap the tourniquet around twice and draw it tight enough to check the flow of blood. Tie the ends with a slipknot, so that if it is necessary to release the tourniquet it can be done very gradually by undoing the slipknot without removal of the tourniquet and movement of the injured limb. A properly applied tourniquet may be left in place for one to two hours without causing harm by pressure. It need not be reapplied unless severe bleeding occurs again; then it should be tightened until bleeding stops.

FIG. 2.—USE OF GAUZE SQUARE OVER WOUND FOR CONTROL OF BLEEDING

Puncture Wounds caused by penetrating objects should always be regarded as serious because of the danger of tetanus (*q.v.*). Puncture wounds do not cause much bleeding unless a blood vessel has been injured. Frequently foreign material such as street dirt or clothing is carried into the nound. These wounds are difficult to clean out. The important care in first aid consists of thoroughly cleansing deep into the wound with bland soap and water, applying a first-aid dressing and sending the patient to a physician for the administration of tetanus antitoxin or toxoid. Do not wait to see nhat will happen even until the next day.

Gunshot Wounds generally penetrate farther than do other puncture wounds and may involve blood vessels or organs where internal bleeding would take place. Shock is a frequent symptom of internal bleeding. The need of a physician, ambulance and hospitalization is imperative.

Infected Wounds.—Infection is caused by germs entering a wound at the time of injury or subsequently. The symptoms are pain. swelling, redness and heat. Sometimes pus. red streaks, swollen lymph glands and fever are present. A physician's care is necessary. First aid until the patient can see a doctor is as follows: rest and elevate the infected part if possible; apply fomentations made with Epsom salts or boric acid and hot water. Do not touch the wound or attempt to squeeze out the pus.

Wounds of the Abdomen.—The danger of abdominal wounds is internal bleeding and rupture of intestines or some other abdominal organ. Operation is usually necessary. Sometimes injuries to the abdomen do not cause external wounds though the patient may have pain with signs of shock. If there is an external wound. apply a sterile dressing and binder and provide careful, immediate transportation to a hospital.

Wounds in Which Foreign Bodies Remain.—If a small foreign body protrudes from a wound, clean the area with soap and water; apply antiseptic; remove the foreign body with forceps boiled in water; and again apply an antiseptic and ready-made adhesive gauze dressing. If the foreign body is large or deeply embedded. do not attempt to remove it. Apply a sterile dressing and take the patient to a physician.

Eye Wounds.—Vision is sometimes seriously and permanently damaged by delayed or improper care of a foreign body in the eye. Do not rub the lid over the eye. Do not examine the eye with unwashed hands. Do not use a toothpick or other instrument in an attempt to remove the foreign body. Do not use an eye cup. Do not apply ointment or eyewash to the eye. Do not touch the eyeball. A sterile applicator or corner of a clean handkerchief dipped in boric acid solution may be used to remove a foreign body that is in the fold between the eyeball and the lid. If the foreign body is fixed on the eyeball, the patient should be sent to a physician. Retain a sterile dressing over the closed eyeball with a strip of adhesive tape. Wounds that penetrate the eyeball are serious. Do not remove any splinter that is partially embedded in the eyeball. Apply a sterile pad and loose bandage and take the patient to a physician or hospital immediately. (See also BANDAGES AND BANDAGING.)

Animal Bites.—Puncture wounds inflicted by pets or stray animals occasionally cause severe infection. Rabies (*q.v.*) may result from a mammal bite, especially a dog bite. Cats and squirrels may also be carriers of the rabies virus. The offending mammal should be kept under observation by a veterinary or police official until it is determined that it is not suffering from rabies. The wound should be cleansed with soap and water and a sterile dressing applied. Obtain medical attention for rabies immunization at once even though the wound is minor. One should never wait to see if trouble develops.

Snake Bites.—The fangs of a poisonous snake cause puncture wounds through the flesh of the person struck. Pain is immediate, and the skin about the bite takes on a dark purple discoloration. As the poison is absorbed into the system, more general effects are noted: weakness, rapid pulse, nausea and vomiting. Prompt first aid is imperative in order to remove as much of the venom as possible. Snake bites on the extremities require the use of a tourniquet, applied somewhat above the wound—that is, on the trunk side immediately after the wound is received. Several cuts should be made over the site of the puncture, mith a razor blade or sharp knife, sufficiently deep to cause bleeding. Apply suction with the mouth or, preferably, by means of a suction cup to extract the poison. The poison if swallowed is not harmful. Shock should be treated and the victim transported to medical care. Alcoholic drinks have no value in snake bites.

Insect Bites.—Some persons are more susceptible to insect bites than others. In the case of a bee, wasp or hornet bite, the sting is usually seen in the wound and should be removed by scraping. Do not pluck out with the thumb and forefinger because squeezing the sting empties the contents of the poison sac into the wound. Local application of baking soda paste, calamine lotion or ice cold compresses gives relief, and considerable benefit can be obtained by the use of antihistamine pills prescribed by a physician. (See also INSECT BITES AND STINGS.)

COMMON MEDICAL EMERGENCIES

Burns.—A burn is caused by dry heat or flame; a scald is caused by steam or hot liquid; chemical burns are produced by the chemical action on the skin; electric burns are caused by the electric flash which damages the skin. The dangers from burns are shock and infection. Small burns may be cleansed and first-aid ointment with sterile dressing applied. the wound being redressed after 12 hours. Do not apply butter, lard, vinegar or similar household items. For extensive burns, remove clothing except where it sticks to the burned area. Keep the patient warm and treat for shock. The outstanding signs of burn shock are thirst, complaint of cold and gray to purple colour of the lips. Cover the burned area with a thin layer of sterile gauze or dressing retained with loose bandage. Do not use absorbent cotton on a burn. Do not remove foreign substance from the burned area or open blisters; this should be done by a physician. Chemical burns should be washed immediately with a large amount of water so that the chemical will not burn deeper. Acid burns should be washed freely nith nater and a paste of bicarbonate of soda applied and covered nith a dressing. Caustic burns should be washed mith a weak vinegar solution and rinsed with nater. (See also BURNS.)

Frostbite.—Exposure of the body to cold results in a stoppage of the flow of blood to the frozen part. The terminal ends of the circulation such as ears, fingers, nose and feet are often frostbitten.

Experience in World War II and the Korean war indicated that the least damage results when thaning is accomplished by immersion of the frozen part in a water bath maintained at a temperature of 86° to 89° F. until a reddish colour is restored to the frozen part. Restore the general condition of the victim with warm drinks and blankets. After the circulation is restored in the frozen area. the victim should be encouraged to exercise the movable parts. Do not rub or massage the frozen part with snow or any other substance. The patient should not smoke during thawing of the frozen part. Blisters which develop over the frozen areas may be opened on the second day. (See also FROSTBITE.)

Nosebleed. — The patient should sit up, loosen collar, clear blood clots and mucus from the nostrils, press the nostrils together firmly or apply pressure on the upper lip just below the nose. If bleeding does not cease in a reasonable time, pack the nose gently with gauze. Be sure the ends of the gauze protrude so that it can be easily removed. Do not use cotton. (See also NOSEBLEED.)

Heart Attack. — Such cases generally resemble fainting with complaint of shortness of breath (air hunger) and pain in the chest or upper abdomen which sometimes radiates down the left arm. The patient is often apprehensive. Keep the patient quiet and lying down. loosen collar and tight clothing; coffee or tea may be given. Call a physician immediately.

Abdominal Pain is an early symptom of many disorders, some of which are serious. Disease of the stomach or bowel is generally evident by vomiting. constipation or diarrhea. Appendicitis may begin with pain in the upper abdomen or tenderness in the lower right side. little or no fever and generally some nausea. A laxative should never be given until the diagnosis is certain. If necessary give a one-pint soapsuds enema, apply an ice bag to the abdomen, give no fluids or food by mouth and have a physician come to the patient. After the age of 40, vomiting after meals, passage of dark blood from the bowels or any abdominal distress with distention indicates the immediate need of a thorough physical examination.

Apoplexy (Stroke). — The victim should be recumbent with head and shoulders raised and adequately covered. Cold applications should be applied to the head. Stimulants are harmful. The patient should not be moved at the time. (See also STROKE.)

Convulsions.—Onset is sudden, though sometimes the patient realizes an attack is coming on. The patient may cry out. lose consciousness and bite his tongue. An attack lasts a few minutes and is followed by drowsiness and mental confusion. Protect the patient from self-injury. Protect the tongue from being bitten by placing a pencil or small stick wrapped with a handkerchief between the teeth. Give nothing by mouth. Encourage the patient to sleep. (See also CONVULSIONS.)

Fainting. — Fainting generally results from a temporary lack of blood reaching the brain. Some healthy persons faint at the sight of their own blood, and for this reason first aid should never be rendered to a person unless he is seated or lying down. If the patient has fainted, keep him lying down with head level. Aromatic spirits of ammonia on a handkerchief held under the nose often restores circulation of blood to the brain. After consciousness returns. coffee, tea or cold water may be given.

Diabetic Coma. — Many diabetics carry special identification which indicates the possibility of sudden unconsciousness. Symptoms of diabetic coma are mild shock, confusion and history of insulin usage. The victim should be transported to the hospital or nearest clinic for insulin injection. (*See* also DIABETES MELLITUS.)

Insulin Shock is a condition resulting from administration of too much insulin. Symptoms are confusion and sometimes unconsciousness. Give sugar, candy or orange juice at once (an exception to the rule of not feeding an unconscious patient).

Dermatitis. — Dermatitis is an inflammation of the skin evidenced by itching, redness and various types of skin lesions caused by external irritants (poison ivy, nettle, turpentine, glass wool, chemicals, etc.). Allergic dermatitis occurs in persons who are particularly sensitive to substances that do not affect others. Persistent skin disorders of this type should be referred to a physician who specializes in skin disorders. Self-medication may result in serious complications and prolonged disability. (See also SKIN DISEASES; POISON IVY.)

Sunburn, Heat Exhaustion and Heat Stroke. — Extensive exposure to sun rays may cause violent reactions in the skin and in the heat regulating mechanism of the body. Light skins react more violently than dark ones. For mild sunburn apply soothing lotions or creams. Blisters should not be broken, but if they are accidentally broken they should be trimmed with scissors sterilized in boiling water. Then cover the blistered area with Vaseline dressings.

The symptoms of heat exhaustion are nausea, vomiting, headache. rapid pulse and excessive perspiration. Rest is imperative. Restore the salt balance in the body by administering salted fluids, one-fourth teaspoonful of salt in each glass of water or other liquid.

Heat stroke is a serious matter. The skin is dry and hot; there is no perspiration; the pulse is fast; cramps develop in the muscles of the arms. legs and abdomen; the temperature is high and should be lowered as quickly as possible by tepid baths and sprays. Massage the arms and legs and give salted fluids by mouth. Ice applications to the head and back of neck are advisable. Keep the victim at rest for 24 hours after the temperature reaches normal (98.6"). (See also SUNSTROKE AND HEATSTROKE.)

Poisoning by **Mouth.**—Swallowing a poison creates an emergency that requires immediate first aid. The poison should be evacuated from the stomach as quickly as possible, preferably by dilution and vomiting. If the patient is conscious, give large glasses of milk or water and then induce vomiting by tickling the back of the throat with the index finger or by administering an emetic (such as a tablespoonful of baking soda or a teaspoonful of table salt dissolved in a full glass of warm water). Use force if necessary. If the patient is unconscious, do not attempt to give an emetic, but with the patient lying on his side hold the mouth open with a stick or pencil wrapped with a handkerchief and induce gagging and vomiting by tickling the back of the throat with the index finger. In order to eliminate as much of the poison as possible. if the patient is conscious after vomiting give a drastic cathartic such as Epsom salts in a glass of warm milk. Keep the body warm; give hot coffee, tea or other warm drink. (See also POISON ; ANTIDOTES.)

Asphyxiation. — A person who has stopped breathing will die if his breathing is not restored immediately. Common causes of asphyxiation are carbon monoxide poisoning (*q.v.*), electric shock, suffocation from poisonous gases in the air, foreign body in the throat or air passage and overdose of sedatives. Start artificial respiration immediately after the person has been rescued and moved to fresh air. The rescuer should not enter a hazardous atmosphere without having a life line fastened securely to his body with adequate assistants present. (See ARTIFICIAL RESPIRATION.)

Drowning. — The immediate need in every case of drowning is the supply of an adequate amount of oxygen to the heart and the brain. This can be obtained only by first aid rendered promptly and intelligently. (See ARTIFICIAL RESPIRATION.)

BIBLIOGRAPHY.—American Red Cross, *First Aid Textbook* and supplements (1945 ff.) ; American Medical Association, *First Aid* Manual (1953); February Publishers, "First Aid Guide For the Small Plant" (1952). (J. H. Cs.)

FIRST-FOOT, in folklore, especially that of northern England and of Scotland, the first person who crosses the threshold on New Year's day (or on Christmas or other days). Good or ill luck was believed to be brought the house by first-foot, and a female first-foot was regarded with dread. In Lancashire a light-haired man was as unlucky as a woman. In Worcestershire luck was ensured by stopping the first carol singer who appeared and leading him through the house. In Yorkshire it had to be a male who entered the house first, but his fairness was not considered an objection. In Scotland the custom of first-footing involving a subsequent entertainment was always more elaborate than in England. Customs associated with first-foot have been known in various other countries, including China.

FIRST INTERNATIONAL: see INTERNATIONAL, THE.

FIRST OF JUNE. The "Battle of the Glorious First of June" was so called because it occurred in the Atlantic ocean at a point 430 mi. W. of Ushant, Fr. (and could not therefore be named after a particular place) and reached a decision on June 1,

1794. It arose out of an attempt by the British to intercept, and by the French to protect, a large consignment of grain which the latter. faced by famine as the result of a bad harvest, had purchased from the United States.

This grain convoy, consisting of more than 100 vessels escorted by 4 line-of-battle ships, sailed from Chesapeake bay in April. The French commander in chief, Louis Thomas Villaret de Joyeuse. intended to meet it with the Brest fleet about 400 mi. from the coast. Lord Howe, commanding the British channel fleet, sailed from Spithead on May 2 with 34 sail of the line primarily to escort an outward-bound convoy, for the protection of which eight ships were detached! six of which were to rejoin on reaching the latitude of Cape Finisterre. He was also making one of his periodic sweeps of the Bay of Biscay by which he maintained an "open" blockade of Brest in the hopes of finding the French fleet at sea.

Howe's fleet was off Ushant on May 5. Finding that the French were still in harbour. he sailed west to put himself between the convoy and Villaret's battle fleet. Meeting with no one, he returned on the 19th to find that the latter had sailed on the 16th, having passed the British in foggy weather. On the 28th the French were sighted. Villaret, in accordance with his instructions to protect the convoy rather than seek a battle, detached the grain ships while he attempted to lure Howe away to the northward. On the morning of the 29th Howe ordered a chase of the French fleet, but soon afterward a heavy mist descended which prevented him from carrying out his plan of attack, though he did obtain the advantage of the weather gauge. During the next two days there was some sporadic fighting in which the British reduced Villaret's force to 26 ships. On the afternoon of the 31st the weather cleared and Howe found himself in an ideal position to attack from the windward position. Having placed his fleet in an exact line with that of the enemy. he drew off for the night. The next morning. Sunday, June 1, he put his plan into action. He aimed at overcoming the usual French withdrawing tactics of firing at the masts of the British in order to immobilize them. Instead of engaging the enemy on the same tack in the normal way, Howe intended to break their line at all points in order to re-engage from to-leeward, thus preventing their retreat. Only seven British ships got through, but the number was enough to disorganize the French line and achieve a notable victory with the capture of six enemy ships and the sinking of another. The duels between ships, particularly those between the flagships "Queen Charlotte" and "Montagne" and that between the "Brunswick" (Captain Harvey) and the "Vengeur," proved that the Revolutionary navy was still capable of hard fighting though most French officers had been exiled or executed.

Howe was criticized for allowing five ships to escape through his line, and, as Villaret later said, "while your admiral amused himself refitting his prizes, I saved my convoy and I saved my head." But Howe, aged nearly 70, was exhausted after five days and nights without rest, and the British people, depressed by their lack of success on land! forgave the shortcomings of the pursuit in their celebration of the first victory at sea over the navy of Revolutionary France.

FIRUZABAD, a town of Iran, in the province of Fars, 72 mi. S. of Shiraz, in 28° 51′, at an altitude of 4,180 ft., in a fertile plain. 15 mi. long by 7 mi.. well watered by a river which flows through it from north to south. Pop. (1956) 5,746. The town is surrounded by a mud wall and ditch. The district has 20 villages and produces much wheat, and the rice of Firuzabad is famous. Northwest of the town are the ruins of the ancient city and of a large building, the palace of Ardashir; beyond them, in the gorge through which the stream enters the plain, are two Sassanian bas-reliefs. .The river leaves the plain at its southern end, and according to Persian history it was there that Alexander the Great, when unable to capture the ancient city, built a dyke across the gorge, thus damming up the water of the river, turning the plain into a lake, and submerging the city and villages. The lake remained until the beginning of the third century, when Ardashir, the first Sassanian monarch. drained it by destroying the dyke. He built a new city, calling it Jur or Gur, and made it the capital of one of the five great divisions of Fars. Firuz (or Piruz), one of Ardashir's successors, called the district after himself—Firuzabad—("the abode of Firuz"), but the name of the city remained Gur until Azud-ud-Dowleh (949–982) changed it to its present name. (P. z. C.; X.)

FIRUZABADI: *see* FAIRUZABADI.

FIRUZKUH, a district of Iran. equivalent to a township, with a population of 30,135 (1954 est.). Its chief place is a village of the same name situated in a valley of the Elburz, about 90 mi. E. of Tehran, at an elevation of over 5,000 ft. and in 35° 45' N. and 52° 30' E.

Firuzkuh town has a population of about 2,500. A cliff on the eastern side of the valley is surmounted by the ruins of an ancient fort popularly ascribed to Alexander the Great. It is an important railway station.

FISCAL POLICY: *see* ECONOMIC UNION; FAIR TRADE LAWS; FREE TRADE; IMPERIAL PREFERENCE; PROTECTION; and TARIFFS.

FISCHART, JOHANN (1546?–1590), the greatest German satirist of the 16th century, was born in Strasbourg late in 1546 or early in 1547. He received a good education there and at Worms. Before 1570 he traveled widely, visiting the Netherlands and probably England, and studying in Paris, Strasbourg and Siena, Italy. 4 later period of study in Basel ended with the degree of *doctor iuris* (Aug. 10, 1574), but from 1j70 to 1580 he lived mostly in Strasbourg, working for his brother-in-law Bernhard Jobin, the printer and publisher. In this decade his main literary works appeared. Three years in Speyer as advocate at the *Reiclzskamrnergericht* (imperial court of justice) were followed by appointment in 1583 as magistrate at Forbach, Lorraine. In the same year he married in Worth, Alsace, Anna Elisabeth, daughter of the Alsatian chronicler Bernhard Hertzog. He probably remained at Forbach until his death there, late in 1590. Of his main works, the earliest are attacks on the papacy. Franciscans and Dominicans: *Nacht Rab* (1570); *Der Barfusser Secten und Kuttenstreit* (1j71); and *Von S. Dominici . . . artlichem Leben* (1571), and two of the latest are polemical satires against the Catholic Church and especially the Jesuits: *Bienenkorb des heiligen romischen Immenschwarms* (1579, virtually a translation of a Dutch satire by Philipp Marnix); and the *Jesuitenhiitlein* (1580). Fischart is the principal German literary opponent of the Counter-Reformation. His Protestantism, however, was never rigidly sectarian. Beginning as a Lutheran, he came to defend Calvinist doctrines—the only major German writer to do so. His more general didactic and satirical writings include *Eulenspiegel reimensweis* (1j72), a moralizing version of the Eulenspiegel stories; *Aller Praktik Grossmutter* (1572), a parody of the farfetched prognostications in contemporary almanacs; and *Der Flöhhatz* (1573), where the hunted flea's lament develops into a satire on women. Well-established genres are represented in the comical *Podagrammisch Trostbüchlein* (1577) in praise of gout, and the more serious *Philosophisch Ehezuchtbüchlein* (1578, based on treatises by Plutarch and Erasmus), in praise of marriage.

Fischart's principal work is the *Affentheurliche und Ungeheurliche Geschichtsschrift* (1575)—renamed *Geschichtklitterung* in later editions (1582, 1590)—a free and greatly expanded prose version of Rabelais's *Gargantua*. Perhaps his most attractive work to the modern reader, however, is *Das glückhafft Schiff von Zurich* (1576), one of the most carefully constructed 16th-century narrative poems, commemorating the boatload of Zurich citizens who rowed to Strasbourg and brought a basin of porridge, cooked in Zurich in the morning, still warm to Strasbourg at night.

Fischart was a man of wide learning and experience, and his writings, with their exuberant wit and serious moral purpose, continue—and end—the didactic and satirical tradition of Sebastian Brant and Thomas Murner, combining it with that of Rabelais, and providing a detailed picture of the German culture of his day.

In subject matter, however, they are mostly adaptations of existing literary works, and their construction is often faulty and their versification sometimes rough-and-ready. Fischart's originality lies rather in the profusion of his ideas, his independent development of his subjects and, above all, in his style, especially in prose. With his vast vocabulary — much of it coined by himself — his delight in playing on words and his exuberant and sometimes grotesquely complex syntax, this "German Rabelais," although largely neglected until well into the 18th century, foreshadows at least some aspects of 17th-century style.

BIBLIOGRAPHY.—Fischart's *Sämtliche Dichtungen* were edited by H. Kurz, 3 vol. (1866–67). Selections were edited by A. Hauffen, in *Deutsche Nationalliteratur,* vol. 18, i–iii (1892–95). Individual works edited in *Neudrucke deutscher Literaturwerke* are: *Aller Praktik Grossmutter,* vol. 2 (1876); *Flohhatz,* vol. 5 (1877); *Geschichtklitterung,* vol. 65–71 (1891); *Glückhafft Schiff,* vol. 182 (1901). *See* also A. Hauffen, *Johann Fischart,* 2 vol. (1921–22) (a detailed study; deals with all earlier literature); A. Leitzmann, *Fischartiana* (1924); R. Zitzmann, *Fischarts "Geschichtsklitterung" in ihrem Verhältnis zu Rabelais* (193j). (J. R. WE.)

FISCHER, EMIL (1852–1919), German chemist, awarded the Nobel prize for chemistry in 1902 in recognition of his services in connection with his synthetic experiments in the sugar and purine groups of substances, was born at Euskirchen, Rhenish Prussia, on Oct. 9, 1852. He studied at Bonn and at Strasbourg, where he graduated Ph.D. in 1874. He acted as assistant to A. von Raeyer at hfunich for eight years, after which he was appointed to the chair of chemistry successively at Erlangen (1882) and Würzburg (1885). In 1892 he succeeded A. W. von Hofmann as professor of chemistry at Berlin.

Fischer devoted himself entirely to organic chemistry, and his investigations were characterized by an originality of idea and readiness of resource which made him the master of this branch of experimental chemistry. The merit of his researches was recognized by all the important scientific societies in the world. In 1890 he was awarded the Davy medal of the Royal society and elected a foreign member in 1899. Under his control the laboratory at Berlin became one of the most important in existence and attracted to itself a constant stream of brilliant pupils. Fischer died at Wannsee, Berlin, on July 1j, 1919, and is buried there.

In 1875, he published his discovery of the organic derivatives of hydrazine and investigated their relation to the diazo compounds. Fischer's research concerned with compounds related to uric acid was on ground that had been broken, more especially by Baeyer, but almost all our knowledge of the purine group *(see* PURINES) is due to Fischer. In 1881–82 he established the formulas of uric acid, xanthine, caffeine, theobromine and some other compounds of this group.

His greatest work was instituted in 1894, when he commenced his great series of papers, wherein the forgoing compounds were all referred to a nitrogenous base, purine. The base itself was obtained after much difficulty, and an immense series of derivatives were prepared, some of which were patented in view of possible therapeutical applications. These researches were published in a collected form in 1907 with the title *Untersuchungen in der Puringruppe.* When the work on the purine group was progressing satisfactorily he attacked the sugar group. Here again Fischer may be regarded as the prime investigator in this field. His researches may be taken as commencing in 1883; and the results are unparalleled in importance in the history of organic chemistry. The chemical complexity of these carbohydrates, and the difficulty with which they could be got into a manageable form — they generally appeared as sirups — occasioned much experimental difficulty; but these troubles were little in comparison with the complications due to stereochemical relations. However, Fischer synthesized fructose, glucose and a great number of other sugars, and showed how to distinguish the formulas of the 16 stereoisomeric glucoses. The study of the sugars made it necessary to examine the nature, properties and reactions of substances which bring about fermentation. Fischer attacked the problem presented by ferments and enzymes, and although we as yet know little of this complex subject, to Fischer and his co-worker Abderhalden is due the credit of having laid the foundation of enzyme chemistry.

In addition to important research on proteins Fischer also made a number of investigations on the Walden inversion and on gallic acid derivatives of the sugars which were related to the tannins. During World War I he was very active in organizing German chemical resources. He increased the supply of ammonia available from coke ovens, encouraged the synthetic nitric acid industry, suggested camphor substitutes and new sources of glycerine. He was particularly concerned with the problem of conserving the food supply. He was concerned with methods of education, the training of chemists and the establishment of national research institutes. His autobiography *Aus meinen Leben* appeared in 1922.

FISCHER, ERNST KUNO BERTHOLD (1824–1907), German philosopher, was born at Sandewalde, Silesia, on July 23, 1824. Educated at Leipzig and Halle, he became a *Privatdozent* at Heidelberg in 1850, and in 1856 a professor at Jena. In 1872 he succeeded Zeller at Heidelberg as professor of philosophy and of the history of modern German literature. In philosophy, where his attitude was mainly Hegelian, his part was that of a historian and commentator, his chief production being *Geschichte der neueren Philosophie* (1852–93). Fischer also made valuable contributions to the study of Kant, Spinoza, Schopenhauer, Bacon, Shakespeare, Goethe, Lessing and Schiller.

The Eng. trans. of his numerous works are: *Francis Bacon,* by J. Oxenford (1857); *Life of Benedict Spinoza,* by F. Schmidt (1882); *A Commentary on Kant's Kritik of Pure Reason, by J. P.* Mahaffy (1866); *Descartes and his School,* by *J. P.* Gordy (1887); *A Critique of Kant,* by *W. S.* Hough (1888). *See* also bibliography in Baldwin's *Dict. of Philosophy and Psychology* (1905).

FISCHER, HANS (1881–1945), German biochemist, best known for his researches on haemin and chlorophyll, was born in Hochst, July 27, 1881. He received his doctorate in chemistry from Marburg in 1904 and in medicine from Munich in 1908. After some years of medical work he took up chemical research in Berlin under Emil Fischer. In 1916 he became professor of medical chemistry at Innsbruck; in 1918 went to Vienna; and in 1921 returned to Munich as professor of organic chemistry and director of the Institute for Organic Chemistry of the technical high school. He died in Munich on March 31, 1945.

He was awarded the 1930 Nobel prize for chemistry for his researches into the constitution of haemin and chlorophyll, especially for his synthesis of haemin. Haemin is a crystalline product of haemoglobin. By splitting in half the molecule of bilirubin, the related bile pigment, Fischer obtained a new acid in which a section of the haemin molecule was still intact. Its structure was identified and found to be related to pyrrole. This made possible the artificial synthesis of haemin from simpler organic materials of which the structure was known. Fischer also showed that there is a close relationship between haemin and chlorophyll, and when he died had nearly completed the synthesis of chlorophyll. He also studied the yellow pigment carotene, which is a precursor of vitamin A, and the porphyrins, iron-free derivatives of haemin widely distributed in nature and secreted by man in certain diseases. (W. J. BP.)

FISCHER, THEOBALD (1846-I~IO), German geographer who gave the concept of the "Mediterranean region" to geography, was born at Kirchsteitz, Thuringia, on Oct. 31, 1846. Having been educated at the universities of Heidelberg and Halle, he pursued his geographical studies in many parts of Europe, and more especially in the Mediterranean lands including the Atlas mountain region of north Africa.

Fischer's thesis for the rank of *Privatdozent* in the University of Bonn (1877) mas entitled *Beiträge zur physischen Geographie der Mittelmeerländer . . .* His most important publications are a collection of *Mittelmeerbilder* (1906) and his work on the Mediterranean peninsulas of Europe in A. Kirchhoff's *Allgemeine . . . Länderkunde,* a masterpiece of methodology which much influenced future geographical studies. He held professorships of geography at Kiel (1879–83) and at Marburg from 1883 until his death on Sept. 17, 1910. (H. G. KG.)

FISCHER VON ERLACH, JOHANN BERNHARD

(1656–1723), Austrian baroque architect most noted for his work in Vienna, was born at Graz. July 20. 1656, and died in Vienna. April 5. 1723. While studying sculpture in Rome. he came under the influence of Francesco Borromini and turned to architecture. Returning to Austria about 1683, he was shon employed by the archbishop of Salzburg to design the grand entrance to the archepiscopal court stables. Then followed four important churches in Salzburg. including the large Kollegienkirche (1694–1707). He began rebuilding the great imperial palace of Schonbrunn about 1700, and erected the fine Clam-Gallas palace. Prague, in 1707. His largest work in Vienna is the magnificent Karlskirche (1715–37). Other buildings there were the Trautson palace (1710–12), the Schonborn palace (1700), the palace of Prince Eugen (1695–9;. enlarged 1707–10), afterward the ministry of finance, the Schwarzenberg palace (1696–172j) and work in the Hofburg (imperial palace) begun c. 1j22.

Many of his later buildings were completed by his son Joseph Emanuel (1693–1742). (M. S. B.; X.)

FISH, HAMILTON (1808–1893), U.S. statesman. was born in New Tork city Aug. 3. 1808. His father was a Revolutionary veteran and friend of George Washington, his mother a descendant of Peter Stuyvesant. Graduating from Columbia college. New York city, in 1827, he was admitted to the bar three years later but soon turned to politics. After service in congress (1843–45), he was elected governor of New York on the Whig ticket in 1848. Six years in the U.S. senate followed (1851–57). A moderate antislavery advocate. he opposed the Kansas-Nebraska bill. but resisted the merger of the northern Whigs in the new Republican party until 1S56, when he supported John Charles Frémont on the Republican platform. In the crisis of 1861 he laboured till the last for peace; in May, however, he became chairman of the powerful Union defense committee of New York, which did an indispensable work 1861–62 in raising money. organizing regiments, buying arms and providing home relief.

Fish's real career opened in ?*larch1869 when Pres. U. S. Grant appointed him secretary of state. For the next eight years he not only dealt with critical foreign issues but gave Grant sagacious counsel on many questions, lent the administration dignity and moderation, opposed corrupt elements within it and made his influence for decency and efficiency felt throughout Washington. On several occasions his threat to resign vanquished his enemies.

His chief diplomatic achievements were the settlement of dangerous difficulties with Great Britain and the preservation of peace with Spain despite troubles in Cuba. By skilful co-operation with Sir John Rose in Canada and Lord Granville in England, he brought about a conference which drafted the treaty of Washington (1871) for the settlement of the so-called "Alabama" claims (arising from the Civil War depredations of the British-built cruiser of that name) and the U.S.-Canadian boundary in Strait of San Juan de Fuca by arbitration. The ensuing Geneva tribunal awarded the United States $15,500,000 for the Alabama claims (*see* "ALABAMA" ARBITRATION). Simultaneously. Secretary Fish had to conduct a stirring battle with powerful groups who wished the U.S. to intervene between Cuban rebels and the Spanish government. When in 1873 hotheaded Spanish authorities seized the ship "Virginius" on the high seas and shot 53 Americans and Britons as filibusters, all of Fish's sagacity and patience were needed to maintain peace. He obtained the restoration of the "Virginius" with Spanish apologies and indemnities.

In an era of shockingly low political standards and much dishonesty among officials, Fish headed a group in the cabinet which worked to keep Grant vigilant against trickery and graft, to restrain him from improper appointments and to prevent gross infringements of civil liberties in the reconstruction of the south. Fish insisted that a corrupt secretary of war be punished, and he played a major part in forcing Grant to get rid of a private secretary, Orville E. Babcock. implicated in the Whiskey Ring scandal. Meanwhile Fish dealt effectively with the Canadian fisheries question, Mexican affairs and other problems. Particularly notable was his work in helping save Grant from the worst consequences of an ill-advised and abortive attempt to annex Santo Domingo.

Returning to private life in 1877, Fish devoted his remaining years to a variety of public-spirited activities, giving special attention to his work as head of the trustees of Columbiauniversity. (A N)

FISH, that class of vertebrate animals which lives exclusively in water, breathes through gills, and whose limbs take the form of fins (see FISHES and FISH CULTURE). The article FISHERIES deals with the subject from the economic point of view, and FISHING with the sport of fishing. The constellation and sign of the zodiac known as "the fishes" is treated under PISCES.

The fish was a symbol of Christ in primitive and mediaeval Christian art. The origin is to be found in the initial letters of the names and titles of Jesus in Greek, Jesus Christ, Son of God, Saviour, which spell the Greek word for "fish," ἰχθύς.

FISH AND WILDLIFE SERVICE. The U.S. fish and wildlife service was organized as one of the major bureaus of the department of the interior on June 30. 1940. It combined the bureau of biological survey, which had been transferred from the department of agriculture. and the bureau of fisheries, transferred from the department of commerce the previous year (July 1, 1939). By this reorganization, the principal work of the federal government on fish and wildlife problems was concentrated in one agency. The service has perhaps as many and as varied functions as any other organization of equal size in the federal establishment. The three major categories in which the activities of the service may be divided are service, research and management. Both of the bureaus from nhich it was formed were established as research agencies but, as the years passed. were charged by law with administrative and service activities.

The biological survey was originally established to study the relationship of birds and later of mammals to agriculture. It was largely a research agency dealing with problems created by wildlife as the agricultural development of the country progressed. It was founded in 188j and carried on research activities until 1900, when enactment of the Lacey act, which partially controlled importations and interstate commerce in wildlife, defined its first regulatory work. The bureau of fisheries was established in 1871 as the United States fish commission to study. the fisheries and to devise'means for increasing and maintaining production from this natural resource. It was given bureau status in 1903 in the newly organized department of commerce and labour; when that department was divided into separate commerce and labour departments, the bureau of fisheries remained in commerce until transferred to the department of the interior.

Administrative Staff Services — Under a recent reorganization program the director and two assistant directors were made responsible for the over-all administration and general policies of the fish and wildlife service, one assistant director handling all wildlife work, another fisheries. Routine administrative and technical staff services were concentrated in the director's office under two assistants to the director, and the solicitor and information officer were also attached directly to the director's office. The solicitor handles all legal work for the service, while the information officer informs the public of the results of investigations and research. An editorial office assumed responsibility for editing all technical bulletins and other official publications and the dissemination of the regulations on migratory waterfowl and Alaska fisheries, which are recommended and enforced by the service. It is also responsible for the mailing and distribution of numerous bulletins and leaflets, including popular rewrites of the technical work, designed to give the public usable information in simple language. One series, the "Conservation Bulletins." is distributed both by the service and by the congressional delegations in a manner similar to that used for "Farmers' Bulletins" of the department of agriculture. This office also assembles photographs and motion pictures for service use.

Supervision of the administrative staff services, which include the usual functions of budget and management, personnel, finance and procurement, and a section for handling foreign aid work under the various federal aid programs, was assumed by one assistant to the director; the other administrative assistant in charge of technical staff services became supervisor of river basin studies, federal aid work, lands and engineering.

Technical Staff Services.—River Basin Studies.—The primary responsibility of the office of river basin studies is to determine the effects of proposed federal and other impoundments and diversions of water on wildlife and fishery values and to recommend means for minimizing the damage that occurs when such proposed projects are actually constructed. It of necessity works closely with the corps of engineers and the bureau of reclamation in studying their various proposed programs.

Federal Aid.—Responsibility for administering the Pittman-Robertson and the Dingell-Johnson acts was delegated to the branch of federal aid. Funds to carry out the purposes of the act were derived from the 11% excise tax on sporting firearms and ammunition and a similar 10% tax on sport fishing equipment. These funds were set aside in the federal treasury for wildlife and fisheries work. The congress in the 1950s appropriated the full amount of the preceding year's receipts for distribution to the states. These acts provided that funds should be distributed to the states partly on the basis of the percentage which the area of each bore to the total land or water area of the United States and partly on the ratio which the number of hunting and fishing licence holders in each state bore to the total in the United States. There were minor differences in the two acts, but the basic philosophy remained the same. These two factors operate to equalize the distribution of funds between the smaller and more heavily populated states where the licence sales are high and the larger and more thinly populated states where licence sales are low.

After the allocation was made, the states were allowed two years in which to use the funds, which had to go for purposes outlined in each act. The federal aid branch of the fish and wildlife service thus was made a checking agency. The states originate the projects and submit them for approval. If they are approved as complying with the terms of the lam, the states proceed with them, subject to periodic inspection by representatives of the division. The states were entitled to a reimbursement of 75% of the costs of work satisfactorily performed on approved projects. On such projects they submit claims, either from time to time as the work progresses or in one account when it is completed. Thus the federal government paid 75% of the costs of these projects and the states contributed 25% from their iunds. Another provision of the acts was that a state which diverted money received from hunting or fishing licences to expenditures other than those of its consen-ation department would be ineligible to participate in the distribution of the fund. Each state also was required to pass specific enabling legislation accepting the terms of the acts before it could participate. All states complied with these provisions and were receiving funds from these sources in the 1950s.

Lands.—The branch of lands was assigned the task of acquiring all lands needed by the service. It appraises and buys lands for refuges, fish hatcheries and other purposes authorized by law. It also appraises lands which the states propose to acquire under the federal aid program administered by the service.

Engineering.—The branch of engineering prepares specifications for structures of the types used by the service, handles all of the cadastral surveying work and carries on all the normal functions of an engineering service for the operating branches.

Regional Offices.—In addition to the services of the administrative staff and the technical staff, six regional offices were established to administer the housekeeping functions of the service at Boston, Mass.; Atlanta, Ga.; Minneapolis, Minn.; Albuquerque, N.M.; Portland, Ore.; and Juneau, Alsk. Control was maintained in the central office where over-all policies and procedures were prescribed in accordance with laws and regulations. The regional offices, however, were permitted considerable discretion within these broad, general policies.

WILDLIFE

Wildlife Research.--Migratory Waterfowl.—The branch of wildlife research carries on the major studies of terrestrial wildlife that are performed by the federal government. This unit made extensive studies of wintering populations of migratory waterfowl and of their migrations and distribution on the major breeding grounds. These studies developed the methods used in determining trends in the populations.

In connection with these studies of migratory birds, a banding program with about 1,800 voluntary bird banders was carried on. From these banding studies it proved possible to work out the migration routes and wintering grounds for specific populations which breed in given areas. Out of this work came the understanding that the migratory waterfowl of North America moved in four rather well-defined flyways, a flyway being the composite of routes followed between the breeding and wintering areas.

Relation of Food Habits to *Agriculture and* Forestry.—The branch of wildlife research studies also the food habits of birds and mammals in relation to agriculture and forestry. Many problems in wildlife management are created by the development of new types of agriculture and the introduction of new crops which invite damage by species previously not harmful. Likewise, the cutting of commercially valuable timber and its replacement by other growth often bring changes in the wildlife populations which affect the forest for good or bad. These general studies of the relationship of wild things to agriculture and forests are carried on in many projects, some of significance in limited areas, others of nation-wide import. Taxonomic and distributional studies of birds and mammals are carried on both in the laboratories and in the field.

Ecology.—A third group of studies of growing importance pertains to the relationships of various species of wildlife to each other and to their environment. This research is aimed at setting the pattern for wildlife management on federal refuges and other areas. Studies are conducted to determine the procedures necessary to develop the kind of environment most productive of the beneficial forms of wildlife. Methods are devised and tested for establishing desirable vegetation and for the suppression or eradication of harmful kinds. The main laboratories for carrying out these studies are on the Patuxent research refuge, near Laurel, Md., and at Denver, Colo. Smaller laboratories were established on the Wichita Mountains wildlife refuge. Oklahoma. and the Bear River migratory bird refuge, Utah. In addition, numerous refuges were equipped with laboratory facilities sufficient to permit field investigations to be carried on as required.

Co-operative *Wildlife Research* Units.—These units, financed jointly by the fish and wildlife service, the Wildlife Management institute, the state game and conservation departments and state agricultural colleges, iunction in a number of states and Alaska. Personnel of these units study wildlife management problems of local and regional significance and train men to continue these investigations or to enter wildlife managerial work. The studies carried on by these units and by the laboratories maintained by the service are integrated so that the resulting information is correlated where possible on a nation-wide basis.

Diseases of *Wildlife*.—Another major subject of research is the diseases of wildlife and, where possible, their control. For example, the cause of western duck sickness was determined to be a botulinus organism, type C. As soon as that fact was known, the investigation was directed toward the discovery of means of prevention or at least of minimizing the outbreaks, which killed many hundreds of thousands of valuable waterfowl. Methods of controlling vegetation and water levels or of dispersing the poisonous toxins were developed and effectively applied in considerable areas. Of special interest in the subject matter of this division are the diseases affecting wildlife which are also transmissible to man.

Control of Destructive *Wildlife*.—Another type of service concerns methods of controlling mammals or birds which become so destructive to agricultural or other interests that their numbers must be reduced. This work was centred at Denver. Satisfactory progress was made in rendering control methods more specific for the animals which it was necessary to control, and to reduce the danger of accidentally killing other forms of life. The studies undertaken at Denver involved primarily the development of repellents, the perfecting of frightening devices, and the contriving of more effective and selective methods of killing. Repellent sprays or dips were developed which proved useful in safeguarding forest tree seedlings, at least for a time. Mechanical devices also were made which protect seed spots and trees and other vegetation irom certain types of rodents. Frightening agents of various types, including streamers to keep small birds from truck fields, automatic flash guns and flashlights or combinations of these have been worked out and applied successfully to many areas where birds were the destructive agency. A method of holding down the number of certain types of predatory birds was devised which, by reducing the reproduction, successfully limited colonies of herring and black-backed gulls and cormorants.

Fur *Resources*.—The problems of production, conservation, restoration and utilization of the fur resources of the United States also are studied. The general lines of investigation relate to methods and seasons of trapping, preparation and marketing of skins, and the variability of fur qualities.

Public Lands.—Still another function—partly research and partly service—of the branch of wildlife research is the study of wildlife problems and the development of wildlife programs on public lands. Most of the calls for assistance come from the bureau of Indian affairs, the national park service: the forest service and the bureau of land management. A small group of experienced biologists attempt to furnish adequate information on which sound administrative programs can be developed.

An important problem relates to the joint use of grazing and forest lands by big game and livestock. This affects tracts, chiefly in the west: which comprise nearly 15% of the total land area of the continental United States. The kinds and amounis of grasses, browse and other forage used by game animals are determined as guides to the carrying capacities of different types of range. The effect of rabbits, gophers and other rodents on range production is investigated, as are also means of controlling undesirable animals. Important also, from an economic standpoint, is the relation of predatory animals—chiefly coyotes! wolves, bears. pumas and wildcats—to livestock and game. In the Rocky mountain region the dual role of bears as predator and game animals is studied. Results from these investigation are quickly put into practical use by the various agencies that administer public lands.

Game Management.—The branch of game management is charged with looking after the welfare of all birds protected by the treaties with Great Britain (for Canada) and with Mexico, and with the enforcement of the Alaska game laws and such federal conservation acts as apply nationally. The most important of these, in addition to the Migratory Bird Treaty act. are the Lacey act, the Migratory Bird Hunting Stamp act, the Bald Eagle act and the Black Bass act. The treaty with Great Britain, signed in 1916, applying to species which migrate between Canada and the United States, provided that all migratory game birds. including the waterfowl. cranes, rails: gallinules. shore birds. doves and pigeons, were to be protected between March 10 and September 1, and migratory insectivorous birds. as well as other migratory nongame birds, at all times. The Mexican treaty, ratified in 1937, not only provided the same protection as the treaty with Great Britain but extended it to families of birds not included in the earlier convention and also contained provisions for control of the transportation of game mammals across the international boundary.

These two treaties provided the backbone of the program of protection of the migratory birds which inhabit two or more of the three countries at some time of the year. The Migratory Bird Treaty act, which implemented both treaties: closed the season on all birds protected by either treaty. The regulations promulgated thereunder established the open seasons and bag limits. The act also charged the secretary of the interior with making certain investigations into the abundance. distribution and migration of these birds, in relation to the zones of temperature and other conditions. If, after making these investigations, it appeared that there were enough of the game species to permit an open season, the secretary was authorized to open it for as long a period as he deemed wise, but not exceeding 3½ months.

This branch was charged with the responsibility of enforcing these regulations and also with looking after the welfare of the birds during the closed seasons. This involves such diversified activities as breaking up marketing and trafficking in birds, seeing that feed is provided where extraordinary conditions have reduced the natural supply, checking reports of damage to crops by migratory birds and applying corrective measures where necessary. As a part of its game-management work this branch conducts extensive surveys of wintering and breeding-ground populations. This information is developed by a wide co-operative program with the Canadian wildlife service and provincial game authorities, the states and with numerous private organizations and individuals. This information is used as a basis for regulating the length of the hunting seasons and for considering changes in other regulations.

The branch of game management issues permits to propagate wild waterfowl for food and restocking, to collect migratory birds for scientific purposes, to import foreign wild birds and animals into the United States. and to control migratory birds destructive to crops and other property.

The Lacey act passed in 1900, provided the first law-enforcement tasks for the biological survey, one of the predecessors of the fish and wildlife service. The act, in brief. and as amended, regulated the importation of wild animals and made it a federal offense to ship game or fur animals or parts thereof, illegally taken, possessed, sold or shipped in one state out of that state and into another. This act proved of tremendous assistance in breaking up market hunting, as well as in running down groups and individuals engaged in illegal traffic in furs. It was particularly useful in checking contraband trade in beavers and to a certain extent that in other furbearers.

The Alaska Game law, passed in 1925, created an Alaska game commission, the executive officer of which was the principal representative of the service in Alaska. It provided for commissioners from the four judicial districts in Alaska to sit with the service representative and to recommend to the secretary such regulations as might be necessary to protect the game and fur resources of the territory. Certain game fishes were added when the act was amended in 1943.

The Migratory Waterfowl Hunting Stamp act, popularly known as the Duck stamp act, passed in 1934, as amended. provided that everyone over 16 years of age who hunted migratory waterfowl must have a stamp costing $2 00. These are sold through the post office and the funds received are made available to the service. Fifteen per cent of these funds might be allowed for administration to cover the actual cost of printing and distributing the stamps and for enforcement of the act. Under the law, not less than 85% of the funds had to be used for the acquisition and maintenance of a system of refuges for waterfowl. The law was of material help in developing the great refuge system for the waterfowl population as it travels the flyways.

The Bald Eagle act, passed in 1940, protected the bald or American eagle, the U.S. national emblem, and charged the service with the enforcement of the act.

Wildlife Refuges.—This branch administers the national systetn of nildlife refuges. In 1954 there were 272 refuges embracing an aggregate of 17,409,968 ac.

The refuge program dates back to 1903, when Pres. Theodore Roosevelt, by executive order, designated Pelican Island on the east coast of Florida as a national wildlife refuge for the purpose of protecting breeding colonies of brown pelicans and assigned it to the bureau of biological survey for administration. There was no money for instituting a patrol, and protection was furnished for several years by the National Audubon society.

From this small beginning, the refuge system grew slowly as the result of various congressional acts. Four refuges were established by special legislation: the National Bison range. Montana, 1908, the Elk refuge Wyoming, 1912; the Cpper Mississippi River wildlife and fish refuge, Iowa, Illinois, Minnesota and Wisconsin, 1924; and the Bear River migratory bird refuge, Utah, 1928. An additional reservation, the Wichita Mountains wildlife refuge, Oklahoma, was established as a result of a special act of Jan. 24. 1905, permitting the president to set up forest preserves and game refuges. It was maintained by the forest service until 1935, when it was transferred to the fish and nildhfe service as a part of the national refuge system.

The American Bison society became alarmed at the serious threat of the extermination of the American bison or buffalo, and in 1907 inaugurated a campaign for the establishment of several government herds of these animals at widely separated points to assure the perpetuation of the species. The Wichita refuge herd was the first one established, to be followed later by those on the National bison range in Montana and the Niobrara refuge in Nebraska. Another special refuge is the National elk refuge at Jackson Hole! Wyo., for the winter care of the southern Yellowstone elk herd.

Various other refuges were established on public lands. many of them consisting only of small islands frequented by colonies of sea birds. The modern refuge system maintained by the service is based on the Norbeck-Andresen act, passed Feb. 18. 1929, commonly called the Migratory Bird Conservation act, which authorized the establishment of a nation-wide system of inviolate refuges and appropriation of funds for their acquisition and maintenance. Refuges were classified in four general groups: special-purpose refuges, largely for colonial nongame birds; big-game refuges; migratory waterfowl refuges; and general wildlife refuges.

Special-purpose refuges are usually created for the protection of a single colony or group of colonies of birds or mammals. They may also be for the protection of a single species. These refuges are mostly small and are usually composed of small islands, either in fresh-water lakes or along the coast. The principal types of birds for which these refuges furnish protection are herons, ibises, pelicans, gulls, terns, skimmers, auklets, murrelets, puffins, murres, shearwaters, fulmars. petrels and cormorants, although incidentally they may protect equally interesting associated species.

The big-game refuges and game refuges are for the primary purpose of protecting herds of big-game animals. Bison, antelope. mountain sheep and elk are the principal species on these refuges but deer and many other mammals are found on one or more.

Migratory waterfowl refuges provide breeding, feeding and nesting grounds for the birds as they pass through or reside within this country. Breeding ground refuges are developed and maintained in the northern states to furnish suitable nesting and feeding grounds to care for the young birds until they are on the wing. These refuges also produce food for transient birds in the fall and spring migrations. Wintering refuges are equally necessary to provide an adequate supply of food for waterfo l during the approximate half of the year when they are away from the breeding grounds. Refuges are provided also along the major migration lines as an aid in safeguarding the birds during their entire life cycle. In addition, there is considerable waterfowl usage of other types of refuges.

General wildlife refuges are comparatively few in number and have been set aside usually to protect areas that are especially significant for the combination of wildlife forms found there. Most important is the Aleutian Islands refuge which protects many varieties of sea birds, arctic foxes and the only remaining large colonies of the sea otter.

Predator and Rodent Control. — This branch carries on such predator and rodent control as may be necessary upon federal lands. In early days of the work, operations were entirely in the western United States, where there is a large percentage of the public domain. The enactment of additional laws and the development of new problems spread the activities of the branch into nearly every state in the union, although most of the operations continued to be carried on in the western range states and in Texas, Oklahoma, Arkansas, Missouri, Nebraska and the Dakotas.

Among the wildlife forms that have become most destructive are various species of rodents and certain predatory forms. The major rodent problems, aside from those occasioned by the introduced house rats and mice, developed in the western states, where green-vegetable and orchard farming and the growing of alfalfa and grains increased greatly the food supplies available to rodents.

As most of the farming in the west is in small areas surrounded by comparatively large acreages of public domain. the federal government was early called upon to co-operate in controlling the numbers of destructive animals. Ground squirrels, prairie dogs, pocket gophers and jack rabbits, in general, do most of the damage. although locally others may be of considerable importance. All these species are the objects of control projects carried on by state and local agencies in co-operation with the fish and wildlife service.

Various methods are used to reduce the numbers of the destructive forms and to hold them to levels at which the damage is not too great. Such control projects tend to develop and recede more or less in proportion to the abundance of rodents. Some species, especially rabbits, hares and field mice, exhibit cyclic phenomena, their populations tending to go up and down at comparatively regular intervals. Their numbers also respond locally to weather conditions. For example. ground squirrels and pocket gophers often are more successful in rearing a large percentage of their young during dry, warm springs than they are if the weather is cold and wet. As most control projects are designed merely to hold down the populations of species to the point where damage is nominal, once that point is reached, there tends to be relaxation of effort and the animals again increase to the point where damage becomes severe.

In addition to these western problems, there are numerous infestations of destructive mammals, which though smaller in geographical extent are equally important to the agriculturalists concerned. Most important are those of pine and meadow mice which girdle and destroy fruit trees in the orchard sections. Particularly intensive problems in this respect have developed in certain parts of New England, New York state, and the Shenandoah valley of Virginia.

The relationship of wild mammals to human disease became of increasing importance. Rodents of various types are carriers of diseases which can be transmitted to humans by ticks. fleas and other insects. Among such diseases the most serious are Rocky Mountain spotted fever, transmitted by ticks, and bubonic plague. by fleas. So far as was known by the 1950s, spotted fever is endemic among native rodents, and while it first came to attention in the Bitter Root valley of Montana, it was known to be carried by rodents in numerous localities in the west and also in some eastern areas. Bubonic plague was discovered among native rodents in California where for many years it seemed confined to coastal cities from San Francisco to Los Angeles, but later it was found among rodent populations in every western state. This spread fortunately was not accompanied by transmission of the disease to humans on an extensive scale, but there were a number of minor outbreaks. The situation, however, furnished an additional strong incentive for drastic control of the plague-carrying animals.

The predatory animal against which most effort is directed is the coyote; much attention is also given to the control of wildcats, mountain lions, wolves and bears. Since bears are regarded as game animals, the service limited its operations to taking individuals known to be stock killers or operated less selectively in areas where losses caused by bears were excessive.

These control operations are carried on in co-operation with many states and local agencies, which put approximately twice as much money into the predator programs as the federal government. Vast areas of public land in the western states furnish a breeding ground for these animals, and the federal government assists in holding don-n their numbers in areas where they occasion economic loss. The principal damage is to sheep and poultry, particularly in localities where they are raised in great numbers. In some localities losses of calves also are serious. There are also areas where predations on deer or other game stocks become so severe as to call for predator control.

Methods used include trapping, den hunting and destruction of the young. shooting and poisoning, the last being used under very rigid restrictions both as to locality and the types of poison. The work was successful in holding down the number of predators to a level where losses were considerably reduced.

FISHERIES

Fisheries Research. — The branch of fisheries research concerns itself with the Life history, habits and interrelationships of fish populations. It devotes a major part of its effort to studying the effect of commercial fishing on these populations and to acquiring adequate knowledge of interrelationships of various species of fish to each other, to other animal life and to the environment. This knowledge is necessary to provide a basis for adequate and intelligent management of this important natural resource. The fish and wildlife service has among its other duties the administration of the commercial fisheries of Alaska. Their chief value is in the salmon industry, and this division devotes a considerable proportion of its time to assembling information on the movements of the salmon, their spawning success and various other factors upon which are based to a large degree the regulations governing the Alaska fishery. The branch established at Little Port Walter a laboratory devoted entirely to work on the pink salmon. Similar but less extensive studies on red salmon were carried out at Karluk on Kodiak Island and at Brooks lake on the Alaska peninsula. These surveys furnish indexes for more accurate regulation of the fishery, both in the interests of maintaining an adequate spawning stock and in permitting the greatest practicable utilization of the runs.

Within the rest of the United States, the fish and wildlife service was given no regulatory control of fisheries, but from time to time congress awarded it special appropriations for studies of important fisheries. Extensive investigations into the Sew England ground fisheries, the most important single source of fresh and frozen fish in the country, also were carried on. Particular attention was paid to the cod and haddock, which are the historical basis of these fisheries and supply an enormous tonnage of fish. Special studies of oysters, crabs and other shellfish have also been conducted on both coasts. Oyster farming developed to a considerable extent, and with it arose many problems. Laboratories for studies of these problems were maintained at Milford, Conn.; Beaufort. N.C.; and Pensacola, Fla. Investigations of crabs were largely confined to Chesapeake bay, the source of most of the crabs on eastern markets. Investigators endeavoured to determine the reason for a decline in the production and to devise practical remedies for bringing the industry back to its former level. Studies on the Great Lakes were largely centred in the 1950s around the sea lamprey and methods for controlling its numbers. As a result of these studies, a joint control project by the United States and Canada was undertaken.

Angling. — The branch concerns itself also with problems involving sport fishing, a great source of recreation in streams, lakes and coastal waters. These studies revolve around three general problems, of which the most important undoubtedly is pollution. They seek to determine the types of pollution that are most destructive to fish life and what can be done to control them. It has been learned that certain pollutants which are dangerous to public health are not destructive to fish life, and, conversely, some which are not objectionable in relation to public health are great menaces to fish and other aquatic life.

The second most important subject of study in relation to angling is that of stream and lake management and improvement. There has been growing appreciation of the fact that waters can be rendered unproductive from many causes, just as land can be made unproductive, and that they are equally susceptible to improvement. The devices which have been used in stream management have been dams or partial dams, deflectors and other devices to create good spawning areas or good living conditions for the fish, or to remedy some of the ill effects of silting, stream channellization, construction of dams and other human interference with the stream. Improvement devices are not used so widely in natural lakes, but artificial impoundments and reservoirs can often be made more productive of fish life.

The third general subject with which this division concerns itself in dealing with sport fishing is the improvement of feeding and handling of fish in hatcheries and studies of diseases and parasites which often become more prevalent in hatcheries than under natural conditions.

Commercial Fisheries. — The branch of commercial fisheries also is largely a research and information collecting agency with no regulatory authority. An important part of its efforts was devoted to improving methods of canning or otherwise preserving fish and fishery products. Included in this work are studies to develop new medicinal, industrial and edible products from fishery resources. This division has been active in developing methods of extracting and testing vitamin-A oils and in finding new sources of this vitamin. It also is interested in developing industrial products from fishery wastes: having, for example, devoted much effort to devising economic and practical methods of utilizing wastes in the salmon-canning industry. It perfected canning processes and other preserving methods which make it possible to use fishes of kinds not previously marketable, thus opening new sources of food for the public. The division devotes considerable time to improving the methods of handling and transporting fish. Fish is a highly perishable product: and the chief drawback to its greater utilization, particularly inland, has been the poor condition in which it often reaches the consumer. Proper methods for packaging. preserving and handling the fish were thus studied by the branch.

Another general type of investigation by this branch relates to the improvement of fishing gear, vessels and methods. Efforts were directed toward the development of types of vessels for employment in the shrimp fishery and conversion for off-season use in some other food fishery or in the menhaden industry.

It operates several boats for finding and marking out new fishing waters. This work proved successful in extending commercial fishery operations into a number of new areas.

Studies also are made of the economic factors that affect the fisheries, including the processing and sale of fishery products. These include cost of transportation and of handling; competition with other foodstuffs; relative prices of fishery and other products; and numerous other factors directly affecting the welfare and productivity of the fishery industries. Means are also sought to develop and increase markets for domestic fishery products.

In connection with these studies. the division maintains a statistical section and conducts a fishery market news service which reports the daily landings. movements and sales of fish at many of the more important ports. The statistical section assembles and distributes information on the annual catch of fish and its value, employment. in the industry, gear and vessels operated and the volume and value of manufactured products. The fishery market news reports and the statistical data are widely used by the industry in day-to-day operations. They also furnish material which federal and state research units find essential for carrying on their programs.

Game Fish and Hatcheries. — This branch operated 92 fish hatcheries in the mid-1950s scattered throughout the United States. Hatcheries for trout and bass and other warm-water fishes are operated particularly for the purpose of stocking sport-fishing waters with game fish. In planting fish produced by these hatcheries, preference is given to stocking waters on federally owned land—a direct responsibility of the federal government. For this reason, priority was given to streams and lakes on national forests, national parks, wildlife reiuges and other public lands. In states having fish hatcheries in addition to the federal ones. co-operative arrangements are made so that the cost of hauling and liberating fish is reduced to a minimum, and hatcheries supply waters closest to them whether or not on federally owned land. In this way maximum results are obtained from both federal and state operations.

For trout propagation, a copious supply of cool water is essential; consequently, most of the trout hatcheries are located where spring or mountain-stream water of the right temperature and quantity is available. The original system of planting newly hatched fry was later largely replaced by a program of planting larger fish. In many instances best returns are obtained by planting trout 6 to 8 in. or more in length. This has been particularly true in the eastern states and in waters close to heavily populated centres where it is possible to grow enough fish to meet the fishing demand and where pollution or siltation of spawning beds may prevent natural reproduction, but where neither oi these detriments have progressed to the point where large trout cannot survive.

Warm-water fish hatcheries produce larger quantities of bass, bream, crappies and a smaller number of other types of fishes. These are planted in streams and lakes where water temperatures and food conditions are not suitable for trout. Much of the output has gone into ponds and lakes which have been impounded as a result of the activities of the soil conservation service and other agencies interested in developing a proper system of water control on stream headwaters. As a result of these operations, there arc now many thousands of such ponds affording good fishing to people in their localities. It is also a regular practice to stock impounded waters on wildlife refuges with the types of fishes most suitable to them.

Increasing attention is given to the productive capacity of the streams and lakes to be planted. Many states, and as far as possible the iederal service, conducted stream and lake surveys to learn the fish-food-producing capacity of those waters and consequently their carrying capacities for fish liie. It is now generally understood that any body of water in a certain stage of development can produce only so many pounds of fish. The maximum may be produced either as a great number of small individuals or as a much smaller number of large ones. Before this was generally known, many waters were overstocked rather than understocked, particularly with warm-water fishes

There are a number of federal hatcheries producing fish for commercial exploitation, the most important of which are the salmon hatcheries of the Pacific coast. The development of hydroelectric power and irrigation on such rivers as the Columbia and Sacramento created tremendous problems for those interested in maintaining the salmon runs. Development of Bonneville dam in Oregon and Grand Coulee dam in Washington, as well as other projected dams, threatened to destroy a large part of the Columbia river run. After careful studies, ladders were installed in Bonneville dam and successfully operated in getting the fish over the dam on the upstream migration. The Grand Coulee dam was so high that it seemed impracticable to build fish ladders, over it, and an alternate scheme oi taking care of a part of the run that iormerly spawned in the Columbia and its tributaries above this dam was developed.

The salmon that came to the Rock Island dam, a private dam some distance below Grand Coulee, were trapped and taken to hatcheries which were built by the reclamation service for this use, where they were spawned and the fish hatched and planted in streams which formerly had no salmon runs. Part of the adults were planted directly in streams to spawn naturally and held there by means of weirs which prevented them from going downstream and again seeking the old spawning grounds.

The continued development of dams on the Columbia led to the inauguration of an intensive program of developing the salmon runs in the tributaries below Bonneville dam. This was an effort to maintain the salmon runs in the lower Columbia to offset the adverse effect oi more dams above that point.

A shad hatchery on the Potomac river just below Washington, D.C., successiully hatched shad and released them. There was great difficulty, however, in determining the success of this operation because the young shad are so delicate that they can neither be handled nor marked as is usually done with salmon, trout and other species.

Another interesting development has been the effort to hatch and artificially rear young lobsters. These are free-swimming and surface-moving animals during the first four stages of their life, and at this time the greatest mortality among them occurs. The first attempts to raise young lobsters in captivity were not successful because some immediately proceeded to eat their fellows. Later they were handled more successfully by placing them in circular tanks in which strong jets of water run continually, keeping the young lobsters on the move and preventing them irom coming into close contact with each other.

Alaska Fisheries.—The branch of Alaska fisheries was charged with two primary assignments—the administration of the law which controls the commercial fisheries in Alaska, and the protection, care and handling of the fur seal herd on the Pribilof Islands. The service was made responsible for recommending regulations which will maintain the productivity of the fisheries. Careiul check is maintained upon the catch, both by personnel of the Alaska division and the division of fishery biology. Observations are made on the spawning escapement and the success of spawning of the various runs of fish.

The making of intelligent and effective regulations is greatly complicated by the fact that five species of salmon are involved, having liie cycles varying from two to five years. Since all of these fishes leave the sea to spawn and then die, the'adjustment of the take to the probable return of each kind to iresh water is difficult.

The fish and wildlife service also eniorces the Alaska fisheries regulations, for which purpose it maintains a fleet of boats and planes for the use of patrol officers. Fisheries are the greatest single resource of the territory, the salmon fishery alone yielding products of an average annual manufactured value for the five-year period ending in 1953 of more than $80,000,000, and producing more than half the income of the territorial government. Other fisheries, however, were growing in importance.

Next to the salmon, the herring fishery has been the greatest single industry administered by the Alaska fisheries branch. It has had a wide fluctuation in production, largely because of the erratic spawning success of the herring populations. These fish normally entrr the fishery three years aiter hatching, and a successiul year class usually furnishes the bulk of the catch for a period of several years. Additional Alaskan fisheries include those ior halibut, sablefish, cod, shrimp and clams. A study of the king crab carried out just before World War II indicated the presence of a sufficient number to justify the development of a U.S. crab-packing industry. Methods were worked out and activities begun in producing canned crabs.

The natives of the Pribilof Islands engage primarily in the harvesting of the seals for the government. receiving a stipulated amount for each skin preserved. They engage also in winter trapping of foxes for which they receive compensation. The iederal government provides medical, dental and school facilities and furnishes housing, fuel, food and clothing In addition, the natives operate a canteen on each island, stocking foodstuffs and other articles. The islands were uninhabited until the Russians took a number of Aleuts there; the modern population is largely a mixture of Aleut and Russian, with some other nationalities intermingled

The fish and wildlife service vessel "Penguin" makes regular trips from Seattle. Wash, to the Pribilof Islands, 2,000 mi, distant in the Bering sea, to transport supplies and personnel.

See also WILDLIFE CONSERVATION; FISHERIES; NATIONAL PARKS AND NATURE RESERVES. (I. N. G.)

FISH COOKERY. The term fish includes many water animals which are classed as "sea food" (*e.g.*, crabs. shrimps, lobsters, turtles, oysters. frogs) besides fish proper. Fish is sold whole. dressed. salted. dried, canned. frozen or alive. It is generally a cheap and wholesome source of nitrogenous food, though compared with meat, bulk for bulk, fish contains more water and refuse. There are three main classes of fish: oily, containing fatty oil dispersed throughout the flesh; white or nonoily (lean), containing oil secreted in the liver; and shellfish. Examples of oily fish are salmon and herring; flat fish and turbot belong to the lean kinds, while the shellfish include lobsters, crab, oysters and clams. Because of the shortness and flakiness of the muscle fibres, fish, with the exception of some shellfish, is easily digested, and should be eaten with vinegar or some form of acid. Oily fish are more nourishing than lean kinds but less easily digested and are best grilled or cooked by dry methods. Lean fish are usually supplemented by sauces, etc.

Preparation of Fish for Cooking.—Fresh fish should be scaled and cleaned. In skinning round fish, proceed from head to tail, and reverse for flat fish. To fillet flat fish place on a board, grasp the tail firmly with fingers dipped in salt (to prevent slipping) and cut an incision just above the tail. Slip the knife under the flesh and raise it gently, at the same time loosening the skin with the thumb and forefinger of the left hand. Round fish may be baked and stuffed. All trimmings should be placed in a pan and covered with water to make fish stock for sauces. Roes in large fish should be removed, cooked separately and served as savouries on toast.

Methods of Cooking Fish.—There are many ways of cooking fish. Boiling is the simplest. though the least nourishing, as much of the flavouring juices is lost. This method of cooking is suitable ior large. round fish or for thick pieces. The water should simmer, not boil. and only enough used to cover the fish. Sea water is excellent ior boiling sweet fish. Add lemon juice or vinegar to the water to keep the fish white and firm and add salt unless it is a salt fish. Boiling is the best method for cooking salt fish. Tasteless fish requires additional spices and flavourings added to the water. Allow five minutes to the pound for thin fish, ten minutes or more for larger fish. Steaming is better than boiling but takes a little longer. Small fillets of fish may be steamed on an oiled plate over a pan of boiling water. Sprinkle fish with lemon juice to keep the flesh white. Steaming is useful in fish cookery for invalids.

Certain fish are best baked and stuffed or baked au *naturel*. Fish may also be baked in a tin with spices and butter or in milk. Paper bags (oiled) are excellent for baking fish. Truss whole fish before baking. Broiling or grilling is suitable for oily fish, which should be placed on a greased gridiron. If thick, split the fish down the centre and grill the flesh side first. Remove head and tail for grilling. Planked fish is grilled and served on a board made for the purpose. Frying is one of the most popular methods of cooking lean fish and may take the form of frying in a bath of boiling fat or pan frying in a shallow pan. Oil is better than any other fat for frying fish, as it keeps the colour a clear golden brown. All fish that is fried must be perfectly dry. It can be served with a sauce, but this is not necessary unless the fish is fried in batter. Certain kinds of fish are tasty if stewed in the form of a *souchy* (in the United States, chowder); *i.e.*, slices of fish simmered in broth with vegetables and spices. A bouillabaisse is a special dish much eaten on the European continent and consists of a stew or chowder of several kinds of fish.

In cooking shellfish other than crabs and lobsters, be very careful not to boil them, as they then become tough. Periwinkles, snails, etc., are served *au naturel* with butter and chopped parsley. Raw oysters and clams may be served in their shells with accompaniments of vinegar, lemon, red pepper and various other relishes.

Sauces for fish are (1) those with a water white sauce (drawn butter sauce) or a fish stock white sauce as a foundation; (2) those with melted butter as a foundation; (3) those with mayonnaise, Hollandaise or other butter-egg yolk sauces. Sharp ingredients, such as capers, horseradish and pickles, are often added.

Roe.—This is a spawn or milt of fish. In the case of large fish the roe is removed and prepared for table separately in various ways. Soft roes, such as herring, etc., are served on toast as a savoury.

Shad roe is a delicacy in the United States. Hard roes. such as cod roes, are frequently dipped in batter and fried in deep fat. Caviar, sturgeon roes (salted), is served plain on sippets of bread and butter as hors d'oeuvres. *(See* also FOOD PREPARATION.)

FISH CULTURE in the broad sense can be considered a branch of animal husbandry, if the latter term is used to include both the rearing of domestic animals and the harvesting and management of wild game. The maintenance of fish indoors in aquariums is treated under AQUARIUM. This article, concerned with the culture of fish for food and sport, is divided into the following sections:

- I. Growing Fish for Consumption
  - 1. Pond-Fish Culture in Temperate Climates
  - 2. Tropical Pond Culture
  - 3. Brackish-Water Pond Culture
- II. Stocking Open Waters
  - 1. Release of Fry
  - 2. Release of Fingerlings and Larger Fish
  - 3. Rearing Warm-Water Fishes for Distribution
  - 4. Introduction of Yew Species
- III. Improvement of the Habitat
  - 1. Changes in Lakes and Streams
  - 2. Fish Passes and Screens
  - 3. Reduction of Mortality From Predation
- IV. Regulation of Fishing for Best Yield
  - 1. Best Exploitation of Existing Stock
  - 2. Obtaining Maximum Recruitment

I. GROWING FISH FOR CONSUMPTION

1. Pond-Fish Culture in Temperate Climates.—The most widely used fishes in pond culture are those of the great cyprinid or carp family, which is dominant throughout tropical and temperate Eurasia. In Europe the carp (*Cyprinus carpio*) is by far the most popular species because of its hardiness, its unfastidious food requirements and the relative ease with which its fry can be reared. As with other domesticated animals. several recognized varieties of carp have been bred by selection for such qualities as rapid growth, plumpness and resistance to disease. Moderate production can be achieved by maintaining carp as a wild population cropped annually. Much better yields are obtained by having specially designed brood ponds where the adults spawn. Young fry are removed at an early age and transported to nursery ponds in which suitable small foods are cultured or supplied. Later they are placed in the large rearing ponds, in numbers computed to give best yield. The fish are harvested after one. two or three years' growth, depending on the fertility and temperature of the pond, the length of the growing season and the density of stocking. Ponds should be fertilized to promote growth of animal foods for the carp; manure is excellent and even chopped vegetation is useful. Near time of marketing, the fish may be fattened by feeding coarse grains.

In continental Europe carp culture is widely distributed. but it is best developed in the central region, above all in Czechoslovakia, which has no sea fisheries. Fishponds were maintained in England during the middle ages, but have been largely abandoned.

Other species of fishes are sometimes reared in European fishponds. either intentionally or because they enter accidentally with the water supply. Among these are such cyprinids as the tench *(Tinca tinca)*, bream (*Abramis brama*), rudd *(Scardinius erythrophthalmus)*, roach (*Leuciscus [Rutilus] rutilus*) and ide *(L. [Idus] idus)*. These are useful only under special conditions—for example, the tench can survive very Ion-oxygen conditions, the rudd consumes a good deal of vegetation and so on. Only the tench compares in value with the carp, but it grows much more slowly. A noncyprinid fish of some importance in pond cultures is the pike *(Esox lucius)*; it sells well, and because of its predacious habits can be used to reduce the numbers of cyprinid fry when these are for any reason excessive. The perch *(Perca fluviatilis)*, sander *(Lucioperca lucioperca)* and the largemouth bass (*Micropterus salmoides)* have been used for the same purpose.

For centuries in Asia carp and crucian carp (*Carassius carassius)* as well as other species have been extensively used. The Chinese make much use of several cyprinids which are rarely bred artificially. Instead, fry about a third of an inch long are taken in fine nets from the large rivers and reared in small ponds until the various kinds can be sorted out. Then they are distributed to ponds and lakes over considerable distances. The most useful species are four. The grass carp or *huan yu* (*Ctenopharyngodon idellus*) is one of the few fishes which consume pondweeds and coarse vegetation. The fathead or *lien yu (Hypopthtalmichthys molitrix*) is valuable because it feeds largely on phytoplankton, the microscopic algae which produce green blooms in fertile waters. The *ching yu* (*Mylopharyngodon piceus*), the black amur of the Russians. has heavy grinding teeth in its throat and favours clams and snails as a diet. *Aristichthys nobilis* consumes zooplankton—the cladocerans, copepods and other small animals that live suspended in the water.

Along the Yangtze river alone there are about 1,800 shallow flood-plain lakes, totaling 8,000,000 ac., which are to varying degrees controlled for fish rearing, using combinations of these four noncompeting species. Each species also may be used separately, or two or more in rotation, depending on the nature and condition of the pond. For example, a pond full of weeds provides excellent food for grass carp for a season; when these are cropped down, a bloom of phytoplankton will probably develop, followed by abundant zooplankton—each of which can be used by the appropriate species.

In India similar use is made of wild cyprinid fry from rivers, especially in Bengal, Bihar and Orissa. Among the most used species are the catla (*Catla catla*), mrigal *(Cirrhina mrigala)* and rohu *(Labeo rohita)*, but several other species of *Labeo* and *Cirrhina* are also taken. Little exact information is available concerning these fisheries; they tend to be family affairs whose methods of operation are kept confidential. Certain fishery establishments having large catchment areas, called *bundhs*, are able to produce fry of these Indian cyprinids successfully.

Japan has an extensive pond culture which produced 5,700 tons each of carp and eels *(Anguilla* species) in 1957. Israeli ponds produced *7,600* tons, Formosa 9,700 tons; but none of the really large pond-fish countries report pond-fish statistics separately from wild fresh-water fish.

Rearing trout for market is a somewhat different industry; the fry, hatched artificially, require cool running water and must be fed. The most popular species is the rainbow trout *(Salmo gairdneri*), but brown trout (*S. trutta)* and the American brook trout (*Salvelinus fontinalis*) are also used. Horse meat. slaughterhouse wastes and scrap fish are used for feeding. Biggest producers are the United States. Denmark and Japan. Japan and Formosa also raise quantities of the tasty ayu or sweetfish *(Plecoglossus altivelis*), a salmonid which feeds on plankton and filamentous algae.

Trout fed on the various foods listed above do not, generally speaking, acquire the delicate flavour of wild trout, so as the time for marketing approaches the trout are given special diets or, if possible, a sojourn of a few weeks in ponds containing natural foods.

2. Tropical Pond Culture.—In the tropics large-scale pond-fish culture is complicated by high temperatures, rapid decomposition and rapid growth of floating vegetation, all of which make it difficult to keep a proper supply of oxygen in a pond. Particularly in Thailand, extensive use is made of air-breathing fishes on that account, for example, the gourami (*Osphronemus goramy)* and the murrel or snakehead (*Ophicephalus* species). Indonesia, particularly Java, has many ponds raising carp; crucian carp; a native cyprinid, tawes (*Puntius javanicus*); a catfish, lélé *(Clarius batra-*

chus); and air breathers. In the Celebes some use is made of Chinese cyprinids whose fry are imported annually—especially the grass carp.

A notable development in tropical pond-fish culture has been increased use of species of *Tilapia*—called mouthbreeders because in some species the female incubates the eggs and carries the young in her mouth. This genus may actually be the oldest object of pond culture: Pierre Chimits has published an illustration of a bas-relief from a tomb antedating zooo B.C. that shows an Egyptian angling for T. nilotica from an artificial pond. Extensive modern use of *Tilapia* began in the Belgian Congo during the 1940s, using T. *melanopleura* and T. macrochir. The most popular species has been T. *mossambica,* widely introduced throughout east Asia and Oceania and in some West Indian islands. This species breeds readily, grows rapidly, tolerates salt water and low oxygen and includes much detritus and algae in its diet.

A rapidly developing branch of tropical and warm-temperate fish culture is the use of rice fields for growing fish. Most rice paddies produce a few nild fish, grown from fry brought in with the irrigation water. By suitable stocking and fertilizing large yields can be obtained from various carps or Tilapia, but some strengthening of the dikes and provision of channels in the fields is recommended. Effects on the rice crop are variously estimated from a small decrease to a slight gain in yield. The potential fish production of the world's rice fields is enormous, and it is available mostly in regions where fish are the accepted major protein of the human diet.

3. Brackish-Water Pond Culture.— River deltas and other marshy areas are sometimes developed into fish-rearing establishments, for example, in southern France, along the upper Adriatic coast of Italy, in India, Indonesia, Formosa, the Philippines. Japan and Hawaii. Most of the fishes used are of marine origin; they breed in the sea, but the young seek brackish or even fresh water. Mullets (*Mugil cephalus* and others) are widely used, eels are popular in southern Europe, as are the gilthead (*Sparus* auratus) and sea bass (Morone labrax). In tropical countries the milkfish (*Chanos chanos*), called *bandeng* or *bangos,* is most popular, along with mullets, the Javan tawes, the ten-pounder (*Elops* saurus) and *Tilapia.* Shrimps and prawns are frequently important by-products, as are adventitious fish like the kakap (*Lates calcarifer*).

In a simple form of brackish-water culture, such as some of the Adriatic *valli,* the ponds are little more than natural salt marshes with channels to the sea closed off by a dike and gate. At appropriate seasons gates are opened and young fish are carried in by the tide. From this type of fishpond there are all gradations up to the extensive *tambaks* of Java, laboriously reclaimed from mangrove swamps and stocked with imported milkfish fingerlings. Tanrhaks are typically 1½ ft. deep; their salinity varies, with the site and season, down to almost completely fresh water. The principal food of milkfish in these ponds is algae, especially the blue-green *Oscillatoria,* giving a direct conversion from vegetable base to useful protein. Other species are used partly because the supply of milkfish is inadequate, partly for their own sake: tawes consumes large amounts of vegetation and may improve milkfish production, while Tilapia helps to control malarial mosquitoes by removing floating algae. About 33,000,000 lb. yearly of fish and shrimps are produced from 200,000 ac. of ponds in Java; the Philippines have 175,000 ac.

The only example of brackish-water culture on a large scale in cool-temperate regions is carried out in Jutland, Den. Each year young plaice (*Pleuronectes* platessa) are caught at sea and transported to the inner expanses of the Limfiord, where they grow rapidly and provide a good harvest.

II. STOCKING OPEN WATERS

1. Release of Fry.—In the natural reproduction of salmonid fishes (salmon and trout), the eggs are buried by the female up to a foot or more deep in gravel nests or redds. During the 1850s it became a popular practice, in Europe, America and the Antipodes, to remove eggs and milt (sex glands containing semen) from mature trout and salmon and hatch them artificially. In the usual dry or Russian method, eggs and milt are squeezed into a pan, stirred gently and allowed to stand for several minutes, then washed. Rate of development depends on temperature. It is measured in degree-days, that is, the sum of successive days' water temperatures on the centigrade scale. After about 200 degree-days the embryo is recognizable inside the shell, and the eggs are said to be eyed. Three hundred degree-days or so later the eggs hatch, the released fry, or alevins, being delicate creatures with the large yolk sac of the egg still attached. Finally, 800 to 1,000 degree-days after fertilization, the remaining yolk is absorbed into the abdomen and the young fish are called fingerlings. In nature, they then emerge from the gravel and begin feeding.

In the early days of salmonid culture, eggs were held in perforated boxes floating in a stream until the fry were ready for liberation. Later, special troughs supplied with running water were built to hold the eggs, and these were soon installed indoors. To increase their holding capacity the troughs were deepened and provided with removable screen baskets to hold the eggs; double baffles divided the trough into compartments and directed the water from below upward through the eggs in each basket. A newer method is to stack perforated trays containing eggs vertically in layers three or four deep in a special frame so that the water is fed by gravity down the stack but up through each tray. This arrangement permits a great saving of floor space in the hatchery building. Care of the eggs has been simplified by the regular application of malachite green, a fungicide which controls the once-dreaded *Saprolegnia.* Previously this fungus, spreading from a few dead eggs, would quickly blanket and kill a whole basket unless checked by laborious picking.

In traditional salmonid culture the fry were hatched and held in the troughs, to be liberated in natural waters after the yolk sac was absorbed. The reasoning was that fertilization of fish eggs in nature must be extremely haphazard, scarcely exceeding 5% efficiency, whereas with artificial fertilization it commonly exceeds 95%. If the eggs were further protected from flood, drought and enemies during the incubation period, it was assumed that the greater part of the mortality of the normal life history would be circumvented. A very few spawners should suffice to maintain a very large body of fish, and all fears of overfishing could be set aside. So plausible did this seem that the various assumptions involved were not tested individually for many decades.

From its beginnings with salmon and trout (Oncorhynchus and *Salmo* species), artificial spawning and hatching were quickly extended to other fresh-water and anadromous fishes (sea dwellers who ascend rivers to spawn). Even ripe sturgeon eggs (Acipenser species), usually slated for processing to caviar, were cultured. The small eggs of whitefish (Coregonus *clupeaformis*), shad (Alosa *sapidissima*) or walleye (*Stizostedion* vitreum) were incubated in special glass jars of about 1½ gal. capacity, the water rising gently through the egg mass. Many hundreds of millions of eggs of these species were reared annually in hatcheries throughout the United States and Canada. Similar procedures were applied to marine fishes like cod (*Gadus* morrhua) and plaice, particularly in the North sea region, Maine and Newfoundland, though there was greater difficulty in handling their buoyant eggs.

These intensive efforts to increase natural fish stocks were on the whole extremely disappointing. The expected large increases in production simply were not realized and direct tests were undertaken to determine the cause of the low yield. For production of marine fishes the most conclusive tests were those of Gunder Dannevig in Norway, who compared a series of four fiords alternately stocked and not stocked with cod fry. The number of young cod produced in them was independent of whether they received hatchery fry or not. Similar results were obtained in experiments with plaice in Loch Fyne by Thomas Fulton. with uhitefish in the Great Lakes by John Van Oosten, and elsewhere. In other experiments some advantage of liberating fry was demonstrated, but at a level far below original expectations. For example, in a 12-year Canadian test with sockeye salmon (*Oncorhynchus* nerka), the fry-liberation technique approximately doubled the smolt (two-year-old salmon) production of a small stock, as compared with nhat a similar number of females produced by natural propagation. Houever, this was not considered enough gain to justify the expense involved and a computation showed that the country's total hatchery effort was producing only a small fraction of the commercial supply of sockeye.

The failure of fry liberation in open waters led to a reluctant but rather general abandoning of the technique. Most hatcheries for cod, plaice, lobsters (*Homarus* species), whitefish, ciscoes (Leucichtkys species) and shad have been closed, as have the Alaskan and British Columbian salmon hatcheries. while in other places new techniques or new objectives have been introduced.

Later studies showed what was wrong with the original assumptions. Fertilization of fish eggs in nature is not haphazard, but highly efficient. Cod, for example, swim belly to belly, and the eggs are impregnated as they are extruded. Similarly, salmon eggs are laid in batches in the redd and are immediately smothered nith milt. D. F. Hobbs in New Zealand finally showed, as late as 1937, that naturally spanned trout eggs are practically all fertile and that total mortality to emergence may be as little as 20% on good sites. Even temporary drying up of a stream does not necessarily kill the eggs, nhich are buried deep and stay moist.

Mortality is greatest after hatching; a young fish at the end of the fry stage (yolk sac just absorbed) has just begun its perilous existence. R. E. Foerster's experiments at Cultus lake, British Columbia, indicate that even such large fry as those of sockeye salmon suffer 95% loss during the first year of life and an additional 90% of the survivors perish before they return from the sea to the river estuary. The mortality among the tiny fry of cod, shad or whitefish is far greater. In this way the hundreds of millions of fry released dwindle to hundreds of thousands, to tens of thousands or to merely a few thousands of adult fish—depending on the species.

Finally, it appears that cultured salmon and trout fry are inferior to naturally hatched fry. Richard Vibert in France demonstrated and measured the greater hardiness of fry reared in gravel in terms of their resistance to extremes of temperature, current and predation. A clue to other harmful effects of life in hatchery troughs is afforded by the work of F. Neave and W. S. Hoar in British Columbia. Pink salmon (*Oncorhynchus* gorbuscha) reared in gravel will, at migration time, snim downstream rapidly at night and re-enter the gravel of the stream bed by day until they reach salt water. Thus they remain inconspicuous during a very vulnerable period of their life. However, once the advanced fry are regularly exposed to even weak daylight, as they are in normal hatchery practice, they lose this behaviour pattern. Instead, they school up and let themselves be carried leisurely downstream by day as well as by night, so that they are exposed to attack by a host of voracious fishes, mergansers. etc.

In spite of all this, fry release may not be completely outmoded. Attempts are being made to adjust hatchery procedures so that fry will be normally hardy, with their natural behaviour intact. An alternative course being tried is to move the hatchery outdoors again. New gravel spawning areas are being constructed and existing ones improved in order to obviate damage from predators, silting, floods and drought. In a large installation involving hundreds of thousands of spawners it is necessary to let the fish deposit their eggs themselves, and fish hatching thus becomes linked up mith stream improvement. Such efforts are justified. however, only when there is no bottleneck to production at a later stage in the life history. This proviso is met by the pink salmon and the chum salmon (*Oncorhynchus* keta), which go directly to sea after emerging from the gravel.

2. Release **of** Fingerlings and Larger Fish.—Another reaction to the failure of fry liberation was the attempt to rear fry to a larger size before releasing them. This proved impractical with most of the small-egg species, but trout and salmon responded. Gradually the surviving hatcheries added rearing ponds and began to raise larger and larger fish. Beef liver was at first the standard diet, but the discovery of its effectiveness against human anemia sent its price skyrocketing and set off a protracted search for substitutes. Along with the search for suitable food, the quest for methods for combating diseases has been of major importance. Infections normally of low and unimportant incidence in the wild (endemic) often developed into epidemics in hatcheries, and many millions of young fish have succumbed to attacks by protozoa. fungi, bacteria and other parasites. Sulfa compounds, antibiotics and general sanitation work about as well with fish as with man. but there must be constant watchfulness for the signs of infection.

In Europe stocking streams with trout is for the most part a business. Typically, the owner of a stream purchases young trout (size and quantity based upon his previous experience) from a private hatchery and leases fishing rights by the day or by the season, expecting to make a profit. In North America fishing rights on most waters are still in the public domain, and responsibility for their stocking has been assumed by state or federal governments. It is impossible to make any over-all assessment of the success of their "maintenance" stocking with fingerling or larger trout. However, it is certainly true that many marginal trout streams, and many good trout streams in populous regions, would provide very little game fish without the "put-and-take" planting of large trout. Where hatchery trout are planted into waters containing a good population of native trout. R. B. Miller in Alberta found that the uild stock pre-empts favourable territories and the newcomers lose weight, and most die after a few weeks or months. Similarly, experiments in Michigan showed very little overwinter survival of planted trout when in competition with wild trout. The practical conclusion is that stocking is most successful, as well as most needed, where wild stock is sparse.

In stocking barren or reclaimed waters, of course, there can be good survival from liberations made at any stage from egg to adult. Often planting eyed eggs in gravel is most convenient, while for inaccessible lakes Gustave Prévost in Quebec showed that fingerlings can be dropped from an airplane without harm. A considerable portion of the production of trout hatcheries is now absorbed by lakes high in the mountains. lakes which lack spawning facilities, and lakes or streams cleared of fish by poisoning.

Anadromous fishes also have shared in the trend toward rearing fingerlings to larger sizes. In justification of this, it has been found that stocks of coho or silver salmon (*Oncorhynchus* kisutch) and Atlantic salmon (*Salmo* salar) are usually limited by the size of their river homes rather than by lack of fry. Hence rearing these fish to smolt size makes the hatchery product a clear net gain to the stock; in fact, that is the only way hatcheries can help in such a situation. The same is true for sockeye in some lakes.

Another powerful stimulus to salmon rearing has been the building of dams on salmon rivers. Some Swedish rivers are now dammed completely, from source to mouth, and their surviving runs of salmon and sea trout (Salmo trutta) are maintained entirely by rearing of smolts. Similarly, the progressive damming of western United States rivers has been accompanied by rapid expansion of rearing facilities for chinook (*Oncorhynchus tshawytscha*), coho and steelhead (Salmo *gairdneri*). Apart from their status as a (quite inadequate) compensation for lost nursery rivers. the average cost-to-benefit ratio for these installations seem to be close to marginal, if it is computed on the basis of the commercial value of the adult salmon produced and caught. However, most of the fish handled are also taken in large numbers by sport fishermen, and so are popularly assigned a value much greater than the fish buyer's price.

Fortunately, there is much scope for additional improvement in hatchery techniques. Evidence of this is found, for example, in experiments mith cohoes at Minter creek in Washington state, in which native stream-reared smolts produced 5 to 15 times as many adult fish as pond-reared smolts of the same stock. Improved diets or other changes should gradually eliminate this differential. Experiments with chinook salmon by Lauren Donaldson in Seattle indicate possibilities of selecting fast-growing and early-maturing stock for hatchery use. Transplanted fish commonly return to the stream where they were planted and very rarely return to their original stream unless it is close by. However, it has gradually become clear that in many instances transplanted fingerlings do not return to a stream nearly as successfully as fingerlings of the native stock, even when the two are similarly reared and similarly treated. The causes and full implications of this phenomenon have yet to be ascertained—in particular, have the missing fish gone somewhere else, or have they perished? Some of the evidence suggests the latter. Meantime, salmon hatcheries operated for maintenance should be wary of regular shipping of eggs or fingerlings from one watershed to another.

In the U.S.S.R., improved techniques of sturgeon culture are being used on the Volga, Don and Kura rivers, to compensate for the loss of spawning grounds cut off by dams and to increase their celebrated sturgeon fisheries.

3. Rearing Warm-Water Fishes for Distribution.—The general enthusiasm for fish culture in North America early spread from trout to warm-water species. It proved impractical to obtain live eggs by pressure from such "nesting" species as the black basses (*Micropterus* species), sunfishes (family Centrarchidae), crappies (Pomoxis species) and catfishes (family Ictaluridae), but these could readily be induced to spawn naturally in suitable ponds. In most species the eggs are guarded by the male parent. The basses require a sheltered gravel nest and the catfishes need a dark hole. Young bass are caught as they rise from the nest and are placed in rearing ponds previously fertilized with manure.

Other fish raised in the northern states and southern Canada include walleye, pike, chain pickerel (Esox niger) and occasionally the prized muskellunge (E. masquinongy). With any of these fish-eating species cannibalism is a major cultural problem which demands frequent sorting to even up the size classes, if major losses are to be avoided. For any considerable yield of fingerling walleye, pike or' muskellunge, feeding large numbers of live minnows (small cyprinids) is necessary. These are usually seined from natural waters.

The original object of the bass and bluegill culture was to stock lakes and rivers—most of which, however, were supplied naturally with far more fingerlings than the hatcheries could hope to add. After the early 1930s the young fish were more and more used for the initial stocking of small ponds. Many thousands of ponds an acre or so in extent have been developed, and both federal and state governments encourage their use for fishing by supplying planting stock. The most popular initial combination is a mixture of largemouth bass and bluegill (Lepomis *macrochirus*) fingerlings; the ratios recommended vary from 1:1 to 1:15. With luck such a mixture may produce a "balanced" pond population: the young bluegills provide food for the bass, while the bass keep bluegill reproduction under control, and both species grow rapidly. In practice the bluegills sometimes overpopulate a pond and fill it with slow-growing useless stock. An equally common trouble is invasion of the pond by unwanted prolific species like golden shiners (*Notemigonus crysoleucas*), green sunfish (Lepomis cyanellus) or black bullheads (*Ameiurus melas*). Remedies include the removal of surplus small fish by seining, drawdown (partial draining), poisoning or "correcrive" stocking with a voracious species like the pike. If a pond is sufficiently isolated so that the accidental appearance of wild fish is very unlikely, the initial stocking can be done using species which reproduce poorly under pond conditions, hence will not overstock the pond: rock bass (*Ambloplites rupestris*), smallmouth bass (*Mi*cropterus dolomieu), channel catfish (*Ictalurus lacustris*) and hybrid sunfish have been used.

Other measures of control have also been recommended. For example, the experiments of H. S. Swingle and his colleagues in Alabama show that controlled applications of certain kinds of inorganic fertilizers induce phytoplankton blooms which indirectly promote rapid growth of bluegills (the bluegills chiefly eat the aquatic insects which are dependent on the phytoplankton) and also, by sheer density, control unwanted submerged weeds. Indeed, when pursued rationally, the whole procedure can develop into an intensive pond-fish culture on the oriental pattern. However, in America the prime purpose is usually recreation, so harvesting of the crop is done by exciting but inefficient hook-and-line methods.

4. Introduction of New Species.—Much of the early fish cultural work in North America was devoted to introducing foreign species or to spreading native fishes more widely over the continent. Carp, tench, brown trout and other fish were brought from Europe. Eastern American species were sent west to Colorado, California and Oregon: the shad, striped bass (Roccus saxatilis), Atlantic salmon, brook trout. lake trout (Salvelinus [Cristivomer] *namaycush*), channel and white catfishes, largemouth and smallmouth black bass, perch, bluegills and various other sunfishes, crappies, and several small catfishes or bullheads. Success has been varied. The shad and white catfish (*Ictalurus catus*) have established moderately important commercial fisheries, and the striped bass is a very popular sport fish in waters near the Golden Gate. The black basses are locally important for angling. Sunfishes, crappies, perch and bullheads are also locally useful. but they often become overabundant and stunted and are blamed for the scarcity of more useful species in many waters. Brook trout thrived mainly in inaccessible waters not inhabited by native western trout, uhereas lake trout have "taken" in a few deep lakes only. The Atlantic salmon could not compete with the very similar steelhead trout. Carp are locally plentiful but do not tend to be overabundant as in eastern America, perhaps because they encounter in western waters an array of large cyprinids—the squawfish (Ptychocheilus oregonense) and its relatives—which eat similar foods and are warm-water predators capable of keeping carp fry at reasonable levels.

In exchange for this array of eastern species, the west had to offer principally its varied salmonids: five species of anadromous Pacific salmon (*Oncorhynchus* species), the lake-dwelling kokanee or fresh-water form of the sockeye salmon. the rainbow trout and its anadromous form the steelhead, two forms of the cutthroat trout (Salmo clarki), the Dolly Varden char (Salvelinus *malma*) and the beautiful golden trout of the southern Sierra Nevada (*Salmo* agua-bonita). Of these, only the rainbow trout has become extensively acclimatized in eastern North America, where it is still increasing in abundance and extending its range. As a stream fish it tends to displace the native brook trout except in the colder parts of trout streams. It has also produced some autumn-spawning runs of large fish in the Great Lakes, and true anadromous steelhead have appeared in Prince Edward Island. The European brown trout has also become widely distributed in the warmer trout streams, and has produced runs of sea trout in a few rivers of southeastern Newfoundland.

The most famous fish of western America is without question the chinook. king or quinnat salmon, which averages 20–25 lb. but often grons to 75 lb. and more. It has long been a principal sport and commercial fish from the Sacramento river to the Yukon. It was to obtain eggs of this salmon, specifically, that Livingston Stone established a fish-cultural station in 1874 on the McCloud river, at that time a remote tributary of the Sacramento. With makeshift equipment, and under the surveillance of the somewhat unfriendly Indians whose traditional fishing grounds had been pre-empted, eggs were eyed and shipped to eastern America and throughout the world. Coastal streams from the Mississippi river to the St. Lawrence received shipments, but unfortunately the great majority of the waters stocked were quite unsuitable, and in none was there any permanent success. The same was true in Europe. However, in the Waitaki river of New Zealand a run of chinooks became established, shortly after 1900, which maintained itself and spread naturally to most other major rivers of the east coast of the South Island. Although the McCloud river's salmon are now extinct and the very site of the early hatchery lies buried beneath the waters of Shasta reservoir, there is sentimental satisfaction in knowing that this historic stock still lives and is providing sport and food.

The success of introductions of new fish throughout the world is more or less inversely proportional to the variety and abundance of the native fish fauna. Australia and New Zealand, with a very limited assortment of native fresh-water fishes, have readily acclimatized such foreign species as carp, tench, bream, perch, brown trout and (in one river) Atlantic salmon from Europe; and, from America, rainbow trout, the chinook salmon and some brook trout and kokanee. South Africa also has provided a home for brown and rainbow trout, largemouth and smallmouth bass and bluegill sunfish. European rivers, with a much more varied fish fauna, have yet found room for American smallmouth bass and the brown bullhead (*Ameiurus nebulosus*), the latter not a particularly welcome immigrant. Asia, richest of all in fresh-water fishes, has apparently not as yet accepted a newcomer, and indeed has felt no need to attempt transplantations.

The acclimatization of desirable new species is difficult and full of pitfalls. Even in success there may be failure. The carp, most prized of warm-water food fishes in Europe, was introduced in North America with high hope but in most places it is now regarded as a nuisance. Indiscriminate stocking of sunfishes and minnows as "forage fish" has ruined many fine trout waters in western North America. The attempt to introduce a new sturgeon into the Aral sea (U.S.S.R.) in the early 1930s was followed by a massive (though not complete) mortality of the native sharp-nosed sturgeon (Acipenser *nudiventris*), which lacked resistance to a trematode (flatworm) parasite brought in with the transplants. In spite of such dangers, there is renewed interest in the introduction of new species almost everywhere in the world. Judicious selection of kinds which will not compete with useful native species, or which will substitute a more valuable for a less valuable species, offers a wide field for careful experimentation. For example, the very limited salmon stock and fishery of the North Atlantic suggests that a profitable industry could be built up around the Pacific pink, chum and sockeye salmon, species whose life history does not conflict with that of the native species (*Salmo salar*). Hence: renewed transplantation efforts are under way in Canada and the U.S.S.R. The tasty kokanee has been introduced in Oregon and California, and should be welcomed everywhere as a useful plankton-eating species, even if it were to supplant some of the less flavoursome and nonsporting ciscoes and small whitefishes. The Asiatic grass carp and fathead have been proposed for reservoirs of southern U.S.S.R. Greatest care should be taken with small omnivorous species like the American sunfishes or the African *Tilapia,* which can so easily take over waters without producing a desirable crop.

III. IMPROVEMENT OF THE HABITAT

1. Changes in Lakes and Streams. — In Britain and continental Europe much effort is sometimes expended by an owner in improving his trout stream or other river by creating pools. riffles or covers that harbour fish or make fishing easy. In North America such efforts are largely co-ordinated by governmental agencies. During the business depression of the 1930s when public works programs employed large bodies of labour for public projects, there mas extensive activity in stream improvement in most states. Provision of shade and shelter. control of bank erosion, formation of pools, etc., were all undertaken — methods being developed and codified in the first instance by C. L. Hubbs and his colleagues in Michigan. Attempts were also made to extend these activities to lakes by making brush shelters where fish would accumulate. providing gravel nesting sites for bass and so on. Some of this effort has doubtless had permanent value, though this was rarely actually demonstrated. Generally speaking. there was no time to develop and test a program suited to the individual stream or lake! nor was there much follow-up work.

A more rewarding activity, which has continued unabated, has been the construction of new lakes and ponds for public fishing and other recreation. There are also indirect subsidies for private fishpond construction. By these means fish-producing waters have been increased by hundreds of thousands of acres—or millions of acres if large multiple-purpose reservoirs are included.

2. Fish Passes and Screens. — Obstructions to the migration of fishes occur in many rivers, either as natural falls or as dams of various sorts. When a dam is constructed it has been found feasible to build fish passes which many kinds of migratory fish will use—for example, salmon, trout) shad, carp, suckers (Catostomidae) and eels. Depending on the size of the river and the height of the dam, these passes range from a simple succession of small pools, each about a foot higher than the last, to multimillion-dollar installations with a complex collection system built across the face of the dam.

The most elaborate and expensive series of fishways are those around the main-stream dams on the Columbia river in Washington and Oregon, where chinook and other salmon are the species principally affected. While these structures allow a large fraction of the adult salmon to pass upstream, there is some delay at each, which eventually may become very serious as more and more dams are built.

Not only must adult fish be permitted to go upstream, but the young must get down safely. For dams up to about 100 ft. high, the spillway or the more slowly moving types of turbines usually offer reasonably good routes. Higher dams present problems which are only beginning to be approached seriously. A young fish can fall any distance through the air into water without harm, so experimental overpasses have been constructed on this principle: the water. containing fish, is broken into spray at some point clear of the dam and the excessive turbulence below it, and the fish can fall safely. However, the trouble lies in guiding the young fish to the point where the safe descent begins; almost every installation presents a different problem. One difficulty is a lack of basic information concerning behaviour patterns, muscular capacity, sensory acuity and physiological tolerance of young fish of different species and at different ages. Active research on this problem is in progress.

Sometimes fishways are built to provide a passage over natural or accidental obstructions, rather than dams. 4 celebrated example is the obstruction of the Fraser river at Hell's Gate in British Columbia, which dates from a series of slides caused by railway construction in 1913–14. Although the most serious damage was corrected by immediate removal of much of the rock, the Gate remained a complete obstacle to the ascent of pink salmon and a partial obstacle to the more vigorous sockeye and chinook salmon up to the time fishways were constructed in 1945–46.

Diversion of water for irrigation has also been a major hazard to anadromous fishes. It has affected particularly the salmon of the Sacramento and San Joaquin rivers of California, and the herringlike hilsa (Hilsa ilisha) in certain Indian rivers. Apart from reduced flow in the streams affected, there is direct loss of downstream-migrating young into the irrigation canals. In the United States, government intervention resulted in the installation of elaborate rotary screens on many intakes to prevent fish from entering the irrigation canals. Later, a series of louvers set at an angle down a concrete channel was constructed on a large Sacramento river diversion; the water flows between the louvers, but most of the fish do not pass.

3. Reduction of Mortality From Predation. — There are numerous kinds of animals which, in consuming useful fish, are in competition with man for what he claims as his own food. However, until man can actually use the fish which might be saved from predators, the latter do not cause any real loss. Thus, generalized complaints concerning the tremendous number of fish destroyed by seals: sharks, cormorants, gars, piranhas or snapping turtles — to mention a few popular culprits — may be true or false, but are of no particular interest. Quite different is the situation where predators attack usable fish concentrated in limited areas; or where they interfere with fishing operations. For example, sea lions may follow a troller and take salmon off the line; gray seals can very skillfully rob pound nets; an abundance of dogfish makes trawling difficult; kingfishers and herons gorge on trout from unprotected ponds; and so on. Here either control or evasive action is indicated. whichever is most feasible. Sometimes no action seems possible: Japanese long-liners lose 20% to 30% of their tuna catch to sharks in tropical waters.

In only a few situations has it been shown that a predator is actually involved in limiting useful fish and that control of the predator is feasible. H. C. White in New Brunswick showed that mergansers (goosanders) set a limit to Atlantic salmon production at a level much below that which the streams could otherwise attain. Systematic control of these birds over a large area was begun and on some streams it increased smolt production fourfold. Similarly it was possible to increase sockeye salmon production threefold by control of squawfish in a British Columbia lake, at a cost amounting to approximately one-tenth of the commercial value of the increase in salmon caught. Local control of char, sculpins, etc., predators of salmon fry, has also been found effective, particularly in association with improvements in redds or water flow.

A spectacular attack on a predator, the sea lamprey, was begun in about 1945 in the Great Lakes. Lampreys are eel-shaped vertebrates that attach themselves to fish or mammals and suck their blood. The sea lamprey (Petromyzon *marinus*) probably became acclimatized in Lake Ontario during a late glacial stage when the lake was a brackish gulf of the Atlantic ocean, but Niagara falls prevented its ascent to the upper lakes. Lampreys frequently attach themselves to boats, so occasional individuals have probably entered Lake Erie since the construction of the first Welland canal. Eventually a pair was bound to breed successfully, but it was only after they had reached Lakes Huron and Michigan in the 1930s that they multiplied disastrously in the numerous suitable spawning tributaries of those lakes. Within a decade lake trout in those waters were commercially, and almost absolutely, extinct. To save the Lake Superior trout, and eventually to restock the other lakes, a system of electrical barriers was installed on all lamprey-spawning streams — some of them quite large rivers. In addition, their waters are being treated with a poison which in the correct concentration kills young lampreys without harming fish.

It is not yet known whether these heroic measures will successfully control or, as their more optimistic sponsors hope, actually eliminate sea lampreys in the Great Lakes. If not, there may be some hope in another direction. In Lake Ontario the lake trout has achieved an uneasy tolerance to lampreys. Many trout are attacked and survive, sometimes bearing more than a dozen healed scars; others seem to avoid attack. Whatever the reasons for this resistance, it may be something that their progeny will retain when transplanted to the upper lakes.

In practice it is difficult to make a clear distinction between predators and competitors; the term "coarse" fish embraces both. Coarse fish removal is sometimes undertaken to benefit the more valuable fish. Some states seine excess carp periodically from shallow lakes to keep in check their roiling (muddying) of the water and uprooting of vegetation. More spectacular is the poisoning of lakes to remove all fish in order to restock with more useful ones. The poison used is usually some form of rotenone, fatal to fish but in the strength used harmless to most other water animals and to all warm-blooded animals. As an example, Diamond lake in Oregon, just north of Crater lake, was poisoned in 1955 to remove an overabundant cyprinid (Sipkateles) population that had been introduced accidentally from the Klamath watershed, probably as a bait minnow. The trout, of course, perished along with the rest, and had to be reintroduced.

IV. REGULATION OF FISHING FOR BEST YIELD

Fishing regulations may be designed simply to divide the available catch among different groups of fishermen or methods of fishing, or they may have as their primary purpose the exploitation of fish in the most rational manner. In pursuing the latter aim, two lines of attack may be distinguished. An attempt may be made (1) to make best use of a stock of fish already in existence or (2) to provide a maximum supply of future recruits.

1. Best Exploitation of Existing Stock. — Any brood or year class of fish decreases in numbers continuously from the time it is hatched. In the first year mortality is severe, but in spite of this the young fish grow so rapidly that the year class as a whole increases in bulk, and may continue to increase for a year or more — depending on the average life span and on feeding conditions. Sooner or later, however, a turning point is reached; losses from natural deaths overtake the rate of growth, the year class begins to decline, and it eventually disappears. For a small minnow this cycle is completed in 2 or 3 years; for the halibut it may take 40 or more. At some time during the cycle the individual fish become large enough to be useful to man. However, if the year class is still increasing in bulk (growth exceeding natural losses) it may be desirable to wait and begin harvesting when a larger total weight is available. But harvesting should not be delayed too long, or the year class will have passed into the declining phase.

More exactly, obtaining maximum yield depends jointly on intensity of fishing and on size at first capture. If fishing is light, greatest yield is obtained by having a small minimum size limit, or none at all, so that thinning out may occur. If fishing is heavy, it becomes important to spare the smaller fast-growing fish so they can be caught when they are larger.

In commercial fisheries the intensity of fishing is determined largely by economic factors: numbers of fishermen and boats tend to increase until catch per trip falls to a level that discourages new investment. Unfortunately, this may happen only after fishing has become so intensive that the stock is no longer yielding at maximum capacity. For example, Michael Graham calculated during the 1930s that North sea fishing grounds for bottom-dwelling species would yield about 13% more if fished 16% less. But to reduce fishing in a manner that makes sense economically, some boats and fishermen must stop fishing entirely. To decide who should stop fishing has so far proved an insoluble problem. However, the biological benefits of decreased fishing were obtained for eastern Pacific halibut stocks (Hippoglossus steno*lepis*), following studies by W. F. Thompson and colleagues, by setting a yearly catch quota.

The other approach, popularized by R. J. H. Beverton and S. J. Holt, is to adjust minimum size limits; it is applicable particularly to trawl and gill-net fisheries. An increase in minimum size by stipulating nets of larger mesh can be instituted without special hardship to the fisherman and even with some saving to him, for nets of larger mesh are usually cheaper and there is less sorting of the catch. Thus, international agreement on larger mesh sizes has been achieved for cod and haddock trawlers of the western North Atlantic; sustained yield increases of 10% to 25% have been predicted as a result — particularly as many of the young fish spared were formerly discarded at sea.

Among the many factors which can complicate this simple theory of exploitation, two important ones are mentioned here. An increase in growth rate sometimes compensates for thinning of the stock; this makes production more stable and also less susceptible to improvement by management regulations. Also, F. I. Baranov long ago showed that an unfished stock of a long-lived species resembles a virgin forest: there is a big crop of mature fish, accumulated and ready to be harvested once. After the first few years of fishing, yield must depend on the (much smaller) annual biological production. Failure to make this distinction has caused and still causes much concern about "depletion" of stocks that actually are only lightly fished.

2. Obtaining Maximum Recruitment. — The above analysis tells how to get the most out of a fishery stock once it is in existence. But in order to have adequate recruits year after year, the spawning stock must not be allowed to become too small. The question is, how small is too small? And can a spawning stock be too large?

Direct study of these questions is made difficult by the tremendous variability of success of reproduction in most fishes. For example, Johan Hjort showed that the 1904 year class of herring (Clupea harengus) in Norwegian waters contributed more to the fisheries of 1908 to 1918 than did all other year classes combined. Usually fluctuations are somewhat less extreme than this, but large enough to be of great practical importance.

In addition to these year-to-year fluctuations, there are long-term trends in ocean conditions which may augment the supply of one species, while another becomes depressed until fishing is no longer possible. The marked increase in cod along the southwest coast of Greenland after 1935 is associated with a small increase in sea temperature in this marginal area. Increases in sprats (Clupea sprattus), herring and cod in the Baltic sea seem to reflect an increase in salinity there. Other times there is no obvious reason for an observed change. For example, in the southern North sea the supply of soles (*Solea* vulgaris) increased severalfold in spite of a regular and fairly intensive fishery.

In view of this large and little understood variability in survival of fish eggs, what should be done about maintaining a spawning stock? In the early years of this century there was widespread concern about a possible inadequate egg supply of both marine and fresh-water fishes, and a prevailing rule of thumb for size regulations was that each fish should be allowed to spawn at least once. Later, fish tended to be divided up into two classes. For oceanic species like cod, haddock (*Melanogrammus aeglefinus*), plaice and herring, the prevalent (but not unanimous) opinion is that recruitment is practically independent of the supply of spawn. Thus, fishing regulations should concentrate on the best utilization of whatever recruits are at hand, without worrying about the future supply.

For the various salmons, trouts, sturgeons and others the situation is quite different. Since these desirable fish are very easily caught as they crowd into estuaries and pass up narrow rivers, it is simple enough to deplete a spawning stock far below the most productive level. Indeed, if fish are caught only near the end of their lives, as is true of many American stocks of Pacific salmon, the only form that management can take is that of making provision for future supplies. Under these conditions what average fraction of a stock should be caught in order to give maximum sustained yield? Direct observation of certain stocks over a period of years indicates that from 50% to 90% should be caught. Thus, no single rate of exploitation can obtain best utilization of all stocks. Ideally each stock should be managed individually. Since this is difficult when species are mixed together in a common fishery, compromise is often necessary.

If numbers of fish caught can be accurately controlled, a better form of the management question is: what absolute number of spawners in each stock will give the best average yield? Already it is clear that too much spawning for best yield can occur, but too little is more common. Although success of reproduction varies, in fresh water as well as in the sea, this variability does not do away with the need for an adequate number of spawners. In poor seasons they may seem wasted, but unless eggs are available in quantity, a good reproductive season will not produce a big crop.

FISH CURING is the method by which fish is preserved in edible condition by drying, salting or smoking or by a combination of these. Fish decomposes rapidly, particularly in warm climates! as a result of the activities of the bacteria and molds that it harbours, and of enzymic self-digestion and atmospheric oxidation. From earliest times preservative processes have been developed and handed down, and these have permitted storage of day-to-day and seasonal surpluses until times of dearth.

Most methods of curing depend on dehydration, whether by evaporation, as in drying in the sun and wind or over smoky fires, or by extraction of fluid from the tissues by osmosis, in the case of treatment with salts. Common salt, which is chiefly used, and the chemicals absorbed from smoke also have specific bactericidal effects.

Drying alone is used in Norway and Iceland to produce stockfish (stock, a "stick") from nonfatty fish such as cod. Once a staple article of diet throughout Europe, it is now mostly eaten in Italy and Nigeria and by Scandinavian epicures in various countries. Hard drying is combined with heavy salting of split cod, etc., in making klipfish (*klipper*, rocks on which the fish was laid out to dry in Norway), an important export from North Atlantic countries to Iberia, the Caribbean and Latin America. French, Spanish, Portuguese and, occasionally, British vessels salt fish on the fishing grounds, usually for subsequent drying ashore. Certain bacteria, peculiarly resistant to salt, cause a form of spoilage known as "pink" from the colour produced.

Fatty fish, such as herring, pilchard and mackerel, are usually eviscerated and mixed with salt so that they become covered with a brine pickle. Packed tight with the pickle in barrels to minimize oxidation of the fat by atmospheric oxygen, this was formerly pre-eminent as an export. The Dutch fishery off the British coast salted and packed the fish on the fishing vessels (busses) at sea. In the 19th century the Scottish herring-curing industry was predominant and an extensive trade was built up, particularly with eastern Europe, but this declined after World War I.

"Red herrings" were ungutted herrings, hard salted and then hung in kilns for several weeks over smoldering sawdust fires, and were once popular in England, but are now mainly exported to the Mediterranean and the Levant. Salmon, also a fatty fish, was similarly cured for long-term preservation by salting in barrels or salting and smoking. For shorter storage these fish were "potted" by heating in a pickle of salt, vinegar and herbs.

The changes in the fish during hard curing produced a characteristic flavour which added variety to otherwise drab diets and is still appreciated by gourmets. However, when the railways in the mid-19th century permitted for the first time rapid inland distribution of fresh sea fish, later chilled in ice, the taste for these rather tough, salty and highly flavoured hard-cured products declined in industrialized countries. Trade in them is therefore generally confined to countries, mostly with warm climates, that are not yet sufficiently advanced economically to rely on the distribution of fresh and frozen fish. Many such countries are also developing their own fisheries and therefore hard-curing methods, suited to the preservation of expected increases in supplies, may continue to be used for some time.

In the more advanced countries, particularly in northwest Europe and North America, during the period 1850–1950, much more lightly cured, mildly smoked products were developed that can only just be distributed satisfactorily, but not stored, without refrigeration. Typical of these are the kipper, which is made from split, gutted herring; the bloater, a whole, ungutted herring; the finnan haddie or haddock, which is cut open in a special way; and various types of smoked fillets. In Germany and Sweden hot-smoked products are preferred, such as buckling (from unsplit herring) and smoked eels, which are cooked in the smoke. All such products contain only sufficient salt and smoke to impart an attractive flavour (colour usually being supplied by harmless dyes), while the slight degree of drying avoids undue toughness. Furthermore, cold storage can be used partially or almost wholly for preserving.

From 1935 onward research workers and engineers investigated the traditional processes with a view to improvement. As a result mechanical dryers and smoking kilns that provide a better degree of control are becoming widely adopted both for the hard export cures and the milder ones for home consumption.

FISHER, ANDREW (1862–1928), Australian statesman, was born at Crosshouse, Kilmarnock. Aug. 29, 1862, and began life as a coal miner. He emigrated to Queensland at the age of 23, and was elected to the Queensland legislature in 1893 In 1901 he was elected to the commonwealth parliament. joined John Christian Watson's Labour cabinet of 1904 as minister of trade and customs, and became leader of the Labour party in 1907 on Watson's resignation. In 1908 he became prime minister, but his administration lasted only six months. At the general election in 1910, however, his party was returned with a sweeping majority, and he was prime minister. for three years, during which period he tackled the question of imperial defense,, adopted Lord Kitchener's report of 1909 and passed a measure establishing universal military training. His ministry fell in 1913, but at the election of Aug. 1914 he was again returned to power and gave Australia a vigorous lead in the early days of World War I. At the end of 191j he resigned and took up the high commissionership, retiring in 1921. He died in London on Oct. 22. 1928.

FISHER, HERBERT ALBERT LAURENS (1865–1940), British historian and statesman whose best-known book, *History of Europe* (3 vol., 193j), illustrates his broad sympathies, wide learning, keen critical faculty and the pictorial quality of his prose. was born in London, March 21, 186j. Educated at Winchester and at New college, Oxford, he became vice-chancellor of Sheffield university in 1912. He entered parliament in 1916, on becoming the president of the board of education. The Education act of 1918 *(see* EDUCATION, HISTORY OF: *Great Britain and the Commonwealth of Nations)* embodied his blend of humanism and humanitarianism. Later, his hope for a united Europe led him to support the League of Nations, and he was a delegate to the assembly, 1920–22. His experience with men and affairs made him an outstanding warden of New college from 1925 until his death in London on April 18, 1940. He resigned from politics in 1926. Fisher's works include: *Studies in Napoleonic Statesmanship: Germany* (1903); *Bonapartism* (1908); *The Whig Historians* (1928); *Lord Bryce* (1926); *The Common Weal* (1924); and his posthumous *Unfinished Autobiography* (1940).

See D. Ogg, Herbert Fisher, 1865–1940 (London, New York, 1947).

FISHER, IRVING (1867–1947), U.S. political economist, who combined the talents of a scientist with the interests of a crusader, was born at Saugerties, N.Y., on Feb. 27, 1867. After taking a bachelor's degree (1888) and a Ph.D. degree (1891) in mathematics from Yale university, he taught mathematics before shifting to economics, becoming a full professor at Yale in 1898. Fisher used mathematical methods to discover original solutions to some of the fundamental problems of economics. His crusading spirit led him into many fields of reform, including economic stabilization. health, eugenics, conservation, prohibition and the League of Nations.

In *The Purchasing Power of Money* (1911) Fisher developed the modern version of the relation between changes in the quantity of money and changes in the general level of prices. In numerous writings he expounded his plan for the "compensated dollar." a dollar of constant purchasing power, sometimes referred to as the "commodity dollar." In place of the conventional gold standard. which defined the unit of money in terms of a given *weight* of gold, Fisher proposed to define the dollar in terms of a given *value* of gold. The constant value of gold was determined by an index number of commodity prices of a given basket of goods.

Among more than two dozen books, his most important were: *Mathematical Investigations in the Theory of Value and Prices* (1892); *The Nature of Capital and Income* (1906); *The Purchasing Power of Money* (1911); *The Making of Index Numbers* (1922); *The Theory of Interest* (1930); *Booms and Depressions* (1932). (D. DD.)

FISHER, JOHN (*c.* 1469–1535), English cardinal and bishop of Rochester, born at Beverley, went in 1484 to Michael House, Cambridge, where he took his degrees in arts in 1487 and 1491, and, after filling several offices in the university, became master of his college in 1499. He took orders; and his reputation for learning and piety attracted the notice of Margaret Beaufort. mother of Henry VII, who made him her confessor and chaplain. In 1501 he became vice-chancellor; and later on. when chancellor. he was able to forward. if not to initiate, the schemes of his patroness in the foundations of St. John's and Christ's colleges, in addition to two lectureships in Greek and Hebrew. His love for Cambridge never waned. and his own benefactions took the form of scholarships, fellowships and lectures. In 1503 he was the first Margaret professor at Cambridge; and the following year was raised to the see of Rochester, to which he remained faithful. although the richer sees of Ely and Lincoln were offered to him. He was nominated as one of the English prelates for the Lateran council (1512), but did not attend. A man of strict and simple life, he did not hesitate at the legatine synod of 1517 to censure the clergy. in the presence of Thomas Wolsey himself, for their greed of gain and love of display; and in the convocation of 1523 he freely opposed the cardinal's demand for a subsidy for the war in Flanders.

A great friend of Erasmus, whom he invited to Cambridge. while earnestly working for a reformation of abuses. he had no sympathy with those who attacked doctrine; and he preached at Paul's Cross (May 12, 1521) at the burning of Luther's books. Although he was not the author of Henry's book against Luther, he joined with his friend, Sir Thomas More, in writing a reply to the scurrilous rejoinder made by the reformer. He retained the esteem of the king until the divorce proceedings began in 1527; and then he set himself sternly in favour of the validity of the marriage. He was Queen Catherine's confessor and her only champion and advocate. He appeared on her behalf before the legates at Blackfriars, and wrote a widely read treatise against the divorce.

Recognizing that the true aim of the scheme of church reform brought forward in parliament in 1529 was to put down the only moral force that could withstand the royal will. he energetically opposed the reformation of abuses. which doubtless under other circumstances he would have been the first to accept. In convocation. when the supremacy was discussed (Feb. 11, 1j31). he declared that acceptance would cause the clergy "to be hissed out of the society of God's holy Catholic Church"; and it was his influence that brought in the saving clause! *quantum per legem Dei licet.*

Through listening to the revelations of the "Holy Maid of Kent," the nun Elizabeth Barton (*q.v.*), he was charged with misprision of treason, and was condemned to the loss of his goods and to imprisonment at the king's will, penalties he was allowed to compound by a fine of £300 (March 25, 1534). Fisher was summoned (April 13) to take the oath prescribed by the Act of Succession, which he was ready to do, were it not that the Preamble stated that the offspring of Catherine were illegitimate, and prohibited all faith, trust and obedience to any foreign authority or potentate. Refusing to take the oath, he was committed (April 15) to the Tower, where he suffered greatly from the rigours of a long confinement. On the passing of the Act of Supremacy (Nov. 1534), in which the saving clause of convocation was omitted, he was attainted and deprived of his see. The council, with Thomas Cromwell at its head, visited him on May 7, 1535, and his refusal to acknowledge Henry as supreme head of the church was the ground of his trial. Paul III was unaware of the grave danger in which Fisher lay; and in the hope of reconciling the king with the bishop, created him (May 20, 1535) cardinal priest of St. Vitalis. When the news arrived in England it sealed his fate. Henry, in a rage. declared that if the pope sent Fisher a hat there should be no head for it.

The cardinal was brought to trial at Westminster (June 17, 153j) on the charge that he did "openly declare in English that the king, our sovereign lord, is not supreme head on earth of the Church of England." and was condemned to a traitor's death at Tyburn, a sentence afterward changed. He was beheaded on Tower Hill on June 22. 1535, after saying the *Te Deum* and the psalm *In te Domine speravi.* His body was buried first at All Hallows. Barking. and then removed to St. Peter's *ad vincula* in the Tower, where it lies beside that of Sir Thomas More. His head was exposed on London Bridge and then thrown into the river. He was beatified in 1886, and canonized by Pius XI in 1935.

Fisher's Latin works are to be found in the *Opera J. Fisheri quae hactenus inveniri potuerunt omnia* (Würzburg, 1595), and some of his published English works in the Early English Text Society, Extra series, no. 27, part i (1876). There are others in manuscript at the *P.R.O.* (27, Henry *VIII*, No. 887). Resides the state papers, the main sources for his biography are *The Life and Death of that renowned John Fisher, Bishop of Rochester* (London, 1655) by an anonymous writer, the best edition being that of Van Ortroy (Brussels, 1893); Bridgett's *Life of Blessed John Fisher, Bishop of Rochester* (London, 1880 and 1890); and Thureau, *Le bienheureux Jean Fisher* (Paris. 1907).

(E. TA.)

FISHER, JOHN ARBUTHNOT FISHER, 1ST BARON (1841–1920), British admiral, was born on Jan. 25, 1841, and entered the navy in June 1854. He served in the Baltic during the Crimean War, and was engaged as midshipman in the "Highflyer," "Chesapeake" and "Furious," in the Chinese War, in the operations required by the occupations of Canton and of the Peiho forts in 1859. He became sub-lieutenant on Jan. 25, 1860, and lieutenant on Nov. 4 of the same year.

The cessation of naval wars, at least of wars at sea in which the British navy had to take a part, after 1860, allowed few officers to gain distinction by actual services against the enemy. But they were provided with other ways of proving their ability by the sweeping revolution which transformed the construction, the armament. and the methods of propulsion of all the navies of the world, and with them the once-accepted methods of combat. Lieutenant Fisher began his career as a commissioned officer in the year after the launching of the French "Gloire" had set going the long duel in construction between guns and armour. He early made his mark as a student of gunnery, and was promoted commander on Aug. 2, 1869, and captain on Oct. 30, 1874. In this rank he mas chosen to serve as president of the committee appointed to revise *The Gunnery Manual of the Fleet.* It was his already established reputation which pointed Captain Fisher out for the command of H.M.S. "Inflexible," a vessel which, as the representative of a type, had supplied matter for much discussion. As captain of the "Inflexible" he took part in the bombardment of Alexandria (July 11, 1882). The engagement was not arduous in itself, having been carried out against forts of inferior construction, indifferently armed, and poorly garrisoned, but it supplied an opportunity for a display of gunnery, and it was conspicuous in the midst of a long naval peace. The "Inflexible" took a prominent part in the action, and its captain had the command of the naval brigade landed in Alexandria, where he adapted the ironclad train and commanded it in various skirmishes with the enemy.

After the Egyptian campaign, he was, in succession, director of Naval Ordnance and Torpedoes (Oct. 1886–May 1891); aide-decamp to Queen Victoria (June 18, 1887–Aug. 2, 1890, at which date he became rear-admiral); admiral superintendent of Portsmouth dockyard (1891–92); a lord commissioner of the navy and comptroller of the navy (1892–97) and vice-admiral (May 8, 1896); and commander-in-chief on the North American and West Indian station (1897).

In 1899 he acted as naval expert at The Hague Peace conference, and on July 1, 1899, was appointed commander-in-chief in the Mediterranean. From the Mediterranean command, Admiral Fisher went again to the admiralty as second sea lord in 1902, and became commander-in-chief at Portsmouth on Aug. 31, 1903, from which post he passed to that of first sea lord. Besides holding the foreign Khedivial and Osmanieh orders, he was created K.C.B. in 1894 and G.C.B. in 1902. As first sea lord, during the pears 1903–09, Sir John Fisher had a predominant influence in all the far-reaching measures of naval development and internal reform; and he was also one of the committee, known as Lord Esher's committee, appointed in 1904 to report on the measures necessary to be taken to put the administration and organization of the British war offices on a sound footing. The changes in naval administration made under him were hotly criticised by his critics, who charged him with autocratic methods, and in 1906–09 with undue subservience to the government's desire for economy; and whatever the efficiency of his own methods at the admiralty, the fact was undeniable that for the first time for very many years the navy suffered, as a service, from the party-spirit which was aroused. It was notorious that Admiral Lord Charles Beresford in particular was acutely hostile to Sir John Fisher's administration; and on his retirement in the spring of 1909 from the position of commander-in-chief of the Channel fleet, Lord Charles put his charges and complaints before the government, and an inquiry was held by a small committee under the prime minister.

Its report, published in August, was in favour of the admiralty, though it encouraged the belief that some important suggestions as to the organization of a naval "general staff" would take effect. On Nov. 9 Sir John Fisher was created a peer as Baron Fisher of Kilverstone, Norfolk. He retired from the admiraltv in Jan. 1910.

From 1910 until Oct. 1914 Lord Fisher remained in retirement, although Winston Churchill, then first lord of the admiralty, constantly consulted him and it was on Fisher's advice that Sir John Jellicoe was designated admiral of the Grand fleet in the event of war. (It is noteworthy that at the time of the Agadir crisis, Fisher expressed to Lord Esher and others strong disapproval of the war office plans involving Great Britain in extensive land operations in France.)

Fisher was recalled as first sea lord in place of Prince Louis of Battenberg in the critical days at the end of Oct. 1914. The "Audacious" had been sunk, Cradock heavily defeated off Coronel, German submarines were active, and the measures to stop the flow of supplies into Germany were not effective. Fisher took the responsibility of weakening the British fleet in home waters and detached the "Invincible" and "Inflexible" to engage von Spee, with the result that a complete victory was gained in the battle of the Falkland Islands. To Fisher's boldness and realism again were due the new blockade policy and the laying of extensive mine fields.

The association between Churchill and Fisher was most happy until it was broken by the Dardanelles enterprise. Fisher lever liked it; his preference was for a landing on the coast of Prussia in the Baltic and the employment of Russian troops against the heart of Germany. But he was overpersuaued by Churchill into reluctant acquiescence to the initial efforts against the Dardanelles.

When, however, the first attempt to force the straits had failed, and German submarines had made their appearance in Turkish waters, and it seemed doubtful whether the demands of the French campaign would allow the British to send the necessary reinforcements to the army in Gallipoli, Fisher felt that he could no longer continue to countenance the project of forcing the Dardanelles. At the War council of May 14, 1915, he had declared that "he was against the Dardanelles and had been all along." Churchill afterward told him that it was not fair to obstruct necessary measures at the Dardanelles and then when things went wrong to turn around and say "I told you so, I was always against it." Fisher replied "I think you are right—it isn't fair." That night Churchill in order to encourage the entry of Italy into the war on the side of the Allies gave instructions that four cruisers should go to the Mediterranean 48 hr. before the time arranged, and the minute was signed "First sea lord to see after action."

That was the first document seen by Fisher on beginning work as usual at four o'clock next morning. He refused to serve with Churchill any more and resigned. His resignation coinciding with the crisis about high-explosive shells, brought down the already shaken Liberal government, and led to the formation of the first Coalition. The manner of his leaving the admiralty became Fisher less than anything in his life, but his motives were neither personal nor unworthy. He felt that as things were he had lost his power of service; that he could only hamper the Dardanelles and be "unfair" to Churchill without influencing events in the direction which he felt was right.

Fisher did useful work later in the war as chairman of the Inventions board, and when he died on July 10, 1920, at the funeral in Westminster Abbey, the crowds felt that they were mourning the greatest British sailor since Nelson. Their reverence was the more remarkable because Fisher never commanded a fleet in action, nor, except the Falkland Islands, is any great victory at sea traceable to his direct inspiration. His enemies accused him of exaggerating the material side of naval pouer at the expense of the moral and intellectual. He was not good in the logical presentation of an argument; he thought pictorially and the sequence of his ideas expressed themselves in a series of verbal explosions. But his prescience amounted at times almost to second-sight, and he had a genius for the burning phrase that lights up the truth from within.

The most amazing quality of the man was that as he grew older he became more radical and revolutionary in his ideas. To the old man in 1919 his own Dreadnought of 13 years was a symbol of effete tradition; his slogan "Sack the lot" was not the prosecution of a personal vendetta against the admiralty chiefs, but expressed his conviction that though the spirit was eternal, its forms were only made to be broken. He wrote two volumes of memoirs: *Memories* (1919) and *Records* (1919); somewhat scrappy and disorderly in composition but full of his glowing vitality.

Fisher married, in 1866, Kate Broughton, by whom he had one son and three daughters. (D. H.; H. SM.)

FISHER *(Martes pennanti)*, a North American member of the weasel family (Mustelidae), black in colour, reaching a total length of about 42 in., and producing valuable fur. The fisher is also called Pekan, Pennant's marten, and, by trappers, black cat. *(See* **MARTEN;** FUR.)

FISHERIES. The term "fishery" as commonly employed embraces every method of pursuit and capture, whether for profit or for sport, of aquatic animals, from whales and seals, which are warm-blooded mammals: to the "tiddlers" prized by urchins. However, neither whaling nor sealing comes within the scope of this article, which is limited to the pursuit of fish properly so-called and is primarily concerned with commercial fisheries for fish for food. Fishing is probably the earliest form of hunting, and, as men were. surely hunters before they were cultivators, is actually the oldest industry in the world.

For the most part, the attitude of man toward fisheries has been that of the spendthrift: Nature gave the increase; he had but to use it if he could. The abundance of fishes in their different species varied from year to year, but there was always abundance and it is only in comparatively recent years that serious apprehensions have been entertained lest the operations of man might jeopardize the stability of the stock. The contrary view still finds vigorous expression in some quarters in spite of the rapid growth both of the volume of fishing and of the efficiency and destructiveness of fishing gears.

Most fishes are enormously prolific. A female turbot will produce in one spawning season more than 8,000,000 eggs, a cod 4,500,000, a plaice 300,000, a herring 31,000. The eggs produced by individuals of most of the species of chief importance are numbered at least in hundreds of thousands; but at all stages of their life the fishes are beset by a host of enemies, among whom it is probable that man has been, until recently, the least destructive.

With the growth of the population of the world and the increasing demand upon available resources of food, it has begun to be recognized that man has hitherto failed to take full advantage of the enormous resources of the sea. Approximately three-quarters of the earth's surface is covered by water; but the great fishing grounds of the world are determined primarily by the depth of water upon them, and are almost entirely within the limit of a depth of 250 fathoms, and chiefly within 100 fathoms. It is improbable that any great abundance of fish is to be found far beyond these limits, and in any case the difficulty and the cost of fishing operations by the methods hitherto in use increase in proportion to the depth of water on the fishing grounds. It is thus on what may be described as the shelves of the continents or the banks of the oceans that the deep-sea fisheries, the chief commercial fisheries of the world, are prosecuted.

Historically speaking, there has been no parallel to the development of the fisheries of the North Atlantic and North Pacific, and more particularly of European waters. Nor must it be forgotten when speaking of the great industrial developments of fisheries in Europe in the 20th century, and particularly of the ubiquitous trawlers of Great Britain, that in the days of the Tudors English fishermen were fishing not only in the North sea and other home waters, but at Iceland, as far east of the North Cape as Vardo, and even off Newfoundland. Throughout the middle ages salt fish played a recognized part in the economy of European nations; it was the Lenten fare of Roman Catholic Europe: a regular part of the rations of armies in the field, and the complement of salt meat in the winter food of northern Europe.

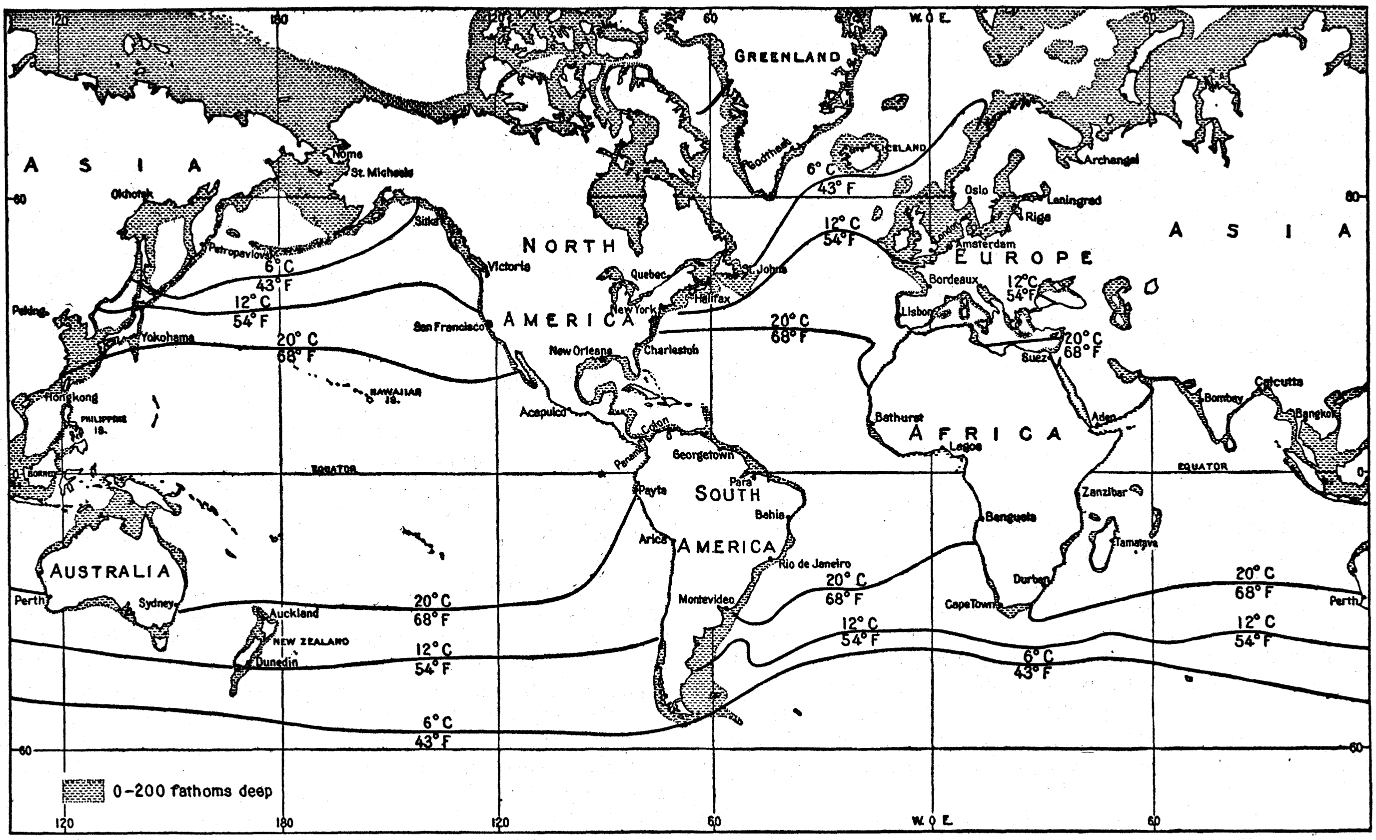
In Great Britain consumption of fish per person is about 32 lb. annually, and the total consumption of fish is normally about a quarter of the total consumption of meat. Fish is also the raw material of various industries: fish-canning; fish-salting; herring-pickling; the manufacture (from surplus fish and fish offal) of fish meal, which is a useful feeding stuff for poultry, pigs and cattle, and of fish-manure; and the production of oil of various grades from medicinal cod-liver oil to cruder oils used for such purposes as tanning, soap-making and tempering steel. Glue and isinglass are also among the by-products of fisheries, and fish skins are also converted into fine leather.

Again, fishing by modern methods provides employment on a large scale in connection with shipyards, ice factories, net factories, motor works, etc. The fishing ships of Great Britain use about 2,000,000 tons of coal and 171,000 tons of diesel and heavy fuel oil a year. The daily transport of fish is an important factor in the activities of the railways. The distribution of fish from the wholesale markets to the retail shops and to the fried fish shops —which handle about 40% of the total quantity of fish consumed — provides employment for many hands. If account be taken of the many trades and occupations which are in some sort ancillary to or activated, in whole or in part, by the fishing industry, it will be seen that, although the number of fishermen is comparatively small (about 43,000 in Great Britain at mid-20th century), the failure of the industry would cause widespread repercussions in the labour market. In every country with a fishing population this would be a calamity; in some, such as Norway and Iceland, where the leading industry is fishing, it would be a disaster.

But the influence of the fishing industry goes farther and deeper than this. It is not generally recognized how great a part fisheries have played in the destinies of nations. A full history of fisheries and even of the fisheries of any one country has yet to be written. When the first man ventured to sea in a dugout, it is probable that his purpose was the better to pursue fish, and not only the modern deep-sea trawlers, liners and drifters, but the merchant and fighting navies are the lineal descendants of the prehistoric fisherman in his dugout. Thus fishing may be presumed to have prepared the way for sea trade, without which modern civilization is inconceivable. The growth of the all-powerful Hanseatic league from the small beginnings of the herring fisheries of Scania, and the rise of the sea power of the Dutch in the 17th century, following upon their predominance in the fisheries of the North sea, are comparatively modern instances of the influence of fishing on shipping. "It is the fish taken upon his majesty's coasts," wrote Sir William Monson, admiral of the Narrow seas, in the reign of James I, "that is the only cause of the increase of shipping in Europe; and he that hath the trade of fishing becomes mightier than all the world besides in the number of ships."

The Tudors in England feared a loss of sea power from the decline of the fisheries which followed the Reformation, and by various measures, including the so-called "political Lent," sought to give a new impetus to the fisheries. The Stuarts, with the same object in view, sought to assert a British dominion over the North sea, and it was with the temporary decline of its fishing fleet that in the subsequent struggle with the Dutch, Great Britain encountered perhaps its greatest humiliation at sea. Moreover, throughout the history of Great Britain, the fisheries have not merely been a "nursery" for the mercantile marine and the royal navy but have directly contributed their quota to the fighting forces at sea, and when in World Wars I and II the fishermen with their ships played a prominent part in combating the menace of mine and submarine. history was repeating itself, as it had from age to age with variations, from the days when the fishermen of the Cinque ports acquired their privileges in return for naval service.

Fishing Methods and Gears. — The methods of catching swimming fish are almost innumerable, but all of them are variations of



FROM THE REPORT OF THE IMPERIAL ECONOMIC COMMITTEE, PART V—FISH

MAP OF THE WORLD WITH THE AREA WITHIN 200-FATHOM LINE STIPPLED SHOWING THE LOCATIONS OF THE PRINCIPAL FISHING GROUNDS, AND THE MEAN ANNUAL ISOTHERMS INDICATING THE DISTRIBUTION OF THE KINDS OF FISH

a few radical methods. One, perhaps the earliest, is that of direct attack by means of a spear and is still in use in some parts of the world. The next is a trap devised to intercept and capture roving fish. The various forms of fishweirs still found here and there, which work on the principle of admitting fish on the flood tide and trapping them on the ebb, are probably of primitive origin. From the fishweir or dam of stone or clay to a similar trap of wattle hedging and then to fixed nets is a natural logical evolution. Another form of trap is that into which fish are attracted by food, examples of which, probably of primitive origin, are the wicker-work traps for catching lobsters, prawns and crabs.

The baited line was probably first used without a hook, as it is even now in the method of catching eels known as "clotting" or "bobbing," that is tying a bunch of worms at the end of a line, and, when it has been taken by the eel, drawing it swiftly in before the eel has had time to disengage its teeth. This method was improved upon by the introduction of a hook, the earliest form of which may have been the thorn hooks still used in parts of Wales and the Thames estuary. From these methods the more elaborate devices employed in modern commercial fishing were evolved, the most important development being the device of bringing the trap, in the form of a net, to the fish, instead of trusting to the natural movements of the fish or the lure of bait to bring the fish to a stationary trap.

In the fisheries of the North Atlantic, which are the most highly developed and commercially organized in the world, the methods of fishing of chief importance are trawling, seining, drifting and lining. Trawling and seining, involve the use of a net which is brought to the fish. In the case of the trawl this is done by dragging a bag-shaped net the mouth of which is kept open either by a beam across the head or by its being towed by a pair of ships each with a warp to one side of the net, or by the pressure of the water upon wooden kites known as otter boards attached to the sides of the mouth, or wings, of the net, and, in the case of the seine, by gradually encircling the fish with a net in the centre of which is a bag not unlike that at the end (known as the "cod-end") of the trawl. The beam trawl is used only on some small fishing craft; the otter trawl is employed on almost all but the smallest trawlers. It is, having regard to all possible circumstances, the most effective instrument for taking demersal (*i.e.,* bottom-living) fish. The efficiency of the otter trawl was improved by several modifications, one of the most notable of which was the Vigneron-Dahl modification, a French invention of about 1924, which incorporated wires of up to 50 fathoms in length as the attachment between the otter boards and wings of the net. The Spanish method of pair trawling is very efficient for catching hake near to the sea bed, and pair trawling for herring off the bottom with large-mouthed trawls is very effective on certain grounds. Seines are used for catching both pelagic and demersal fish. The forms' most used in pelagic fisheries are the purse seine and the rather similar ring net.

Both involve first surrounding a shoal of fish with a curtain or wall of netting, the top of which is buoyed at the surface, and secondly, drawing together the bottom of the net by purse lines to trap the fish in a hemisphere of netting. The most efficient form of seine for catching demersal fish is the Danish seine, invented in Denmark, where it is the principal means of catching demersal fish. It is also used widely in other European countries, particularly Scotland and England. This method involves first encircling an area of the sea bed with two ropes of equal length of up to about one mile, which are attached one to each wing of a trawl-shaped net, and secondly drawing in the rope to an anchored ship so diminishing the area of sea bed surrounded. Fish are driven before the moving ropes to the centre of the encircled area and are then taken in the net which is eventually drawn up to the ship.

The principle of the drift net differs from that of the trawl and of the seine in that it is not actively approached to the fish. On the other hand, it differs from the stationary trap and the many forms of stationary net in that it is attached either to a floating buoy or to a drifting ship (hence the name) and moves with the buoy or ship under the influence of wind and tide. It is lightly and strongly made of cotton and is the instrument principally used in the great herring fisheries. Each herring net measures from 50 to 60 yd. long and about 14 yd. deep, but the nets are used in "fleets," as many as 85 or more of them being employed at one time from one vessel so as to form an extended wall of netting hanging perpendicularly in the water. The net is generally fished about 3 yd. below the surface of the water, being kept at the right level by a series of buoys or "pellets" connected with the headline by strops. This net is devised to intercept sizable fish which in the attempt to pass it are caught by the gills. Drift nets of various dimensions are used for catching "pelagic" fish, that is to say, fish that swim in the upper layers of the water, chiefly herring, mackerel, pilchards and sprats. Drift nets of larger mesh are also used for catching salmon.

Fishing by means of lines with baited hooks was formerly of much greater commercial importance than at present. There are three methods of lining, hand-lining, long-lining and trolling. In hand-lining the line is drawn by hand as soon as the fish is felt; in long-lining the line is shot and left unattended until it is time to haul; in trolling the lines are towed through the water and hauled when fish are caught. Hand lines are of greatest commercial importance in the Pacific tuna fisheries. A long line is fitted with a great number of hooks attached to the main line by thin strong lines of materials which vary according to the character of the fish and to local custom. Long lines may be set at low water on the sands, but more often they are worked from fishing vessels in deep water. Deep-water lines are anchored and buoyed at each end, and sometimes at intervals along their length, when used to catch demersal fish, bat are not anchored when used pelagically. On a large liner the number of hooks on one line may vary from 1,000 to 5,500. Deep-sea long lines are chiefly used demersally for cod and halibut and pelagically for tuna. The baits vary according to local conditions and include mussels, squid, herring and small pelagic fish.

FISHERIES PRODUCTION

World Fisheries. — The pursuit of fish is world-wide. No estimate of the output of the fisheries of the world can be wholly reliable because in many parts of the world where fishing is actively carried on no statistics are compiled. This applies particularly to inland fisheries, many of which are of great economic importance. However, most of the countries of Europe, the United States, the British dominions and Japan publish some form of annual statistics. A comprehensive statistical account of the greater part of the world fisheries is published in the *Yearbook of Fisheries Statistics* of the Food and Agriculture organization of the United Nations; of the fisheries of Europe in the *Bulletin Statistique* des *Pêches Maritimes* of the International Council for the Exploration of the Sea; and of the fisheries of the U.S. in the *Statistical Digest* of the fish and wildlife service of the U.S. department of the interior.

The fisheries in the cold and temperate waters of the northern hemisphere, with a yield equal to about 80% of the world total, produce an overwhelmingly great part of the world's fish supplies. Probably the best estimate of the annual world production of fish since World War II is that published by the Food and Agriculture organization of the United Nations, which put the figure at 27,100,000 metric tons in 1953. The published statistics of 1953 did not include the fisheries of the U.S.S.R. and China among the major fishing countries; with the exception of Japan they omitted most of the orient and the islands of the South Pacific and South Atlantic; also they omitted Turkey, parts of South and Central America, the West Indies and the greater part of Africa. The known quantity of world fisheries production in 1953 was 16,128,100 metric tons. Asia produced 43%, Europe 27%, North America 13% and the U.S.S.R. 9% of the estimated world total. By oceans the approximate share of estimated world production was Pacific 53%, Atlantic 46% and Indian Ocean 1%.

Japan is by far the foremost fishing country in the world, producing 4,576,500 metric tons in 1953, or 17% of the estimated world production. The production in 1953 of the other major fishing countries was, in metric tons, U.S. 2,385,200, Norway 1,505,500, United Kingdom 1,121,600, Canada 924,700, and, estimated, U.S.S.R. 2,500,000 and China 3,000,000. In Europe, next in order of greatest yield after Norway and the United Kingdom came the German Federal Republic with 730,400, Spain with 634,700, France with 520,300, Iceland with 424,700, Portugal with 392,400, the Netherlands with 343,300 and Denmark with 342.800 metric tons.

Shellfish. — The term shellfish embraces the edible species of both crustaceans (crabs, lobsters, crawfish, prawns and shrimps) and molluscs (oysters, mussels, cockles, scallops, clams, whelks, etc.). Their economic importance varies from country to country but is nowhere comparable with that of the fisheries for what are commonly known as wet fish. For instance. in Great Britain the total value of all shellfish (1953) was £1,229,000 as compared with £41,000,000 worth of wet fish, while in the U.S. the total landings of shellfish (1953) were worth $153,126,000 as compared with $199,149,000 worth of wet fish. The 1953 catch of shrimp in the U.S. was valued at $76,641,000 to the fishermen and that of oysters was worth $29,000,000 (*see* OYSTER). Lobsters are an important article of commerce in Canada and the U.S.; considerable quantities are exported. Japan has a considerable trade in canned crab meat and South Africa in canned and frozen crawfish.

The yearly values of the lobster and crab fisheries of Great Britain, producing 1,766,000 lobsters and 11,396,000 crabs, are £314,000 and £342,000 respectively. It is interesting to observe that the shrimp fisheries, yielding 37,000 cwt. annually, reach a value of about £143,000. The most prolific of the fisheries for molluscs are the cockle and mussel fisheries, in that order. The potential output of the mussel fisheries of Great Britain is very great, but the liability of mussels on beds polluted by sewage to transmit such intestinal diseases as typhoid makes cleansing essential and this, although economically practicable, restricts the fishery. The chief importance of the shellfish fisheries of Great Britain lies in the fact that they contribute to the livelihood of the declining population of inshore fishermen.

BRITISH FISHERIES

It is worthwhile in a study of fisheries to consider the British fisheries in some detail because they are, so far as sea fishing is concerned, the most highly organized in the world, with the possible exception of those of Japan. The inland fisheries of Great Britain are of little commercial significance. The salmon fisheries are exploited commercially, and thus have a certain importance, but reliable statistics of the catch of salmon in the British Isles are not available. The salmon fisheries of many of the rivers of Great Britain have suffered from reckless pollution. At their best they could not bear comparison in the commercial sense with those of the western rivers of North America which provide, in the various breeds of Pacific salmon, the raw material of a great canning industry and trade. The value of the trout and freshwater fisheries of Great Britain is almost wholly recreative.

It is as a deep-sea fishing nation that Great Britain is supreme, for no country has as great a fleet of powerful vessels equipped for distant voyages. In 1953 the fishing fleet of Great Britain included 1,015 steam and 593 motor vessels of more than 30 gross tons; nearly all of the steam vessels were trawlers, and most of the motor vessels drifters or seiners. In general steam power was preferred for the large distant water trawlers although some of these were motor driven, but late additions to the fleet of near-water trawlers, seiners and drifters were exclusively motor vessels. Comparative figures for the fleets of other European countries (vessels over 30 tons gross in 1953) were: German Federal Republic 200 steam and 356 motor, France 60 steam and 1,247 motor, the Netherlands 42 steam and 45j motor, and Norway 1,699 steam and motor vessels. The sea-fishing fleet of Denmark consisted of 1,336 vessels of more than 15 tons, most of them seiners and all motor driven.

Of the 1,147 vessels of more than 15 tons fishing from ports in England and Wales 616 were steam trawlers and 181 motor trawlers, 135 drifters or drifter-trawlers, mostly steam powered, 97 motor seiners and 56 motor liners. In Scotland the steam trawlers and motor drifters and seiners are the most numerous and important fishing vessels. British trawlers visit the fishing grounds

TABLE I.—*Quantity and Value of Demersal and Pelagic Fish of British Taking Landed in Great Britain in 1913, 1926 and 1953*

Year	Demersal		Pelagic (chiefly herring)	
	Quantity (cwt.)		Quantity (cwt.)	£ Value
1913	11,096,000	9,096,000	12,317,000	4,633,000
1926	10,961,000	13,541,000	8,000,000	3,503,000
1953	14,723,000	36,556,000	4,882,000	4,439,000

of the whole of the continental shelf from Iceland to West Africa and from the eastern Barents sea to the west of Scotland, Rockall and the southwest of Ireland, as well as the Newfoundland banks and Greenland.

The relative importance of the different methods of fishing in Great Britain may be gauged by reference to the following figures: quantity (in cwt.) of wet fish of British taking landed in Great Britain in 1953, by method of capture—trawl 12,405,100, seine 1,271,300, lines 282,800, drift net 3,843,400, ring net 588,700.

Trawlers, seiners and liners take chiefly demersal fish (known to the trade as white fish), but some mackerel are taken by these methods and at certain seasons herring trawlers land considerable quantities, particularly from the North sea Fladen ground and at the Smalls. Herring trawling has been most highly developed by Germany and adopted by France, the Netherlands and Belgium. The relative values of the demersal and pelagic fisheries may be gauged by reference to Table I.

In considering these figures, note that after World War I the herring fisheries, which depend for the most part upon the export trade in cured herrings, suffered seriously from the disorganization of the markets of Europe and particularly those of prewar Russia, which country formerly absorbed more than 50% of the export. The demersal fisheries, on the other hand, which depend mainly upon the home market for fresh fish, were not affected by postwar conditions to a great extent.

Trawling is known to have been practised in Great Britain as early as 1640. The industry was greatly enlarged when the Brixham and Barking smacks opened up the prolific North sea grounds in 1815 and again at the end of the 19th century with the advent of the steam trawler and with visits to Icelandic grounds. The greatest development of trawling in the first half of the 20th century was in arctic waters. The first voyage to the White sea was made in 1905; the most prolific Bear Island grounds, yielding an average of about 120 cwt. to each trawler per day's absence from port, were first successfully fished in 1929. Arctic and Icelandic waters in 1953 yielded respectively 3,006,000 cwt. and 4,036,000 cwt., together representing 34% of the total quantity of all wet fish landed in Great Britain in that year, or 48% of the total British demersal catch. Cod constitutes 75% of the arctic yield. Of other demersal fisheries in 1953, the North sea supplied 25% of the total British demersal catch.

The whole British fishing fleet includes many different designs of vessels, but certain major classes can be recognized. The specifications of typical vessels of these classes are given in Table II.

New methods of fishing are always being tried. The introduction of the Danish seine and its development in Scotland to fly-seining for catching fish just off the bottom, are comparatively recent, as is the practice of ring-netting for herring. There also have been developments of trawling in the direction of improved efficiency of the trawl itself, such as the introduction of Vigneron-Dahl gear around 1924 and the adoption of pair trawling. Later developments in fishing were associated with the use of supersonic

TABLE II.—*Specifications of Typical Vessels of the Main Classes of the British Fishing Fleet*

Type	Length in feet	Beam in feet	Depth in feet	Gross tonnage	Crew
Arctic steam trawler	173	30	14.3	560	28
Large North sea steam trawler	126	23	12.6	270	15

Motor Danish seiner	56	16	7.4	36	4
Motor drifter	73	19	9.5	90	10

recording echo-sounders for locating shoals of fish and the construction of trawls to fish in midwater.

Trawlers did excellent work in World Wars I and II when they were employed principally as minesweepers and escort vessels, usually armed with guns and depth charges.

Especially after the introduction of steam power in the fishing industry, there was a growing tendency in Great Britain toward the centralization and industrialization of fisheries. Table III indicates the relative importance of the major fishing ports in which the commercial fisheries are chiefly concentrated (of the Scottish ports, Aberdeen and Granton alone are largely devoted to steam trawling; of the rest the herring fisheries supply the bulk of the catch, as is also the case of Yarmouth among the English ports).

From a general economic point of view this centralization has advantages, but it had a regrettable sequel in the depression of the smaller fishing ports, which have been unable to withstand the competition of their more powerful and better organized rivals. Their contribution to the fish supply of the country at mid-20th century was no more than 5% of the total—but they had played a great part as a "nursery" of seamen for the mercantile marine and the royal navy and had been the chief source of strength of the lifeboat service.

With the centralization of the fisheries and the development of the steam trawler, by means of which a smaller number of men

can catch a greater quantity of fish, the number of fishermen regularly employed declined. This fact must be reckoned a misfortune to an island nation dependent for its existence on the freedom, of the seas and, therefore, on an adequate supply of seamen to sail and to defend the sea routes.

FISHERIES OF THE BRITISH COMMONWEALTH

If a chart of the world is studied with special reference to the sea areas within the depth of zoo fathoms—that being roughly the limit of the depth of the fishing grounds—it will be seen that most of the principal fishing grounds are fairly easily accessible from different parts of the British commonwealth.

Canadian fisheries together in 1953 yielded a total of 924,700 metric tons, comprised of 240,000 tons of cod and allied species, 237,200 of herring and 86,000 of salmon. The Canadian Great Lakes' fisheries yielded 47,300 metric tons in 1953. In that year about 11,300 metric tons of halibut from the Pacific were landed in the province of British Columbia, where salmon contributes half of the total value of what are the most valuable fisheries of any Canadian province; besides halibut, herring is another important species. Canada built up a large export trade which in 1953 distributed 27,000 metric tons of canned fish and 118,000 metric tons of fresh and frozen fish.

Comparatively little attention was bestowed upon the fisheries of Australia and in the latter 1950s the fishing grounds were only partially explored. The lack of interest in fisheries may be accounted for partly by difficulties of transport and partly by the relative cheapness of meat. Surveys show that there are large areas of trawlable water around the coasts, particularly off New South Wales and South Australia, and there is every reason to believe that they are prolific of fish. The Australian government, through the department of commerce and agriculture, promoted the development of the fisheries. The small trawling industry in New South Wales expanded steadily, and the development of pelagic fishing was begun. Total landings of all fish in Australia in 1952–53 were 51,600 metric tons, including 3,600 of oysters.

The fisheries of New Zealand yielded 35,300 metric tons in 1952. The trawling industry was modernized and expanded, the constitution of the trawler fleet changing from 20 steam and 28 motor trawlers in 1930 to 5 steam and 192 motor trawlers in 1952. The fishery for crawfish increased, but the Danish seine fishery declined. Oysters of a high quality are produced, particularly in the Foveaux strait (New Zealand).

South African fisheries were developed considerably after about 1933, partly as a consequence of continuing surveys which revealed rich and extensive fishing grounds, some quite close to Capetown and others not far from Durban. Trawling and lining increased. The catch of fish was increased more than threefold in the years after World War II to reach a level of 350,000 metric tons in 1953. The export trade, amounting to about £300,000 a year in 1938, rose to £7,820,000 in 1953, an important item of export being preserved crawfish tails, of which 3,300 metric tons were valued at £1,900,000. There is a considerable market for fresh fish in South Africa, particularly in the towns of the Rand.

The fisheries of the tropical regions of the commonwealth stand on a different footing from those hitherto mentioned. It is probable that in the warmer seas there is a greater number of species of fish, but that there are no such great concentrations of any one species as are found in the colder regions. Moreover, the areas within the 200-fathom line are on the whole less extensive in the tropics than in the northern seas, but fishing is practised on practically all the shores of the tropical colonies and of Ceylon, India and Pakistan. On the west coast of Madras about 54,000 metric tons of fish are landed annually and attempts have been made there to develop trawling. There are few statistics for other coasts of India, but it is probable that the economic importance of the inland fisheries is greater than that of the sea fisheries. The fisheries of Bengal supply about 16,000 metric tons of fish yearly to Calcutta alone. In Ceylon and Malaya the sea fisheries are actively exploited, and the governments undertook experimental work with a view to the development on more modern lines of age-old fishing industries.

In British West Africa, where climate and distribution difficulties necessitate fish being cured or processed, the British government, through the colonial office, tried to develop fisheries along the two main lines of fish farming and trawling. Trawling was started in Sierra Leone and in Nigeria. New canneries in the Gold Coast were prepared for increased catches of fish.

Generally speaking, it may be said that throughout the commonwealth there developed in the first half of the 20th century a disposition to pay greater attention than formerly to the food resources of the sea, and that this disposition had been translated into active measures.

JAPANESE FISHERIES

The fisheries of Japan are that nation's principal source of animal protein. Japanese fishermen make an annual catch of about 10,000,000,000 lb. of fish, shellfish and other aquatic products, about one-sixth of the total world catch. Approximately 1,500,000 persons are engaged either full or part-time in fishing and processing of marine products, and about 363,000 boats are used in the industry.

The development of Japan's fisheries, and its leading role in the production of fishery products, is associated with the geographical position of the country, its formation and its large and dense population. It has long stretches of coast, and much of its land area is unsuitable for agriculture and cattle rearing. The fisheries are, in general, not centralized; there are many small coastal fishing villages and few large fishing ports such as prevail in Europe and North America.

Japanese fishing is concentrated largely in the coastal waters of Japan proper, but operations also are conducted in the Yellow, East and South China, Okhotsk and Bering seas; in the North, Central and South Pacific ocean; and on Antarctic whaling grounds. Hokkaido leads in production, accounting for about one-third of the total catch. Honshu and Kanto are also regions of major production.

The principal species taken by Japanese fishermen are sardines, herring, mackerel, cod, tuna, bonito, sea bream, salmon and flatfishes. Shellfish (chiefly crustaceans and octopuses) and seaweed are important contributions to the Japanese food supply.

Aquiculture is important in Japan as in most oriental countries. The main products are carp, eel, mullet, trout, oysters, clams and seaweed.

The fisheries of Japan provide considerable foreign exchange, since large quantities of canned tuna, salmon and crab meat; fresh and frozen tuna and swordfish; fish liver oils and other fishery products are exported.

See Fish and Wildlife Service of U.S. Department of *the* Interior, ***Commercial Fisheries Review,*** published monthly.

UNITED STATES FISHERIES

United States fisheries, second largest in the world, are prosecuted on the seaboard of the Atlantic and Pacific oceans, in the Bering sea, in the Great Lakes and in many prolific rivers. In the Atlantic ocean, U.S. fisheries are conducted from the Grand Banks of Newfoundland to Campeche bank off Yucatan, Mex. On the west coast of North America, the range extends from the Bering sea to the coast of Peru. The variety of fish, shellfish and other aquatic products taken is so great that no summary account can do justice to it. For details, reference must be made to the reports of the United States fish and wildlife service of the department of the interior.

The importance of United States fisheries increased considerably during the first half of the 20th century, largely because of an increase in the output of manufactured products, particularly canned and frozen fishery items, and fish meal and oil.

The total landings of about 4,600,000,000 lb. in the latter 1950s were made by about 153,000 fishermen, and valued at about $325,000,000 to them. About 11,000 documented vessels of 5 net tons and over, and about 48,000 motorboats and 26,000 other boats, were used in making the catch. Processing and handling by primary wholesalers and manufacturers increased the value of the fishermen's catch to $548,000,000, and distribution to $775,000,000, while the ultimate consumer paid over $1,000,000,000 for a year's production.

Fishery products are taken commercially by U.S. fishermen in 40 U.S. states. However, well over 50% of the catch is normally made in only six states: California and Alaska on the Pacific coast; Massachusetts, New Jersey and Virginia on the Atlantic coast; and Louisiana on the Gulf of Mexico. Purse seines account for about 46% of the total weight of the catch; otter trawls for 23%, and lines for 10%.

A discussion of important U.S. fisheries which account for about 80% of the annual catch follows:

Atlantic Menhaden.—This fish, taken along the Atlantic and Gulf coasts, accounts for nearly 40% of the total volume of fish and shellfish taken by U.S. fishermen. The fish are not well known since nearly the entire catch is manufactured into meal and oil. The meal is used largely in poultry feeding, while the oil has many industrial uses and is widely used in Europe for manufacture into margarine. The catch of menhaden first exceeded 1,000,000,000 lb. in 1948, and in 1956 amounted to 2,067,000,000 lb. Nearly the entire catch is made with purse seines.

North Atlantic Trawl Fisheries.—This gear accounts for the major portion of the food fish taken in the North Atlantic states. The catch amounts to about 700,000,000 lb. annually and consists largely of cod, flounder, haddock, ocean perch, pollock and whiting. The major portion of the catch is made in international waters off the New England states, Nova Scotia and Newfoundland.

Pacific Salmon. — The salmon support the major fisheries of the states of Alaska, Washington and Oregon. The fishery reached its peak in 1936 when the catch amounted to 791,000,000 lb. Following that year, production declined and amounted to only 286,000,000 lb. in 1955, the smallest catch in nearly 50 years. Most of the catch is canned. The fish are caught principally in purse seines, pound nets and gill nets.

Pacific Tuna. — Tuna are the leading species taken in the Pacific Coast states, and they are the principal canned fish packed in the U.S. The major portion of the catch, which is landed in California, is taken off Mexico. Central and South America. In 1955 the U.S. catch of 265,000,000 lb., and imports of 145,000,000 lb., principally from Japan, were used to pack 193,000,000 lb. of canned tuna.

Shrimp. — Shrimp are the most important species taken in the South Atlantic and Gulf states, and they are the most valuable item taken by U.S. fishermen. These shellfish are captured principally by trawls operated by about 8,000 fishing craft. In 1955 the catch totalled about 250,000,000 lb., somewhat less than the record 265,000,000 lb. taken in 1954.

Herring. — The U.S. has two distinct herring fisheries, one on each coast. The Atlantic fishery is centred in Maine where the fish are packed as canned sardines. The Pacific fishery occurs principally in Alaska where the fish are used largely in the manufacture of fish meal and oil. In 1955 the herring catch in Maine amounted to 99,000,000 lb., while 63,000,000 lb. were taken in Alaska. Most of the Maine catch and all of the Alaska catch is taken with purse seines.

Pacific Sardines. — The Pacific sardine fishery, centred in California, is an outstanding example of the rapid growth and decline of a major fishery. First taken in large numbers in World War I, the fishery grew from 4,000,000 lb. in 1915 to 1,502,000,000 lb. in 1936 and then, because of disappearance of the fish, declined to less than 10,000,000 lb. in 1953. Following 1953, the fish became more abundant and a catch of 143,000,000 lb. was made in 1955. The entire catch is taken with purse seines, and the fish are canned or manufactured into meal and oil.

Crabs. — Various species of crabs are taken in all of the coastal states (including Alaska). The blue crab fishery centred in the Chesapeake bay, South Atlantic and Gulf states accounts for the major portion of the catch, followed by the larger Dungeness crab of the Pacific Coast states, and the giant king crab taken largely in the Bering sea. The total catch of crabs normally totals about 145,000,000 lb. Most of the catch is taken with pots and trot lines.

Oysters. — The U.S. oyster fishery is the largest in the world and produces about 80,000,000 lb. of oyster meats annually. The major portion of the catch is taken in Virginia, Maryland, Washington, Louisiana' and New Jersey. The Atlantic and Gulf fishery is based on the native eastern oyster, while on the Pacific Coast most of the oysters harvested consist of Pacific oysters grown from seed imported from Japan.

Disposition of the U.S. Catch. — The 1955 U.S. catch of 4,600,000,000 lb. was utilized as follows: fresh and frozen, 1,401,000,000 lb., or 30%; canned, 1,093,000,000 lb., or 24%; cured, 85,000,000 lb., or 2%; and for by-products and bait, 2,021,000,000 lb., or 44%.

Foreign Trade. — A large portion of the U.S. supply of fishery products is derived from imports. In 1954 imports were valued at $252,000,000 and accounted for nearly 39% of the total U.S. supply of fishery products. The principal items imported are: frozen and canned tuna; frozen groundfish and other fillets; fresh and frozen lobsters, shrimp, salmon and halibut; and canned sardines. Exports of fishery products from the U.S. in 1954 were valued at $31,500,000. They consisted largely of fish liver oils and canned salmon, sardines and anchovies.

Administration of the Fisheries. — The administration of the fisheries of the continental U.S. is in the hands of the various states except in certain fisheries where authority has been delegated to international agencies or other bodies as a result of a treaty. In the absence of a treaty, only the state governments have authority to regulate the fisheries. The fish and wildlife service of the department of the interior is the federal fishery agency.

Its activities include the conduct of a wide range of biological and technological research; assembling and publishing detailed statistics; issuing daily market news reports in important fishing or fish distributing centres; conducting economic surveys, exploratory fishing operations, and a wide variety of fishery educational and market development activities; and operation of fish hatcheries throughout the United States. In Alaska, the fish and wildlife service controls the Pribilof island seal herd numbering several million animals.

PISCICULTURE

The prospect of considerably increasing by artificial means the stocks of those multitudinous fishes which are the foundation of the great modem commercial fisheries seems remote. There is no reason to discourage researches directed to the artificial propagation of fish of every kind, but for the present the more practical line of inquiry will be that which aims rather at the prevention of wasteful exploitation than at artificial contributions to the stock.

Certain fishes lend themselves to the art of pisciculture, more or less according to circumstances. Among freshwater fishes those of the carp family can be successfully bred and reared in captivity, and fish farming with this species is practised on a commercial scale in many eastern countries and in Czechoslovakia.

Trout can be profitably hatched in special receptacles and reared in suitable ponds to the yearling or two-year-old stage, or even further, to be disposed of either for stocking or restocking sporting waters or for consumption in hotels and restaurants. The process is comparatively simple. Usually the ripe female fish are "stripped," the eggs being allowed to fall into a vessel of water into which a little milt from the male is introduced, the eggs thus fertilized being then transferred to the hatching receptacles. The same process can be applied to sea fishes, and experiments have been carried out in the distribution of newly hatched larvae of plaice and cod in waters where it is desired to increase the stock; but there is no convincing evidence in the case of these fishes that the result sought has in any case been achieved. The great fecundity of sea fishes is nature's provision against an enormously high rate of mortality, and the number of larvae which it is practicable to hatch in a hatchery of reasonable size is so small by comparison with the natural distribution that it is inherently improbable that the output of a hatchery could make an appreciable difference in the abundance of the stock. The investigations undertaken by Capt. G. M. Dannevig in selected Norwegian fjords in 1904 and 1905 tended to confirm this conclusion. (See *Report for 1906 of the Lancashire Sea-fisheries Laboratory*, Liverpool, 1907.)

A possible exception may be found in the results of the work of the Commission on Inland Fisheries in the artificial rearing of young lobsters from the egg to the lobsterling stage in the quiet waters of Rhode Island, U.S. There appears to be some evidence of improvement of the lobster fisheries resulting from this work, but whether the improvement is to be attributed to this cause or to such methods of conservation as, *e.g.*, protection of the berried female, and whether in the former case the improvement has been proportionate to the cost involved, is open to some doubt. (See *Annual Reports of the Commissioners of Inland Fisheries, Rhode Island*, especially those for 1908 [special paper by A. O. Mead] and 1910 [appendix].)

Artificial methods of cultivation have chiefly proved useful where it has been desired to populate streams or parts of streams which are understocked, or to introduce into a river a new species of fish. The shad was successfully acclimatized in the rivers of California and in the Mississippi by the distribution of artificially propagated eggs from the eastern rivers of the United States. The quinnat and Atlantic salmon and the brown and rainbow trout were

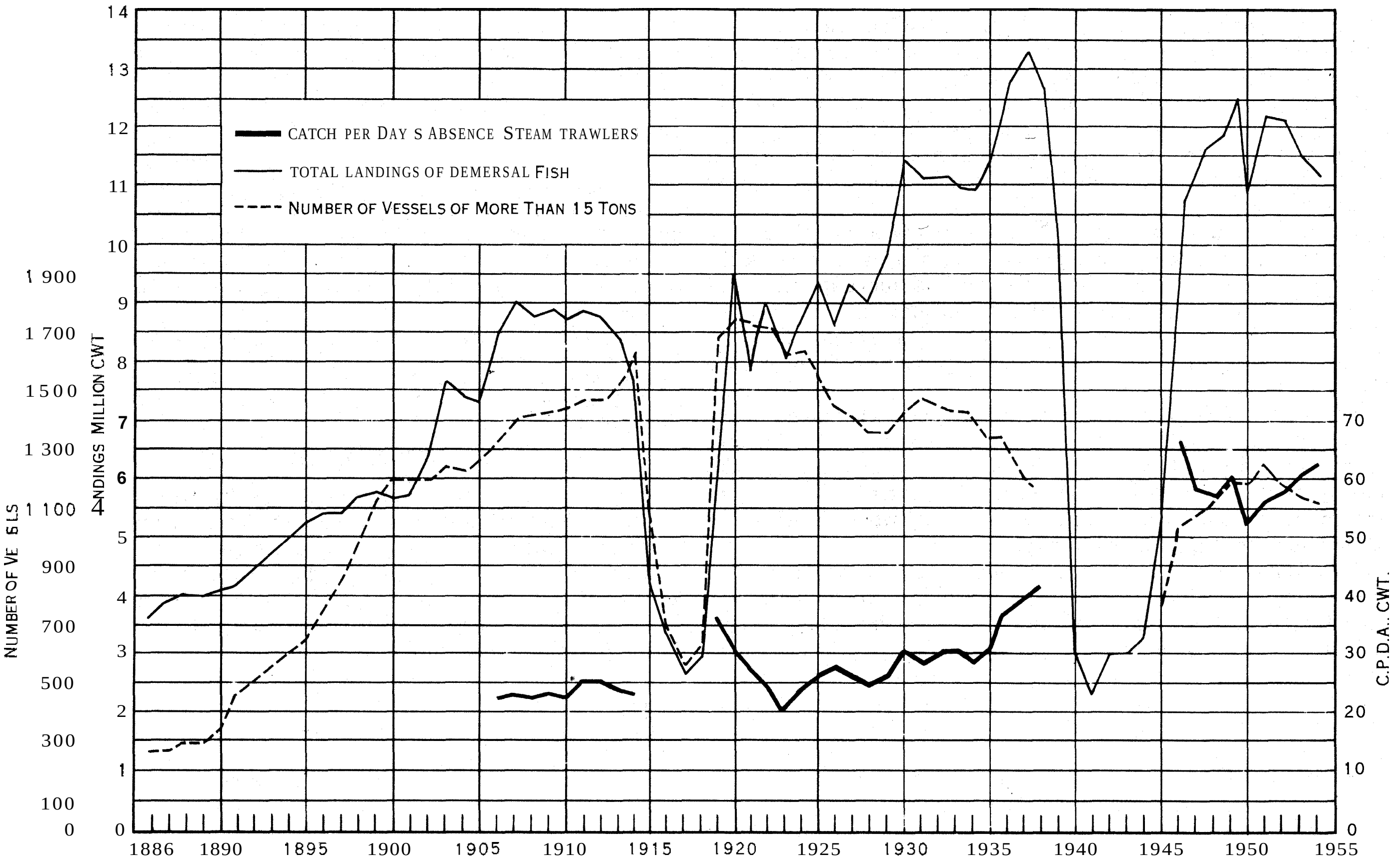

CHART SHOWING THE TOTAL LANDINGS OF DEMERSAL FISH AND THE NUMBER OF FISHING VESSELS OF OVER 15 TONS (EXCLUDING DRIFTERS. 1899–1950) IN ENGLAND AND WALES. YEARLY FROM 1886, AND THE AVERAGE CATCH PER DAY'S ABSENCE FROM PORT (C.P.D.A.) MADE BY BRITISH STEAM TRAWLERS FROM 1906 (EXCLUDING WAR YEARS)

by similar means successfully naturalized in the rivers of New Zealand. Experiments carried out in certain British rivers for the purpose of improving the native stock of salmon by the introduction of fresh blood by crossing with the stock of other rivers by means of artificial fertilization of the eggs were inconclusive.

There is another branch of pisciculture which may be broadly summed up as transplantation. This method is familiar to every oyster planter and is usefully employed in the cultivation of other molluscs, such as cockles, mussels, etc. The main purposes of transplantation of molluscs are to relieve overcrowding of young fish and to place the mature fish on beds where the conditions are suitable for fattening. Transplantation is an essential feature of successful oyster farming (see OYSTER).

Successful results have attended the transplantation of eels. Millions of elvers have been annually captured in the Severn river and exported to Germany for distribution in suitable waters in that country. Similarly elvers are trapped in the Danish fjords and transplanted to suitable lagoons to become the source of a profitable industry.

Reference is made below to the rapid growth of plaice transplanted from the eastern waters of the North sea to the Dogger bank, and Denmark undertook such transplantation on a pioneer commercial scale. Similar experiments in the transplantation of plaice from the outer lagoons of the Limfjord in Denmark to the inner, which are rich in food but are blocked against the immigration of flat fish by dense growths of sea grass (*Zostera*), laid the foundations of a profitable fishery in these waters.

Experiments in a Scottish loch showed that it is possible to increase substantially the growth rate of flounders in enclosed waters by fertilizing the water with inorganic salts to induce increased plankton growth and subsequently increased supplies of fish foods, but this method of fish culture seemed unlikely to prove an economic proposition outside fish farms.

So far as experience goes, then, it is clear that attempts to increase the supply of sea fish by artificial hatching had been unsuccessful, that the increase of the stock by transplantation succeeds in the case of molluscs and in the case of flat fish in special circumstances, such as those appertaining in the Danish fjords, and might prove successful with certain fishes in more open waters. Artificial propagation from the egg is useful for the introduction of a new stock of fish in suitable river waters either by the distribution of eyed ova or, where that is impracticable, by the distribution of young fish which have reached an age at which they can take care of themselves. It is extremely doubtful whether it is ever worth while to distribute the newly hatched larvae, which are very delicate, and on distribution in the open waters of a stream or of the sea are exposed to a thousand hazards.

Scientific Research and Fisheries Conservation.—At the International Fisheries exhibition of 1883, T. H. Huxley said. "I believe that the cod fishery, the herring fishery, the pilchard fishery, the mackerel fishery, and probably all the great sea-fisheries are inexhaustible; that is to say that nothing we do seriously affects the number of fish." In an earlier passage of his argument, which was, in effect, that the fish were so prodigiously numerous and the quantity caught by man so insignificant by comparison with the other destructive agencies at work that regulation of man's operations would be futile, he qualified his conclusion with the words, "in relation to our present method of fishing."

In 1883 the use of steam po er for fishing was hardly regarded seriously (the first experiment was made in 1877 with an old paddle tug out of North Shields), the otter trawl had not been invented, and the carefully designed steam trawler had not been dreamed of. Every innovation is an object of suspicion, especially among such conservative folk as fishermen, and Huxley was familiar with the complaints laid against the beam trawl before the royal commission of 1864 of which he was a member. Circumstances later became very different and, whatever view may be taken of the controversial topic of overfishing no one is now likely, with full knowledge of the evidence. to say that the operations of man are insignificant in their effects upon the composition of the stock of fish.

The exhibition of 1883 gave impetus to a demand for scientific investigation of the sea and its resources which had already made itself felt. Ten years had passed since the "Challenger" sailed on its famous voyage. The fishery board for Scotland had just begun systematic inquiries; abroad. notably in Germany, marine science was establishing itself and in Great Britain the next year was to witness the establishment of the Marine Biological Association of the United Kingdom. With the rapid development of fishing which followed the introduction of steam and later (about 1895) of the otter trawl, the old apprehensions were intensified and compelled the serious attention of the governments, so that, when in 1899 the king of Sweden invited representatives of the countries interested in the fisheries of the North sea and the Baltic to a conference at Stockholm to discuss the subject of co-operation in the study of marine problems the response was general. After a second conference in Christiania (Oslo) in 1901, the International Council for the Exploration of the Sea was constituted to co-ordinate the national researches of the participating countries. Later all the countries of northern Europe with important fishing interests together with Portugal and Spain became members of the council and the council's investigations covered the whole of the continental shelf of Europe and northern Africa outside the Mediterranean. In 1919 there was established the Commission Internationale pour l'Exploration de la Mer Méditerranée, fashioned in many respects on the model of the International council.

The aim of economic marine biology was well summed up in the object set before it by the International Council for the Exploration of the Sea: "the rational exploitation of the sea." To exploit the sea rationally means. presumably, to get as much out of it as is possible at the least possible cost and without waste.

The first necessity is to know, or at least to have a rational conception of what the stock of fish is and what are the factors governing these fluctuations of it which have puzzled and alarmed generations of fishermen. The first step in any such inquiry must take the form of statistics. The most complete and comprehensive statistics of sea fisheries are those of Great Britain. The International council and the United Nations' Food and Agriculture organization realize the importance of uniformity of method in the collection and presentation of statistics, but few other countries were as well equipped as Great Britain for their collection. The British statistics record annually the total landings of fish and of each of the most important food fishes separately. their values. the region in which they were taken, and the fishing power expended in their capture including the types, numbers and tonnage of fishing vessels. Note is taken of the proportions of the different trade categories in the landings—large, medium and small—and observers at the ports measure the lengths of fish in samples typical of the catches landed and also collect material to enable the age census of fish stocks to be made.

Increased landings from any region may be the result merely of increased fishing; therefore, note is taken of the number of voyages made and the length of time spent in fishing, from which is calculated the quantity of fish landed per day's absence from port or per 100 hr. of fishing. Allowance has to be made, as well as may be, for increased size and power of the ships fishing, and for increasingly efficient gear. Further observations on the populations of fish, particularly on the young fish that have not yet grown to a marketable size, are made by scientists working on specially equipped research vessels. The actual stock can never be other than estimated approximately; but the data collected by the methods just enumerated enable a reasoned opinion to be formed as to whether, making due allowance for all other factors, the stock is being overfished.

The accompanying chart, which illustrates generally the method of comparison of landings with fishing power, presents two interesting features. The first is the similarity between the ascending curves of landings and of steam power employed until t o new factors, the general adoption of the otter trawl and the development of fishing on the more distant grounds, appear to be reflected in a steep rise of the curve of landings. The second is the high point at which the interrupted curve of catch per day's absence from port starts immediately after each of the wars, during which little fishing had taken place, and its rapid decline apparently reflecting the influence of renewed fishing. In this curve the threefold increase in weight of the overfished North sea stock during the war years is somewhat masked by the increasing landings from the arctic.

Table IV of the landings of North sea plaice is an interesting illustration of what appears to be the effect of fishing operations on the composition of the stock of a single species of fish.

The graph and the table are to be regarded merely as samples of the statistical data by means of which the endeavour is made to record changes of the stock (which, in the nature of things can, at best, only be estimated) and to form a reasoned opinion as to the relation between these fluctuations and the operations of men.

Table IV.—*Quantities of Large, Medium and Small Plaice, Landed at English Ports from the North Sea by All Classes of British Vessels in Each Year from 1906 to 1927*

(In 000 tons)

	Large	Medium	Small	Total (excluding unsorted)
Pre-World War I 1906	10	7	9	26
1907	8	8	14	30
1908	8	8	13	29
1909	6	9	14	29
1910	5	8	11	24
1911	5	8	13	26
1912	5	9	11	25
1913	5	8	10	23
War 1914	4	6	10	20
1915	2	2	2	6
1916*	1	2	1	4
1917*	1	2	1	4
1918*	2	0	2	13
Postwar 1919	9	13	2	24
1920	13	12	5	30
1921	6	11	6	23
1922	5	10	11	26
1923	3	6	12	21
1924	2	5	14	21
1925	2	4	16	22
1926	1	3	14	18
1927	1	4	16	21

*Estimated figures.

Such statistical data are the starting point of biological investigations and may furnish the test of provisional biological conclusions. In order that all factors affecting the stock of fish may be taken into account, it is necessary to study the life histories of the food fishes severally and collectively. Since the life histories of fishes, as of other animals, must be governed mainly by the factors of their environment, that environment must also be studied. The most important factors of the environment are, to express it very generally, climate and food, the former naturally reacting to a great degree upon the latter. What corresponds to climate in the sea is—again speaking in general terms—the physicochemical composition and the movements of the water. It is an established fact that all animal organisms depend ultimately for their food supply in the sea, as on land, upon plant life.

The fixed seaweeds are found only in a narrow fringe in shallow water around the coasts, but in the upper water layers of the whole ocean to such depths as sunlight can penetrate are multitudes of microscopic plants, constituting the phytoplankton, upon which above all depends the great productivity of the sea. These plants are eaten by the small animals constituting the zooplankton which, in their turn, are eaten by larger animals, until at the other end of the food chain the fishes are exploited by man, who thus ultimately depends upon vegetable growth. The plant harvest of the sea depends on many physical and chemical factors, the most important being suitable temperatures, an adequate supply of sunlight, of carbonic acid and of certain chemical salts.

In 1924 the International Fisheries commission was established for the preservation of the North Pacific halibut fisheries, followed in 1937 by the International Pacific Salmon Fisheries commission and in 1940 by the International Commission for the Northwest Atlantic Fisheries. The convention of the International Overfishing conference, 1946, with a permanent commission for its administration which was drawn up as a result of the findings of the International Council for the Exploration of the Sea came fully into operation in 1954. These bodies all had the object of reviewing the results of scientific investigations of fisheries and framing regulations designed to achieve better international co-operation in and rational exploitation of the fisheries. An Indo-Pacific Fisheries council was set up in 1948 and a General Fisheries Council for the Mediterranean in 1952, both primarily for co-ordination of scientific investigations.

Branches of Research. — Thus, fishery research is divided broadly into five branches — statistics, to which reference has already been made; investigations of fishes; investigations of their food, including both the planktonic organisms and the invertebrates found at the bottom of the sea; hydrographical investigations; and investigations into improved methods of fishing and of fish preservation. The factors to be taken into account are so numerous and so complex and the area of inquiry so wide that the only hope of arriving at well-founded conclusions within a measurable space of time lies in organized team work. This fact was recognized by the representatives of the member countries of the International Council for the Exploration of the Sea who undertook shares of a program of work organized internationally through the council. Neither must it be forgotten that the deep-sea fisheries are for the most part prosecuted in waters in which all countries have equal rights of fishing. If, therefore, any practical results are to ensue from the knowledge acquired, in the form of regulation of fishing operations, or, as is not wholly inconceivable, actual cultivation of the stock, these measures must be applied with the good will and co-operation of all the interested countries.

A detail of the study of the life history of fishes of peculiar economic importance is the investigation of the rate of their growth and the variations of the rate of growth responding to different circumstances. For this purpose it is essential to have an index of age. The ages of some fishes — notably of flat fishes and cod — are fixed by counting the annual rings in the ear bones or otoliths, of others — notably the herring — by counting similar rings in the scales. The technique of age determination is by no means simple, and in the case of some samples, considerable difficulty is experienced in making accurate assessments of age.

Again, it is necessary to study the food of fishes by examination of the contents of the stomachs, and to correlate the information thus gained with information as to the distribution and abundance of food organisms. That an adequate supply of suitable food is essential to healthy growth is axiomatic, and it has been suggested that the present rate of destruction of small fish might advisedly be accelerated in order to promote the more rapid growth of the survivors. There is some evidence that overcrowding on unfished grounds during World Wars I and II slightly reduced the growth rate of plaice, but there seemed to be little cause to apprehend that food supplies were overtaxed.

It is also necessary to follow the migrations of fishes and to know the rate of depletion of the stocks caused by removal of fish by fishing, which can both be most directly done, where practicable, by marking large numbers of them and offering rewards for well authenticated information as to the time and locality of their recovery. Marking technique usually involves attaching some form of numbered and conspicuous tag or label to the fish.

Some or all of these various methods of investigation have been applied to the most important of the food fishes particularly the plaice, herring, cod, haddock and hake.

A classical example of the study of growth rate is that carried out in connection with the investigations of the plaice fisheries, where, by marking large numbers of young plaice, 7 to 8 in. long, taken in the shallow waters on the east side of the North sea, transplanting a proportion of them to the Dogger bank, where there is an abundance of suitable food, and leaving others where they were caught, it was proved that the transplahted fish developed at a remarkably greater rate than those left behind. The former, in 12 mo. grew about 5 in. in length and to nearly four times their original weight, while the latter grew little more than 2 in. in length and no more than doubled their weight.

An interesting illustration of deductions from scale reading was furnished by the investigations of Johan Hjort of the Norwegian herring fisheries, by means of which he showed that frequently and, indeed, usually, fish of a certain year group predominated over all other year groups over a series of years, from which it appeared reasonable to deduce that the stock of herrings from year to year depended mainly not upon regular annual accretions, but rather upon occasional floods from particularly prolific years. This phenomenon of the better survival of one year's brood of young fish than that of another is common to other species of fish and its occurrence is used as the basis of fishery forecasting.

The most important examples of the study of the migrations of fish by marking are the experiments conducted in connection with the plaice investigations mentioned above and those with marked cod carried out by Hjort and reported in his *Fluctuations in the Great Fisheries of Northern Europe*, and those with marked herring showing the large-scale movements between Icelandic and Norwegian waters. A notable example of the study of migration by other means than marking was furnished by Johannes Schmidt's investigations of the eel, in the course of which, by following the larval eels, he traced the European eels to their spawning place in the Sargasso sea.

The hydrographical investigations take the form not only of the study of the physicochemical composition (and temperature) of the sea, upon which depends the harvest of the plant growth which, as already observed, is the beginning of the chain of marine life, but also of the movements of the water at the surface, near the bottom and in the intermediate layers, which govern to a great degree the actual distribution of the stock of fish particularly in the larval stages. For these purposes various ingenious instruments have been contrived and are constantly being improved upon; water bottles for the collection of samples at known depths, self-recording thermometers and current meters, drift bottles adjusted to float at or near the surface, or to trail along the sea bottom. By means of such instruments and by many and various lines of investigation a few of which only it has been feasible to indicate above, the endeavour is being made to probe the mysteries of life in the sea.

Investigations of means of improving fishing methods are taking the line of developing means of locating concentrations of fish, such as using echo sounders, and of finding and developing the best gear for a particular fishery.

Provision for Researches. — The government of Great Britain, through the Scottish home department and the fisheries department of the ministry of agriculture and fisheries, with their laboratories at Aberdeen and Lowestoft and several research ships, takes direct responsibility for economic investigations and also supports by liberal grants unofficial institutions devoted to marine research, on no other condition than that their work shall be of such a standard of excellence as to make it worthy of support. The chief of such institutions are the Marine Biological Association of the United Kingdom, with its headquarters and laboratory at Plymouth; the Dove Marine laboratory at Cullercoats, the oceanographical department of the University of Liverpool and the Scottish Marine Biological laboratory at Millport (*see* also MARINE BIOLOGY).

The organization of fishery research varies from country to country, but it can be stated in general terms that in practically every country of Europe provision is made for such researches in a greater or less degree, and with a greater or less measure of government support; that in the U.S. the provision for fishery investigations partly under the direction of the states, partly under that of the central government, is elaborate and extensive; that in varying degree of development corresponding inquiries are in progress in most of the British commonwealth, and, indeed, in every country in which the economic importance of fisheries had gained recognition.

To pass under review the investigations of the first half of the 20th century and their results would be a gigantic task. No more has been possible here than to indicate briefly some of the lines of investigation and their aim.

The uses of science do not end with those studies which bear upon the capture of fish. The art and science of catching fish has developed far more rapidly than that of the disposal of fish when caught. The problem of keeping fish taken on distant voyages in a fresh state is not wholly solved by the use of ice. The fish which. in the course of a distant voyage go first into the hold. and, on return to port, come last out of it, are seldom fit for the fresh fish market; modern day methods of pickling herrings aye practically the same as those of the Dutchman William Beukels in the 17th century. In almost every phase of the handling and use of fish there is work ior the biochemist, and the problem of how to make the best use of the fish when caught became the subject of serious scientific study. Considerable progress was made in devising methods of preservation suitable for application to fish.

The most important advance in fishery technology was the development of quick-freezing; this allowed fish to be kept in cold storage for long periods without noticeable change in condition and thus increased the inland consumption of fish and gave impetus to the development of factory trawlers, several of which were operating by mid-20th century.

FISHERIES, LAW OF. As fishing is carried on both within and beyond regions over which national laws are in operation, any consideration of the law of fisheries must consider both national and international aspects of the subject. The English lam applicable within territorial waters (as to the extent of which *see* WATERS, TERRITORIAL) is explained in the first place, and that of the United States next.

ENGLISH LAW

There is some.confusion in the nomenclature used by early writers on the English law of fisheries, but the classification may be reduced to fisheries which are exclusive, and those which are not. In exclusive fisheries the right of fishing belongs to the owner of the soil, or is derived from him. These fisheries are sometimes referred to as "several" or "free." They may be corporeal. where they comprise both the soil and the fishing, or incorporeal, where they have been granted without the soil. Fisheries which are not exclusive comprise (1) common fishery, which is the right of the public to fish in tidal waters not appropriated as exclusive fisheries, and (2) common of fishery, where one or more persons have a right to fish in common with the person who owned the exclusive right. A fishery does not necessarily include all fish. Thus one person may own the soil and oyster fishery: and another the fishery for floating fish. Royal fish, *i.e.,* whales and sturgeons, are under the statute *De Praerogativa Regis* (1324) the property of the crown and not of the finder.

"Ancient records from Domesday downwards show us that the most ancient and usual mode of enjoying the profit of fisheries, both in tidal and non-tidal waters, was by wiers, kiddels, fishgarths, stake nets, bucks, and other engines fixed into and permanently erected in the soil of the fishery" (Stuart Moore). Thus fisheries originally were profits of the soil over which the water flowed. This is still the general principle. The title to a fishery arises from the right to the soil. The rule is so well established that upon it has been based the converse proposition, namely, that ownership of a several fishery is evidence of the ownership of the soil *(Attorney-General* v. *Emerson,* 1891, A.C. 649). A fishery may be severed from the soil. or *solum,* and become a *profit à prendre in alieno solo* and an incorporeal hereditament, *i.e.,* a right exercisable over the property of another person. This broad principle is not restricted to inland or nontidal waters. It gives to the owners of lands on the foreshore or within an estuary or elsewhere where the tide flows and reflows a title to fish in the water over such lands, and this is equally the case whether the owner be the crown or a private individual. But in the case of tidal waters (whether on the foreshore or in estuaries or tidal rivers) the exclusive character of the title is qualified by another and paramount title which is *prima facie* in the public. "The common people of England" (wrote Lord Hale) "have regularly a liberty oi fishing in the sea or creeks or arms thereof, as a public common of piscary, and may not without injury to their right be restrained of it, unless in such places, creeks or navigable rivers where either the king or some particular subject hath gained a propriety exclusive of that common liberty." The subjects of the crown are entitled as of right not only to navigate but to fish in the high seas and tidal waters alike. This is probably a right enjoyed, so far as the high seas are concerned, by common practice from time immemorial, and it was probably in very early times extended by the subject without challenge to the foreshore (*i.e.,* to between high- and low-water mark) and to tidal waters which were continuous with the ocean, if indeed it did not in fact first take rise in them. The right into which this practice has crystallized resembles in some respects the right to navigate the seas or the right to use a navigable river as a highway. To the practice and the right there were and are exceptions. The king had the prerogative of excluding the right of public fishing in tidal waters. He could keep the fishery in hand. or grant it to a subject, but, since Magna Carta. no new exclusive fishery could be created by royal grant in tidal waters, and no public right of fishing in such waters, then existing: could be taken away without competent legislation. (This statement is summarized from the judgment of the privy council in *Attorney-General for British Columbia* v. *Attorney-General for Canada,* 1914, A.C. 153. Though the question at issue arose in relation to British Columbia, it was governed by the law of England, which, accordingly, was stated in the judgment.)

The public right above referred to depends upon the water being tidal and not comprised within the limits of any several fishery. There is no public right to fish in nontidal waters, although navigable. The public right (which is subject to statutory regulations referred to later) includes the right of fishing over the ioreshore (*i.e.,* between high- and low-water mark) when not within the limits of a several fishery, and of laying lines and drawing nets. It does not include the right of fixing stakes or fixed engines on the foreshore, or the right of drawing up boats above high-water mark and leaving them there for future use, though such rights may be gained by custom by fishermen in a particular locality. The public right does not include a right to appropriate part of the foreshore for the storage of oysters to the exclusion of the rest oi the public but they may take shell fish but not shells although placed there by fishermen *(Truro Corporation* v. *Rowe,* 1902. 2 K.B. 709). Oyster ponds or layings on a foreshore where there are no natural oysters are. it appears, the property of a private person, and may exist quite apart from the existence of a several oyster fishery *(Foster* v. *Warblington G.D.C.,* 1906, 1 *K.B.* 648). Disturbance of a several fishery is an infringement of a legal right, therefore the law presumes damage; other damage need not be proved (*Nicholls* v. *Ely Beet Sugar Factory Ltd., 1936,* Ch. 343 C.A.).

The public rights of navigation must be exercised with due regard ior the rights of owners of fisheries. If. by negligent navigation, injury is caused (*e.g.,* to an oyster bed), damages may be recovered. On the other hand, navigation must not be obstructed; *e.g.,* by the deposit of unreasonably large masses of oysters in the bed of a navigable river (*Mayor of Colchester* v. *Brooke,* 1845, 7 Q.B. 339). (S. D. C.; X.)

Statutory Provisions.—The following are some of the principal provisions as to British fisheries.

The Sea Fisheries act, 1883, confirmed the North Sea Fisheries convention of 1882 and made the principal provisions binding upon any person "within the exclusive fishery limits of the British Islands," or, if outside those limits, on "any person belonging to a British sea-fishing boat." The act therefore applies to British fishermen and fishing boats in all waters. Matters dealt with include questions of precedence on the fishing grounds and avoidance of damage in setting gear, and the prohibition of the carrying or use of cutting instruments.

The Sea Fisheries Regulation act, 1888, as amended by later acts provides for fishery jurisdiction in the territorial waters of England and Wales to be vested in local fisheries committees with Dower to make by-laws regulating methods and seasons of fishing. By-laws are subject to-confirmation and in certain circumstances to revocation by the minister of agriculture and fisheries. Members of committees are appointed by local authorities and the minister, and their expenses fall on the appointing local authorities.

The Sea-Fishing Industry act, 1933, as amended by the Sea Fish Industry act, 1938, provides for regulation by order of the landing of foreign-caught sea fish, prohibition of landings from specified fishing grounds, regulation of mesh of nets and prescription of minimum sizes for fish.

The Sea Fisheries act, 1868, as amended by later acts, provides for the making of orders conferring a right of several (*i.e.,* private) fishery in oysters, mussels or cockles, or for the improvement or regulation of such fisheries in public waters. The Sea Fish Industry act, 1951, set up a White Fish authority to re-organize, develop and regulate the white fish industry.

The Fishery Board (Scotland) act, 1882, established a fishery board for Scotland, whose functions were transferred to and vested in the secretary of state for Scotland by the Re-organization of Offices (Scotland) act, 1939, and are administered by the Scottish home department. Legislation affecting sea fisheries in Scotland only includes a series of sea and herring fishery acts dating from 1770.

The Herring Fishery (Scotland) act, 1889, legalized the cran and quarter-cran as measures for herrings, prohibited Sunday and daylight fishing for herrings in certain areas and trawling within the three-mile limit or in defined areas; and authorized the fishery board by by-law to close the whole of the Moray firth to trawling. (As to the Moray firth, *see* WATERS, TERRITORIAL.) The Sea Fisheries (Scotland) Amendment act, 1885, empowered the board to make by-laws prohibiting or regulating methods of fishing within the exclusive fishery limits. The Sea Fisheries Regulation (Scotland) act, 1895, extended the board's power of making by-laws. The Trawling in Prohibited Areas Prevention act, 1909, prohibited the landing and selling in Great Britain of fish caught by trawling in prohibited areas adjoining Scotland.

The Herring Industry act, 1935, amended in 1938, 1944 and 1948 and administered jointly by the departments responsible for fisheries in England, Scotland and Northern Ireland and by the ministry of food, established the herring industry board with power to make a scheme (the Herring Industry scheme, 1935, amended in 1946) to reorganize, regulate and develop the herring industry.

The Inshore Fishing Industry act, 1945, provided financial assistance which was increased in 1948 for the purchase or improvement of boats and gear. The White Fish and Herring Industries act, 1948, also empowered the fisheries ministers to license vessels fishing for white fish in the North sea.

The Salmon and Freshwater Fisheries act, 1923, consolidated and amended former acts relating to the constitution of fishery boards for districts in England and Wales, with power to make by-laws varying the statutory close seasons, to grant licences to fish, and to fix licence duties. The River Boards act, 1948, placed river systems under the control of single authorities exercising, *inter alia,* the functions of the fishery boards. Salmon fisheries legislation applicable to Scotland must still be sought in a series of acts dating back to before 1850.

The Diseases of Fish act, 1937, prohibited the importation of live fish of the salmon family and controlled (by licence) the importation of freshwater fish and fish eggs.

The Merchant Shipping acts, 1894 to 1950, and regulations made thereunder, contained numerous provisions applicable to fishing boats and fishing crews, skippers and mates in relation to registry of boats, safety at sea, terms of engagement and discharge and certificates of competency.

UNITED STATES; INTERNATIONAL

From adoption of the United States constitution and through subsequent supreme court decisions, the several states were presumed to have governmental and possessory rights over the fish within their borders (*McCready* v. *Virginia,* 94 U.S. 391; *Geer* v. *Connecticut,* 161 U.S. 519). For Great Lakes states this extended to the mid-lake Canadian boundary, and for coastal states, a 3-mi.-wide strip of ocean called territorial waters. This strip is measured along the shore's sinuosities, except that a straight line is drawn across bays where not more than 10 mi. wide, and that "historic" bays (*e.g.,* Chesapeake) are wholly included. Superior federal power was considered possible for migratory fish (*Manchester* v. *Massachusetts,* 139 U.S. 240; see migratory birds, *Missouri* v. *Holland,* 252 U.S. 416). However, later decisions (*e.g., United States* v. *California,* 332 U.S. 19; *Takahashi* v. *Commission,* 334 U.S. 410) implied dominant federal control, possibly ownership, of all marine life and ocean bottom, perhaps even including tidal areas, though state use is permissible pending exercise of federal power. As a matter of actual practice, the several states continued to exercise full management of fisheries within their territorial waters excepting fisheries under international management. Federal attempt to take over control pursuant to court decisions appeared unlikely because of the opposition it would arouse.

Only vessels licensed by the United States may fish in U.S. territorial waters. By a 1950 amendment, no foreign-flag vessel might land in the United States fish caught on the high seas or received there from catching boats, except as provided by treaty (46 U.S. Code Sec. 251). The question arose but had not yet been determined by congress at mid-century as to the admissibility into the U.S. of fish from trust territories the same as domestically caught fish.

Except for ocean fisheries, each state has full right of taxation and, except for Alaska, regulation, even to prohibiting fishing, except as restricted by reservation Indian treaties (*Tulee* v. *Washington,* 315 U.S. 681). Federal control is absolute in territories, but is exercised exclusively only in the District of Columbia. In Alaska, Metlakatlans were granted special statutory fishing privileges (*Alaska Pacific Fisheries* v. *United States,* 248 U.S. 78), but Indian "aboriginal rights" to exclusive fishing were judicially rejected (*Miller* v. *United States,* 159 F 2d 997).

With required congressional approval, Washington and Oregon negotiate for regulating Columbia river fisheries. Similarly, groups of Atlantic, Gulf and Pacific states each, under congressional authorization, have research and recommendatory marine fishery commissions with no regulatory power.

Because of the general indifference of federal power-dam builders toward the damage done to other natural resources, particularly fisheries, legal questions were raised concerning the power of a federal agency to interfere with and even destroy state resources such as domestic fisheries (as distinguished from ocean fisheries). This became particularly important on the Pacific coast where fish which spawn in the lakes and rivers furnish a substantial food supply and the basis for a great industry.

Considerable agitation existed at mid-20th century, particularly on the Pacific coast, for clarification of international fishery laws. Ocean waters beyond three miles often are asserted free for anyone to fish, though England and Norway instituted litigation for a greater distance before the International Court of Justice. There is good support for a nation claiming special interest in its coastal fisheries beyond territorial waters, and a U.S. presidential proclamation of Sept. 28, 1945, did so. However, the United States protested certain Latin-American claims over broad areas which did not recognize existing U.S. fishing activities. When not violating rights of others, a state or nation may control its fishermen and vessels any distance seaward (*Skiriotes* v. Florida, 313 U.S. 69, concerning Florida sponge fisheries).

International fishery problems are wholly federal. The United States entered into a large number of fishery treaties of the usual character dealing with specific fishery rights (A. P. Daggett, "The Regulation of Maritime Fisheries by Treaty," *Am. J. of Int. Law*, vol. 28, no. 4, p. 693), but the International Fisheries commission, created first as a research body by a treaty negotiated in 1923, by a new treaty of 1930 became the first international body actually to give joint international (as distinguished from separate national) management to an ocean fishery (Pacific ocean halibut from Alaska to California). Its regulatory powers apply within as well as outside of each nation's territorial waters. Its success stimulated the similar creation by treaty (1937) of International Pacific Salmon Fisheries commission for the regulation of the sockeye salmon fishery common to British Columbia and the state of Washington, also the more complicated Northwest Atlantic Fisheries treaty between European as well as American nations historically fishing in that area, and still later tuna treaties with Mexico and Costa Rica. This increasingly popular method for the conservation of ocean fisheries by the nations directly involved must be distinguished from proposals for world-wide management through such organizations as the United Nations—proposals vigorously opposed by all elements of the U.S. fishing industry. The Food and Agriculture organization gave some indication of seeking increased authority, and the proposed International Trade organization charters also indicated a desire to invade this field.

Fishery disputes between the United States and Great Britain concerning U.S. fishing in Newfoundland and Nova Scotia waters, and related liberties, occurred frequently after the British claimed that the War of 1812 abrogated privileges granted in 1783, despite a treaty of 1818. The famous Atlantic Fisheries arbitration of 1910, though largely adverse to the United States, effected a peaceful settlement. Perhaps more bitter were contentions arising from U.S. seizure of Canadian vessels engaged in pelagic taking of Pribilof Island fur seals (seals, though mammals, being treated with fish). The U.S. claim of proprietorship of these seals while at sea was rejected by arbitration in 1893. The herd was saved by a 1911 treaty between Japan, Russia, Great Britain and the United States prohibiting pelagic sealing and giving the herd management to the U.S., which in turn shares the proceeds. Japan denounced the treaty in 1941. The herd at mid-20th century was handled under a temporary agreement between Canada and the United States.

The United States aggressively supported international protection of whales, regulated under a multilateral treaty of 1946.

(E. W. AL.)

FISHES, a name that was generally applied to all those vertebrate animals that live in water, swimming by fins and breathing by gills. Modern authorities are inclined to separate the lampreys and hagfishes, which have no gill arches and no jaws, as a distinct class. the Agnatha or Cyclostomata (*q.v.*) and relatives, opposed to all other vertebrates, wherein jaws are present and which are grouped together as Gnathostomata. The Chondrichthyes or cartilaginous fishes, that is the selachians (*q.v.*), or sharks and their allies! are also made a class distinct from the true bony fishes, Osteichthyes or Pisces, differing from them in having no ossified internal skeleton or segmented fin rays, and never comparable scales or bony plates, never ribs, an air bladder, or lung. These differences are not only considerable, but of much evolutionary significance according to the present interpretation of the fossil record.

The History of Fishes.—The most primitive vertebrates are fish-like, and the oldest known are the marsipobranchs, which appear to have had gills contained in a series of separate muscular pouches to expand and contract during respiration, and to have been quite without jaws or gill arches. Several types of marsipobranchs, one free-swimming (Anaspida), another a bottom form covered with a hard bony shield in front (Aspidocephali or Cephalaspida), are known from the Silurian and Devonian periods. The most primitive known marsipobranchs are already quite specialized creatures; their more primitive ancestors are not known. From what kind of invertebrates the vertebrate phylum arose, as it presumably did, is obscure. Various structural peculiarities of the lampreys and hagfishes lead to the conclusion that they, and they alone, are direct living descendants of these early forms.

The Palaeozoic marsipobranchs were of smallish size, seldom more than a few in. long, but there are remains of armoured fishes, the class Placodermi, in Devonian and lower Carboniferous strata, some of which grew to be 20 ft. or more. These are probably specialized derivatives from the ancestors of the sharks, which from varied, scattered fossil fragments in upper Silurian and lower Devonian rocks, are thought to have had an antiquity only less than that of the marsipobranchs. A rather complete fossil record of a primitive shark, *Cladoselache,* which might have been the ancestor of more recent forms, is known from the upper Devonian. No remains that can definitely be referred to modern sharks are known before the Mesozoic, but most types of these appear by the close of that critical era.

It is thought that the true fishes (Osteichthyes or Pisces) arose as an offshoot from the shark stem at a very early period, some time during the Silurian. The earliest known family of these, the palaeoniscids (ganoid family Palaeoniscidae), were present throughout the Devonian, attained their maximum development during the Carboniferous and lasted until toward the end of the Jurassic period. A few scattered representatives of families related to them are still living, but it was not until the middle of Mesozoic time that the orders comprising the great majority of living species began to appear. Their evolution was rapid, and most modern families were represented in the Eocene, the beginning of Caenozoic times. The three late periods of Palaeozoic history, Silurian, Devonian and Carboniferous, are known as the age of fishes, but it was not until the Carboniferous that true fishes became dominant, until the succeeding age of reptiles that any such comparable to species now living appeared, or the more recent age of mammals that the families now most abundant arose.

In the world today there are more living species of true fishes than of any other class of vertebrate animals; 30,000 would not be a high estimate of the number. They show a very great diversity of structure, as well as of size and colour, and inhabit every conceivable kind of water, from mountain torrents to the depths of the ocean.

General Features **of** a Fish.—The fish is a bilaterally symmetrical animal, adapted to an aquatic life. Its evolutionary position is near the base of the great vertebrate subphylum, characterized by an axial vertebral column or backbone, of a series of separate elements known as vertebrae, which affords protection for main longitudinal nerves and blood vessels, as well as support for other parts of the body. The body cavity of a fish, which contains its vital organs, is situated in the lower. anterior part of the body. The posterior part, behind the body cavity, consists mainly of bone and muscle, and usually has the primary function of propelling the animal through water. It is technically called the tail, and is indeed homologous with the shrunken and relatively useless tails of various land vertebrates, in which locomotion is a function of the limbs.

A perch or bass may be taken as the type of a standardized, modern fish. Here the head and body, together, are spindle-shaped, compressed from side to side, streamlined. The head is cuirassed with bony plates beneath the skin, the body covered with numerous thin, elastic, overlapping scales. Backward and downward from the eye, the bones of the sides of the head form a flat plate or gill cover, beneath which are several bony gill arches, the posterior edges of which bear the gills. New water is continually taken in at the mouth, passes backward over the gills, and escapes under the free hind edge of the gill cover. The gills themselves, which look like a broad, flat, dense red fringe, consist largely of numerous finely divided blood vessels.

Blood is pumped to the gills by the heart, passes through these fine blood vessels, where it absorbs oxygen from the water, and then is redistributed to different parts of the body, where oxygen is used up in the production of various kinds of energy. In other words, a fish breathes oxygen just as all animals do, taking it from the water by means of its gills, just as higher vertebrate animals do from the air by means of their lungs.

In the mid-line of the back of perch or bass there are one or two fins, more or less separate, connected or confluent (the dorsal fin). These consist of membrane stretched between supporting rays. The rays of the anterior fin or part of a single fin are stiff, sharp spines, of the posterior, flexible, jointed and more or less divided or branched. In the same median plane, at the hind tip of the body there is one cauda! or tail fin, with flexible rays, which is the chief organ that propels the fish through water. In the mid-line below, under and similar to the posterior dorsal fin, is the anal fin, with a smaller number of spines (only one to three) at its front end. In addition to these dorsal, caudal and anal fins, lying in the vertical plane which would divide the fish's body into symmetrical halves, there are two sets of paired fins. These are the pectoral or breast fins, of flexible (soft) rays only, one on each side of the body behind the head, and the ventral or pelvic fins, close together, one on either side of the mid-line of the body below the pectorals (farther back in more primitive fishes). In perch or bass the ventrals consist of an initial spine and five flexible, jointed, branched rays. In the light of modern investigation, there can be little doubt that the paired fins of fishes are homologous with the limbs of higher animals, that the latter complex structures were derived from the former relatively simple ones. They are, as it were, a marker pointing to the trend of evolution.

The primary purpose of the spines of a perch or bass's anterior dorsal fin is defense, the posterior dorsal and the anal fins steady its course like the feathering of an arrow, the paired fins are used to balance and steer, and the caudal fin to steer and propel the body forward. When analyzed, a fish's motion through water is found to have something of a weaving character, the body thrown into curves which press backward, sending it forward. Elongate, eel-like fishes wriggle through water, propelled by motion of the length of the body. A fish of standard shape, with flexibility mostly toward the tail, is more dependent on its caudal fin for propulsion.

To live a fish must eat, and though there are many types of fishes with a different, more specialized feeding habit, in general they are carnivorous and their jaws are set with numerous teeth to hold their prey, ranging from small crustacea (shrimp-like animals) to other fishes only smaller than themselves. Food, as well as water to aerate the gills, is taken into the one cavity of the mouth, which opens freely back to the outside under the gill cover behind these; and there is a row of short, stiff rods, known as gill rakers, on the inner, concave face of one or more of the gill arches, opposite the convex face which bears the gills. This helps retain the food until it is brought against the opening to the gullet and swallowed. The front of the gullet is otherwise kept closed by muscular control, to avoid taking in more than a small amount of water.

Digestive System.—A fish's food passes from the gullet, which is a simple tube, into the stomach, the front end of which is usually marked by a slight constriction, and which has a greater diameter than the gullet. or than the intestine behind it. It may be U-shaped, or it may be a blind sac with openings to the gullet and intestine close together. In any event, it is here that the processes of digestion commence. The character of the walls of the stomach differs from that of those of the gullet, and they contain gastric glands. The character of the stomach in different fishes varies greatly, correlated with their type of food. In some this organ is relatively straight and simple, in the gray mullet (*Mugil*) and gizzard shad (Dorosoma) it resembles the gizzard of a fowl. Many fishes have a varying number of blind, tubelike sacs of uncertain function, the pyloric caeca, attached near the exit from stomach to intestine.

The beginning of the intestine is generally marked by the presence of a ringlike thickening of the walls of the canal, and by entrance of the ducts leading from the liver, a large organ which varies in size and colour in different fishes and usually has a gall bladder, and from the pancreas, a smaller gland more or less partially embedded in the liver. Food enters the intestine in a liquid condition, and the function of that organ is its assimilation, that is, to pass it on to be absorbed by the blood. The length of the intestine, as is the character of the stomach, is correlated with the nature of the fish's food. In species which feed almost exclusively on other fishes, the intestine is thrown into a few loops, or may run almost straight from stomach to vent, which is normally situated near the lower hind corner of the body cavity. In species the food of which consists largely of vegetable matter, the products of the digestion of which are presumably not so easily digested and assimilated, the intestine is very long and variously coiled, to fit a great amount of absorptive surface into limited space. The stone roller (*Campostoma*), a North American carp, is unique in having it wound round and round the air bladder. At its termination the intestine runs straight to the vent, and has often a somewhat increased diameter. This part is the large intestine or rectum, its principal function in true fishes being to carry off waste products. In sharks and rays, on the other hand, much of the food absorption takes place in the large intestine, which in these has a complicated internal structure known as the spiral valve, so that the nutritive products travel round and round as down a winding stairway. The spiral valve of sharks has the same function of increasing absorptive surface as the variously lengthened small intestine of other fishes.

Circulatory System.—To understand the economy of a fish one may think of it advantageously as a living submarine. Food is the fuel which, burning throughout the living tissue, provides the power for life, growth and motion. The blood stream not only carries this food, but also oxygen to keep the "fires" burning, to every organ of the body. The pump which controls the flow of blood is, of course, the heart. A fish's heart is situated anteriorly, immediately behind and below the gills, in the pericardial cavity, which is separate from the main body cavity behind it. The heart of a fish has three or four chambers. Venous blood, collected from over the body flows into (1) a sinus venosus, then passes to (2) the auricle, and then into (3) the thick-walled, muscular ventricle, the rhythmical contraction of which drives it on; finally it enters a bulb at the base of the main artery carrying it to the gills. These may be compared with the intake of air at the bottom of a furnace, the faster or slower circulation of the blood, to the furnace draft. The bulb pulsates like the ventricle in sharks and some other of the lower forms. but is nonmuscular in the more specialized great majority of fishes. Having been aerated in the gills, the blood stream flows into a main lengthwise artery above the body cavity and below the vertebral column, whence finer and finer branches distribute it to all parts of the body.

The fundamental pattern of fish organization and anatomy is so much like that of higher warm-blooded animals, more complex, correlated with the greater complexity of their life on land, as to be excellent evidence that the latter evolved from fishes, even without the various more or less connecting links afforded by creatures which still exist or are known from fossils. As a specialized structure which has only undergone minor changes from fish to man, there is the vertebrate eye. The eye of a man is so much like that of a fish as to make it highly improbable that the two evolved independently. Per contrast, looking for a structure in fishes without homology or parallel elsewhere, one might choose the air bladder, in most fishes a sac filled with a mixture of gases, which lies along the upper part of the body cavity. It has various functions, the primary one in the generality of fishes being that of a hydrostatic organ, to accommodate the animal to varying pressure at different depths of water. A study of the embryological development of this organ shows that it arises from the gullet, much as the lungs of higher vertebrates do. Furthermore, many fishes can supplement oxygen obtained from water by gills, with air taken into the gullet. For example, goldfish are doing this when they gulp air at the surface of their bowl, when the oxygen in the water is exhausted. In a few fishes the inner walls of the air bladder are richly supplied with blood vessels, and it normally acts as a secondary organ of respiration. Whereas lungs might be said not to have evolved from an air bladder, yet both lungs and air bladder presumably actually arose from a pouch of the gullet which originally had a respiratory function.

Compared to the sea, fresh waters are more often low in oxygen content, and the probabilities are that such a structure arose in fishes inhabiting such fresh waters, for which it was advantageous to obtain supplementary oxygen. Sharks have no air bladder, but one is generally present in the diverse groups of marine as well as fresh-water bony fishes, thus an hypothesis that modern bony fishes evolved from fresh-water forms of the past. In one direction these would have given rise to the majority of fish species of today, both fresh-water and marine, in the other to lung-breathing amphibia, and through them to the higher vertebrates, reptiles, birds and mammals.

Archaic Fishes. — The fossil record shows us that true fishes (Pisces) mere present on the earth from the beginning of the Devonian period, estimated as a matter of 355,000,000 years, that sharks and other presumably ancestral fish-like creatures were living even further back in geologic time. It was in the Carboniferous period in the latter part of the Palaeozoic era that the first family of bony fishes, of which there is a living representative appears. This family (Coelacanthidae, in the superorder Crossopterygii) is known from fossils all through the ensuing Mesozoic era, for a span of an estimated 200,000,000 years, but was supposed to have become extinct at least 50,000,000 years ago, until a trawler off the South African coast caught one in 40 fathoms of water in 1938. It was a large-mouthed, ugly-looking fish, some five ft. long, weighing more than 100 lb., and was named Latimeria chalumnae. *Latimeria* has hard scales, most of its fins have elevated, fleshy bases and it has a peculiar tail fin, with a projection in the centre. Such a tail was characteristic of its probably numerous relatives which lived in the Jurassic period, differing from one another more widely than Latimeria does from those it resembles closely. This unique specimen was mounted and is preserved in a South African museum, a witness to what strange creatures may live unsuspected in ocean depths.

This discovery of an archaic, living fish, previously known only from fossils, is not without precedent. The Australian lungfish (Epiceratodus forsteri), a fresh-water species, found in Queensland in 1871, is very like members of its family which occurred in the Triassic and Jurassic periods of the Mesozoic era, which is estimated as existing more than 125,000,000 years ago. The fossil record shows lungfishes as a group to be among the most ancient true fishes, extending back into the Devonian period. There are also two others which survive today, the South American (*Lepidosiren*) and African (Protopterus) lungfishes, related to one another but only remotely so to those known from the past.

Epiceratodus is a large, sluggish fish, said to reach a length of more than five ft. It has a rather elongate body, pointed in front and behind, compressed from side to side, covered with large, overlapping scales. Its paired fins are placed low, the pectorals near the head, ventrals near the tail. They have the form of padNes, with fleshy bases. Otherwise there is only a pointed caudal or tail fin. Its air bladder, which opens into the gullet by a duct, extends back the whole length of the body cavity. This fish has a small mouth and feeds on crustaceans, worms and the like in the abundant water plants of the more or less stagnant pools which it frequents. From time to time it comes to the surface and renews the air in its air bladder or "lung," which thus supplements the gills as an organ of respiration. When, in the hot season, the oxygen content of the water of the shrunken pools is lowered by decomposing plants or animal matter, it gets along very nicely on atmospheric air.

South American and African lungfishes superficially resemble the Australian, except that they have fine. inconspicuous scales, their paired fins are very narrow, filamentous, and the South American is more elongate and eel-like. The African lungfish (Protopterus) was much studied and is very thoroughly known. It is a voracious, predatory fish, feeding indiscriminately on any aquatic animals small enough to be mastered. A favourite habitat for it is floodwater swamps and marshes. It is said to rise to the surface for air as the Australian lungfish does, and when the swamps dry up seasonally it burrows into the mud, curls up with its nose toward the surface and lies dormant breathing air into its lungs by a small aperture through the caked mud, and subsisting on its accumulated fat and other tissues until the water comes again. Fish thus encapsuled in the hardened mud are frequently dug up and shipped dry to distant parts of the world without injury.

The air bladder of Protopterus consists of an anterior unpaired part and two long, tapering lobes which extend backward for the length of the body cavity, having a more complicated structure and being more lung-like than that of Epiceratodus. This fish further parallels the Amphibia by passing through a larval tadpole stage, wherein it breathes with plume-like external gills as do various larval salamanders. The Amphibia are presumably no more descended directly from lungfishes than the lung of land vertebrates is a modified air bladder, but the parallelism gives an insight into the origin of both.

The three lungfishes still living, widely separate in different parts of the world, are relics of a distant past when their tribe was more numerous and more generally distributed, and are spoken of as relict forms.

In tropical African fresh waters there are fishes of an ancient type belonging to a family (Polypteridae) so far unknown in the fossil record. These were supposed to be related to the Coelacanthidae, and with them to be members of the large group or superorder Crossopterygii which flourished long ago, a view which is not held at present. They are elongated fishes which have the head covered with hard plates, the body with rhombic, thickly enamelled scales, broad rounded pectoral fins behind the head, and ventral fins placed far back, a series of finlets, each with an initial spine, along the back, and a rounded caudal or tail fin. *Polypterus* bichir is said to reach four ft., and to be mainly predaceous, feeding on smaller fishes. The air bladder of *Polypterus* is used in respiration, supplementing the gills, rather than as a hydrostatic organ, and its young have plume-like external gills. A second genus, *Calamichthys*, resembles *Polypterus* but is more elongate, eel-like. They form the suborder Polypterini in the order Chondrostei.

Other living representatives of ancient types of fishes are the sturgeons (Acipenseridae) and related paddlefishes (Polyodontidae), belonging to the suborder Acipenseroidea of the order Chondrostei; gar pikes (Lepisosteidae); and the bowfin (Amiidae), both in the order Holostei; all found in fresh water. Some of the sturgeons, however, descend to and get their growth in the sea.

Sturgeons are among the largest fresh-water fishes. Species which enter American Atlantic and Pacific rivers from the sea were recorded to lengths of 18 and more than 12 ft. respectively, and a Russian species is said to reach 30 ft. It is not unusual for exclusively fresh-water forms to run more than six ft. They have long snouts, with tactile barbels before the mouth, which is on the lower side of the head, longitudinal series of bony plates with nodules between them on the body, instead of scales, fins without spines, the pectoral fins behind the head, ventrals far back, a small dorsal, and anal fin below it near the tail, and the vertebral column bent upward into an upper lobe of the caudal fin, which is longer than the lower.

Thus, in several respects, notably in the shape of tail and caudal fin, they resemble modern sharks. In this connection it will be of interest to consider the evolutionary history of fishes' fins. We may suppose an original, simple fin fold extending along the midline of the back, around the end of, and forward along the lower mid-line of the tail to opposite the hind end of the body cavity, there dividing in two to follow along the two sides of the lower surface to back of the head. The paired fins would be an anterior and posterior relic of the double fold. The vertical fins, dorsals on the back, anal usually present on the lower mid-line of the tail, and caudal fin, would have been derived from the simple median fold. The original caudal fin, thus formed, was presumably weak for driving purposes, and its efficacy improved by bending its axis upward so that its lower base is directed more or less backward, and increasing the size of same. In a very primitive, elongate, living shark (Chlamydoselachus), which must mostly swim in an eel-like manner, the axis of the tail runs straight back, but may be bent upward somewhat in swimming. as the caudal fin on its mid-line below is definitely nider than on its mid-line above. Other sharks show variously intermediate conditions to that which pertains in the numerous species of the modern shark families Carcharinidae, etc., where the axis bends into an upper lobe (considerably longer than the lower, which is situated at the proximal end of the bent part) as it does in the sturgeons, In the mackerel sharks (Isuridae), particularly strong, swift swimmers, this lower lobe has become almost equal to the upper axial one, to form a firm, crescentic, driving caudal fin. In the great majority of modern bony fishes, the caudal fin is superficially symmetrical, but anatomically shows an ancestral upward flexure of its axis.

The family Acipenseridae is not of great antiquity or known to have occurred before the Tertiary period, where more modern fishes were also present, but extinct sturgeon-like fishes ancestral to them go back to middle Mesozoic, apparently a connecting link with the earlier palaeoniscids. Sturgeons are the most generally distributed archaic types of fishes still living. They are excellent food fishes, and their roe, made into caviar, is an item of much commercial importance.

The North American paddlefish (Polyodon spathula), belonging to a related family, is one of the strangest large fishes living. It has the general contours of a sturgeon, with a similar unsymmetrical (heterocercal) tail and caudal fin, but its skin is smooth and naked, lacking scales, plates or nodules. It has a large mouth. and a very small eye at the base of a very long, flat, paddle-shaped snout. about half as long as the whole rest of the head and body. The paddlefish inhabits sluggish waters of the lower Mississippi valley, grows to be more than four, but rarely more than six ft., weighing between 100 and 200 lb., and was reduced in numbers by commercial fishing, for its roe, from which caviar is made, as from that of sturgeons. It was thought to use its snout or paddle to stir up mud and feed on creatures therein contained, but perhaps this is only suggested by the shape of that peculiar organ. It feeds largely by sifting out clouds of minute animals (plankton) floating free in the water, which are taken into its large mouth and strained through its exceptionally long, fine gill rakers. The paddle, which is richly supplied with sense organs, doubtless helps locate these. But this is not its only method of feeding, for it will sometimes take a baited hook.

Besides American paddlefish, one similar species (*Psephurus* gladius) is found in the rivers of China, where it grows to a larger size, sometimes 20 ft. or more. These two are generally considered relict species from an age when their family had a more general distribution, though fossil evidence of it is scant and goes no further back than the Eocene.

There is no known fossil record of the family of the gar pikes (*Lepisosteus*), which still abound in North American fresh waters, back of the Eocene when they were more generally distributed, but they persisted little changed from that period some 45,000,000 years ago. A gar pike is an elongate, cylindrical, predaceous fish. Its jaws are elongate to a greater or less degree and set with formidable teeth. Its paired ventral fins are placed about in the centre of its lower surface, rounded dorsal and anal fin below it are far back near the tail. Its caudal fin, also rounded, is still slightly unsymmetrical externally. in evidence of a heterocercal past. Perhaps the most interesting feature of this fish is its scales, which are thick, hard, rhombic, nonoverlapping and articulate with one another by peg-and-socket joints. Scales more or less of this type evidently evolved before the thin, elastic, overlapping scales, which are the rule in modern fishes, and which allow more freedom of motion. They become more and more frequent as one follows back the series of fossil fishes into the geologic past. *Polypterus*, also, has such scales, but the gar pikes are the best example of them in living species. On large individuals of the alligator gar (*Lepisosteus* spatula) of the lower Mississippi valley, which reaches a length of nine ft. or more. it is said that these heavy, enamelled, plate-like scales may even turn an axe. Gar pikes are sluggish fishes, lying motionless at the surface in quiet waters, but are highly predaceous, rushing upon such prey as comes within range with lightning speed. They are very destructive to smaller species and have little food value.

The bowfin (Amia *calva*), an abundant fish in the Great Lakes region, Mississippi valley, and southeastern G.S., is the sole living representative of a family (characterized, among other things, by a single, large bony plate at the throat) known from fossils far back to the Jurassic period of Mesozoic time. It is, nevertheless, a very ordinary appearing fish, a foot or so in length. with normal. rather small scales, a large mouth. long dorsal fin of flexible rays. rounded pectoral and caudal fins. In fact, several unrelated, generalized modern fishes resemble it in superficial appearance, and. at first glance one would not suspect the bowfin of belonging to the archaic category, did one not notice that its caudal fin is slightly more heterocercal than that of the modern fish. The bowfin is a strong, tough, voracious fish, feeding on any animals that come its way, mostly smaller fishes. It is exceedingly tenacious of life, can breathe air with its air bladder to supplement its gills, and thus live in foul water, or for a long time out of water.

Herring, Trout, and More or Less Related Fishes.—The oldest and most primitive group of modern true bony fishes is presumably the Isospondyli, that to which the herring, salmon and trout belong. What seem to be true herrings occur as far back as the close of the Mesozoic era (Cretaceous), and there were species of the herring-like bonefish (*Albula*), not unlike that of today, in the Eocene. There is also more or less conclusive evidence that the Isospondyli are ancestral to various other groups of more specialized fishes of today.

A typical herring is a compressed, streamlined, silvery fish, a few in. to a ft. long, with large, thin. overlapping scales, modified to form a sharp, serrate keel, along its mid-line below, and with no evident lateral line. It has a single, rather short, soft-rayed dorsal fin near the middle of the back, paired ventral fins small, near the middle of the lower outline, and a well-forked caudal fin It has a large mouth but uses small food, its teeth are small or lacking, gill rakers long and numerous, and it swims in schools.

There are several allied, but more primitive, herring-like fishes. Such is the heavy-scaled tarpon (Tarpon atlanticus), which grows to a large size, feeds on smaller fishes and is much sought by big game anglers. The elongate, predaceous big-eyed herring (*Elops saurus*), related to the tarpon, is another. It has fine scales, a conspicuous lateral line, and is cosmopolitan, though varying slightly, probably only racially, in different warm seas. Two other fine-scaled species, the cylindrical bonefish or banana fish (*Albula vulpes*), with a small mouth and somewhat pig-like snout, which inhabits all tropical seas. and the milkfish (Chanos chanos), a valued food fish, inhabiting warm waters of the Indo-Pacific ocean, belong to this category. Then there are the mooneyes or toothed herrings (Hiodon) of North American fresh waters, which have strong, sharp teeth.

There are variations from type within the herring family proper (Clupeidae). Here different species are more or less elongate or deep-bodied, compressed or cylindrical, with larger or smaller scales, the keel along their lower mid-line stronger or weaker, lacking in the cylindrical round herrings (Etrumeus). Species of this family are most numerous in warm seas. All are good food fishes, but those of temperate and cool latitudes (which, in general, grow the largest) are of much the greatest commercial importance. The northern sea herrings (*Clupea* harengus in the Atlantic, and *Clupea pallasii* in the Pacific), because of their great abundance, are the basis for perhaps the most commercially important of all fisheries. Several species of the temperate North Atlantic are anadromous, that is, run up rivers into fresh water to deposit their spawn. Of these the North American shad (Alosa sapidissima) reaches an unusually large size for this family, weighing between two and six lb.. and is particularly prized for the table. Incidentally, the shad lends itself to fish-cultural methods. its eggs have long been hatched artificially and the fry liberated. and it was successfully introduced into rivers of the Pacific coast where it was not native. Here, however, it meets with less favour than in the east. There are comparable species (*Hilsa*) which enter the rivers of China. The Menhaden (Brevoortia *tyrannus*), a marine herring of warm and temperate waters of the western North Atlantic which reaches a length of more than a ft., carries the herring tendency to be plankton feeders to an extreme, subsisting largely on diatoms, minute drifting plants which are the basic food supply of the ocean. It gets very fat and plentiful on this lowly but abundant pasturage, swims in dense schools which are much preyed upon by predaceous fishes and is taken commercially for its oil and for fertilizer.

The anchovies are a family of smaller, more fragile fishes, particularly abundant along continental shores, and are closely related to the herrings. They are easily recognized from their rounded or conical snout projecting beyond a very large mouth, and commonly have a silvery band along the side. Although a warm-water family, the most important species occur in temperate seas, as Engraulis encrasicholus of the Mediterranean and *Engraulis ringens* of Peru. This last is excessively abundant in the cold, upwelling "Humboldt current" waters along that coast, and a principal food of the sea birds (which are the basis of the Peruvian guano industry) as well as of other aquatic animals. A genus (Coilia) of estuarine fishes belonging to the anchovy family, wherein the posterior portion of the body is lengthened and tapering, the anal fin very long, confluent with the small, pointed caudal fin, is abundant in fresh and coastal salt waters of the orient. This little fish is caught in vast numbers with special nets in Tungting lake, China, and dried in the sun.

The gizzard shads (*Dorosoma*), found in muddy, fresh, brackish and salt water, are of another family close to the herrings, their most obvious superficial difference from these consisting in a small mouth more or less below the snout. They have generally been considered mud-eaters, and whereas it was recently claimed that they are plankton strainers instead, their differences from herrings would certainly correlate with a mud-eating habit. Their young, which are more herring-like than the adult, doubtless, and the smaller species of which the same is true, very probably feed mainly on plankton.

Contrasted with herrings, trout and salmon are predaceous in habits, and, as a rule, have strong teeth to seize and hold their prey. There is little difference between a trout and a salmon. They are a northern, cold-water family, extending into the Arctic regions. Those species which are regularly anadromous, getting their growth in the sea and returning to fresh water to spawn, and which reach the largest size, are generally known as salmon. In temperate latitudes the great majority of trout spend their entire life in fresh water; but, wherever found in the lower courses of the streams, they enter salt water to some extent, and in the far north they run in and out of fresh and salt water rather indiscriminately.

A trout is a somewhat elongate, symmetrical fish with large mouth and strong teeth. Its body is covered with small, smooth scales, often so fine as to escape notice. Its fins are entirely of soft rays, without spines, the ventrals placed near the centre of the lower mid-line, a short dorsal fin near the middle of the back, the caudal or tail fin broad, and squarish to more or less forked. In the mid-line of the back, in the tail region well behind the dorsal fin, there is a small flap without rays, known as the adipose fin, of uncertain—if indeed it has any—function. Such an adipose fin is a peculiar, superficial characteristic of certain primitive groups of fishes, as of the trout and salmon family in this case.

Trout and salmon fall naturally into two main divisions, the black-spotted trout, and the charrs. These differ in the shape of, and arrangement of the teeth on the central bone in the roof of the mouth (vomer), which is straight with teeth for its entire length (deciduous in the Atlantic salmon) in the black-spotted trouts, boat-shaped with teeth only on the front, raised end in the charrs. The superficial character of colour will differentiate these groups more readily. The black-spotted trout have, sometimes scant, sometimes profuse, small black spots on the body and fins, the charrs may have red, blue or pale, but no black spots. Both Atlantic and Pacific salmon belong to the black-spotted group, which, except as represented by the sea-run Atlantic salmon or its landlocked races, or as planted artificially. is absent from eastern North America, but occurs native from the eastern slope of the Rocky mountains westward. The European black-spotted trout and the Atlantic salmon belong to the genus *Salmo*. The trout of western America are referred to that genus also, but the Pacific salmon, which have a slightly longer anal fin and a different life history—they spawn once and then die—are usually separated as a distinct genus *Oncorhynchus*. It is not certain, however, that western trout are not actually more closely related to the Pacific salmon (*Oncorhynchus*) than they are to those of Europe and to the Atlantic salmon (Snlmo).

The charrs (*Salvelinus*) are a circumpolar group abounding in the far north, occurring southward in cold, hill streams, or isolated in lakes, where they were apparently left by the retreat of the glacial period. They, as well as the black-spotted trouts. are represented by many local varieties, which merge into one another, and few distinct species, of which the eastern brook trout of North America is one, although silvery, sea-run individuals of this species are difficult to differentiate from those of the others. The black-spotted trout of Europe run freely into salt water; the sea-run fish is somewhat different from those in the streams, was formerly considered a distinct species, but is now thought to be identical and the differences entirely the result of environment. In the mountainous region of western North America there are many varieties of black-spotted trout which tend to merge into one another except where isolated by physiographic barriers. Those inhabiting fast water at high altitudes have finer scales and brighter colours, and there is a Rocky mountain series of forms differing from that of the Sierras and coast ranges. There is also a strain of coast range trout that runs to sea, reaches a large size and is known as steelhead salmon, though no more related than other trout to the true Pacific salmon (Oncorhynchus), of which there are five well-marked species.

The lake trout (Cristivomer) of northern North America, is somewhat different from either charrs or black-spotted trout, but more related to the former. Its vomer is boat-shaped with teeth in front, and also a ridge or crest of teeth extending back in the centre; and its dark upper parts are usually profusely spotted with pale. It has a large mouth. strong teeth, reaches a large size, is generally common northward and in temperate latitudes, at least, inhabits the cool depths of deep lakes.

The grayling (*Thymallus*) is a fish of this family found in Arctic and northern fresh waters, more or less southward in the mountains. It differs from trout and salmon in a smaller mouth and weaker teeth, less fine scales, and an expanded dorsal fin, which is high, broad, and brightly coloured.

The whitefishes (Coregonidae) form a subfamily of, or a family related to, that of salmon and trout. They differ from them in having smaller mouths, weaker dentition, slightly larger scales and being plain coloured, usually whitish on the sides. darker along the back. They are found exclusively in fresh water, except in the far north where they sometimes enter the Arctic ocean or its tributary bays, and are primarily lake fishes. All are good, some rank high as food fishes. particularly the lake whitefishes (*Coregonus*), with deep, compressed bodies, weighing up to 20 lb. or more. The round whitefishes (*Prosopium*) are more of a river fish. The smaller, schooling, lake herrings (*Leucichthys*) are very herring-like in superficial structure and in habits, but have the adipose fin characteristic of trout and whitefish families. A large, predaceous, salmon or pike-like whitefish, known as the inconnu or coney (Stenodus mackenzii), which reaches 15 lb. (occasionally 30 lb.) occurs in the larger rivers of far northwestern North America from the Mackenzie to the Yukon, with a similar fish in Siberia. It has weak, bristle-like teeth in bands, evidence that it is a specialized whitefish, not a transition form between the white fishes and the strong-toothed trout.

The smelts are a family of small, active, carnivorous marine fishes allied to the trouts, which they resemble in general contours and fin arrangement. They are commonly between six in. and a ft. in length, and are dark along the back, with silvery sides. They are an important item in the diet of larger species and are delicious food fishes. Smelts are abundant coastwise in northern and temperate seas. Some species. *e.g.* the common smelt of eastern North America (*Osmerus mordax*), run into fresh water, and even become landlocked in inland lakes. Others are confined to considerable depths in the ocean. A fine-scaled Arctic smelt, known as the capelin, swarms along the beaches where it deposits its eggs at spawning time.

In the orient there are small, elongate, fragile, translucent: trout-like fishes known as glassfishes (Salangidae), occurring in both fresh and salt water and represented by numerous species. Their body is scaleless or with fine deciduous scales, a small adipose fin is present, the dorsal fin placed well behind the ventrals which are near the middle of the body, anal fin rather long, still farther back and caudal fin forked. They have rather large mouths and very variable dentition. Many have elongate heads and large canine teeth, predaceous fishes in miniature, for they are slender and usually less than six in. They are considered a delicacy by the Chinese.

The common lizard fishes of the cosmopolitan genus *Synodus* and closely related genera, which are strictly marine and occur along the shores of all tropical seas, are quite trout-like superficially, though structural differences place them in a different, doubtless related order. They have an adiose fin like a trout, ventral fins more anterior in position though well behind the pectorals, somewhat coarser scales and a very large mouth with strong teeth, which opens to well back of the eye. They are elongate fishes which reach a length of a ft. or so and live in water of no great depth along sandy shores. They frequently lie on the bottom, where their gray or reddish mottled colours render them inconspicuous, but are swift, predaceous and very destructive to smaller fishes. A member of the lizard fish family, *Harpodon nehereus,* is found along the shore and in the mouths of the rivers of India. where it is a prized food fish. known as "Bombay duck" when salted and used as a relish. It has an enormous mouth, a small eye near the tip of the snout, large ventral fins and reaches a length of some 16 in.

Various peculiar fishes of the ocean depths, where daylight fades until it penetrates no farther, approaching perpetual abyssal darkness, lighted only by gleams of phosphorescence, have more or less certain relationship to, and have likely been derived from lizard fishes, or, if not, from the Isospondyli, to which lizard fishes are related. They are sometimes included in a heterogeneous order called the Iniomi. There are the fragile, little lantern fishes (Jlyctophidae), very abundant in individuals and species in the open sea. They have large eyes, large mouths, and a fin arrangement, including an adipose fin, much like that of a lizard fish, or of a trout for that matter, a series of small, luminous spots, suggesting portholes, along their lower sides, and give off flashes of phosphorescent light. hlany, which usually have large, silvery scales, easily detached, live deep down in the daytime and come to the surface at night; others are confined to the depths.

Lantern fishes are weak creatures with feeble teeth, but black, scaleless fishes of the depths belonging to the genus Astronestltes, which resemble them somewhat, are predaceous and have long fangs. They have an adipose fin, many fine luminous spots on the sides and below and a long, fleshy barbel at the throaf. This genus is sufficiently common to deserve mention as one of those closely related to lizard and lantern fishes. It has few species, no close relatives and is placed in a family by itself. The lancet fish (*q.v.*) is placed in the Iniomi, as also are a number of divergent kinds of deep-sea fishes of uncertain relationships, classified in as many distinct families. For instance, there is *Chauliodus,* an elongate fish with fang-like teeth exaggerated; Malacostercs, a peculiar form with an enormous mouth; *Ipnops* which is eyeless, but has the whole top of its flat head occupied by a pair of peculiar organs which possibly function as eyes, though more generally supposed to be luminous organs. Most of these fishes that live in the dark ocean depths are blackish in colour and many have variously placed organs to give off phosphorescent light. The hatchet fishes (*Argyropelecus*), one of the commonest types. which may come nearer the surface, are small, deep-bodied, flat from side to side, bright silvery in colour and are thought to swim in schools.

Two important families of fresh-water fishes, related to and sometimes included in the Isospondyli, though quite unlike herring or trout, are the Osteoglossidae and Mormyridae. The former has only five species, scattered around the world, two in South America, one in Africa, two in northern Australia and the East Indies. The latter has many divergent species and is confined to Africa. In the Osteoglossidae the ventral fins are placed well back, dorsal and anal fins, with soft rays only, variously long or of moderate length, not far removed from the caudal fin. The scales are large except in one of the South American fishes, in which they are rather small. This species! known as pirarucu (Arapaima *gigas*), is one of the largest fresh-water fishes, reaching a length of 1j ft. or more and weight of some hundreds of lbs. It has a large mouth, small eye, ventral fins behind the middle of the body, low dorsal and anal: and a small rounded caudal fin.

The hlormyridae are small-mouthed, slimy fishes, with small, often fine and inconspicuous scales. Their fin rays are all soft, the dorsal and anal fins placed well back and the caudal fin forked. The ventral fins, well behind the pectorals, are about in the centre of head and body, or farther forward. The dorsal fin may be long, occupying most of the back, the anal fin short (in *Mormyrus*), to the dorsal fin short and the anal fin long (in Hyperopisus), or the two of approximately the same moderate length, placed over one another. The body is usually rather elongate, but may be short and compressed (as in *Petrocephalus*). The peduncle (tail end of the body) is narrow and usually long. The eye is large (in some species of *Petrocephalus*) to small (in others of *Mormyrus*). The outline of the head and position of the mouth vary greatly, even in related species, but tend toward a few contrasting types. In *Mormyrops* the front of the head is narrowed (vertically), the mouth horizontal and terminal; in *Petrocephalus* the snout is short, bluntly rounded in profile, the mouth more or less beneath it. In *Gnathonemus* the lower jaw usually projects somewhat beyond the upper; in *G. petersii* it tapers into a thick, fleshy, forward directed barbel; in *G. rhyncophorus* and others the snout is narrowed, elongate, curved downward to suggest the trunk of an elephant, with the little mouth at its tip. Such a snout finds its extreme development in *G. curvirostris* and G. *numenius,* where it is some four times as long as the head behind the eye.

Eels.—Eels are fishes, with the body form of, but no relationship to, a serpent. They were almost certainly derived from more normal fishes, their differences, such as lack of ventral or posterior paired fins, correlated with their different manner of life and locomotion. There are eels everywhere, from inland fresh waters to the depths of the ocean. Superficially more or less alike, they differ fundamentally so greatly that they are classified in a number of families. It is more than likely that eels were derived from divergent groups of fishes. There are eel-like fishes the relationship of which to more normal forms is obvious. The others are commonly grouped together, and those which are not obviously unrelated, placed in the order Apodes. The lampreys and hagfishes (Cyclostomata, *q.v.*) are not eels, although commonly so-called.

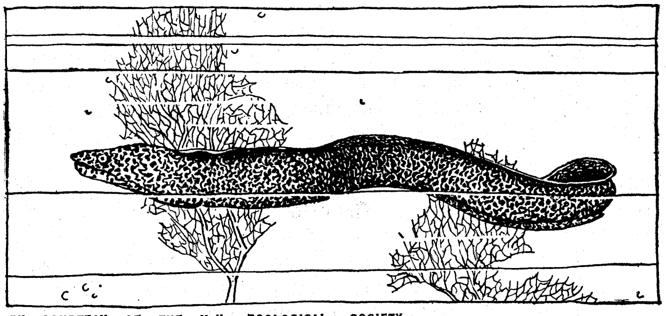
Of the several families in the order Apodes, the common eels (Anguillidae) ; conger eels (Congridae); snake eels (Ophichthyidae); and morays (Muraenidae) might form an evolutionary series, in which the common eels are closest to, the morays farthest removed from, normal fishes. So iar as known, all species of these, and of related families, spawn in the sea, and their young pass through a larval, transparent stage, quite unlike the adult.

The common eels (*Anguilla*) sometimes called fresh-water eels, were likely derived from the Isospondyli. They differ from all other families of Apodes in having the body covered with small, embedded, rudimentary scales. These scales may easily be seen with a hand lens. They are elongate and have a peculiar arrangement, placed obliquely, in groups, those in each group at right angles to those in an adjacent group. Similar scales occur in some of the Ophidiidae, eel-like fishes with no apparent relationship to true eels. *Anguilla* has a large mouth, lower jaw usually slightly projecting, strong teeth and is an active, predaceous, bottom fish, eating hungrily any animal food, living or dead. It has well-developed pectoral fins, a short slit before their bases, being the only posterior opening from the gill chamber. The dorsal fin, running along the back, and anal fin below, join broadly around the tip of the tail. It inhabits shallow coastal salt waters, and fresh waters as well, penetrating far inland, and not infrequently becoming landlocked and reaching a large size in lakes or ponds. Possibly little eels can reach such places by underground seepage, through which larger ones are unable to escape. Eels can live in foul water, for some time out of water, and there are reports of their moving overland in met weather, but these are not too well substantiated. They must return to the sea to spawn, and the spawning grounds of the European and American species were shown to be far out in the deep-blue water of the Atlantic. Common eels are extensively and generally used for food. The others are not so used as a rule, and the flesh of some, for instance the morays, locally at least is thought to be unwholesome.

The conger eel of the North Atlantic (Conger conger), which is abundant off the coast of Europe and there extensively marketed, is superficially so like a common eel that it might easily be mistaken for one. It is strictly marine, found in somewhat deeper water, reaches a larger size, its dorsal fin commences not far behind the head instead of toward the middle of the back and it is entirely without scales. There are several other genera also in the family Congridae.

The snake eels (Ophichthyidae) are a very varied group abundant in the shore waters of the tropics and comprising a number of genera. They are characterized by a finless tip of the tail, dorsal and anal fins not meeting around it. The pectoral fin may be well-developed, rudimentary, or absent, dorsal and anal fins very low, or the dorsal quite high. The mouth may be large or small, teeth strong or weak, and the snout usually projects more or less beyond the lower jaw, but does not always do so. Some are very slender and elongate, even for an eel. Some are feeble, others strong and aggressive, and when stranded at the edge of the water, as they sometimes are, become threatening, simulating a snake. Some are plain coloured, others brightly marked, and in the East Indies one or more have a colour pattern which resembles that of poisonous sea snakes found in the same waters, and which feed largely on eels.

The morays (Muraenidae) have a very small gill opening, never have a trace of a pectoral fin, and their dorsal and anal fins, which



BY COURTESY OF THE N.Y. ZOOLOGICAL SOCIETY

SPOTTED MORAY (GYMNOTHORAX MORINGA), AN EEL, ABUNDANT IN THE WEST INDIES. IT IS YELLOWISH IN COLOUR AND IS THICKLY MARKED WITH DARK SPOTS

may be rather high, especially the dorsal, or very low, are continuous around the tip of the tail. There are a number of genera and many species in this family, which is particularly abundant about coral reefs in the tropics. The typical morays (Gymnothorax, etc.) are heavy-bodied, somewhat compressed eels, with a rather high dorsal fin beginning well forward, before or behind the hind border of the head. Their snout is pointed, nape convex, jaws about even, mouth large, extending to well back of the eyes, teeth numerous, strong and sharp. They are strong and predaceous, hunting the crevices of the reef, where fishes on which they prey find security from other enemies; and the largest reach a length of five ft. or more. They may be plain coloured, mottled, or more boldly patterned. The genus Echidna comprises less aggressive, short-bodied, compressed species, with blunt teeth. There are several species in the East Indies, one small one in the West Indies, and so forth. They are commonly dark coloured with pale markings.

There are several peculiar deep-sea families of Apodes, of which the snipe eels (Nemichthyidae) constitute one of the strangest. These are very slender and elongate, the tail often ending in a finless filament and their finely-toothed jaws are narrowed and lengthened to suggest the bill of a snipe. In some species the jaws are twice as long as the remainder of the head and spread apart at the tips. It is difficult to see how such a mouth would be used in feeding, and it was suggested that its function is that of clinging to other larger fishes by which the snipe eel is carried about. Snipe eels have large eyes, and well-developed pectoral fins. They are recorded from water two or three mi. deep, and rarely within 50 fathoms of the surface.

The gulpers (*Saccopharynx* and Gasnostomus) are deep-sea eels, usually placed near the Apodes, but considered a separate order. They are black creatures of the depths, which rarely come to light, with enormous mouths and distensible stomachs, and thus are capable of swallowing fishes really larger than themselves. Their body tapers backward into a slender lash and their tiny eyes, which are probably functionless, are placed near the tip of the snout. *Saccopharynx* is known up to some six ft. The symbranch eels, also made a distinct order, inhabit sluggish fresh waters, water holes, and penetrate underground drainage. These differ from the Apodes in that their gill openings, instead of being separate, one on either side of the neck, join below across the throat. They have a small eye, tail tapering to a point, dorsal and anal fins rudimentary and no pectoral fins. Only two or three species are known. Fluta alba, represented by two or three poorly defined geographical races, is abundant in the orient and East Indies; *Synbranchus* marmoratus is common and generally distributed in tropical America.

The spiny eels (*Mastacembelus*), of which there are a number of species in the fresh waters of southern Asia, the Indies and Africa, have very uncertain if any relationship to other so-called eels. Their bodies are not greatly lengthened, more or less compressed, and covered with fine scales. They have well-developed pectoral fins, and soft dorsal and anal fins (of about equal length) join broadly around the tip of the tail. They have spines on the side of the head, two or three spines in the front of the anal fin, and many short, sharp spines along the mid-line of the back. They are further characterized by a pointed, more or less proboscis-like snout and are considered excellent food fish.

Pikes and Carps.—The orders of fishes to which the pikes (Haplomi) and the carps (Ostariophysi) belong were presumably derived from the Isospondyli, though their relationship to herring and trout is neither close nor clear. A pike (Esox) is a predaceous fresh-water fish. It has a long, streamlined body, covered with small, smooth scales, a long head and great mouth with projecting lower jaw and formidable teeth. Its paired pectoral fins are placed low, under the hind margin of the head, ventral fins about midway in the length of the body, rounded dorsal and anal fins, of about equal size and one above the other, far back near the caudal, which is moderately forked. The few species of pikes, found across the northern continents, are very much alike. They are strictly freshwater fishes of lakes and sluggish streams, where they lurk along the edges or near vegetation, to rush upon and seize any hapless fish (or other animal in the water) that comes within range, not excepting smaller individuals of their own species.

The larger species of pikes range well to the north. The American race of the northern pike (Esox *lucius*) occurs native from Alaska to New York and the Ohio valley. It reaches a length of four ft. and a weight of 40 lb. The European race grows to be 10 or more lb. heavier.

The tooth carps, of which many and varied species abound in coastal salt, in brackish and in fresh water, particularly-of the tropics and subtropics, although also placed in the Haplomi, are little fishes of an entirely different character, rarely more than a few in. long. Some are slender, not unlike the pikes in shape, though others have deep, compressed bodies. They have similar fine scales, fins of soft rays only, not dissimilarly placed, the dorsal fin more or less behind the middle of the back and towards or over the anal, not in the middle of the back as it usually is in the true carps. Unlike the pikes, and unlike true minnows, which belong to the carp family (tooth carps are sometimes erroneously called minnows), their caudal fin is usually not forked but rounded. Instead of being large, their mouths are even relatively small. Some are carnivorous, with small, firm, pointed teeth, but only tiny creatures need fear them, whereas they themselves are an important item in the food supply of larger fishes. The males of many species of tooth carps have bright colours, quite unlike those of the females, or assume them at breeding time.

There is a division of this group of fishes represented by many varied species in tropical American fresh waters, which, instead of laying eggs, give birth to living young, and have the anal fin, which is more anterior in position than in the others, developed into an intromittent organ in adult males. The males are frequently considerably smaller than the females, or with more decorative fin development, as well as bright colours. Various viviparous tooth carps are of very small size, multiply rapidly and become very abundant in quiet streams and pools, where they are a natural check on mosquitoes by consuming their aquatic larvae. One such North American species, Gambusia *affinis,* with a usual maximum length of about two in. and the males considerably smaller. was widely introduced as a mosquito control. On the other hand, one of the largest tooth carps which may grow to be a ft. long, the four-eyed fish (*Anableps*), is a member of this division. It is an elongate fish, with very peculiar eyes which project upward like those of a frog, and are divided into an upper part adapted for vision in air and a lower for vision in water.

Another division of tooth carps (the family Amblyopsidae) contains the blind fishes mhich inhabit the limestone caves of eastern North America in utter darkness. The most specialized of these is the Mammoth Cave blind fish (*Amblyopsis spelaeus*) an elongate, sluggish, colourless (whitish) fish, reaching a length of about five in. It has a large mouth and catholic appetite, but tiny, functionless eyes, and the body and head with many vertical ridges of tactile papillae. A peculiar feature of this family is that the vent is placed anteriorly, close behind the gill openings. Besides the blind species, it comprises eyed forms, one of which, the rice-ditch killifish (Chologaster cornutus] is abundant in streams and 101%-landswamps in the southeastern U S.

Two other small fishes of the order Haplomi, with no close relatives and superficially like the tooth carps, should be mentioned. The mud minnows (*Umbra*) of eastern North America and Austria-Hungary, growing to four or five in., resemble somewhat structurally a fossil pike known from the Miocene, more so than they do present-day pikes. They are active, very hardy little fish, found in streams and stagnant pools with a bottom of deep mud into which they dive when alarmed. The Alaska blackfish (*Dallia* pectoralis) is a large-mouthed, hungry little fish so abundant in some of the fresh-water summer pools in Siberia and northern Alaska, as to be an important food item with the natives, although it only grows to about eight in. It is said to freeze solid in winter, but be as lively as ever when spring thaws it out.

The order Ostariophysi comprises three superficially quite unlike series of fishes, catfishes, characins and carps, the relationship of which is proved by their having a same complicated structure of earbones, which would hardly have evolved independently in the three groups. They were presumably derived in fresh water from isospondylous ancestors, though direct evidence of this is lacking. They first appear in the fossil record of the lower Tertiary, then already separated into these three main types.

The standard catfish is scaleless, often with a broad head. It has fine teeth in bands, a more or less transverse mouth surrounded by several barbels, a strong spine in the front of the dorsal and of the pectoral fins, the ventral fins near the middle of the body and a small adipose fin over the anal, which is of moderate length. Numerous species of catfishes occur in the fresh waters of North America, Asia, Africa and South America, varying progressively more widely around this type in the respective continents in the order mentioned. In North America the most obvious difference between the different species is one of size. The Mississippi catfish (*Ictalurus furcatus*) may reach a length of five ft. and a weight of around 150 Ib.; the tadpole catfish (Schilbeodes *gyrinus*) is about five in. This last is one of several small, related, bottom species with poison glands at the base of their pectoral spines, a prick from which is like the sting of a bee but more severe.

In Asia, and particularly in Africa. there are catfishes without an adipose fin, with a long soft-rayed dorsal fin only on, and occupying most of the back, an only relatively shorter anal fin below it (*Clarias*). Others have a small dorsal fin, placed well forward, its spine weak and a long anal fin. *Parasilurus,* which is abundant in Asia, and *Schilbe,* which occurs in Africa, have no adipose fin; *Eutropius,* which is abundant in Africa, has a small adipose In Africa there are catfishes with broad sucker-like mouths on the lower side of the head, wherewith they cling to and presumably scrape the moss off rocks (Euchilichthys), and an electric catfish (*Malopterurus* electricus)—with a thick, soft skin, no spines, no rayed dorsal but an adipose fin—which is capable of giving a severe shock.

It is in South America, however, that the catfish tribe reaches its maximum expansion, and, in addition to standard forms. superficially similar to those occurring in the other continents, there are many others very unlike them. Catfishes were presumably among the few modern fresh-water fishes which reached South America prior to its long isolation from the other continents by sea during the Tertiary, and, lacking competitors, expanded there in many directions. They occur in every kind of water, even mountain torrents, where one small catfish (*Cyclopium*), by means of a sucking disk surrounding the mouth and its pectoral fins, can edge along the bottom against the current, and even climb up a vertical wall out of the water. There is a family (Pygidiidae) of tiny, slender, degenerate catfishes, which are parasitic, and attach themselves to other fish or animals like leeches. One of these, the candiru (*Vandellia*), which commonly lives inside the gill cavity of other fishes, on the blood of which it subsists, has the evil reputation of at times entering the urethra of unwary bathers. Catfishes are without true scales, but some of South America (*Callichthys*, Couydoras, etc.) have the body cuirassed by a double series of scale-like plates which meet along the middle of the sides, and the neotropical family Loricariidae of most aberrant. bottom catfishes, with sucking disk surrounding the mouth, have the body more or less completely armed with smaller scutes. There are a number of genera and many species of this family. Plecostomus and its relatives, some of which reach a large size, are not unlike catfish and have an adipose fin with an initial spine. Loricaria and its relatives are most peculiar, flattened, elongate, the cuirassed body, backward from the dorsal fin, tapering and slender.

Catfishes are, and presumably always were, a continental, freshwater group. but two types are also marine. Species of *Arius* and related genera, which are quite standard in appearance, inhabit warm coastal waters around the world. Many catfishes guard their eggs and newly hatched young, and some of this kind have very large eggs which they carry in their mouth until hatched. Relatives of *Plotosus* are another dissimilar, less generally distributed type, plentiful in the orient. Back to the level of their ventral fins they are normal appearing catfishes, but the posterior part of the body is lengthened, and a long anal fin extends evenly around the tip of the tail and forward, as the dorsal fin, a varying distance, sometimes equally far, on the back, instead of a rayless adipose fin being present. These two kinds of marine catfishes have reached, and established distinct species and even genera in the fresh-waters of Australia and New Guinea, although the group as a whole is continental and absent from land masses which have not been connected with the northern continents after the beginning of the Tertiary. Although they may not be utilized as food, so far as is known all catfishes are good to eat.

The characins are a varied group of fresh-water fishes confined to Africa and tropical America. Typical characins are active, streamlined, longer or shorter-bodied fishes. with fins without spines, a short dorsal more or less in the middle of the back and over the ventrals, pectorals behind the head placed low, a small adipose present over the longer or shorter anal and a forked caudal fin. Their mouths and feeding habits vary greatly; the mouth may be very small, the teeth insignificant or even absent, or the mouth large, with highly developed fangs. A common condition, especially in short-bodied, compressed forms, is a rather small mouth, with hinged lower jaw which drops down very freely, and strong, cusped incisor teeth. In a few genera the adipose fin is absent. There are many genera, some of the predaceous ones being moderately large fishes, but most are rather small, and a good many minnow-sized. In Africa species of the generalized genus *Alestes* are variously short-bodied and compressed, or more slender; the tiger fishes *(Hydrocyon)* are salmon-shaped fishes with notably large, strong, sharp teeth. The largest tiger fishes grow to three or four ft. They are usually silvery on the sides, with a tendency to narrow, parallel, lengthwise streaks. The large-mouthed, pike-like *Sarcodaces odoe* grows to one or two ft. *Distichodus* and *Citharinus* have small mouths with small or minute teeth. The latter, with a very deep, compressed body, grows large, two or three ft. in some species.

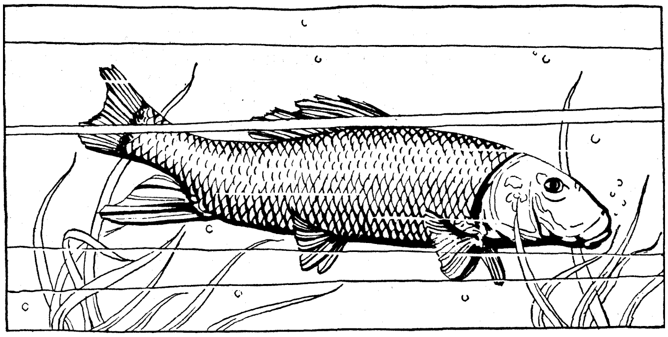
In South America, numerous small, more or less short-bodied and compressed species related to *Astyanax*, correspond to those related to *Alestes* in Africa. There are deep-bodied, fine-scaled fishes known as piranhas (*Serrasalmus*) with somewhat larger mouths and stronger teeth, a long anal fin with an oblique base and the lower edge of the body keeled and serrated, which reach a maximum length of about 18 in. At perhaps half that size they occur in some rivers in immense schools, and are reputed to attack and consume any warm-blooded animal that falls or ventures into the water: and to be dangerous to man. Fishes of the genus *Hydrolycus*, which may grow to two ft. or more, have large mouths and two very long fangs in the front of the lower jaw. *Curimatus* and related genera comprise small species with a very small mouth and no teeth. Species of *Pyrrhulina* are handsome, slender, small-mouthed little fishes, wherein the adipose fin is lacking. They are often kept in aquaria. *Hoplias*, a very ordinary looking, large-mouthed, strong-toothed fish, which grows to one or two ft., also lacks an adipose fin, and has little in its superficial appearance to suggest its belonging to this family.

Resemblances between certain South American and African characins was considered evidence of a fresh-water, that is, a land connection between the two continents. presumably in Tertiary times. However, recent taxonomic ichthyologists, most familiar with this family as a whole, are rather unanimous in the belief that it differentiated independently in the two areas, that these resemblances are parallelisms, subgroups comprising both African and South American species being matters of convenience, rather than truly phylogenic.

In the fresh-waters of South America there is an abundant and varied family of eel-like fishes, the Gymnotidae, thought to be a derivative or branch of the characins. These have the body behind the head relatively deep, but tapering to a long, slender tail. The anal fin, which is very long, occupying most of the lower edge of the body, is rippled to propel the fish slowly forward (or backward). There are \\ell-developed pectoral fins behind the short gill slits, no ventral fins, the dorsal fin insignificant or absent. There is sometimes a narrow caudal fin, or the anal may extend back around the tip of the tail, or this project in a finless filament. The profile, snout and mouth are very variable. In most species the snout is moderate or short, and blunt, the mouth rather small. In some the snout is long and narrow with a tiny mouth at its end, and even decurved *(Stevnavchorhynchzts)* as in some of the Mormyridae. In fact there are certain parallels, though presumably no relationship between the Gymnotidae and that African family.

The most notable gymnotid, and perhaps the largest, is the electric eel (*q.v.*) (*Electrophorus electricus*), which sometimes reaches a length of more than nine feet, and differs from most others in having a projecting lower jaw, the body cylindrical instead of compressed, and lacking even rudimentary scales. Large eels can give the most powerful electric shock of any animal, that from one five feet long being sufficient to knock a man down. This faculty is doubtless used in defense. It is also used to stun, without killing, the small fishes on which the electric eel feeds, and one of the remarkable things about it is the perfect control the eel has over its severity, appropriate to a given application. The electric eel is generally distributed through northern South America, frequenting pools, and well-shaded places in narrow, sluggish waters, and, though rather generally avoided on account of its electric potentialities, is occasionally used as food.

The carp like fishes make the third division of the Ostariophysi, presumably the most recent one in time, as they have not reached South America, which conlinent was isolated by sea from the others for a considerable period in the Tertiary. Their differentiation and distribution are sufficiently recent to be traceable with reasonable certainty. Carps (Cyprinidae) are ordinarily symmetrical fishes with larger or smaller scales, dorsal and anal fins rather short, the former near the middle of the back, with ventral fins about under it on the lower side of the body, pectoral fins behind the head placed rather low, caudal fin emarginate or forked. They lack teeth in the mouth but have them on the pharyngeal (throat) bones. There are ordinarily no spines in-the fins, but an initial spine is not infrequently present in the front of the dorsal, occasionally more than one such, and rarely a spine in the front of the anal fin also. One or two pairs of barbels may be present about the mouth. The family is a large one and there are other variations from type. The suckers (Catostomidae) are primitive carps, little different from, and sometimes considered merely a subfamily of, the Cyprinidae. They are bottom feeders with small sucking mouths, and so are various true carps for that



BY COURTESY OF THE N.Y. ZOOLOGICAL SOCIETY
COMMON SUCKER (CATOSTOMUS COMMERSONII), ABUNDANT IN THE GREAT LAKES AND NORTHWARD. A FISH WITH PROTRUSIBLE MOUTH AND FLESHY LIPS ADAPTED FOR SUCKING UP MUD AND ORGANIC DEBRIS FROM THE BOTTOM

matter, but differ in that their pharyngeal teeth are simple, and in a single comb-like row. Those of the true carps are fewer in number, variously specialized, and often in two or three rows. Suckers were presumably ancestral to the carps, evolved and lost their oral teeth at a period when mature, sluggish drainage, nhich they still favour, was widely distributed. The valleys of Asia, south of the line of deserts which must be of great antiquity, are the centre of differentiation.and have probably been the centre of distribution, for true carps. Here but a single. specialized Chinese species of sucker (*Myxocyprinus asiaticus*) remains. There are numerous species of suckers in North American fresh waters.

The carp family occurs in greatest abundance and variety in eastern 'and southern Asia. To mention a few of the numerous types there represented. the genus *Barbus*, of which numerous subgenera may be recognized, are,mostly symmetrical, free-swimming fishes with moderate or large eyes, moderate or small mouths. with or without an initial spine in the dorsal fin, usually two pairs of barbels, sometimes only one, or none. Southern species usually have compressed bodies and large scales. highland and northern species tend to be more elongate with finer scales. The common carp *(Cypvinus carpio)* and the related goldfish (*Carassius auvatus)* are not unlike this genus, but have a long dorsal fin for the family, likely a primitive character, a serrate spine not only in the front of the dorsal but of the anal fin, and the carp has well-developed molar teeth, a specialized character.

What seems to be an evolutionary line is traceable from *Barbus*, through bottom-feeding forms represented by *Garra*, which has a broad sucking disk on the chin, then through *Varicorhinus*, to numerous, closely related silvery fishes of the genus *Xenocy-*

pris, with a characteristic small cross mouth more or less below the snout, and which are probably secondarily freer swimming. There are several more or less related or unrelated genera of breams. with a longer or shorter sharp keel along the lower edge of the body. Most are well compressed, from side to side. some are deep-bodied, others slender and elongate like the abundant Chinese knifefishes (*Hemiculter*), small or moderate sized silvery fishes with a smooth spine in front of the dorsal fin. Another group of carps comprises genera related to Schizothorax, abundant in high central Asia with a few representatives farther east in hilly country. These have a characteristic row of enlarged scales bordering the vent and base of the anal fin, those over the body small. sometimes rudimentary. or even lacking.

Elopichthys bambusa, common in China: is a large, slender, fine scaled, swift predaceous carp: with long, firm jaws; and predaceous species of the genus *Opsariichthys* have a protuberance on the upper jaw fitting into a notch in the side of the lower, to compensate for lack of teeth in the mouth. There are also groups of mostly minnow-sized fishes. *Phoxinus* are fine-scaled minnows, perhaps most nearly related to those which are so abundant in genera and species in North America. *Pseudorasbora parva,* with a small, very oblique mouth, is abundant and widely distributed, represented by several poorly defined geographical forms. There are numerous bitterlings (Rhodeus, etc.), deep-bodied, compressed, large-eyed. active little fishes, usually three in. or less though some species grow to moderate size, which lay their eggs inside the shells of fresh-water mussels, where they are relatively safe until hatched and the fry leave this shelter. The oviduct of the female is protruded as a long tube to deposit the eggs.

The gudgeon series (Cobio and related genera) is abundant and varied in eastern Asia, very scantily represented in Europe and has not reached Africa or America. It varies from very carp- or minnow-like fishes of moderate or small size (Leucogobio, *Gnathopogon*), to bottom species with small mouths, fringed with papillae, placed under the snout. Such gudgeons occupy a comparable ecological niche to that which suckers do in America. They comprise numerous small species of Pseudogobio, and more elongate, generally larger species of Saurogobio.

The loaches make a third division of carp-like fishes. They are usually rather small. frequently somewhat eel-like, tend to have fine, inconspicuous scales; are sometimes altogether without scales and usually have more barbels than the two pair frequently present in the carps. In some superficial characters they seem intermediate between catfishes and carps, but are probably a more recent group even than the latter, and may have been derived from them. Loaches are more heterogeneous than carps or suckers and very likely have a multiple origin. They have a peculiar anatomical character, in that the air bladder is enclosed in a bony capsule. Some are very sensitive to weather changes, and this encapsuled bladder may be correlated with sensitivity to atmospheric pressure. The eel-like pond loaches (*Misgurnus*), which are sometimes kept in aquaria and called weatherfish, become restless at the approach of a storm. Some small species (allied to *Barbatula*), which are numerous in High Asia where barometric pressures run very low, have the capsule more or less incomplete, although they are closely related to others in which it is complete. Loaches have no spines in the fins, but in some there is a concealed. erectile, defensive spine on the side of the head, more or less beneath the eye. Of these the spined loach (*Cobitis* taenia) is abundant, with a certain amount of geographic variation, across Eurasia from England to Japan: There are a number of shorter-bodied, freer-swimming, more streamlined Asiatic species'of the genus Botia, also with a facial spine, which tend to be boldly patterned or brightly coloured, and usually have a forked caudal fin.

The subfamily Homalopterinae comprises a miscellaneous lot of loach-like fishes. the closeness of their relationship to other loaches. or for that matter to one another. being somewhat uncertain. *Gastromyzon* and related genera placed here. which cling to the bottom in swift water. have a short, much depressed body, wide from side to side and flat below. with a small cross mouth on the under side of the head. the paired fins expanded in a horizontal plane. Loaches are abundant in Asia, also occur in Europe and one small species is found in Abyssinia.

Houndfishes, Flying Fishes, Trumpet Fishes and **Pipefishes.**—Houndfishes (Belonidae), sometimes called needlefishes or silver gars, are slender, elongate marine species, abundant along the shores of all warm seas. They have large eyes, the jams, set with numerous sharp teeth, lengthened to form a beak which is longer than the remainder of the head. Their fins are entirely without spines, the ventrals placed well back. rather behind the middle of the body, nhich is covered with fine, inconspicuous scales. The dorsal and anal fins are placed opposite one another near the tail, and the caudal fin is forked or lunate. They are silvery in colour, darker, usually greenish along the back and swim near the surface, singly or in small groups, preying on lesser surface fishes. The smaller species gron to one or two ft , the largest to at least four or five ft. Many of them frequently leap above the surface of the sea. their long bodies propelled through the air like a thronn javelin or spear, and there are said to be instances of men in small boats being struck and seriously wounded by them. The large kinds, especially, have the lower lobe of the caudal fin somewhat larger and firmer than the upper, no doubt correlated with this leaping habit. In most the body is cylindrical, little if at all compressed (*Tylosurus,* etc), but one genus (*Ablennes*) with a flat, compressed body, turns on its side in the air. Though only locally so used. probably all this family are good food fishes, even large species with green bones.

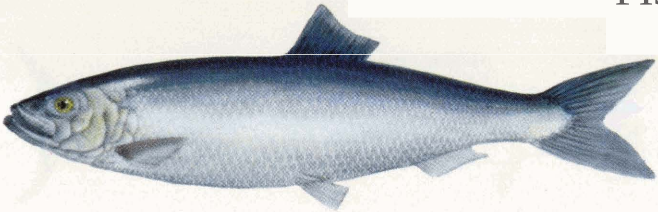
The halfbeaks (Hemiramphidae) are related to the houndfishes. but in these the lower jaw only is lengthened and forms a pointed, toothless spear. Exceptionally, both jaws are short (*Chriodorus*). Halfbeaks have small mouths and are mainly planktivorous. Just how their spear-like lower jaw functions is uncertain. It may attract bits of floating vegetation which slide back to the mouth as the fish swims along. They are small fishes, seldom more than a ft. long, abundant coastwise in warm seas. a few occurring in fresh water. Those found furthest offshore (*Hemiramphus*) have a forked caudal fin, with the lower lobe longer than the upper, as it is in the flying fishes and some of the houndfishes. This fin is usually at least emarginate, but there are more or less fresh-water or estuarine species wherein it is rounded, in the East Indies, etc., and these are viviparous (*Hemirhamphodon, Zenarchopterus*).

Some halfbeaks skitter along the surface of the water, sculling vigorously with their caudal fin, and with the body out of water at an angle, the short pectoral fins spread to balance and support it. It is logical to suppose that this habit gave rise to the related flying fishes, that in the course of evolution the halfbeak's pectorals lengthened and strengthened to make of the flying fish the efficient aerial glider that it is. Everywhere in nature we find an animal's structure closely correlated with its habits, usually aith no indication of which evolved first, and, as a matter of fact, they mere presumably very nearly synchronous. In this order of fishes (Synentognathi), if, as is supposed, the houndfishes are primitive and flying fishes, its terminal member. the habit of leaping came first, and gradually turned to flight, as it gave rise to structures which made flight possible.

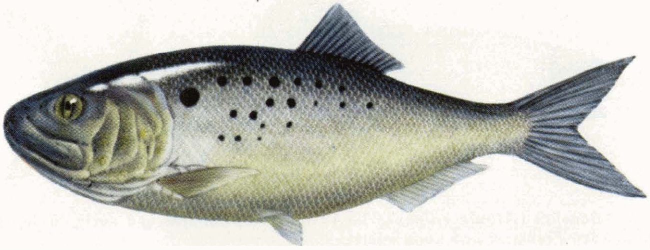
The flying fishes (Exocoetidae) are large-eyed, blunt-headed, silvery-sided fishes which swim at the surface of all warm seas. They have moderate-sized smooth scales; short, posteriorly placed dorsal and anal fins, of soft rays only; and are notable for their very long, firm pectoral Sns, which support them in the air. Their caudal (tail) fin is forked, its lower lobe firm and is longer than the upper. Two types of flying fish are common. The "four-winged" species have the ventral fins placed more or less behind the centre of the body, also large, and spread in flight to supplement the lift from the pectorals. The largest of these reach a length of around 18 in., and make the longest aerial excursions. The "two-winged" species, which are somewhat short-bodied and seldom more than six in., have the ventral fins small, less far back. not spread in flight.

An adult flying fish leaves the water with vigorous thrusts of the tail, spreading its wings rigidly as it does so. There was considerable argument as to whether it received any momentum or support from fin movement when in the air. It is now generally conceded that it does not, that. essentially at least, it is a glider. The

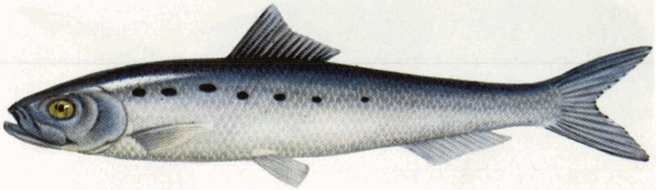
FISHES



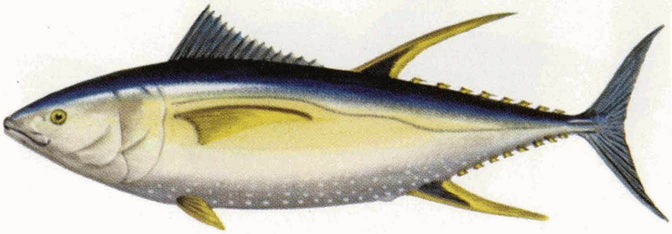
Herring *(Clupea harengus)*; 12-17 in. Both sides of the North Atlantic



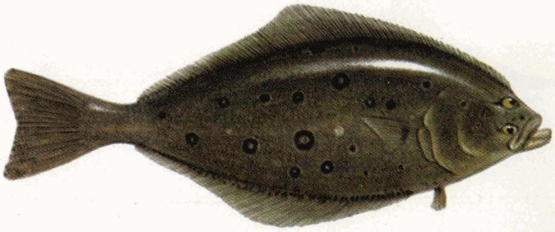
Atlantio menhaden *(Brevoortia tyrannus)*; *15* in. Nova Scotia to Florida



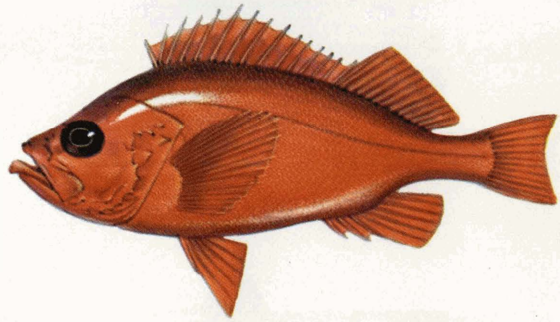
Pacific sardine *(Sardinops sagax)*; 8-14 in. Southeast Alaska to Lower California; Peru and Chile



Yellowfin tuna *(Thunnus albacares)*; *5-9* ft. Tropical and temperate Atlantic and Pacific

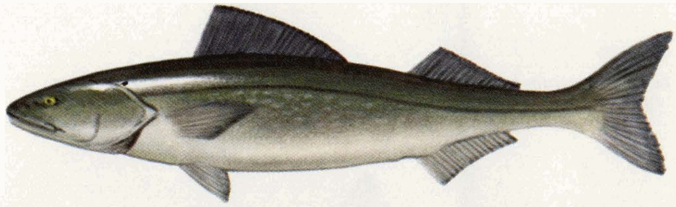


Atlantic halibut *(Hippoglossus hippoglossus)*; *7-8* ft. North Atlantic:, south to Bay of Biscay, south to New Jersey

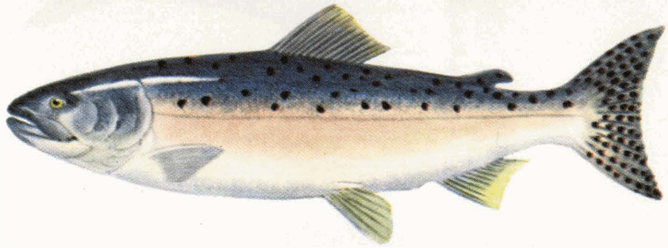


Redfish or ocean perch *(Sebastes marinus)*; 10-22 in. North Atlantic; North sea to Spitsbergen; Iceland; Greenland south to New Jersey

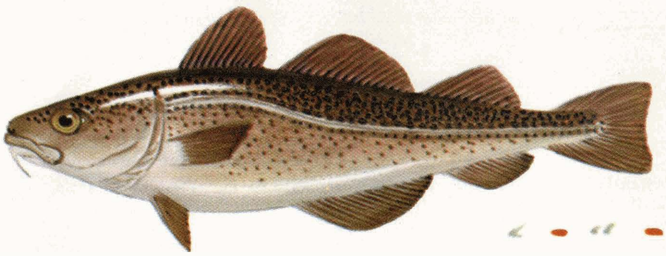
Mackerel *(Scomber scombrus)*; 12-24 in. North Atlantic: Noway to Spain and Gulf of St. Lawrence to North Carolina



Sablefish *(Anoplopoma fimbria)*; 20-36 in. Northwest Alaska to southern California



Pink salmon *(Oncorhynchus gorbuscha)*; 20-30 in. North Pacific: Asia, Alaska to Oregon

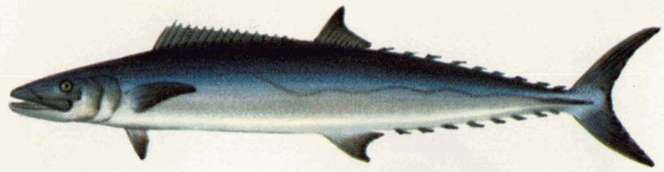


Atlantic cod *(Gadus morhua)*; *40-50* in. Greenland to the Carolinas

COMMERCIALLY IMPORTANT FISHES

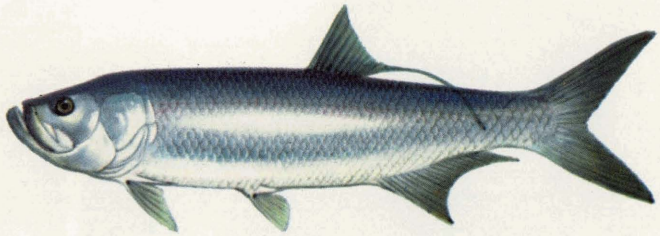
PAINTED ESPECIALLY FOR "ENCYCLOPÆDIA BRITANNICA" BY TOM DOLAN, UNDER THE SUPERVISION OF LOREN P. WOODS, CHICAGO NATURAL HISTORY MUSEUM

FISHES

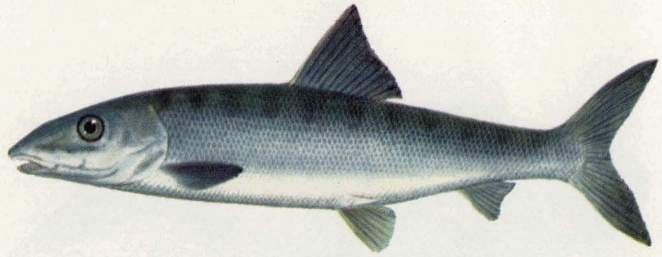


King mackerel or kingfish (*Scomberomorus cavalla*); 36-65 in. Tropical Atlantic

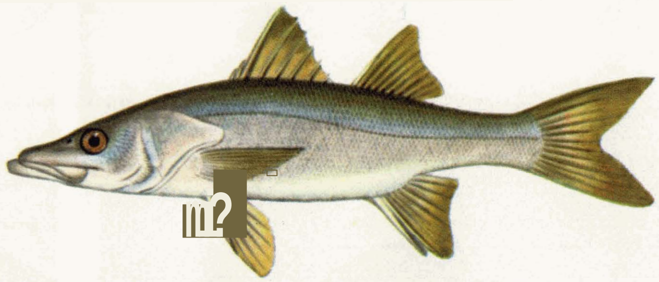
Wahoo (*Acanthocybium solanderi*); 30-78 in. All tropical oceans



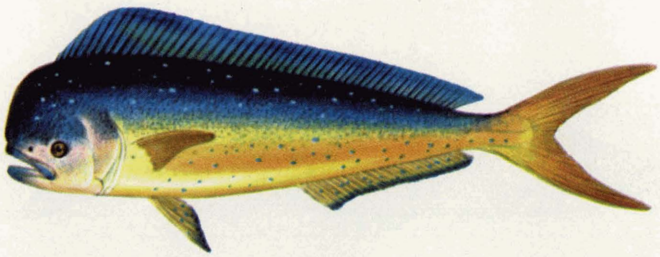
Tarpon (*Megalops atlantica*); 30-74 in. Tropical Atlantic



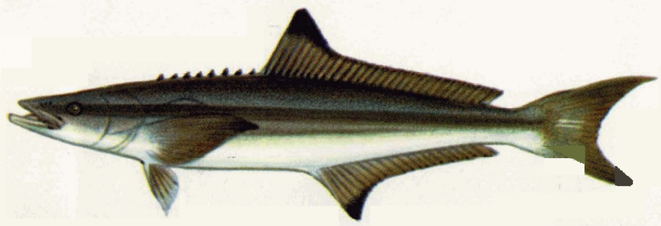
Bonefish (*Albula vulpes*); 15-42 in. Tropical teas and north to Japan, San Francisco and Long Island



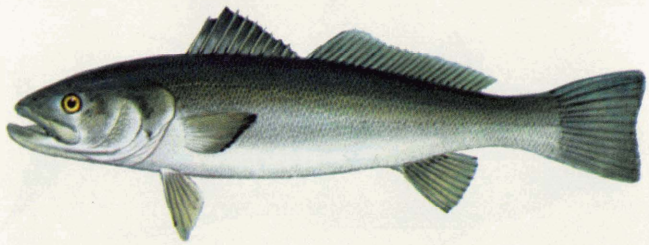
Snook (*Centropomus undecimalis*); 24-55 in. Gulf of Mexico, West Indies, south to Panama and the Guianas



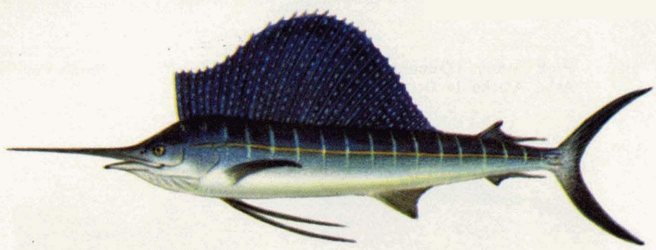
Dolphin (*Coryphaena hippurus*); 24-63 in. All warm oceans



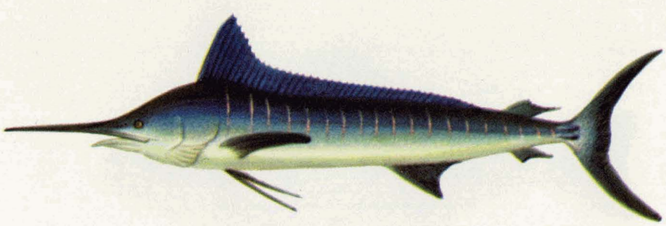
Cobia (*Rachycentron canadum*); 30-70 in. All warm seas



White seabass (*Cynoscion nobilis*); 25-65 in. California to southern Alaska



Atlantic sailfish (*Istiophorus albicans*); 60-124 in. Western Atlantic, Quif of Mexico, West Indies to Brazil



Striped marlin (*Makaira audax*); 161 in. Tropical Pacific

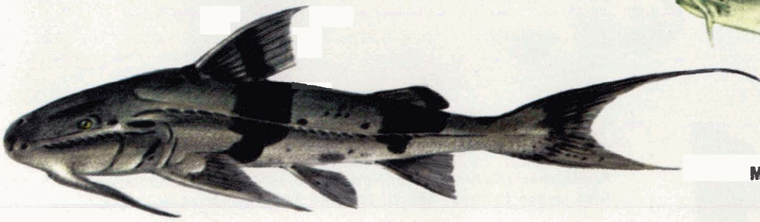
GAME FISHES OF THE WORLD

PAINTED ESPECIALLY FOR "ENCYCLOPÆDIA BRITANNICA" BY TOY DOLAN, UNDER THE SUPERVISION OF LOREN P. WOODS, CHICAGO NATURAL HISTORY MUSEUM

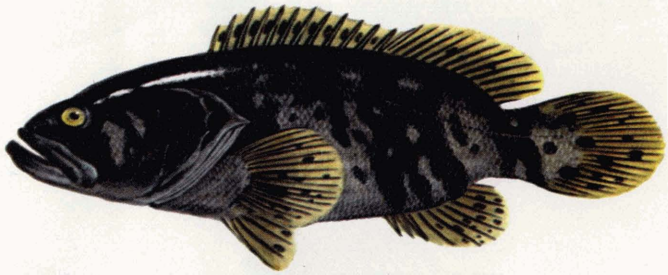
FISHES

Wels (***Silurus glanis***)**;** *6* ft., **occasionally** to **10 ft.** Central and eastern Europe, **Baltic** to Caspian teas

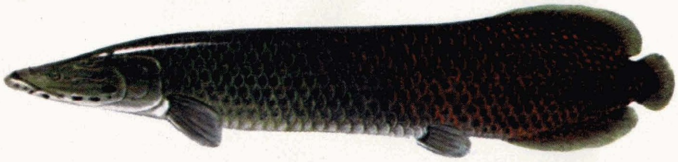
Sturgeon (***Acipenser sturio***); **6-10** ft., to **18** ft. Atlantic; Baltic, Mediterranean and Black seas; Danube river



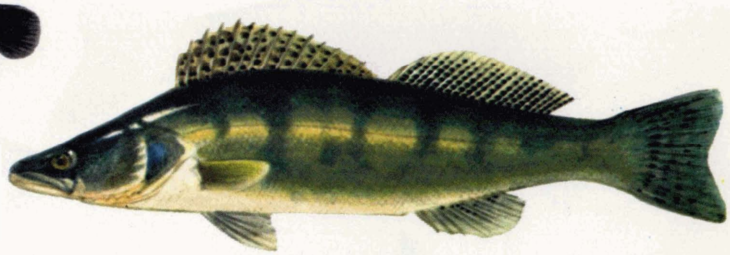
Goonch (***Bagarius bagarius***)**;** *6* ft. Rivers of India



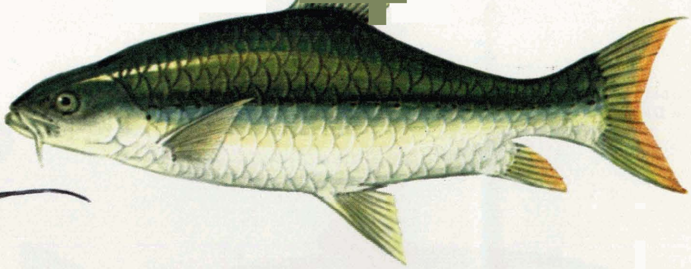
Giant sea perch (***Promicrops lanceolatus***)**;** *8* ft. Western Pacific and **Indian** oceans



Pirarucu (***Arapaima gigas***)**;** 8 ft. Rivers of South America from the Guianas to Argentina



Pike perch (***Lucioperca lucioperca***)**;** *6-20* in. Central Europe **and** USSR



Mahseer (***Barbus tor***)**;** *66* in. Rivers of India, **Assam** and Burma

Indian "trout" (***Barilius bola***)**;** 12 in. Rivers from northern India to Thailand

Tucunara (***Cichla ocellaris***)**;** 25 ft. Amazon river system and the Guianas

Dorado (***Salminus maxillosus***)**; 3 ft. Paraná and Orinoco rivers, South** America

GAME FISHES OF THE WORLD

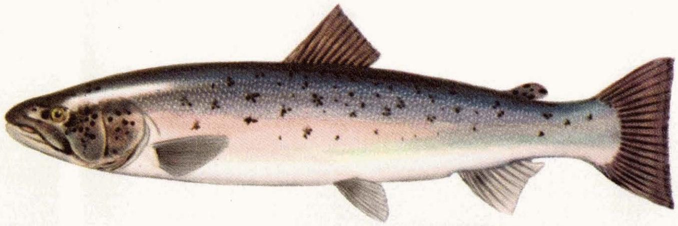
PAINTED ESPECIALLY FOR "ENCYCLOPÆDIA BRITANNICA" BY TOM DOLAN, UNDER THE SUPERVISION OF LOREN P. WOODS, CHICAGO NATURAL HISTORY MUSEUM

PLATE IV

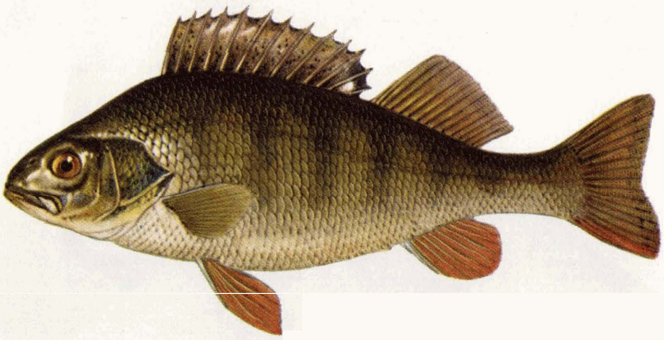
FISHES

Chub (*Squalius cephalus*); 12-24 in. England; Europe to Asia Minor

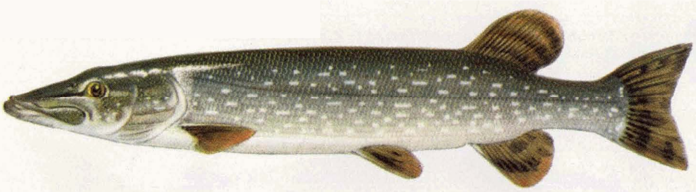
Barbel (*Barbus barbus*); 12-30 in. Engand, France and Germany to the Danube



Atlantic salmon (***Salmo salar***); **20-48 in.** North **Atlantic coastal regions** south to **New England** and **France**

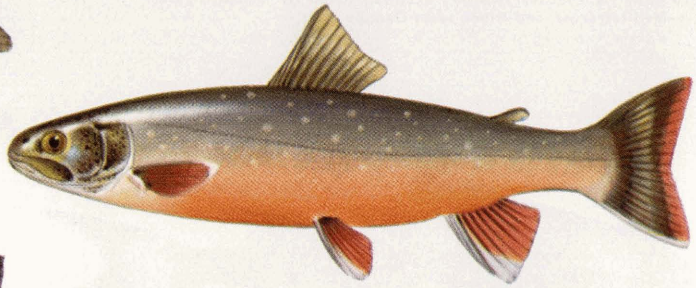


Perch (***Perca fluviatilis***); *6-12* In. England, Europe and northern Asia

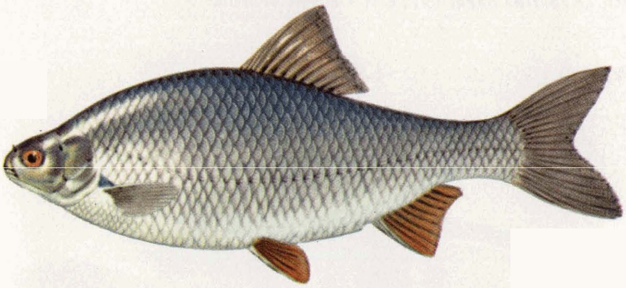


Northun **pike** (***Esox lucius***); 16-40 in. Cool md **cold** waters of **Europe, Asia** and **North America**

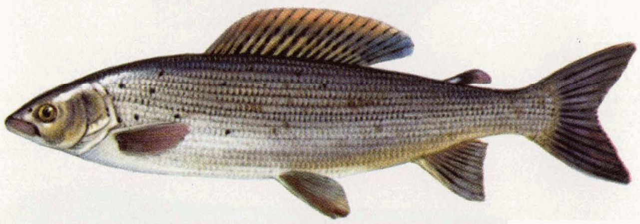
Brown trout (*Salmo trutta*); 6-12 in. Europe and Asia Minor; introduced into North and South America, Africa, India and New Zealand



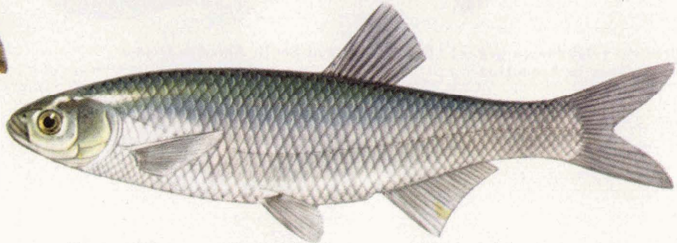
Arctic char (*Salvelinus alpinus*); 10-16 in. Circumpolar, south to the Alps, Japan to about 55° N. lat. and North America



Roach (***Rutilus rutilus***); 6-12 in. Europe, north of the **Alps** and **Pyrenees**



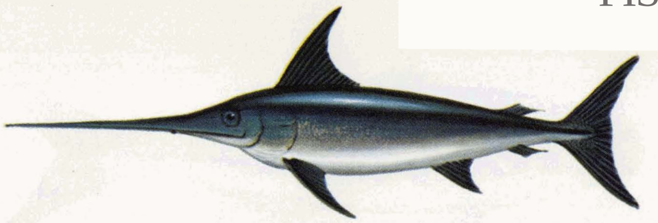
Grayling (***Thymallus thymallus***); **10-20** in. All **of** Europe **except** Spain, southern **France** and **Italy**



Bleak (***Alburnus alburnus***); *4-8* in. **England** and Europe, north of the Alps

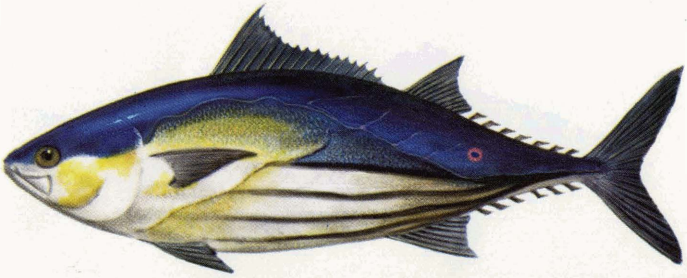
GAME FISHES OF THE WORLD

PAINTED ESPECIALLY FOR "ENCYCLOPEDIA BRITANNICA" BY TOY DOLAN, UNDER THE SUPERVISION OF LOREN P. WOODS, CHICAGO NATURAL HISTORY MUSEUM

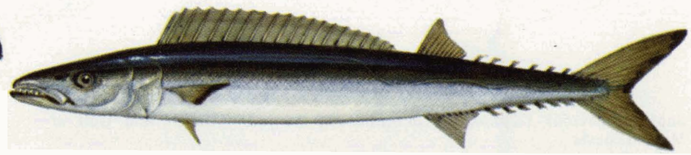


Swordfish (*Xiphias gladius*); 15 ft. All temperate and tropical oceans

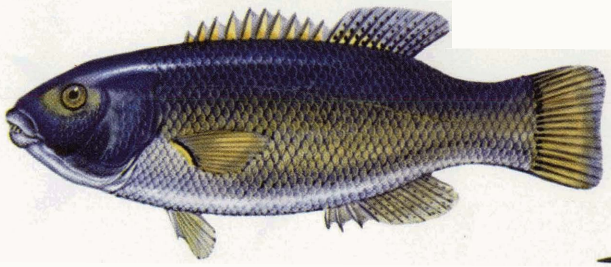
Murray cod (*Maccullochelia macquariensis*); *6* ft. Murray river system, southern Australia



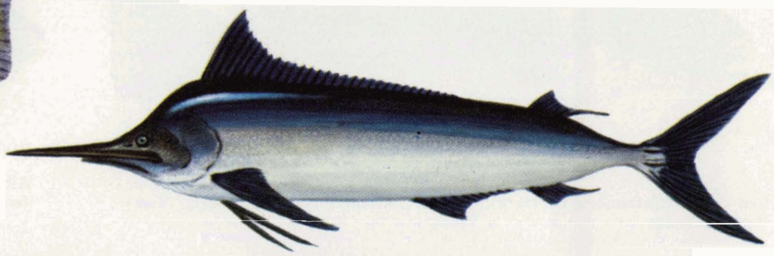
Skipjack tuna (*Euthynnus pelamis*); *3* ft. Pelagic temperate and tropical oceans



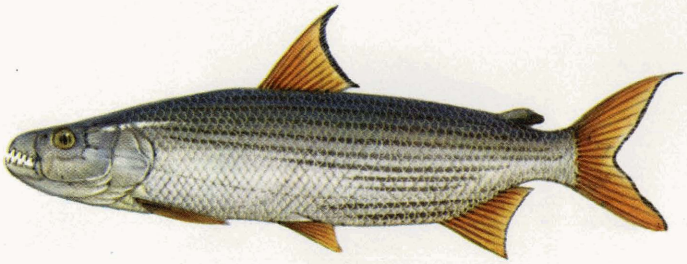
Barrácouta or snoek (*Thyrsites atun*); *4* ft. Coasts of South Africa, southern Australia and New Zealand



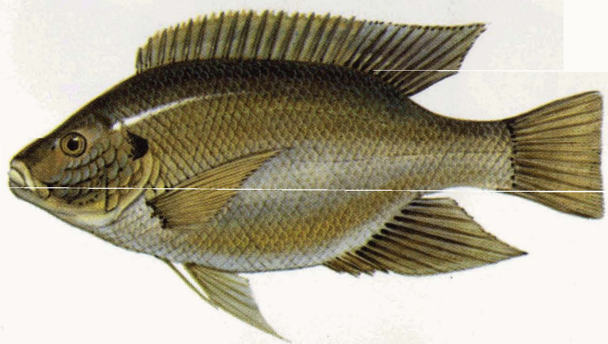
Groper (*Achaerodus gouldi*); *3.5* ft. Rocky coasts of Australia



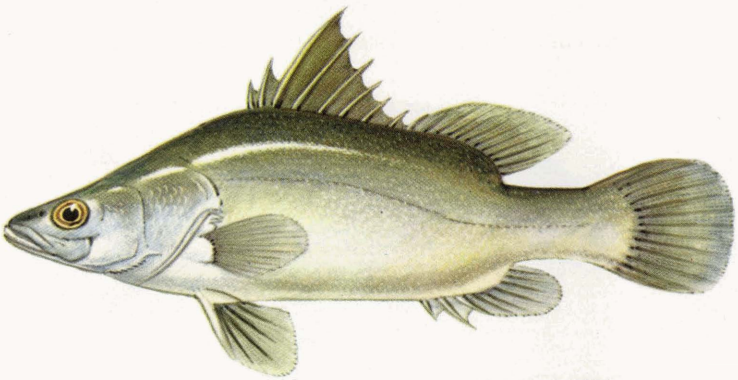
Black marlin (*Makaira indica*); 14.5 ft. New Zealand and Australia



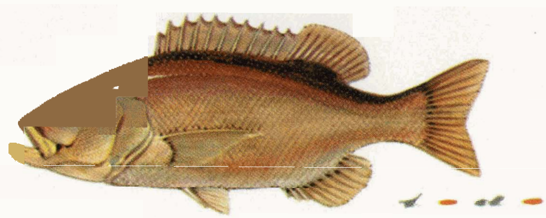
Tigerfish (*Hydroscion lineatus*); *2* ft. Large rivers and lakes of Africa



Tilapia (*Tilapia nigra*); *12* in. Athi river system, British East Africa



Nile perch (*Lates niloticus*); *6* ft. West Africa and Nile drainage



Red steenbras (*Dentex rupestris*); *4* ft. Cape seas, Africa

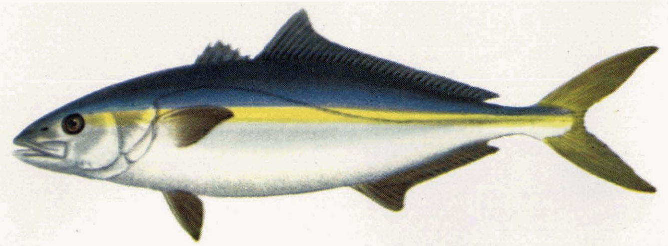
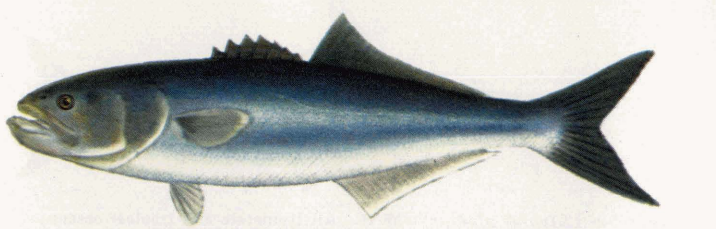
PLATE VI

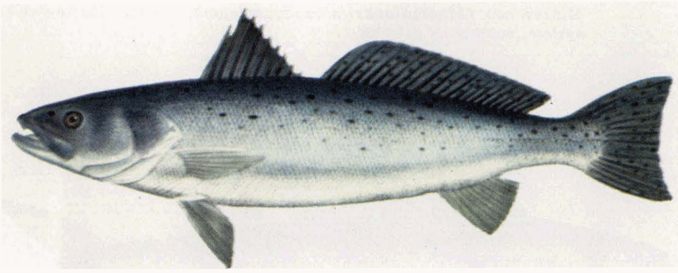
FISHES



Yellowtail (***Seriola dorsalis***); *65* in. Pacific coast, southern California and Lower California



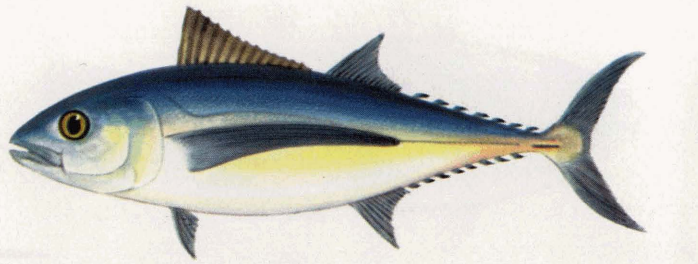
Bluefish (***Pomatomus saltatrix***); 40 in. Temperate and tropical oceans except waters of Oceania and eastern Pacific



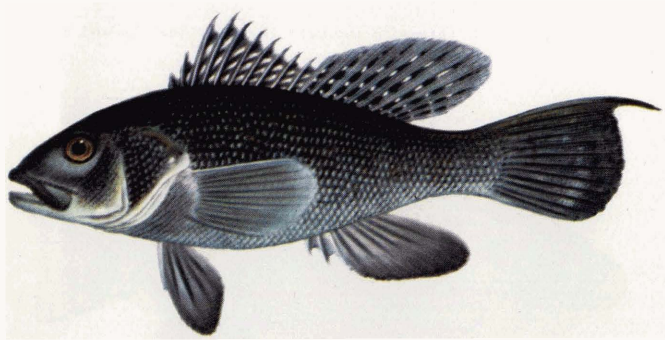
Spotted **seatrout** (***Cynoscion nebulosus***); **34** in. **Atlantic** and **Gulf of Mexico coasts**

Weakfish (***Cynoscion regalis***); 46 in. Atlantic, Nova Scotia to Florida

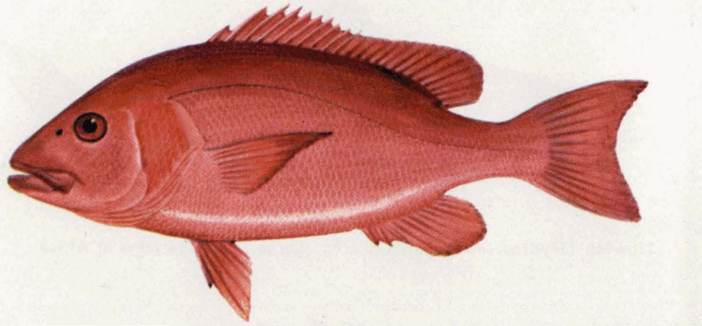
Red drum (***Sciaenops ocellata***); *52* in. Atlantic and **Gulf** coasts, New York to Texas



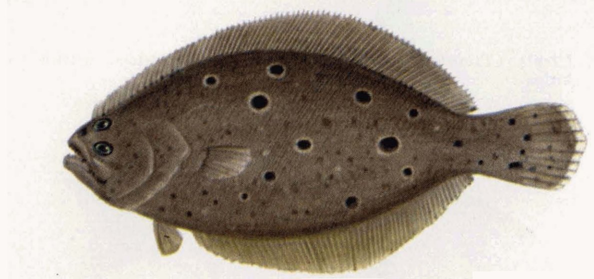
Albacore (*Thunnus alalunga*); 42 in. Alaska to Lower California through temperate Pacific to Hawaii and Japan



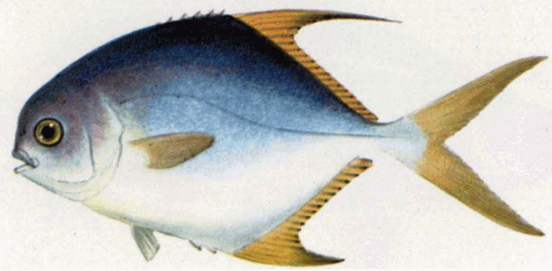
Black sea **bass** (***Centropristes striatus***); *24* in. Atlantic coast, Cape Cod to northern Florida



Red snapper (***Lutjanus blackfordi***); *30* in. Western tropical Atlantic



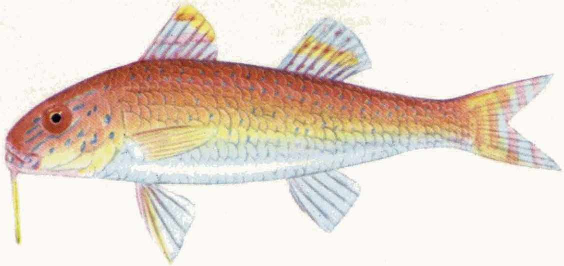
Summer flounder (***Paralichthys dentatus***); 36 in. Atlantic coast, Maine to Florida



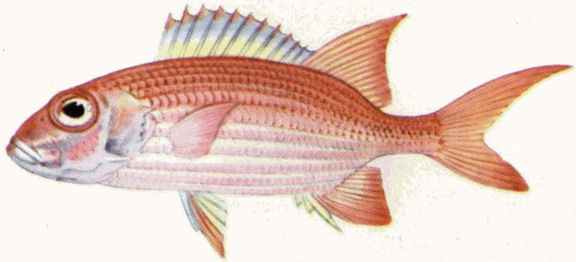
Permit (*Trachinotus falcatus*); *43* **in. Tropical Atlantic**

NORTH AMERICAN MARINE FISHES

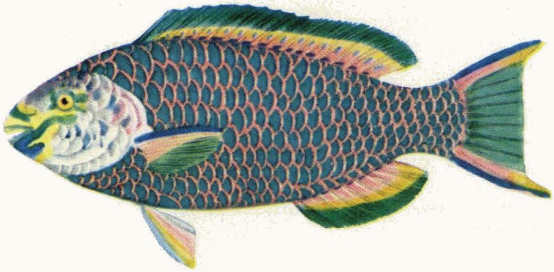
PAINTED ESPECIALLY FOR "ENCYCLOPADIA BRITANNICA" BY TOM DOLAN, UNDER THE SUPERVISION OF LOREN P. WOODS, CHICAGO NATURAL HISTORY MUSEUM



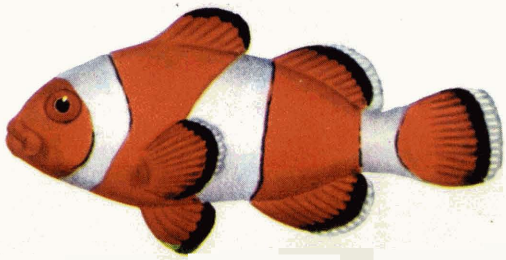
Spotted goatfish (*Pseudupeneus maculatus*); 10 in. Warm Atlantic



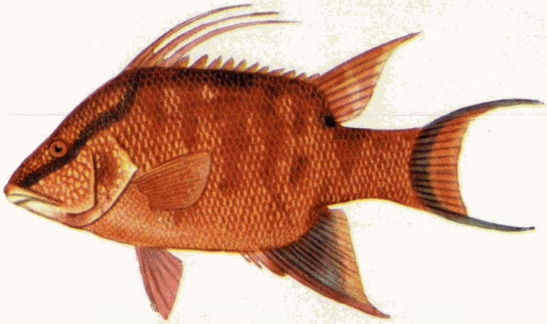
Longspine squirrelfish (*Holocentrus rufus*); 10 in. Bermudas, West Indies and Gulf of Mexico



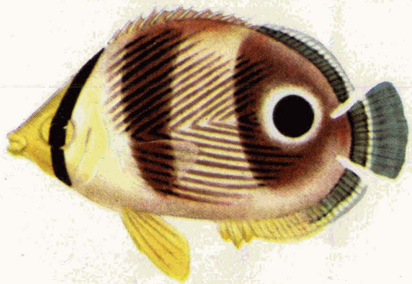
Queen parrot fish (*Scarus vetula*); 24 in. Warm Atlantic



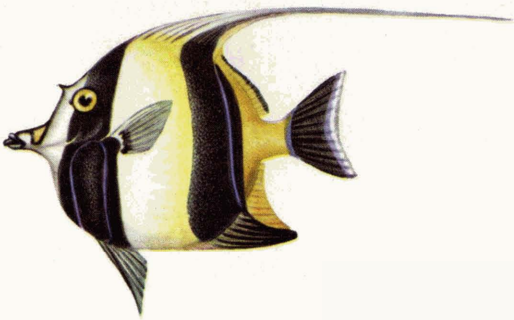
Anemone fish (*Amphiprion percula*); 3 in. Indo-Pacific



Hogfish (*Lachnolaimus maximus*); 26 in. Warm Atlantic

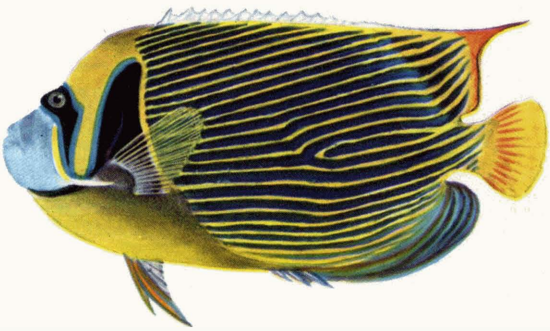


Foureye butterfly fish (*Chaetodon capistratus*); 6 in. Western tropical Atlantic



Moorish idol (*Zanclus cornutus*); 8 in. Indo-Pacific

Achilles tang (*Acantburw achilles*): 12 in. Indo-Pacific



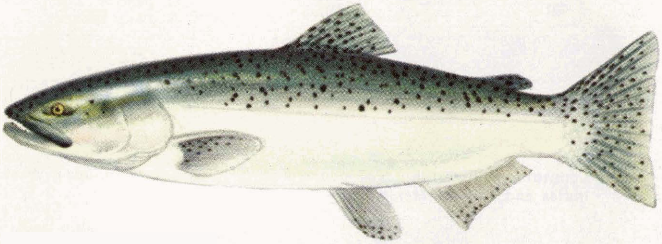
Imperial angelfish (*Pomacanthus imperator*); 14 in. Indo-Pacific

Lionfish (*Pterois volitans*); 8 in. Indo-Pacific

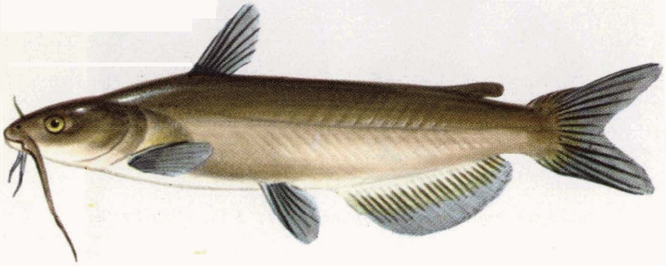
CORAL REEF FISHES

PAINTED ESPECIALLY FOR "ENCYCLOPÆDIA BRITANNICA" BY TOM DOLAN, UNDER THE SUPERVISION OF LOREN P. WOODS, CHICAGO NATURAL HISTORY MUSEUM

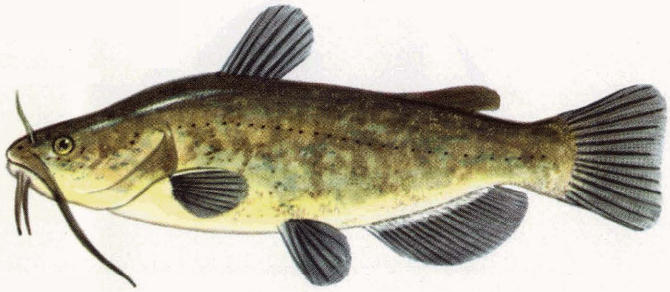
FISHES



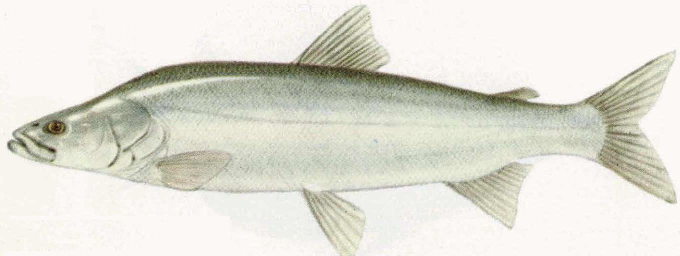
Chinook salmon (*Oncorhynchus tshawytscha*); 36-58 in. Pacific coast, California to Alaska and south to China. (Salmon migrate from the sea to fresh water to spawn)



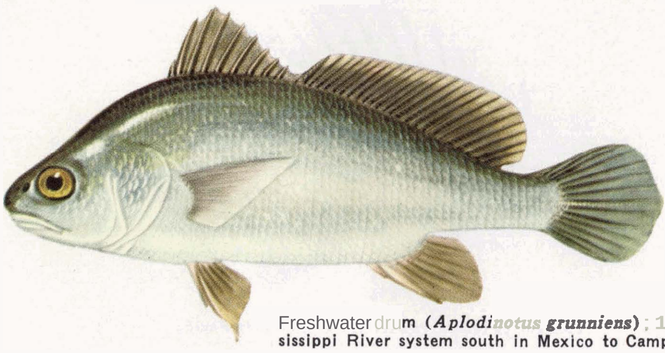
Channei catfish (*Ictalurus punctatus*); 11-30 in. Central U.S., Ap-palaohlans to Rookies



Brown bullhead (*Ictalurus nebulosus*); 6-16 in. Eastern U.S. and south-ern Canada



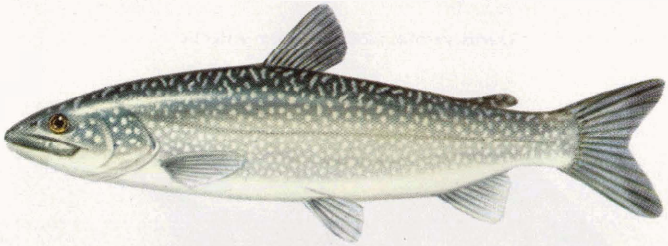
Inconnu (*Stenodus leucichthys*); 40-60 in. Yukon and Mackenzie rivers; also in northern Asia



Freshwater drum (*Aplodinotus grunniens*); 12-30 in. Great Lakes, Mis-sissippi River system south in Mexico to Campeche

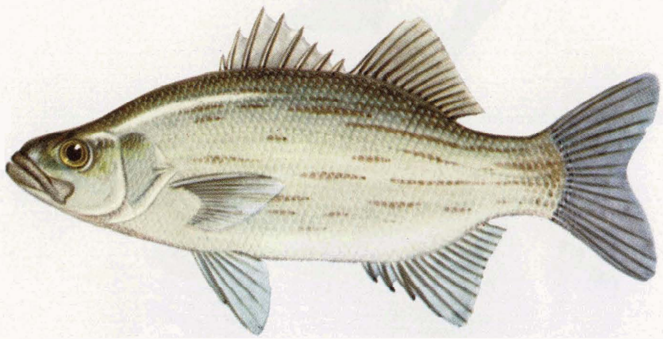
Cutthroat trout (*Salmo clarki*); 12-30 in. Western U.S. and Canada

Brook trout (*Salvelinus fontinalis*); 5-18 in. Northeastern U.S. and eastern Canada



Lake trout (*Salvelinus namaycush*); 15-36 in. Alaska; Canada south to the Great Lakes

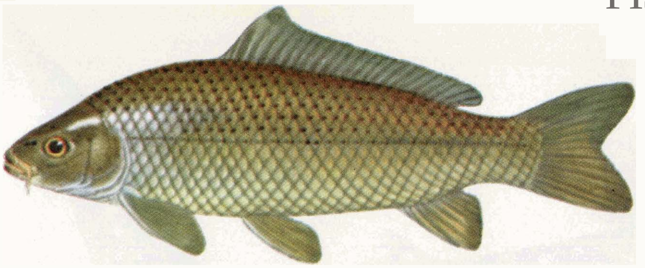
Rainbow trout (*Salmo gairdneri*); 20-45 in. California to southeastern Alaska; introduced into Europe and New Zealand



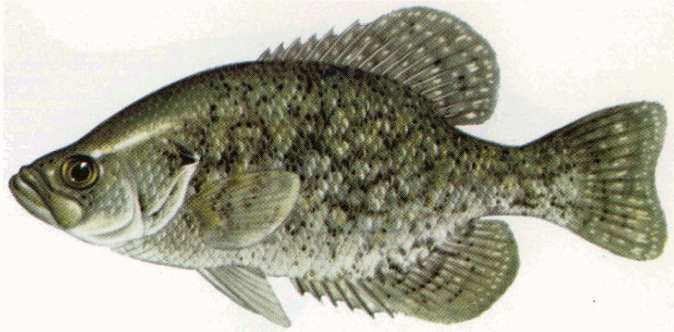
White bass (*Roccus chrysops*); 7.5-16 in. Great Lakes, Mississippi river valley to northeastern Mexico

NORTH AMERICAN FRESH-WATER GAME FISHES

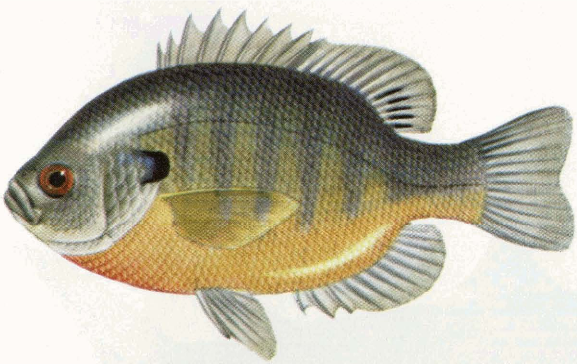
PAINTED ESPECIALLY FOR "ENCYCLOPÆDIA BRITANNICA" BY TOM DOLAN, UNDER THE SUPERVISION OF LOREN P. WOODS, CHICAGO NATURAL HISTORY MUSEUM



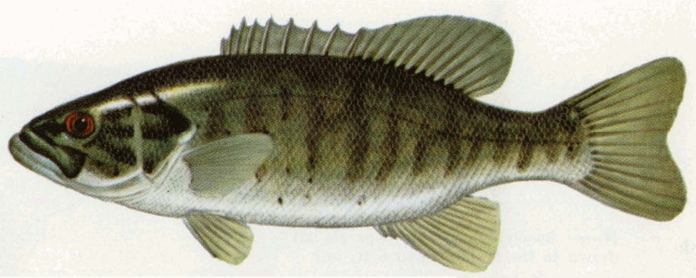
Carp (*Cyprinus carpio*); **10-40 in. Also** found in Europe and Asia



Black crappie (***Pomoxis nigromaculatus***); **5-12** In. **U.S.,** east of Great Plains, but not found In New England

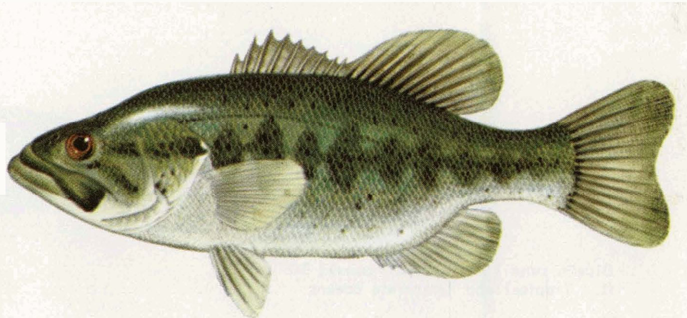


Bluegill (*Lepomis macrochirus*); **6-8 In.**, Throughout **most** of **conterminous** U.S., but **originally** from central states

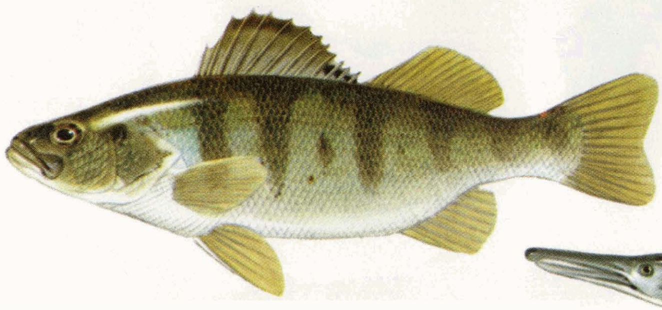


Smallmouth bass (*Micropterus dolomieui*); **10-22 in. North central** U.S. and **adjacent parts of Canada**

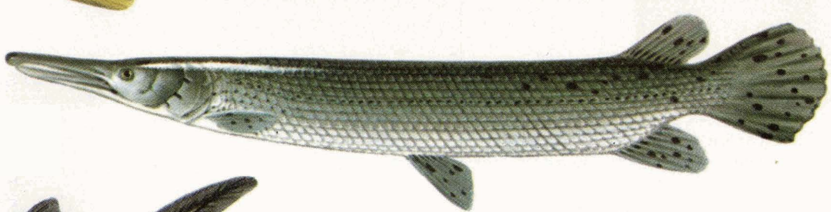
Walleye (*Stizostedion vitreum*); 12-30 in. **Northeastern US.** and **Canada**



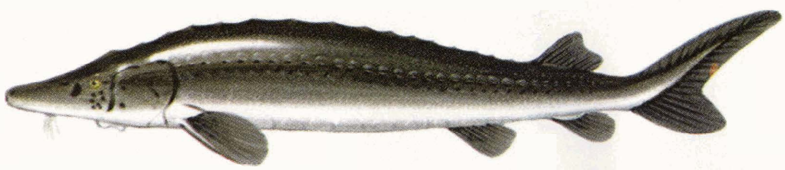
Largemouth bass (*Micropterus salmoides*); **10-20 in. U.S., east of Great** Plaint



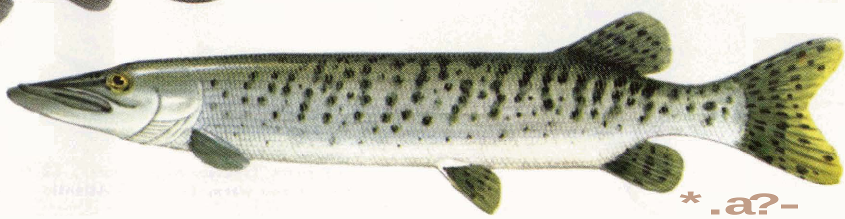
Yellow perch (*Perca flavescens*); **6-12** in. North-eastern **U.S.** and Canada



Alligator aar (*Lepisosteus spatula*); *5-9* ft. Lower **Mississippi** river and tributaries; **Gulf coast** of Florida to **Tampico**, Mexico



Lake sturgeon *(Acipenser fulvescens)*; **20-55** in., **oc**-casionally to **96** in. Great Lakes, upper **Mississippi**, lakes and streams of Canada to latitude **60°** N.



Muskellunge (*Esox masquinongy*); *24-45* in. Great Lakes basin, Ohio and upper **Mississippi rivers**

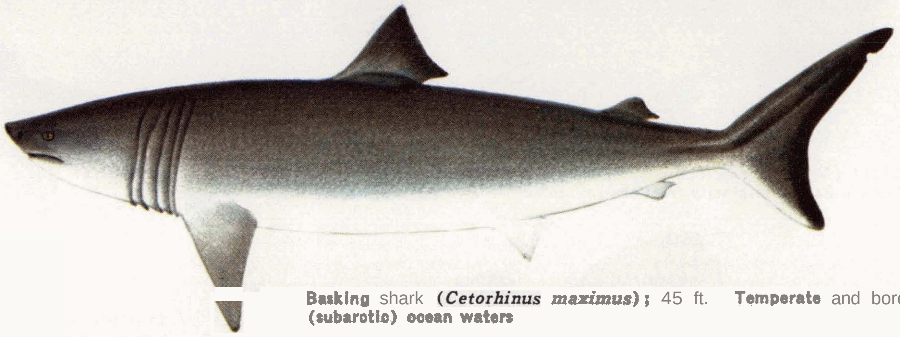
NORTH AMERICAN FRESH-WATER GAME FISHES

PAINTED ESPECIALLY FOR "ENCYCLOPÆDIA BRITANNICA" BY TOM DOLAN, UNDER THE SUPERVISION OF LOREN P. WOODS, CHICAGO NATURAL HISTORY MUSEUM

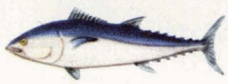
FISHES

Whale shark (***Rhincodon typus***); *60* ft. All tropical oceans

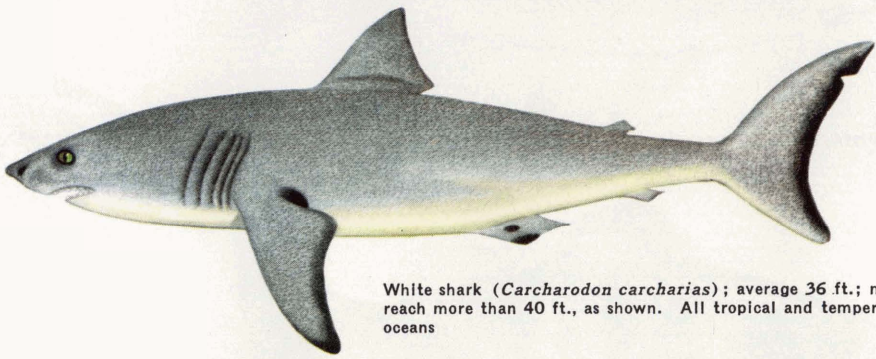
Note: Specimens on this page are all drawn to the scale of man 6 ft. tall



Basking shark (***Cetorhinus maximus***); 45 ft. **Temperate** and boreal **(subarctic) ocean waters**

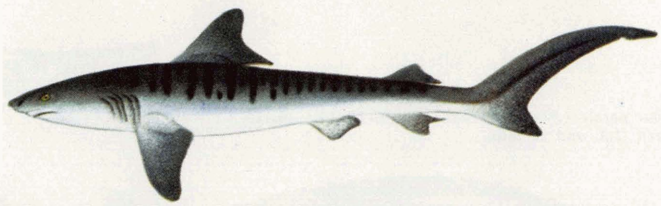


Bluefin tuna (***Thunnus thynnus***); **10** ft. Tropical and temperate oceans

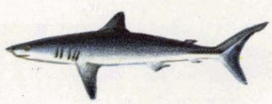


White shark (*Carcharodon carcharias*); average 36 ft.; may reach more than 40 ft., as shown. All tropical and temperate oceans

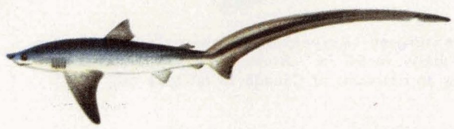
Atlantic manta ***(Manta birostris)*** ***(below)***: ***22*** ft. across the wings. Tropical and warm temperate Atlantlo



Tiger shark (***Galeocerdo cuvieri***); **average 18 ft.;** may reach 30 ft. as shown. **Tropical** and **subtropical oceans**



Mako shark (***Isurus oxyrinchus***); **12** ft. **Tropical** and warm **temperate** Atlantic



Thresher shark (*Alopias* ***vulpinus***); **20** ft. Tropical and warm temperate oceans **offshore**

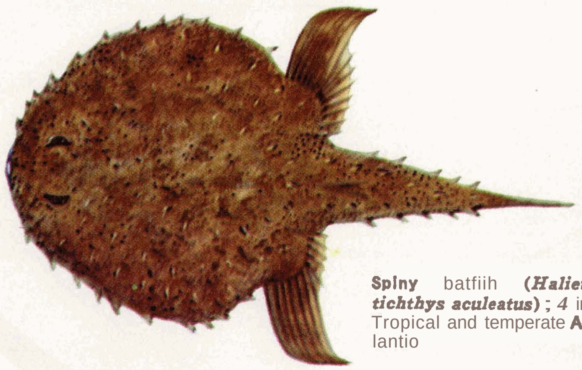
Mud **skipper** (***Periophthalmus schlosseri***); *8* in. East **Indies**

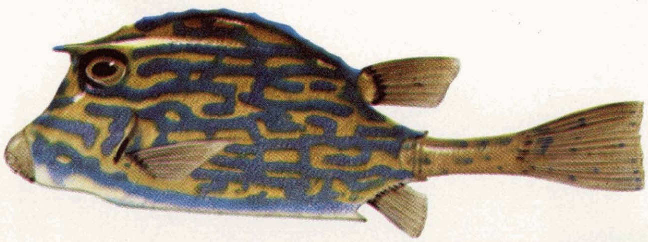
Four-eyed fish (***Anableps** anableps*); ***12*** in. Rivers of eastern South **America**



Spiny batfiih (***Halieu-tichthys aculeatus***); *4* in. Tropical and temperate **At-**lantio

Sea horse (***Hippocampus erectus***); *6* in. Attantlo **coasts, New** York to Brazil

Shrimp fish (***Centris-cus scutatus***); *6* in. **East Indies**



Cowfish (***Lactophrys quadricornis***); *15* **in. Western tropical** Atlantic, Carolinas to Brazil

Sea **dragon** (***Phycodurus eques***); 12 in. South Australia

Sargassum fish (***Histrio histrio***); *5* in. Tropical **Atlantic**

FISHES OF CURIOUS SHAPES AND HABITS

PAINTED ESPECIALLY FOR "ENCYCLOPÆDIA BRITANNICA" BY TOY DOLAN, UNDER THE SUPERVISION OF LOREN P. WOODS, CHICAGO NATURAL HISTORY MUSEUM

flying fish can see where it is going in the air and can alter its direction by banking to one side or the other. When its momentum is spent and it drops back to the water, it frequently dips the lower lobe of its caudal fin first, and sculling vigorously, shoots ahead for the new start of a shorter flight. It may do this two or three times before going under again. Flying fishes rise highest above the water, and make their swiftest and longest flights, by night or day, across the wind in a strong breeze. They usually fly to escape predaceous fishes which pursue them, or when alarmed, as by the bow of an approaching ship, but under these optimum flying conditions seem to do so also for sport, when one sometimes sees schools of the smaller ones in the air together, glistening in the sun. They cover considerable distances entirely clear of the water; an eighth of a mi. was estimated as the maximum for large ones. A few species of flying fishes are cosmopolitan. pelagic, found around the world, the commonest fish life one sees at great distances from land, especially in the trade-wind belts. A number of others have a more restricted distribution, are commonest coastwise or near islands. All are excellent eating, and there are local native fisheries for them, sometimes employing a light to attract them at night. On windy nights individuals frequently come aboard ship, striking the deck, or losing their balance by hitting the rigging, and falling aboard. By day they usually see where they are going and sheer off.

Sticklebacks (Gasterosteidae) are very small fishes of northern fresh, brackish and shore waters, usually three in. or less long. They have large eyes, an even relatively small mouth and a symmetrical, streamlined body, ending in a very narrow, firm peduncle. The caudal fin may be squarish, or slightly rounded or emarginate. They are well armed with a varying number of rather short. sharp, strong spines along the mid-line of the back before the soft-rayed dorsal fin, one at the front of the anal fin, and the ventral fins, placed under or a little behind the pectorals, consisting mainly of a pair of dagger-like spines.

Sticklebacks become very abundant in shallow water grown with aquatic vegetation, full of the tiny animals on which they feed; or drift into more open stretches in small schools. Their breeding habits are highly specialized. At spawning time the male assumes bright colours; selects a territory, where he builds a more or less barrel-shaped nest, mostly of bits of vegetation and attached to water plants; induces usually more than one female to enter it and deposit her eggs; and guards it against all comers, whether intruders or rivals. It is now seen that his formidable armature of spines is more for attack than defense. Though not ordinarily a rapid swimmer, when on the war path he shows great speed and dexterity in the water. Battles between males are frequent and sometimes to the death.

The two commonest sticklebacks, the three-spined *(Gasterosteus)* and nine-spined *(Pygosteus* or *Pungitius)* have a very wide. circumpolar distribution in both fresh and salt water, varying into confusing geographic and ecological forms, and are both plentiful along the Atlantic coast of America south about to, New York. The strictly marine 15-spined stickleback *(Spinachia spinachia)* of the coasts of northern Europe, which builds a nest by binding together fronds of seaweed with a sticky secretion from its kidneys, is a more elongate fish and reaches a larger size, growing to some seven in.

The trumpet fishes are elongate species which occur in tropical shore waters. They have a slight resemblance to the unrelated houndfishes, which is entirely superficial. Instead of long, toothed jaws, they have a small mouth at the end of a long tubular snout. There are two quite unlike trumpet fishes, *Aulostomus* and *Fistularia,* the former reaching a length of at least one or two ft., the latter, which is the more slender, sometimes four or five ft., though usually smaller. Both have short, soft-rayed dorsal and anal fins opposite one another near the tail. and *Aulostomus* has a row of short spines in the mid-line of the back, suggesting those of a stickleback. Its relationship to the sticklebacks. though not close, is probably real, for there is a singular small fish *(Aulorhynchus)*, in the cool coastal waters from California northward, in some respects intermediate toward it from *Spinachia.* This has paired ventral fins placed under the pectorals as in the sticklebacks, not well back as in trumpet fishes. The other trumpet fish, *Fistularia,* has no spines on the hack, and a very peculiar tail, with a long, thread-like lash extending backward from the centre of a small, forked caudal fin. There are few species of trumpet fishes, two of *Aulostomus,* which is uncommon generally recognized, one from the Atlantic and one from the Indo-Pacific; and those of *Fistularia,* which is common, are not well defined.

There are several strange, compressed little fishes, usually uncommon in warm seas, with long, tubular snouts and presumably related to the trumpet fishes. They are of three quite unlike types, represented by the genera *Solenostomus*, *Macrorhamphosus* (the snipefish), and *Centriscus.* Their small, soft-rayed dorsal and anal fins are far back near the tail, and they have an anterior, more or less spinous dorsal fin. In *Centriscus* the body is covered with thin scutes, the anterior dorsal fin has a heavy initial spine more or less coalesced with the armature of the back, and projecting backward beyord the tail which, with its soft dorsal, anal and caudal fins, is bent abruptly downward. This strange little fish is translucent, and is said to swim in a vertical position, at least at times.

If these stood alone, one might assume a line of descent from the sticklebacks, through the trumpet fishes, to the peculiar, specialized forms last mentioned. This would suggest that the variously functionless or specialized anterior spinous ddrsal fin usually present in such a series, foreshadowed, as it were experimentally, the simple, well-developed, functional, defensive spinous dorsal of the modern spiny-rayed fishes, which, abundant in species and individuals, now dominate many of the waters of the world. It would fit in with the thought sometimes held (not by the writer') that characters may arise in evolution as blueprints, so to speak. of something to be of value later. It is probably more reasonable to look on the series the other way round, as branching off from spiny-rayed fishes, parallel and ancestral to those of today, of which *Solenostomus,* etc., are exceedingly specialized remnants, and the sticklebacks a terminal member of the series.

The pipefishes, of which *Syngnathus* is the typical and most abundant genus. are very slender. elongate marine fishes. with a tiny mouth at the end of a tubular snout. the body angular in cross section, consisting of numerous bony rings, with a varying development of keels and ridges on head and body. They have good-sized eyes, a shortish dorsal fin of numerous slender, flexible simple rays placed more or less in the middle of the back. usually a tiny anal fin approximately below it and a small fan-shaped caudal fin at the end of the long, narrow. segmented tail. The pectoral fin is short and broad and ventral fins are lacking. Their eggs, and young, until these are large enough to fend for themselves, are carried by the male, usually in a pouch placed behind the vent, and his anal fin is inconspicuous or absent.

Pipefishes inhabit all warm and temperate seas, and are abundant in species and individuals, particularly about the shores of continents and continental islands. A few are commonly found in estuaries or inhabit fresh nater. They customarily live among seaweed, and one species *(Syngnathus pelagicus)* is plentiful across the eastern North Atlantic in drifting sargassum, where its mottled colours give it a low visibility. They normally glide through the water so slowly, propelled by their weak fins. that often they may be captured in the hand easily, but make better speed for short distances by an eel-like motion of the whole body, Pipefishes vary in size from one or two in. to one or two ft., and whereas a majority of the species are sufficiently alike to be placed in one comprehensive genus *(Syngnathus)*, a number of other genera are recognized for the more aberrant.

The sea horse *(Hippocampus)*, perhaps the most unfish-like true fish, is little more than a very peculiar pipefish, which has become short-bodied and compressed, its neck constricted and head bent downward at right angles to the rigid body. its slender tail devoid of a terminal fin, and prehensile. Sea horse? frequently assume an erect position with the head up, either clinging to senneed nith their tails or snimminq free in the water. Their head and arched neck are quite horse-like in outline, strongly suggesting the piece known as knight in the game of chess. The breeding and general habits of sea horses are quite like those of other pipefishes. When full grown they vary from about two in. to a ft. There are numerous species along the shores of warm seas, differing from one another in such minor characters as size, relative length of snout, development of keels and knobs and the number of their bony rings. The most aberrant (Phyllopteryx) lives in the rockweed in Australian waters, and is camouflaged by a very irregular form and membraneous flaps from head to tail simulating the weed.

The trumpetfish-like genus Solenostomus, already mentioned, has the body, although less completely cuirassed, with bony plates as pipefishes have, and resembles them in sufficient other structural characters to indicate a true though distant relationship, thus tying up the family Syngnathidae with the stickleback-trumpetfish series. A logical, evolutionary picture of this series would start with unknown, primitive spiny-finned fishes, superficially not unlike the modern ones, consider Solenostomus, etc., and the trumpetfishes divergent, specialized fragments remaining from transition forms, the family Gasterosteidae, little sticklebacks, abundant inhabitants of northern fresh, brackish and salt waters, a modern terminal member of the series in one direction, the Syngnathidae, pipefishes and sea horses, abundant in warm seas, the same in another direction.

The Squirrelfishes, the Perches and Basses, and their Relatives.—Squirrelfishes (Holocentrus) are rather small, blunt-headed, large-eyed, active, symmetrical fishes, one or more species plentiful in shallow water along the shores of all tropical seas. They have a moderate or rather small mouth with bands of small teeth, two dorsal fins, connected at their bases, the anterior with strong spines, longer than the posterior with soft rays, which is close to the narrow peduncle; and the caudal fin is firm and well forked. The anal fin, placed under the soft dorsal, has four initial spines, the first very small, the third very long, strong and sharp. The pectoral and ventral fins are of moderate size, the ventral, under or slightly behind the pectoral, consists of an initial spine and seven flexible, branched (soft) rays. There is a backwardly directed, dagger-like spine near the lower, posterior edge of the side of the head (on the corner of the preopercle). Their bodies are covered with rather large or moderate sized, firm scales, with toothed edges and their predominant colour is red, with white, sometimes yellow, and striped lengthwise, not infrequently with black markings on the fins. *Myripristis* is a not uncommon, somewhat shorter-bodied, close relative of the squirrelfishes, and found in the same waters, probably living somewhat deeper down, unless perhaps at night. It is more uniformly red in colour, and has an even larger eye. It lacks the dagger-like spine at the lower edge of the head, and those in its fins are not so large and strong. Fishes that swim deeper tend to be red in colour, as compared with their close relatives in shallow water, and it is not unlikely that the squirrelfishes are a shallow water invasion from greater depths. The several other families, related to them and grouped together as berycoid fishes, inhabit relatively deep water.

In superficial characters the berycoid fishes parallel the group of perches and basses (percoid fishes), which is the most modern, standardized group, abundant in world centres of fish concentration and competition, such as warm shore waters. They are of an older lineage, known to have been abundant in the upper Cretaceous, and are presumably ancestral to these. There are a number of percoid families very like the sea basses, etc., all of which have standardized ventral fins consisting of one unsegmented spine and five branched soft rays, whereas the berycoids more often have a larger number of branched rays in the ventrals. Then there are divergent groups of specialized fishes, wherein there is evidence of descent from standard spiny-rayed forms, whether from the percoids, berycoids or pre-berycoids is not always clear. Those supposed to have been derived from the percoids often have the number of ventral soft rays reduced below, seldom if ever increased to more than five. Two interesting little North American fresh-water fishes (Percopsis and Columbia) with two true spines in the front of the soft-rayed back fin, one or two in the front of the anal, small rough scales and an adipose fin like a trout or catfish, are probably to be considered specialized derivatives of some earlier group, possibly the Haploini, in the direction of the spiny-rayed fishes (Acanthopterygii), rather than as representatives of the ancestors of these, which, lacking further evidence, must remain uncertain.

The three large central percoid (perch-bass) families are the perches (Percidae) of northern fresh waters, the sunfishes (Centrarchidae) confined to North American fresh waters and the sea basses (Serranidae) which are abundant in the shore waters of warm and temperate seas. All are symmetrical, standardized fishes, with a spinous anterior and soft-rayed posterior dorsal fin, the two more often confluent than separate. Their ventral fins, placed nearly under the pectorals, have consistently one spine and five branched rays, their scales are of moderate or small size, more often rough than smooth, their mouths, usually of moderate size, sometimes large, or smaller, their caudal fin rounded, truncate or emarginate, rarely well forked, spinous dorsal, soft dorsal and anal fins about equally long.

In the perches the spinous and soft rayed dorsal fins are more or less separate, though often contiguous. The perch (Perca) is abundant in quiet waters of Europe and America, those from the two continents very much alike, little more than geographic races of the same fish. It very exceptionally approaches five lb., and is usually much smaller, an excellent pan fish, familiar to all fresh-water anglers, with a pointed head, black cross bands extending from the back onto the sides and the lower fins variously yellow or red. The few species of pike-perches (Stizostedion) are more elongate fishes with large mouths and formidable teeth. Their fin arrangement and other structures show them to be nothing more than large, predaceous perches, which have assumed pike-like habits, superficial characters and appearance. One of these, the so-called walleyed pike, is a food fish of importance in America. In America there are also numerous genera and species of slender minnow-sized perches known as darters, inhabiting brooks and the edges of wider waters. They have mottled colours which render them inconspicuous on the bottom or among water weed, resting or moving slowly about, but show great agility when they have occasion to do so. Male darters, as a rule, become differently, often brightly coloured in the breeding season.

The sunfishes, of which there are a number of species, especially in the Mississippi valley drainage, are typically pond fishes, with deep, compressed bodies, their spinous dorsal fin continuous with that of soft rays behind it. They are of small size, only a few of the larger being of any importance as food fishes. Most sunfishes assume bright colours, often in an intricate pattern, red, orange, and iridescent blue or green, thus their name. The American black basses (Micropterus) belong to the sunfish family, but are more elongate, active, predaceous, reach a larger size, commonly reaching two or three and sometimes between five and 20 lb., and rank very high as fresh-water game fishes, as well as being excellent for the table. They lack bright colours, approach the true basses in form and have a notch between the spinous and soft dorsal fins, which are only confluent at the base. All members of this family scoop out a hollow in the bottom of pond or stream where they deposit and guard their eggs.

The sea bass family (Serranidae) is one of the largest and most varied, comprising very many genera and species of standardized carnivorous marine fishes, which range close to the bottom in shallow or moderately deep water. They vary greatly in size, and are usually excellent food fishes. Their bodies, are, as a rule, symmetrical, streamlined, with at most a shallow notch between the spinous and soft portions of the dorsal fin. A few species found in north temperate waters, however, have two separate dorsal fins, at most in contact at the base, and other characters which make of them a well-defined subfamily (Moroninae), sometimes given full family rank. These are the true basses in the narrow sense and are not strictly marine. Belonging to this group are the European bass (*Morone* labrax), two large, comparable species found in both fresh and salt water; the American striped bass (Roccus saxatilis) and oriental spotted bass (Lateolabrax japonicus); the American fresh-water white and yellow basses; and brackish water white perch. In the vernacular the smaller species of this family are in general known as perches, the larger as basses. As a matter of fact, these two names are frequently and less appropriately used for similar but more or less unrelated fishes—belonging to other families.

In tropical seas fine-scaled sea basses related to the groupers (*Epinephelus*) are abundant, represented by a number of genera and many species. Some attain a very large size, the largest up to

MARGARET GRUNT (HAEMULON ALBUM), A MARINE PERCH OF THE FAMILY HAEMULIDAE, PEARLY WHITE IN COLOUR. IT RANGES FROM FLORIDA TO BRAZIL

five or seven ft., weighing 600 to 800 lb. The number of spines in the dorsal fin in this group is unusually standardized, a difference of one or two (or about 10%) sometimes a criterion to separate not only the species but the genera.

Besides these three central ones, there are several other important families of related marine percoid fishes, mostly inhabitants of warm shore waters, which differ from perches and basses, in that their gill covers are spineless, the maxillary slips under the edge of the preorbital when the mouth is closed and there is a specialized axillary scale at the upper corner of the base of the ventral fins. The snappers (Lutianidae) are of moderate size, characterized by large mouths and strong teeth. They usually have deeper, more compressed bodies, emarginate caudal fins, are more active swimmers, and range about in small schools preying on smaller fishes. The somewhat similar grunts (Haemulidae), so-called from the grunting sounds they make, mostly small species and particularly abundant in West Indian waters, have a weaker dentition. The porgies (Sparidae), varying in size, have molar teeth on the sides of the jaws, and the front teeth frequently incisor-like. In the Leiognathidae, more active, weak-toothed fishes with well-forked caudal fins, the mouth parts are excessively protractile, can be thrust out or drawn back.

The croakers (Sciaenidae) are a large family of carnivorous fishes, generally abundant on the sandy shores of all warm seas, somewhat less closely related to the central percoid families. They have a long soft-rayed dorsal, and short anal fin, the anal spines reduced in size and number to two or even one. Most of them feed on or close to the bottom, but a few, like the weakfish and so called sea trout (Cynoscion *regalis* and C. *nebulosus*) of the eastern U.S., swim more actively higher up in the water. The shape of the body, size and shape of the mouth varies greatly in this family. The weakfish has a symmetrical, streamlined body, a large mouth with projecting lower jaw and slightly emarginate caudal fin. Bottom feeding species such as the croaker (*Micropogon*) and kingfish (*Menticirrhus*) have a rather small mouth, the lower jaw somewhat the shorter, and sometimes barbels on the chin. In the croakers the caudal fin tends to be rounded, sometimes is pointed, never deeply forked. They are notable for croaking or grunting sounds which they make, and for unusually large, more or less ivory-like otoliths or free ear bones. One of the largest species is the sea-drum (Pogonias) reaching a length of four ft. and weight of nearly 150 lb.; the smallest are seldom more than a few in. long. The most notable, and one of the very few found in fresh water, is the fresh-water drum (*Aplodinotus grunniens*) of the Great Lakes and Mississippi valley, which grows to three or four ft. and weighs 50 or 60 lb.

Some of the most excellent or important food fishes and most sought after game fishes are members of these percoid families. There is the walleyed pike in the Percidae. black basses in the Centrarchidae. The striped bass is unexcelled for the table, often weighing 50 and recorded more than 100 lb., and is much sought by devotees of rod and line. The weakfish of the Sciaenidae furnishes excellent sport as well as being an important market fish. In the West Indies and adjacent regions, snappers (Lutianidae) are of the choicest food fishes; grunts (Haemulidae) a very popular pan fish; porgies (Sparidae) in all markets; and the larger groupers (Serranidae) probably of greater market importance.

Flatfishes or Flounders.—The flatfishes (Heterosomata) are in one respect the most remarkable of any in the sea. Fishes in general, be they shark, sea horse, perch, or something in between, are bilaterally symmetrical, but a flatfish lies on one side on the bottom, and has both eyes on the other (upper) side. Furthermore, their upper side is dark, usually mottled gray or brown, their underside, with rare exceptions, is white, colourless. They can change the tint and even pattern of the upper side to make it correspond more completely with their surroundings and reduce their visibility. At rest they lie motionless on the bottom, their flat, compressed bodies at times more or less covered with sand or mud, with the eyes, which protrude slightly and can be moved freely, exposed. They glide short distances and settle to rest again, but many of them swim up freely into the water at times, in pursuit of small fishes or other creatures on which they feed.

Their bilateral asymmetry is made no less remarkable by the fact that when a tiny flatfish hatches from the egg it swims or drifts free in water for a time and has an eye on either side of the head like a typical fish. The great halibut (Hippoglossus *hippoglossus*), largest of the flatfishes, which reaches a maximum length of about nine ft. and weight of 700 lb., goes to the bottom when an in. or two, smaller species when a fraction of an in. long. Most species lie consistently with one or the other side up, according to their kind, a few with sometimes one, sometimes the other up in different individuals. As the time approaches for giving up its free-swimming habits, one eye of the larval flatfish travels around the top of the head from that which will be the lower to the upper side.

The soles are well distinguished from other Heterosomata by their very small eyes, small crooked mouths, and frequent absence of pectoral fins. For the rest, species with a large symmetrical mouth and symmetrical ventral fins were placed in a "halibut tribe"; those with smaller crooked mouth and ventral fins nearly or quite symmetrical, in a "flounder tribe," species of northerly distribution which are dextral (lie with the right side up); those with the mouth symmetrical, large or small, the ventral fins unsymmetrical, in a "turbot tribe," which extends into warmer waters and comprises sinistral species (that lie with the left side up). This is still a convenient way to classify these fishes, although it does not express all the phylogenetic relationships recently worked out within the group. There are many genera and species of flatfishes, especially along the shores of northern seas. They are common enough in the tropics also, but usually smaller species and a less important factor of the fish fauna there. So far as is known, all flatfishes are good to eat and some are very highly prized for the table. They are important food fishes in the cool and temperate shore waters of all seas.

The origin and relationships of flatfishes were a puzzle until it was pointed out that *Amphistium paradoxum*, a fossil fish from the upper Eocene, with an eye on either side of the head as in normal fishes, was in many respects intermediate between them and the Zeidae, of which the John Dory (*Zeus* faber) is the best known of a few living representatives. The Zeidae are deep-bodied, compressed fishes, with a narrow peduncle, a spinous and a soft-rayed dorsal fin, and six to eight soft ventral rays. They are very likely a specialized offshoot of the berycoids. Their classification with the Heterosomata, although not now universally accepted, is probably correct.

The Silverside-Barracuda, and Labyrinth Fish, Groups.—The silversides (Atherinidae) are slender fishes a few in. long, very abundant in salt water on mainland shores of warm and temperate seas, and with comparatively few fresh or brackish water species. They swim near the surface, and most of them are pale-greenish above, white below and with a bright silvery band along the side. In the economy of the sea they are an important food item with larger fishes and with sea birds. This colouring presumably decreases their visibility, especially to enemies below, and prevents their ranks being depleted. They are carnivorous, and in turn prey on smaller aquatic creatures.

Silversides have two dorsal fins, the anterior, near the middle of the body, very small, of a few flexible spines and connecting membrane, well separated from the posterior of soft rays, which is placed well back more or less over the hind part of the usually somewhat longer anal fin. Their spinous dorsal fin would seem to be a nonfunctional rudiment, inherited from more perch-like species, and their paired ventral fins, placed somewhat farther back than the pectorals, have five soft rays as in percoid fishes, but they are generally considered more primitive than, rather than derivative from, these. They have large eyes, streamlined bodies and are active swimmers, usually with a rather well-forked caudal fin.

The mullets (Mugilidae) and barracudas (Sphyraenidae) are two other families of fishes, with a similar small, well separated, anterior spinous dorsal fin. Although superficially quite unlike each other and the silversides, the differences are obviously closely correlated with habits of life. The three families are related and belong in the same natural order or suborder (Percesoces).

Mullets are schooling fishes of small or moderate size, with short soft-rayed dorsal and anal fins, placed one above the other, well back. Their bodies are streamlined, more or less cylindrical; and they have a small, transverse, toothless mouth, slightly on the under side of the head and are bottom feeders. They are strong swimmers and proficient at leaping out of water. The marine species are abundant in shallow water on muddy or sandy shores, often running into brackish water, and are gray, and white or silvery in colour. One of the largest (*Mugil cephalus*), one or two ft. in length, with dark streaks along the rows of scales above, occurs cosmopolitanly in all warm seas. There are a few fresh-water mullets, one of which (Agonostomus or *Dajaus* monticola) inhabits most of the streams in the West Indies and Middle America. Contrasted with mullets, the barracudas are moderate or large-sized, highly predaceous, pike-like marine fishes, with large mouth, projecting chin and formidable teeth. The smaller species grow to a ft. or two in length, the largest, the great barracuda of the West Indies (*Sphyraena* barracuda), questionably distinct from an East Indian form, to five or six, possibly even ten ft.

Silversides are good to eat. A large one (Basilichthys or *Odontesthes* bonariensis), resembling a smelt, is abundant in Argentina, where it is called "pejerrey" (that is, kingfish) and particularly highly prized. A small brackish water species (*Menidia* beryllina) is fried en masse and called "white bait" near New York. Although relatively little marketed in the U.S., mullets are a favourite table dish in some countries and are raised by Chinese in coastwise ponds. The smaller species of barracuda are usually considered exceiient, the large ones thought to be unwholesome in some localities. Whether it is that their meat may have intrinsic toxic properties, or that it spoils very quickly, is uncertain. The danger to swimmers from barracudas is doubtless exaggerated, but large, predaceous fishes may strike at anything moving in water, and accidents, where a barracuda is the culprit, certainly occur.

The Melanotaeniidae, small, compressed, usually deep-bodied fishes, numerous species of which inhabit the fresh waters of Australia and New Guinea, are closely related to the silversides, although they do not look much like them. They have a longer soft-rayed dorsal, and especially anal fin, the anterior spinous dorsal somewhat stronger and higher, close to although separate from the soft-rayed fin behind it. The threadfins (Polynemidae), with comparatively few marine bottom species, which are sometimes placed in the same order, have the spinous not greatly smaller than the soft dorsal, soft dorsal and anal fins short, caudal fin well-forked, the pectoral fins low down, consisting of two parts, the lower part of free thread-like filaments, which can be moved independently and serve as organs of touch.

The goatfishes (Mullidae) are an easily recognized family of moderate sized marine fishes, closer to the percoids. There are numerous species in warm seas, usually valued for food. A goatfish has two dorsal fins, spinous and soft-rayed, of approximately equal size, the ventral fins placed about under the pectorals, and a well-forked caudal fin. It has a long, curved snout, which may project slightly beyond the tip of the lower jaw, and a pair of long, fleshy tactile barbels at the chin. The prized "red mullet" of Europe is a goatfish. The cardinal fishes (Apogonidae or Cheilodipteridae) are another easily recognized family, this one classified as of the percoid series. They are short-bodied little fishes from two or three to ten in. long, with two separate dorsal fins not greatly different in size, a large oblique mouth and unusually large eyes. There are numerous species, a majority referred to the genus Apogon common in the shallow shore waters of all tropical seas, and in fresh water in New Guinea. They have a tendency to be nocturnal, and some, at least, carry their eggs in their mouths. Small West Indian species (Apogonichthys) are known to inhabit the shells of living conchs. There are a few longer-bodied, stronger-toothed genera of this family in deeper water,

The labyrinth fishes, of somewhat the same evolutionary level as the Percesoces, are fresh-water species with a breathing organ accessory to the gills, which enables them to live out of water for protracted periods. Two or three snakeheads and a number of small fishes allied to the climbing perch, which belong to this group, are plentiful in Africa but it is primarily south Asiatic. At the base of the labyrinth fish series there are the snakeheads (*Ophicephalus*), in which a pair of pouches from the top of the pharynx, lined with thickened and puckered membrane richly supplied with blood vessels, function as might rudimentary lungs. These are vigorous, elongate, large-mouthed fishes, more or less cylindrical in front and compressed behind, with a single, long, even-bordered dorsal fin of soft rays only occupying most of the length of the back, an only shorter anal below it, the small ventrals about under the rounded pectorals and the caudal fin also rounded. Their bodies are covered with rather small, smooth scales. This is a generalized type of fish suggesting the bowfin in appearance, but, of course, with no relationship to it, beyond that of having a not dissimilar manner of living. Snakeheads are very tenacious of life, can push themselves along the ground out of water with the pectoral fins and can survive being buried in the mud of marshes and pools when these have temporarily gone dry. The largest species reach a length of three or four ft.

Other fishes of this group have a more complicated labyrinth-like accessory breathing organ in a chamber above the gills. One of these, the climbing perch (Anabas *testudineus* or scandens), found in fresh or brackish water of southern Asia and adjacent continental islands, is not unlike a snakehead in shape and general appearance, with a smaller mouth, blunter head, larger eye and its long dorsal and anal fins are spinous except for a short posterior part of soft rays. It reaches a length of nine or ten in. Climbing perches migrate from pond to pond at night, and use their spread gill covers as well as their fins in hitching along overland. When in water they frequently come to the surface to gulp air; and it is said that they will suffocate if unable to do so; also that after rain they come out of water and invade gardens in search of earthworms, and that the natives of some parts of India dig them up with a shovel for food where they lie dormant in the mud of temporarily dried up waters.

The goramy or gouramy (*Osphronemus*) is a deep-bodied, compressed fish, with a dorsal fin—which has about an equal number of spines and soft rays—along the posterior half of the back, a longer anal fin with more rays than spines and the first soft ray of the ventral fins produced in a very long filament. about as long as its head and body. Gouramies reach a length of 20 in. and are an excellent food fish, introduced in various tropical countries where they are not native. Smaller, similar fishes of the genus Trichogaster, frequently kept in aquaria, have the ventral fins reduced to the single, long filament and a rudimentary spine. Several small labyrinth fishes are favourites for household aquaria because of their bright colours and interesting breeding habits. The paradise fish (Macropodus) has large, decorative fins, the dorsal and anal pointed behind, and the caudal fin forked in the common species. It makes a floating nest of foam by blowing bubbles of air and a sticky mucus, which adhere together, and beneath which the eggs are placed. Unlike the paradise fish, the fighting fish (Betta) has a short dorsal fin with not more than one initial spine, spines in the front of the long anal fin few or absent. The dorsal fin, although short, may be high, caudal fin is large and somewhat pointed. Fighting fishes are only three in. or so long. They build a bubble nest like the paradise fish and the males not only guard nest and eggs assiduously, but are so combative that they are sometimes pitted against one another for sport, as are gamecocks. Another small aquarium fish, seldom over two in. long (*Ctenops* vittatus), is called purring gouramy on account of the sound which it makes, especially during the mating period. In making this sound, the fish, with gill covers and fins extended, shakes itself violently, and it can sometimes be heard more than 25 ft. away.

Mackerel-Like Fishes.—The mackerel-like fishes (Scombriformes) are an adaptation to strong, continuous swimming in open water. They are carnivorous and marine, have pre-eminently streamlined bodies and a firm, well-forked caudal fin, their propelling organ, set on a firm, narrow peduncle, which is frequently keeled in a horizontal plane, that of the fin's motion. Whatever the mechanics involved may be, this kind of tail is obviously advantageous to wide-ranging aquatic animals. Its form in the whales and porpoises, which are mammals, simulates that in the big mackerels, though differing by an angle of 90°, for they move their flukes in a vertical instead of a horizontal plane.

The Scombriformes as now recognized, are characterized by expansion of the tail (hippural) bones which support the rays of the symmetrical caudal fin, so as to mask almost completely its hereditary asymmetry. The principal families in this order are the pompanos and crevallys (Carangidae); mackerels (Scombridae); spearfishes and swordfish (Istiophoridae and Xiphiidae). In the Carangidae, the most primitive or perch-like of these, the spinous dorsal fin is much shorter than the soft-rayed fin behind it, its spines weak, the premaxillaries are more or less protractile and snout and upper jaw not fused. In the Scombridae the snout and upper jaw are fused, more or less pointed and beak-like. The spinous dorsal fin may he short, well-separated from the posterior dorsal fin of soft rays, or long although weak, depressible in a slot in the back and very low posteriorly, but extending approximately to the front of the soft dorsal. The soft dorsal, as well as the anal fin, below or slightly behind it, is short, but both are followed by a series of independent small finlets, each of a single branched ray, which extend back to the peduncle. The Istiophoridae and Xiphiidae are strange, large fishes in which the fused snout and upper jaw project far forward as a hard spear or sword, round in cross section in the former, and horizontally flattened in the latter.

There are at least three natural divisions of the Carangidae. The large. predaceous, wide-ranging amberjacks (Seriola), abundant in all warm seas, and perhaps the most primitive. In these the spinous dorsal fin is very small and low, the anal fin is considerably shorter than the soft dorsal and the pectoral fins are short. A slight arch in the front of the lateral line blends into its posterior straight part which runs in the centre of the tail and a gristly keel in the mid-line of the narrow caudal peduncle is more or less developed. The largest amberjacks reach a length of five or six ft. Their young have dark crossbands and hover about driftwood, small boats, or follow coastwise sharks. Of two or three related genera, the pelagic pilotfish (Naucrates *ductor*), which follows offshore sharks, is most interesting. It is quite like an amberjack, but somewhat more slender and cigar-shaped, with a smaller mouth; and with age, first the membranes connecting the spines of its dorsal fin, and then the spines themselves, become obsolete. It only grows to be a ft. or two in length, is blue above instead of greenish in colour, and its crossbands, which are persistent through life, are somewhat broader than those of young amberjacks. In short, it is essentially a somewhat specialized young amberjack which retains its youthful habits and colours to maturity.

In the crevallys (Caranx) the anal fin is preceded by two short, stout spines, separate from the rest of the fin, and is little shorter than the soft-rayed dorsal above it. As the fish grows large, the pectoral fin becomes long and falcate. The lateral line consists of a more or less arched anterior, rather clearly defined from the posterior straight part. The scales, fine over the rest of the body, are enlarged on the peduncle into keeled scutes. The peduncular keel, thus formed, may be strong or weak, the keeled scutes confined to the peduncle, or extending forward to occupy the entire straight part of the lateral line. A number of genera allied to Caranx differ widely from one another, and yet are so connected by intermediates, that the number recognized becomes a matter of judgment, and there is little doubt they evolved from a common ancestor. In the scads (*Trachurus*), cooler water fishes than the others, more abundant in temperate than in tropical seas, enlarged scutes extend the whole length of the lateral line, though usually less firm and without keels on its anterior arch. The mackerel scads (Decapterus) are more elongate and cigar-shaped. Contrasted with them there are several deep, short-bodied, compressed genera (Selene, Vomer or Argyreiosus, *Alectis*). Young moonfishes (Vomer) look a good deal like a silver dollar. Young threadfishes (Alectis *ciliaris*) are also almost circular in outline, with dark crossbands and with a number of anterior rays of soft dorsal and anal fins prolonged as thread-like filaments, which extend back well beyond the tail. They drift widely in ocean currents, and are indistinguishable in all warm seas. Most young fishes are more slender than adults of the same species, but there is a tendency for young Carangidae to be considerably deeper and more compressed than their elders, probably correlated with a drifting habit.

The pompanos (*Trachinotus*) have a small, horizontal mouth, beneath a blunt, rounded snout, short pectoral fins and the curve of the lateral line low and even as in the amberjacks, but their anal fin is little shorter than the soft dorsal above it, as in Caranx. They have a very small spinous dorsal fin, reduced to isolated rudimentary spines in the adult. The leather jacks (Scornberoides and *Oligoplites*) are quite different from, although probably related to. the pompanos. They are usually elongate, more compressed, with large mouth and projecting lower jaw, linear, more or less fused scales which give the skin a leathery texture, and are bright silvery in colour.

In the true mackerels (Scomber), the spinous dorsal fin is short and distant from the soft dorsal; there are a pair of small keels at the bases of the upper and lower lobes of the forked caudal fin, but none in the centre of the peduncle. Members of this genus are less than two ft. and weigh less than four lb. They swim at the surface in close-ranked schools. These schools are sometimes of immense size in the common mackerel (Scomber *scombrus*) of the North Atlantic, a familiar and important food fish. This species invades and spawns in cooler waters in summer than are frequented by most of this family, and is remarkable for a surface fish in that it also swims at considerable depths. It lacks an air bladder, and on this basis was considered generically distinct from its close allies, but lacking one is probably correlated with the great difference of pressure at varying depths, and to be considered here as no more than a species character. The mackerel schools disappear in winter and where they go is not well understood.

Other members of the mackerel family have a central, gristly keel on the peduncle, the spinous dorsal fin usually extending along the back to approximately the front of the soft dorsal, although low behind and depressible in a slot. Those of the genus Scomberomorus or *Cybium* are slender and of moderate or large size. The American Spanish mackerel (Scomberomorus *maculatus*), a very choice food fish, has a maximum weight of about ten lb., and the Florida kingfish (Scomberomorus cavalla), a well-known game fish, may reach a length of five ft. and weigh 100 lb. There are several genera of mackerels of moderate or large size, those reaching a weight of 20 lb. or less are commonly known as bonitos, and the larger species as tunas. The largest is the tunny or blue-fin tuna (*Thunnus* thynnus) which not infrequently exceeds 1000 lb. It has the body covered with fine, inconspicuous scales, and silvery marks on the Sides. It is a very active, full-blooded fish, with body temperature appreciably above that of the water in which it swims. This species and two or three of its close relatives have a somewhat different structure of the vascular system from other mackerels, which led to their unjustifiable classification in a different family by some authors. The oceanic bonito (Katsuwonus pelamis), which reaches a maximum weight of about 20 lb., has enlarged, more or less fused scales forming a corselet in the shoulder region, most of the body scaleless. It is a heavy, barrel-shaped fish, pointed at both ends, with lengthwise dark stripes on the lower parts, and is truly pelagic, roaming the open ocean far from land in small schools which prey on flying fishes.

The sailfishes (*Istiophorus*) and marlins (*Makaira*) have a long dorsal fin extending on the front of the back to over the first anal fin, small, low second dorsal and anal fins farther back, the ventral fins slender, reduced to one or two rays, body covered with irregular, linear scales and a small keel at the base of each lobe of the deeply forked caudal fin, but no central keel on the peduncle. In the sailfishes the ventral fins are long, the dorsal fin is very high throughout, although depressible in a slot in the back; in the marlins it is moderately high in front and becomes low behind. Sailfishes are slender and compressed, and although they reach a length of more than eight ft., seldom weigh more than roo lb., whereas the largest marlins approximate 1,000 lb.

The broadbill swordfish (Xiphias) has a short, high dorsal fin on the front of the back, pectoral fins placed very low and ventral fins absent, a keel in the centre of the peduncle and smooth, scaleless skin. The largest swordfish exceed 800 lb. They prey on smaller schooling fishes such as mackerel and herring, apparently killing or disabling them with their sword so they can be picked up easily. Swordfish are taken commercially with the harpoon, a dangerous pursuit, as they not infrequently drive their sword through the bottoms of small boats engaged therein. There are also many instances of the swords of swordfish and spears of marlins being driven into the timbers of wooden ships at sea, and broken off. Hatching from a tiny egg, the swordfish passes through two or three unlike phases before it approaches the form and appearance of the adult. At one time it has a long, high dorsal fin. at one time it has scales, showing its relationship to sailfish and marlins. The several scombriform families just passed in review contain highly valued food fishes, and nhereas a few of the many species of crevallys and mackerels are locally considered unwholesome, it is questionable whether it is that their flesh has intrinsic toxic properties, or that it spoils quickly.

The family Bramidae, containing short-bodied, compressed, deep-nater fishes, wherein there is no distinct spinous division in the long dorsal and anal fins, and the scales are somewhat larger than is the rule with this order, are also placed in the scombriformes. So is the dolphin (*Coryphaena*) without close relatives. The common dolphin (C. *hippurus*) is a slender, streamlined, very swift swimming fish which reaches a length of about six ft., and is one of the most truly pelagic. Small groups of dolphins swim at the surface of all warm, blue seas, when far from land preying on flying fishes for the most part. They sometimes come head and shoulders out of water to seize one when it takes to the air, or speeding under the shadow of another are ready for it nhen it drops back into the water. The dolphin is very beautifully coloured, marked with blues, and bright yellow behind. When taken from the water, pink and green flushes run over its sides It has an even-bordered, undifferentiated dorsal fin extending the whole length of the back, old males a high, narrow crest which gives their forehead a vertical profile.

This fish is the dolphin of sailors. The name dolphin is also used for porpoises, which are mammals, not fish at all, particularly for the offshore, blue water porpoise (*Delphinus delphis*). This sometimes caused confusion which extended far back in language, for the dolphin of heraldry, as figured, usually combined characters pertaining, or supposed to pertain, to these two unlike marine animals.

The bluefish (*Pomatomus saltatrix*), a highly predaceous schooling species found in the Atlantic and Indian oceans, and particularly valued as a food fish on the Atlantic coast of the U S . has much the contours, fin arrangement and appearance of an amberjack, the most obvious differences being an appreciably broader peduncle without a trace of a keel, and that the scales, although small are slightly rough (ctenoid). It was sometimes classified with the Scombriformes, but is actually a percoid, a freer-swimming, wide-ranging representative of the sea bass family (Serranidae). One might arrange the mackerel-like fishes in a rational series of increasing specialization, from the bluefish to the crevallys, to the mackerels, to the swordfish. but this would not be a true evolutionary line. Each more highly specialized group probably branched off from some spiny-rayed fishes at an earlier phase of the history of these, and has been changing in its present environment for a longer period. It is even questionable if the family Carangidae is an entirely natural one, if its different divisions had a common origin, or rather have followed a somewhat parallel evolutionary course. Through close relatives of the mackerels, a series leads to increasingly slender, deep-water forms, in which a typically mackerel-like though tiny caudal fin is evidently vestigial, and the elongate, band-shaped, bright silvery cutlass fish (Trichiurus) of shore waters, with large mouth and canine teeth, dorsal fin extending the length of the back, no ventral fins and the finless tail tapering to a slender filament, seems to be a terminal member of this series.

The pomfrets (Stromateidae) are small, deep-bodied, compressed shore species, usually valued for food, which bear a strong, superficial resemblance to some of the Carangidae, though their relationship to the Scombriformes is uncertain. They are characterized by having small ventral fins present in the young, but reduced or altogether absent in the adult, and the oesophagus armed with numerous horny teeth. Several peculiar pelagic species are usually placed near this family, *e.g.* the little banded man-of-war-fish (*Nomeus gronovii*) which accompanies the Portuguese man-of-war (Physalia), and when alarmed swims up close under the iridescent bubble-like float of this dangerous jellyfish for protection, familiarity enabling it to avoid its long, stinging tentacles.

Coral-reef Families, Triggerfishes and Others. — There are several series of fish families supposed to have been derived from the modern percoids. The surf fishes (Embiotocidae), cichlids (Cichlidae), and demoiselles (Pomacentridae), are mostly small, active centrarchid (sunfish)-like fishes. with the anterior part of the dorsal fin, of strong spines, confluent with the posterior part, of soft rays. The surf fishes, of which a number of species are abundant in shore waters from British Columbia to California, and others are recorded from Japan, are notable for giving birth to a relatively small number of large young, instead of laying eggs. The cichlids and demoiselles have a single nostril on each side, instead of the usual two. The former are fresh-

ANGELFISH (ANGELICHTHYS CILIARIS) A CHAETODONT FROM THE WEST INDIES

water fishes of Africa and South America, the latter very abundant about coral reefs, many of them brightly coloured. The distribution of these two families suggests that they had a common origin in tropical seas and diverged on the basis of this habitat difference. The cichlids all care for their eggs and young; a number of African species carry the eggs until hatched and harbour the young in their mouths.

The butterfly and angelfishes (Chaetodontidae) are another abundant coral-reef family. They have deep, compressed bodies, covered with rather small, rough scales, small mouths with bands of fine bristle-like teeth, the anterior spinous and posterior soft-rayed parts of the dorsal fin continuous, with the base of the latter, and of the similar anal fin below it, masked with fine scales. The butterfly fishes are of small size, and a profusion of different species are mostly boldly marked with black bands, frequently with ocelli, especially in the young. Many have similar patterns, but those of so two are quite identical. Their markings, combined with bright colours, mostly yellows, make them very conspicuous. A coral reef itself is often monotone, or with its colour in masses. It is its great variety of gay, active fishes, preeminently conspicuous as one looks down through clear water, which makes of it one of the most colourful phenomena in nature. The fishes in most environments are coloured so as to give them a low visibility, a protection from their enemies, or not to attract the attention of their prey. The colours of active reef fishes were called immunity colours, the hypothesis being that the reef is a labyrinth, providing so many avenues of escape that the danger from predators is minimized. It is also to be noted that these highly coloured fishes are not themselves predatory. The angel differ frvm the butterfly fishes in having a strong, backwardly directed spine at the corner of the preopercle (on the lower side of the head). The angelfishes as a whole grow larger than the butterfly fishes. Some have bright, massed colours, and are among the most gaudy denizens of the reef, others are rather uniformly dark in hue.

The limits of the Chaetodontidae are not well-defined, there being several different fishes, more or less obviously allied to, but not properly belonging in, this family. Another, perhaps the most numerous, coral reef group, the wrasses and parrot fishes, is more clearly set apart. The wrasses (Labridae) are characterized by a small mouth, rather thick lips, strong, well-spaced, usually pointed teeth in the jaws, the throat bones heavy and bearing teeth which are often blunt grinders. Most have moderately elongate, compressed bodies, covered with large, smooth scales, the anterior spinous and posterior soft-rayed parts of the dorsal fin are continuous, usually even, and the spinous as long or longer than the soft part, which is opposite and approximately equal to the anal fin. With a little experience one can recognize a member of this family at sight, although its many genera differ considerably from one another. Some have small, fine scales, some are short-bodied, some little, others excessively compressed. They have a characteristic manner of swimming, gliding about propelled by a rowing motion of the pectoral fins, only using the tail when extra speed is requisite. Their tail is usually deep and compressed. The caudal fin, although large and deeply forked in the adults of some species, is an adornment rather than a propeller. The reef species are, as a rule, brightly coloured; any colour in the rainbow may be present, according to species, in a fine intricate pattern or in masses. Comparatively very few wrasses are found outside the tropics in cooler northern waters. One such, the tautog or blackfish (*Tautoga onitis*) of the Atlantic coast of the U.S., is an excellent food fish; and another, the bergall or cunner (*Tautogolabrus adspersus*), is found in really cold water, as far north as Labrador. The parrot fishes (Scaridae) are little more than heavy-bodied, large-scaled wrasses, in which the jaw teeth, instead of being well-spaced, are fused above and below, to form a hard, parrot-like beak, no doubt capable of biting off bits of coral. Most of these are highly coloured also, although some found over muddy or in weed bottoms are dull, or mottled so as to be inconspicuous. Their colours are usually massed; a few are red or blue, but in most green predominates, with red, orange, yellow or blue markings. A great many wrasses are small, some of moderate or large size; the parrot fishes on an average are larger.

The Acanthuridae, another tropical marine family, have well-compressed, usually deep bodies, fine, inconspicuous scales, a narrow peduncle and emarginate to forked caudal fin, a good-sized eye placed high, a small mouth placed low and are largely herbivorous. An evenly-margined, sometimes high dorsal fin of weak spines and soft rays extends along most of the back, and a similar anal fin, shorter because it has only two or three initial spinous rays, is placed under its posterior part. The surgeonfishes (Hepatus, sometimes called *Acanthurus* or *Teuthis*) are the commonest genus in this family. There are a number of species. characterized by a strong sharp-edged spine on the caudal peduncle, depressible in a groove, and when erect pointing forward and outward. Most are dull coloured, some yellow or blue. or with bright markings. Another genus has the dorsal and anal fins excessively high, another has immovable nodules on the peduncle in place of the depressible spine. Just how the Acanthuridae are related to the Chaetodontidae is uncertain. The peculiar Moorish idol (*Zanclus*), widely distributed across the Indo-Pacific Ocean, seems to occupy a somewhat intermediate position between the two families. In some respects the Acanthuridae approach the plectognath fishes, next to be considered.

The Plectognathi are supposed to be the terminal member of the central line of specialization evolved from percoid fishes. They comprise several unlike families which are clearly more closely related to one another than to anything else. All have small. nipper-like mouths, soft-rayed dorsal and anal fins alike, placed well back and over one another, the scales abnormal or absent and are weak swimmers. The triggerfishes (Balistidae) have a leathery skin reinforced with small, nonoverlapping scales, a spinous dorsal fin placed well forward, consisting of one strong. and one or two weak, depressible spines behind it, the first weak spine locking the strong spine when that is erect. The mechanism involved suggests the trigger of a gun, thus the name triggerfish. The filefishes (Monacanthidae) are more strongly compressed, thinner bodied, the leathery hide with fine inconspicuous asperites only, and have a single high but more slender spine on the front of the back, with the small one behind it inconspicuous or obsolete. The boxfishes (Ostraciontidae) have the head and body completely encased in fused bony plates, leaving only the tail and bases of other fins free to act as propellers. Their cuirass is either four angled, squarish, or with a raised ridge in the centre of the back, making it triangular in cross section; and some species, called cowfish, have horn-like spines projecting forward above the eyes. The porcupine fish (Diodon), on the other hand, is covered with long, strong spines, and can inflate the body so that they project in every direction. The swellfishes (Tetraodontidae) have a loose skin, variously smooth or with fine prickles, and can inflate themselves with water or air until they become approximately spherical. All the above fishes are of small or moderate size, but the great ocean sunfish (Mola) grows to some eight or ten ft. and weighs more than a ton. This singular fish has a short, deep, compressed body, with rounded outlines, a thick, tough, wrinkled skin, a tiny mouth, small eye, small, rounded pectoral fins behind short gill slits and high, pointed dorsal and anal fins, the distance between their tips somewhat greater than its total length. Behind these the body ends abruptly without tapering backward, and is fringed from top to bottom by a narrow caudal fin.

None of the plectognaths have paired ventral fins, their place being taken by a spiniferous projection at the end of the long pelvic bone in the triggerfishes and some of the filefishes, and no trace of them remaining in other of the filefishes, boxfishes, porcupine fishes, swellfishes or sunfishes. The triggerfishes and filefishes have crowded incisiform teeth on the jaws, the boxfishes a single series of narrow teeth. In the porcupine fishes the jaws are covered with a bony plate and resemble the beak of a parrot fish; in the swellfishes such a beak is divided into four parts by a median suture in each jaw, and in the sunfishes it is relatively weak.

The filefishes are the most: sluggish family. They swim to some extent by rippling their even-bordered dorsal and anal fins, and are great drifters, motionless among weed where they are concealingly coloured, as often as not head down, and can frequently be caught in the hand. Filefishes abound coastwise and are occasionally carried offshore by currents. The triggerfishes are more active, use their caudal fin more for propulsion, but the young are great drifters in floating weed, found far out to sea, and some of the species are truly pelagic, occurring in small schools in mid-ocean. The offshore species tend to have the dorsal and anal fins high and pointed, and to swim by moving them from side to side. Those with low, even fins doubtless ripple them much as the filefishes do, but in some of the larger coastal forms, where these fins become higher and more pointed as the fish increases in size, it is correlated with this somewhat different mechanics in their use. The swellfishes, with short dorsal and anal fins, scull with them in normal swimming, and the offshore species have the higher and more pointed fins. The ocean sunfish, wherein these fins are particularly high, firm, pointed, and placed far back, must propel itself entirely by moving them from side to side, as it lacks any caudal locomotor apparatus. This fish is usually seen lying more or less on its side at the surface of the sea, often far from land. How it manages to nourish its great bulk with so tiny a mouth, where it lives and what its habits may be at other times, are something of a mystery.

In some localities the meat of the back of smellfishes was considered a delicacy, but known to be dangerous. The ripe spawn of these fishes is poisonous, and it is likely that the poison may permeate the rest of the fish when it is dead. Perhaps its virulence varies according to species and according to locality. Some are considered sure death by Pacific islanders and strictly avoided. Most fishes are good to eat, and information on the toxic properties of those few which are not is vague, only less vague as regards swellfishes than others. Various plectognaths have the reputation of being poisonous, *e.g.* the filefishes and porcupine fishes, which have no meat worth bothering with anyway; also the boxfishes, although these are sometimes cooked in the shell and eaten without ill results. In some localities the larger plain-coloured triggerfishes are regularly marketed; in others the bright-coloured reef species have an evil reputation.

Sculpin-Like Fishes and **Gobies.**—Typical marine sculpins (*Myoxocephalus*) are abundant, smallish fishes inhabiting shallow, coastal waters of northern seas. They have good-sized eyes placed near the top of large, spiny heads, large mouths with bands of small teeth and are greedy and omnivorous. Their anterior spinous, contiguous although separate posterior dorsal fin of soft rays, and similar anal fin below it, do not differ greatly in size; pectoral fins are large and rounded, ventral fins narrow, with a more or less concealed spine and only three soft rays. Their tails are slender, the small caudal fin usually squarish. Their skin is mostly smooth, or with a few wart-like tubercles, lacking true scales, Sculpins spend much time resting on the bottom, move forward a few inches and come to rest again, and their mottled colours match giving them a low visibility in their environment. An abundant Atlantic species (M. *octodecimspinosus*), which has an unusually long spine on the side of the head, when taken from the water commonly assumes a defensive attitude by drawing the upper jaw down and forward, slanting these long spines up and back at an angle of forty-five degrees, meanwhile emitting a low, drumming sound.

The sculpin (Cottidae) is a northern cold water family, containing many genera. The fresh water genus *Cottus* comprises' similar smaller fishes with big, broad heads, which are spineless except for one or more small, concealed spines on the edge of the preopercle. Other marine forms, especially those in deep water, differ more widely from this type.

A skeletal peculiarity of sculpins, namely, a bony stay across the cheek, is shared by various related marine families. Scorpion fishes (Scorpaenidae) replace them in the tropics, with deeper-bodied, more compressed, less strictly bottom species, commonly found among seaweed. These have equally spiny, although smaller and less broad heads, and usually stronger spines in the dorsal and front of the anal fins, which are capable of inflicting painful, sometimes serious wounds. The poison fish (Synanceja) of the western Pacific has definite poison glands associated with the dorsal spines. It is a sluggish fish, lying on the bottom, sometimes partly buried in the sand, where it could be stepped on easily, and is greatly feared. The freer-swimming, brightly mottled. more conspicuous lionfish (Pterois), with very wide, expanded fins. which is found in the same seas, also has a bad reputation. Fishes of this family allied to the genus *Sebastodes,* misnamed rock cod, and more appropriately known as rockfishes, are plentiful in cooler water along the shores of the North Pacific. They are more active, have weaker spines, reach a larger size and are of considerable market value, as is their single Atlantic representative, the bright red rosefish (*Sebastes* marinus). They are ovoviviparous. The eggs hatch within the body of the mother and hundreds of tiny young are born. Other scorpion fishes and sculpins, what is left of them when their big heads have been removed, are good to eat, although little used as food. The flatheads (Platycephalidae), with much depressed, flattened spiniferous heads, are an allied warm-water family, represented by numerous species along the shores of the Indian and western Pacific oceans.

The sea poachers (Agonidae) are more or less slender and elongate relatives of the sculpins, with an angular body covered with longitudinal rows of scutes. The peculiar lumpfish (*Cyclopterus lumpus*) of the North Atlantic, has a short, thick, lumpy body, the ventral fins rudimentary, forming the bony centre of a sucking disk on the breast. It is a bottom species, but its young are found in detached, drifting rockweed. They are usually green or purplish, sometimes mottled gray in colour, and with whitish markings, a pattern obviously designed to give them a low visibility in the rockweed, as that of the mousefish (Histrio) does in the yellow gulf weed of the open ocean. The sea snails (Liparidae), which also have a pectoral sucking disk, are small, sluggish, tadpole-like, bottom fishes, wherein the body and even the fins are veiled in smooth thin skin. They mostly inhabit Arctic seas. The greenlings (Hexagrammidae) are food fishes living about rocks and kelp in the North Pacific. Their bodies are covered with small scales and they are notable for the presence of several well-developed lateral lines. They are usually elongate and compressed, dorsal fins are confluent, occupying the length of the back and the spines of the anterior are weak. Their heads are essentially spineless. The related cultus cod (Ophiodon elongatus) has a single lateral line, less compressed body and very large mouth with strong teeth. It reaches a length of more than three ft., a weight of 30 or 40 lb., and is one of the most important cold-water food fishes of the Pacific coast of America, although its flesh is bluish or greenish in colour. The sablefish or so-called "black cod" (*Anoplopoma fimbria*) of these same waters, is highly valued for the table about Seattle, Wash. It is a streamlined fish mostly blackish in colour, with two well-separated dorsal fins and a forked caudal fin.

Fishes of the above and related families which comprise the sculpin series are present in greatest variety in the cool waters of the North Pacific. Many types of 'them are not found elsewhere, and comparatively few found elsewhere are not there represented. The scorpion fishes are the most perch-like, the sculpins have standardized characters of the group best developed and obviously adapted to their manner of life and there are other peculiar, more highly specialized families. It is reasonable to suppose the tropical, cosmopolitan scorpion fishes were ancestral to the series, which expanded in North Pacific waters, and the sculpins, one of its few divisions represented in the Atlantic, to have reached that ocean via the Arctic.

The gurnards (Triglidae) are well-defined, warm-water, marine fishes of rather small size, presumably related to the sculpin series. Their rather large, pointed heads, encased in a complete armature of more or less spiny plates, with eyes placed high, mouth low and horizontal, are very characteristic. Their body is covered with small scales, pectoral fins large and broad, with the three lower rays detached, thickened, and used to finger the bottom. American species (*Prionotus*), known as sea robins, are little used for food, although perfectly good to eat, after the large head is removed. Mediterranean species (*Trigla*) with smaller and less spinous heads, are of market importance.' The deep-water gurnards (Peristedion) are peculiar fishes from deep water of the continental slopes, obviously close to the Triglidae. Their snout is produced in two long, flat processes which extend forward beyond the mouth, body covered with longitudinal rows of large, keeled scales. They have two free tactile rays at the base of the pectoral fins, branched barbels at their chins and are characteristically bright red in colour. Also related are the flying gurnards (*Cephalacanthus*), which, though not common, are generally distributed in tropical seas. They have a blunter head, with a long, backwardly directed spine at its lower hind corner, and exceptionally large, broad pectoral fins. Sea robins have the habit of swimming upward, then spreading their pectoral fins and gliding slowly back through the water to the bottom; and the flying gurnard sometimes launches into the air in a like manner and is supported by its spread pectorals for a short flight, not comparable with that of the true flying fishes, however.

The gobies (Gobiidae) are mostly small, bottom fishes, comparable with although not directly related to those of the sculpin series. They are very abundant in individuals and in species in the shallow shore waters of all warm seas. A relatively small number occur in fresh water, but they are an important factor in the meagre fresh-water fish fauna of tropical oceanic islands. Gobies are variously elongate or shorter bodied, usually with smooth scales of moderate size, and no evident lateral line, sometimes with fine scales, or scaleless. The size of their mouth varies; and they usually have good-sized eyes, placed rather high, but there is a blind species (Typhlogobius *californiensis*) in Lower California, living in holes and crannies of the bottom, in which the eyes are rudimentary. They have two separate dorsal fins, the anterior supported by weak spines, the posterior, of soft rays, similar to the anal fin below it, usually a rounded or more or less pointed caudal fin, and broad, rounded pectoral fins, with ventral fins below or slightly in advance of them. There are two principal subfamilies, of which the more primitive Eleotrinae have ventral fins separate from one another, as is usual. In this subfamily there is sometimes a small, hooked spine at the angle of the preopercle, and the species tend to be larger, some growing to one or two ft., although most gobies do not exceed a few inches. In the Gobiinae the ventral fins are joined to form a shallow cup, presumable of service in clinging to the bottom. They are fairly active little fishes, but concealingly coloured when at rest on the bottom or in seaweed. Among the many other forms in this subfamily which have a more or less limited distribution, one of the most abundant (Bathygobius), characterized by having the upper pectoral rays free from one another, slender and silk-like, is found at the edge of tropical shores, represented by no more than poorly defined races in different seas around the world.

The mudskipper (*Periophthalmus*) is a specialized goby that spends much of its life out of water, skipping about actively on moist mud or among rocks at low tide, chasing insects or other small fry on which it feeds. It has bulging eyes at the top of a frog-like head, and supports the front of its body with the pectoral fins, which have fleshy, muscular bases, and are bent downward, while its tail rests on the ground behind, or is used to propel it in its longest leaps. When out of water its large gill chambers are kept filled with air. It probably breathes as well, to some extent, through its skin, as when it clambers out and rests on some mangrove root with only the tail in water. It is said that the mudskipper is unable to live submerged for any length of time.

Relatives of Weevers and Blennies.—Having concluded those obviously related to, and presumably derived from, the percoid stem, we come to a variety of modern, specialized fish families, about the derivation of which, and their relationship to one another, ichthyologists are in less agreement. The weevers (*Trachinus*) are fishes growing from six to 18 in., found in the Mediterranean and on other European shores. They are notable for having a spine on the gill cover, and those of the dorsal fin, grooved, and associated with poison glands, thus capable of inflicting an extremely painful sting. They are elongate, compressed fishes with eyes near the top of the head, over the large mouth, which slants upward, body covered with small scales. There is a short, anterior, spinous dorsal fin, long, even, soft-rayed dorsal and anal fins extend along the upper and lower outlines of the body. The caudal fin is squarish, ventral placed appreciably in advance of the pectoral fins. The shallow-water lesser weever (Trachinus *vipera*) often buries itself in the sand with only the eyes, mouth and tip of the dorsal spines exposed. The sand stargazers (Dactyloscopidae) of similar body form and presumably similar habits, are exceedingly fragile sand-coloured little fishes less than five in. long, with no pungent spines, not uncommon on sandy tropical shores; the stargazers (Uranoscopidae) are sluggish bottom fishes which may grow to be one ft. or so in length, which have a large, cuboid head more or less covered with bony plates and small eyes which look upward placed near the front of the head, over an almost vertical mouth. The toadfish (*Opsanus* tau) is a representative of another family (Batrachoididae). It is a sluggish bottom fish of shallow shore waters, reaching a length of one ft. or more, tadpole-shaped, with a big, flat head, bulldog-like mouth with strong, blunt teeth, rounded fins, no scales and a fringe of skinny tabs along the lower jaw. Toadfishes place their eggs in some crevice, empty shell or other receptacle, and one or both parents guard them until hatched. The young hide in seaweed before taking up life on the bottom.

The above families are known as trachinoid fishes, and various others with more uncertain relationships are often included in that group. There is a small, heterogeneous lot of fishes with long, even dorsal fins, which includes two well-known American food fishes, the whitefish (Caulolatzlus) of the Pacific coast and the tilefish (Lopholatilus) of the deep water of the North Atlantic continental slopes. There are the uncommon jawfishes (Opisthognathidae), small species with large eyes, very short snouts, large mouths and very long upper jaws. The Nototheniidae are a family of superficially more or less sculpinlike fishes which replace the cottoids, to which they are not related, in the higher latitudes of the southern hemisphere.

In reviewing the principal of the many types of fishes among perhaps 30,000 living species, those of peculiar structure correlated with some unusual and standardized manner of life are most difficult to place. They were presumably successful and persisted, while any relatives which might give a clue to their position were swept away long ago in the tide of evolution. Such are the tadpole-shaped little clingfishes (Gobiesocidae), with a large sucking disk between and behind the ventral fins, which form a part of it, more efficient and different in structure from any similarly placed sucker in other groups. They have smooth, scaleless skin, eyes near the top of their round, flattened heads, dorsal and anal fins of soft rays, placed well back. Those found in deeper water are most often reddish or pinkish in colour, and some species exceed a length of six inches. One common in the West Indies (Abraciosa fasciatus or *rupestris*) is only one or two inches and matches the colour of the rocks to which it clings in the wash of the surf.

Where the remoras (Echeneididae) belong in the evolutionary system is even more uncertain. These singular fishes have a large, oval sucking disk occupying the top of their flattened heads and extending more or less onto the front of the back, with a central lengthwise ridge and series of slightly movable transverse plates like the slats of a blind, wherewith they attach themselves to sharks and other large fishes. They are almost invariably associated with such hosts, which, at least, furnish them free transportation to distant waters. They are more or less slender and elongate, stream-lined fishes, with minute scales which are easily overlooked, fair-sized eyes, projecting lower jaws, ventral fins about under the pectorals, dorsal and anal fins of soft rays, placed well back, and an emarginate caudal fin. They are usually grayish in colour and they lack countershading. Inasmuch as they rarely swim free in the water, countershading would have no significance for them. The one (Echeneis) most commonly attached to coastwise sharks is elongate and has a dark, lengthwise band. One (Remilegia) which attaches to small whales is especially stout-bodied with the sucking disk relatively large. *Remora remora* is the species usually attached to offshore sharks, *Remora* brachyptera often found within the gill cavity of large fishes and Rhombochirus particularly associated with marlins. The sucking disk of the remoras represents and is presumably derived from a spinous dorsal fin, and they have superficial characters which suggest relationship to the cobia (Rachycentron), one of the mackerellike series, which has that fin reduced to isolated, short spines. But they are widely separated from mackerellike fishes in current classifications.

Other forms which may be mentioned here are the little, slender, silvery sand lance (Ammodytes) which swarms along northern beaches, darting in and out of the loose sand, an important item in the food of various fishes and sea birds, also the iridescent pearlfish (Fierasfer) which spends most of its life inside molluscs or echinoderms. This is a slender little fish with a long tail tapering to a thread, and no caudal fin. It has been observed to enter sea cucumbers through their small posterior opening, with remarkable facility either headfirst or tailfirst, and to rest inside with its head projecting from the apertures on the lookout for food.

The blennies and related families are a very large and varied series of marine fishes which have the ventral fins placed well forward, often at the throat, with a reduced number of rays, or these fins lacking altogether. There are three principal families of blennies. The Blenniidae are tropical or subtropical. They lack scales and for the most part are little fishes with more or less frog-like heads, rather small, transverse mouths with a row of comb-like teeth in each jaw, a rather high, continuous dorsal fin, the front part with rather weak spines, of about equal extent, with the soft-rayed part behind, and a rounded caudal fin. Numerous species are found associated with gobies in shallow shore waters, resting on or moving deliberately over the bottom, ready to dart away with agility and hide in some hole or cranny. The Clinidae are also small, tropical fishes, with more symmetrical, compressed bodies covered with scales, a more normally shaped head, larger, more normal mouth, rather large eyes and the long dorsal fin supported by more pungent spines for most of its length, usually with few, frequently only one soft ray at its hind end. They hide among seaweed, rather than living actually at the bottom. The Pholidae, on the other hand, are primarily fishes of cold northern seas. They have elongate, compressed, more or less eel-like bodies, usually fine, inconspicuous scales, a long, low, even dorsal fin with spines only, no soft rays, the ventral fins often reduced to a tiny spine and single soft ray, sometimes lacking. Blennies have variously patterned colours to render them inconspicuous in their particular habitat.

There are a number of mostly cold-water families, closely or more distantly related to the blennies. The wolf fishes (Anarhichadidae) comprise a few large species of the north, with deep, compressed heads and foreparts of the body, large mouths and heavy formidable teeth, a long, high, even dorsal fin supported by flexible spines, broad pectoral, and no ventral fins. Those of the not especially elongate genus Anarhichas, reach a length of three or four ft.; the eel-shaped *Anarrhichthys* is said to grow to eight ft.

Most of the species of the rather stocky eel-like eelpouts (Zoarcidae), with short, rudimentary ventral fins under the gill cleft, and the cusk eels (Ophidiidae), with ventral fins near the chin, each developed as a long, forked barbel, are found in moderately deep water. The genus Brotula, which inhabits shore waters of tropical seas, comprises fishes one or two ft. long, with moderately elongated, compressed bodies, covered with fine scales, good-sized eyes and mouth, with small teeth in bands, several barbels on the jaws, long, even, soft-rayed dorsal and anal fins meeting in a point around the tail and ventral fins reduced to a pair of filaments placed under the gill cleft. The family to which it belongs (Brotulidae) is large and varied comprising 40 or 50 genera, most of which occur at varying distances down in the cool depths of the ocean. Strangely enough, two inhabit subterranean fresh-water streams of Cuban caves. These are almost colourless little blind fishes, with tiny rudimentary eyes.

Cods and Anglers. — The cod (*Gadus morrhua*) is probably the best known fish to seafaring peoples of the North Atlantic, which is the cradle of our modern commerce and civilization. It is a cold-water species that abounds on offshore banks, and from early days fishermen have made long voyages in its pursuit. It frequently reaches a weight of 50 lb., and may attain four times that weight and a length of six ft. It is a symmetrical fish, with good-sized eyes, a large mouth, the upper jaw projecting slightly beyond the lower, and a barbel at the chin. Its body is covered with small, smooth scales, its fins are without spines, and, like its close relatives, it has the distinction of three separate dorsal, and two separate anal fins. Cod come close in shore, and also range far down the continental slopes into deep water. They usually swim near the bottom, but occasionally rise into upper waters in pursuit of surface swimming fishes. They range about in hungry schools, devouring any animal food that comes their way, from crabs and molluscs on the bottom, to fish and squid higher up in the water.

Of the several close relatives of the cod found in the same waters, all excellent food fishes, the haddock (Melanogrammus *aeglefinus*), has a smaller mouth and is more exclusively a bottom feeder; the pollack (Pollachius *virens*) is more streamlined, with a slightly projecting lower jaw (its barbel minute), a larger, more forked caudal fin, and usually swims at or close to the surface; the little tomcod (Microgadus *tomcod*), which runs into shallow water and enters estuaries in late fall and winter, rarely exceeds one ft., and is usually smaller.

The cod family (Gadidae) also comprises somewhat different fishes. The European lings (Molva), which have large eyes and a well-developed chin barbel, are more slender and elongate, with but two dorsal fins, the anterior short, the posterior long, over the single, almost equally long anal fin. The common species which is around five ft., is extensively dried for food in Iceland. Fishes known as hake or ling in America, as fork-beards in England (Phycis), have a similar fin arrangement, except that their ventral fins are each reduced to a long, bifid filament, and are placed at the throat. There is one fresh-water member of the cod family, the burbot (Lota), found in northern lakes. The European hake and American silver hake (*Merluccius*) are close to the cods but usually placed in a separate family. These are predaceous fishes with large mouths and numerous sharp, slender teeth, a projecting lower jaw and no barbel. They have two dorsal fins and one anal fin, but approach the condition in the cod, etc., in that the long, posterior dorsal and anal fins are marginate, imperfectly divided in two.

The grenadiers or rattails (Macrouridae) are strange, bottom fishes of the cod order (Anacanthini), which inhabit the deep sea, rarely straying up the continental slopes to inside the 25-fathom line. They have rather large, sometimes angular heads, mouths and eyes of varying size, the latter often large, usually a small barbel at the chin, a short, anterior dorsal, placed about over the pectorals, which are about over the ventral fins, a long body covered with small scales, tapering backward into a slender rat-like tail, and no caudal fin, a long posterior dorsal and anal fin, the former commonly, and the latter sometimes very low or vestigial. Among deep-sea fishes the rattails are numerous in individuals, and in species which inhabit varying depths. More than 15 genera are recognizable.

The Anacanthini are very distinct from any other order of fishes. Earlier classifications placed them near the blenny-like series, which they suggest in various mays. More recent classifications derive them from much further back in the evolutionary line, perhaps directly from the Isospondili, but their position is by no means certain. Their tails and caudal fins are strictly isocercal, lacking the structural asymmetry characteristic of those of most fishes, doubtless a secondary character, and probably inherited from ancestors with eel-like tails. Their fins are without spines, but might easily be so secondarily. The number of rays in their ventral fins is very variable, one to nine in the Gadidae, and may be as high as 12 in the Macrouridae. In any event, they are highly specialized rather than primitive fishes, as evidenced by the complexity of the cod skull.

There is general agreement that the Pediculati (anglers, etc.) are the most specialized side branch of the spiny-rayed fishes. They are usually short-bodied, more or less shapeless forms, and have a short, fleshy arm to support the broad pectoral fins, small gill openings, somewhat behind. in or near the axil of these fins, and the anterior dorsal fin reduced to more or less isolated, slender spines. The North Atlantic angler (*Lophius piscatorius*) which reaches a length of three or four ft. and may weigh as much as 50 lb., is common in cold, shore waters, and ranges well south at considerable depths. It has a very large, broad head, about as long as its tapering, scaleless body, an enormous transverse mouth with projecting lower jaw and bands of formidable pointed teeth Its eyes are on the top of its head. its first, slender dorsal spine situated near the tip of the snout, has a skinny tab or "bait" at its apex, which was observed to lure smaller fishes to their doom over the great mouth of the angler, lying inconspicuously on the bottom. The frogfishes (Antennariidae) are small, sluggish fishes of irregular outline which hide in seaweed, where their colours and markings render them inconspicuous. These too have good-sized mouths opening obliquely upaard, a very slender, movable spine with a bait at its apex over the tip of the snout, and probably either angle in the same way for little shrimps and the like, or clamber through the weed stalking their prey. The mousefish (Histrio) is wonderfully camouflaged in the drifting weed where it lives. But the Ceratioid fishes or deep-sea anglers, sometimes called sea devils, are the most remarkable in this group. There are numerous, mostly small species of these, of different strange shapes, commonly black in colour, often with large mouths and many fang-like teeth, which live in the darkness of the oceanic abyss, and frequently have a phosphorescent, luminous bait. A unique feature in the life history of ceratioid fishes is that the male, nhich is tiny compared to the female, attaches himself to some part of her exterior with his mouth, and becomes a parasite for the rest of his life. His organs, except those connected with reproduction. degenerate and he becomes fused with her; even their vascular systems connect.

Distribution and Migration.— Almost every known type of water has its fish life, from mountain torrents to the depths of the ocean. There are three main habitats, each with fishes peculiar to itself and that enter the others to a very limited degree, namely fresh water, shore water and deep sea; thus there are three main fish faunas, fresh-water fishes, shore fishes and deep-sea fishes.

Sharks were presumably always marine, but there is some evidence that the ancestors of modern "true" fishes (Osteichthyes or Pisces) inhabited fresh water, where various archaic relict forms still live. Be that as it may, almost every modern order of fresh-water fishes has marine species or relatives, and presumably came out of the sea. which its ancestors may have entered at an earlier epoch. An exception is the continental order Ostariophysi (catfishes. characins, carps), nith no knonn marine relatives, and no marine species except a few catfishes which are doubtless secondarily so.

Some fishes are most abundant in the transition zone of brackish water between salt and fresh. as about the mouths of streams. Most of these can also live in quite fresh or quite salt water, some better in the one, some better in the other. Some fishes, notably species of the trout and herring families. make regular migrations between salt and fresh. In the Arctic regions fishes cross the line between fresh and salt water more freely than in warmer climes. However, it was found that tropical salt-water fishes enter rather freely local fresh water that is heavily impregnated aith lime. The line between fresh water and marine shore fish faunas is then a somewhat intangible one. Nevertheless, and in spite of the fact that living conditions are so similar in the two habitats that many of their fishes are much alike, it was one of the most effective barriers in general to fish distribution. Fresh water will not support the abundance of fishes to be found in salt, competition was less keen and specialization less active there, and its fishes are, in general, more primitive.

The deep-sea habitat is the most peculiar, its fish life most specialized, and unlike that found anywhere else. At the same time competition was less keen in the deep sea than in shore waters, enabling primitive types and groups to persist there. The three obvious physical characters of the depths of the ocean to which fishes living there must be adjusted, are pressure, cold and darkness. The fishes' bodies are so permeable to water that pressure evidently is balanced and makes surprisingly little difference to them, provided they do not change their level too quickly. Cold must act as a deterrent, preventing warm-water shore fishes especially, from entering the domain of. and competing nith deep-sea forms. Most of their peculiarities are directly or indirectly traceable to darkness.

Various shore fishes go to considerable depths at times. The shore fauna is dominant on offshore banks and on the continental shelves in general. Certain cold-water species, found in shallow water along coasts to the north, range farther south in deep water. The deep-sea fauna becomes dominant below the 100-fathom line. A few of its members very occasionally cross the 25-fathom line shoreward; and, at intermediate depths. representatives of both faunas are found. However, although deep-sea fishes were presumably derived from those of shore waters, their specializations are so pronounced that there is seldom difficulty in assigning a species from where the two mingle to one or the other category. There furthermore seems to be a narrow transition zone on the continental slopes between shore and deep-sea faunas, which has character of its own, some fishes peculiar to it, with shore affinities, but not related to those in nearby shore waters. On the Atlantic slope of North America we have two dogfishes (*Scylliorhinus retifer* and *Pristiurus* arae) representing the European dogfishes; *Zenopsis ocellatus* representing the European John Dory; and the tilefish (Lopholatilus chantaeleonticeps) representing the blanquillos of Middle and South America. Pelagic fishes, found at the surface of the open ocean far from land, for the most part belong to a division of the shore fauna, not to the deep-sea fauna. On the other hand, many little lantern fishes mhich follow the zone of darkness to the surface at night, obviously belong to the deep-sea fauna. Not only are they specialized for life in dim light. but their relatives live deeper down.

It would be possible to subdivide the deep-sea fauna according to zones of depth which its members occupy. A large number of its species—so far as known—have a more or less limited range in this or that sea. But they live in a remarkably uniform environment with few natural barriers, and, as our scant knowledge of them increases, closely related if not identical forms turn up in the most nidely separated parts of the continuous ocean.

By contrast, there are and were various natural barriers to the dispersal of fresh-water fishes. To begin with, they cannot cross salt water. Those of one part of the world differ from those in another, correlated not only with differences in the aquatic environment, but with the geologic history of the lands. The fresh-water fish fauna is separable into a number of natural divisions and subdivisions which make an interesting contribution to the science of zoogeography (see ZOOGEOGRAPHY; DISTRIBUTION OF ANIMALS). The order Ostariophysi (catfishes, characins, carps), which dominates continental fresh waters today. appears to have been distributed from the larger land masses to the north The dispersal of catfishes reached South America prior to the long isolation of that continent by sea in the Tertiary, and, with few competitors the catfishes expanded there into a great variety of normal and aberrant branches and forms. The dispersal of carps came later and, not being able to cross salt water, they have not reached South America. Ostariophysi are dominant in the larger East Indies but entirely absent, except for marine groups of catfishes, from Australia. New Guinea and Madagascar. which were isolated by sea for a longer period. The eastern limit of their range is approximately at "Wallace's Line." In such ways the subdivisions of the fresh-nater fish fauna correlate nith what is known of geologic history from other sources.

The various elements of which this fauna as a whole is composed, each has a different derivation. Its subdivisions should be based, not only on the presence or absence of one or another element, but also on the balance between those which are present. A (I) Continental dixision has the Ostariophysi dominant, as opposed to a (II) Peripheral division where a large proportion of the fishes have marine affinities. The former occupies the continents (with the exception of Australia) and most continental islands. It has an Arctic Peripheral fringe where relatives of the pikes (Haplomi) and of the trouts are abundant. and this fringe fades into it southward. The genus *Galaxias* mhich occurs in the southernmost margin of South America and tip of Africa gives these small areas a Peripheral complexion.

The Continental fauna may be divided again into (1) Northern, which occupies Eurasia and North America, with carps and their relatives very abundant; and (2) Austral. in Middle and South America, and Africa. The (A) Holarctic division of the northern fauna is found in Europe, North America, and crosses Asia, where it is separated geographically from the (B) Oriental division in China, India, etc., by mountains and deserts. Finally, the (a) Palaearctic fauna in Eurasia is characterized by the presence of loaches, the (b) Nearctic in North America by an abundance of suckers. The (A) African and (B) Neotropical divisions of the Austral fauna are very comparable, characterized by great variety and abundance of catfishes, characins and cichlids, which led to recurrent but probably erroneous belief that there was a fresh-water (land) connection between Africa and South America in the Tertiary. There is an abundance of mormyrids in Africa, of gymnotids in South America, families parallel in some ways, but presumably unrelated.

Such are the main components of the continental fauna, although these may be subdivided further to advantage. For instance, the carp family makes up a greater proportion of fresh-water fish life in East and South Africa than in West Africa. They are a relatively recent invasion from Asia which found more room in the periphery than in the centre of abundance of the already established Nile-Congo fishes. In temperate North America, fishes in the elevated or broken terrain from the Rocky mountains westward are different from those of the eastern part of the continent. In Asia and North America particularly, the fish life varies according to temperature zones, dependent on differences in latitude or altitude.

The Peripheral fauna is characterized by groups of fishes found in the fringes of, penetrating more or less deeply into, and becoming dominant only where the continental fauna is weak. It is less tangible, has less unity and is less correlated with the history of the lands. Its (1) High Latitude part consists of an (A) Arctic and subarctic fringe where the trout family is abundant, and (B) a barely recognizable touch at the edge of southern land masses, which do not extend into such high latitudes. Its (2) Tropical part is dependent on long isolation of fresh waters by the sea, and may be divided into the (A) Australian; (B) West Indian; and (C) Insular-Oceanic faunas. The Australian, in Australia, New Guinea and the Soenda Islands, is characterized by the Melanotaeniidae, fresh-water cardinal fishes, halfbeaks and representatives of marine catfishes, and so forth; the West Indian by fresh-water mullets and an abundance of lire-bearing tooth carps; the Insular-Oceanic is still more reduced, and gobies are its principal factor, augmented in the western Pacific by fresh-water species of Kuhlia, a primitive percoid.

The marine shore fish fauna varies in different parts of the ocean, primarily on the basis of water temperatures, which are much affected by ocean currents. Its (I) Tropical division extends around the globe, and is little varied, with representatives of the same fishes in most of them, even distant seas. A branch of this tropical fauna, the (1) Pelagic, is characterized by a few cosmopolitan species found across the surface of the open oceans far from land, the blue shark, pilot fish, dolphin, oceanic bonito, two or three flying fishes, mousefish in drifting sargassum. The majority of its species, with more limited ranges, occur (2) Coastwise or about islands. For them there are two main centres of abundance, the East Indian and the West Indian. The (A) Coastwise Tropical Indo-Pacific fauna is remarkably uniform from the East Indies west to the Red sea, and east to the Hawaiian Islands. Although it becomes progressively less rich eastward, and many species occur only limited distances beyond the Indies into the Pacific ocean, others are found all the way from the Red sea to Hawaii, and a few, such as the Moorish idol (*Zanclus cornutus*) and a swellfish (Tetmodon *hispidus*), even to tropical American waters. The Tropical fauna of the west coast of America is somewhat intermediate between the Indo-Pacific and (B) West Indian, but perhaps more referable to the latter. The distance between the American coast and the Hawaiian Islands seems to have been, in general, an equally or more effective barrier to the distribution of shore fishes than the geologically recent land barrier of Central America.

The (II) Boreal fauna is characterized by cod, Sculpin, smelt, northern blenny families, and their relatives, flatfishes in abundance and northern herrings. It is best developed in the northern North Atlantic, changes its character little as it fades into the Arctic. Temperate faunas between the Boreal and Tropical are less strong and well-marked, largely dependent on ocean currents and configuration of the lands, isolated from one another and difficult to classify. The Tropical fauna centres about coral reefs, and usually has a fringe north of where such occur and lacking reef elements, but otherwise little changed; where Sciaenidae are abundant on sandy shores. On the east coast of North America this fringe extends north to the Carolinas, the Boreal extends south to Massachusetts, the intervening area is dominated by the former in summer, by the latter in winter, and the two faunas are well contrasted. There is the merest suggestion of a warm Temperate fauna between in the presence of the tautog (*Tautoga onitis*), abundance of the sea bass (Centropristes striatus), etc.

On the west coast of North America an opposite condition prevails. The Boreal merges into a strong, widely distributed (III) Cold Temperate North Pacific fauna in southern Bering sea, which is characterized by rockfishes (Sebastodes, etc.), greenlings, and other aberrant cottoids; farther south, as it merges into the (IV) Warm Temperate California fauna, by surf fishes. The California, which corresponds with the Warm Temperate Mediterranean fauna of the eastern Atlantic, amalgamates southward with the northern fringe of the Tropical, and the Tropical becomes pure only at about Cape San Lucas.

In the southern hemisphere an (V) Antarctic fauna, characterized by the Nototheniidae, extends northward to New Zealand, the southern end of South America and Kerguelen Island. The warm temperate Peruvian fauna is of especial interest, although it occupies only a narrow strip of relatively cool northward flowing or upwelling sea along the west coast of South America. It is characterized by a very great abundance of a species of anchovy (*Engraulis* ringens), an abundance of croakers (Sciaenidae) and several fishes which have their closest relatives in widely separated and distant parts of the ocean. But its closest affinity is with the California fauna to the north. The configuration of ocean currents is such that warm water spreads poleward along the east coast, and cool water extends equatorward along the west coast of the continents (see OCEAN AND OCEANOGRAPHY). It follows that the Tropical faunal area is particularly narrow along the west coast of America, and is or was crossed by various warm temperate fishes.

The distribution of fish life in the past was influenced by the same agencies and barriers which affect it at present. Few barriers are insurmountable. Environmental differences, as between fresh and salt waters, coastal waters and the dark depths of the ocean, warm water and cold, were the most effective barriers in the long run. It is also probable that each strong fauna is to some extent a closed corporation, which can only be penetrated to a limited degree by that adjacent to it. This very likely keeps the line between fresh-water and shore fishes, or, in the western Atlantic, between cold-water and warm-water fishes as distinct as it is.

Wide stretches of relatively currentless ocean, free from islands, are a barrier to the dispersal of shore fishes. On the other hand many of these have pelagic young which drift great distances in ocean currents, hence a very wide distribution. Currents are often a factor in the migration of the individual to and from its nursery grounds, which may differ ecologically and geographically from those it occupies when grown. As regards fresh-water fishes, the isolation afforded by different drainage systems is apparently too temporary to have more than a slight effect. Fresh-water fishes of western are quite different from those of eastern North America, but the continental divide has nothing to do with it. The mountain-loving black-spotted trouts of the west have crossed this easily enough and are native on the eastern slopes of the Rockies, to be stopped by the Mississippi valley lowlands. It is the broad mountain area of the Rocky mountain system that prevented an invasion of the west by eastern fishes.

Birds are the only animals that have migrations as regular as, or more extensive than, fishes; and fish migration is much more complicated than that of birds. It is usually similarly correlated with the change of seasons, but less predominantly with reproduction. Search for food and optimum temperatures are larger factors in it. Furthermore, a fish has three directions to migrate into a different environment, north and south (latitudinal), on shore and offshore (horizontal) and up and down (vertical). The migration of shore fishes commonly combines the three.

As regards spawning migrations, there is a strong tendency for fresh-water fishes, in some species more than in others, to run upstream to spawning grounds. The value of this habit is obvious. It places the baby fishes in an appropriate nursery ground, in narrower waters, and where they have fewer enemies to contend with. A similar migration is better developed in anadromous fishes, those which get their growth in the sea and ascend fresh waters to spawn. These have appreciably fewer eggs than comparable species which spawn in salt water, correlated with less wastage of eggs and fry. The chinook and blueback salmon have wandered an unknown distance in the Pacific from the mouths of the rivers in which they spawn, and ascend these rivers for hundreds of miles to their spawning grounds. Like other Pacific salmon they spawn but once and die, and the return downstream and out to sea is made by the succeeding generation, which spent its early life in fresh water. There is thus a single complete round-trip migration in the life of an individual Pacific salmon.

Fishes are peculiar among vertebrate animals in that the majority hatch from tiny eggs, and there is so great a discrepancy in size between young and old that they occupy different ecological niches more often than not. It follows not infrequently that young and old belong in different faunas. In this case the small salmon is a part of the fresh-water, the larger salmon a part of the marine shore fauna. Any spawning migration implies a return migration of the young which is usually more protracted in time and often follows a different pattern.

The best known anadromous fishes belong to the relatively primitive order Isospondyli, and like other anadromous fishes can become landlocked and go through their entire life cycle in fresh water. As previously mentioned, there is some evidence that the ancestors of bony fishes were inhabitants of fresh water, and the question of theoretical interest suggests itself, whether the Isospondyli are not to be considered a fresh-water group becoming adapted to life in the sea. Probably not, except in so far as being a generalized group it is also adaptable. Most primitive Isospondyli are marine. The big-eyed herring (*Elops*) and bonefish (*Albula*) have larval, pelagic young, and those of the tarpon are unknown.

The anadromous shad runs up rivers to spawn, from Florida to New Brunswick, progressively later in the spring northward, but this does not imply northward migration along the coast, for it is different fish that come into each river from the sea. It is not improbable that some northward movement is associated with the shad's vernal migration, however. Northern coastal waters become too cold for it in winter, and whereas it may reach sufficiently warm water by moving offshore, direct evidence of its doing so is lacking thus far. There is an anadromous Chinese herring (*Hilsa*), corresponding to the American shad and an equally prized food fish, which runs up the Yangtze river a 1,000 mi. or farther from the sea.

A few (catadromous) fishes live in fresh water but spawn in the sea. Among these the fresh-water eels (Anguilla) are preeminent. European and American species, which are very much alike, are known to spawn in adjacent areas of the open Atlantic southeast of Bermuda, at a probable depth of 200 fathoms or somewhat more. Their young are larval, elongate but flattened, transparent, uneel-like and pelagic, living near the surface of the Gulf stream drift, on the first leg of the long two-way migration in the life of an individual. The larval stage of the European species until, shrinking somewhat in size, it metamorphoses into a tiny cylindrical, although still transparent replica of its parents, lasts nearly three years, that of the American about one-third as long, by which time they have respectively drifted to the shores of Europe and America and enter coastal waters. Such tiny eels are sometimes very abundant in New York harbour in spring. They work into shallow water, quickly lose their transparency, become dark in colour, and begin to grow again. Some remain in salt water along the coast. Others travel up stream as far inland as the rivers are quiet or muddy—it may be hundreds of miles—or get into ponds, and live their years in fresh water. When fully adult and ready to spawn, however, those in fresh water return to the coast. In fall such mature eels become more or less silvery in colour, and, instead of going down into the mud for the winter, head out to sea on the long migration back to the spawning grounds, from which only the next generation will return. As they do so their eyes grow larger, and there are other changes in their appearance. Marine or pelagic larval young, unsuited to fresh-water existence, are a characteristic of eels in general, and this stage obviously makes it necessary for Anguilla to spawn in the sea. Occasional individuals which become hopelessly landlocked in fresh water can not reproduce their kind. It is also significant that there are primitive Isospondyli, for instance *Albula*, with elongate, larval young not unlike those of the eels, suggesting the possibility that these played a part in the evolution of eels from that group.

The migrations of marine shore fishes are largely determined by water temperatures and search for food, and in the case of their young by nursery grounds. Their breeding migrations are, for the most part, of lesser extent or complicated with these other factors. The common mackerel of the east coast of America is an example. Nobody knows exactly where its schools spend the winter, perhaps at a considerable depth in the ocean, but they appear off the Carolinas in spring and work northward. They spawn in summer abundantly from Massachusetts bay to the Gulf of St Lawrence and over offshore banks, but it would seem that they move into these favourable feeding grounds when water temperatures permit, and their spawning there is more or less incidental. The blue-fin tuna and swordfish of the western Atlantic invade the same grounds in summer, but have certainly spawned elsewhere. The mackerel's migration presumably combines a movement to and from a greater depth farther offshore with northeast-southwest movement along the coast. and there is even some evidence that those north and south of Cape Cod in spring are different fish. Its young follow along the coast for some distance in fall, those which are abundant in Long Island sound at that season presumably having come from New England.

As has been said, the shore waters between Cape Cod and the Carolinas are occupied by warm-water fishes in summer and by cold-water fishes in winter. Of the former the tautog and striped bass may be little migratory, merely becoming less active in the colder months. Other bottom fishes such as the summer flounder and sea robins move offshore into deeper water with falling temperatures. To what extent they edge southward while doing so is uncertain. The arrival in spring and departure in fall of the menhaden is closely correlated with water temperatures, and its migration along the coast is probably combined with an inshore-offshore movement, but it is very improbable that it goes to any considerable depth. It is abundant southward at any season, but temperatures at the edge of the Gulf stream would be sufficiently warm for it. It spawns to the south in winter, progressively later northward, and in the area under consideration in summer, so different lots of fishes must be involved. The pattern of bluefish migration seems to be somewhat intermediate between that of mackerel and menhaden. Like these, it spawns in its summer range. Its young grow rapidly, and have a well-marked southwesterly migration along the coast in fall.

To cite examples of fishes of northern distribution which are abundant in shore waters south of Cape Cod in winter, schools of cod, which normally wander considerable distances in search of food, invade the area from the northeast when its temperatures fall to a suitable level and the warm-water fishes withdraw from it. As a rule only an occasional individual of the little tomcod is to be met with here in summer, but in late fall a wave of this species invades inshore waters, presumably coming up along the bottom from a greater depth, to spawn in winter in shallow bays and estuaries. The long-horned sculpin, which is abundant in the colder months, and spawns in late fall and winter, doubtless also comes up aiong the bottom, probably with little or no southward movement from northern shore waters where it is plentiful the year round. Much remains to be learned about the migration of any fish, even in this narrow and comparatively accessible area, where a large part of the species are migratory. Enough was said to show that whatever north-south migration there may be is complicated by retreat to offshore or deeper waters which have less seasonal temperature change. More favourable spawning grounds for most, be they warm-water or cold-water species, are inshore, and so they spawn inshore in summer or winter as the case may be, and the temperature migration is also a spanning migration. A series of fishes could be selected showing every intergrade in migration pattern between that of those which are strictly marine and spawn when they approach the coast, and those which are anadromous and run far up the rivers for that purpose.

Some warm-water marine fishes, especially, are pelagic, many shore fishes have pelagic young. When their nursery grounds lie in a well-marked ocean current, they may be drifted great distances. How they get back to where they came from is usually obscure. The young of many tropical species are drifted northward along the American coast by waters of the Gulf stream, occurring in temperate latitudes in summer and fall. In the majority of cases they occur merely as stragglers, and the presumption is they are lost and do not get hack. But young of the common pompano, for instance, are frequent in small schools on sandy ocean shores in autumn, far north of where adults occur. They have by then reached a sufficient size to migrate southward along the coast, and presumably do so. The several tropical crevallys (*Caranx*) common on the Atlantic coast of America have somewhat different nursery grounds from one another. A known nursery ground of *Caranx crysos* is in the Gulf stream, where these little fishes were found in numbers so far to the eastward as to raise the question whether they might seek African rather than American shores when large enough to navigate independently of currents. This particular species does occur along African as well as American coasts. Grown fish, though not ordinarily pelagic, would be quite capable of crossing back from Africa to South America, or young of another generation might drift back in equatorial currents. Too little is definitely known of the migrations of marine fishes, and these remain a fertile field for hypothesis and investigation.

The Place of Fishes, Their Size, Speed, Age, etc.—Though not the only, fishes are the principal free-swimming, aquatic animals. Most of the vast number of aquatic invertebrates are either more dependent on the bottom, or, because of lowly organization or small size, drift about in the currents. The molluscan squids, just as the mammalian whales and porpoises, are very exceptional in having invaded the fishes' proper sphere. Thus removed from serious competition by other groups, fishes are abundant everywhere, have expanded into every conceivable ecological niche and evolved a much greater diversity of forms than any other class of vertebrates. Fish competition was primarily with fishes, one species balanced against another, making for evolutionary divergence in every direction, and fishes present a particularly fertile field for the student of evolution.

The basic food supply of animals is plant life, and the mass of vegetation, such as is found in terrestrial, is relatively small in aquatic environments, taking them as a whole. This is compensated by the very great abundance of diatoms, microscopic, drifting plants, in water that is within the reach of sunlight. Although their mass is quite adequate, diatoms are too tiny to be utilized directly as food by more than a very few fishes, but by serving as pasturage for creatures somewhat larger than themselves, by one or more stages their stored up food substances are presently brought within fishes' reach. Most important of these intermediate creatures are small, also planktonic (drifting) crustacea (shrimp-like animals), frequently so abundant as to form clouds in water. They are a principal food of many, if not most newly hatched fishes.

Some fishes are omnivorous, some are herbivorous, subsisting mainly on such water plants as there are in fresh water, along the shore, or adrift, but the majority are carnivorous. An increasing proportion of the larger ones eat other fishes smaller than themselves, simply because these are the most available food. The saying "fish eat fish" is by no means an invariable rule, but is rather generally applicable. And the largest factor of basic food supply on nhich the pyramid of fish life rests is made available to it by diatoms. It must be almost entirely from diatoms of sunlit waters that the food chain, which is their subsistence, extends to the carnivorous fishes, living in the dark miles, down in the ocean.

One principal, underlying and easily traceable reason for the great divergence in character of different fishes, depends, directly or indirectly, on how far back each reaches for subsistence toward the base of the food pyramid. The menhaden goes all the way and feeds on diatoms. The minority of fishes which are herbivorous are specialized in diverse ways correlated with that habit. The predaceous bluefish feeds on menhaden and other fishes of comparable size. There is also a basic cause for the diversity of fish life in the vastness of aquatic environment. Fishes of one heritage may have been superseded by those of another in centres of abundance and competition, yet persist somewhere, perhaps in fresh, perhaps in deep, perhaps in isolated waters.

Fish utilize every available resource. Many fresh-water species eat insects which drop upon the surface by chance, or the aquatic larvae of terrestrial insects. The former are a main food supply of trout in summer, and these go on comparatively short rations through the minter. Rivers wash waste products of the land to the sea, which nourish fishes, or marine animals on which fishes feed. It follows that off the mouths of great rivers is one situation where fish life is usually abundant. Fishes are abundant and in great variety about coral reefs, but coral-reef fishes do not lend themselves to becoming the basis of a fishery more extensive than that for local consumption. There are three reasons for this. The irregular bottom makes it easy for fishes to escape. and difficult to operate fishing equipment. No one species is dominant, or sufficiently abundant to be captured and handled in quantity conveniently. As a rule, the coral-reef habitat is narrow and isolated, easily fished out, and slow to recover by influx from similar areas. The extensive offshore, cold-water banks of the North Atlantic show an opposite condition in these respects to that which pertains on coral reefs, and have been one of the chief sources of commercial fish. Here the supply of bank cod which range widely in schools, seeking favourable pasturage, is still adequate in spite of all the cod that have gone to market; that of the more sedentary halibut has given out at spots which used to be the most favoured by that species. Fish life is abundant where two environments meet, relatively scarce over monotonous stretches. Fishes abound along shores, and are plentiful on offshore banks where the life of the bottom meets that of the upper waters, scarce across the open ocean. Their great abundance in cool water of the Peruvian coast is probably correlated with the abrupt change to warm ocean water a relatively short distance out.

From the time that a tiny fish leaves the egg until it becomes full grown, and lives out its life span, it is part of the intricate balance of aquatic life, although its position therein alters as greatly as its size increases. The increase or decrease in abundance of various fishes is of importance to man, but, especially as regards salt-water species, we have too little knowledge of their enemies, food and other requirements throughout their life cycle, of the balance of aquatic life, which may vary in different waters, and of which they are a changing part, to take appropriate measures for the control of their numbers, which may be indirectly dependent on the microscopic diatom, or the only larger crustacean. Further research is requisite for an intelligent approach to such problems.

The size to which each species of fish grows is less standardized than that of most other animals. A fish probably continues to grow through life, although at a diminishing rate, much as a tree does. However, its life span is so much shorter, that its size is less an index of age than in a tree. Most of its growth is made in its youth, and how much that shall be depends on various factors, of which available food supply must be one, but is not the only one. Unusually large individuals of any species are not necessarily unusually old ones. As regards the normal and maximum age fishes attain, there is little exact information for most species. From a study of the gro th marks on their scales it is known that the different Pacific salmons (*Oncorhynchus*), which spawn and die at maturity, reach an age of two to six years. The life span of one or more small fishes is no more than a year. Some pike in fresh water, and halibut in the sea, probably live 50 years, it may be considerably more. But reported instances of any fish passing the century mark are unsubstantiated and more or less mythical. The smallest fish is reputed to be a tiny goby (*Mistichthys luzonensis*), in a Philippine Island lake, only one-half in. long when mature. The largest is probably the whale shark *(Rhineodon)*, more than 50 ft. and weighing several tons. Among Pisces, Osteichthyes or true fishes the largest sturgeons and the ocean sunfish probably exceed 2,000 lb., the largest blue-fin tuna, and marlins, weigh more than 1,000 lb.

Greatest swimming speed is very likely attained by some member of the group of mackerel-like fishes to which tuna and marlin belong. Here again exact knowledge is scant, but it is safe to say that, unless in short spurts, very few attain 20 mi. per hour. It is not improbable that the fastest swimmer can make 30, and 40 or 50 are in the fringe of possibility, but one may well be skeptical of records, however circumstantial, of more than 50 mi. per hour claimed for any fish.

Sound does not pass readily between air and water, and fishes have the reputation of being mute. This is not the case, however. Many are quite vocal, and some particularly so in the breeding season. The range of noises that they make is not very great—grunting, tooting, chirping, clicking, rattling, humming or drumming sounds—the voice of one species different from that of another and usually recognizable. A school of sea drum (*Pogonias*) in spring make quite a racket which can be heard through the bottom of a boat lying at anchor in some bay. They are recognized immediately, and it may be assumed that their voices can be heard and recognized by others of their kind. In spite of attempts to do so, very little direct evidence was obtained so far that fishes hear underwater sounds, but there is considerable indirect evidence that they do.

A fish's vision is doubtless somewhat more restricted than our onn in various ways, but less restricted than, for this or that reason, it was supposed to be. Some fishes certainly have colour vision, and there is no good reason to suppose that fishes in general do not. The deflection of light at its surface doubtless prevents fishes from seeing objects out of water, in varying degrees with light conditions. However, the archerfish *(Toxotes)* sees insects on overhanging vegetation sufficiently clearly to knock them off with jets of water; a speeding dolphin sometimes follows the course of a flying fish in the air, to seize it when it drops back into the sea; and the behaviour of trout in a stream leads one to suppose that they can see a man on the bank when he sees them, if less clearly. Fishes utilize chemical sense, which we may call smell, to a varying degree according to their kind, in obtaining their food. From the behaviour of sharks it is certain that most of them rely on their noses to a considerable extent. On the other hand, free-swimming, predaceous fishes, like the mackerels and bluefish which strike at a glittering metal lure, the trout rising to an artificial fly, are presumably largely dependent on sight. Many fishes have highly developed tactile organs, and fishes are thought to have special organs for sensing conditions peculiar to their aquatic life and environment.

We assume, probably correctly, that fish behaviour is more mechanical than that of the higher animals, in no wise to be compared psychologically with our own. Nevertheless, it has plenty of features to suggest an anthropomorphic interpretation, or that the difference in mentality is as much one of degree as of kind. An underlying factor in fish behaviour seems to be that the individual fish seeks to swim at a given distance from others of its kind, no more and no less. This distance varies according to the fish's condition, and still more according to its species. It is very short in herrings and mackerels that swim in dense schools, and varies all the way to fishes that are essentially solitary. Many sedentary fishes living in a circumscribed area at or near the bottom, defend their property rights to the area, being domineering within its confines or driving intruders from it; and these property rights, when asserted, tend to be respected by their neighbours or strangers. This is most marked in, but by no means confined to fishes protecting their mates, eggs or young.

BIBLIOGRAPHY.—Bashford Dean has issued a bibliography of fishes in three volumes, 1916–23, published by the American Museum of Natural History; the Pisces section of the *Zoological Record*, published annually by the Zoological Society of London, should be consulted.

General Works: J. J. Kaup, "Apodal Fishes," *Catalogue of Fishes in British Museum* (1856). A. Gunther, 8 vols. (1859–70), G. A. Boulenger, "Perciform Fishes" (1895); T. W. Bridge and G. A. Boulenger, *Cambridge Natural History, Fishes* (1904); D. S. Jordan, *Guide to the Study of Fishes* (1905); E. S. Goodrich, "CYCLOSTOMES AND FISHES,)' *Lankester's Zoology*, VOL. ix (1909); J. Zool.* (1905). (J. T. N.)

Colours of Fishes.—If a beauty contest among animals were staged, representatives of fishes would rank among contestants for highest honours. The most colourful insects, the most resplendent birds of the tropics are rivalled in gorgeous colour by some fishes. It would be difficult to find, or paint, or imagine a more brilliant blue than that of the "neon tetra" of the home aquarists, a more intense red than that of the redbelly dace of American streams, a brighter silver than that of the ocean bream. These, of course, are extreme (although not isolated) examples. Most fishes, like a large proportion of insects and birds, are coloured no more brilliantly than are their usual surroundings.

The colours of fishes are most commonly greenish, olive or brown, but range through most of the visible spectrum from red and orange through yellows and greens to blue, with such mixtures as orange-brown and purple common. The colours are usually mixed with black to produce dark shades and are often combined with white to yield such colours as pink and lavender. A single colour may cover the entire fish but more commonly two or more colours are combined to form definite markings, particularly on the back. The lower surfaces are very often light gray, white or silvery. Black spots, bars or streaks are very frequent elements in colour patterns, As in most groups of animals the different species, and often the two sexes, are distinctively coloured.

The almost limitless range of colours and patterns that fishes exhibit is attributable to variations in the number, distribution and mode of combination of only a few kinds of minute pigment cells (chromatophores). Black pigment cells (melanophores), each containing myriad microscopic granules of melanin, are of almost universal occurrence. They produce black markings as well as general shading and are involved in the elaboration of the iridescent greens and blues that appear on most fishes. These latter "physical colours" result from the play of light on tiny, needle-like crystals of guanine that overlie a background of melanin. The underlying black absorbs the red and yellow components of light. When the iridocytes or leucophores (the guanine-containing cells) occur alone, a silvery or white appearance results. When yellow pigment is added to an appropriate mixture of melanophores and iridocytes, green is produced. Although certain fishes, particularly in the families Belonidae and Cottidae, have a green chemical pigment in the bones, the greens and blues that appear in the skin are almost invariably the result of such combinations of colour cells as are mentioned above, rather than to special pigments or to special chromatophores. Yellow, orange and red areas when viewed under high magnification are stippled with yellow xanthophores or red erythrophores, or with both of these carotinoid pigment cells. Pink, purple and lavender colours in fishes are the result of different combinations and arrangements of erythrophores and iridocytes, or to a mixture in fine pattern of spots and streaks of red and white, or of red and blue, or of red. blue and white. When small areas of yellow are interspersed the result is a brown or some other secondary colour.

These colour cells "expand" or "contract" in response to visual stimuli, to the physiological state of the fish and to various internal secretions and drugs. By this mechanism fishes are able to change their appearance rapidly as they move from one environment to another. What actually happens is that the pigment granules within the colour cells either become dispersed throughout the whole star-shaped cell, to intensify the colour concerned; or become aggregated into a dot at the centre of the cell, to accomplish a fading of this colour.

The melanophores react particularly fast and those in different parts of the body may respond in the opposite way. As a result, changes in shade and in dark and light patterns may be accomplished almost instantaneously. Changes in other colours, as from green to brown, are less rapid and less universal, and often require time for the decrease or elimination of certain pigments and for the increased manufacture or deposit of other biochromes. Actual changes in the amount of melanin and of guanine also take place when fishes are shifted from a light background to a dark one or *vice versa.*

Because of their capacity to change colour, fishes are past masters at camouflage. In this self-protective scheme the flat-fishes (flounders and soles) are famously adept. As these fishes move about over the sea bottom, the upper side (bearing both eyes) quickly takes on the colour of the surrounding mud, sand or rock. The pattern is also matched. Thus white fragments of shells are imitated by white spots on the body. Even the size and the abundance of dark and light objects are reproduced. These changes take place within a few minutes and are effected through the sense of sight. Similar transformations, even more rapid although not quite so perfect, are exhibited by other fishes, such as the groupers of tropical shore maters. Some reef fishes show vertical bars when at rest, but horizontal stripes when swimming.

Even more astonishing colour adaptations are attained by some fishes that live in marine plants of different colours, although the change may require days or weeks since some pigments in the skin must be lost and others gained. Thus the kelp blenny (*Heterostichus rostratus*) of California is wonderfully well concealed, whether it lives among the large brown "leaves" of the giant kelp (*Macrocystis*) or in the beds of eelgrass (*Zosfera*). In the kelp it is uniformly brown, just like the alga. In the eelgrass it is striped with the intense green of this plant and with brilliant silver that matches the streaks of light between the slender blades of the plant. The two colour phases could hardly be more unlike and certainly appear to represent different species. They may, however, be changed back and forth experimentally.

In its imitation of the backgrounds the kelp blenny does not rely solely on perfect colour matching. It seldom swims horizontally. Ordinarily it heads up or down in line with the plants and may even waft its tail back and forth to simulate the movements of the leaves. A South American leaf-mimicking fish (*Monocirrhus*) drifts along just like a leaf. Baby gars (*Lepisosteus*) look like tiny twigs and float stiffly at the surface. Other fishes increase the efficacy of camouflage by imitating in posture or movement the environmental objects which they match in colour. In the light of such facts it is difficult to understand why some scientists doubt the reality of protective coloration and of adaptation in general.

Species that live on sand or other drab-coloured backgrounds do not possess a capacity to change colour that is at all comparable to the abilities of the kelp blenny. Those that live in a single kind of plant may imitate that plant only. The sargassum fish (*Histrio histrio*) does not show great range in colour variation but does simulate closely the floating sargassum weed in which it invariably occurs. The resemblance is so perfect that the fish is almost invisible even at close range as it slowly crawls about in the plant. Like other animals of the floating sargassum it shows white marks that look like the white growths of bryozoans on the alga.

Some biologists suggested that fishes and other animals take on the colour of the particular plant in which they live merely because they imbibe the plant pigment either directly by feeding on the plant or indirectly by eating smaller herbivorous animals. For fishes this is not true. Their colours are usually otherwise constituted and the changes can be effected when the experimental fish that are being kept in aquaria with differently coloured plants are fed the same type of food and are denied access to the plants by being kept in glass jars submerged in the aquaria. The last-mentioned test shows that the colour matching, like bottom mimicry by flatfishes, is effected somehow through the sense of sight.

That protective coloration involving only darkness and lightness in fishes really has survival value was experimentally proved (see ANIMAL COLORATION). Even before such proof was obtained field naturalists firmly believed that background mimicry arose through the evolutionary process of natural selection. The simulation of the background colour by fishes is too universal to admit of any other explanation. Nearly all species that swim near the surface—such as herrings, flying fishes and mackerels—are bright green or blue above, and are more commonly green inshore and blue offshore. just as is the ocean. The blue fishes of the coral reefs are the ones that swim into open water. Seen from beneath, all surface swimmers (*e.g.* halfbeaks and silversides) are silvery below and thus match the surface film nhich shines from below like a mirror. Most gobies, flatfishes and other species that live on the bare bottom are uniformly coloured or speckled or mottled with neutral colours. Tide-pool sculpins and blennies that habitually live among varicoloured aquatic plants, in contrast. are brightly and variously coloured. commonly grading from bright green through browns to red and often matching the peculiar pinkish-lavender of the coralline algae. Most fishes of the "twilight zone" of moderate depths are red, but in their own environment they are probably plainly coloured and concealed. Since red rays penetrate less deeply than the green, only green is reflected and it is absorbed. On a similar basis, coral-reef fishes that are red are almost invariably nocturnal. As is well known, red becomes invisible in dim light.

Cryptic (concealing) coloration is effected in almost all fishes, as in most other animals that live in light, by "obliterative countershading" (first stressed by the artists A. H. and G. H. Thayer). The back is enough darker than the lower parts to offset the shadows below, so that the whole image appears flat and indistinct. The exceptions among fishes interestingly prove the rule. Many deep-sea fishes, living below the zone of light, are as dark or darker below than above. The remoras (Echeneidae) are lighter above, but they adhere to sharks by their backs which are thus in the shadow. The "batensoda" (Synodontis), a catfish of the Nile, also reverses the usual scheme of countershading, but this fish habitually swims upside down. Some critics suggested that the darkening of the most exposed parts is the direct effect of light, but it was demonstrated that countershading is inherited and, therefore, that it is almost certainly the result of natural selection.

Although they render a fish in hand or in an ordinary picture very conspicuous, black bands and stripes are also regarded as concealing and protective, for at a moderate distance they disrupt the telltale fish outline. To be most effective such ruptive markings must extend to the very edge of the body and fins—and this they usually do. The eye is a particularly revealing organ, but in many fishes it is more or less completely obliterated by a black streak or bar or by radial markings. These markings pass across the whole eye or through the otherwise conspicuous pupil. That they are of definite significance is suggested not only by their frequent occurrence but also by the fact that they extend across several entirely different tissues. Streaks that pass through the pupil can commonly be resolved into seven parts: two outside the orbit; a pair on the sclerotic coat and conjunctiva; two on the iris; and one on the pupil. The sclerotic sectors extend under the orbital margins, so that the streaks remain continuous when the eye rolls. As Hugh B. Cott and William H. Longley pointed out, such "coincident disruptive" markings can hardly be the result of chance, or have any other basis than natural selection.

Usually the sexes in fishes are coloured alike, or the male in the spawning season is merely more intensely or more deeply pigmented, but in many species having a complicated breeding behaviour the male is much more colourful than the female The puppy (*Lebistes reticulatus*) of aquarium fame is a familiar example The "darters"—dwarfed perches that inhabit the riffles of streams in the eastern U.S.—exhibit nuptial male colours that are among the brightest in the whole animal series. Among marine fishes the dragonets show a similar sexual dichromatism. Darwin's theory of sexual selection (see SELECTION: Sexual Selection), although discredited of late. does seem to explain in part the development of such sexual differences in colour. Sex recognition and intimidation of rivals, however, are probably more significant.

Some pigmentation appears to have a simpler significance. in that it serves a physiological function primarily. Thus the melanin that is usually concentrated over the brain presumably shields this vital organ from harmful effects of light rays. The black pigment in the peritoneal lining of the body cavity may similarly protect the viscera. The particularly black peritoneum of herbivorous fishes may furnish necessary protection for enzymes that aid in digestion of plant tissues. Melanin and guanine are excretory products of metabolism. Their discharge through the skin may serve the animal in this physiological way. But the pigments also provide protective coloration. Evolution often "kills two birds with one stone."

Some critical biologists thought that the skin pigments of fishes merely represent excretions, or serve no function at all. On this basis Jacob Reighard attempted to explain the extraordinarily varied and brilliant colours of coral-reef fishes. He argued that the fishes are adequately protected by their proximity to safe retreats among the coral growths and are, therefore, immune to attack. The riot of colour (with hundreds of distinctive and constant patterns) then "just happened." This "immunity theory" of tropical fish coloration is not generally accepted, although other explanations are not wholly convincing. Alternative theories are (1) that the reefs are so brightly coloured as to render the fish inconspicuous; (2) that the bright markings are mostly of the ruptive category that destroy the fish's outline; (3) the colours may not appear as bright to some predators as they do to us; and (4) that the colours are recognition marks that keep the schools intact and bring mates together and, since the species about the reefs are so numerous, the distinctive markings must be greatly varied. There is probably some truth in each theory.

There is little el-idence that fishes with poisonous flesh or foul taste are conspicuously coloured for their own protection, as many insects are supposed to be. Even the dangerous sting rays and the poison-spined madtoms (small catfishes of eastern North America) are as concealingly coloured as their innocuous relatives. "Warning coloration," however, may be exhibited by some of the surgeon fishes (Hepatidae), which have a needle-like spine on the tail. The flashy orange of the garibaldi or ocean goldfish (*Hypsypops rubicundus*) of southern California appears to advertise the presence of this fish, which boldly fights to defend its home territory. Since revealing coloration seems seldom to have been evolved by fishes, it is not surprising that in this group (unlike the Insectai there are few examples of the mimicry of a poisonous or unsavoury species by an innocuous one living with it. One probable case is that of an eel that simulates a poisonous sea snake.

Vivid colours were developed in some fishes by selective breeding. From time before history the Chinese and Japanese produced goldfish breeds as bright and varied in colour as they are bizarre in form. In recent years aquarists bred a jet-black "mollie" (*Mollienisia latipinna*), a red "swordtail" (*Xiphophorus hellerii*) and many beautiful colour phases of the "platy" (*Platypoecilus maculatus*). See also ANIMAL COLORATION; PIGMENT, ANIMAL.

FISH FLY, the name given, especially in North America, to small insects of the genus *Chauliodes* and allied genera, related to the alder flies (*q.v.*). Fish flies belong to the order Neuroptera (*q.v.*), suborder Megaloptera. The larvae are aquatic.

FISHGUARD AND GOODWICK, a market town, seaport and urban district on the northern coast of Pembrokeshire, Wales, near the mouth of the Gwaen. Combined pop. (1951) 4,839. Area 2.9 sq.mi. The town is perched high above a smaller harbour village also called Fishguard, or Abergwaen, on an inlet on the south side of Fishguard bay. On the west side of the bay are Goodwick and Harbour Village. From Fishguard harbour a service is maintained with the Irish ports of Rosslare, Waterford and Cork. When the harbour, which is protected by a breakwater more than ½ mi. long (see BREAKWATER), was built by the former Great Western railway, it was hoped to make it a port of call for ocean liners. In 1908 transatlantic liners did call to disembark mails and passengers, but this part of the scheme had to be abandoned because of the difficulties of approach in rough and misty weather. The neighbourhood is interesting for the landing by Gen. William Tate. an Irish-American adventurer, with French soldiers and convicts, at Careg Gwastad point in 1797. His force soon capitulated to the local militia (who were preceded, according to legend, by the women of the town whose tall hats and red cloaks caused them to be mistaken for soldiery). The surrender was signed at the Royal Oak inn at Fishguard.

FISH HAWK, a common name in America for the osprey (*q.v.*).

FISHING. Primitive man fished to obtain food. Yet even when his very existence depended on success in catching fish and. of course, in hunting animals. he must have found pleasure and excitement in both pursuits. The desire to hunt and fish has remained a powerful force in man's nature; the excitement of the chase and the fascination of water are still strong.

This article deals with fishing as a sport: for commercial fishing see FISHERIES. For the various craft used in fresh-water and salt-water sport fishing see BOATING. See also HUNTING AND FISHING. PRIMITIVE.

The main divisions of the article are as follows:

I. HISTORY

As fishing ceased to be a means of supporting life and became a sport, man gradually chose the more pleasurable means of catching fish. In the 20th century sport fishing, or angling, came to mean fishing with a rod, reel, line and hook. It is still a growing sport, above all in the more industrialized countries. and practised with pleasure by many nations and for many different sorts of fish. The basic methods of fishing are few in number and although anglers, fish and types of lake and river differ, the styles of fishing are all remarkably similar. These few basic methods, the equipment for them, the angling lore, and the ethics and customs they assume have all evolved by a slow process.

Fishing has been referred to in the literature and portrayed in the art of every civilization. Two thousand years B.C. an Egyptian angling scene mas depicted with figures shown fishing with rod and line. with a hand line and with a net. There are references to fishing in ancient Greek, Roman, Assyrian, Jewish and Chinese writings.

Paleolithic man drew on the walls of his cave pictures of the fish he caught as well as of the animals he hunted. The Chinese were by far the most advanced, for somewhere between 1500 and 900 B.C. it was written "fishermen used the silk of cocoons for their lines: a piece of sharpened iron for their hooks, thorn sticks for their rods and split grain for their bait."

The hook must be one of the earliest tools on which man depended for his existence: the argument as to which came first, spear, net or hook. has not been resolved. Man first used sharp bones, thorns and pieces of wood as rudimentary hooks or "gorges" (pieces of flint, stone or bone the fish could swallow with bait but could not eject afterward). When he attained skill in working with wood, stone, shells and, much more important, with metal, fishhooks were among his first products.

The history of fishing as a sport had its starting point in modern Europe in 1496 when Wynkyn de Worde printed at Westminster the Treatyse of Fysshynge *With* an Angle, part of the second edition of The Boke of *St.* Albans. This, the first angling manua! in any language, is generally thought to have been written by Dame Juliana Berners. This work lists 12 artificial flies and the method of making each. So little have the basic principles of fishing altered that six of these flies are still in use.

1. Basic Methods.——Angling gradually developed in technique. literature and equipment according to four basic methods — fishing with bait, trolling, bait casting and fly-fishing.

Bait Fishing. — Bait fishing is the oldest form of fishing. A bait, that is, something that a fish will eat. is impaled on or pressed round a hook. Common baits were and still are worms. larvae, insects (including flies), small fish or minnows, pieces of meat, shellfish and pastes made of flour. The hook is attached to a line. These two items composed the original equipment for bait fishing and are still used in the form of a hand line for sea fishing. Such tackle, however, is very limited in its use. for unless the bait is heavy. or unless some weight is used, it is difficult to cast far, it is impossible to fish over reeds and similar vegetation and it is troublesome to recover the bait or bring a fish to land unless the bank is very clear. The answer to these problems was a rod, a length of stick or cane to which the line was tied.

It is strange that in all the ancient illustrations a very short rod of only a few feet is shown, and man seems to have been very slow in seeing the advantages of a longer one. It is not known when or where a long rod, one as long as ten feet: was first used but there is strong evidence to suggest that the Romans saw the advantage of joining two or more pieces of cane together. This not only gave additional reach. but allowed the rod. when unjointed, to be carried about more easily. The reference is made by Martial (40–*c.* 104 A.D.), a poet who loved fishing and other country pursuits. Scholars have differed over the correct interpretation of the reference, but it seems reasonable to suppose that a nation as advanced as Rome, with different sorts of cane procurable in its colonies, hit upon the simple expedient of jointing two pieces together.

The bait fisherman, then, equipped with a rod, could reach out from the bank and over vegetation. He could thus let his bait lie on the bottom of river or lake if he wished, holding it there against the current if necessary by adding a weight or weights to his line; alternatively he could let his bait drift down with the current. By using a float or bobber, that is, a buoyant article like a piece of cork, he could suspend the bait at a desired depth. The float also acted as an indicator, its sudden movement or submersion warning him that a fish was nibbling his bait or taking it into its mouth.

Trolling.—By this method the bait is trailed behind a slowly moving boat. The bait is either a small fish or some lure which, when drawn through the water, spins, wobbles or vibrates. It is a very old method of catching fish, particularly large fish, and has been used, for example in the South seas, since earliest times. In the 19th century the term "trolling" was used in Great Britain to describe early forms of bait casting and the term "trailing" was used to describe trolling.

In South Africa still, what in the United States is called casting or bait casting and in Great Britain spinning is often referred to as trolling. This is, however, an exception and the term has come to be generally used to describe the trailing of a lure behind a boat.

Bait Casting and Spinning.—This is the casting of a lure or minnow, or a dead fish, which when drawn in by recovering line or when influenced by current imitates a small or wounded fish, frog or other bait. Of much later development than the other three methods, bait casting is linked in its growth with the invention and improvement of the fishing reel. In Great Britain all bait casting is called spinning; in North America the term "spinning" refers only to the casting of a lure using the fixed-spool or spinning reel, and spin casting designates the use of the enclosed fixed-spool reel.

Fly-Fishing.—Generally thought to be a modern development, fly-fishing is in fact a very old form. In the 3rd century A.D., the Roman poet Aelian described the way the Macedonians caught trout with an artificial fly and gave the "dressing," that is, the materials and method of making the fly they used. Dame Juliana also gave this dressing as did Izaak Walton in 1653, and this same fly is still used with only minor alterations.

In fly-fishing the angler seeks to imitate with silk, feathers, hair, wool and other materials the flies and insects that live in or near water and on which many fish feed. Artificial flies can also be lures which imitate small fish or other bait, or confections, which, for reasons only to be guessed at, arouse curiosity and rapacity in fish.

2. Development of Equipment.— The four basic methods of fishing outlined above have remained fundamentally unchanged, but gradual improvements in fishing tackle have allowed man to cast farther, to cast more accurately, to present his bait, fly or lure in a more natural and lifelike fashion and to handle hooked fish with greater certainty. The history of fishing as a sport is therefore largely the history of its equipment.

At the end of the 15th century, man fished, as he hunted, for pleasure and to obtain food. His tackle had progressed little in 3,000 years. His rod was a massive pole, about 15 ft. in length, made from local woods and hooped at both ends with iron. His line, probably of plaited horsehair, was tied to the end of his rod and his hook, bound to a strong single strand of horsehair, was attached to the end of the line. His effective casting range was the length of his rod plus the length of the line, so the greatest caution had to be exercised in approaching the water and every advantage of cover taken.

Even more difficult was the handling of a big fish after it had been hooked. The angler, having no running line, had to tire the fish within the limits of his rod and his short line. If a fish insisted in swimming away beyond these limits the fisherman had either to hold him with the risk of breaking his tackle or to throw his rod into the water, let the fish tow it round until it tired, and then recover his rod and renew the struggle.

This primitive and limited equipment was to endure for another 150 years, through a century and a half of constant and rapid progress in almost every other field. During this period of restless invention, no one offered the simplest idea to extend the range of the fisherman; it was not until 1651 that Thomas Barker, in his Art of Angling, mentioned a ring of wire on the top of a rod and a simple form of winch which held, retrieved and released line to run through this ring. Four years later, in the second edition of The Compleat Angler, Izaak Walton mentioned the use of a reel to hold the line. He wrote, "Note also, that many use to fish for a salmon with a ring of wyre on the top of the rod, through which the line may run to as great a length as is needful when he is hooked. And to this end, some use a wheele about the middle of their rod, or nearer their hand, which are to be observed either by seeing them or a larger demonstration of words." Walton was obviously writing about a piece of equipment of which he had little knowledge and no practical experience. That so passionate an angler should not have used so fundamental an improvement shows that the use of reel and end ring was still exceptional.

The angler, then, in Walton's day was just beginning to have an opportunity to extend the scope of his activities. A crude reel and running line permitted him to cast his bait or lure a little farther and to allow a fish to run well beyond the old limits of a line fixed to the end of the rod. He had other advantages too, for by 1655 Charles Kirby, a London hookmaker, had greatly improved the quality of the fishhook by using improved methods of tempering and hardening the metal. The hook, with an offset bend of the point, which he invented and which bears his name, is still in use all over the world. In 1613 there was mention of a landing net. although it is likely that this piece of equipment, which is used to lift a large fish out of the water, was in use a century or so before. In 1657 Barker mentioned the need to use a line 26 yd in length (five times more line to play a fish with than was given by the old tight-line method) and a "landing hook," which is now called a gaff. This is a large hook attached to a shaft which is used to lift large fish ashore or into a boat. While the use of horsehair as a scarcely visible link between hook and line was to continue into the 20th century, experiments were made with other materials. In 1667 Pepys wrote of using a gut string with a minnow as a bait, while in 1676 Col. Robert Venables mentioned the use of a lute string. Of less use to the fisherman of those times was a patent made out to one Thomas Grant in 1632 for a "fish call or looking glass to lure fishes to net, spears, or hooks." one of the first 60 patents ever granted in Britain.

Despite much progress in the development of fishing tackle, however, the improvement of having wire rings, or guides, throughout the length of the rod and not only at the end is not mentioned until 1726. The nature of the reference in the Gentleman Angler makes it clear that such rings and the use of a "winch or wheel" were far from common.

About this time a transfer of the manufacture of fishhooks from London to the small Worcestershire town of Redditch was to have a far-reaching effect on the angler's equipment and thus indirectly on his methods and his sport. Until this period the fishhook trade had been centralized in London and to a much lesser degree in Yorkshire and Ireland. About 1730 the needle industry was establishing itself in Redditch and was quick to see, and seize, a kindred product. In the space of about 70 years the whole of the world trade in fishhooks had become centralized in this town. Not only was the making of hooks greatly improved, but the Redditch manufacturers progressed from these articles to other items of tackle, and gradually from what had been a cottage industry grew the first organized factories concentrating on all types of angling equipment.

Although it seems that relatively few fishermen took advantage of the increased scope given by a fishing reel, progress continued to be made. In 1770 a London tackle dealer was advertising "brass multiplying reels"—reels which were geared to give increased winding speed. Such reels never became popular in Great Britain, and although it seems certain they were first made in that country, they were developed in the United States, where George Snider of Kentucky pioneered this type of reel in 1810. Indeed from the beginning of the 19th century progress in equipment. and especially in fly-fishing equipment, ran on very parallel lines in both Great Britain and the United States. In North America, however, most of the fish are predaceous and the Americans therefore concentrated on bait-casting tackle; in Great Britain, where few fish are wholly predaceous, the emphasis was on bait fishing.

Another great step forward was taken between 1840 and 1850 with the development in the area of the river Trent of what became known as the "Nottingham" reel (fig. 1). This reel, made first in wood and later in metal, spun very freely on a spindle or "centre pin." It had an enormous effect on many sorts of bait fishing, for it allowed float and bait to proceed unchecked with the current and greatly increased the area that a river bait fisherman could cover efficiently. It also permitted a heavy lure or heavy tackle to be cast a long way and was therefore to lead to great progress in casting and in sea fishing, besides having considerable effect on the design of reels for fly-fishing.

Rods, too, were being improved, although the process was a slow one. Early in the 19th century the tips of rods were being made from several strips of cane glued together, and by 1847 tips made of six strips were known in Britain. There is divergency of opinion as to who made the first complete rod in the hexagonal form but it seems likely it was made in the United States between 1865 and 1870. About this same period, too, there were improvements in turning rods, particularly those in greenheart, a South American wood, and rods gradually started to become lighter and shorter.

Progress on lines was likewise slow and although silk, cotton and flax lines began to be used from about 1850. horsehair. sometimes mixed with silk, remained popular until almost the beginning of the 20th century. The period from 1870 until the beginning of the next century was the second great era of development in fishing methods and equipment.

Rods became still shorter and lighter, and anglers began to give up the heavy rods made from native woods like ash, and even the lighter woods like greenheart, in favour of the much lighter and more efficient rods built from strips of cane in hexagonal form and known as split, or built, cane. The wire rings through which the line ran, the fittings to hold reels in position and the ferrules used for joining the parts of the rod together were all lightened and improved. Silk lines came into general use and fly lines began to be "dressed"; that is, covered with coats of linseed oil which was then allowed to oxidize. These dressed lines were far heavier than the old horsehair lines, could be cast much farther, and most important, could be cast against a wind. The use of these lines altered the whole concept of fly-fishing and resulted in the use of the floating fly. Silkworm gut, first mentioned in 1722, at last began to supersede horsehair as the link between line and hook.

It was in the field of fishing reels, however, that the greatest progress was made, both in improved materials and improved design. The distance a lure could be cast was greatly increased, first by a method of coiling loose line in a basket and casting out these coils, and then, as the Nottingham reel was improved and became more and more free running, by actually casting from the reel.

In the United States, progress was made in the same may and in similar fields. The fly rod became even lighter and shorter than those in Great Britain and fly lines likewise were greatly improved. The multiplying reel (fig. 2) became a precision tool and, having much less spool inertia than the British Nottingham reel, became a much better casting instrument. This lack of inertia, coupled with the fact that bait casting was often practised from a boat, led to the short bait-casting rod of between four and six feet.

In 1896, William Shakepeare of Kalamazoo, Mich.. invented the level-wind. a mechanism which traversed back and forth across the spool as the reel revolved and laid the line level upon it. About the same time wooden lures, called plugs, were also developed.

The difficulty of casting direct from a Nottingham reel and the skill required to control such a reel when casting led to the invention that was to have the greatest effect on angling. A long rod and a casting weight of at least one-quarter of an ounce were required to set the reel in motion and unless it was skilfully controlled throughout the cast the speed of the reel overtook the speed of the line and a tangle resulted. Between 1878 and 1884 reels were developed which operated on a turntable system. To cast, the reel was turned so that the axis of the reel lay along the rod instead of across it. This allowed the line to slip in coils over the edge of the spool instead of running out with its rotation, thus eliminating spool inertia. The line was recovered by turning the axis back to the normal position and winding in. These reels made casting easier, but they had certain disadvantages, in particular in the way they twisted lines. In 1905, however, Holden Illingworth, a Bradford, Eng., textile manufacturer, patented the first fixed-spool, or spinning, reel, on which the spool remained stationary with its axis along the length of the rod and on which the line was recovered by a bail, or flyer. Two years later he greatly improved this reel. The main purpose of the Illingworth reels was to cast very light baits, and the seven-foot rod he designed for use with them remained basically unaltered. This type of reel was gradually improved as the years went by and began also to be used on the continent of Europe. In Great Britain, however, the lack of game fish and limitations set on spinning for trout restricted development except in the field of float fishing.

3. Developments After World War II.—Great improvements in fishing tackle were made after World War II. Fixed-spool reels (fig. 3) enjoyed wide popularity in Great Britain and on the European continent, where their manufacture was taken over and improved by specialist firms such as, for instance, French clockmakers. After the war they were also introduced with enormous success into the United States and other countries.

In the United States rods made of glass fibre are favoured over those of all other materials. In Great Britain and Europe, however, the split-cane rod still holds pride of place and the glass-fibre rod has not found great popularity. The fixed-spool reel has been

FIG. 3.— FIXED-SPOOL REELS: (TOP) CLOSED-FACE: (BOTTOM) OPEN-FACE

further improved and the use of nylon monofilament lines with it has greatly increased its efficiency. In the United States a different type of fixed-spool reel, one with an enclosed spool, the closed-face or spin-casting reel. has been perfected and has won wide popularity (fig. 3). Paired with the flexible and highly active glass-fibre rod and using 6 to 10 Ib. test lines and $\frac{1}{8}$ to 1 oz. lures; the spin-casting outfit is preferred in some areas. Lines are made from various man-made fibres and fly lines have been greatly improved by plastic dressings. The wide use of plastics has lightened and improved many other articles of fishing equipment.

Equipment in the second half of the 20th century was further improved: tackle was made lighter and simpler to use; the effective casting and fishing range became almost unlimited. Yet with all these advantages, the angler still has to locate the fish and ofier them the right sort of bait or lure in such a way that it appears natural and does not alarm them. He must still be able to read the weather and understand water. Angling, like other field sports, remains basically a matter of applied natural history.

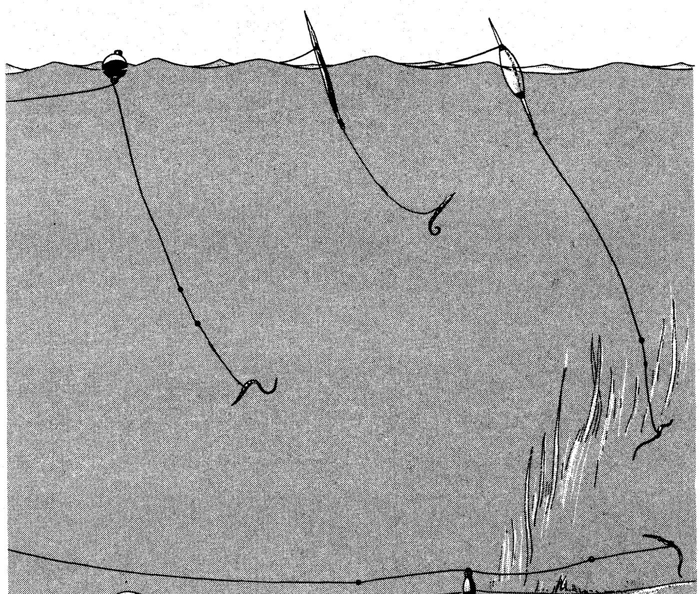
4. Angling Literature.—–Most of the best writing on fishing has been in English, for up until World War II nearly all the advances in all forms of fishing as a sport were made either in Great Britain or in North America. Izaak Walton set the standard with *The Compleat Angler*, the greatest of fishing books. and the works of Thomas Barker, Col. Robert Venables, W. C. Stewart, F. M. Halford, George La Branche, E. M. Hewitt, G. E. M. Skues, Robert Hartman and, more recently, A. J. McClane, Ted Trueblood. B. Venables and R. Walker, to mention very few, will long be read with both profit and enjoyment by fishermen everywhere. In France too, the writings of L. De Boisset and of Charles Ritz are more than uorthy of what Walton called "the contemplative man's recreation."

II. FRESH-WATER FISHING

1. Bait or Still Fishing. — This term has been used in the most general sense to describe one of the four basic methods of fishing. There are, however, a large number of ways of still fishing with bait. All involve the use of hook and line and, for most sport fishing, a rod or pole Fishing from the banks of a stream, a pond or a lake. from a pier or breakwater, or from an anchored or drifting boat are the most common methods. A large number of different baits are used, according to the species of fish sought and the type of nater being fished. A float or bobber or some other signaling device. as a trip (see Ice Fishing, below), may be used but frequently is dispensed with in deep lakes or choppy nater The discussion of float fishing below indicates the basic techniques and tackle involved. (In the United States, especially in the Ozarks and the middle west, the term "float fishing" also refers specifically to a float trip in which the fishermen drift in a boat down a selected stretch of river, fishing as they go.) Float fishing and ledgering (using a sliding sinker to fish a bait on the bottom) are both known as coarse or bottom fishing in Great Britain *(see* under *Great Brztain* and Ireland, below).

Float *Fishing* —*A* float, or bobber, is a small buoyant object used to suspend the bait at a given depth, and to act as an indicator that a fish is taking or has taken the bait. It is also used as a means of conveying the bait to where the fish are known or suspected to be Float fishing has been brought to a high degree of efficiency in England, where it is mostly employed to catch the species classed together as "coarse fish." The methods used in England will therefore be described. and other types of float fishing used elsenhere will be discussed as variations of these methods.

Tackle — Float tackle consists of the line, the float and the equipment below it in the water (fig. 4). At the very bottom is the hook. which usually is attached to a length of nylon monofilament called a leader. The distance between float and hook depends on the type and depth of water being fished and the species of fish sought. A number of small lead weights, or sinkers, may be used. These are usually small lead shot, partially split so they



(TOP LEFT AND BOTTOM) T B THOMAS

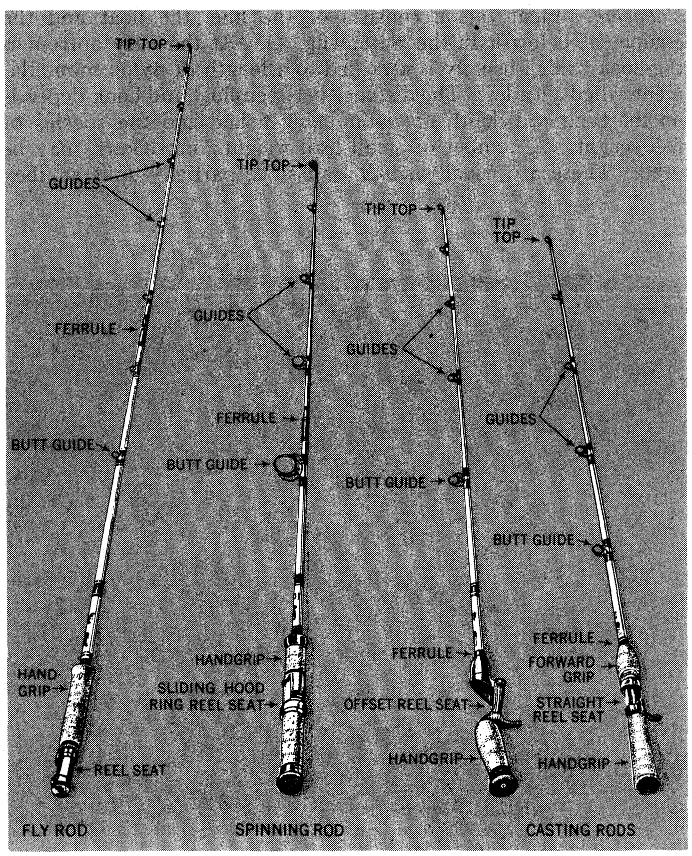
FIG. 4 —FLOAT TACKLE (TOP. LEFT TO RIGHT) BOBBER. PORCUPINE QUILL. ANTENNA; (BOTTOM) LEDGER

can be clamped on the line between float and hook. Their purpose is to give added casting weight; they "cock" the float, that is, cause it to ride upright in the water so that any indication of the bait being taken (a "bite") is seen. Sinkers also are used to suspend the bait at the right depth or, if there is any current, at the right depth and in the right position in the current, or to keep it on the bottom of the river or lake.

The question of depth is important for the float fisherman, for much of his art consists of presenting the right bait in a lifelike manner at the depth at mhich his quarry is feeding. Fish, according both to species and to prevailing conditions such as the water temperature, the strength of the current or the time of year, may be feeding just under the surface or at various depths right down to the bottom. The angler must first decide at what level he is going to fish. This he generally does by attaching a lead weight to his hook and taking soundings to determine the depth of the water. Then he adjusts his float, usually by means of metallic. rubber or plastic rings which hold it to the line, so that his bait "fishes" at the depth at which he reckons the fish to be.

The angler's line is attached to a leader and is usually between 25–100 yd. long. of nylon monofilament, braided nylon, Platyl or Terylene. This line is held on a reel which will either be of the Nottingham type or more likely a fixed-spool reel.

The float-fishing rod used in England is a long one, usually 10–15 ft. Such length is essential, for the waters fished often require 10–15 ft. of terminal tackle and without this length of rod it would be difficult to cast such tackle or land a fish. Because such rods are held for long periods, they must also be as light as possible. They are usually made in three pieces and at least two-thirds of such rods are made of light, "whole" bamboo cane. The best canes for this purpose are tonkin, from China, and Spanish reed from Spain and the south of France. Rods of this type have a number of wire rings (guides) along their length through which the line runs. uith a big ring at the butt and a smaller one at the tip usually made of agate or some similar hard substance. The handles are made of cork and they have a simple system of two



FROM "THE WISE FISHERMEN S ENCYCLOPEDIA." ED BY A J. MCCLANE, BY PERMISSION OF WM. H. WISE & CO., INC. PUBLISHERS

FIG. 5.— BASICTYPES OF RODS USED WITH DIFFERENT REELS

sliding rings to hold the reel in place.

In the United States a lightueight telescopic rod made of glass is preferred Bait-casting, spinning and spin-casting rods also are used for still fishing on occasion, and the traditional long bamboo "cane pole" prevails in many locations It is used without a reel, a length of line being tied to the tip of the pole, which often is of one piece

Ice *Fishing* —This winter sport is especially popular in the northeastern United States and the upper Mississippi-Great Lakes-St Lawrence valley region of the United States and Canada The ice must be thick enough—usually a minimum of three inches—for safety and holes are cut through it with an ice bar, a heavy, long-handled chisel, or spud, or an ice auger; a dipper is used to clear the chips from the hole One fisherman can tend several holes. Minnous. grubs and nymphs are favoured baits, usually used with a very small jig or ice spoon. Equipment commonly includes a short (three feet), uhippy, glass-fibre rod with a simple centre-pin reel or a cleatlike device to hold a nonfreezing monofilament line and a tipup or tilt (see fig 6) that signals when a fish has taken the bait; it is allowed to run before the hook is set For larger fish the tipup may hold the reel in some models below water to prevent freezing Many pan fish (mostly crappies bluegills and perch) are caught, but also northern pike especially in the Great Lakes region, walleye. pickerel; bass and lake trout, with occasional catches of other species. Ice fishing usually is done with one or more companions and frequently large groups take part.

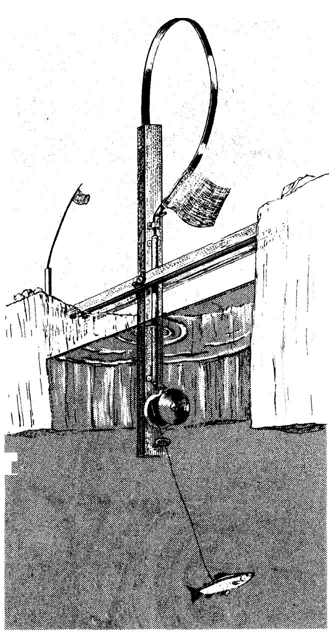


FIG 6 — ONE TYPE OF TIPUP ASSEMBLY ICE FISHING

2. Trolling.—Trolling is generally used on waters where fish are hard to locate and in particular for fish that swim deep in the water. It is used all over the world but has been brought to its highest peak of efficiency in North America. There is considerable skill involved in trolling the right bait at the right speed and depth in the right places. Local knowledge is of particular importance in this type of angling.

Lures for trolling are numerous. Any of the lures described below (see *Bait Casting* or *Spinning),* or a live or dead fish or other bait mounted so that it spins or wobbles. may be used. These are trailed slowly behind a rowboat or one driven by a motor. The amount of line out controls the depth at which the lure is worked. In deep waters and for deep-swimming fish, metal lines are sometimes used.

The rod used is usually short, between five and seven feet, although longer rods are used in Great Britain and Europe. The rod is held or placed roughly at right angles to the direction in which the boat is moving so that the recovery (resiliance) of the rod tip helps to hook the fish.

A slightly different type of trolling is used in Britain and Norway for Atlantic salmon. This is known as harling and it is practised in rivers. The lure is fished from the stern of the boat in the usual manner, but instead of towing the bait, the boat is held by the oarsman in the current and the flow of the stream causes the bait to behave like a small fish. In this way the lure can be held over the parts of the river where fish are thought to be resting.

3. Bait Casting or Spinning.—Bait casting is the North American term for casting out a bait, plug or lure and recovering it with a multiplying reel. Spinning and spin casting refer to the use of fixed-spool spinning and spin-casting reels. In Great Britain, on the other hand, spinning refers to all of these methods.

Casting tackle consists of a rod, from 5 ft. up to about 10½ ft. in length. a reel containing about 100 yd. of line. a leader, or trace. and the lure. The line is usually of either nylon monofilament, braided nylon. Dacron or Terylene. The leader, or trace, which is the scarcely visible link between line and lure is usually of nylon monofilament or, if used for fish with sharp teeth, wire. It may be fitted with one or more swivels to prevent the line from becoming twisted. Leaders may be from nine inches to four feet Iong.

There are very many different sorts of lures. A small fish, mounted to spin or wobble through the water, is now little used.

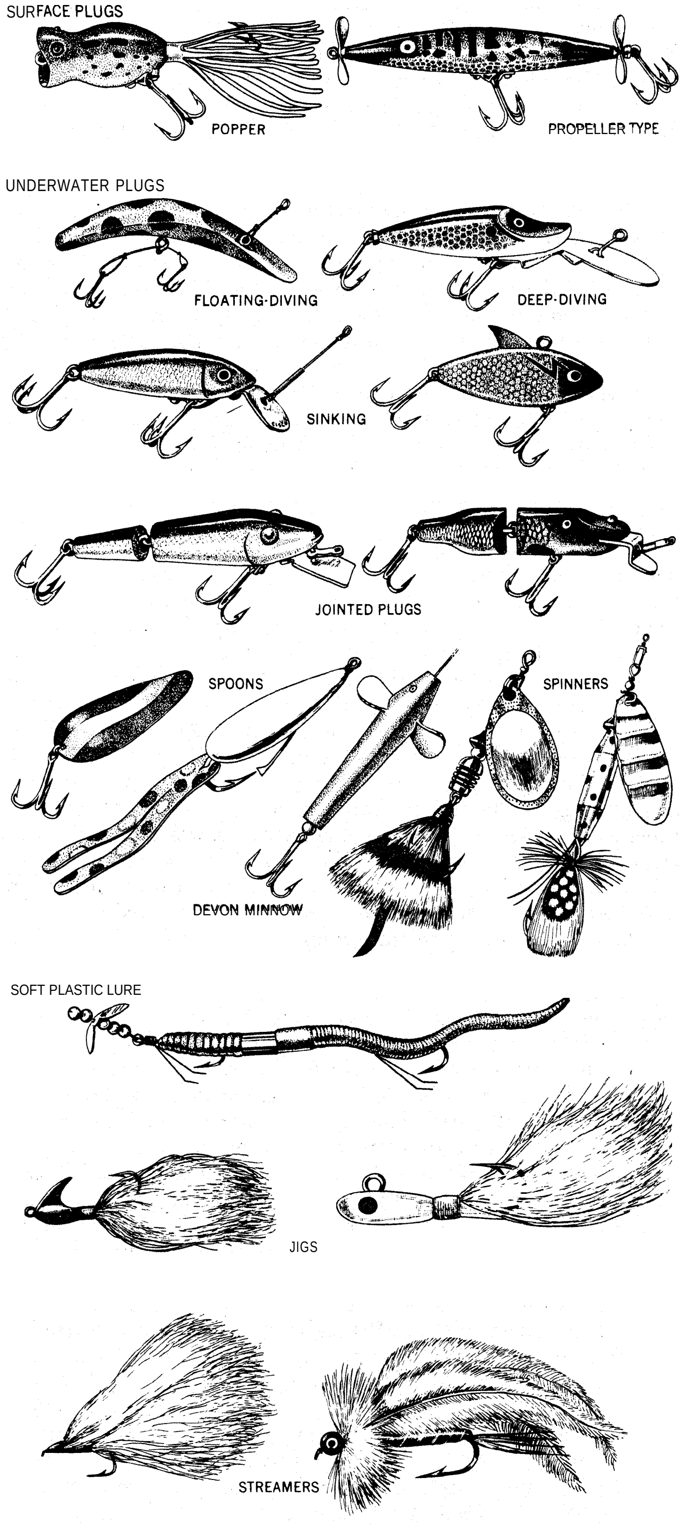

FIG. 7.— REPRESENTATIVE SELECTION OF FISHING LURES

In Xorth America plugs, lures first made of wood but now mostly of pliable plastic in a vast variety of shapes. colours, sizes and weights and behaving in a most lifelike way when drawn through the water, are used (fig. 7).

In Great Britain the most popular lure for many years has been the Devon minnow, a cylinder of wood, metal or plastic fitted with two fins which cause it to spin. Spoons, that is spoon-shaped metal lures which spin, wobble or vibrate, are used all over the world.

Although the methods of fishing are similar, the methods of casting with the three different types of reel—the centre-pin, the multiplying and the fixed-spool—are very different.

The centre-pin reel is now little used. It is difficult to cast with becduse of the considerable inertia which must be overcome before the drum of the reel will start to spin. Once the drum does start to spin, however, it spins too fast for the bait, which decreases its speed as it travels through the air, and unless it is controlled the speed of the line being drawn off the reel becomes much slower than the speed at which the drum is revolving and a tangle of the line results.

The centre-pin reel is used with a rod 8½–10½ ft. long. The rod must be limber so that the build-up of casting power which causes the reel to start to revolve is gradual. The lure is swung back behind the angler and then forward and upward. The reel is prevented from spinning during the swing but this pressure is released early in the forward cast. As the lure flies out over the water the speed of the drum is controlled either by finger pressure or by some form of governor so that it does not exceed the speed at which the line is being drawn off. While these reels are difficult to cast with. and their rate of recovery, being ungeared, is slow, they are excellent reels with which to play fish.

The multiplying reel is less difficult to use, as its drum is much lighter than that of a centre-pin reel. A shorter rod and a shorter swing can be used. These reels are mounted on top of the rod, and the drum is controlled by pressure from the thumb so that its speed does not exceed that of the line. Sumerous forms of governors are in use to control the drum speed automatically.

In North America and in parts of Scandinavia multiplying reels are mostly used with a short. single-handed rod of between 4½ and 6 ft. The lure is propelled with a short, snappy, overhead cast which gives great accuracy. In Great Britain these short rods are little used and, as the multiplying reel is there used for large fish like pike and salmon, a longer double-handed rod of eight to ten feet is generally employed; longer rods, usually about nine feet, are used likewise on the uestern coast of North America for steelhead (trout) and Pacific salmon. The gear ratio of multiplying reels normally is four to one; the rate of line recovery is therefore very fast.

The methods of fishing are the same the world over and irrespective of the species of fish sought. On rivers the cast is usually made across or slightly donnstream. If the current is strong enough to impart fishlike motion to the lure by causing it to spin or wobble. the angler does not wind in. In slower water he assists the current by winding slowly. The depth at which his lure is "fishing" is again very important, and leads may be used to sink the lure down in the current.

Another effective way is to cast the lure upstream and to recover it donnstream by winding very fast. In Great Britain this is a particularly effective way of catching salmon in the summer.

Probably the most interesting iorm of casting is that practised in North America particularly for black bass These fine sporting fish like to lie in weedy water in the vicinity of snags like old logs. The angler, approaching carefully in a boat, casts a floating lure from either a bait-casting or a spinning reel. Considerable accuracy is essential, for the lure must be dropped precisely in the right place Having cast the lure to where he thinks a bass lies, the angler moves it gently so that it causes a slight commotion bn the surface, as would a frog or a swimming mouse. The accuracy needed the savage way in which a bass takes the lure and the excitement of being able to watch the lure working makes this as exciting a method of casting as the dry-fly is of fly-fishing.

When a fish is hooked. it is played by allowing it to pull against the spring of the rod and is allowed to swim away from the angler by being given line from the reel. With the revolving drum reels. that is, the multiplier and the centre-pin, line is given by allowing the reel drum to rotate backward, but with the fixed-spool reel this obviously cannot happen. These reels are therefore fitted with a slipping clutch, the tension of which is controllable. This tension is set so that when a fish exerts a certain amount of pull the spool is allowed to rotate and line given in this way. The rotation is also controllable by finger pressure.

With the centre-pin or "single action" reel, line can be recovered against the pull of the fish by winding, for the wind on these reels is direct and not through gears. With the other two types, however, the angler cannot exert enough pulling power through the gears and has therefore to use his rod as well, in a method known as pumping The point of the rod is dropped and as it is lowered the angler winds in line. He then clamps his thumb on the multiplier or his finger on the fixed spool so that neither will rotate and raises his rod, thus recovering line, repeating the process until the fish is brought close to him.

The spinning. or fixed-spool, reel is initially much easier to use tha'n the other two. although maximum efficiency requires considerable skill. practice and dexterity. 4 s the line slips off the end of the spool, there is no inertia to overcome and as the drum does not revolve there is no problem of control to prevent line tangles

There are two types of rod ,used with these reels—a single: handed one of from 4 to 8 ft and a double-handed one of $8\frac{1}{2}$–$9\frac{1}{2}$ ft. With both types the method of casting is similar. More importantly, there are two types of reel, the bail and the closed-face (spin-casting). With the bail type the right forefinger gathers and holds the line. The pickup mechanism or bail, that is, the mechanism which recovers the line on winding in, is lifted so that it no longer retains the line. The cast is then made, the forefinger releasing the line very late on the forward swing. To reel in the line, the pickup mechanism springs forward and as the handle is turned collects the line and distributes it onto the spool.

In the latter half of the 1950s spin-casting reels which uere a combination of fixed-spool and multiplying reels were perfected in the United States: the line peels off the drum in the same way as nith a stationary drum reel but the drum is enclosed in a bell-shaped cover. They are used on top of the rod like a multiplier and controlled in the same way by the thumb. These spin-casting reels are extensively used in North America and in Scandinavia.

The lack of inertia of these reels enables them to cast much lighter lures than the other two types. They are, however. intended for use with fine lines, and with lines of more than ten pounds breaking strain they progressively lose efficiency. This is because with thicker lines the gap between the top of the line on the spool and the lip of the spool widens rapidly, with consequent increase in friction.

Rods used with spinning reels require a large butt ring (the first ring up the rod). The line peels off these reels with a considerable cone and the large ring cuts down friction and prevents the cone from flapping against the rod. This is not the case with spin-casting reels so spin-casting rods do not have a large butt ring.

4. Fly-Fishing.— In this sport the angler uses a natural fly or. very much more commonly, an artificial fly made from silk, furs, feathers and other materials, so that it imitates one of a large number of flies which live in or near water. Flies are also made which imitate small fish, worms or other bait, while the flies used to catch salmon imitate nothing in nature. Sometimes flies that imitate frogs or mice are "tied" or "dressed" for black bass fishing. The original purpose of the artificial fly was to imitate some insect, however, and most 20th-century fly-fishing is with insect-imitating flies rather than with lures.

While fish feed on an enormous number of different flies, both aquatic and terrestrial, the basis of fly-fishing is the imitation of two insect groups found all over the world. Ephemeroptera and Trichoptera (caddis flies). in their various stages of development.

The first-named are known to fishermen as May flies, ephemerids or upwinged flies. Broadly speaking. their life cycle is in three stages—as nymph. subimago or dun, and imago or spinner—and each stage is imitated by fly-fishermen (*see* MAY FLY). Not dissimilar to the life of the May flies is that of the very many species which make up the insect group Trichoptera—the flies the angler knon s as caddis flies or sedges (*see* CADDIS FLY). Imitation of the different stages in the lives of these two groups of flies has developed the different methods of fly-fishing

Excluding salmon fishing, a totally different problem which will be dealt with separately, the various methods of catching trout with a fly can be applied, with perhaps slight Iocal differences. to the catching of other fish For this reason fly-fishing in general will be described on the basis of fly-fishing for trout.

The use of the natural fly is a style of angling little used but one no doubt of great antiquity. This method of fishing is known as dapping. One style of dapping is used with a very short line, using some insect such as a bluebottle, crane fly or grasshopper as bait. It is practised on bushed streams and the angler, concealing himself behind or in a tree lowers the impaled insect to struggle on the water and thus attract trout. Another form of dapping developed on the Irish and Scottish lochs. The bait is generally either the May fly, the largest of the upwinged flies, or the crane fly or. daddy longlegs. The rod is long, 14–15 ft. in length. and the line very light, with floss silk (embroidery floss) attached near its end. One or two flies are impaled on the hook and fly, and floss silk and line are allowed to blow out over the water with the wind, which is essential to this form of fishing. The fly is lowered onto the water well away from the boat and thus behaves in a very natural manner. Another form of fishing with a natural fly is practised in the maritime provinces of Canada in the spring. One or two of the ephemerids which hatch there in May are hooked onto a small hook called a midge hook and cast out onto the water. Such types of fishing obviously have many limitations, not least the difficulty of keeping the fly on the hook, and no doubt this prompted anglers to make imitation flies.

There are two main methods of fishing with the artificial fly—wet-fly fishing and dry-fly fishing. In the former the fly is used under the water, where it imitates a nymph, a drowned dun, some other water insect or a small fish. In the latter the fly floats on top of the water and represents a dun, spinner (spent spinner) or caddis fly (sedge), or some terrestrial insect blown onto the nater.

Wet-fly fishing is by far the older of the two methods, for fishing with a floating fly was only developed toward the end of the 19th century. Originally men fished with a 12- to 14-ft. limber rod, a tapered line of horsehair, a leader or cast of horsehair and the fly Fishing consisted almost entirely of casting across a stream and allowing the fly or flies (for with the wet fly several flies are often used) to swing round in the current. It was not until Stewart wrote The *Practical Angler* in *1857* that the advantages of fishing upstream were demonstrated. Trout and other fish swim nith their heads facing upstream and Stewart showed that they could be approached much more simply and effectively from below and that the fly cast in this manner behaved in a more lifelike way. The method was easier to describe than to perform. The sport was dependent to a great extent on the wind, for it was impossible to cast against it, and, because long casting was not possible with so limited an outfit, a wind-ruffled surface allowed the angler to approach within range of the trout. It was not until the 1880s that rods and, above all, lines were improved enough to enable the angler to cast in any direction under most conditions of wind.

The development of the split-cane rod and the heavy, oil-dressed line brought about great changes in fly-fishing. The wet-fly fisherman was enabled to cast a much longer line, upstream or downstream. In Great Britain the concentration was first on the floating fly and then on improved ways of representing insect life just below the water's surface. In the United States progress was initially a little behind Great Britain in these two types of fishing, but similar styles were soon developed to suit the local conditions; the American angler also saw an advantage in the heavy line that his British counterpart overlooked. By its weight, and with a long cast. the heavy line enabled a fly, either one imitating some water creature or one representing a small fish. to be fished deep down in the water. Methods using the sunk line have been used for many years in North America and, as a result, in many other countries. Such methods are still, however, little known or used in Great Britain.

Before examining in greater detail the individual methods of catching fish nith an imitation fly. it is necessary to explain how the fly is cast and thus presented in different ways.

The only aeight that assists the angler to cast a fly is the neight of his line Until the 1880s lines were undressed—that is, they were not covered with the coats of oxidized oil and. later, plastic that now render the line relatively heavy. The modern line may be level (a line of between 20–30 yd of the same diameter throughout), double tapered (tapering from a fine end up to a thick middle and back to a fine end), or forward tapered (tapering quickly to a thick portion and then quickly back to a long, fine back end).

This line is used aith a limber, springlike rod With some yards of line lying on the aater in front of him, the fisherman lifts his rod sharply from a position roughly horizontal to a position just past the vertical. As the rod is moved to the rear. the neight of the line and the pull of the water cause it to bend When a position of just past the vertical is reached the rod is stopped. As it recovers and straightens itself it throws the line upward and backward in a loop. The caster allows this loop to straighten until the line is nearly straight out behind him He then brings the rod forward through the same arc and the line follows. behaving in the same way as when it was thrown to the rear. To lengthen the line the caster holds a few yards in his left hand which he releases late in the forward stroke. The weight and impetus of the line going forward carries out this slack line. This lengthening of line is called shooting.

A leader or cast is tied to the end of the line This is a two- to three-yard length of nylon monofilament or transparent silkworm gut The fly is tied on the end; if more than one is used these are tied to short lengths of nylon or gut, called droppers, which are attached at intervals to the leader.

There are many styles of wet-fly fishing The angler. wading in the nater, may cast a short line upstream, pulling the flies toward him at a rate slightly quicker than that of the current by lifting his rod so that they represent the nymph just before emergence He may imitate the same stage in the fly's life by casting a longer, floating line upstream, and letting his flies drift down with the current He may cast a short line across the stream and allow his flies to swing with the current or, holding his rod high, allow the droppers to play on the surface of the water (dapping) like a dun struggling to leave the surface or a caddis fly dipping as it lays its eggs He may cast a long, heavy line across and downstream and allow his fly to sink well down, imitating a small fish or a nymph swimming on the bottom. The skilled angler uses each method according to the prevailing conditions. If his fly is close to the surface the strike or "take" of a trout is revealed by a movement in the water which he calls a rise. If he is fishing deeper he feels a pull on his line. In either case he raises his rod and sets the hook.

In dry-fly fishing the lure is manipulated to imitate a fly floating on top of the water. While a wet fly is slim and sparsely dressed so that it sinks easily, the dry fly is fuzzy. When the fly becomes wet and sodden the dry-fly fisherman whisks it through the air a number of times to dry it.

There are tao sorts of dry-fly fishing—fishing to the rise and "fishing the water." In the former the angler is casting his imitation to trout that are feeding during a hatch of fly. The correct choice of fly under these circumstances is crucial, as feeding trout become conditioned to eating just the one type of insect and will ignore every other sort which is brought down by the current. Fishing to the rise is a particularly interesting and exciting sport, for often the trout can be plainly seen in the water and the fisherman is trying to catch one individual fish.

In the other type of dry-fly fishing the trout are not activelv feeding. Here the angler casts his fly, searching the water for a fish which can be tempted and paying particular attention to parts of the stream where his experience tells him a trout may be lying.

Both wet and dry flies are used on lakes as well as on rivers and streams, though the most common form of lake fishing is mith wet flies from a boat. The boat is allowed to drift with the wind and the angler casts in front and to the side. A dry fly is sometimes used, particularly when there is a hatch of fly. Lakes are also fished by wading, as in streams. in shallow waters along the shores, and from the bank; a particularly popular sport in Great Britain is fishing from the shores of reservoirs which have been stocked with trout. This type of fishing often requires very long casts. and specialized, powerful rods are needed.

The tackle used for these different types of fishing varies greatly. Rods run in length from about 7 ft.. used on small streams, to $10\frac{1}{2}$ ft., still used for boat fishing in Scotland; most rods run between 7 and 9 ft., being generally about 6 in. shorter in North America than in Europe. Rod actions, that is, the degree of stiffness depend on the type of fishing and the weight of line it is necessary for them to cast. A rod for big migratory trout, such as the American steelhead or the European sea trout, obviously needs to be more powerful than a rod for trout of, say, a pound in weight.

FIG. 8.— SINGLE-ACTION FLY REEL

The line is the most important part of the fly-fisherman's equipment, and must be of the right weight to bring out the power of the rod. At the same time, for dry-fly fishing, it must not be too heavy, for it has to float. The reel is a simple, single-action type, often in North America with an automatic, spring-powered pickup that rewinds any free line, of the right weight to be in harmony with the rod and big enough to contain sufficient line for the type of fishing for which it is used.

There are many different types and patterns of artificial flies, usually named after the fly they imitate (*e.g.*, March brown), the materials from which they are made (*e.g.*, snipe and purple quill) or the inventor (*e.g.*, Greenwell's glory). Local conditions dictate the shape and nature of local flies. for a rough river will need a different type of fly from that used for a smooth stream or a lake. Thus there are the well-hackled dry flies of New York state, designed with a big tail to ride on rough water, and the spider flies of Yorkshire, sparsely dressed wet flies made of soft hackle, ideal when fished just under the water on a fast river. All over the world there are fly dressers who. working either in factories or individually, create flies of silk, fur and feather. Many anglers tie their own flies. finding both pleasure in making them and added interest in their use.

Salmon Fly-Fishing.—Salmon fly-fishing differs from other types

FIG. 9.— AUTOMATICFLY REEL SHOWING DRIVE MECHANISMS

because these fish, which enter the rivers from the sea to spawn, do not eat during their stay in fresh water. The angler, therefore, is not seeking to imitate some part of their immediate diet. although it is reasonable to suppose the lures which interest them remind them in some way of food they have eaten. Flies tied in a wide variety of sizes, colours and patterns, but not representing any particular insect, are used.

One of the methods of fly-fishing for salmon is known as sunk-line fishing. The sunken fly is principally used early in the year. that is. in North America in April, May and early June and in Great Britain in February and March. Salmon entering a cold river are interested in fairly large lures, fished well-sunken in the water and moved as slowly as possible. The size of fly varies from river to river, from very large flies three inches long down to smaller ones half an inch in length. For this style of fishing the angler uses a heavy line which takes his fly well down in the water, and casts rather more downstream than across, letting his fly swing slowly across the stream with the current.

Greased-line fishing was developed in the early days of the 20th century and was principally the invention of A. H. E. Wood of Glassel, Scot. Wood discovered that even in conditions of low water and warm weather salmon could be caught with a small, sparsely dressed fly fished just under the surface. The object of this style of fishing is to bring the fly across the current in a natural manner. and to keep the fly up in the water the line is greased. With this method salmon can be caught in the summer in low water under conditions which hitherto were regarded as hopeless. In addition, when taking the fly the salmon usually breaks the water in a "head and tail" rise, making this style a particularly exciting one.

It is most unusual for salmon in Britain and indeed in most parts of Europe to take a floating fly. In Canada and on some rivers in Iceland. however, the dry fly is most successful. A big, fuzzy fly is used and the technique is broadly the same as already described for trout.

In the United States and Canada short (8–11 ft.). single-handed rods are used except on one or two very rough rivers in the Gaspé area. In Europe, for the most part, long, double-handed rods of 11–15 ft. are best suited to the prevailing conditions.

III. SALT-WATER FISHING

The four basic methods of fishing are likewise used in salt water. Bait fishing and trolling are widely used; casting and spinning are used much less but are rapidly growing in popularity, especially in U.S. waters; and fly-fishing, although also growing in popularity. is practised only in a few areas and for a few species of fish. While the methods are basically the same as those used in fresh water, the tackle used is often very different due to the conditions of greater depths, wider areas, rocks, tides and currents.

1. Fishing With Bait.—The various methods of bait fishing are commonly used for sea fish, irrespective of whether the angler is fishing from a beach. off rocks, from a pier or from a boat. The baits used are those which form a normal part of the diet of sea fish—worms which live in sand or mud, marine shellfish and small sea fish either whole or cut up. Ground baiting, while not so frequently and extensively used as by the fresh-water bait fisherman, is still used in many parts of the world. Called chum in the United States, and "rubby-dubby" in Great Britain, ground bait consists mostly of pulped-up oily fish, like the North American menhaden or the Cornish pilchard. Bags containing crushed fish are eithet trailed behind a boat or placed so that the tide carries out a slick to draw fish to the bait on the angler's hook. Sometimes the chum is spooned over to drift down tide.

The most commonly used methods are those greatly similar to the fresh-water methods of bait fishing. A lead sinker, sometimes one pound in weight, though more normally four to eight ounces. is used. Shapes and weights vary greatly according to the type of bottom, the depth of the water and the number of hooks, which may be held away from the line and leader by wire or plastic booms.

Such tackle can be cast out from beach or rocks, cast or lowered into the water from a pier or jetty or lowered from a boat to where the fish are known or suspected to be.

Surf fishing, casting from the shore, has long been a popular form of sea fishing in. for example, South Africa and the United States, and this style of angling is probably the one growing most rapidly all over the world. It is a highly skilled form of fishing, for great knowledge is often necessary to locate the fish and very considerable skill is needed to make long casts with heavy weights and to handle big fish in heavy surf.

A long rod, 9–11 ft , is ordinarily used in surf fishing. All three types of reel are used and at one time the centre-pin reel was used a great deal, particularly and with exceptional skill in South Africa. Because such reels are so difficult to control, the multiplying reel, designed for surf casting. is being used by more and more fishermen. The fixed-spool (spinning) reel, used with light tackle, gained greatly in popularity after World War II, especially in North America.

Surf fishing has probably reached its highest degree of skill and the highest degree of organization along the Massachusetts coast. Some surf fishermen camp out on the beach in "beach buggies," vehicles equipped with oversized balloon tires to enable them to give high performance on sand, as well as with bunks and cooking equipment. Small aircraft are used as spotters on occasion to locate a shoal of fish and radio the information to the buggies, which race to the reported area. Surf fishing is sometimes very effective at night.

The British sea angler, less fortunate in the fish around the coast and fishing often in very heavy currents, which demand heavy leads and shorter, stouter rods, nevertheless fishes in a very similar way. Because conditions vary so greatly even within a small area, tackle likewise varies and rods run from 7 ft. up to 12 ft. In many other parts of the world, where conditions are rather more similar to those in North America, surf casting in the American style is becoming increasingly popular, even in countries like New Zealand and parts of South America, so well blessed with fine trout fishing.

Many forms of bait fishing can be practised from a boat. The most common is again a form of bait fishing using a sinker. As always the fish must first be located. and a knowledge of the "marks." that is, the exact location of their feeding grounds and thus of navigation, is essential. The boat angler must also find out at what depth the fish are feeding. The usual method is to lower the sinker until it touches bottom and then to wind in line until a bite is received. The angler notes how many turns of his reel he has made from the bottom to the depth at which the fish are feeding and is thus able to ensure that his bait is fishing at the right depth. Usually the sinker is left on the bottom and the hooks are adjusted to the right depths.

The one disadvantage of such fishing is that heavy leads have to be used. Other methods using lighter and more sporting tackle can also be used from a boat. For fish which sometimes swim high in the water, fish like the sea basses and the mackerels, an unleaded line and tackle can be allowed to run out with the tide or current or can be trailed behind a slowly moving boat. Another form of bait fishing is used on the west coast of Canada and the United States for coho and spring or Tyee salmon. The bait is a strip of herring. cut so that when drawn through the water or when influenced by current it moves in a lifelike manner. A small lead of about an ounce is fixed a yard or so above the bait, and bait and lead are either cast and retrieved, trolled. or allowed to hang in the current. These methods are called "strip casting" or "mooching." Caught on light tackle, the Pacific salmon is a very sporting fish indeed.

Not dissimilar is the method developed in the 1940s and 1950s for catching blue and mako sharks off the Cornish coast of England. The ideal conditions occur when the wind is blowing against the tide. The boat is allowed to drift, putting out a trail of "rubby-dubby" which runs off with the tide and attracts the sharks to the angler's bait. This bait, usually a whole herring or pilchard, is allowed to trail behind the drifting boat, suspended at the required depth by a cork float. Sharks caught in this way give a very good fight, and although these British fish are not as large as those in many other parts of the world, they do run to more than 300 lb. and provide a sporting method of fishing.

2. Float Fishing.—This is practised all over the world for fish that can be caught close to the surface, and because very light tackle can be employed it is a particularly sporting way of catching salt-\later fish. Fresh-water tackle is often used and a very popular outfit is a seven-foot, light spinning rod and a fixed-spool reel. Very many species of fish are caught by such means and members of the bass, mullet and mackerel families are taken on float tackle all over the world.

A particularly interesting and unusual form of float fishing is practised in the southern states of the United States, generally for speckled weakfish (Cynoscion *nebulosus*). The bait is a shrimp fished a yard or so below an egg-shaped float with a concave top. These are cast out either from a bait-casting or spinning outfit and then retrieved in a series of jerks. These jerks cause the float to be pulled under the water, and the air escapes from the concave top causing a very audible pop which attracts the weakfish to the bait. In this way the float acts both as a bite indicator and as a means of attraction.

3. Trolling. — This style of fishing is greatly practised for sea fish, for it is the best way of locating fish in great expanses of water, often of considerable depth. With the exception of trolling for what are known as big game fish, a specialized technique which will be dealt with separately. the methods of fishing are very similar to those used for fresh-water fish.

Typical of salt-water trolling is the method used on the west coast of North America to catch the large Pacific salmon (*Oncorhynchus tshawytscha*). All types of craft are used, from rowboats to special power-driven ships designed for this sport. Behind such crafts are trailed spoons, plugs and dead fish, either whole or cut up. A very popular method is to use a dead herring preceded by a large spoon called a "herring dodger." The dodger acts both as an attractor and to cause the herring to move in a lifelike manner. Basing itself on this sport of trolling for Pacific salmon is the famed Tyee club of Campbell River, British Columbia. This club lays down rules as to tackle that may be used. and presents buttons to anglers who catch large specimens of these salmon—bronze for 30-lb. fish; silver for 40-lb. fish, gold for 50-lb. fish and diamond for those of 60 lb. and above.

4. Bait Casting. — Casting and spinning for salt-water fish is becoming more and more popular every&-here,in particular where big predatory fish are found close to the shore and in sheltered waters. Tackle and methods are in many cases identical with those used in fresh water.

5. Fly-Fishing. — The flies used in this particularly sporting method are lures imitating small fish, shrimps. etc. Generally a strong, nine-foot rod is used, for long casts have to be made and many of the fish caught are relatively big and powerful. Europe and the British Isles have few places suitable for fly-fishing in the sea. but Florida and some of the other southern states of the U.S. offer splendid fly-fishing for bonefish, small tarpon and other species. Farther north the striped bass takes a fly well in places on both the Atlantic and Pacific coasts while on the latter fly-fishing for coho salmon offers splendid sport.

6. Big Game Fishing. — The fish sought in this form of angling are the big fish of the world, principally the members of the tuna. shark and swordfish or billfish families which may run from 100 lb. in weight to well over 2,000 Ib. Although such trophies are caught on heavy bait fishing tackle, the most popular, effective and sporting method is trolling. Deep-sea trolling is a highly specialized form of fishing requiring a boat designed for the purpose and heavy-duty tackle designed for handling very big fish.

The craft ior big game fishing must be capable of withstanding heavy seas and is equipped with a "fighting seat," a turntable chair from which the angler can exert the maximum pressure on a fish many times his own weight. The rod, a massive one of glass fibre or laminated wood. has a butt that fits into a socket in the chair. The reel is usually a very large multiplying reel, although some British big game fishermen prefer a centre-pin reel, and is usually designed so that a harness that fits over the angler's shoulders or around the small of his back can be connected to it. thus allowing the fisherman to use all his strength against the fish. The reels have a throwout lever or other device to release the spool and allow it to run free, and usually a braking device or drag to regulate line tension. The line is made of Dacron or Terylene and the leader of wire.

Craft designed for such fishing generally have outriggers — long poles to which the lines are attached by what Americans call clothespins and the British clothes pegs, which hold the lines well clear of the boat, thus allowing more than one line to be used. The age-old problem of locating fish and determining the depth at which they are feeding has been solved in part by the use of echo sounders and other electronic aids.

FIG. 10. — BIG GAME REEL BUCKLED TO HEAVY-DUTY ROD

Big game fish are sought throughout the world and since. as with other sports, the establishing of records is no small part of the interest. the International Game Fish association was formed in 1939. Having its headquarters in Miami. Fla., with a committee of experts in the sport, the I.G.F.A. acts as a clearinghouse for information. as arbiter in disputes and as the awarding authority for world records of big game fish, according to species and the type of tackle, classed by strength, on which each record was made.

IV. FISH AND FISHING IN THE PRINCIPAL ANGLING COUNTRIES OF THE WORLD

A. North America

U.S. and Canadian anglers are extremely fortunate in their native fishing for, although in so vast an area fish and types of fishing vary, and, as always in a society becoming increasingly industrialized, the town-dwelling angler needs to travel a long way to obtain good sport, wonderful lake, river and sea fishing exists in North America. Furthermore, in most U.S. states and Canadian provinces fishing is not private but is open to all who hold the necessary licence. Licence fees (and nonresident licence fees) vary widely from state to state as do regulations covering. species by species, size limits and catch or creel limits and establishing open and closed seasons. Fees are used to help finance hatcheries and other fishery management and conservation programs. (See Fish Culture; Wildlife Conservation.) Especially after World War II, new highway construction and increasing use of light airplanes made many previously hard-to-reach fishing waters–particularly in northern Wisconsin and Minnesota and the remoter regions of the western United States and of Canada–more easily accessible. (See also Boating.)

In North America as elsenhere various fishes are known by many local names The following discussion is based on the more generally accepted common names; the scientific nomenclature follows that of the American Fisheries society. Some fish caught in more than one country are separately dealt with only under the country in which they are most important to fishermen, for example, *Carp* under Great *Britain and Ireland*.

1. Fresh-Water Fish. — Atlantic *Salmon* (*Salmo salar*).—The Atlantic salmon, sometimes knonn as the Kennebec salmon, is found in North America from northern Maine, its last stronghold in the United States, to northern Canada. The same fish is found in northern Europe and the British Isles.

Salmon ascend from the sea to the headwaters of the rivers in which they were born to spawn. When the eggs hatch in the early spring the tiny fish. which are known as alevins, live upon the contents of a yolk sac until they grow into uhat are called salmon parr or pink. The immature salmon spends from one to three or more years in the river until, usually when two years old. and in the spring or early summer. it descends the river and migrates to the sea. At this stage, when it is known as a smolt, it is about six inches long and weighs only a few ounces. A fish that has spent one year in the sea is known as a grilse. The salmon increases very rapidly in size and the average run of fish returning for the first time to fresh water weighs between 8 and 20 lb. After spawning, individuals that do not die return to the sea but they invariably lose condition in fresh water, becoming thin and often suffering from fungus diseases. In this state they are known as kelts. (For details of the life cycle of the salmon see SALMON AND SALMONIDAE.)

For the angler the one notable difference between the North American and the European salmon is that the former will take a dry fly. Fly-fishing only is the rule in North America and no bait casting or live bait fishing for these fish is allowed. Some, of the best rivers in Quebec and New Brunswick, like the Miramichi and the Restigouche, are wholly or partly in private hands but many other salmon rivers including all those in Nova Scotia are open to everyone.

Landlocked Salmon (Salmo salar sebago and *Salmo* salar *ouananiche*). — These two fish are Atlantic salmon which do not migrate to the sea, the difference being that the former, originally only found in Maine, lives in lakes with no access to the sea while the latter lives in rivers in the Lake St. John area in Quebec which have access to salt water. Neither run as big as the migratory fish but both are very fine sporting fish which take fly and spinner very well. An eight-pound landlocked salmon is a big one.

King *Salmon* (*Oncorhynchus tshawytscha*).—The largest of the Pacific salmon, known also as Tyee, Chinook and spring, these huge fish are found from California as far north as Alaska. They are usually caught by trolling in the river estuaries but at times can be caught by strip casting and "mooching," by fly-fishing and by bait or plug casting. Many west coast rivers have a run of small male grilse, known as "jack springs." which give great sport on a fly rod. In certain rivers very big fish run — for instance at River's inlet on the mainland of British Columbia, fish of between 40 and 60 lb. are common.

Coho Salmon (*Oncorhynchus kisutch*).—Known also as the silver salmon, the coho is a great sport fish, being principally caught in the sea, in estuaries and low down in rivers. Its distribution is similar to the king and like all Pacific salmon its condition deteriorates rapidly in fresh water. It can be caught trolling, strip casting, bait casting and on a fly. Generally the fly, a long lure made from deer or polar bear hair, is trolled, but on occasions coho will take a fly cast to them. A very game fish, it jumps repeatedly when hooked. It is not as large as the king. averaging about nine to ten pounds.

Lake Trout (*Salvelinus* [*Cristivomer*] *namaycush*).—The largest of the North American char (*q.v.*) and a very fine table fish. the lake trout, also known as Great Lakes trout, is found only in the northern states of the United States and across Canada. in deep lakes. Though it can be caught on the surface on fly and casting and spinning tackle in the spring when the ice melts. it is usually caught by very deep trolling. It reaches a weight of 50 to 100 lb.

Brook *Trout, or* Speckled Trout (*Salvelinus fontinalis*).—Originally native to the northeastern states of the U.S. and to eastern Canada. this beautiful fish has been widely planted all over North America. Being a char it requires cold water. and although it will feed on the surface in the spring it prefers deep water. Very voracious, it will take most baits and lures and taks a well-sunken fly very well. The brook trout is excellent eating. It runs to the sea in the maritime provinces and Maine. Depending on the food supply weights range from less than one to more than ten pounds.

Dolly *Varden Trout* (*Salvelinus malma*).—A voracious, bottom-feeding char, this fish is found in British Columbia and the western states. It will take any bait or lure and will run to the sea if it has access to it. A gvod table fish) it weighs up to 30 lb.

Arctic Char (*Salvelinus alpinus*).—The same migratory char that runs up the Icelandic rivers also ascends the rivers of northern Canada. Little is known about its distribution but fish over 15 lb. in weight are not uncommon.

Cutthroat Trout (*Salmo clarki*).—This is a true trout and a native of the Pacific drainage from California to Alaska. It is a voracious fish which will take fly, bait or lure. It runs to the sea when it has access. Excellent for eating, the record is more than 40 lb.. though a four-pounder is a good fish in most waters.

Rainbow *Trout* (*Salmo gairdneri*).—Rainbow trout is the other of the North American true trout and a wonderful sporting fish; it has been transplanted from the Pacific drainage to many other areas of North America and to many other countries. A very strong fighter which takes fly, lure and bait. it weighs from 1 to more than 30 lb. The extremely large rainbow caught in Lake Pend Oreille. Ida.. are locally called Kamloops (because the lake was stocked with trout from the Kamloops area of British Columbia) or Rootenay. The rainbow trout has strong migratory tendencies and when it has access to the sea or a large lake, as one of the Great Lakes, becomes sea-run and is known as a steelhead. Steelhead trout are caught on bait, fly and spinner.

Brown Trout (*Salmo trutta*). — Introduced into North America from Europe, the brown trout gives the same excellent sport there as it gives in the lands where it is native (see Great Britain and Ireland, below).

Arctic Grayling (*Thymallus arcticus* or *signifer*).—The grayling is native to Montana (a subspecies, tricolor) and to Alaska and northern Canada. It is a splendid sporting fish which takes fly, spinner and bait.

Smallmouth Block Bass (*Micropterus dolomieui*).—A fish of extraordinary strength for its size, the smallmouth black bass is one of the world's great sporting fish. Originally native to the northern states and northeastern Canada, it has been transplanted to many other areas. Excellent eating. these fish will take fly, spinner, plug and bait. Fish between four and five pounds are not unusual.

Largemouth Black Bass (*Micropterus* salmoidesj. — Though bigger than the smallmouth, it is not quite so game but will take fly, spinner. plug and bait.

Yellow Perch (*Perca* flavescens). — The yellow perch, also known as the ringed perch, is one of the most popular North American pan fish. It is a close relative of the European perch (*Perca fluviatilis*). It is caught on live bait (minnows, crayfish and worms are popular) and on flies. The average weight is less than one pound but many lakes have larger perch and catches may average two pounds and over.

Northern Pike (*Esox lucius*).—The northern pike is common to northern states of the U.S. and across Canada. Although it will take worms and other bait. its main food is fish of all species. For this purpose the pike has a large mouth equipped with hundreds of teeth. It is a long. streamlined fish with great power of propulsion at its tail giving high speed in swimming over a short distance. Its eyes are placed well forward so that its vision is likewise forward and its green, dappled body is perfectly camouflaged for the ambushing of smaller fish. At times a voracious feeder. it takes bait. live or dead fish and lures. Northern pike of 10 to 15 Ib. are not rare and some weigh more than 40 lb.

Muskellunge (*Esox masquinongy*).—A very large member of the pike family. the muskellunge is native to the northeastern and north central states of the U.S. and to eastern Canada. It takes dead or live fish and large lures. Muskellunge weigh up to about 70 Ib.

Walleye (*Stizostedion vitreum vitreum*).—This game fish is known by many names including walleyed pike, pike perch, walleyed perch and. in Canada. *doré*. Its original range was in Canada west to Alberta and southward in the Great Lakes-Mississippi valley region: it is non· found all over the United States and Canada. It is excellent eating. Mostly it takes bait: live and dead fish and lures. Weights average 2 to 5 lb. and go up to more than 20 lb.

Pan-fish.—In many parts of the United States the fishes known as pan-fishes give sport to many anglers. This group includes, in addition to yellow perch, the white crappie (Pomoxis *annularis*), the black crappie (Pomoxis *nigromaculatus*), the bluegill (*Lepomis* macrochirus) and a number of other members of the *Lepomis* species usually referred to as sunfishes. All the above will take bait, small flies and small lures. All are good eating.

2. Salt-Water Fish. — Salt-water fishing is probably the fastest growing phase of the sport of angling. not only in North America but in many other parts of the world, with thousands of new fishermen and boatmen joining the quest for the sporting fish of the sea each year. In the following discussion several of the more important big game and other salt-water fish, and methods of fishing them, are described briefly to illustrate various aspects of the sport, and the more popular quarry are identified. The range of many species is, of course, world-wide and major occurrences of interest to sportsmen are mentioned below as well as in sections dealing with particular waters, as Central and South America.

Sailfish —Noblest of the salt-water species must be the billfishes or spearfishes. which include the sailfish, marlins and swordfish. Certainly none of the true finfishes approaches them in size except the bluefin tuna. Most numerous member of the tribe, or at least the one most often caught, is the sailfish, of which there are two valid species and possibly others. The two are known as the Atlantic sailfish (*Istiophorus americanus*) and the Pacific sailfish (*Istiophorus* greyi). As in all spearfishes, the cylindrical spear of the sailfish is an elongation of the upper jaw. But the sailfish is unique in that its dorsal fin is enlarged to saillike proportions. When the fish swims deep the great fin is lowered and folded into a groove on its back. However, when it feeds on the surface the sail is often partly raised as it pursues bait fish or bait. Sailfish are coveted as trophies, and no fish is more widely sought by neophyte big game anglers. In the Atlantic ocean, the average fish caught runs 6 or 7 ft. in length and ranges in weight between 40 and 50 lb.; some weigh up to about 100 lb.

The Pacific sailfish is a heavyweight by contrast, with average weight of 100 Ib. A Pacific sailfish caught with hook and line off Galapagos Islands in 1947 weighed 221 lb. The range extends from California to Ecuador, Japan. the Marianas and the Philippines, into the Red sea and Persian gulf and off the east African coast. Acapulco, Mex., was developed as a tourist area largely as a result of its excellent sailfishing The centre of fishing activity for the Atlantic sail is off the seaboard coast of Florida and the Gulf of Mexico, but the fish are also taken in many other areas including the Bahamas, Cuba, Puerto Rico, Jamaica, Venezuela, British Honduras and Brazil.

Sailfish are occasionally caught by drifting a deep bait, but most often they are sought on the surface and usually seen before the strike. Baits of balao, needlefish, flying fish or mullet or strips of large fish smoothly filleted and shaped are favourites. They are trolled behind a slowly moving boat, preferably from outriggers which, together with the rolling of the boat, cause the baits to skip and swim over the nave tops. The sailfish may rush and strike a bait or it may rise up under it. In any event, the fisherman in the fighting chair takes the rod and puts his reel into free-spool. Should the fish strike, a sharp rap will be felt by the fisherman who then takes his fingers off the spool and gives line freely until. gauging by the speed of the reel. he feels certain the fish has the bait. The brake is then applied, and the hook is driven home. The sailfish, as all spearfish, is believed to first strike a bait with its bill to stun it. The theory is that it then circles and takes the bait as it drifts down from the free-running reel.

A hooked sailfish provides a spectacle which lures the fisherman again and again to the sport. Suddenly the blue water seems to explode, and the huge fish. sail erect, surges upward. It "walks" the waves momentarily. Then it plunges. "greyhounding" in a series of cascading leaps. It yields only when exhausted. The mate on the boat, with gloved hands, seizes the wire leader as it emerges from the water, reaches down and grabs the fish by the bill. A sailfish or small marlin is never gaffed. At the angler's command the mate either slides the fish into the boat or snips the leader and lets it go free. Most sailfish, unless they are wanted for mounting. are released to fight another day. The flesh is palatable only when smoked.

Marlins. — Similar in many ways to the sailfish, except for its lack of an enlarged dorsal fin, is the white marlin (Makaira *albzda*). This billfish grows somewhat heavier than the Atlantic sail and somewhat smaller than the Pacific sail. Average weight may be 60 to 70 lb. although 100-pounders are frequently taken. A fish of 161 lb. was caught with rod and reel off Miami Beach, Fla., in 1938. Dark blue, and silver underneath. the white marlin is distinguished from the blue marlin, which is found in the same waters, by its rounded first dorsal and pectoral fins. The blue marlin has sharply pointed dorsal and pectoral fins. It is also much darker than the white and much heavier. Surface feeding, a white marlin shows the top section of its tail, or caudal fin, in the northern part of its range. Off Bimini, the same fish usually shows no fins until it moves in on the bait, when the raised dorsal fin is seen cutting the water. White marlin strike baits similar to the kind used for sailfish although off Long Island and New England whole squid or a rigged eel is used rather than bait fish. Once they rap the bait they must be given the "drop-back" with a free-spooled reel. They prove just as spunky as the sails when hooked, rearing and plunging to rid themselves of the hook. The range of the white marlin pretty much overlaps that of the Atlantic sailfish except that it extends northward into chilly New England waters as well. When the July run of whites is on at Ocean City, Md., some boats may catch and release a dozen of these game fish.

The huge blue marlin (Makaira *nigricans*) is often a running mate of the white. In the Atlantic ocean, big game anglers troll for the smaller white marlin or for sailfish and hope to spot the sharp, triangular dorsal fin of the cruising blue. The boat may troll a strip bait or a small bait fish. At the same time it may have a sewn mackerel (with backbone removed to give added "life" to the bait) bouncing along from an outrigger. Many captains who fish for the big marlins and swordfish keep the best bait aboard and wait for sight of the quarry before presenting it, as baits are torn up from too much trolling. In the Bahamas a fair-sized bonefish is considered an excellent marlin bait. Once the fish is sighted the bait is put over and is drawn past the blue. Should the fish rap the bait with his bill, the angler free-spools the reel and gives the familiar drop-back. Blue marlin are powerful fish. They leap and "greyhound" but they also dive very deep. At times they will dive and then die from exhaustion many fathoms beneath the boat Unless the angler has heavy tackle he will be unable to pump the fish to the surface. Blues are caught along the eastern Atlantic coast as far north as New England but they are more plentiful in the warm tropical waters of the Bahamas. Cuba and Puerto Rico. They are also taken in Venezuela and Barbados. Average weight of blue marlin is between 300 and 400 lb. A 780 lb. blue was caught off San Juan, P.R., in 1959.

There are two other marlins, less fished for because of their remote habitat but in the same class with the blue. One of them, the black marlin (Istiompax *indicus* or *marlina*), is considered the greatest of the finfishes. It is a native of the Pacific, ranging from the Gulf of California south to Peru. It is known off many of the Pacific islands including Hawaii and the Philippines, and in waters off Australia and New Zealand. But the black made its mark with anglers off Peru; big game fishermen from many lands visit the Cabo Blanco club to fish for 1.000 lb. specimens. The fishing for it is typical of all marlin trolling.

The striped marlin (*Makaira audax*) grows almost to the size of the blue. Its range is largely that of the Pacific black marlin but it is more abundant. Average fish run from 250 to 350 lb. A fish neighing 692 lb. was caught with rod and reel off Balboa, Calif., in 1931.

Swordfish —Most striking of the billfishes is the broadbill swordfish (*Xiphias gladius*), distinguished by the prolongation of its upper jaw into a long, flattened, sharp-edged and pointed sword which is nearly one-third the total length of the fish. Snordfish are especially prized among big game fishermen. To begin with they cannot be fished for until they are seen on the surface. And when they are on the surface they are often surfeited with food and not interested in the angler's offering of a whole fish or a squid. Again, when they do rush the bait they are not easily hooked, and when they are hooked their relatively soft mouths leave room for the familiar mishap of the pulled-out hook. The fish average from 250 to 350 lb. but 500-pounders are common. Exceptional was the 1,182-lb. swordfish caught off the famed grounds at Iquique, Chile, in 1953, by big game angler Lou Marron of New Jersey.

Swordfish are from common to rare over much of the world. They are a valuable market fish and because of their habit of lolling on the surface and their fearlessness of boats, they are easily harpooned for the commercial market.

Tuna.—While there are several species of tuna and all of them are eagerly sought by fishermen, none approaches the magnificent bluefin (Thunnus *thynnus*) for sheer size or abundance. The bluefin has been reported in most of the warm or temperate seas of the world. Young fish of the species—fish of 8 to 15 lb. or more—are often found with false albacore and the bonitos, cousins in the family tree. Fishermen trolling feather or nylon lures in the wakes of fast cruisers may catch one or the other. If a watch is kept on the boat's wake, the fish may be seen to snatch the lures within 20 ft. of the stern. This is particularly true in the Atlantic ocean. In some Pacific fishing areas, among them California, the small bluefins are more readily taken with live bait after having been chummed to the boat with live sardines. Even in such miniature sizes the bluefins recklessly strip line from the reels in their steep dives. Tuna of 75 lb. have been known to completely empty reels of 500 yd. of 15-thread line.

But while the peppery little tuna provide great sport for legions of sport fishermen and a summertime charter boat business on both coasts of the United States, it is the giant bluefins that fascinate one coterie of anglers to the extent that they spend small fortunes to catch just one. Records of giant tuna being taken by nets or harpoon are centuries old. Not until 1898, however, when Charles A. Holder succeeded in boating a 183-lb. bluefin with rod and reel off Catalina, Calif., did anglers everywhere raise their sights on these leviathans of the deep. Holder organized the Catalina Tuna club the day after his catch. The fish were caught without benefit of the friction brakes which are built into modern reels. Improvement of equipment was accompanied by a comparable increase in the size of the fish caught. Bluefin tuna are rumored to grow as large as 1 600 lb. A specimen harpooned off Rhode Island in 1913 weighed 1,225 Ib. One weighing 977 lb. was caught on rod and reel at St. Ann's bay, Nova Scotia, in 1950.

Giant tuna are fished for in several different ways, of which the chumming method is the most frequently used in the United States and Canada, and off the Scandinavian coast. Whole or large chunks of herring or menhaden are used to lure the fish. A similar fish or chunk of fish is drifted or floated out on a large hook which is twisted to a steel leader. Chum is used to lure the huge fish to the baits in the tide rips off Nova Scotia. The same method is used at Montauk point, Block Island, and along the New England coast. A system of slowly swimming a live mackerel or whiting is also successful when the tuna are seen on the surface.

During the May run of giant tuna off Bimini and Cat cay in the Bahamas, the schools of northbound fish are spotted from lookout perches on fast cruisers. The boat races ahead to intercept the school. Near the point of interception a whole mullet is sent overboard and jigged rapidly. If the maneuver has been correctly timed. one of the tuna may break away from the school and seize the bait.

The torpedo-shaped tuna, with body grooved to receive certain of the fins for streamlined speed swimming, is among the fastest fish in the sea (estimated 40 m.p.h.). A giant hooked on a line is almost tireless in its deep-boring rushes. However, skilled anglers have brought 500- and 600-lb tuna to the boat in as little as 20 minutes. The average fight may last two hours. Should the fight go to five and six hours, the odds are with the tuna. The tuna is still fresh or "green" and the angler is exhausted. Once the tuna has been brought alongside the boat. the mate grabs the leader with a gloved hand and sinks a "flying gaff" into the fish The flying gaff has a detachable head which is fastened with heavy manila hemp to a cleat on the boat. After the death flurry, a noose is swung over the tuna's mackerellike tail and it is pulled aboard with the hoist.

Other tuna prominent in the angler's book are the yellowfin or Allison's tuna (Thunnus *albacares*) and the bigeye tuna (*Thunnus obesus*). Neither approaches the size of the bluefin tuna although they may reach several hundred pounds. Smaller still is the albacore (*Thunnus* alalunga) which averages from 15 to 50 lb.

Tarpon.—Trophy of the brackish waters, the rivers, inlets and back bays of tropical climates, the tarpon (*Megalops* atlanticus) also is often referred to as the silver king, grande *écaille*, sabalo, and by many other names. It sometimes reaches a weight of nearly 300 lb. and is highly prized for its spectacular, leaping fight. A fish of 283 lb. was taken with rod and reel from Lake Maracaibo, Venez., in 1956. When a school is rolling on the surface each tarpon breaks the surface with its snout, and the dorsal fin with its whiplike appendage comes into view. Finally the broad tail sweeps up, and the fish is gone to repeat the roll in another moment. Tarpon gulp air during their rolling to augment gill breathing. Scientists believe this direct absorption of air explains their ability to thrive in stagnant pools and poorly oxygenated water.

Excellent baits for tarpon are live pinfish or mullet. Most tarpon fishermen, however, prefer to use artificial lures. Sometimes the fish will strike at slow-moving, deep-running plugs. Other times they will engulf noisy surface plugs. Fly-fishermen catch baby tarpon on white and silver flies. These restless fish may be taken on spinning rod and bait-casting tackle as well as strong deep-sea rod and reel. As a rule the light tackle is most effective when the fish are in shallow water or narrow drains. Their fight then consists of leapfrogging and tail-walking rather than long, swift runs. Cnder such conditions tarpon as large as 160 lb. have been caught on 14-lb. test lines. When tarpon are swimming in strong currents, however, they will rush down tide, and heavy tackle is needed. Most important in tarpon fishing are needle-sharp hooks to penetrate the bony plates of the jaws. Even more horny than the mouth surfaces are the great silver scales of the fish. Gaffs will hardly penetrate the scales, and as a result tarpon are always gaffed in the mouth. The same bright scales, larger than silver dollars on 100-lb. fish, are the souvenirs of the tarpon fishing trip. As food the tarpon is worthless. Therefore, unless the fisherman wants the fish for a mount, he pulls a scale from the exhausted quarry and then sends the tarpon back to the school.

Bonefish.—Few fish have been so widely acclaimed for their swiftness as the bonefish (*Albula vulpes*). Although a relatively small fish, nith average weight running from four to six pounds and only rarely caught over ten pounds, the silvery bonefish can flee at sizzling speed when hooked or alarmed. A favourite of the light-tackle fishermen, the bonefish will often strip a reel and break free in the first surging run to escape into deep water. This first flight invariably is in a straight line and sometimes will continue for 100 yd. or more before the nervous energy that made it possible is spent. If the fisherman stops the first run, the fight is half won. Barring accidents with sharp coral which could cut the line, the tiring quarry eventually will be brought alongside the boat and netted. Bonefish prefer to feed on shallow, grassy flats, or banks, following the incoming tide into only a foot or two of crystal-clear water. They have piglike snouts, ideal for rooting in the bottom and digging out small shellfish and crustaceans which are then crushed between a rock-hard tongue and an equally hard palate. Often when rooting up the bottom their tails break the surface. Fishermen poling the flats in shallow-draft skiffs look for these signs of "tailing fish." Another clue to the presence of fish are little puffs of mud stirred up by the feeding. Fishermen hastily, although stealthily, intercept the feeding fish and cast to them with baits of shrimp, hermit crab, conch or crayfish.

Light bait-casting rods and reels once were the favourite for bonefish. They have been largely replaced by spinning tackle. Fly-fishermen, using a heavy salmon-type rod and a forward-tapered fly line with plenty of backing and special streamer flies. also catch them. These fish may also be chummed to an anchored boat with bits of shrimp. Bonefish are native to many areas of the world including the Florida keys, Bermuda, the Bahamas, Cuba, Puerto Rico, Venezuela, California, Mexico, Hawaii, Australia, Japan and India. Some of the best bonefish flats are at Andros Island in the Bahamas. A bonefish taken in Hawaii in 1954 meighed 18 Ib. 2 oz. Sometimes confused with bonefish and also eagerly sought are ladyfish, or chiro (Elops *saurus* in the Atlantic, Elops *affinis* in the Pacific). The permit (*Trachinotus falcatus*) is a swift but scarce fish of the Florida keys and Bahama flats and may be taken while bonefishing. It has been caught at over 40 lb.

Striped Bass.—The striped bass (Roccus *saxatilis*), a member of the perchlike fishes of the sea bass family Serranidae, is said to be the most popular inshore fish of the United States. At least this is true along much of the east coast where the striped bass, also called striper, rockfish, greenhead or lineside, is sought throughout much of the year, from South Carolina to Maine. It is equally popular in parts of California and in Coos bay, Oregon, where the fish now flourishes as a result of being transplanted in San Francisco bay from New Jersey in 1877 and 1882 The original stock of 434 small fish multiplied until striped bass became important as a recreational fish in California second only to the salmon. Commercial fishing for stripers was permitted in California until 1935 when a law was passed making it a game fish, setting fishing limits on size and numbers, and forbidding its sale. California authorities estimated that by the second half of the 20th century 200,000 anglers fished for stripers in the state's waters and spent $10,000,000 annually in pursuit of their sport. Striped bass are fish of brackish and fresh water as well as the salt sea. They spawn in swift currents of rivers several miles inland. The young fish may spend a year or two in fresh water before descending to the ocean. Adult bass are known for their extended migrations. On the Atlantic coast the principal spawning area of the striper is Chesapeake bay. During the spring movement Chesapeake bay bass or "rocks" as they are known in that area. travel northaard to populate hundreds of miles of surf and bays. In California waters and in such Oregon waters as Coos river, bait fishing for the species has been brought to a fine art Favourite baits are chunks of pilchard or other herringlike fishes. Live bullheads up to six inches in size are used, as well as clams and worms.

Throughout much of the east coast range of the striper. most fish. particularly the larger ones, are caught on artificial lures—plugs of various shapes and sizes, bucktail jigs and lures shaped of tin or chrome-finished lead. However, eels of a foot or so in length, killed and carefully rigged with hooks. prove excellent lures for night casting. Striped bass are most often sought at night in the boiling surf by casters or "squidders" who aear nading boots of armpit height. Less hardy anglers charter fishing boats and troll lures along the edge of the surf or over rocks and wrecks. Striped bass generally attain greater size on east coast grounds of their origin. Fish of 20 and 25 lb. are common. During the fall run in New England, scores of 35- to 45-lb. fish are taken daily, with occasional 50- and 60-lb. fish.

Bluefish—The hard-fighting bluefish (Pomatomus saltatrix) best illustrates the phenomenon of cyclic abundance and scarcity among the pelagic fish of the sea. Bluefish have always been an important food species. Over the years, catch records show the bluefish has repeatedly gone from peak periods to poor periods and back again. Basis for an intensive sport fishery along the east coast of the United States, the bluefish, sometimes described as elft, tailor, snapper, or greenfish, is spread through many of the warm seas of the world. Some of the largest specimens have been reported from Africa although a hook and line record of 24 lb. 3 oz. was established in the Azores in 1953. A savage predator of the ocean, a school of bluefish will chop shoals of bait fish to fragments, providing a feast for the sea gulls and food for creatures of the ocean's bottom. Bluefish are taken from the surf by casters who use lures and plugs. Immature blues, or snappers. are a favourite of the cane-pole fishermen of the bays Most bluefish. honever. are caught by trolling metal or feathered jigs from slow-moving boats. The troller "follows the gulls" to find feeding bluefish. Bluefish when they are in teeming numbers respond quickly to chum of ground menhaden A piece of fish on a hook with a nire leader as protection against the sharp teeth of the blue is the bait.

Yellowtail.—The Pacific yellowtail (Seriola dorsalis) is beautifully streamlined and solidly muscular. Anglers seek it in many waters for the fish is abundant in Australia, New Zealand, and off South Africa, as well as along the Pacific shores of California, Mexico, and throughout the range to Chile. In California. at least, the fish supports a large party boat business. The Pacific yellowtail is a surface feeder, rising from kelp beds to take chum of live sardines tossed overboard by slowly cruising boats. Once the fish have found the chum, a live sardine is baited on a hook and allowed to drift back to the fish.

Yellowtails are strong fighters and delicious eating. Average size may run from 5 to 20 lb. but specimens up to more than 100 Ib. have been caught.

Flatfish.—There are said to be over 50 genera and 500 species of flatfish starting with the giant Atlantic halibut (Hippoglossus hippoglossus) and ranging down to the tiny hogchoker (Trinectes *maculatus*). The Atlantic halibut is rarely found by the angler, but the California halibut (Paralichthys *californicus*) which grows to about 60 lb.. in contrast with more than 600 lb. reported for the Atlantic halibut, is caught by sport fishermen. Flatfish have colour and both eyes on one side only, right or left. When very young they have normally placed eyes but with growth one eye migrates over the top of the head and settles beside the other. Other names in general usage for the various flatfishes are flounder, fluke, dab, sole and plaice. Some species cling to the deep offshore grounds and are never taken by angling. But in inshore waters, whether warm or cold, there is almost always one member of the huge family which will take the fisherman's baited hooks. Some species such as the winter flounder (*Pseudopleuronectes americanus*) spend their lives within an inch or two of the bottom where they feed by digging out worms and small crustacea from the mud. Other flatfish such as the summer flounder. or fluke (*Paralichthys* dentatus) will even break the surface in pursuit of bait fish. The summer flounder, which may weigh up to 20 Ib., is most often taken with a live minnow on a hook that is dragged with the tide along the bottom. Less active members of the family such as the winter flounder are usually caught with bits of sea worms or clams on small hooks fished right on the bottom.

Channel Bass, Snook, Bonito and *Others*.—The channel bass or red drum (Sciaenops ocellata) is found on the Atlantic coast south of New England and caught on lures and bait, particularly by surf casting. A large fish, it weighs up to 80 lb. A number of species of snook (Centropomus *undecimalis*) are found in both the Atlantic and Pacific oceans. It is a very game fish which can be caught by most fishing methods and it takes a fly well. Average weight is 4 to 9 lb. but the record is more than 50 lb. The common Atlantic bonito (Snrda sarda) is a fish of the mackerel family, found in the Atlantic and the Mediterranean, similar in form to but smaller than the tuna; the striped bonito (S. *orientalis*), which is world-wide, and the Pacific bonito or Chilean bonito (S. *chiliensis*) of the Pacific also are caught as bonito (*q.v.*). These very fast fish give great sport, although the average weight is well under 15 Ib.

Among other salt-water quarry the crevallé, jack crevallé or common jack (*Caranx* hippos), a very strong fish found on both coasts, can be caught on bait and by casting or trolling. It may weigh from 2 or 3 lb. to about 30 lb. The genus includes the blue runner. the skipjack, yellow jack and other crevallés. The dolphin (*Coryphaena hippurus*), a very beautiful fish (not to be confused with the aquatic mammal of the same name) and excellent eating, is found on both coasts and off Hawaii. Its principal food is the flying fish and it is generally caught by trolling. The average weight is under 25 lb.; some weigh more than 80 lb

The weakfish or sea trout (Cynoscion *regalis*) and the spotted weakfish or spotted sea trout (Cynoscion *nebulosus*) are found south of New York state on the Atlantic coast. They take various baits, especially shrimps. and can be caught on a fly and on lures. They make excellent eating. A large one weighs ten pounds.

4 great many other salt-water fish are sought by U.S. and Canadian fishermen. Among the more popular are pompano, barracuda (or barracouta), amber jack, grouper. coney, snapper, cod, mackerel, pollack, sea bass. shark and flounder.

B. Central and South America

1. Mexico.—Though there is good river fishing in Mexico, particularly for rainbow trout, it is for the superb fishing off its coasts that this country is renowned among anglers. The world's biggest tarpon are caught in the mouth of the Panuco at Tampico, Acapulco is famed for Pacific sailfish, while Veracruz offers a wide variety of sporting sea fish—bass, marlin, grouper and many others. All three are well-known angling resorts and all three have famous "rodeos"—competitions among anglers for the largest fish of a species caught during the period of the event.

2. Bahamas.—This group of islands offers some of the finest sea and big game fishing in the world and Bimini and Cat cay are as famed among salt-water anglers as the Restigouche, the Spey or the Aaro are famed among salmon fishermen. Giant tuna and marlin offer sport to the big game enthusiasts while tarpon, barracuda, kingfish. wahoo, bonefish and many other species can be caught on lighter tackle.

3. Jamaica, Barbados, Tobago, Trinidad and the Leeward Islands.—These are similar to the Bahamas in the sport they offer: big game fish, barracuda or great barracuda. tarpon and kingfish. In Jamaica there is a fresh-water fish, the mountain mullet (Agonostomus monticola), which gives good sport on light tackle.

4. Cuba.—Highly famed for its sea and big game fishing which is similar to that of the Bahamas, Cuba also has fine fresh-water angling. Large tarpon are caught in some of the fresh-water lakes and there is splendid fishing for largemouth black bass and bonefish.

5. South America.—The great native sporting fish of this vast subcontinent is the dorado (*Salminus maxilosus*), a very strong fish which runs to more than 40 lb. Usually it is caught on heavy bait-casting tackle in the Orinoco, Uruguay, Paraguay and Paraná rivers, in the Amazon and its tributaries and in Bolivia. One of the world's largest fresh-water fish, the pirarucu, or arapaima (*Arapaima gigas*), is caught in the Amazon and its tributaries and in British Guiana. It runs up to several hundred pounds in weight. It is usually caught on live bait. Other good native sporting fish are the tucunare (Cichla *ocellaris*) of British Guiana, a perchlike fish which takes a big fly well; the boga, a characid, and the pacú, also a characid of Argentina, which are caught on bait; and the trucha of Chile, which will take fly or spinner.

Of greatest importance perhaps to the fresh-water angler is the fact that brown and rainbow trout, char and Atlantic salmon have been introduced with great success into many of the rivers and lakes of Colombia, Peru, Chile and Argentina. Particularly in the latter two cases, brown and rainbows grow to a very large size in the glacier-fed rivers of the southern Andes and Patagonia and the trout fishing in these areas is probably unequalled in the world.

Off Cabo Blanco in Peru is some of the finest big game fishing in the world. Here the cold Humboldt current meets the equatorial current and in this area there is an enormous concentration of all big game fish. Most sought of these is the giant black marlin (Makaira indica) which runs over 1,500 lb.

All round the coast of South and Central America there is good fishing. Surf casting is growing in popularity, particularly in Argentina and a small band of enthusiasts enjoys excellent sport.

C. Great Britain and Ireland

Fishing in this area is divided into game fishing, that is, fishing for salmon, trout and sea trout, coarse fishing, which includes all the other fresh-water species, and sea fishing. The salmon season, varying according to river, runs roughly from January to October, the trout season, likewise variable, from March to September and the statutory coarse fish season runs from June 16 to March 14.

1. Game Fish.—Salmon (Salmo *salar*).—This is the Atlantic salmon described under North America, above, and its life history is the same, the chief difference being that in Great Britain and Europe the salmon rarely will rise to a dry fly. The salmon do not feed in fresh water but will take a large wet fly and are also caught on spinning lures and on worms and prawns. Salmon run up most rivers in the British Isles except those of northeastern, eastern and southeastern England. Some of the best rivers are the Wye and the Eden (England), the Usk, Teifi and Dee (Wales), the Dee, Tweed, Tay and Spey (Scotland), and the Blackwater, Lee and Boyne (Ireland). The record British salmon was caught in the Tay and weighed more than 60 lb.

Trout (Salmo *trutta*).—There is one native species of trout in the British Isles, the brown trout, and apart from some rivers in eastern and southeastern England, these fine fish are widely distributed. They do, however, vary greatly in size and colour, the latter depending greatly on the colour of their background. In the chalk streams of Hampshire a two-pound trout is common, due to the vast amount of food obtainable in these alkaline rivers. A trout the same age from the acid rivers of Devonshire would probably weigh between four and six ounces.

Trout live on insects in their various stages, small fish including their own species, worms and most small forms of life living in the water. They are caught on artificial flies and on spinning lures and will take most forms of bait. The principal English trout rivers are the Test and Itchen in Hampshire, the Kennet in Berkshire, the Dove in Derbyshire, the Wharfe and Ure in Yorkshire and the Eden in Cumberland. The Usk is the best trout stream in Wales while Scotland and Ireland both have great numbers of fine trout streams, the best in Scotland probably being the Don while the Suir and Maigue in Ireland would be hard to beat. Trout, too, thrive in lakes and reservoirs like the Irish limestone lochs, Loch Leven in Scotland and many man-made reservoirs throughout the British Isles. The largest trout weigh up to about 40 lb. This is most exceptional and a four-pound trout is a big one anywhere. The American rainbow trout has been introduced into Britain but only with success in certain reservoirs and in the river Wye in Derbyshire. Both brown and rainbow trout are excellent table fish.

Sea *Trout* (Salmo *trutta*).—This fish, one of the great sporting fishes of the world, is the same species as the brown trout but has seagoing habits like the North American rainbow steelhead. The sea trout is spawned in November at the same time as the brown trout and spends about two years is the river before migrating to the sea. Unlike the salmon it remains close to the shore during its salt-water life and a great deal is known about its existence in the sea. After several months in salt water the young sea trout will probably return to the river for the first time and thereafter will return each year of its life to spawn.

Sea trout are caught on wet and dry flies, on spinning lures and on bait. They are very strong fish and are great leapers, jumping clear of the water many times in their efforts to escape the hook. Although much of their life is spent away from man, they are very shy and are generally best caught at night.

Sea trout run up most of the unpolluted rivers of the British Isles and are known by many local names. In Scotland the small fish returning for the first time are called finnock or harling. In Ireland sea trout are called white trout, in Wales sewin and in many other parts they are referred to as salmon trout. Weights of more than 20 lb. have been recorded but any fish over 6 lb. can be accounted a good one. They are particularly good table fish.

The west country is well blessed with good runs in streams like the Tavy, Taw and Torridge. In Wales the Dovey holds very big fish and both Scotland and Ireland have an embarrassment of riches in this regard, with Loch Maree in the former particularly worthy of note.

2. Coarse Fish.—Besides casting or floating his bait to the fish, the skilled coarse fisherman brings the fish to his bait and holds them in the vicinity by the use of ground bait. This usually consists of bread or poultry meal, soaked to varying consistencies. For heavy water a solid, doughy ground bait is needed to sink down in the current. For still waters, ground bait that acts like a cloud is used. A certain quantity of the bait the angler is using on his hook is mixed in the ground bait so that the fish are conditioned to feeding on it.

The diverse character of rivers and lakes, and the differing species in them, have led to the development of a number of fishing "styles." The Hampshire Avon in England, for example, is a deep, fast and very clear stream; the normal method of float fishing there is long trotting. A big float and heavily weighted terminal tackle are allowed to drift away with the current to perhaps 30 yd. below the angler. The rod used is limber, between 10–11 ft. in length, and the reel, usually a Nottingham reel, is very free running. The Thames, England, style on the other hand requires a very light, stiff,14-ft. rod. The float is fished very close to the rod tip with a very short length of line between them. The float travels along with the current as far as the length of rod allows it, and then is lifted and cast into the water again. Indeed there are still Thames fishermen who use, a "roach pole"—a light rod about 20 ft. long, with no rings, and the line tied to its end. In Europe, a somewhat similar long rod with tight line is still widely used for float fishing.

Another method of float fishing is float ledgering. The terminal tackle is heavily leaded, particularly close to the hook, and the distance between hook and float is greater than the depth of the water. Some of the lead thus rests on the river bed, anchoring the bait in a current, and allowing it to lie on the bottom. (See also Ledgering, below.)

The following method is typical of float fishing. A float fisherman seated at the head of a fast stream about six feet deep, with maggots as bait, will adjust his tackle so that the bait is just tripping the bottom of the stream. He throws in a handful of maggots as ground bait and then follows them down the stream with his hook bait. As his bait is carried down with the current, the angler watches his float. Should a fish take it, the float will stop, or dip, or be pulled under the water. At this indication the angler sets the hook by jerking his rod sharply, thus pulling his hook home in the fish. If the fish is of any size it has to be "played" by keeping pressure on it with the flexible rod and allowing it to swim away by giving it line off the reel. When the fish has been tired in this way, it is brought back close to the angler and lifted out by means of the landing net, a small hoop net on the end of a shaft.

Ledgering.—A basic method of angling all over the world, ledgering is closely allied to float fishing, but no float is used. Although there are many differing applications, the idea is to anchor the bait on the river or lake bottom by means of a sliding weight, or sinker, in Great Britain called a ledger. These vary in design, but it is essential that the weight hold the bottom and allow the line to pass freely when a fish takes the bait so that no resistance is felt. Various lengths of rod are used, probably the most popular being one of about seven feet in length, used with a fixed-spool reel. Ground bait is used in the same way as for float fishing.

As no float is used other methods of detecting a "bite" must be employed. Some watch the tip of the rod which is pulled down when a fish takes the bait. Indicators of various simple types are used which are attached to the line. When the indicator moves the angler sets the hook. A form of ledgering has been devised to catch carp, a very shy fish, at night, and for this purpose a simple electrical buzzer is used which sounds when the line is pulled out.

Fishing Matches.—Match fishing for coarse fish is a sport of enormous popularity on the continent of Europe and in England. The match organized by the Birmingham Anglers' association, for instance, draws 4,000 competitors, all fishing in one afternoon on one stretch of river. As can be imagined the organization of such an event is a considerable undertaking.

Matches usually last four or five hours. The river is divided into the required number of "swims," each marked with a numbered peg. The competitors draw for peg numbers and the purpose of the match is to catch the heaviest weight of fish. As each fish is landed it is placed in a "keep net" (a large, sack-shaped net) and thus kept alive until the end of the competition. At the end of the allotted time each angler's catch is weighed and the fish are then returned to the river.

Considerable sums of money are won in such contests, in prize money, in sweepstakes and in betting. It is not unusual for the winner of a big match to leave the waterside several hundred pounds the richer.

Pike (Esox *lucius*).—The largest purely fresh-water fish in Britain, the pike is the only fish of this type common to both Europe and North America.

Pike are caught on spinning (bait-casting) tackle, by trolling and by live baiting with a small fish. Despite their size they are not strong fighters, although in some of the cold-water Irish lochs their performance in this regard is more spectacular. They vary a good deal in size—in some parts of England a ten-pounder would be thought a good fish while in Ireland anything under 20 lb. would be considered of no account.

Many are the stories of the pike's rapacity though, like all predators, it ignores the smaller fish around it when not hungry.

Perch (Perca *fluviatilis*).—Olive green in colour, with dark bars down its side and red fins, the perch, a relative of the North American yellow perch, is a very handsome fish and, although troublesome to prepare, a fine table fish. It is most voracious and can be caught with a fly. by casting and trolling and by all types of bait fishing. Gregarious in habit, like all shoal fish it becomes more solitary as it becomes older and bigger.

Perch are caught all over the British Isles and weigh up to about six pounds. When unhooking a perch the angler must watch out for the spines in its front dorsal fin.

Roach (*Rutilus rutilus*).—In England the roach is to the coarse fisherman what the trout is to the game angler: there are hundreds of thousands of men whose ambition is to catch a "two-pounder." The roach is a silvery fish with a dark back and red fins, very timid and invariably the member of a shoal. Its diet mainly is composed of insects, fresh-water shrimps and weed, although after spawning big roach will feed on very small fish and can be caught on small spinners. Roach will take an artificial fly but for the most part they are caught on the very many different styles of bait fishing. They are common in nearly all English counties. in eastern Wales and southern Scotland, but are not native to northern Scotland or Ireland. In North America the name has been applied to several fish (see ROACH).

Rudd (*Scardinius* erythrophthalmus).—Looking like a roach but more golden in colour, the rudd is more localized in distribution, although unlike the roach it is common in Ireland. The rudd (*q.v.*) is a surface feeder, will take a fly well and can be caught by many of the different forms of bait fishing. Weights of more than four pounds have been recorded. It has been introduced to the United States where it is sometimes knoun as the pearl roach.

Chub (Leuciscus *cephalus*).—Big (up to about ten pounds), voracious, gregarious except when very large, and extremely shy, chub are greatly prized by coarse fishermen. They are widely distributed throughout England, eastern Wales and southern Scotland and can be caught by all means of angling provided due caution is employed. They take a fly well in summer. Famous chub rivers are the Hampshire Avon, the Herefordshire Wye and the Annan in Dumfriesshire. (For North American chub see CHUB.)

Dace (Leuciscus *leuciscus*).—Looking rather like a small chub, the dace never grows to a large size (under two pounds). It is nevertheless a good sporting fish and is usually caught on light float tackle. It takes the fly well, with a very fast rise. (For North American dace see DACE.)

Carp (*Cyprinus carpio*).—An exceedingly powerful and shy fish, the carp was considered almost impossible to catch except under exceptional circumstances and with the lightest of tackle. After World War II a means of capturing these fish was found. The method of fishing has already been described under *Ledgering*. Carp weighing 25 to 30 Ib. are not rare. The carp, originating in Asia, is also found in Europe and North America, where fly-fishing tackle often is preferred. (See also CARP.)

Barbel (*Barbus* barbus).—Originally native only to the Thames, the Trent and rivers of Yorkshire in Great Britain (but also found in central Europe), the barbel has been introduced into others, notably the Hampshire Avon via the Dorset Stour. It is an exceedingly powerful fish, beautifully shaped for living in very fast, strong water on clean gravel. A bottom feeder, the barbel is usually caught by deep-bait fishing although after spawning it will take a spinning bait. It is a very powerful fish running to a good size, up to 14 lb. and more.

Tench (Tinca *tinca*).—A handsome greenish fish, the tench feeds entirely on the bottom and is generally caught in the summer months at dawn or dusk. Living mostly in slow rivers and in lakes and ponds, the tench is usually caught on float tackle and is a powerful fish to handle. Tench are big at five pounds. Although they are little eaten in Britain, tench are excellent table fish.

Bream (Abramis brama).—A flat-sided fish. living mostly in slow muddy rivers and in lakes, the bream is another bottom feeder. It is caught by most forms of bottom fishing, is common to most of the English counties and is caught in quantity in Ireland. Weights of more than 13 lb. have been reported. In North America the name sometimes is given to a number of fish including bluegills and pinfish.

Eel (*Anguilla anguilla*).—Born in the Sargasso sea, the European fresh-water eel runs up most British rivers as an elver, a tiny, wriggling, wormlike creature two or three inches long. It spends several years in fresh water, during this time feeding voraciously. Having the ability to cross wet grass, it is found in landlocked ponds. It returns to the sea to spawn and die. The eel is mostly regarded as a nuisance by British anglers but big eels, those weighing several pounds, are powerful fish and the flesh is delicious. The eel of eastern North America is the Anguilla rostrata; that of Japan the Anguilla *japonica*. (See also EEL.)

Grayling (Thymallus thymallus).—The grayling is a beautiful silvery fish with a large, often deep purple, dorsal fin. It is of the same family as the highly prized North American game fish, the Montana grayling (*Thymallus* signifer tricolor) and the arctic grayling (Thymallus *arcticus* or *signifer*). It is closely related to the salmon and the trout and indeed behaves very much like the latter. These fine sporting fish are at their best from October to December, take both wet and dry flies well, and are also caught on float tackle. They are river fish and are only found in the cleanest of streams. Being by origin arctic fish, they will feed in the coldest of weather. They are much more prized on the European continent than in Britain both for the sport they offer and for their excellence as table fish. A two-pounder is a good fish anywhere.

3. Sea Fish.—The following are the most common sea fish sought by anglers in the British Isles:

European Sea Bass (*Morone* labrax).—The sea bass, a member of the sea perch family (Serranidae), is to the sea fisherman what the salmon is to the fresh-water angler. These fine predatory fish are found everywhere in British water and indeed members of the bass family are found all over the world. Silver, with a blue back and a spined dorsal fin, the bass is particularly fond of river estuaries. It is caught by every method of fishing and can at times be taken on the fly. An eight-pounder is a big fish. (See also BASS.)

Mackerel (Scomber *scombrus*).—The Atlantic mackerel, a widely distributed fish, is the strongest fish ounce for ounce in British waters. Like the sea bass it is predaceous and can be caught by most angling methods. On light tackle mackerel give wonderful sport and can sometimes be taken on a fly. It weighs up to four pounds. (See also MACKEREL.)

Gray Mullet.—There are a number of gray mullets, forming the family Mugilidae, the commonest British species being *Mugil* cephalus, known in North America as the striped or black mullet. Generally very difficult fish to catch, on occasions they lose all caution. Like the European sea bass they are fond of estuaries and will snim up into fresh water. They are usually caught by float or bottom fishing. Weights run up to about ten pounds.

Skate (Raja batis).—A very large member of the ray (*q.v.*) family, the skate is caught by fishing with heavy tackle on the bottom. It uses its flat body to obtain maximum resistance from the water and thus puts a very great strain on the rod and tackle. Excellent eating, the skate runs up to several hundred pounds in weight, particularly off the Irish coast.

Plaice (Pleuronectes *platessa*).—The plaice (*q.v.*) is a flatfish which is excellent eating. It is caught in a variety of ways, the most interesting being drifting with a worm as bait with a small spoon above the norm. It is thought that the spoon revolving suggests to the plaice that another fish is about to take the bait. The common European flounder (*q.v.*) (*Platichthys flesus*) is caught in the same way.

Pollack (*Gadus* pollachius).—A very strong and sporting fish, the European pollack, or pollock, is caught in a variety of ways. When hooked, it dives with great force for the bottom. It reaches a weight of more than 20 lb.

Blue Shark (Prionace *glauca*).—The sport of fishing for these large fish was unknown before the 1950s. They are principally caught off the Cornish coast by the methods already described. A large blue weighs up to 180 lb.

Mako Shark (*Isurus oxyrhynchus*).—This very large shark is caught in the same way as the blue shark and in the same waters. It weighs up to 350 lb. in British waters.

Tope (*Eugaleus* or *Galeus* galeus).—A small but very game member of the shark family, tope are caught in a variety of ways. The females are always bigger than the males and weigh up to about 70 lb.

Conger (Conger *oceanicus* or conger).—A very large and fierce eel, the conger is usually caught on bait of fresh fish. Fishing over a wreck is generally the best way of taking conger, which may weigh more than 80 lb.

D. EUROPE

The fish, both sea and fresh-water, just described are likewise common to European waters. Their distribution of course depends on geographical factors. There are, however, several fish not native to British waters which afford sport to anglers of the European continent. Principal among these is the European pike perch (*Lucioperca* lucioperca), a close relative of the American walleyed pike and a good sporting and table fish which can be caught on casting or spinning tackle and by bait fishing, and the huchen (Salmo hucho), a salmon found only in the Danube and its tributaries. The huchen runs as big as the Atlantic salmon and is usually caught in winter by casting with a mounted dead fish. In eastern Europe and in Russia there are several fish, particularly members of the chub family, which are not found farther west. Little is known about them from a fishing point of view and they have no common English names. Members of the char family (*Salvelinus* species), a troutlike fish found in some of the deep British lakes, are much more common in some of the more northerly countries and run to a good size. They do, however, vary greatly in size and colour from one locality to another and again have no common names in English.

1. Northern Europe.—Iceland has wonderful trout, sea trout and salmon fishing and also has a run of migratory arctic char (*Salvelinus alpinus*), the fish which runs into northern Canadian waters. Pike and perch are common in Norway but so are the even more sporting salmon, sea trout, trout, char and grayling. Salmon run very big (to more than 75 Ib.) on some of the Norwegian rivers, notably rivers like the Namsen and the Aaro. Sea trout also run big and on rivers like the Aurland and the Laerdal take the dry fly well. There is excellent salt-water fishing for most of the sea fish already mentioned. There are good salmon rivers in Sweden, too, although not as good as those in Nonvay. The Em is without doubt the best sea trout river in the world. There is also excellent fishing for pike and perch both in the lakes and, most unusually, in the Baltic where both fish are sea-run. Denmark has only one salmon river but does have excellent trout and sea trout fishing. The Danes have developed a technique for catching sea trout in the sea on spinning lures. There is also excellent sea fishing off the Danish coast and big game fishing for bluefin tuna, or tunny (Thunnus *thynnus*), running up to near the 1,000-lb. mark in the waters between Denmark and Sweden. There is salmon fishing in northern Finland and excellent fishing for trout, sea trout, char, grayling, pike and perch all over the country. The trout run big, particularly those which go up the streams from the larger lakes in order to spawn.

2. Central and Southern Europe.—All the fish so far mentioned are found in Germany, although pollution has killed off the salmon run in rivers like the Rhine. There is particularly good trout and grayling fishing in southern Germany and wonderful carp fishing in Schleswig-Holstein. Excellent trout and particularly fine grayling fishing is found in most parts of Austria as well as good fishing for pike and perch, char and huchen. The Traun is one of the best rivers in the world for trout and big grayling. The rivers of Czechoslovakia offer good trout and grayling fishing; there is an abundance of splendid pike, perch, pike perch and particularly carp. There is also good huchen fishing. In Switzerland there is very good fishing for most of the fish found in Europe, and trout and pike run very big in some of the lakes.

Good coarse fishing is to be found in some of the slower rivers of France and still excellent trout fishing in the more mountainous regions and in Normandy where there are chalk streams of the type found in southern England. The North American black bass has been introduced into some French waters and there are some good salmon rivers in Brittany. The sea fishing in the Mediterranean is very good. There is very good trout fishing in the Ardennes, good coarse fishing in the slower rivers and also plenty of sea fishing. The Netherlands has no trout fishing to speak of, but offers much water containing pike, perch, pike perch, roach, bream and carp. Sea fishing resembles that of Great Britain. Most of the European fish can be caught in Luxembourg and there is good trout fishing in the mountain streams.

Trout and grayling are fished in the mountain rivers of Italy and there are pike, perch, tench, carp, roach and chub in the slower rivers and lakes. The sea fishing is excellent. Spain has very fine salmon fishing in the Eo and Narcea and plenty of good trout fishing in mountain streams. There is very good trout and sea trout fishing and some salmon fishing in Portugal, which also has some of the best sea bass fishing in river estuaries. Swordfish and tuna can also be caught off the coast. Yugoslavia probably has the best trout fishing in Europe and every year trout up to ten pounds and more are taken on the dry fly. There is also excellent grayling fishing, huchen fishing in the Danube tributaries, and good fishing for carp, perch and pike.

3. U.S.S.R.—Angling is a very popular sport in the U.S.S.R. where there are many species of sporting fish, some of which are not known elsewhere. In the western part of the Soviet Union most of the European fish already described are found—Atlantic salmon in the north, trout, char and grayling well distributed, and in the slower rivers pike, perch, pike perch, roach, chub, carp and bream. There are several members of the chub family not found farther west, the taimen, a close relative of the Danube huchen, a landlocked Atlantic salmon (*Salmo relictus*) found in the northern lakes, and a number of members of the whitefish family (Coregonidae). The Pacific salmon which ascend the rivers of Canada and the United States also run in the Soviet rivers.

E. Africa

In the vast territory of Africa there are countless fresh-water and salt-water fish which have no common names in English. Certain of the native species give good sport and are thus sought by the angler, while trout, black bass and carp have been introduced into many parts.

Trout, both brown and rainbow, have been introduced into most of the mountain rivers in Cape Province, Natal and the Transvaal in South Africa, and on some of these rivers the fishing can be very good by any standards. The North American black bass, both the smallmouth and the largemouth, have also been successfully transplanted, and while they do not fight with quite the vigour they display in their native, colder waters, they are a very welcome addition to the fish available to anglers. The carp has also been introduced and runs to weights over 40 lb., particularly in the Transvaal. Of the native fresh-water fish a barbel called the yellowfish (*Barbus carpensis*) is a good fighter and will sometimes take a fly, and various members of the cichlid (*q.v.*) family (genus *Tilapia*), known locally as kurper, give good sport. The sea fishing off the coast of South Africa is magnificent, including big game fish like sharks, tuna and swordfish and smaller fish like elft (the North American bluefish), kabeljau, snapper and countless others.

There is very fine trout fishing for both brown and rainbow trout in Kenya, particularly in the Nyeri district. and the largemouth black bass has been introduced. There are also native fish of the *Barbus* genus. Off the coast sailfish, marlin, swordfish, tuna and barracuda are very numerous.

The great sporting fish of central Africa is the tiger fish (*Hydrocyon*) and this provides the best sport in that territory, including Northern Rhodesia. There are several species of tiger fish, the smaller ones running up to about 6 lb. and the larger ones to more than 20 lb. They are beautifully coloured fish with huge, dangerous teeth and can be taken on bait-casting lures with a steel leader. The giant Nile perch (*Lates niloticus*) runs up to hundreds of pounds in weight. There is good trout fishing in Southern Rhodesia, and the American black bass has also been introduced there. Of the native fish both the tiger fish and *Tilapia,* known locally as bream, are much sought after. In Uganda, trout have been introduced, both brown and rainbow. There are also Nile perch, members of the *Barbus* genus, tiger fish and a sporting fish called locally a barbel, which takes a casting lure well.

Tiger fish provide the best sport in West Africa, particularly in the Niger and its tributaries, although huge Nile perch and a fish called pella are fished for. There is excellent sea fishing, particularly for barracuda and also for tarpon.

F. Asia

1. India and Pakistan.—During the long British rule in India, brown and rainbow trout were introduced into the rivers of Kashmir and into some other mountain rivers. The principal native sporting fish of India and indeed of other parts of Asia is the mahseer (*Barbus tor*). A large fish running up to 200 lb. and more and with extremely powerful jaws, the mahseer thrives best in cold, fast rivers. Small fish will take a wet fly but the bigger ones are usually caught on bait or on spoons. Very strong hooks are required.

Other sporting fish are the carnatic carp (*Barbus carnaticus*), the baril (*Barilius bola*), which take a fly well, the rohu or labeo (*Labeo rohita*), and a predatory fish, the murral, which is widely distributed. There is also good fishing in the river estuaries for fish called bahmin, nair and seer.

2. Ceylon.—Rainbow trout have been introduced with success into some of the rivers of Ceylon, particularly into the streams in the Nuwara Eliya district. European carp have also been planted in some of the lakes and run to a good size. There are mahseer in some of the rivers but they run very small. A predatory fish called a walliya can be caught on bait-casting or spinning tackle.

3. China and Southeast Asia.—Sport fishing has flourished in the countries where British or American influence has been strong; although there are many species of fish in the vast area of China and southeast Asia, and fish represent a major item of diet, sport fishing with western equipment is little practised. There is, however, no keener angler anywhere than the Chinese and in Malaya, due to both British and Chinese enthusiasm, angling has grown in popularity. The local fish have no English names but in the rivers members of the mahseer family (*Barbus*) and off the coast many different kinds of sea fish, including sharks and swordfish, are caught in large numbers.

Pacific salmon run in the waters of Japan but although the Japanese are first-class commercial fishermen, fishing is not generally popular as a sport.

G. Oceania

1. New Zealand.—All the fresh-water sporting fish of New Zealand have been introduced and no finer trout fishing, both for brown and rainbow trout, but particularly for the latter, exists. The trout run very big, particularly in the North Island. Salmon, both the Pacific and Atlantic species, have been introduced to the South Island. The Atlantic salmon has become landlocked but the quinnat salmon (the Chinook or Tyee salmon of North America) remains seagoing and is taken in the rivers on spoons and similar baits.

The big game fishing, particularly in the Bay of Islands and the Bay of Plenty, is first class, swordfish and sharks being the principal quarry. Since World War II sea fishing, particularly surf casting, has become increasingly popular in New Zealand.

2. Australia.—A number of native fish of high edible and sporting value are found in the Australian rivers, the principal ones being the Murray cod *(Maccullochelia macquariensis),* the perch *(Prectoplites fluviatilis)* and the golden perch *(Prectoplites ambiguus)*. Brown and rainbow trout have been introduced with success on a very wide scale. Australia is blessed with splendid sea fishing, both for big game fish—swordfish, tuna, shark—and for smaller fish like jewfish, kingfish, barracuda, grouper and yellowtail. Some of the world's finest trout fishing is found in Tasmania.

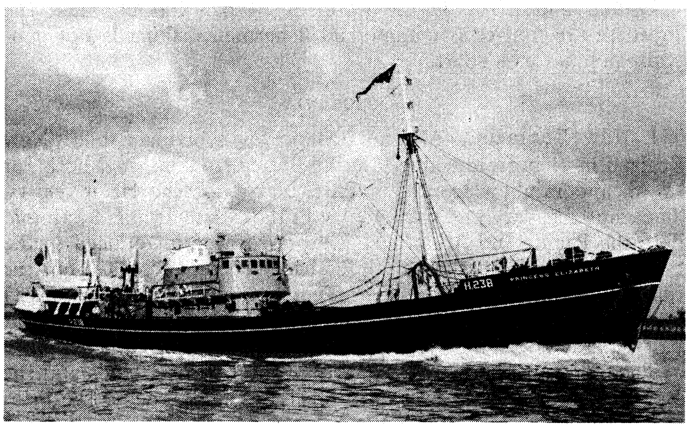
FISHING FROG: *see* ANGLER.

FISHING VESSELS. The first fishing vessel was probably a log pushed from a river bank by a primitive fisherman who straddled it to get to a good hole across the river. This desire for mobility has been the guiding force in the development of these craft. The log soon proved unsatisfactory, so it was hollowed out and the ends pointed. As explorations extended, canoes were built by making frameworks of wood and covering them with skins or bark, and later by strips of wood planking. Lengthening, deepening and widening the canoes made them more and more seaworthy. At first the deck covered only the bow, but it was later extended to the stern and finally all over to take rougher water. Houses and quarters were installed for longer voyages. Oars and sails provided motive power for the earliest types, but in modern times mechanical propulsion and equipment for hauling lines and nets were developed. Eventually there evolved such modern monsters as the 700-ft. whale mother ships.



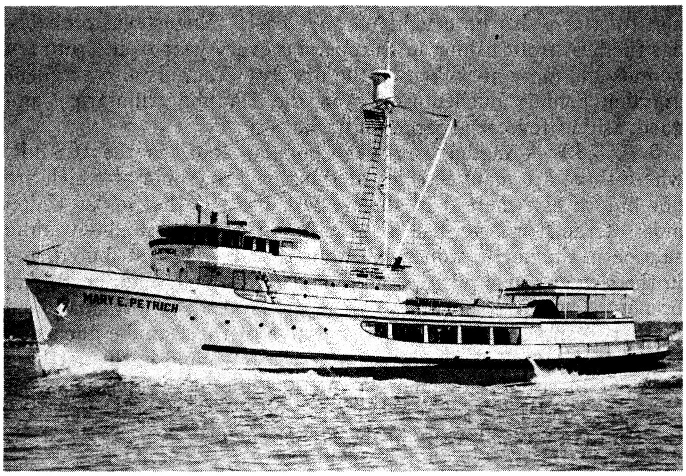
BY COURTESY OF ST. ANDREW'S STEAM FISHING CO., LTD., HULL

BRITISH LONG-RANGE DEEP-SEA TRAWLER, OPERATED IN THE NORTH ATLANTIC TO CATCH COD AND OTHER BOTTOM FISH BY MEANS OF TRAWL NETS

As shipbuilding technology developed, so did the techniques of catching fish, and the character of fishing vessels changed to suit the methods employed. Three basic types of fishing evolved: fishing with a spear or harpoon; fishing with a hook and line; and fishing with a net. Vessels for spear fishing developed from the primitive canoe to the modern whale-killer ships that catch whales with explosive harpoons. Hook-and-line vessels developed in a wide range of types and sizes up to the modern tuna clipper or long-liner. Net fishing vessels developed an equal range of varieties extending in size up to the 200-ft. trawlers used on the Atlantic codfish banks.

Vessels used for fishing in the protected waters of rivers, lakes and sounds are small and are nearly always open vessels without closed decks. Although subject to many variations in shape and in materials of construction, they are essentially the same the world over. While the open boat is still widely used for commercial fishing in many parts of Africa, Asia and South America, in Europe and the United States most such craft are used by fishermen who fish for sport only.

Short-range boats designed to fish in exposed bays or to make short runs out into the ocean are by far the most numerous of commercial fishing vessels and are used throughout the maritime world. Generally about 20 to 45 ft. in length, they are either partly or totally enclosed; they always have partial decks over the bow and stern and quite often have full decks broken only by fish holds or hatches. There is an infinite variety of craft of this kind. Sails are still used to a limited extent in some areas. but the internal combustion engine is now practically the universal source of Dower.



BY COURTESY OF JAMES E. PETRICH

U.S. TUNA CLIPPER

Live bait is carried in the large tank on the after part of the vessel. Tuna are caught from it by poles with short lines and hooks

Intermediate-range boats can go out into the open sea and stay for several days. They range from 45 to 80 ft. in length and use various types of fishing gear. With fully enclosed decks, mechanical propulsion, and accommodations, they can fish in relatively exposed waters a considerable distance from their home port. They operate mainly out of ports in the more highly industrialized countries.

Long-range vessels range from 80 to 200 ft. in length. Among the various types are the trawlers that operate from both sides of the Atlantic into the Atlantic fishing grounds; the tuna clippers that operate off the western coasts of the Americas; the tuna handliners and bait boats operated by the Japanese; and the whale-killer ships operated by Japanese and European interests in the Antarctic. All such craft are highly mechanized and expensive.

Means of preserving a catch of fish is a necessity for intermediate-range and long-range fishing vessels. Salt was the first medium but it was largely replaced in the 20th century by ice. Modern vessels, particularly the long-range type, use mechanical refrigeration extensively. In such fisheries as the Pacific tuna, fish are held for three or four months before the vessel returns

to port.

Mother ships that accompany smaller fishing vessels to distant fishing grounds form a special category. These ships are equipped to supply, feed and maintain large numbers of men for a long period of time and to process the fish on board. The codfishing schooners of the North Atlantic were probably the first mother ships. They remained at sea for long periods while individual fishermen in dories brought the fish aboard to be salted down. Many types of mother ships have been tried and many are still operating. The whale factory ships are the largest. Salmon, tuna, cod and crab canneries and freezer ships of various kinds operate in different parts of the world.

In early times, as distinctive types of vessels were developed in different areas, they generally were named for the area plus an additional name, the derivation of which has often been lost in time. The Yorkshire "Coble," Hasting's "Lugger" and Chesapeake "Sharpie" are examples.

As communications developed and fishing spread throughout the world, the old names and place designations have been dropped and they are now generally named for the type of fishing gear they use. Vessels fishing with nets are called trawlers, draggers, seiners, gill netters and drifters. Vessels using hooks and lines are called long-liners, hand-liners, trollers: pole boats and bait boats. *See* also FISHERIES; SEINING, NETTING AND TRAWLING. (G. C. NM.)

FISH LOUSE, small Crustacea, viz., members of the orders Eucopepoda, Branchiura, Isopoda and Amphipoda which are external and gill parasites of fishes and other marine animals. *See* CRUSTACEA; COPEPODA; MALACOSTRACA.

FISK, JAMES (1834–1872), U.S. financier whose flamboyant techniques in promoting securities earned for him the name "Barnum of Wall Street," was born April 1, 1834, at Bennington, Vt. He was successively a circus hand, waiter, peddler, dry-goods salesman, stockbroker and corporate official. In 1864 he formed the brokerage firm later known as Fisk and Belden and became a stock market operator for Daniel Drew. In 1867 Fisk joined Drew and Jay Gould in wresting control of the Erie railroad from Cornelius Vanderbilt. As vice president and comptroller of the road, Fisk used corporate funds to corrupt public officials,produce Broadway shows and support Broadway beauties, including the well-known Josie Mansfield, to such an extent that he was also called "The Prince of the Erie." Fisk was Gould's lieutenant in the attempted corner of the gold market which led to the fateful "Black Friday" of Sept. 24, 1869. Fisk was shot by E. S. Stokes, a former business associate, on Jan. 6, 1872, and died the following day in New York city.

See W. A. Swanberg, *Jim Fisk: the Career of an Improbable Rascal* (1959). (J. R. LT.)

FISK, WILBUR (1792–1839), U.S. educator and Methodist clergyman, was born at Brattleboro, Vt., on Aug. 31, 1792, the son of Isaiah and Hannah (Bacon) Fisk. He studied at Peacham academy and the University of Vermont, and graduated from Brown university in 1815 (A.M., 1818). Licensed as a local preacher at Lyndon, Vt., in 1818, he was received into the New England Conference of the Methodist Church in June of that year. While stationed at Charlestown, Mass. (1819–20), Fisk attended a camp meeting, where—according to his statement—he experienced "a supernatural work of grace leading him into a higher Christian life." In 1823 he married Ruth Beck of Providence, R.I., and for three years thereafter was presiding elder of the Vermont district, becoming in 1826 chaplain of the Vermont legislature. While in Europe (1835–36) he was elected bishop of the Methodist Episcopal Church (May 1836) but declined consecration. His high repute as an educator did much to raise the estimate of Methodism in New England, where before his time it had suffered because of its indifference to learning. He was a founder and principal of Wesleyan academy, Wilbrahm, Mass. (1825–30); a founder and first president of Wesleyan university, Middletown, Conn. (1831–39); and a member of the Connecticut board of education (1838). Pulmonary hemorrhages, from which he had suffered since childhood, resulted in his death on Feb. 22, 1839, at the height of his career.

See J. Holdick, *The Life of Wilbur Fisk, D.D.;* J. H. Brown (ed.), *Lamb's Biographical Dictionary of the United States.* (W. C. B.)

FISKE, BRADLEY ALLEN (1854–1942), U.S. naval officer who invented a number of instruments that revolutionized naval warfare, was born in Lyons, N.Y., June 13, 1854. He graduated from the United States Naval academy in 1874. At the battle of Manila bay (1898) he was navigator of the gunboat "Petrel," and was cited by Adm. George Dewey for heroic action in inaugurating fire control from a fighting top. During the Philippine insurrection, Fiske commanded the monitor "Monodnock."

His fame rests, however, upon his inventive genius. Chief among his inventions were the electric range finder, an electric ammunition hoist, a naval telescope mount and sight, and the torpedoplane (*q.v.*). Bluff and outspoken, Fiske was in controversy with secretaries of the navy through several administrations. He was one of the ablest exponents of adequate naval preparation, and his enthusiasm frequently ran afoul of a conservative navy department. His resignation, in May 1915, was the outcome of a long dispute on naval policy. Fiske saw many of his inventions developed and used successfully in World Wars I and II. He wrote *From Midshipman to Rear Admiral* (1919), an account of his experiences in the U.S. navy.

He died in New York city on April 6, 1942.

See D. W. Knox, *A History of the United States Navy* (1936). (W. B. CK.)

FISKE, JOHN (1842–1901), U.S. historical writer and popular lecturer, was born in Hartford, Conn., March 30, 1842. His name, originally Edmund Fisk Green, was legally changed to that of a great-grandfather, John Fisk, in 1855; he later adopted the spelling Fiske. Graduated from Harvard in 1863, Fiske practiced law for a short time, delivered two series of lectures at Harvard in 1869 and 1871, was assistant librarian from 1872 to 1879, and thereafter devoted himself to writing and lecturing.

In his best known philosophical work, *Outlines of Cosmic Philosophy* (1874), Fiske undertook to demonstrate the compatibility of science and religion by maintaining that both could be comprehended under the generalizations of the then vigorously disputed concept of evolution.

Fiske wrote 13 volumes of United States history, 10 of them dealing with the colonial period and all of them based on his public lectures. Fiske's historical writing, although concerned largely with the development of governmental institutions, also contained material on social life and economic interests. One of his last works, *The Mississippi Valley in the Civil War* (1900), reflected the newer interest of historians in sectional influences in political life. He died at Gloucester, Mass., on July 4, 1901.

BIBLIOGRAPHY.—Josiah Royce, "Introduction," *Miscellaneous Writings of John Fiske,* 12 vol. (1902) is the best analysis of Fiske's thought; John S. Clark, *The Life and Letters of John Fiske,* 2 vol. (1917), furnishes personal data; Edward Arthur White, *Science and Religion in American Thought* (1952), provides interpretation and context. (E. A. WE.)

FISKE, MINNIE MADDERN (MARIE AUGUSTA DAVEY) (1865–1932), U.S. actress whose career in the theatre was long and distinguished, was born in New Orleans, La., Dec. 19, 1865. Her father, Thomas W. Davey, was a theatrical manager. Mrs. Fiske first appeared on the stage at the age of three under her mother's maiden name as "Little Minnie Maddern." At five she made her New York debut in *A Sheep in Wolf's Clothing* and later the same year performed as Eva in *Uncle Tom's Cabin.* The next several years were spent as a child actress; she made her first appearance as an adult star in 1882. In 1890 she married Harrison Grey Fiske, a playwright and theatrical manager. In 1893 she enjoyed a modest success in *Hester Crewe,* a play written by her husband, but *Tess of the D'Urbervilles* (1897) was her first truly great success. At about this time also, she began to specialize in the plays of Ibsen and Shakespeare, and her interpretations of Ibsen's heroines were especially acclaimed.

In 1901 Fiske opened the Manhattan theatre in New York to oppose Charles Frohman's Theatrical Syndicate, which then dominated the U.S. theatre. Although Fiske lost a great deal of money during the six years this theatre was in operation, he and his wife gave New York some of its greatest theatre. The most important plays in which Mrs Fiske starred during this period were Paul Heyse's *Mary of Magdala* (1902), *Hedda Gabler* (1903), *Becky Sharp* and *Leah Kleschna* (1904), Langdon Mitchell's *The New York Idea* (1906) and Ibsen's *Rosmersholm* (1907). After the closing of the Manhattan, Mrs. Fiske appeared in Edward Sheldon's *Salvation Nell* and in several Ibsen plays. On Feb. 1j, 1932, she died of a heart ailment.

BIBLIOGRAPHY.—William Winter, *The Wallet of Time* (1913); Walter Pritchard Eaton, "The Theatre Mrs Fiske Knew," *Theatre Arts Monthly* (May 1932); F. C. Griffith, *Mrs. Fiske* (1912). (S. W. H.)

FISK UNIVERSITY, an institution of higher education in Nashville, Tenn., named for Gen. Clinton B. Fisk of the Freedmen's bureau, was established in 1865 and opened in Jan. 1866 as the Fisk school to provide for the education of southern Negroes. In 1867 it secured a charter as Fisk university under the auspices of the American Missionary association to educate young people "irrespective of color." Shortly thereafter, a Tennessee statute restricted attendance to Negroes, but later the college again admitted foreign and U.S. students of all races and creeds.

See NEGRO, AMERICAN: *Educational and Cultural Developments.*

FISTULA, a term used in surgery to designate an abnormal communication leading either from the surface of the body to a normal cavity or canal, or from one normal cavity or canal to another. These communications are the result of disease or may be congenital. Fistulas between arteries and veins also may occur, usually as the result of injury. (F. L. A.)

FIT. In medicine, a fit is an extreme emotional outbreak, a spasm or paroxysm. More commonly the term is used to describe a convulsive state which may be followed by semiconsciousness or unconsciousness or coma. *See* CONVULSIONS; EPILEPSY.

FITCH, (WILLIAM) CLYDE (1865–1909), U.S. playwright, whose best-known play was *Beau Bruntmel,* produced in 1890, was born on May 2, 1865, in Elmira. N.Y., and graduated from Amherst college, Amherst, Mass., in 1886. An interest in literature led him to establish himself in New York city, where he began writing short stories for various magazines. He was a prolific writer, producing 33 original plays and 22 adaptations. His best plays were social satires and character studies focusing on some human strength or weakness. Among the more important aside from *Beau Brummel* were *The Climbers* (1901), *The Girl With the Green Eyes* (1902), *The Truth* (1907) and *The City* (1909). He also wrote a large number of frank melodramas and historical plays. Fitch excelled in comedy, realistic dialogue and theatre technique, but in general his plays lack strength and universality. He died in France on Sept. 4, 1909.

See M. J. Moses and V. Gerson (eds.), *Plays by Clyde Fitch* (1915) and *Clyde Fitch and His Letters* (1924).

FITCH, JOHN (1743–1798), U.S. metal craftsman and one of the earliest builders of steamboats, designed and built a steamboat which operated successfully in 1787.

Born Jan. 21, 1743. in Windsor, Conn, he received but six years of common schooling. He was then put to work, first on a farm and later apprenticed to a brass founder and clockmaker. He set up his own business but did not succeed financially, and in all his later efforts he was always short of funds.

Settling in Bucks county, Pa., in 1785, Fitch became interested in propelling boats by steam power, an interest that continued until his death. He failed to obtain subsidies from the Continental congress and applied to the state governments, who refused funds but granted him exclusive rights to operate steamboats on their waters. He built several models of steamboats and with these persuaded some Philadelphians to form a company which furnished money to build a 45-ft. boat. On Aug. 22, 1787, in the presence of members of the Constitutional Convention, this vessel was successfully operated on the Delaware river. He built a larger boat propelled by steam-powered paddle wheels, which made regularly scheduled trips, carrying passengers and freight, between Philadelphia, Pa., and Trenton, N.J. The schedule was maintained and published in the Philadelphia daily papers.

Fitch's claims to invention of the steamboat were challenged by James Rumsey, and this controversy resulted in the issuance of pamphlets in 1787–88 in which both men set forth their claims.

Fitch was granted a U.S. patent for steamboats on Aug. 26, 1791, and a French patent in the same year.

He started construction of another steamboat but it was wrecked by a storm. This so discouraged the members of his company that they declined to advance any more money. He went to France in 1793 but failed in his attempts to interest that country in steam navigation. He returned to the U.S. despondent and in poor health. He died at Bardstown, Ky., on July 2, 1798.

Fitch built steamboats propelled by oars. paddle wheels and a crude type of screw propeller. These vessels operated reliably, but he did not give thought to building and operating costs and so failed to demonstrate the economic value of steam propulsion. As a result, the use of steam power was not continuous following his early efforts; and Robert Fulton, who did not launch a boat until after Fitch's death, is given more credit for the origin of this type of transportation. (M. R. D.)

FITCH, RALPH (fl. 1583–1606), London merchant, one of the earliest English travellers and traders in Mesopotamia, the Persian gulf and Indian ocean, India proper and Indochina. In Jan. 1583 he embarked in the "Tiger" for Tripoli and Aleppo in Syria (*see* Shakespeare, *Macbeth,* act i, sc. 3), together with J. Newberie, J. Eldred and two other merchants of the Levant company. From Aleppo he reached the Euphrates, descended the river to Fallujah, crossed southern Mesopotamia to Baghdad and dropped down the Tigris to Basra (May to July 1583). There Eldred stayed behind to trade, while Fitch and the rest sailed down the Persian gulf to Ormuz, where they were arrested as spies and sent prisoners to the Portuguese viceroy at Goa (September to October). Through the sureties procured by two Jesuits (one being Thomas Stevens, formerly of New college, Oxford, the first Englishman known to have reached India by the Cape route, in 1579) Fitch and his friends regained their liberty, and escaping from Goa (April 1584) travelled through the heart of India to the court of the great Mogul Akbar, then probably at Agra. In Sept. 1585 Newberie left on his return journey overland via Lahore (he disappeared in the Punjab), while Fitch descended the Jumna and the Ganges, visiting Benares, Patna, Kuch, Behar, Hugli, Chittagong (1585–86), and on by sea to Pegu and Burma.

He visited the Rangoon region, ascended the Irawadi some distance, acquired a remarkable acquaintance with inland Pegu and even penetrated to the Siamese Shan states (1586–87). Early in 1588 he visited Malacca; in the autumn of this year he began his homeward travels, first to Bengal; then round the Indian coast, touching at Cochin and Goa, to Ormuz; next up the Persian gulf to Basra and up the Tigris to Mosul (Nineveh); finally via Urfa, Bir on the Euphrates, Aleppo and Tripoli, to the Mediterranean. He reappeared in London on April 29, 1591. His experience was greatly valued by the founders of the East India company, who specially consulted him on Indian affairs. He died *c.* Oct. 5, 1611.

FITCHBURG, a city of Massachusetts, U.S., located on the Mohawk trail 46 mi. N.W. of Boston, was named for John Fitch who did much to secure incorporation. It is one of the seats of Worcester county. Originally known as Turkey Hills, Fitchburg was first settled in 1740 and was essentially an agricultural community until the first decade of the 19th century. It was established as a town Feb. 3, 1764, and incorporated as a city March 8, 1872.

For years Fitchburg's principal industries were the manufacture of machinery, paper and textiles.

After mid-20th century the leading industries were the manufacture of metal products, paper and allied products, and machinery. Fire arms, leather goods, juvenile wheel goods and toys, locksmith supplies and padlocks, saws, shoes and slippers, and synthetic yarns are other major products. A state teachers college was established there in 1894.

For comparative population figures *see* table in MASSACHUSETTS: *Population*. (J. F. Z.)

FITCHEW, a nameapplied to the ferret and also to the polecat (*qq.v.*). Earlier forms of the word are ficheux, fecheu and fitcholl.

FITTIG, RUDOLF (1835–1910), German organic chemist, known for the reaction by which aryl hydrocarbons may be synthesized, was born on Dec. 6, 1835, in Hamburg. After studying for his Ph.D. (1856–58) under Friedrich Wöhler at Göttingen, he was assistant to Wöhler, then became professor at Tübingen in 1869, and successor to Adolf von Baeyer at Strasbourg in 1876. He helped to edit *Annalen* der Chemie from 1895 to 1910. The Wurtz-Fittig reaction, first used by Fittig in 1864 to prepare toluene from brombenzene, methyl iodide and sodium, is a general method by which aryl halides react in ether with sodium to produce hydrocarbons. Fittig and his students published approximately 400 papers which contributed much to synthetic organic chemistry. Among the subjects treated in the papers were the discovery of pinacone reaction (1859); diphenyl (1862); isophthallic acid (1869); complex potassium manganese cyanides (1868); and the synthesis of mesitylene (1869). In the course of later research cumerone, diacetyl and phenanthrene were produced; piperine and unsaturated acids were studied; the diketone formula for quinone was proposed; alpha-naphthol was synthesized; and the relationship between gamma-hydroxy acids and lactones was clarified. Fittig had tremendous influence on organic chemistry. He died on Nov. 19, 1910, in Strasbourg. (V. Bw.)

FITTON, MARY (*c.* 1578–1647), identified by some writers with the "dark lady" of Shakespeare's sonnets although there is no hint in her authenticated biography that she was acquainted with Shakespeare. The daughter of Sir Edward Fitton of Gawsworth, Cheshire, she was baptized there on June 24, 1578. She became maid of honour to Elizabeth I c. 1595. She was the mistress of William Herbert, later earl of Pembroke; she married Capt. William Polwhele and, on his death, a Captain Logher. She died *c.* 1647 and is represented, apparently as dark in colouring, on the Fitton monument in Gawsworth church.

FITTON, WILLIAM HENRY (1780–1861), British geologist, was born in Dublin in Jan. 1780. Educated at Trinity college, in that city, and at Edinburgh university, he took a medical practice at Northampton in 1812, and for some years the duties of his profession engrossed his time. In 1820 he settled in London and devoted himself to the science of geology. His "Observations on some of the Strata between the Chalk and the Oxford Oolite, in the South-east of England" (Trans. Geol. *Soc.* ser. 2, vol. iv.) embodied a series of researches extending from 1824 to 1836, and form the classic memoir familiarly known as Fitton's "Strata below the Chalk." In this great work he established the true succession and relations of the Upper and Lower Greensand, and of the Wealden and Purbeck formations, and elaborated their detailed structure. He had been elected F.R.S in 1815, was president of the Geological Society of London 1827–29, and was awarded the Wollaston medal by the Geological Society in 1852. He died in London on May 13, 1861.

See the obituary notice by R. I. Murchison in *Quart. Journ. Geol Soc.* vol. xviii., 1862, p. xxx.

FITZGERALD, the name of a historic Irish house, which descends from Walter, son of Other, who at the time of the Domesday survey (1086) was castellan of Windsor and a tenant-in-chief in five counties. From his eldest son, William, known as "de Windsor," descended the Windsors of Stanwell, of whom Andrew Windsor was created Lord Windsor of Stanwell by Henry VIII; the barony is now vested in the earl of Plymouth, his descendant in the female line. Of Walter's younger sons, Robert was given by Henry I the barony of Little Easton, Essex; Maurice obtained the stewardship (*dapiferatus*) of the great Suffolk abbey of Bury St. Edmunds; Reinald the stewardship to Henry I's queen, Adelaide; Gerald (also a dapifer) became the ancestor of the Fitz-Geralds.

As constable and captain of the castle that Arnulf de Montgomery raised at Pembroke, Gerald strengthened his position in Wales by marrying Nesta, sister of Griffith, prince of south Wales, who bore to him famous children, "by whom the southern coast of Wales was saved for the English and the bulwarks of Ireland stormed." Of these sons William, the eldest, was succeeded by his son Odo, who was known as "de Carew," from the fortress of that name at the neck of the Pembroke peninsula; William's eldest son, Gerald, had been slain by the Welsh. The descendants of Odo held Carew and the manor of Moulsford, Berks, and some of them acquired lands in Ireland. But the wild claims of Sir Peter Carew, under Queen Elizabeth I, to vast Irish estates, including half of "the kingdom of Cork," were based on a fictitious pedigree. Odo de Carew's brothers. Raymond Fitz-gerald (*q.v.*) and Griffin, took an active part in the conquest of Ireland.

Returning to Gerald and Nesta, their son David "Fitz Gerald" became bishop of St. David's (1147–76), and their daughter Angharat mother of Gerald de Barri (Giraldus Cambrensis; *q.v.*). A third son, Maurice, obtained from his brother the stewardship of St. David's, c. 1174, and having landed in Ireland in 1169, on the invitation of King Dermod, founded the fortunes of his house there, receiving lands at Wexford, where he died and was buried in 1176. His eventual territory, however, was the great barony of the Naas (in Kildare), which Richard Strongbow, earl of Pembroke, granted him with Wicklow castle; but his sons were forced to give up the latter. His eldest son, William, succeeded him as baron of the Naas and steward of St. David's, but William's granddaughter carried the Naas to the Butlers and so to the Loundreses. Gerald, a younger son of Maurice, who obtained lands in Offaly, was father of Maurice "Fitz Gerald," who was justiciar of Ireland from 1232 to 1245. In 1234 he fought and defeated his overlord, the earl marshal, Richard, earl of Pembroke, and he also fought for his king against the Irish, the Welsh and in Gascony, dying in 1257. He held Maynooth castle, the seat of his descendants.

Earls of **Kildare.**—The justiciar left a grandson Maurice (son of his eldest son Gerald) and a younger son Maurice; the latter was justiciar for a year in 1272, while the former, as heir male and head of the race, inherited the Offaly lands, which he is said to have bequeathed at his death (1287) to John "Fitz Thomas," whose military life was crowned by a grant of the castle and town of Kildare, and of the earldom of Kildare to him and the heirs male of his body (May 14, 1316). Dying shortly after, he was succeeded by his son Thomas, son-in-law of Richard de Burgh, the "red earl" of Ulster, who received the hereditary shrievalty of Kildare in 1317, and was deputy justiciar in 1320 and justiciar of Ireland in 1327–28. His younger son Maurice "Fitz Thomas" (1331–90), 4th earl, was frequently appointed justiciar, and was great-grandfather of Thomas (1427–77), 7th earl, who between 1455 and 1475 was repeatedly in charge of the government of Ireland as "deputy," and who founded the "brotherhood of St. George" for the defense of the English Pale. His son Gerald (*c.* 1456–1513), 8th earl, called Mór ("the Great"), was deputy governor of Ireland from 1481 for most of the rest of his life, though imprisoned in the Tower of London t o years (1494–96) on suspicion as a Yorkist. He was mortally wounded while fighting the Irish as "deputy." Gerald (d. 1534), 9th earl, followed in his father's steps as deputy, fighting the Irish, till the enmity of the earl of Ormonde, the hereditary rival of his house, brought about his deposition in 1520. In spite of temporary restorations he died a prisoner in the Tower.

In his anger at his rival's successes the 9th earl had been led, it was suspected, into treason, and while he was a prisoner in England his son Lord Thomas Fitzgerald (*q.v.*) broke out into open revolt (1534). He and his five uncles were hanged as traitors in Feb. 1537, and acts of attainder completed the ruin of the family.

But the earl's half-brother Gerald, a mere boy, had been carried off and, after many adventures at home and abroad, returned to England after Henry VIII's death, and to propitiate the Irish was restored to his estates by Edward VI (1552). Having served Mary I in Wyat's rebellion, he was created by her earl of Kildare and Lord Offaly on May 13. 1554, but the old earldom (though the contrary is alleged) remained under attainder. Although he conformed to the Protestant religion under Elizabeth I and served against the Munster rebels and their Spanish allies, he was imprisoned in the Tower on suspicion of treason in 1582. But the acts attainting his family had been repealed in 1569, and the old earldom was thus regained. In 1585 he was succeeded by his son Henry ("of the Battleaxes"), who was mortally wounded when fighting the Tyrone rebels in 1597. On the death of his brother in 1599 the earldom passed to their cousin Gerald, whose claim to the estates was opposed by Lettice, Lady Digby, the heir-general. She obtained the ancestral manor of Geashill with its territory and was recognized in 1620 as Lady Offaly for life. George (1611–60), 16th earl, had his castle of Maynooth pillaged by the insurgents in 1642, and after its subsequent occupation by them in 1646 it was finally abandoned by the family.

The history of the earls of Kildare after the Restoration was uneventful save for the reacquisition in 1739 of Carton, which thenceforth became the country seat of the family. James (1722–73), 20th earl, who obtained a viscounty of Great Britain in 1747, built Leinster house (now the place of assembly of the oireachtas, "national parliament") in Dublin, and formed a powerful party in the Irish parliament. In 1756 he was made lord deputy; in 1760 he raised the Royal Irish regiment of artillery; and in 1766 he received the dukedom of Leinster, which remained the only Irish dukedom till that of Abercorn was created in 1868. His wealth and connections secured him a commanding position. Of his younger children, one son was created Lord Lecale; another was the well-known rebel, Lord Edward Fitzgerald; another was the ancestor of Lord De Ros; and a daughter was created Baroness Rayleigh. William Robert (1749–1804), 2nd duke, was a cordial supporter of the Union, and received nearly £30,000 for the loss of his borough influence. In 1883 the family was still holding more than 70,000 ac. in County Kildare; but, after a tenure of nearly 750 years, arrangements were made to sell the land to the tenants under the land purchase acts. In 1893 Maurice Fitzgerald (1887–1922) succeeded his father, Gerald (1851–93), 5th duke; Maurice's brother Edward (1892–) succeeded as 7th duke in 1922.

Earls of **Desmond.**—The other great Fitzgerald line was that of the earls of Desmond, who were undoubtedly of the same stock and claimed descent from Maurice, the founder of the family in Ireland, through a younger son Thomas. Thomas "Fitz Maurice" Nappagh ("of the ape"; 1261–98), justiciar of Ireland in 1295, obtained a grant of the territory of "Decies and Desmond" in 1292. His son Maurice Fitz Thomas or Fitzgerald (d. 1356). inheriting vast estates in Munster, and strengthening his position by marrying a daughter of Richard de Burgh, earl of Ulster, was created earl of Desmond (*i.e.*, south Munster) on Aug. 22, 1329. The greatest Irish noble of his day, he led the Anglo-Irish party against the English. He surrendered in England to the king and was imprisoned, but eventually regained favour, and was even made deputy in 1355. Two of his sons succeeded in turn. Gerald (1359–98), 3rd earl, being appointed deputy in 1367, despite his adopting his father's policy which the crown still wished to thwart. But he was superseded two years later, and defeated and captured by the native king of Thomond shortly after. Yet his sympathies were distinctly Irish. The remote position of Desmond in the southwest of Ireland tended to make the succession irregular on native lines, and a younger son succeeded as 6th earl in 1420. His son Thomas, earl from 1462 to 1467, governed Ireland as deputy from 1463 to 1467, and upheld the endangered English rule by stubborn conflict with the Irish. Yet John Tiptoft, earl of Worcester, who superseded him, procured his attainder with that of the earl of Kildare, on the charge of alliance with the Irish, and he was beheaded on Feb. 15, 1468, his followers in Munster avenging his death by invading the Pale. His younger son Maurice, earl from 1487 to 1520, was one of Perkin Warbeck's Irish supporters, and besieged Waterford on his behalf. Maurice's son James, earl from 1520 to 1529, was proclaimed a rebel and traitor for conspiring with the French king and with the emperor. At his death the succession reverted to his uncle Thomas (1454–1534), at whose death there was a contest between his younger brother Sir John "of Desmond" and his grandson James, a court page of Henry VIII. Sir John secured possession till his death (1536), when his own son James succeeded de facto, and de *jure* on the rightful earl's being murdered by the usurper's younger brother in 1540. Intermarriage with Irish chieftains had by this time classed the earls among them, but although this James looked to their support before 1540, he thenceforth played so prudent a part that in spite of the efforts of the Butlers, the hereditary foes of his house. he escaped the fate of the Kildare branch and kept Munster quiet and in order for the English till his death in 1558. His four marriages produced a disputed succession and a break-up of the family. His eldest son, Thomas "Roe" (the Red) was disinherited, and failed to obtain the earldom, which was conferred by Elizabeth I on his half-brother Gerald, "the rebel earl" (c. 1533–83) (see DESMOND, GERALD FITZGERALD).

But the influence of the Fitzgeralds remained powerful even after the forfeiture of their estates following the murder of the 15th earl. The disinherited Thomas "Roe" left a son, James "Fitz Thomas," who, succeeding him in 1595 and finding that the territory of the earls would never be restored, assumed the earldom and joined O'Neill's rebellion in 1598, at the head of 8,000 of his men. He was eventually seized (1601) by his kinsman the White Knight, Edmund Fitz Gibbon, whose sister-in-law he had married, and was sent to the Tower. The sugan ("man of straw") earl lingered there obscurely as "James M'Thomas" till his death in 1607. In consequence of his rebellion and the devotion of the Irish to his house, James, "the queen's earl," son of Gerald, "the rebel earl," who had remained in the Tower since his father's death (1583), was restored as earl of Desmond and sent to Munster in 1600, but as a Protestant he achieved nothing, and he died the following year. Later claimants to the title lived abroad, taking service under the Habsburgs until the last, the condé de Desmond, was killed in 1632.

The **Fitzmaurices.**—There can be no doubt that the house of Fitzmaurice was also of this stock, although their actual origin, in the 12th century, is doubtful. From a very early date they were feudal lords of Kerry, and their dignity was recognized as a peerage by Henry VII in 1489. The isolated position of their territory (Clanmaurice) threw them even more among the Irish than the earls of Desmond, and they often adopted the native form of their name, "MacMorrish." Under Elizabeth I the lords of Kerry narrowly escaped sharing the ruin of the earls. The conduct of Thomas (c. 1520–90) in the rebellion of James "Fitzmaurice" Fitzgerald (*q.v.*) was suspicious, and his sons joined in that of the earl of Desmond, while he himself was a rebel in 1582. Patrick, his successor (c. 1541–1600), was captured in rebellion (1587), and when free. joined the revolt of 1598, as did his son and heir Thomas, who continued in the field till he obtained pardon and restoration in 1604, though suspect till his death in 1630. His grandson withdrew to France with James II, but the next peer became a supporter of the Whig cause, married the eventual heiress of Sir William Petty, and was created earl of Kerry in 1723. From him descended the family of Petty-Fitzmaurice, who obtained the marquessate of Lansdowne (*q.v.*) in 1784, and still hold among their titles the feudal barony of Kerry together with vast estates in that county.

From the three sons by a second wife of one of the earls of Desmond's ancestors descended the hereditary White Knights, knights of Glin and knights of Kerry, these feudal dignities having, it is said. been bestowed upon them by their father, as lord of Decies and Desmond. Glin castle, County Limerick, is still the seat of the (Fitzgerald) knight of Glin. The knights of Kerry received a baronetcy in 1880. (J. H. R.; E. A. MACL.)

FITZGERALD, LORD EDWARD (1763–1798), one of the most attractive and gallant of Irish rebels, was the fifth son of James, 1st duke of Leinster, and Emilia Mary, daughter of the 2nd duke of Richmond. Born at Carton house, County Kildare, on Oct. 15, 1763, he was brought up in France, where his mother lived, after his father's death, in the duke of Richmond's house at Aubigny. Returning to England in 1779, he joined the Sussex militia and went on active service in America in 1781 on the staff of Lord Rawdon. He was severely wounded at the battle of Eutaw Springs (1781). He returned to Ireland in 1783 and was elected to the Irish parliament as member for Athy. He voted with the opposition minority, led by Henry Grattan and J. P. Curran, but took no active part in public affairs. He toured Spain in 1787, and then sailed for New Brunswick as a major in the 54th regiment. He showed his high sense of adventure by traveling (1789) across Canada through unexplored territory, from Fredericton to Quebec. The Bear tribe of Hurons made him one of their chiefs, and he went on down the Mississippi to New Orleans, before returning to England.

Elected member for Kildare, Fitzgerald refused Pitt's offer to command an expedition against Cádiz. In London he associated with the Whigs who followed Charles James Fox and R. B. Sheridan, and joined the Society of the Friends of the People. Visiting Paris in Oct. 1792, he lodged with Thomas Paine and attended the debates of the convention. On Nov. 18 he attended a British banquet in Paris, where he joined in the toast to "the speedy abolition of all hereditary titles and feudal distinctions." He also repudiated his own title, and for these actions he was cashiered from the army. On Dec. 27, 1792, he married Pamela, a protégé of Madame de Genlis. It was commonly believed that Madame de Genlis was Pamela's mother; the father was claimed to be Philippe Égalité, duc d'Orléans.

Fitzgerald and his young wife returned to Dublin in Jan. 1793. There the United Irishmen society was rapidly expanding and Wolfe Tone. as secretary of the Catholic committee, was preparing a popular agitation under the inspiration of the French Revolution. Fitzgerald at once resumed his seat in the Irish parliament and within a few weeks was ordered to apologize for his defiance of the government. Wolfe Tone was actively engaged in Paris by May 1796, trying to obtain French military aid for an Irish insurrection. Fitzgerald had already joined the United Irishmen, who were openly advocating an independent Irish republic. In the same month he and his friend Arthur O'Connor went to Hamburg to negotiate for French assistance in an Irish rising. They contacted Gen. Lazare Hoche in Basel, but the Directory would not negotiate with Fitzgerald because of his wife's connection with the Orléans family. Fitzgerald therefore left O'Connor to continue the mission which resulted in Hoche's abortive expedition to Bantry bay in Dec. 1796. After his return to Ireland Fitzgerald became increasingly involved with the United Irishmen.

In July 1797 Fitzgerald declined to stand again as member for Kildare because free elections were impossible under martial law. A military committee was formed, under Fitzgerald, to prepare for co-operation with a French landing, or, if necessary, to organize an Irish insurrection, for which they claimed that 280.000 men were now ready to rise. Delays on the French side decided the committee to prepare for a general rebellion on May 23, 1798. Informers had revealed all the main plans to the English authorities, and on March 12 the members of the Leinster provincial committee were arrested while meeting at Oliver Bond's house. Fitzgerald was not present, since he had been warned to keep away; but he refused to escape and leave his friends. On May 11 a reward of £1,000 was offered for his capture; he was betrayed by an informer and arrested, after a fierce struggle, in a house in Thomas street, Dublin, on May 19. He mortally wounded one of his captors and was himself shot in one arm and disabled. Fitzgerald was removed to Newgate jail and there died of his wounds on June 4, 1798. Lord Edward—gay, humorous, entirely unselfish and courageous—lacked the qualities that were needed either for international conspiracy or political leadership in his own country.

Fitzgerald's widow had to leave Ireland before he died. She went to Hamburg and there later married the American consul, J. Pitcairn, but remained devoted to Fitzgerald's memory. She died in Paris in Nov. 1831.

See Thomas Moore, ***Memoirs of Lord Edward Fitzgerald,*** rev. ed. **(1897).** **(D. G.)**

FITZGERALD, EDWARD (1809–1883), English writer, translator of Omar Khayyám, was born as EDWARD PURCELL, at Bredfield. Suffolk, on March 31, 1809. His father, John Purcell, who had married a Miss FitzGerald, assumed in 1818 the name and arms of his wife's family. From 1816 to 1821 the FitzGeralds lived at St. Germain and at Paris, but Edward was educated at Bury St. Edmunds and at Trinity college, Cambridge, where he became acquainted with Thackeray and W. H. Thompson. In 1830 he returned to Paris, but soon chose to settle in the Suffolk town of Woodbridge where he passed a secluded, leisurely life devoted to flowers, music and books. With Tennyson, his intimacy began about 1835 and with Carlyle about 1842. In 1851, FitzGerald published *Euphranor,* a Platonic dialogue. born of memories of the old happy life at Cambridge. In 1852 appeared *Polonius,* a collection of aphorisms, some original, the rest borrowed from English classics. In the following year he issued *Six Dramas of Calderdn,* freely translated, and having turned to oriental studies under the guidance of his friend E. B. Cowell, afterward professor of Sanskrit at Cambridge. in 1856 he anonymously published a version of the *Salámán and Absál* of Jámi in Miltonic verse. In the same year he married Lucy, daughter of Bernard Barton. the Quaker poet, but they were soon separated. In Jan. 1859 a little anonymous pamphlet was published as *The Rubáiyát of Omar Khayydm.* The poem seems at first to have attracted no attention, until in 1860 Rossetti discovered it, and Swinburne and Lord Houghton quickly followed. The expression which it gave to the perplexity of the times led to the demand for a second edition in 1868. Meanwhile FitzGerald had produced in 1865 a version of the *Agamemnon,* and two more plays from Calderón. In 1880–81 he issued privately translations of the two Oedipus tragedies; his last publication was *Readings in Crabbe,* 1882.

From 1861 onward FitzGerald's greatest interest centred in the sea, and for some years, till 1871, he spent the months from June to October mainly in "knocking about somewhere outside of Lowestoft." On June 14, 1883, he passed away painlessly in his sleep. He was "an idle fellow, but one whose friendships were more like loves"; his wit and human side are displayed in his inimitable letters. Tennyson's dedication of his *Tiresias* to FitzGerald's memory, in some touching reminiscent verses to "Old Fitz" (1885) was the signal for the universal appreciation of Omar Khayyám in his English dress. (E. G.)

An edition of FitzGerald's works appeared in 2 vol. **(1887)**; his ***Letters and Literary Remains*** were edited **by** W. Aldis Wright (7 vol., 1902–03); other ***Letters*** were edited ***by*** F. R. Barton (1923), and those to Bernard Quaritch **by** C. O. Wrentmore **(1926).** His *Dict.* **of *Mme. de Sévigné was*** edited by his great niece, M. E. F. Kerrich, 2 vol. (1914). ***See*** also **T.** Wright, ***Life of*** E. ***FitzGerald,*** 2 vol. (1904); A. **C.** Benson, E. *FitzGerald* (1905); Morley Adams, ***Omar's Interpreter, a New Life of E. FitzGerald*** (1909).

FITZGERALD, F. SCOTT (FRANCIS SCOTT **KEY** FITZGERALD) (1896–1940), U.S. novelist famous for his depictions of the "jazz age" (the 1920s), was born in St. Paul. Minn., Sept. 24, 1896. He attended a series of schools—St. Paul academy, Newman, Princeton—which tended to confirm his feelings that he was always tantalizingly near, but never endowed with, great wealth. an emotion explored fully in some of his finest fiction. Princeton, which he left without finishing in 1917, and the army, in which he served. 1917–19, disappointed him profoundly as he later confessed: Princeton did not put him on its football team and the army did not send him overseas. He began *This Side of Paradise* (1920) in the army and rewrote it on the advice of Maxwell Perkins at Scribner's. Largely autobiographical, it sounded the rallying cry of the rebellious youth of the decade of revolt just beginning. Two volumes of short stories, Flappers and Philosophers (1920) and Tales of the Jazz Age (1922), were followed by a second novel, The *Beautiful* and Damned (1922), which purported to treat the exciting revolt of sophisticated youth while affirming the meaninglessness of life. Fitzgerald's real genius was revealed with the appearance of The Great Gatsby (1925), a story about Jay Gatsby's pursuit of an immense but elusive dream and the resulting destruction of both Gatsby and dream through the casual cruelty of fabulous wealth—a story of the fantastic '20s but also a story which probes deeply the American character. Some of Fitzgerald's finest stories appeared in All the Sad Young Men (1926), but it was not until 1934 that another novel appeared—Tender *Is* the Night, a frightening story of Dick Diver's spiritual bankruptcy and disintegration of character. A final volume of short stories followed—Taps at Reveille (1935). Fitzgerald himself, like Diver, was discovering that his moral resources were disappearing—a process he described with agonizing vividness in a series of essays, "The Crack-Up" (1936). He was attempting to recapture his lost talent in a novel about Hollywood when he died in 1940 The unfinished novel together with Fitzgerald's notes was published in 1941 as The Last Tycoon.

FITZGERALD, GEORGE FRANCIS (1851–1901), Irish physicist, whose researches were mainly concerned with electromagnetism, radiation and electrolysis. He was born in Dublin on Aug 3, 1851, and educated at Trinity college there. where he spent the rest of his life, becoming fellow in 1877, tutor in 1879, and professor of natural and experimental philosophy in 1881. He was elected a fellow of the Royal society in 1883 and was awarded the society's Royal medal in 1899. FitzGerald was renowned for his extensive knowledge of physics, his critical powers and his brilliant speculations. His studies on radiation led him to the conclusion, shortly afterward established experimentally by H. R. Hertz (*q.v.*), that the oscillatory discharge of an electric condenser might produce electric waves, the basic discovery in wireless telegraphy. In his study of the negative result of the Michelson-Morley experiment he formulated the hypothesis that the length of a body in motion through the ether is contracted in the direction of the motion, an assumption since known as the FitzGerald-Lorentz contraction because of the independent derivation and considerable development of it made by H. A. Lorentz (*q.v.*). FitzGerald's papers, edited by J. Larmor, were published as The Scientific Writings of the Late George Francis *FitzGerald* (1902). In addition to his scientific work, FitzGerald was interested in education and it was largely through his efforts that technical education was established in Ireland. He died in Dublin on Feb. 22, 1901. (D. McK.)

FITZGERALD, JAMES (called FITZMAURICE) (d. 1579), Irish leader, styled by English writers "the arch traitor," who was constantly in rebellion against the English government from 1565 until his death, was the son of Maurice, brother of James Fitzgerald, 14th earl of Desmond. In 1568, during the detention (1565–73) in England of his cousin, Gerald, the 15th earl, James assumed the leadership of the family and proceeded to rouse the southern chieftains to rebellion against the English by appealing to the necessity for them to protect both their lands and their religion.

In alliance with the brothers of the earl of Ormonde, with the earl of Thomond and with the son of the earl of Clanricarde. Fitzgerald had by July 1570 extended the rebellion as far as Kilkenny. At this point, however, an expedition under Sir Henry Sidney was mounted against Munster, Fitzgerald and his followers were forced into hiding, and the province was placed under the command of Sir John Perrot. Fitzgerald had sacked Kilmallock early in 1570 and Perrot, vowing to "hunt the fox out of his hole," took the field against him in 1571. However, the following year, in alliance with a Scots force landed in Ulster, Fitzgerald burned Athlone. Eventually, in Feb. 1573, he submitted to the English and took an oath of loyalty to Elizabeth I.

Earl Gerald refused, on his return to Ireland, to join in a fresh rising and in 1575 James Fitzgerald went abroad. He made unsuccessful appeals for support against the English in Ireland to Henry III of France and Philip II of Spain, but was favourably received by Pope Gregory XIII who appointed him leader of a holy war in Ireland against Elizabeth. Aided by Thomas Stucley, an English adventurer at the papal court, Fitzgerald made two unsuccessful attempts to launch an expedition against Ireland before, in 1579, a force was fitted out in Lisbon. Fitzgerald set out, ahead of the main body, in June 1579. With the papal nuncio and a few troops he landed at Dingle in Kerry in July but the expected general rising did not take place, mainly because the earls of Desmond and Kildare failed to lend adequate support. Fitzgerald was killed on Aug. 18, 1579, in a skirmish a few miles east of Limerick. Subsequently his body was hung, drawn and quartered by the English at Kilmallock.

See J O'Donovan, The Irish Correspondence of James *Fitzmaurice* of Desmond, Royal Society of Antiquaries of Ireland, 2nd series (1859).

FITZGERALD, RAYMOND or REDMOND (d. *c.* 1182), surnamed Le Gros, was the son of William Fitzgerald and brother of Odo de Carew. He was sent by Strongbow to Ireland in 1170, and had the chief share in the capture of Waterford and in the successful assault on Dublin. He was sent to Aquitaine to hand over Strongbow's conquests to Henry II, but was back in Dublin in July 1171, when he led one of the sallies from the town. Strongbow offended him later by refusing him the marriage of his sister Basilea, widow of Robert de Quenci, constable of Leinster. Raymond then retired to Wales, and Hervey de Mountmaurice became constable in his place. At the outbreak of a general rebellion against the earl in 1174 Raymond returned with his uncle Meiler Fitz Henry, after receiving a promise of marriage with Basilea. Reinstated as constable he secured a series of successes, and with the fall of Limerick in Oct. 1175 order was restored. Mountmaurice meanwhile obtained Raymond's recall on the ground that his power threatened the royal authority, but the constable was delayed by a fresh outbreak at Limerick, the earl's troop refusing to march without him. On the death of Strongbow he was acting governor until the arrival of William Fitz Aldhelm, to whom he handed over the royal fortresses. He was deprived of his estates near Dublin and Wexford, but the Geraldines secured the recall of Fitz Aldhelm early in 1183, and regained their power and influence. In 1182 he relieved his uncle Robert Fitzstephen, who was besieged in Cork.

FITZGERALD, LORD THOMAS (10th earl of Kildare) (1513–1537). known as "Silken Thomas," the eldest son of Gerald Fitzgerald, 9th earl of Kildare, was born in London in 1513. He spent much of his youth in England, but in 1534 when his father was for the third time summoned to England to answer for his maladministration as lord deputy of Ireland, Thomas, at the council held at Drogheda, in February was made vice-deputy. In June the Ormond faction spread a report in Ireland that the earl had been executed in the Tower, and that his son's life was to be attempted. Inflamed with rage at this apparent treachery, Thomas rode at the head of his retainers into Dublin, and before the council for Ireland (June 11, 1534) formally renounced his allegiance to the king and proclaimed a rebellion. His enemies, including Archbishop John Allen (of Dublin), who had been sent by Henry VIII to watch Fitzgerald, took refuge in Dublin castle. In attempting to escape to England, Allen was taken by the rebels, and was murdered (July 28, 1534) by Fitzgerald's servants in his presence. He was solemnly excommunicated by the Irish Church. Leaving part of his army (with the consent of the citizens) to besiege Dublin castle, Fitzgerald himself went against Piers Butler, earl of Ossory, and succeeded at first in making a truce with him. But the citizens of Dublin now rose against him, Ossory invaded Kildare, and the approach of an English army forced Fitzgerald to raise the siege. Fitzgerald from his stronghold at Maynooth ravaged Kildare and Meath throughout the winter. He succeeded to the earldom of Kildare, on his father's death in the Tower on

Dec. 13, 1534, but he does not seem to have been known by that title. On March 23, 1535, the Geraldine stronghold fell and most of the garrison were put to the sword. This proved the final blow to the rebellion. Fitzgerald spent the next few months in raids against the English and their allies, but his party gradually deserting him. on Aug. 18, 1535, he surrendered himself to Lord Leonard Grey (d. 1541), probably on conditions. He was placed in the Tower of London. In Feb. 1536 his five uncles were also seized, some of them with great injustice, and brought to England. The six Geraldines were hanged at Tyburn on Feb. 3, 1537.

FITZHERBERT, SIR ANTHONY (1470–1538), English judge and legal systematizer, was born at Norbury, Derbyshire, and from 1523 until shortly before his death in 1538 was justice of the court of common pleas. He was the author of *La Graunde Abridgement* (1514), a digest of important legal cases written in Old French; *The Office and Authority of Justices of the Peace,* first printed in 1538 (last ed. 1794); *New Natura Brevium* (1534, last ed. 1794), with a commentary ascribed to Sir Matthew Hale.

FITZ NEAL or **FITZ NIGEL, RICHARD** (d. 1198), treasurer of Henry II. and Richard I. of England, and bishop of London. Richard, who was born before 1133, succeeded to the office of treasurer in 1158, and held it continuously for 40 years. His name appears in the lists of itinerant justices for 1179 and 1194, but these are the only occasions on which he exercised that office. Before 1.184 he became dean of Lincoln and in 1189 Bishop of London.

Richard Fitz Neal's *De necessariis observantiis Scaccarii dialogus,* commonly called the *Dialogus de Scaccario,* is of unique interest to the historian. It is an account, in two books, of the procedure followed by the exchequer in the author's time, a procedure which was largely the creation of his own family. When read in connection with the Pipe Rolls the *Dialogus* furnishes a most faithful and detailed picture of English fiscal arrangements under Henry II. The speakers in the dialogue are Richard himself and an anonymous pupil. The date of the conversation is given in the prologue as 1176–77. This probably marks the date at which the book was begun; it was not completed before 1178 or 1179. Soon after the author's death we find it already recognized as the standard manual for exchequer officials. It was frequently transcribed and has been used by English antiquarians of every period. Hence it is the more necessary to insist that the historical statements which the treatise contains are sometimes demonstrably erroneous; the author appears to have relied excessively upon oral tradition. Richard Fitz Neal also compiled in his earlier years a register or chronicle of contemporary affairs, arranged in three parallel columns. This was preserved in the exchequer at the time when he wrote the *Dialogus,* but has since disappeared. Stubbs' conjectural identification of this *Liber tricolumnis* with the first part of the *Gesta Henrici* (formerly attributed to Benedictus Abbas) is now abandoned as untenable.

See Madox's edition in his *History* of *the Exchequer (1769)*; and that of A. Hughes, C. G. Crump and C. Johnson (Oxford, 1902). F. Liebermann's *Einleitung in den Dialogus de Scaccario* (Gottingen, *1875)* contains the fullest account of the author.

FITZ-OSBERN, ROGER [ROGER FITZWILLIAM] (*fl.* 1070), succeeded to the earldom of Hereford and the English estate of William Fitz-Osbern in 1071. In 1075, disregarding William I.'s prohibition, he married his sister Emma to Ralph Guader, earl of Norfolk, at the famous bridal of Norwich, at which the two earls plotted a conspiracy against the king. Roger, who was to bring his force from the west to join the earl of Norfolk, was held in check at the Severn by the King's forces. On the collapse of his confederate's rising, Roger was tried before the Great Council (1075) deprived of his lands and earldom. and sentenced to perpetual imprisonment. He died in prison.

FITZ-OSBERN, WILLIAM, Earl of Hereford (d. 1071), was an intimate friend of William the Conqueror, and the principal agent in preparing for the invasion of England. He was the son of Osbern the seneschal, one of William's guardians during his minority, who had been murdered by the young duke's unruly barons. Fitz-Osbern founded a monastery at Lire about 1042. He became seneschal to the duke, and urged on the plans for the invasion of England. At the Conquest he received the earldom of Hereford with the special duty of pushing into Wales. During William's absence in 1067, English affairs were left in the hands of Fitz-Osbern and of Odo, bishop of Bayeux. Fitz-Osbern also acted as William's lieutenant during the rebellions of 1069. Fitz-Osbern was one of the feudal lords of the Welsh marches, and built several castles for the defence of the border. In 1070 William sent him to assist Queen Matilda in the government of Normandy. But Richilde, widow of Baldwin VI. of Flanders, having offered to marry him if he would protect her son Arnulf against Robert the Frisian, Fitz-Osbern accepted the proposal and joined Richilde in Flanders. He was killed, fighting against Robert, at Cassel in 1071.

See E. A. Freeman, *Norman Conquest,* vols. iii. and iv. (1867–79); Sir J. Ramsey, *Foundations of England,* vol. ii. (1898).

FITZ OSBERT, WILLIAM (d. 1196), was a Londoner who had served in the Third Crusade, and on his return took up the cause of the poorer citizens against the magnates who monopolized the government of London. He complained in particular of the unfair assessments of the "aids" for the king's ransom (1194). The chronicler Roger of Hoveden gives Fitz Osbert a high character, and he was implicitly trusted by the poorer citizens. He attempted to procure redress for them from the king; but the city magistrates persuaded the justiciar Hubert Walter that Fitz Osbert was planning a general rising. The troops were sent to seize the demagogue, smoked him out of the sanctuary of St. Mary-le-Bow, in which he had taken refuge, and dragged him to the Tower where he was sentenced to death. He was hanged in chains at Smithfield on April 6, 1196 with nine of his followers.

FITZ PETER, GEOFFREY (d. 1213), earl of Essex and chief justiciar of England, was a sheriff, a justice itinerant and a justice of the forest under Henry II. During Richard's absence on crusade he was one of the five justices of the king's court who stood next in authority to the regent, Longchamp. In 1190 Fitz Peter succeeded to the earldom of Essex, in the right of his wife, who was descended from the famous Geoffrey de Mandeville. In attempting to assert his hereditary rights Over Walden priory Fitz Peter came into conflict with Longchamp, and revenged himself by joining in the baronial agitation through which the regent was expelled from his office. Though refusing to give him formal investiture of the Essex earldom, Richard appointed him justiciar in succession to Hubert Walter (1198). Fitz Peter continued Walter's policy of encouraging foreign trade and the development of the towns; many of the latter received, during his administration, charters of self-government. He was continued in his office by John, who found him an able instrument of extortion. He profited to no small extent by the spoliation of church lands in the period of the interdict. But he was not altogether trusted by the king. The contemporary *Histoire des ducs* describes Fitz Peter as living in constant dread of disgrace and confiscation. In the last years of his life he endeavoured to act as a mediator between the king and the opposition. It was by his mouth that the king promised to the nation the laws of Henry I. (at the council of St. Albans, Aug. 4, 1213). But Fitz Peter died a few weeks later (Oct. 2). Fitz Peter was neither a far-sighted nor a disinterested statesman; but he was the ablest pupil of Hubert Walter, and maintained the traditions of the great bureaucracy which the first and second Henries had founded.

See the original authorities specified for the reigns of Richard I. and John. Also Miss K. Norgate's *Angevin England,* vol. ii. (1887) and *John Lackland* (1902); A. Ballard in *English Historical Review,* xiv. p. *93;* H. W. C. Davis, *England under the Normans and Angevins* (1905).

FITZROY, ROBERT (1805–1865), English vice-admiral, hydrographer and meteorologist, who commanded the "Beagle" on its famous voyage of circumnavigation, was born at Ampton Hall, Suffolk, on July 5, 1805, a grandson on his father's side of the third duke of Grafton and, on his mother's, of the first marquis of Londonderry. He entered the navy in 1819. After service in the Mediterranean and on the South American station he was promoted in 1828 to the command of the "Beagle," a brig of 240 tons, which was employed on the survey of the coasts of Patagonia and Tierra del Fuego.

She returned in 1830, and Fitzroy brought with him four Fuegians. Three survived and were taken back the next year, when he was reappointed to the "Beagle" to continue the survey. She sailed on Dec. 27, 1831, carrying, as a supernumerary. Charles Darwin. On Oct. 2, 1836, she returned, having surveyed the Strait of Magellan and part of the coast of South America and run a chronometric line around the world. In 1839 Fitzroy published in two volumes *Narrative of the Surveying Voyages of H.M.S.S. Adventure and Beagle . . .*, with a third volume by Darwin.

In 1842 he became a member of parliament for Durham and was appointed conservator of the Mersey. Early in 1843 he was appointed governor and commander in chief of New Zealand. His policy favoured the Maoris, and the settlers secured his recall in Nov. 1845. After serving as superintendent of the Woolwich dockyard and as commander of the "Arrogant," an experimental screw frigate fitted out under his supervision, he retired in 1850. In 1854 he was appointed chief of the newly formed meteorological department of the board of trade, and henceforward his career was devoted to practical meteorology.

In 1863 he published his *Weather Book;* the views in it were far in advance of his time. His last years were devoted to the Lifeboat association. He committed suicide on April 30, 1865.

Fitzroy's other publications included *Remarks on New Zealand* (1846), *Sailing Directions for South America* (1848) and occasional papers in the *Journal of the Royal Geographical Society.*

See *Symons's Met. Mag.*, no. 33, pp. 161–164 (1898), and *Mar. Obs.*, vol. i, pp. 50–52 (1924). (G. My.)

FITZSTEPHEN, WILLIAM (d. *c.* 1190), biographer of Thomas Becket and justice itinerant, was born in London. He entered Becket's service between 1154 and 1162. The chancellor employed him in legal work, made him sub-deacon of his chapel and treated him as a confidant. Fitzstephen appeared with Becket at the council of Northampton (1164) when the disgrace of the archbishop was published to the world; but he did not follow Becket into exile. He joined Becket's household again in 1170, and was a spectator of the tragedy in Canterbury cathedral. His life of Becket is the most valuable we have. Though he writes as a partisan he gives a precise account of the differences between Becket and the king. It also contains a description of London which is our chief authority for the social life of the city in the 12th century. Despite his connection with Becket, William was sheriff of Gloucestershire from 1171 to 1190, and a royal justice in the years 1176–80 and 1189–90.

See his "Vita S. Thomae" in J. C. Robertson's *Materials for the History of Thomas Becket,* vol. iii. (Rolls series, 1877). Sir T. D. Hardy. in his *Catalogue of Materials,* ii. 330 (Rolls series, 1865), discusses the manuscripts of this biography and its value. W. H. Hutton, *St. Thomas of Canterbury,* pp. 272–274 (1889), gives an account of the author.

FITZ THEDMAR, ARNOLD (1201–1274), London chronicler and merchant, was born in London: Aug. 9, 1201, of parents whose families had come to London from Germany. He became, as he tells us, alderman of a London ward and an active partisan in municipal politics. In the Barons' War he took the royal side against the populace and the mayor, Thomas Fitz Thomas. The popular party planned, in 1265, to try him for his life before the folk-moot. but he was saved by the news of the battle of Evesham which arrived on the very day appointed for the trial. In 1270 he was one of the four citizens to whom the muniments of the city were entrusted. To this we probably owe the compilation of his chronicle. *Chronica Maiorum et Vicecomitum,* which begins at the year 1188 and is continued to 1274. From 1239 onwards this work is a mine of curious information. Though municipal in its outlook. it is valuable for the general history of the kingdom, owing to the important part which London played in the agitation against the misrule of Henry III. Arnold was by no means blind to the faults of Henry's government, but preferred an autocracy to the mob-rule which Simon de Montfort countenanced in London.

The *Chronica Maiorum et Vicecorniturn,* with the other contents of Arnold's commonplace book. were edited ior the Camden Society by T. Stapleton (1846), under the title *Liber de Antiquis Legibus.* Our knowledge of Arnold's life comes irom the *Chronica* and his own biographical notes. Extracts, with valuable notes, are edited in G. H. Pertz's *Mon. Gerrnaniae historica, Scriptores,* vol. xxviii. *See* also *J. M.* Lappenberg's *Urkundliche Geschichte des Hänsischen Stahlhofes zu London* (Hamburg, 1851).

FITZWALTER, ROBERT (d. 1235), leader of the baronial opposition against King John of England, served John in the Norman wars, and was taken prisoner by Philip of France, and forced to pay a heavy ransom. He was implicated in the baronial conspiracy of 1212. He was outlawed, but returned under a special amnesty after John's reconciliation with the pope. He continued. however. to take the lead in the baronial agitation against the king, and upon the outbreak of hostilities was elected "marshal of the army of God and Holy Church" (1215). He secured the support of the city of London. The famous clause of Magna Carta (§ 39) prohibiting sentences of exile, except as the result of a lawful trial, refers more particularly to his case. He was one of the 25 appointed to enforce the promises of Magna Carta; and his aggressive attitude was one of the causes which contributed to the recrudescence of civil war (1215). He was one of the envoys who invited Louis to England. and was the first of the barons to do homage when the prince entered London. Though slighted by the French as a traitor to his natural lord, he served Louis with fidelity until he was captured at the battle of Lincoln (May 1217). Released on the conclusion of peace he joined the Damietta crusade of 1219, but returned at an early date to make his peace with the regency.

BIBLIOGRAPHY.—The *Histoire des ducs de Normandie et des rois d'Angleterre* (ed. *F.* Michel, 1840) gives the fullest account of his quarrel with the king. *See* also Miss K. Norgate's *John Lackland* (1902), W. McKechnie's *Magna Carta* (1905), and Stubbs's *Constitutional History,* vol. i. ch. xii. (1897).

FITZWILLIAM, a family with English and Irish branches: important in English history. The alleged descent of the Fitzwilliams from an illegitimate son of William the Conqueror is almost certainly fictitious. The fortunes of the English branch of the family really began with Sir William Fitzwilliam (1460–1534), sheriff of London, who acquired the future family seat at Milton, Northamptonshire, in 1506. His grandson, also Sir William Fitzwilliam (*q.v.*), was thrice deputy of Ireland. The latter Fitzwilliam's grandson took the Irish title of Baron Fitzwilliam of Lifford in 1620. In later generations the Irish titles of Viscount Milton and Earl Fitzwilliam (1716) and the English titles of Baron Milton (1742) and Viscount Milton and Earl Fitzwilliam (1746) were added.

William Wentworth Fitzwilliam (1748–1833), 2nd earl (English peerage), was an active Whig and inherited the large Wentworth estates in Yorkshire on the death in 1782 of his uncle the marquess of Rockingham, thus becoming one of the richest members of the nobility. He was lord lieutenant of Ireland (1794–95) and, in opposition to Pitt, strongly supported Grattan's Catholic emancipation campaign. He was president of the council in 1806 and thereafter mainly in opposition. He died at Milton in 1833.

Fitzwilliam's son. Charles (1786–1857), 3rd earl: officially adopted the surname Wentworth-Fitzwilliam. William Thomas George Wentworth-Fitzwilliam (1904–), 8th earl, succeeded to the title in 1952.

An Irish branch of the family, the Fitzwilliams of Meryon, were descended from a 12th-century member of the family who went to Ireland under Prince John. The titles of Baron and Viscount Fitzwilliam died out with the 8th viscount in 1833. The most celebrated member of this branch was Richard (1745–1816), 7th viscount, who left his library to Cambridge university and also a fund for creating the Fitzwilliam museum at Cambridge.

FITZWILLIAM, SIR WILLIAM (1526–1599), lord deputy of Ireland, was the eldest son of Sir William Fitzwilliam (d. 1576) of Milton, Northamptonshire. where he was born. In

1559 he became vice-treasurer of Ireland and a member. of the Irish House of Commons: and between this date and 1571 he was (during the absences of Thomas Radclyffe, earl of Sussex. and of his successor, Sir Henry Sidney) five times lord justice of Ireland. In 1j71 Fitzwilliam himself was appointed lord deputy. but like Elizabeth's other servants he received little or no money, and his period of government was marked by continuous penury and its attendant evils, inefficiency, mutiny and general lawlessness. Moreover, the deputy quarrelled with the lord president of Connaught, Sir Edward Fitton (1527–1579), but he compelled the earl of Desmond to submit in 1574. Returning to England in 1575 he was governor of Fotheringhay Castle at the time of Mary Stuart's execution. In 1588 Fitzwilliam was again in Ireland as lord deputy, and although old and ill he displayed great activity in leading expeditions. and found time to quarrel with Sir Richard Bingham (1528–1599), the new president of Connaught. In 1594 he finally left Ireland. and five years later he died at Milton. From Fitzwilliam. whose wife was Anne. daughter of Sir William Sidney. were descended the barons and earls Fitzwilliam.

FIUME: *see* Rijeka.

FIVE NATIONS: *see* Iroquois.

FIVES. *A* ball game played by two or four players in a court enclosed on three or four sides, the ball being struck with the hand protected by a glove. Certain forms of the game in the United States and in Ireland are known as handball (*q.v.*). The etymology of "fives" is uncertain. Nevertheless. since "fives" has been used to describe handball play and boxing it is reasonable to conclude that the word is associated with the five fingers of the hand acting in unison. Long before the present games of fives were known Dr. Samuel Johnson defined the word as "a kind of play with a bowl" and, later, a "bunch of fives" was a familiar expression for the closed fist. Games using hand. ball and wall were various and without set rules or carefully defined areas until late in the 19th century. They were played in the tennis courts from mediaeval times to at least the end of the 18th century. in the Fleet prison and against any straight wall or angle of walls which presented itself to child or man. Most of these games could also be played with the racket. As Nicholas says in the *Familiarum Colloquiorum Opus* (1526) of Erasmus: "We shall sweat less if we play with a racket." And Jerome replies: "Let us leave nets to fishermen; the game is prettier if played with the hands."

The three versions of the modern game are named after well-known English schools. (J. Ae.)

Eton Fives.—The peculiar features of the Eton fives court arose from the game's being first played at Eton college against the chapel wall with buttresses forming the side walls and with the balustrade of the chapel steps projecting into the left-hand side of the court. which was divided latitudinally by a step.

The modern standard court has retained all these characteristics, being enclosed on three sides and open at the back, with a shallow "step" dividing the upper or top portion from the lower or bottom portion. The buttress which projects from the left-hand wall is now called the "pepperbox" which, with the "step," encloses a small square section of the floor called "Dead Man's Hole." The "line" of the court is the lower angle of a sloping ledge running across the front wall at the height of 4 ft. 6 in. Items of equipment required are padded gloves and special balls about $1\frac{3}{4}$ in. in diameter and $1\frac{3}{4}$ oz. weight, covered in white kid.

The game is played by four persons, two against two, the server standing in the upper court; the taker of service stands in the lower court ready to return the service. The partners of both server and taker of service also stand in the lower court, the server's partner having choice of position. To start the game, the server must throw the ball above the line on to the front wall so that it then hits the right-hand wall before dropping into the lower court to suit the taker of service. who is said to be "cutting." The rally is not started until the "cutter" has received a service to his liking and returned it above the line; thereafter the ball is returned alternately by either side, the rally ending when the ball is hit either below the line or out of court. Only the side serving may score, game being 12 points. The Eton Fives association, to which schools and clubs are affiliated, regulates the game and is responsible for the organization of the amateur championship for the Kinnaird trophy presented by Lord Kinnaird in 1926 and the Public Schools competition for the challenge cup presented by the association in 1949. (P. C. C.)

Rugby Fives is played in a four-walled court without any form of hazard. The dimensions of the standard court are length 28 ft., width 18 ft., height of front wall 1j ft., height of back wall 6 ft. The front wall is distinguished by a wooden board running horizontally across it at an even height of 2 ft. 6 in. from the floor. A few courts have no back wall and others have a lower one. The ball is hard and solid, approximately 2 in. in diameter and weighing about $1\frac{1}{4}$ oz. Specially padded gloves are worn. The game may be played by two or four players and is won by the first side to win 1j points or the first player to score 2 points after each has 14. Only the receiver can score points and when he wins a rally he scores one point. but should his opponent (the server) win it, he becomes receiver. The server starts a rally by throwing the ball up so that it first hits the front wall and then the nearest side wall; he must strike it after the first bounce and before the second so that it hits first the side wall and then the front mall. The opponent must return the service. before the second bounce, on to the front wall above the board, either directly or after it has hit any of the other walls. The players then hit the ball alternately.

The game is regulated by the Rugby Fives association. Open singles and doubles championships, schools' singles and doubles competitions and Scottish and north of England championships are held. Most courts are owned by schools and universities.

Winchester Fives is similar to Rugby Fives except that the court has a "buttress" on the left-hand side wall about 10 ft. from the front wall, which means that the rest of the court is that much narrower. There are fewer courts of this type. (R. A. C.)

Bibliography.—Lord Aberdare (ed.), Lonsdale Library, vol. xvi, *Rackets, Squash Rackets, Tennis, Fives and Badminton* (London, Philadelphia, 1934); David Egerton and John Armitage, *Eton and* Rugby *Fives* (London, 1936).

FIX, THEODORE (1800–1846). French journalist and economist: was born at Soleure. Switz. He contributed most of the geographical articles to the *Bulletin universal des sciences.* In 1840 his essay on *L'Association des douanes allemandes* won him a prize from the Xcademie des Sciences Morales et Politiques. In his *Observations sur les classes ouvrières,* published in 1846. he argued against all attempts to regulate artificially the rate of wages. He died at Paris on July 31, 1846.

FIZEAU, ARMAND HIPPOLYTE LOUIS (1819–1896), French physicist best known for his experiments in light, particularly the speed of light, was born at Paris. Sept. 23, 1819. As he was wealthy, he was able to follow his inclinations and devote himself to experimental work in physics. Between 184j and 1849 he worked in conjunction with Foucault (*q.v.*). They investigated the infrared portion of the solar spectrum and made other observations in heat and light. In 1849 Fizeau published the results of his experiments on the velocity of light; he also gave the first reliable value of this velocity by a terrestrial method, as well as the correct explanation of the Doppler principle (*see* Light: *Wanes and Interference*) as applied to the light coming from a star (*q.v.*), and showed how it could be used to measure the relative velocities of stars in the line of sight.

In 1851 he carried out a series of experiments on the velocity of light in a moving medium, and measured the shift of interference fringes resulting from light passing through a column of moving water. These experiments were designed to see if any relative motion of ether and matter could be detected (*see* Ether). Later experiments describe the use of a condenser for increasing the efficiency of an induction coil and the application of interference methods for measuring the expansion of crystals. He became a member of the French Academy in 1860 and of the Bureau cles Longitudes in 1878; in 1863 he was appointed *inspecteur de physique* at the École Pblytechnique Paris.

Fizeau died at Venteuil. Sept. 18. 1896.

FLACH, JACQUES GEOFFROI (1846–1919), French jurist, was the author of several works on the history of medieval

France. Born at Strasbourg on Feb. 16, 1846, he settled in Paris after the war of 1870. From 1884 he was professor of comparative legislation at the Collège de France, and he also held posts at the École des Sciences Politiques and at the École d'Architecture in Paris, He died in Paris on Dec. 5, 1919.

Flach's great work, *Les Origines de l'ancienne France,* was produced in four volumes—Le *Régime seigneurial* (1886); *Les Origines communales, la féodalité et la chevalerie* (1893); *Le Renaissance de l'état. La Royaute' et le principat* (1904); and *Les Nationalités régionales. Leurs Rapports avec la couronne de France* (1917)—which, although not always consistent, were characterized by originality and vigour and were based on a wide use of manuscript sources.

Flach also wrote *Études critiques sur l'histoire du droit romain au ntoyen âge* (1890) and *L'Origine historique de l'habitation et des lieux habités en France* (1899).

FLACIUS, MATTHIAS (1j20–1j75), surnamed ILLYRICUS. Lutheran reformer, was born at Albona, in Illyria, on March 3, 1520. He studied under Baptista Egnatius in Venice, and from 1j39 onward at Basel, Tiibingen and Wittenberg. There he was welcomed (1541) by Melanchthon and there he came under the decisive influence of Luther. In 1j44 he was appointed professor of Hebrew at Wittenberg. He took his master's degree on Feb. 24, 1546, ranking first among the graduates. He opposed strenuously the Xugsburg Interim and the compromise of Melanchthon known as the Leipzig Interim *(see* ADIAPHORISTS). Melanchthon wrote of him with venom as a renegade (*alumnus in sinu serpentem*), and Wittenberg became too hot for him. He removed to Magdeburg (Nov. 9, 1551), where his feud with Melanchthon was patched up. On May 1;, 1557, he was appointed professor of New Testament theology at Jena: but he was soon involved in controversy with Strigel, his colleague, on the synergistic question (relating to the function of the will in conversion). In Oct. 1j66 he became pastor of the Lutheran community at Antwerp. In 1567–73 he sought asylum both in Frankfurt and Strasbourg. but in both cases was compelled to leave. Then the prioress Catharina von Meerfeld of the convent of White Ladies at Frankfurt harboured him and his family in despite of the authorities. He died on March 11, 1jjj. His son Matthias was professor of philosophy and medicine at Rostock. In spite of his harried life, Flacius was a pioneer of the scientific study of church history and—if we except. a great exception, the work of Laurentius Valla—of hermeneutics also. There is permanent and continuous value in the principles embodied in Flacius' *Catalogus testium veritatis* (1jj6; rev. ed. by J. C. Dieterericus, 1672) and his *Clavis scripturae sacrae* (1567), followed by his *Glossa compendiaria in N. Testamentum* (1jjo).

BIBLIOGRAPHY.—J. B. Ritter, *Flacius's Leben und Tod* (1725); *M.* Twesten, *M. Flacius Illyricus* (1844); W. Preger, *F. Flacius Illyricus und seine Zeit* (1859–1861); *G.* Kawerau, in Herzog-Hauck's *Real-enzyklopadie* **(1899)**.

FLAG, a word of Teutonic (Germanic) origin used from the 15th–16th centuries in various northern European languages (*flag* in English, *flagg* in Swedish, *vlag* in Dutch and *Flagge* in German), to signify a piece of cloth, bunting or similar material displaying the insignia of a community, an armed force, an office or an individual. A flag is usually (not always) oblong and attached by one edge to a staff or halyard. It can be viewed from either side. The part nearest the staff is called the hoist, the outer half is called the fly. The width usually exceeds the depth. Flags of various forms and purpose are known as standards, banners, ensigns, pendants (or pennants), pennons. guidons and burgees. Originally used mainly in warfare, flags were (and to some extent remain) insignia of leadership, serving for identification of friend and of foe. and useful as rallying points. They are now also extensively used for signalling, for decoration and for display. As the usefulness of a flag for purposes of identification must depend on its blowing out freely in the wind, the material preferred is, with a few exceptions, light. It is thus obviously advantageous to choose a device or pattern which will be the same on both sides of the flag, which would otherwise have to be made of a heavy, opaque cloth, probably doubled. This consideration tends to exclude any wording, and further considerations of visibility tend to favour the simpler patterns. Any colours or devices may be used. but European usage normally follows the practice of heraldry and of common sense in discouraging the juxtaposition of "metal" and "metal" (*i.e.*, of yellow and white) or colour and colour without "metal" interposed. The flag of the Vatican City is an exception to this rule.

HISTORY

Historically, the use of terms such as "banner" and "standard" has varied considerably. but modern usage would restrict the term "banner" to a piece of cloth attached by its upper edge to a pole or cord. A banner in this sense differs from a flag in having. frequently, a reverse side on which the device is either different from the front or unrecognizable; as, for example. with lettering reversed. It may likewise be questioned whether the pennon attached to a lance—that is, to a weapon and not merely to a staff—is a flag in the modern use of the word.

Early History.—The earliest insignia, used in battle, were not flags at all. These are usually described as standards and are not to be confused with the later flags (serving the same purpose) to which that term is now applied. These standards consisted of some solid object fixed on a bracket at the top of a pole, sometimes with streamers attached. The object displayed was a sacred symbol; of the four standards carried before the kings of ancient Egypt, for example, one is claimed to have represented the king's placenta. Predynastic monuments dating from the reign of Rameses II show these sacred standards "as the actual agents of the enemies' discomforture." A similar standard is shown on an early tomb at Ur of the Chaldees, and there can be little doubt that these standards were known to and venerated by peoples of the earliest civilizations. Evidence is abundant, for example. of such standards being borne in Assyria from the 9th century B.C. They are shown as associated with such kings as Xssur-nasir-pal (in 88j B.C.), Sargon and Sennacherib, and they were evidently used not only in battle but in hunting. The standards are shown mounted on chariots, with streamers or tassels (usually two) attached; and they were evidently guarded with some care.

While these especially sacred emblems were carried before kings, other similar insignia were borne by military units and ships. An Assyrian statue of 671 B.C. shows a soldier with the standard of his unit, and Egyptian vessels are shown on pottery as bearing signs of the harpoon or fish, probably associated with their ports of origin. In some instances the streamers may have become more prominent than the sign itself, and a lance with a pennon is shown in Assyrian sculpture of 885–860 B.c.; but the standard in its solid form remained normal and was evidently transmitted via Crete to the Aegean. An occasional variant may have been the display (as in China) of the head of some previously discomfited enemy. This might be the origin of the Greek custom of bearing a helmet or other piece of armour on a spear point. The various Greek cities, however, had more distinctive signs, such as a sphinx or Pegasus, and the Romans followed suit, using the effigies of gods. of generals or of animals (wolves, horses and bears). According to Pliny, it was G. Marius who, in his second consulship, ordered that the Roman legions should have only the eagle as standard. This eagle effigy was later revived by Napoleon as a deliberate archaism and, more recently, in fascist Italy. It has otherwise fallen into disuse.

The vexillum, or Roman cavalry flag, was nearer to being a flag in the accepted sense and is still used in ecclesiastical ceremony. It is described by Livy as a square piece of cloth fastened to a bar fixed crosswise on a spearhead. This description is confirmed by reference to Roman coins: medals and sculpture. The labarum, the imperial standard of the later Roman emperors, was of similar pattern but on a larger scale, of purple silk and embroidered in gold. The vexillum may have had special appeal to Christians because it was cruciform. It gained in importance from the time of Constantine's conversion and bore thereafter the monogram of Christ or some other religious emblem. Used in Byzantine religious processions, the ecclesiastical banner has thus an unbroken continuity with ancient Rome. Its attachment to a horizontal bar makes it suitable for the display of elaborate scenes and figures, visible only from the one direction, and the foot of the banner often ends with a gold fringe coming to two or more points. This form of banner was also used in the middle ages on warlike expeditions, more particularly perhaps on those which had some religious significance. The banner bearing the device of St. Martin's hood, originally kept by the monks of the abbey of Marmoutier and used in battle by the counts of Anjou, was presumably of this pattern. It was said to have been taken into battle by Clovis in 507, and Charlemagne fought under it at the battle of Narbonne. It mas used by the kings of France but was replaced by the oriflamme of St. Denis, first taken into battle by Louis VI in 1124 and last seen on the battlefield at Agincourt in 141j. By one account the oriflamme would seem to have been a plain red square, but it is also said to have had three points with tassels of green silk. Similar in form may have been the banner entrusted to William the Conqueror by Pope Alexander II, and similar again the English standard which gave its name to the battle of the Standard in 1138 The latter, however, was a ship's mast on wheels and carried, as well as a silver pyx, three sacred banners dedicated respectively to St. Peter. St. John of Beverley and St. Wilfrid of Ripon. A banner of this ecclesiastical pattern was known in the middle ages as a gonfalon or gonfanon and was borne by the chief magistrates of certain Italian cities, and also used at sea. Banners of this type are still sometimes hoisted on the masts which front the cathedral church of St. Mark's at Venice, It.

Oriental Flags.—The examples so far given illustrate the use formerly made in ancient and mediaeval times of insignia which, serving the same purpose as flags, were essentially different in form. Flags recognizable as such were the invention. almost certainly, of the Indians or Chinese. It is said that the founder of the Chou dynasty in China (1122 B.C.) had a white flag carried before him; and it is known that in A.D. 660 one of the minor princes was punished for failing to lower his standard before his superior. Chinese flags had devices such as a red bird. a white tiger or a blue dragon. They were carried on chariots and planted upon the walls of captured cities. The royal flag had, however, all the attributes of kingship, being identified with the ruler himself and treated with a similar respect. It was thus a crime even to touch the flag-bearer. The fall of the flag meant defeat. and the king mould rarely expose his flag and his person together, the flag being normally entrusted to a rather reluctant general.

Flags had equal importance in ancient India, being carried by chariots and on elephants. The flag was the first object of attack, and its fall would mean confusion if not defeat. Indian flags were evidently of modern pattern but often triangular in shape, scarlet or green in colour, having a figure embroidered in gold and a gold fringe. If these and the Chinese flags had a common origin in the standards of ancient Egypt and Assyria, they might have developed from the streamers attached to the pole. This possibility gains some likelihood from the fact that some Indian flagstaffs were surmounted by a figure similar to that displayed on the flag itself. Mogul royal insignia included, however, other things besides the flag, and more especially yaks' tails and the state umbrella. Indian flags seem also to have been used, as in China, for signalling, and there is an instance of a white flag being used as a signal for a truce as early as A.D. 1542. Indian and Chinese usage spread to Burma, Siam and southeastern Asia generally, and the *Kidung Sunda* (A.D. 1357) contains many references to the flags used by Majapahit and other heroes, and also to the pennons on their lances. Flags with a background of white, yellow or black silk are mentioned, with devices (of an elephant or bull or water hen, for example) embroidered on them in gold. A Siamese treatise on war gives the impression that the flags were unfurled as the march began.

The use of flags was probably transmitted to Europe by the Saracens. But Islam influenced this usage in that the use of any identifiable image is forbidden by the Koran as idolatrous. Flags are often mentioned in the early history of Islam and may have been copied from India. But these are greatly simplified and appear to have been plain black or white or red. Black was supposed to have been the colour of Mohammed's banner: the colour of vengeance. We learn of a black flag being used by the Abbasids in A.D. 746 (A.H. 129), the Omayyads and 'Alids choosing white by contrast and the Khawarij (Kharijites), red. A plain red flag is thus retained by the state of Oman. Green was the colour of the Fatimite dynasty and eventually became the colour of Islam. In adopting the crescent sign, however. c. 1250, the Osmanli Turks were reverting to a sacred symbol used by King Assur of Assyria in the 9th century B.C. and probably of greater antiquity than that. The crescent moon, with or without an additional star or stars, has since become the accepted symbol of Islam. It appears, usually white, in the flags of Egypt. Turkey, Tunis, Libya, Madagascar, Pakistan and some of the Malay states. with backgrounds of green. red or black. The Egyptian flag has three stars representing Egypt, Nubia and the Sudan, but this is of fairly recent date.

The Use of the Cross.—The use of the flag and the pennon was probably copied by the Europeans from their Saracen opponents during the third crusade (1189–91). or perhaps slightly earlier. It was the assembly, in one army, of knights from almost every nation in Christendom that necessitated their differentiation from the enemy and from each other. Heraldry first appeared in England in 1127 but was undoubtedly established during the decade 1190–1200, hastened both by the crusade and by the adoption of closed helmets in which the wearer was unrecognizable. Closely connected with heraldry was the adoption of the flag. Thus, the Knights of St. John adopted as their standard a white cross on a red field: this was confirmed to them by a papal bull of 1259 which enjoined them to wear surcoats of the same pattern. This wearing of a cross in some form had considerable significance. In assuming it, the crusader at once proclaimed his vow and demanded the aid of all Christians toward its fulfilment. It partly superseded his own personal device—associated as that may have been with local quarrels and feuds—and marked him out as a man with a mission approved by the church. Once in the Holy Land, it showed on which side he was fighting and tended to show further, by the variation in its form, from what part of Christendom he came. Knights of the religious orders displayed no such local affinities. but the ordinary knights discovered the germs of nationality in realizing that men whose religion might be the same spoke languages which were different. The knights who followed the emperor Frederick I Barbarossa, Philip II Augustus of France and Richard I of England copied the flag and the pennon from their opponents and the cross from each other, but they saw to it, in some instances, that their crosses should differ in shape and colour. Thus, the French adopted a scarlet flag with a white cross, the English and Germans a white flag with a scarlet cross. It is not clear to what extent other variants were adopted by other national groups; but it is known that the returning crusaders retained their uniform after their return to Europe and with it their "national" flag, associated with their respective patron saints. This was certainly the case in England, where the cross of St. George was firmly established in the 13th century. It contrasted with the flags used by the king and the nobility to symbolize more personal and local loyalties. It was not entirely peculiar to England and was known as the cross of St. George in 13th-century Germany. The French cross in white on scarlet also remained in use and was revived on a national basis by Louis XI in 1479. In general, these flags rose or fell in esteem with the idea of nationalism which they symbolized. They were not so much in evidence in periods when the conflict was less between France and England than between Burgundy and Valois or between Lancaster and York.

Other national flags with the cross device either developed during the third and later crusades or were imitated by nations which had not been strongly represented in the Holy Land. Thus, the flag of Denmark (a white cross on a red field, called the *Danebrog*) was certainly used from 1308 and may well date from 1219, the year indicated by tradition and well supported by probability. The Norwegian flag was similar, but the Swedish flag developed as a yellow cross on a blue field. The Swiss flag, a white cross on red, first appears in 1339 and in a context that shows a significant identification of a national with a holy cause. The Scottish flag of St. Andrew, a diagonal white cross on a blue ground, is of uncertain but clearly mediaeval origin, and the same is true of the

Irish flag of St. Patrick with the cross borne diagonally red on white and perhaps as old as the 12th century. The European nations which thus adopted and still use the cross in some iorm include Great Britain, Denmark, Finland, Greece, Iceland. Norway, Portugal. Sweden and Switzerland. It was formerly used by Latvia. Outside Europe the cross is used by the British dominions. the Dominican Republic and Samoa. At an international conference held at Geneva in 1863 it was further agreed that the hospitals. ambulances and medical personnel of all armed forces should bear a red cross on white, the Swiss flag with reversed colours. This has since remained the symbol of the International Red Cross organization.

Tricolour Flags.—The French Revolution began a new phase in flag design. The revolutionary tricolour was to invade the rest of Europe and to spread by example to other parts of the world. But if the tricolour was revolutionary in intent, it was not wholly novel in design. Austria had a flag with horizontal stripes of red, white and red in 1200 or earlier. and a previous revolution, that of the Dutch against Spain. had left the Netherlands with a flag (from 1574) of orange. white and blue in horizontal strips of equal width. Orange was probably found to be an unstable colour, and it was gradually replaced by red in the 17th century, leaving the Dutch flag exactly as it is now, although the use of the orange colour was not actually prohibited until 1795. The tricolour thus stood for revolution, and it is important to remember, in this connection, that the revolutionary movement which transiormed France did not wholly originate there but derived something from the revolt of the Austrian Netherlands in 1787–89. This revolt centred at first in Brabant, where a tricolour in black. yellow and red vertical stripes. these being the Belgian colours, appeared as early as 1790. This gave the French revolutionaries a good precedent for hoisting their vertical tricolour. which also first appeared officially in 1790, with the red stripe in the hoist and the blue in the fly. In 1794 this order was reversed so as to have the blue in the hoist with the white (as before) in the middle. It was eventually found more pleasing to the eye to vary the width of the stripes in the percentage of blue 30, white 33 and red 37. This French tricolour replaced the Bourbon device of the fleur-de-lis (used since 1589) and, with one short interruption in 1815–30, has remained the French flag ever since, being used, unmodified! for almost every purpose.

During the 19th and 20th centuries, as monarchies were replaced in most countries by republics, a tricolour was usually taken as the proper symbol of republicanism and even copied. perhaps largely for considerations of legibility and economy of manufacture. by countries still monarchical. The following countries now use the tricolour in some form, occasionally with some slight addition: Afghanistan. Andorra, Belgium, Bolivia. Bulgaria, Colombia, Ecuador. Ethiopia. France. Germany. Guatemala, Honduras, Hungary, India, Iran. Iraq, the Republic of Ireland. Italy, Jordan, Luuembourg, hladagascar, Mexico, the Netherlands, Paraguay, Perak, Rumania. the Union of South Africa, Syria. Venezuela and Yugoslavia (see also below). It was also used. during their period of independence, by Estonia, Latvia and Lithuania. Very similar to the tricolour are the flags with three stripes, horizontal or vertical, using only two colours, such as are used in Spain, Honduras, Nicaragua, El Salvador. Peru and Argentina.

Other National Flags.—Flags which are based neither on the cross, nor the stars and stripes nor the tricolour are either heraldic or oriental. The heraldic flags, embodying part or the whole of a coat of arms. include the flags of Portugal. the Vatican City, San Marino and formerly Albania. Oriental flags include those of Israel. Yemen, Saudi Arabia, Kuwait. Ceylon, Thailand (Siam), Cambodia, Tibet, Nepal, South Korea. Mongolia and Japan. These vary greatly in pattern: some, like that of Saudi Arabia, are open to criticism as illegible at a distance; others, like that of Japan. are simple and effective.

Forms and Functions.— It has been shown that many of the flags of Christendom date from the period of the .third crusade or have developed since by imitation. There mere always certain exceptions. Spain being one; but the use of flags was widespread, and the cross occurred in most flags which could be called national. But these flags were subdivided according to shape and purpose into standards. banners, guidons. pennons and streamers. There were also many flags of a personal. family or local significance which were of a different and usually more complex pattern. To distinguish first between the main types, it should be said that the standard was the largest flag and intended. from its size, to be stationary. It marked the position of an individual before a battle, during a siege, throughout a ceremony or at a tournament. Its use was that of the royal standard which marked the palace, castle, saluting base. tent or ship where the sovereign was actually present. Standards were also used formerly by the greater nobles and bore their own personal insignia. Standards were originally long and tapering toward the fly. ending in two points. Banners were square or oblong and were borne in action (as the standard was not) before royal and noble warriors down to the rank of knight banneret. These again bore the personal or family device. The guidon. a word derived from the French *guyd-homme,* was similar to the standard but rounded in the fly or with two swallow tails, both rounded. Guidons were borne by leaders in battle who were of merely knightly rank and so not entitled to display a banner. In the British army they have thus come to be borne by dragoon regiments of cavalry, such as the 1st (Royal) dragoons. the 2nd (Royal Scots Greys) arid the 6th (Inniskilling) dragoons. The household cavalry regiments and Dragoon Guards have standards, by contrast. and the hussars and lancers have no flags at all. The pennon. a small triangular flag. was carried by each knight on his lance. One purpose of the pennon was to obviate accidents on the line of march in much the same way as a red flag is tied to any long pole or rod which extends beyond the tailboard of the truck which carries it. But the pennon served as well to strike terror in the enemy and also to denote rank. To create a knight banneret, the king or his representative might tear off the fly of the knight's pennon and so turn it into a small banner, which would serve at least until a proper banner was made. The streamer (now known as a pendant or pennant) was a long. tapering flag from 20 to 60 yd. long and about 8 yd. broad at the hoist and ending in two points. From its shape it could hardly be used except at sea. and it was there used in the 1jth century, flown from a pole rising above the fighting top and later from the yardarm or topmast. It came eventually to distinguish the warship from the merchantman and, more specifically, the warship in commission from the warship laid up in harbour. The pennant is now white in the royal navy, with a St. George's cross near the hoist, and denotes a warship in commission, being hoisted when the captain assumes his command. As the oblong flag or banner might be used in a variety of ways, it came to have different names according to its exact use. In Great Britain these names included ensign (*q.v.*), jack (*q.v.*) and colour, all of which are still in use.

BRITISH AND COMMONWEALTH FLAGS

British Flags.—While it would be impossible to trace here the process in all European countries by which the feudal heraldic flags gave way to flags of national significance—a process especially complex where the amalgamation of territories was involved—it is at least practicable to indicate in outline how the British flags developed.

First of these is the royal standard, about the exact origin of which there is some doubt. The three lions of England would seem, however. to date from the period when other flags and heraldic devices first appeared; that is, the end of the 12th century. Originally described as "leopards," they seem to have been used as a personal device by Richard I c. 1195. They appeared on the standards of John, Henry III, Edward I and Edward II and at first by Edward III. But this last king claimed in 1340 to be king of France as well as of England, and therefore quartered the English lions with the French lilies, giving the lilies the place of honour. The French lilies of that period were scattered over the whole field as if taken from a piece of patterned cloth. with incomplete lilies round the edge. The standard of this type was used with only temporary variation until 140j. when Henry IV followed the French example of 1365.and reduced the lilies to three. two above and one below. The standard thus revised was used without

DRAWN FOR ENCYCLOPÆDIA BRITANNICA, INC., BY GEORGE ARMSTRONG

HISTORIC FLAGS OF THE 19TH AND 20TH CENTURIES modification until 1603, when James VI of Scotland came to the English throne. James's standard displayed the quartered arms of France and England in the first and fourth quarters, the Scottish lion (in its border, or tressure) in the second and the Irish harp in the third. This standard remained in use until the reign of William III, when the arms of Nassau mere embodied. Fresh complications were introduced by George I and George II, nho placed the arms of Hanover in the fourth quarter. After the French Revolution, however, by the treaty of Amiens in 1802, George III renounced the title of king of France and removed the lilies from his standard. The arms of Hanover, borne in pretense ovtr those of England. Scotland and Ireland. were dropped in 1837, and the royal standard has ever since appeared in its present form, with the lions of England in the first and fourth quarters. the lion of Scotland in the second and the harp of Ireland in the third. The royal standard in one or another of these forms has been displayed by the kings of England and Great Britain throughout their history and, generally speaking. by them alone. To this rule, however, there are two exceptions. In the first place, the royal standard went out of use during the period of the Commonmealth, its place being taken by a special flag devised by the protector. Oliver Cromwell. for himself—the cross of St. George in the first and fourth quarters, the cross of St. Andrew in the second and the Irish harp in the third. with his own arms in pretense. In the second place. the royal standard used to be displayed by the lord high admiral when in command of the fleet and was thus used by Lord Howard of Effingham in 1588, by the duke of Buckingham in the reign of Charles I and by the duke of York during the Dutch Wars. This usage died out nith the office of lord high admiral itself, the royal standard now being flown only by the sovereign.

The union flag of Great Britain first appeared (in its early form) at the accession of James I. It displayed the red cross of England superimposed on the nhite cross of Scotland, with the blue field of the latter. As red on blue is not permissible, the red cross had to be bordered with nhite. its own correct field. It is clear from James I's proclamation that this flag was primarily intended for use at sea. to be hoisted on the maintop. Ships from English ports would hoist St. George's cross at the foretop while those from Scottish ports would hoist St. Andrew's flag. Charles I however, in 1634 restricted its use at sea to the royal navy. This usage was interrupted during the Commonwealth period and complicated for a time under Cromwell by the addition of an Irish harp, but mas resumed on the restoration of Charles II in 1660. So the old flag. the Great Union. continued in use until 1801, the date of the legislative union with Ireland. The object was then to incorporate the cross of St. Patrick (diagonal, red on white) nith the union flag as it then existed. Thus to combine the three crosses. without losing their identity. was no easy task. Each had to be distinct and each had to retain its fimbriation. or bordering, nhich denotes its original ground. In the first union flag, the red cross of St. George uith the white fimbriation that represented the original white field was simply imposed upon the white saltire of St. Andrew with its blue field. To place the red saltire of St. Patrick on the white saltire of St. Andrew would have been to obliterate the latter, nor would the red saltire have its proper bordering denoting its original uhite field; even were the red saltire narrowed in width, the portion of the white saltire that would appear would be not the St. Andrew's saltire but only the fimbriation appertaining to the saltire of St. Patrick. The difficulty was resolved by making the white broader on one side of the red than on the other. In fact. the continuity of direction of the arms of the red St. Patrick's saltire was broken by its portions being removed from the centre of the oblique points that iorm the St. Andrew's saltire. Thus both the Irish and Scottish saltires can be distinguished easily from one another, while the red saltire has its proper white fimbriation.

The union flag, both in its old and new forms. has been used and is still used, in two nays. It can be flown by itself or it can be incorporated as part of another flag (an ensign or military colour, for example). Flown by itself. the union flag has a sharply differentiated use afloat and ashore. At sea and hoisted at the mainmast of a king's ship, it is the flag of an admiral of the fleet. At sea and hoisted at the jack staff in the bows of a ship, it indicates a man-of-war and is properly called the union jack (a jack being any flag flown from that staff). It must be used at sea in no other way, and its misuse can involve, for the offender, a heavy fine. On shore it is flown over fortresses and military headquarters but is also used indiscriminately by all British subjects for merely decorative purposes. It has come to be called the union jack, and this usage, inaccurate as it may be. would now be difficult to change.

Ensigns.——Whereas the jack is flown from the jack staff in the bows of a ship and whereas a special significance attaches to the flag hoisted at the main masthead. the ensign is the flag flown at a ship's stern. The word "ensign" means "insignia," and there can be no doubt that an ensign was originally the banner of the highest-ranking person on board a mediaeval ship when equipped for war. It is thus strictly comparable with the ensign formerly borne by a company of infantry and actually entrusted to a young officer, the ensign-bearer or simply ensign. The conversion of a sailing ship for warlike purposes involved the construction of a wooden castle in bows and stern, and it was the sterncastle which housed the steering gear. The senior military officer on board needed to be near the helmsman, and his banner would be flown near his own station in battle; that is, in the stern. By Tudor times the national ensign was tending to supersede personal insignia as part of a general process which might he called the nationalization of war: the process by which the hereditary military ranks of earl, baron. banneret and knight were replaced by the commissioned ranks of general, captain, lieutenant and ensign. Pictures of English ships in the reign of Henry VIII show the St. George's cross at all mastheads and also on the ensign poles. After 1603 the union flag seems to have been as universally used, but with the streamer or pennant of the older St. George's pattern. The "Prince Royal" is shown wearing these flags in 1610, with the royal standard at the main topgallant masthead to show the king's presence on board.

Even in the Elizabethan period it was the custom to divide a fleet (like an army) into three divisions. the centre, the van and the rear. These came to be known, respectively, as the red. the white and the blue squadrons. They were distinguished by ensigns of the appropriate colour with the St. George's cross in the upper canton. An ensign of this pattern is shown in a picture of the "Sovereign of the Seas" in 1637, reminding us that the canton with the union flag pattern did not immediately take its place. After 1660 the royal navy was reorganized during the second and third Dutch Wars. The main fleet of about 100 ships. with merchantmen now excluded from battle, continued at this period to fight in a strict formation first introduced *c.* 1652. Each of the three main squadrons was commanded by an admiral and subdivided into three divisions. Each squadron had a centre division directly commanded by the admiral, a van division commanded by a vice-admiral and a rear division commanded by a rear admiral. As the admiral of the red squadron was also in supreme command (and might in fact be the lord high admiral in person',; he flew the union flag at the main. There was therefore no admiral of the red squadron designated as such (until 1805), the flag officers (or flagmen as they were sometimes called) numbering nine in all, with the admiral of the fleet as the senior and the rear admiral of the blue squadron as the junior of all. All the ships flem their appropriate ensign but shifted it on transfer to a different squadron. When the legislative union of England and Scotland took place in 1707, the cross of St. George was replaced in the ensign by the union flag pattern. At the same time merchantmen were instructed to fly the red ensign. being later forbidden to use either of the other ensigns or the pennant or the jack. In the 18th century the concentration of the entire battle fleet under one flag officer became unusual. Smaller fleets. of 30 ships at most, could be commanded as a single squadron without rigid subdivision: and it became the custom for all ships to fly the ensign of the commander in chief. The system of red and white and blue became a mere system of seniority among flag officers, whose number now far exceeded the original nine. An admiral of the blue squadron flem his flag at the main topgallant mast and all his ships. the flagship included, bore the blue ensign. A vice-admiral of the red flew his flag at the fore topgallant mast, his ships hoisting the red ensign. A rear admiral of the white flew his flag at the mizzen, his ships following suit with white ensigns. The system was defective in that the ensigns varied in colour without differing much in significance. They were altered in 1801. when the present union flag took the place of the old, but otherwise remained in simultaneous use until 1864. when the royal navy adopted the white ensign as its own (influenced, perhaps, by the fact that Lord Nelson was vice-admiral of the white when he died, with the result that all the ships at Trafalgar flew that ensign during the battle). The red ensign was now restricted to the mercantile marine, and the blue ensign was assigned to the royal naval reserve and to ships not of the royal navy but nevertheless in the public service.

The white ensign is therefore essentially the flag of the royal navy. It should not be flown anywhere or on any occasion except by a ship (or shore establishment) of the royal navy, with but one exception: by a grant of William IV dating from 1829, vessels belonging to the Royal Yacht squadron, the chief of all yacht clubs,. are allowed to fly the white ensign. From 1821 to 1829 ships of the squadron flew the red ensign, as that of highest dignity, but as it was also used by merchant ships, they obtained the grant of the white ensign as being more distinctive. Some few other yacht clubs flew it until 1842. when the privilege was withdrawn by an admiralty minute. By some oversight the order was not conveyed to the Royal Western of Ireland, whose ships flew the white ensign until 1857 when the usage was stopped. Since that date the Royal Yacht squadron alone has had the privilege. Any vessel of any sort flying the white ensign, or pennant, of the navy is committing a grave offense. and the ship can be boarded by any officer of Her Majesty's service, the colours seized, the vessel reported to the authorities and a penalty inflicted on the owners or captain or both. The penalty incurred is £500 fine for each offense, as laid down in section 73 of the Merchant Shipping act, 1894.

The blue ensign is exclusively the flag of the public service other than the royal navy and is as well the flag of the royal naval reserve. It is flown also by certain authorized vessels of the British mercantile marine, the conditions governing this privilege being that the captain and a certain specified portion of the officers and crew shall belong to the ranks of the royal naval reserve. When flown by ships belonging to British government offices the seal or badge of the office is displayed in the fly: for example, hired transportsfly it with the yellow anchor in the fly; themarine department of the board of trade has in the fly the device of a ship under sail; the telegraph branch of the post office shows in the fly a device representing Father Time with his hourglass shattered by lightning; the ordnance department displays upon the fly a shield with a cannon and cannon balls upon it. Certain yacht clubs are also authorized by special admiralty warrant to fly the blue ensign. Some of these display it plain; others show in the fly the distinctive badge of the club. Consuls general, consuls and consular agents also have a right to fly the blue ensign, the distinguishing badge in their case being the royal arms.

The royal air force uses: as its distinctive flag, an ensign of the colour known as R.A.F. blue with the union device in the upper canton and the R.A.F. aircraft distinguishing mark (a target of red, white and blue, with red in the centre) in the fly. This ensign is hoisted at R.A.F. establishments and is also seen afloat. flown by the launches of the Air-Sea Rescue service. Another ensign variant is flown by vessels belonging to the war department and navigated by men of the British army service corps fleet.

Until the later years of the 18th century the ensign was always flown from a flagpole in the stern of the ship called the ensign staff. As the old type of lateen mizzen sail came to be replaced, however, by the new fore-and-aft rigged mizzen, the ensign staff was found to be in the way of the new spanker boom and was therefore removed. The ensign was henceforward hoisted on a halyard which led to the spanker gaff. This arrangement has since been faithfully observed in shore establishments of the royal navy and also by the royal air force, the flagpole being a miniature version of a mizzenmast complete with gaff. The hoisting and lowering of the ensign is usually made with a ceremony each morning and night, with the appropriate bugle calls and with all present at attention.

Commonwealth Dominion Flags.—Various countries of the British Commonwealth have national flags which are based upon the British ensigns or which otherwise incorporate the union flag pattern. Canada flies as its national flag a red ensign with the arms of the dominion in the fly, the red ensign being similarly used as the merchant flag. Australia uses the blue ensign with the addition of six white stars of which five are arranged as in the constellation called the Southern Cross. New Zealand has the blue ensign but with four red stars outlined in white, also suggesting the Southern Cross as a symbol of the Antipodes. The Union of South Africa has a flag of which the union pattern forms a part. The colonies in the British Commonwealth mostly use the union flag with a badge or shield placed in a white disk covering the centre. Their ships mostly use the ordinary red ensign. (For descriptions of the flags of the Asian countries of the Commonwealth of Nations. see Flags *of Other Countries,* below.)

The Admiralty and Trinity House.—There are two other British sea flags which are worthy of brief notice. These are the admiralty flag and the flag of the master of Trinity House. The admiralty flag is a plain red flag with a clear anchor in the centre in yellow. In a sense it is a national flag, for the sovereign hoists it when afloat in conjunction with the royal standard and the union jack. It would appear to have been first used by James, duke of York, as lord high admiral, who flew it when the sovereign was afloat and had the royal standard flying in another ship. When a board of commissioners was appointed to execute the office of lord high admiral, this was the flag adopted, and in 1691 the admiralty ordered the navy board. then a subordinate department, "requiring and directing it to cause a fitting red silk flag, with the anchor and cable therein, to be provided against Tuesday morning next, for the barge belonging to this board." In 1725, presumably as being more artistic: the cable in the device was twisted round the stock of the anchor. It was thus made into a foul anchor, the thing that a sailor most hates, and this despite the fact that the first lord at the time, the earl of Berkeley, was himself a sailor. The anchor retained its unseamanlike appearance and was not cleared till 181j, and even to this day the buttons of the naval uniform bear a foul anchor. The anchor flag is solely the emblem of an administrative board; it does not carry the executive or combatant functions which are vested in the royal standard, the union or an admiral's flag. But on two occasions it has been made use of as an executive flag; in 1719 the earl of Berkeley, who at the time was not only first lord of the admiralty but also vice-admiral of England, obtained the special permission of George I to hoist it at the main instead of the union flag; and in 1869, when H. C. E. Childers, then first lord, accompanied by some members of his board, went on board the "Agincourt," he hoisted the admiralty flag and took command of the combined Mediterranean and channel squadrons, thus superseding the flags of the two distinguished officers who at the time were in command of these squadrons. (It is hardly necessary to add that throughout the navy there was a very distinct feeling of dissatisfaction at the innovation.) When the admiralty flag is flown by the sovereign it is hoisted at the fore! his own standard being of course at the main and the union at the mizzen.

The flag of the master of Trinity House is the red cross of St. George on its white ground, but with an ancient ship on the waves in each quarter; in the centre is a shield with a precisely similar device surmounted by a lion.

The sign of a British admiral's command afloat is always the same. It is the St. George cross. Formerly it was borne on the main, the fore or the mizzen, according to whether the officer to whom it pertained was admiral, vice-admiral or rear admiral; but, as ironclads superseded wooden ships. and a single pole mast took the place of the old three masts, a different method of indicating rank was necessitated. Today the flag of an admiral is a square one, the plain St. George cross. When flown by a vice-admiral, it bears a red ball on the white ground in the upper canton next to the staff; if flown by a rear admiral there is a red ball in both the upper and lower cantons. As most modern battleships have two masts, the admiral's flag is hoisted at the one which has no masthead semaphore. The admiral's flag is always a square one, but that of a commodore is a broad white pennant with the St. George cross. If the commodore is of the first class, the flag is plain; if of the second class, the flag has a red ball in the upper canton next to the staff. The same system of differentiating rank prevails in most navies, though very often a star takes the place of the ball. In some cases the indications of rank are differently shown; for instance, in the Japanese navy the distinction is made by a line of colour on the upper or lower edges of the flag.

(C. N. P.)

FLAGS OF THE UNITED STATES

The first flag flown in the British colonies in America was a square of white bunting or silk adorned with a large red cross of St. George. the arms of which extended to its full length and breadth. It was carried by John Cabot when he discovered the North American continent in 1497, and the ships that brought the colonists to Jamestown, Va., in 1607, and to Plymouth, Mass., in 1620, displayed it as a matter of course as it was the English flag.

The Puritans of New England objected to the cross and in 1634 John Endecott, who was to become governor of Massachusetts ten years later, cut part of the cross from the flag at Salem. Formal complaint was entered in November of that year that the flag had been defaced by Endecott, and it was charged that the mutilation might be construed as an act of rebellion against England. When the case was tried, it was testified that the mutilation had been done not as an act of disloyalty but from the conscientious conviction that. as the cross had been given to England by the pope, it was a relic of Antichrist and that to allow it to remain was an act of idolatry. Endecott was found guilty of "a great offence" for which he was worthy of admonition, and he was debarred from holding public office for a year.

When Sir Edmund Andros was commissioned as governor of New England in 1686, he designed a flag showing the cross of St. George on a white ground nith the initials "J R." signifying "Jacobus Rex" in the centre of the cross surmounted by a crown. A New England flag of *c.* 1700 was blue with the cross of St. George in the canton and a tree in the upper-left-hand corner.

At the time the British took over New York city from the Dutch in Sept. 1664, the union jack mas displayed in place of the Dutch flag. Banners of many different designs were used by the different colonies. In the early days of the revolutionary struggle each state adopted a flag of its own. That of Massachusetts bore a pine tree. South Carolina had a flag adorned with a rattlesnake. The rattlesnake with 13 rattles was a common decoration, usually accompanied by the inscription. "Don't tread on me." The snake and the motto appeared on the banner of John Proctor's battalion raised in Westmoreland county, Pa.. and was carried by this battalion in the Revolutionary War. The New York flag was white with a black beaver on it, and the Rhode Island flag also was white adorned with a blue anchor and with 13 white stars in its blue canton. The colours carried by different regiments differed with the taste of their commanders.

The first flag containing the stars of which there is any record was hoisted in 1775 on the armed schooner "Lee," captain, John Manley, of Massachusetts. The flag was nhite with a blue canton containing 13 five-pointed stars. In the centre of the flag was a blue anchor at the top of which was a scroll bearing the word "Hope." Virtually this was Rhode Island's flag.

The importance of a flag for the ships which congress had ordered to be outfitted in 1775 was recognized; a letter from Col. Joseph Reed Washington's military secretan, dated Oct. 20, 1775, recommended that a flag be adopted "by which our vessels may know one another" and suggested the pine tree flag, then in use on other ships. Primarily. flags uere designed for naval ships. Differing from various regimental banners carried by individual units, the Stars and Stripes was not carried by any U.S. army land forces until 1834 (by the artillery). The colours were not carried by the infantry until 1841. and the standard mas not carried by the cavalry until 1895. In the navy it is called the ensign.

On Jan. 1. 1776 the day the new continental army "came into being." to use Washington's own words. a new flag was displayed on Prospect hill, in the American lines besieging Boston. It had 13 red and white stripes and the British union jack, with its crosses of St. George and St. Andrew, on a canton. This showed loyalty to the crown, as the colonists were not then planning independence. This flag was merely the British red ensign, modified by placing six white stripes on the red field. It was known contemporaneously as the continental flag or congress colours. in recent years as the Grand or Great Union or Cambridge flag.

This flag was flown from the ships of the new continental navy when it sailed from Philadelphia three days later. As that interval of time was too limited for information to have arrived from Boston, it is evident that some prior arrangement had been made. That this was the work of a committee of congress which conferred with Washington in Oct. 1775 has been suggested, but this is unlikely as there is no mention of it in the report of the committee.

The continental flag continued to be used even after the Declaration of Independence had made the crosses of England and Scotland inappropriate. Congress even tacitly approved it in the following September by directing that it be used on privateers. That the inappropriateness was recognized is shown by a letter written by William Richards, a navy quartermaster, in Oct. 1776, complaining of the lack of a suitable flag and that one could not be obtained until a design was fixed, so the navy continued to use the continental flag.

It was not until June 14, 1777, almost a year after the adoption of the Declaration of Independence, that the Continental Congress adopted a design for the national flag. It resolved that "The flag of the United States shall be thirteen stripes, alternate red and white, with a union of thirteen stars of white on a blue field, representing a new constellation." A comparison of this design with that of the continental flag shows that the only change was a union of stars to replace the union of the crosses of England and Scotland, using the same blue field. Hence the Stars and Stripes evolved in two stages from the British red ensign.

Although the 13 stars were usually arranged in a circle, no rule had been made and there was thus no uniformity. Some flags were made with 12 stars in a circle and 1 in the centre, others with three horizontal rows of 4. 5 and 4. In others the stars were arranged as if they had been placed on the arms of the combined crosses of St. George and St. Andrew. one row horizontal and another perpendicular for the cross of St. George and two diagonal rows representing the cross of St. Andrew.

The first record of the Grand Union flag being hoisted on a naval ship is that of 2nd Lieut. John Paul Jones on board the "Alfred," at which time he wrote: "I had the honor to hoist with my own hands the flag of Freedom, the first time it was displayed on the Delaware." Although his appointment was dated Dec. 22, 1775, the squadron did not sail until Feb. 17, 1776. That Jones hoisted the Stars and Stripes on the "Ranger" July 4, 1777, is in error, for he then had not taken command, and there can be found no printed official announcement of the new flag (adopted June 14, 1777) until Sept. 3, 1777.

The belief that the flag raised at Ft. Stanwix (Ft. Schuyler) near what is now Rome. N.Y., mas the first Stars and Stripes in battle is incorrect, because that flag had no stars. William Colbreath, a soldier at the fort, wrote in his diary (still extant): "Aug. 3d. Early this Morning a Continental Flagg made by the Officers of Col. Gansevoorts Regiment was hoisted and a Cannon Levelled at the Enemies Camp was fired on the Occasion."

Col. Marinus Willett's report, Aug. 21, 1777, to Gov. Jonathan Trumbull, reads: "Aug. 8 brought off 5 of the enemies' colours and displayed them on the flagstaff of the impromptu made continental flag." John McGraw, aiso a soldier there, carved on his powder horn a plan of the fort with a continental flag flying.

The first Stars and Stripes flown in battle by land forces (and still preserved in the North Bennington, Vt., museum) is the famous 76 flag. its outer stripes white, flown in the battle of Bennington, Aug. 16, 1777.

The theory that Washington's coat of arms, which contained stars and stripes, suggested the new flag has no supporting evidence, nor was a suggestion from such a source necessary, as there were several striped flags in existence at the time, and mention has already been made of flags in America with stars.

Later investigators leaned to the conclusion that the design was drawn by Francis Hopkinson, a member of the naval committee and a signer of the Declaration of Independence. He was an artist, and there are extant bills which he presented to congress for artistic work.

The first public assertion that Elizabeth, or Betsy, Ross made the first Stars and Stripes appeared in a paper read before the historical society of Pennsylvania on March 14, 1870, by William J. Canby, a grandson of Betsy Ross. In 1857 his aunt, a daughter of Betsy by her third husband, asked him to write from her dictation the story of the making of the flag she had heard her mother tell many times. The story was that in June 1776, before the adoption of the Declaration of Independence. General Washington, Robert Morris and George Ross, representing a committee of the congress, came to her upholstery shop in Arch street, Philadelphia, Pa., shoued her a rough draft of a flag with stars and stripes and asked if she could make such a flag. She did. and it was taken to the state house. where the congress was in session, and shown to the members; they adopted it as the flag of the United States and ordered her to make many of them.

This story was long regarded as authentic. but nowhere can there be found any record of the appointment of a committee to design a flag in June 1776; no record of the adoption of any flag by the congress prior to June a year later. and, no "United States" for over a decade to come. The only record of any flags made by Betsy Ross is at Harrisburg, Pa., voucher dated May 29, 1777, for £14 and some shillings for making flags for the Pennsylvania navy.

There was no change in the number of stars or stripes from the adoption of the design until Jan. 13, 1794, when congress in recognition of the admission of Vermont and Kentucky, voted to add two stripes and two stars, one for each of the new states to take effect May 1. 1795. This new Aag, with 1 j stripes and 15 stars, remained unchanged until 1818, when there were 20 states in the union. Tennessee. Ohio, Louisiana. Indiana and Mississippi having been admitted, and so congress on April 18 of that year voted that the flag should contain 13 alternate red and white stripes representing the original 13 states, and that a star for each new state should be added on July 4 following its admission. The table gives the date of admission to the union of each state, following the first 20.

Admissions of States to the Union

State	Date of admission	Star added	Number of stars
Illinois	Dec. 3, 1818	July 4, 1819	21
Alabama	Dec. 14, 1819	July J, 1820	23
Maine	Mar. 15, 1820	July 4, 1820	
Missouri.	Aug. 10, 1821	July 3, 1822	24
Arkansas	Jan. 15, 1836	July 4, 1836	25
Michigan	Jan. 26, 1837	July 4, 1837	26
Florida	Mar. 3, 1845	July 4, 1845	27
Texas	Dec. 29, 1845	July J, 1846	28
Iowa	Dec. 28, 1846	July 4, 1847	29
Wisconsin	May 29, 1848	July 4, 1848	30
California	Sept. 9, 1850	July 4, 1851	31
Minnesota	hlay 11, 1858	July 4, 1858	32
Oregon	Feb. 14, 1859	July 4, 1859	33
Kansas	Jan. 29, 1861	July 4, 1861	34
West Virginia	June 20, 1863	July 4, 1863	35
Nevada	Oct. 31, 1863	July 4, 1865	36
Nebraska	Feb. 9, 1867	July 4, 1867	37
Colorado	Aug. 1, 1876	July 4, 1877	38
North Dakota	Nov. 2, 1889	July 4, 1890	
South Dakota	Nov. 2, 1889	July 4, 1890	
Montana	Nov. 8, 1889	July 4, 1890	43
Washington	Nov. 11, 1889	July 4, 1890	
Idaho	July 3, 1890	July 4, 1890	
Wyoming	July 10, 1890	July 4, 1891	44
Utah	Jan. 4, 1896	July 4, 1896	45
Oklahoma	Nov. 16, 1907	July 4, 1908	46
New Mexico	Jan. 6, 1912	July 4, 1912	48
Arizona	Feb. 14, 1912	July 4, 1912	
Alaska	Jan. 3, 1959	July 4, 1959	49
Hawaii	Aug. 21, 1959	July 4, 1960	50

Display of **the U.S.** Flag. — The national flag of the United States has 13 horizontal stripes, 7 red and 6 white, with a red stripe at the top and bottom, and a union or canton of blue in the upper quarter next to the staff and extending down to the bottom of the fourth red stripe. As of July 4, 1960, the union contained 50 five-pointed stars, arranged in nine horizontal rows of, alternately, six and five stars. This arrangement was fixed by the executive order of Pres. Dwight D. Eisenhower of Aug. 21, 1959, which also fixed the proportions of the flag: hoist (width) of the flag, 1; fly (length) of the flag, 1.9; hoist (width) of the union,&; fly (length) of the union, 0.76; width of each stripe, $\frac{1}{13}$.

C.S. military forces display the flag during daylight hours. Aboard navy ships there are occasions when the flag is also displayed at other times. When a ship is at anchor, the ensign is normally displayed on the flagstaff at the stern. When the ship is under way, the ensign is usually hoisted to the gaff, a spar on the after mast. Whenever the flag, or ensign, is hoisted or lowered, the national anthem is played. On Memorial day the army half-staffs the flag only until noon. On that day the navy's ensign is half-staffed only during the few minutes of firing the salute. The flag flies day and night over Francis Scott Key's grave (Frederick, Md.), the war memorial (Worcester, Mass.), Ft. McHenry (spotlighted) and in several cemeteries over plots where U.S. soldiers and sailors lie.

There are five federal laws dealing with the display of the flag. The first provided that no trade-mark could be registered if it contained the flag, the coat of arms or other insignia of the United States. The second authorized the display of the flag on Mother's day. The third fixed penalties for the improper use or desecration of the flag in the District of Columbia, and the fourth provided for the dismissal of any employee or official of the government who, when the country was at war, criticized the flag in an abusive manner. According to a warning issued by the department of justice, based on a proclamation by the president, any alien tearing down or mutilating the flag would be 'regarded as a menace to the public peace and subject to arrest and punishment. The fifth federal law, signed by Pres. Dwight D. Eisenhower on July 9, 1953, penalizes the display of flags of international organizations or other nations in equal or superior prominence or honor to the flag of the United States at any place within the United States or any of its territories or possessions, except at the headquarters of the Cnited Nations.

Nearly every state has its own criminal codes prohibiting misuse of the flag, or any pictures of it, in connection with advertising. The penalties run from $10 to $1,000, or imprisonment from 30 days to five years.

Most of the states direct that the flag shall be displayed at all schoolhouses while the school is in session and also that pupils shall pledge allegiance to the flag. Some states forbid the display of any red or black flag along with the national flag in any procession or public hall.

Lack of uniformity in the matter of displaying the flag by civilians led to the adoption of a flag code. The National Americanism committee of the American Legion called a conference in Washington, Flag day. June 14, 1923, and delegates from 72 patriotic organizations there assembled adopted a universal flag code. Although that code lacked any federal authority, it was generally followed. When World War II came. congress was asked to enact a federal flag code. This was done. and on Dec. 22, 1942, the president signed the joint resolution, known as public law 829. The first section declares the codification of existing rules and customs for the guidance of civilians not required to conform to the regulations issued by the different official branches of the government.

SEC. 2. (a) It is the universal custom to display the flag only from sunrise to sunset on buildings and stationary flagstaffs in the open. However, the flag may be displayed at night upon special occasions when it is desired to produce a patriotic effect.

(b) The flag should be hoisted briskly and lowered ceremoniously.

(c) The flag should not be displayed on days when the weather is inclement.

(d) The flap should be displayed on all days when the weather permits, especially on New Year's Day, January 1; -Inauguration Day, January 20: Lincoln's Birthday, February 12; Washington's Birthday, February 22; Armed Forces Day (third Saturday in May); Easter Sunday (variable); Mother's Day, second Sunday in May; Memorial Day (half staff until noon), May 30; Flag bay, June 14; Independence Day, July 4; Labor Day, first Monday in September; Constitution Day, September 17; Columbus Day, October 12; Veterans Day, October 27: Armistice Day, November 11; Thanksgiving Day, fourth Thursday in November; Christmas Day, December 25; such other days as may be proclaimed by the President of the United States; the birthdays of States (dates of admission); and on State holidays.

(e) The flag should be displayed daily, weather permitting, on or

PROPER METHODS OF DISPLAYING AND SALUTING THE FLAG OF THE UNITED STATES OF AMERICA

near the main administration building of every public institution.

(f) The flag should be displayed in or near every polling place on election days

(g) The flag should be displayed during school days in or near every schoolhouse

SEC. 3. That the flag, when carried in a procession with another flag or flags, should be either on the marching right; that is, the flag's own right, or, if there is a line of other flags, in front of the centre of that line [figs. 1 and 2].

(a) The flag should not be displayed on a float in a parade except from a staff, or as provided in subsection (i).

(b) The flag should not be draped over the hood, top, sides, or back of any vehicle, or of a railroad train or a boat When the flag is displayed on a motorcar, the staff shall be fixed firmly to the right side (only) of the chassis or clamped to the radiator cap.

(c) No other flag or pennant should be placed above or, if on the same level, to the right of the flag of the United States of America, except during divine services conducted by naval chaplains at sea, when the chaplain's private pennant may be flown above the flag during divine services for the personnel of the navy.

No person shall display the flag of the United Nations or any other national or international flag equal, above, or in a position of superior prominence or honor to, or in place of, the flag of the United States at any place within the United States or any Territory or possession thereof. *Provided,* That nothing in this section shall make unlawful the continuance of the practice heretofore followed of displaying the flag of the United Nations in a position of superior prominence or honor, and other national flags in positions of equal prominence or honor, with that of the flag of the United States at the headquarters of the United Nations.

(d) The flag of the United States of America, when it is displayed with another flag against a wall from crossed staffs, should be on the right, the flag's own right, and its staff should be in front of the staff of the other flag [fig. 3].

(e) The flag of the United States of America should be at the centre and at the highest point of the group when a number of flags of States or localities or pennants of societies are grouped and displayed from staffs [fig. 4].

(f) When the flags of States, cities, or localities, or pennants of societies are flown on the same halyard with the flag of the United States, the latter should always be at the peak [fig. 5]. When the flags are flown from adjacent staffs, the flag of the United States should be hoisted first and lowered last. No such flag or pennant may be placed above the flag of the United States or to the right of the flag of the United States.

(g) When flags of two or more nations are displayed, they are to be flown from separate staffs of the same height. The flags should be of approximately equal size. International usage forbids the display of the flag of one nation above that of another nation in time of peace [fig. 6].

(h) When the flag of the United States is displayed from a staff projecting horizontally or at an angle from a window sill, balcony or front of a building, the union of the flag should be placed at the peak of the staff unless the flag is at half staff [fig. 7]. When the flag is suspended over the sidewalk from a rope extending from a house to a pole at the edge of the sidewalk, the flag should be hoisted out, union first, from the building [fig. 8].

(i) When the flag is displayed otherwise than by being flown from a staff, it should be displayed flat, whether indoors or out, or so suspended that its folds fall as free as though the flag were staffed.[1]

(j) When the flag is displayed over the middle of the street, it should be suspended vertically with the union to the north in an east and west street or to the east in a north and south street [fig. 10].

(k) When used on a speaker's platform, the flag, if displayed flat, should be displayed above and behind the speaker [fig. 11]. When displayed from a staff in a church or public auditorium, if it is displayed in the chancel of a church, or on the speaker's platform in a public auditorium [or on the floor], the flag should occupy the position of honor and be placed at the clergyman's or speaker's right as he faces the congregation or audience. Any other flag so displayed in the

[1]When displayed either horizontally or vertically against a wall, the union should be uppermost and to the flag's own right; that is, to the observer's left. When displayed in a window, the flag should be displayed in the same way; that is, with the union or blue field to the left of the observer in the street.

chancel or on the platform should be placed at the clergyman's or speaker's left as he faces the congregation or audience [fig. 12]. But when the flag is displayed from a staff in a church or public auditorium elsewhere than in the chancel or on the platform [as the congregation's flag] it shall be placed in the position of honor at the right of the congregation or audience as they face the chancel or platform. Any other flag so displayed should be placed on the left of the congregation or audience as they face the chancel or platform.'

(l) The flag should form a distinctive feature of the ceremony of unveiling a statue or monument, but it should never be used as the covering for the statue or monument.

(m) The flag, when flown at half staff, should be first hoisted to the peak for an instant and then lowered to the half-staff position. The flag should be again raised to the peak before it is lowered for the day. By "half staff" is meant lowering the flag to one-half the distance between the top and bottom of the staff. Crepe streamers may be affixed to spear beads or flagstaffs in a parade only by order of the President of the United States.

(n) When the flag is used to cover a casket, it should be so placed that the union is at the head and over the left shoulder. The flag should not be lowered into the grave or allowed to touch the ground.

SEC. 4. That no disrespect should be shown to the flag of the United States of America; the flag should not be dipped to any person or thing. Regimental colors, State flags, and organization or institutional flags are to be dipped as a mark of honor.

(a) The flag should never be displayed with the union down save as a signal of dire distress.

(b) The flag should never touch anything beneath it, such as the ground, the floor, water, or merchandise.

(c) The flag should never be carried flat or horizontally, but always aloft and free.

(d) The flag should never be used as drapery of any sort whatsoever, never festooned, drawn back, nor up, in folds, but always allowed to fall free. Bunting of blue, white, and red, always arranged with the blue above, the white in the middle, and the red below, should be used for covering a speaker's desk, draping the front of a platform, and for decoration in general.[2]

(e) The flag should never be fastened, displayed, used, or stored in such a manner as will permit it to be easily torn, soiled, or damaged in any way.

(f) The flag should never be used as a covering for a ceiling.

(g) The flag should never have placed upon it, nor on any part of it, nor attached to it any mark, insignia, letter, word, figure, design, picture, or drawing of any nature.

(h) The flag should never be used as a receptacle for receiving, holding, carrying, or delivering anything.

(i) The flag should never be used for advertising purposes in any manner whatsoever. It should not be embroidered on such articles as cushions or handkerchiefs and the like, printed or otherwise impressed on paper napkins or boxes or anything that is designed for temporary use and discard ; or used as any portion of a costume or athletic uniform. Advertising signs should not be fastened to a staff or halyard from which the flag is flown.

(j) The flag, when it is in such condition that it is no longer a fitting emblem for display, should be destroyed in a dignified way, preferably by burning.

SEC. 5. That during the ceremony of hoisting or lowering the flag or when the flag is passing in a parade or in a review, all persons present should face the flag, stand at attention, and salute. Those present in uniform should render the military salute. When not in uniform, men should remove the headdress with the right hand holding it at the left shoulder, the hand being over the heart. Men without hats should salute in the same manner. Aliens should stand at attention. Women should salute by placing the right hand over the heart. The salute to the flag in the moving column should be rendered at the moment the flag passes [fig. 13].

SEC. 6. That when the national anthem is played and the flag is not displayed, all present should stand and face toward the music. Those in uniform should salute at the first note of the anthem, retaining this position until the last note. All others should stand at attention, men removing the headdress. When the flag is displayed, all present should face the flag and salute.

SEC. 7. That the pledge of allegiance to the flag, "I pledge allegiance to the flag of the United States of America and to the Republic for which it stands, one Nation under God, indivisible, with liberty and justice for all,"[3] be rendered by standing with the right hand over the heart. However, civilians will always show full respect to the flag when the pledge is given by merely standing at attention, men removing the headdress. Persons in uniform shall render the military salute.

The eighth section empowers the commander in chief of the army and navy to change or add to the rules whenever desirable.

A U.S. flag painted on the side of a ship should have the union toward the bow of the ship and the stripes flowing aft, as if flying in the wind. The flag is the same when looked upon from either side, and depending upon the direction in which it is moving.

Personal and Official Flags. — As it is the prerogative of the U.S. president to design his own flag (though not all presidents have exercised this privilege), there is no set pattern. but the field is always blue. The flagstaff is ebony and is the only flagstaff authorized (army regulations, 1917) to bear the "eagle, alert" staff head. The correct staff head of all other U.S. flags is the spear (or "acorn, ball"; navy staffs may bear the star, lance, ball or flat truck), never the eagle. The vice-president's flag design includes a part of the great seal in colour, encircled by 13 blue stars, on a rectangular white field. The flag of the secretary of the treasury exhibits crossed anchors encircled by 13 white stars on a rectangular blue field. That of the secretary of the army includes part of the great seal, in colour, and four white stars on a rectangular red field; while the design of the secretary of the navy's flag exhibits a fouled anchor and four white stars on a rectangular blue field. For five-star generals of the army the flag is a rectangular "scarlet field with five white stars placed on an imaginary circle," and for fleet admirals it is a rectangular "dark blue field with five white stars placed on an imaginary circle." Other cabinet officers, undersecretaries, assistant secretaries and staff officers have distinguishing flags indicative of their office and rank. The United States shield, taken from the great seal, has seven white stripes and six red vertical stripes (pales), representing the original 13 colonies supporting the nation, indicated by the blue band in which there are no stars.

Confederate Flag. — When a bloc of southern states seceded from the union, the selection of a suitable flag was much discussed. Early in Feb. 1861, a convention of six of the states met in Montgomery, Ala., to consider the form of government to be set up, and a committee, appointed to select a flag, recommended that

> . . . the flag of the Confederate States of America shall consist of a red field with a white space extending horizontally through the centre equal to one-third the width of the flag, the red spaces above and below to be of the same width as the white; the union blue, extending down through the white space and stopping at the lower space; in the centre of the union a circle of white stars corresponding to the number of States of the Confederacy.

This report was adopted on March 4, 1861. The flag thus approved came to be known as the Stars and Bars. It was first displayed over the state house in Montgomery.

At the battle of Bull Run, or Manassas as the Confederates called it, the similarity in colours of the flags of the Northern and Southern armies led to confusion, and at the suggestion of Gen. G. T. Beauregard a battle flag was devised and used by the Southern armies throughout the war. It was based on a design suggested by Col. William Porcher Miles and Col. Walton, and consisted of a red field on which was placed a blue St. Andrew's cross separated from the field by a white fillet, and adorned with white stars to the number of Confederate states. The Stars and Bars having proved to be unsatisfactory, demand was frequently made for the adoption of a flag of different design. Finally, in May 1863, the Confederate congress, in session in Richmond, Va., adopted a new design.

The resolution recommending it set forth that the flag should be a red square containing the battle flag designed by General Beauregard, the only objection being that it resembled the white English ensign and might be mistaken for a flag of truce, and so on March 4, 1865, a broad transverse strip of red was added to it.

(GY. A.; G. W. Do.; X.)

FLAGS OF OTHER COUNTRIES

Europe. — France. — The Chape de St. Martin and the oriflamme were succeeded by the *cornette blanche* of the Bourbons, when Henry IV came to the throne in 1589. This was a white flag, usually carrying the fleur-de-lis arms of royalty, and it was used until the Revolution. The origin of the well-known French tricolour, which was then adopted, is clear from a perusal of contemporary papers. When the Bastille was taken and destroyed on July 14,

[1]Subsection (k) is often read too literally. The flag always holds the position of honour, the "military right of line." This is at the right of a person or persons facing people who are facing them, whether the staffed flag is in chancel, on platform or on the floor. Honour is a matter of position, not altitude.

[2]Note the order of the colours—blue, white and red—as the government enumerates them.

[3]On Flag day, 1954, public law 396 added the two words "under God" to the pledge, making it read: "I pledge allegiance to the flag of the United States of America and to the Republic for which it stands, one Nation under God, indivisible, with liberty and justice for all."

1789, the Parisians wore cockades of red and blue, the colours of the coat of arms of the city, in conformity with instructions from the national assembly the preceding day. Three days later the king went to the *hôtel* de *ville* and the newspaper Le *Moniteur,* in its issue of July 20, in describing the incident, related that the mayor of Paris "presented to the king a cockade, the same as that which the citizens had adopted. His majesty received it and put it on his hat," where the white cockade of the Bourbons was already placed. Red. white and blue were thenceforth known as "the national colours," symbolizing the unity of king and people. The white flag flown by the navy was not changed until the following year. On Oct. 24, 1790, the assembly passed a law providing for a flag of three vertical stripes of red, white and blue to be flown from the jackstaff on the bowsprit, and the ensign had the same combination as a canton on the white flag. On Feb. 15, 1794, the ensign was denounced in the assembly as "an outrageous caricature" inasmuch as "the republican colours are relegated to a corner of the flag." The white ensign was thereupon abolished and the tricolour jack was substituted for it. The law provided that the colours be reversed so that the blue stripe would be next to the staff.

The restoration of the Bourbons after Waterloo brought back the cornette blanche, but with the accession of Louis Philippe in 1830 the tricolour returned to stay. It is the only French flag, being used for all purposes.

The Netherlands.—The flag of this country had its origin in the colours of the prince of Orange, the leader of the Dutch in their War of Independence. His colours were orange, white and blue, and two flags used in 1574 are still preserved. Just how or why the top stripe was changed from orange to red, as it is today, is not clear. As early as 1597 the use of red is recorded, and in 1634 the governor general of the Dutch East Indies, in placing an order for bunting for the manufacture of flags, requested either orange or red. This indicates that the two colours were considered interchangeable. Orange remained the official colour and in at least four flag books published in the first half of the 18th century the Dutch flag is described as orange. white and blue, although the accompanying illustrations show a red stripe, not orange. It was not until Feb. 17, 1795 that the states-general prohibited the use of orange and on the following Sept. 25 described the red, white and blue emblem as the national flag.

Belgium.—The Belgian flag has three vertical stripes of black, yellow and red. These colours were first used by the Brabançons in 1790 and were probably taken because they are the colours of the coat of arms of Brabant. However, it should be noted that they are also the same as the colours of the arms of all the principal provinces of Belgium. In 1830, when the Belgians revolted against the Netherlanders. the French tricolour, as the symbol of liberty, was flown. When success was achieved and the kingdom of Belgium established, the Brabançon colours were taken for the national flag.

Germany.—Each kingdom and principality had its own local flag and coat of arms, and there never was a flag common to all of Germany until the establishment of the empire in 1871. Then the flag which had been adopted four years before by the north German confederation—black. white and red in three horizontal stripes—was taken for the national flag of Germany. These colours came from the black and white arms of Prussia and the red and white colours of the Hanseatic league. When the republic was inaugurated in 1918, the colours were changed to black, red and gold, a flag which had been flown during the revolutions of 1848.

Austria.—After the incorporation of Austria with Germany the Austrian flag ceased to exist, but no account of national flags would be complete without mentioning it. as it was probably the oldest one in use. It dates from early in the 13th century when Duke Frederick II of Austria adopted a horizontal white stripe on a red field for his coat of arms and banner. The earliest authentic date for this is 1232, and it continued to be the flag of Austria with no intermission until the *Anschluss* of 1938. It was restored after World War II.

Czechoslovakia.—When Czechoslovakia was formed after World War I, it adopted a flag of red, white and blue, the colours of the coats of arms of Bohemia, Moravia and Slovakia. The flag had two horizontal stripes of red and white with a blue triangle at the hoist. After the occupation by Germany in 1939 the colours were retained but in Bohemia and Moravia they were arranged in three horizontal stripes, with white at the top and blue at the bottom.

Switzerland.—The origin of the Swiss flag. a white couped cross on a red field, is usually ascribed to the year 1339, but the only authority for that date is an account written 100 years later. The first historical mention of the white cross emblem occurs in 1444, when the Swiss were charged with having worn red crosses on their military tunics, instead of the customary mhite, to deceive the enemy. However, this shows that the white cross was already the established Swiss device, although not on a flag. Apparently its use was by custom only; not until May 16, 1814, was it officially recognized as "the military emblem of the ancient Swiss."

Spain.—In mediaeval times and until 1785 the royal armorial banner was the only flag in Spain which could be considered as national. In that year it became a cornette *blanche.* A Bourbon was on the throne and he used the white flag of that family charged with the royal arms. In order to difierentiate clearly between the ships of Spain and those of other countries nhich were ruled by Bourbons, all of whom used the white flag, a new national flag of red and yellow was adopted, taken from the Spanish coat of arms. A central horizontal stripe comprising half the area, was yellow; on each side was a strip of red. This flag lasted until the overthrow of the monarchy in 1931 when a tricolour of red, yellow and purple was adopted. The Iiacionalistas under Gen. Francisco Franco used the flag of the monarchy in the civil war and restored it as the national flag when they became victorious in 1939. The coat of arms is placed on the centre.

Portugal.—Armorial banners were used in Portugal until well into the 19th century. In 1821 the *cortes* approved a resolution which provided that the national cockade be blue and white, "the colours used on the shield of Alfonso Henriquez." the first king of Portugal. in the 12th century. In 1830 a flag was adopted of those two colours. blue occupying two-fifths of the flag next the staff, white the remainder. The coat of arms was centred on the line dividing the two colours. In 1910 the monarchy was overthrown and green and red replaced the blue and white.

Italy.—The flag of Italy is green, white and red in three vertical stripes. This flag first appeared on May 14, 1795, at Bologna in a student demonstration. These three colours, however, had been favourites in northern Italy for several hundred years, ever since Dante used them as symbols of the three cardinal virtues, faith, hope and charity. In Sept. 1796 the newly formed Cisalpine republic adopted the flag for its troops taking part in the Napoleonic campaigns in Lombardy. When Napoleon was crowned king of Italy in 1805, he took the flag for his new kingdom, but with his downfall Italy again disintegrated and the flag ceased to exist. On March 4, 1848, Charles Albert, king of Sardinia, resurrected the flag, and when Italy was again united under his son in 1861 it became the emblem of the entire country.

Scandinavia.—The flag of Denmark has a white cross on a red field and is known as the Danebrog. Historically the first evidence of use of this flag is on the seal of Waldemar, duke of South Jutland. on a document of 1308. The merchant flag is of the usual rectangular shape; the naval ensign is swallow-tailed.

The flags of the other Scandinavian countries are all based on the Danebrog. Sweden uses a yellow cross on a blue field; yellow and blue are also the colours of the national coat of arms. uhich consists of three gold crowns on blue. This flag dates from the reign of Gustavus Vasa, who was crowned in 1528. The naval ensign is swallow-tailed with a tongue; *i.e.*, it has three points.

Iiornay was united to Denmark for 400 years, until 1814, when it came under the Swedish cronn. The Danish flag nas retained, but with the addition of the lion of Norway in the upper corner. Because of the difficulty of distinguishing this from the flag of Denmark, a change was made in 1821, the lion being eliminated and a blue cross superimposed on the white cross of the Danish flag. Norway was completely independent after 1905 but continued to use the same flag. The naval ensign has three points.

The flag of Finland has a blue cross on a white field, "the blue for the colour of the lakes, the white as the emblem of the snow-fields," as a member of the Finnish diet said when the flag was first suggested in the 1860s. The coat of arms is placed on the cross. The naval ensign is swallow-tailed.

The flag of Iceland is the reverse of that of Norway, a red cross bordered with white on a blue field.

Hungary.—The Hungarian flag has three horizontal stripes of red, white and green. In the early midde ages the royal banner had red and white horizontal stripes. In some way green came to be associated with them, and a coat of arms was developed in the 14th century with those three colours. During the reign of Maria Theresa (1740–80) a national flag of red, white and green made its appearance, but it does not seem to have come into general use. It was not until 1848 that the diet prescribed that "the ancient flag shall again be used." This definitely established the national flag of Hungary. After the establishment of the Communist government the new national emblem—a rising star, above a hammer crossed with an ear of wheat, the whole encircled by sheaves of wheat—was placed on the tricolour flag.

Poland.—The national flag was flown after 1919 but was not officially adopted until 1927. The colours, red and white, go back to the old Polish banner of Lech. a white eagle on a field of solid red. According to legend the brothers Czech and Lech set out from Yugoslavia to find a new home for their people; Czech stopped and founded Prague; Lech kept on. and seeing a white eagle in a tree he chose it as part of his emblem when he founded Warsaw.

U.S.S.R.—The flag of the Russian empire was white, blue and red in three horizontal stripes and was first displayed in the reign of Alexis in 1667. His son, Peter the Great. founded the Russian navy, and about the year 1712 a blue cross, shaped like the letter X, on a white field mas taken for the naval flag. With the fall of the empire in 1917 and the establishment of the Soviet government all imperial emblems were abolished and the red flag of revolution became the national flag. A crossed hammer and sickle in yellow are in the upper corner, symbolizing the artisan and the husbandman, and above them is a five-pointed star outlined in yellow. This star is said to typify the five continents which, according to Soviet belief, are eventually to embrace the doctrines of Marx.

It is strange, but nevertheless true, that the red flag, symbolical of revolution, originally had precisely the opposite connotation. After the fall of the Bastille in 1789 rioting became frequent in Paris, which induced the assembly to pass an act providing for martial law; the hoisting of the red flag was to be the signal that martial law had been declared. It was so displayed several times during the ensuing two years; then came the fateful day of July 17, 1791, when the red flag was raised and the troops, under the marquis de Lafayette, fired on a riotous mob on the Champ de Mars, killing several hundred. Popular indignation at this act strengthened the extreme radical elements. and the next year the mob used a red flag inscribed "Martial law of the people against the revolt of the court," on the principle that the people constitute the sovereign power, and that whenever a government opposes the people it is the government which is in revolt and the people are justified in declaring martial law against it. Several similar instances occurred in the next few years, both in France and elsewhere, firmly establishing the red flag as the symbol of opposition to the government.

Yugoslavia.—Yugoslavia has three horizontal stripes of blue, white and red for its national flag, with a red star outlined in yellow on the centre. The flag of Serbia until the close of World War I had the same three colours, but the top stripe was red. the bottom white. It had its origin in the uniform worn by the Serbs in their insurrection against the Turks. They wore white shirts uhich hung to the knees, under a blue coat, with red caps. A company of soldiers thus garbed presented three lines of red. blue and white.

Rumania.—The flag of Rumania has three vertical stripes of blue, yellow and red, adopted in 1859. The colours are taken from the coat of arms, shown in the centre stripe.

Bulgaria.—The Bulgarian flag has three horizontal stripes of white, green and red. The naval ensign carries the national coat of arms—a gold lion—on a red canton.

Albania.—The flag of Albania is a resurredtion of the banner of the national hero, Skanderbeg, who successfully fought the Turks for 24 years in the 15th century. It has a black double-headed eagle on a red field. After the occupation of the country by the Italians a gold fasces was superimposed on the eagle, and after World War II a red star, outlined in yellow, was placed above it.

Greece.—The Greek War of Independence started on March 25, 1821, when Bishop Germanos raised a banner of blue, surmounted by a white cross, at Lavra. In the following January a flag of five blue and four white stripes, with a white cross in the upper corner, was adopted by the revolutionary assembly at Epidaurus.

Ireland—The national flag of Ireland, adopted in 1921, has three vertical stripes: green, the old colour of the Irish clans; white, for peace; and orange, the colour of the Orangemen.

Asia and Africa.—Turkey.—The Turkish flag has a white star and crescent on a red field. The story usually told is that the star and crescent was the emblem of Constantinople and that Mohammed II appropriated it when he captured the city in 1453. In fact. however, the crescent became the symbol of the followers of Mohammed the Prophet very early in the spread of Islam, and it was on the red flag of the Osmanli Turks 200 years before the capture of Constantinople. The Osmanlis were then a small tribe in the sultanate of Roum in Asia Minor. but they expanded rapidly, overrunning eastern Asia and the Balkans and establishing the country that came to be Turkey. On the other hand, the star was not added to the crescent on the flag until about 1798.

Egypt.—The flag of Egypt is green, charged with a white crescent and three white stars. Green is the colour sacred to Mohammed, and it was used by the Fatimite dynasty which ruled Egypt in the middle ages. The three stars represent the triple sovereignty over Egypt, Nubia and the Sudan.

Jordan and *Iraq*.—The two Moslem countries Jordan (formerly Transjordan) and Iraq, formed after World War I, have nearly identical flags. Both are based on one adopted by the Sharif Husain of Mecca, which had three horizontal stripes of black, white and green, with a triangle of red next the staff. The symbolism of green has already been explained. White and black were the colours of the first two dynasties of caliphs, the Omayyads and the Abbassids, respectively, and red was the colour used by Husain's ancestors. Arabia was conquered by Ibn Sa'ud. who introduced his own green flag, but in the meantime Husain's two sons had become kings of Transjordan and Iraq, and they preserved his flag. In Jordan a white star is placed on the red triangle; Iraq uses two white stars and the point of the triangle is cut off, forming a red trapezoid.

Iran.—The flag of Iran is a horizontal tricolour of green, white and red, with an ancient device. the lion and sun, on the centre. The lion and sun device is omitted when the flag is flown by the people and on the merchant flag.

Ismel.—The national flag of the state of Israel is white with two Yale-blue bands extending the full length of the flag. In the centre of the wide white stripe is a shield of David, made of six Yale-blue bands, forming two equilateral triangles with their bases parallel to the two blue bands.

Japan.—The naval ensign of Japan has a red rising sun with 16 rays on a white field; the national flag has a red ball on white. These flags were adopted in 1859, although the sun banner had long been an emblem of the mikado.

China.—The flag of China in the days of the Manchu emperors was the imperial dragon. The republic established in 1912 adopted a flag having five horizontal stripes of red, yellow, blue, white and black, representing the five races or clans of China. This lasted until 192j when the banner of the Kuomintang party replaced it. This flag has a red field with a canton of blue charged with a white sun having 12 rays.

India.—The national flag has three horizontal stripes: deep saifron, symbolizing the spirit of renunciation and humility; white, the path of light, truth, simplicity; bottle green, relation with the soil. In the centre of the white stripe, in dark blue, is the wheel of the Law of Dharma, a representation of Chakra of Asoka, the Buddhist ruler of the 3rd century B.C.

Ceylon.—The national flag is known as the lion flag. It has two vertical stripes, green and saffron; the balance is a red field in which is shown a lion holding a sword. The whole has a border of yellow. This flag was first hoisted on the morning of Feb. 4, 1948, and proclaimed a new era in the history of Ceylon, when it became a self-governing dominion of the British Commonwealth.

Pakistan. — The national flag has one vertical white stripe one-quarter the flag's width, the remaining three-quarters being a field of solid bottle green in which is shown a white crescent and one white star.

Burma.—The national flag has a solid red field, with a dark-blue canton in which is one large white star surrounded by five smaller white stars.

Siam.—The flag of Siam (Thailand) has five horizontal stripes of red, white, blue, white and red. The naval ensign has the Siamese badge, a white elephant, on a red disk placed on the centre of the flag.

Latin America. — Mexico. — The flag of Mexico, three vertical stripes of green, white and red, was adopted in 1821, when Mexico gained its independence. The Mexican device — an eagle with a serpent in its beak, standing on a cactus — is on the centre stripe.

Argentina and Uruguay. — The flag of Argentina is a white stripe placed horizontally on a light-blue field, with a golden sun, taken from the coat of arms, on the centre. It originated in the colours of the uniforms worn by the Argentinians when they repulsed a British invasion in 1806. The flag was adopted Feb. 13, 1813. Uruguay, which co-operated with Argentina in the early wars, uses the same colours in horizontal stripes, five white and four blue, with the same golden sun on a canton.

Venezuela, Colombia and Ecuador. — The flags of these countries — three horizontal stripes of yellow, blue and red — are all taken from the ensign hoisted by Gen. Francisco Miranda over his expedition of 1806, when the revolutions in South America against Spain commenced. Venezuela has seven white stars in a semicircle on the blue stripe. The yellow stripe occupies the upper half of the Colombian and Ecuadorian flags, as it did on Miranda's ensign. Colombia has a white star on the centre of the merchant flag and the coat of arms on the naval ensign. The coat of arms is placed in the centre of the Ecuadorian flag; the merchant marine flag is plain.

Peru. — The Peruvian flag has a white vertical stripe on a red field, with the coat of arms on the centre. It is said that these colours were suggested by a dream which José de San Martin, the Argentinian, had the night after he landed in Peru with an army to assist in the Peruvian war for independence. The flag as now designed was adopted Feb. 25, 1825.

Brazil. — The flag of Brazil is green with the coat of arms on a yellow lozenge. The day Dom Pedro proclaimed the independence of the country, Sept. 7, 1822, he wore an arm band of green and gold.

Paraguay.—The flag of Paraguay is red, white and blue in three horizontal stripes, with national badges on the centre, a different badge on each side. In its present form it dates from Nov. 17, 1842.

Bolivia. — The flag of Bolivia was adopted July 14, 1888. It is a tricolour of red, yellow and green, representing the country's animal, mineral and vegetable riches. The coat of arms appears on the yellow stripe of the flag used on public buildings and by official institutions.

Chile. — The flag of Chile dates from Oct. 18, 1817. It is divided horizontally into white and red and has a blue canton on which is a white star of five points, one point for each letter of the name Chile.

(R. E. Wy.; Gy. A.)

OTHER FLAGS

International Flags.—Besides the flags flown by separate nation-states there are now several flags, apart from the red cross already mentioned, which are used internationally. The flag of the United Nations is blue with the globe (as seen from the north pole) surrounded by a wreath all in white. Then there is the flag of the European union, in green and white; and the flag of the Americas, a white flag with three blue Maltese crosses, which offends the laws of heraldry by placing yellow (of the sun's rays) on white. The flag used at the Olympic games is white with five interlaced circles in blue, yellow, black, green and red. Other international flags are the flag indicating condition of health aboard ship, plain yellow, and the pilot flag, yellow and blue vertical stripes. But these, like the flags of the international code and the white flag indicating surrender or truce, are really signals and are dealt with elsewhere under that heading (see SIGNAL COMMUNICATION). All flags, it should be noted, however, can be used to some extent as signals Striking the flag denotes surrender. Dipping the flag (lowering it slowly and rehoisting it smartly) is a form of salute A flag hoisted at half-mast is a sign of mourning. A ship's ensign hoisted upside down is a signal of distress. In a ship that has surrendered, the captors may hoist their own ensign above the ensign of their opponents, primarily to persuade their own side to cease fire. In World War II, submarines re-entering their base used sometimes to hoist a black flag with some symbol to indicate a recent success.

Yachting Flags. — In Great Britain yachts may fly on occasion an ensign, a racing flag and a burgee. Ensigns may be white, blue, blue with a badge, red with a badge or plain red. The white ensign has been confined (since 1858) to yachts of the Royal Yacht squadron. The blue ensign may be flown by any yacht which is entitled to a royal naval reserve warrant on the conditions applicable to any merchantman. The blue ensign with a club badge in the fly is flown by yachts belonging to clubs which have the prefix "Royal" and an admiralty warrant The red ensign with a club badge is flown by yachts belonging to clubs which have only a royal and not an admiralty warrant. The red ensign may be flown by any yacht, whether belonging to a club or not. The burgee is essentially a club flag, being triangular and more often seen than the ensign. Burgees are numerous in Great Britain and still more numerous in the United States; that of the Royal Thames dates from 1775, others from the period 1820–50. The racing flag is flown only during a race to indicate which yachts are competing. It may be hauled down as a signal that a yacht has given up the race. The racing flag is intended to distinguish one yacht from another and may be of any design the owner pleases. A white-bordered union flag may also be carried, to use as a protest or pilot signal.

House Flags. — Merchantmen in British registry fly certain flags in addition to the blue or red ensign. Although they may not fly the union jack, they map fly at the jack staff a white-bordered union jack as a sign of nationality. They may fly from their foremast, when leaving port, the flag of the country for which they are bound. They may also fly their house flag indicating the shipping line to which they belong. House flags originate, it has been claimed, from the flags hoisted on Bidston hill (overlooking the old entrance to the Mersey) to inform the owners in Liverpool of their ships' arrival or departure from the Hoyle lake, which was invisible from their office windows. But the ownership of 18th-century ships was complex, and the permanently established shipping lines appeared more after 1815. Earliest of these was, of course, the East India company Its functions were largely taken over by the Blackwall frigates, which had their own house flag; and these eventually yielded place to the ships of the Peninsular and Oriental Steam Navigation company whose house flag dated from 1832. Few existing house flags can claim much greater antiquity (except that of the Hudson's Bay company), because the earlier sailing-ship lines went out of business after a period of competition with steamship companies of an almost equal seniority. Among the better-known British house flags are those of the Cunard White Star, Clan, British India, Royal Mail, Orient, Union-Castle, Canadian Pacific, Anchor, Bibby, Ellerman's Wilson and Blue Funnel lines. House flags are also flown by merchantmen of other countries, such flags as those of the Messageries Maritimes, the Batavier, the Lloyd Triestino and the Nippon lines being among the most familiar.

For flags carried by troops, see COLOURS, MILITARY. (C. N. P.)

FLAGELLANTS, in religion, the name given to those who scourge themselves, or are scourged, by way of discipline or penance (Lat. *flagellare,* to whip). Voluntary flagellation, as + form of exalted devotion, occurs in almost all religions. According to Herodotus, it was the custom of the ancient Egyptians to beat themselves during the annual festival in honour of Isis. In Sparta children were flogged before the altar of Artemis Orthia till the blood flowed. At Alea, in the Peloponnese. women were flogged in the temple of Dionysus. In the Christian church flagellation was originally a punishment, and was practised not only by parents and schoolmasters but also by bishops, who thus corrected offending priests and monks. Gradually, however, voluntary flagellation appeared in the *libri poenitentiales* as a very efficacious means of penance. In the 11th century this new form of devotion was extolled by some of the most ardent reformers in the monastic houses of the west. The early Franciscans flagellated themselves with characteristic rigour, and it is no matter of surprise to find the Franciscan St. Anthony of Padua preaching the praises of this means of penance. But the flagellant fraternities were the result of spontaneous popular movements, the real sources of which are not easily analyzed. About 1259 these fraternities were distributed over the greater part of northern Italy. The contagion spread very rapidly, extending as far as the Rhine provinces and across Germany into Bohemia. Day and night, long processions of all classes and ages, headed by priests carrying crosses and banners, perambulated the streets in double file, reciting prayers and drawing the blood from their bodies with leathern thongs. The magistrates in some of the Italian towns expelled the flagellants with threats, and for a time the sect disappeared. The disorders of the 14th century, however, the numerous earthquakes, and the Black Death, which had spread over the greater part of Europe, produced a condition of ferment and mystic fever which was very favourable to a recrudescence of morbid forms of devotion. The flagellants reappeared from eastern Europe, and, in spite of discouragement, spread to the Rhine, and penetrated as far as Holland and Flanders. A band of 100 marched from Basle to Avignon to the court of Pope Clement VI who saw in the movement a menace to the priesthood, and in Oct. 1349 published a bull commanding the bishops and inquisitors to stamp out the growing heresy. In pursuance of the pope's orders numbers of the sectaries perished at the stake or in the cells of the inquisitors and the episcopal justices. In 1389 the leader of a flagellant band in Italy called the ***bianchi*** was burned by order of the pope, and his following dispersed.

John Gerson insisted that the flagellants were creating a cultus and ritual of their own in antagonism to those of the church. This view was borne out by the facts, in Germany in 1414, when there was a recrudescence of the epidemic of flagellation which was preached as the only way to salvation. It was suppressed by the Inquisition, but held its ground among the lower ranks of Catholic piety. In the 16th century it subsisted in Italy, Spain and southern France. Henry III of France met with it in Provence, and attempted to acclimatize it at Paris. Flagellation was occasionally practised as a means of salvation by certain Jansenist convulsionaries in the 18th century. In 1820 a band of flagellants appeared during a procession at Lisbon; and in the Latin countries, at festivals, one may still see brotherhoods of penitents flagellating themselves before the assembled faithful.

FLAGELLATA, single-celled animals (Protozoa [*q.v.*]) characterized by the possession of flagella—delicate, hairlike, protoplasmic processes which serve as organs of locomotion (functioning similarly to an oar or to the propeller of an airplane).

FLAGELLUM, a relatively long, filamentous organelle characteristic of many protozoans, bacteria and certain algae having flagellated stages in their life cycles, as well as of specialized cells (choanocytes) of sponges. Flagella serve primarily as swimming devices, but in some cases may be used to create food-bearing water currents or to investigate the surroundings Each filament consists of a sheath and an inner axoneme nhich generally is attached to a cytoplasmic granule (blepharoplast). In electron micrographs the axoneme typically shons 11 fibrils (2 central, 9 peripheral). Although they are usually placed anteriorly, flagella sometimes are attached posteriorly or laterally. and occasionally form the margin of a ribbonlike undulating membrane as in certain parasites (*e.g., Trypanosoma, Trichomonas*). Cilia (*q.v.*), similar in structure to flagella, are typically shorter, more numerous and usually arranged in rows. See also PROTOZOA; BACTERIOLOGY; ALGAE; SPONGES. (R P. H)

FLAGEOLET, in music, a kind of *flûte à bec* aith a new fingering, invented in France at the end of the 16th century and in vogue in England from the end of the 17th to the beginning of the 19th century. The flageolet differed from the recorder (*q* v.) in that it had four finger holes in front and two thumb holes at the back instead of seven finger holes in front and one thumb hole at the back.

FLAGET, BENEDICT JOSEPH (1763–1850), U.S. Roman Catholic prelate. first bishop of the old west, was born Nov. 7, 1763, in Contournat, France. Entering the Sulpician society, he mas ordained a priest in 1786 (or 1787), thereafter teaching theology. He was one of several Sulpicians sent in 1792 to establish the first seminary in the United States. During the following 17 years he served as missionary to Vincennes, Ind.; attempted to found a college in Havana. Cuba; and taught at Georgetown college in Washington, D.C., and at St. Mary's seminary in Baltimore, Md.

When Bishop John Carroll's (see CARROLL, JOHN) diocese of the United States was divided in 1808, Flaget was nominated for one of the four new sees; and on Nov. 4, 1810, he was consecrated by Carroll as bishop of Bardstown, Ky. His diocese extended from Kentucky to the Great Lakes, from the Alleghenies to the Mississippi; eventually 35 dioceses were created from it.

Flaget's various religious establishments were the wonder of the Roman Catholic world, and he became one of the most influential men in the councils of the American church of that period. The Sisters of Loretto and the Sisters of Charity of Nazareth, founded in 1812. were engaged in the elementary education of girls. St. Thomas seminary uas followed by the foundation of two boys' colleges near Bardstown, St. Joseph and St. Mary's, which became noted for the education of many leading southern statesmen. Among his priests were the famed missionaries Stephen T. Badin and Charles Nerinckx. His cathedral of St. Joseph in Bardstown, dedicated in 1819, is today a national monument. The see was moved to Louisville just prior to Flaget's death on Feb. 11, 1850.

See J. H. Schauinger, *Cathedrals in the Wilderness* (1952) and *Stephen T. Badin: Priest in the Wilderness* (1956). (J. H. S.)

FLAGLER, HENRY MORRISON (1830–1913), U.S. financier, a pioneer in Florida development, was born at Hopewell, N.Y., on Jan. 2, 1830. At the age of 14 he went to work as a clerk in a country store in Ohio. About 1850 he became a grain dealer and accumulated a small fortune, but lost it in a salt-manufacturing venture. He borrowed money in 1867 and entered into partnership nith John D. Rockefeller and others who owned oil refineries. The business uas incorporated as the Standard Oil company in 1870, and Flagler was prominently associated with its management for many years. He built a number of palatial hotels in Florida, spending nearly $50,000,000 there. He died May 20, 1913, in West Palm Beach, Fla. (H. J. SG)

FLAGSTAD, KIRSTEN (1895–), Norwegian opera and concert singer, was born in Hamar on July 12, 1895. At the age of 18 she sang as Nuri in Eugen d'Albert's *Tiefland*. Her debut was so successful that she uas sent to Stockholm for study. There followed years in the Oslo and Gothenberg operas; and then, nith her marriage in 1919, came several years of retirement. In 1933 she sang at the Wagner festival in Bayreuth, Ger. This led to her engagement in the Metropolitan Opera, New York city, and her debut there, Feb. 2, 1935, as Sieglinde in Die *Walküre*. Her success at the Metropolitan, in London and elsewhere was remarkable, and she was hailed as one of the great Wagnerian singers.

FLAGSTAFF, a city of northern Arizona, U.S., seat of Coconino county Of the 60 sq mi. within the city limits about 48 sq.mi., comprising Coconino national forest lands, are unoccupied Arizona State college, founded in 1899, the Lowell observatory, the Naval observatory's Flagstaff station, the Atmospheric Research observatory and the Museum of Northern Arizona are located in Flagstaff. Once a mere cow-and-lumber town, it became a tourist centre, the railhead for the Glen canyon dam, 135 mi. N., the base of extensive logging and lumber operations and a trading centre for ranchers. The average annual precipitation is 19 in.; the altitude is 6.900 ft. Nearby are the Grand canyon, Oak Creek canyon, Hopi and Navaho reservations and five national monuments. Lumberjacks celebrating the 4th of July 1876, nailed a U S. flag to the top of a tall pine and called the unnamed settlement Flagstaff. A council-manager form of government was adopted in 1958. For comparative population figures see table in ARIZONA: Population. (GA. D.)

FLAHAUT DE LA BILLARDERIE, AUGUSTE CHARLES JOSEPH, COMTE DE (1785–1870), French general and statesman, was born in Paris on April 21, 1785. He entered the army as a volunteer in 1800 and received his commission after the battle of Marengo. He became aide-de-camp to Joachim Murat and was wounded at Landbach in 1805. He served at Friedland (1807), in Spain (1808) and then in Germany. Flahaut fought in the Russian campaign of 1812, and in 1813 became general of brigade, aide-de-camp to the emperor and, after the battle of Leipzig, general of division. After Napoleon's abdication in 1814 he was placed on the retired list. The Hundred Days brought him into active service again. A mission to Vienna to secure the return of Marie Louise resulted in failure. He was saved from exile by Talleyrand's influence, but was placed under police surveillance. Later he settled in England.

Flahaut returned to France in 1827, and in 1830 was made a peer of France. He remained intimately associated with Talleyrand's policy, and was for a short time in 1831 ambassador at Berlin. He was afterward attached to the household of the duke of Orleans, and in 1841 was sent as ambassador to Vienna, where he remained until 1848, when he was dismissed and retired from the army. After the coup *d'état* of 1851 he was again actively employed, and from 1860 to 1862 was ambassador at the court of St. James.

Flahaut died on Sept. 1, 1870.

FLAHERTY, ROBERT JOSEPH (1884–1951), U.S. film maker and explorer, called the father of the documentary film, was born at Iron Mountain, Mich., on Feb. 16, 1884. His Nanook of the North (1920–22), based on 16 months of living with and photographing Eskimos, set a new standard for dramatic interpretation of a way of life. In a review of his Samoan film, Moana, in the New York Sun (Feb. 8, 1926), John Grierson first called Flaherty's methods documentary. Flaherty collaborated with F. W. Murnau (Tabu, 1929–31) and John Grierson (Industrial Britain, 1933) and then spent 18 months on a tiny ocean-battered Irish island, filming Man of Aran (1933). He worked for Alexander Korda on Elephant Boy, for the U.S. Film service and Pare Lorentz on The Land (1941) and for the Standard Oil company on Louisiana Story (1948). His death occurred at Dunnerston, Vt., on July 23, 1951.

Flaherty preferred filming life in faraway places, declaring that primitive man had a freedom that modern man has lost. His inexhaustible curiosity and patient, probing camera provided accepted models of excellence for all nonfiction film makers. He was also the author of two novels and of *A* Film-Maker's Odyssey (1939). See also MOTION PICTURES: Art of the Motion Picture.

See Richard Griffith, *The World of Robert Flaherty* (1953).

(R. D. MACC.)

FLAIL, a farm hand-implement used for threshing grain. A flail consists of two pieces of wood, the handstaff or helve and the beater, held together at one end by a thong. The former usually is a light rod about 5 ft. long. and the latter a cylinder about 30 in. long and $1\frac{1}{4}$ in. in diameter. With this implement one man could thresh 7 bu. of wheat, 8 of rye, 1 j of barley, 18 of oats or 20 of buckwheat in a day. The flail is of immense but unknown antiquity, and until the middle of the 19th century flailing by hand was one of the chief methods of threshing. Variants were still used in less developed areas, such as west China, in the second half of the 20th century, and variants were used on vegetable and flower seeds and special crops when the quantity involved did not justify a special machine.

FLAMBARD, RANULF, or RALPH (d. 1128), bishop of Durham and chief minister of William Rufus, was the son of a Norman parish priest. Migrating at an early age to England, the young Ranulf entered the chancery of William I. He was disliked by the barons, who nicknamed him Flambard in reference to his talents as a mischief-maker. He appears to have played an important part in the compilation of the Domesday survey. in which he is mentioned as a clerk by profession, and as holding land both in Hants and Oxfordshire. Before the death of the old king he became chaplain to Maurice, bishop of London, but early in the next reign Ranulf returned to the royal service. He is usually described as the chaplain of Rufus; he seems in that capacity to have been the head of the chancery and the custodian of the great seal. But he is also called treasurer; and there can be no doubt that he was an agent of the extortion from which all classes suffered between 1087 and 1100. He profited largely by the tyranny of Rufus, farming for the king a large proportion of the ecclesiastical preferments which were illegally kept vacant, and obtaining for himself the wealthy see of Durham (1099). On the accession of Henry I, he was imprisoned, but escaped from the Tower of London. A popular legend represents the bishop as descending from the window of his cell by a rope which friends had conveyed to him in a cask of wine. He took refuge with Robert Curthose in Normandy. and received the administration of the see of Lisieux. After the victory of Tinchebrai (1106) the bishop made his peace with Henry, and was allowed to return to Durham where he passed the remainder of his life. His private life created much scandal, but he distinguished himself, even among 'the bishops of that age, as a builder and a pious founder. He all but completed the cathedral which his predecessor, William of St. Carilef, had begun; fortified Durham; built Norham Castle; founded the priory of Mottisfout and endowed the college of Christchurch. Hampshire. As a politician he ended his career with his submission to Henry. Ranulf died on Sept. 5, 1128.

FLAMBOROUGH HEAD, a promontory on the Yorkshire coast, England, between Filey and Bridlington bays of the North sea. It is a lofty chalk headland capped with boulder clay, pierced with caves and fringed with rocks of fantastic outline. Sea birds breed abundantly on the cliffs. A lighthouse, 214 ft. above sea level, marks the point lat. 54° 7' N., long. 0° 5' W. Flamborough village is 2 mi. west of the extreme point.

FLAMBOYANT STYLE, in architecture, the last phase of the Gothic in France, characterized by the dominance in tracery (*q.v.*) of the line of double curvature, known as the "ogee curve," which generates the flamelike forms that give the name flamboyant to the style. Flamboyant forms begin to appear in the late 14th century, as in one of the chapels of Amiens cathedral (1373). By the middle of the 15th century they were almost universal. Borrowing from the English the idea of the reversed curve and of flowing tracery, the French developed them with greater freedom (see DECORATED PERIOD and GOTHIC ARCHITECTURE). The best flamboyant tracery is often simpler and more direct than the English curvilinear work; grace of form and attenuation of line, a restrained use of cusps and generally slim proportions are the aims sought. In the 16th century, tracery returned to lower and more stumpy proportions with a great use of round and elliptical arches.

All work of the flamboyant period is characterized by lavishness of detail, multiplication of miniature niches, fantastic and elaborate crockets, pierced, traceried gables, curved-sided pinnacles and the practice of intersecting and interpenetrating mouldings of different profiles as, for instance, a cornice and a raking gable mould. Double and triple bases are frequent, the upper bases being penetrated by projecting shafts which have their own bases below. Among the outstanding examples of the style are the church of St. Maclou at Rouen (begun 1432); St. Wulfram at Abbéville (1480); upper part of the cathedral at Rouen (1481–92); the Palais de Justice at Rouen (c. 1500); north transept of the cathedral of Beauvais (1500–48); and the spire of the northwest tower of the cathedral at Chartres (1506). (T. F. H.; P. F.)

FLAME, as a phenomenon of the physical world, is generally understood to be burning gas. Its prerequisite is the formation of an explosive mixture, as, for example, coal gas and air. If such a mixture is ignited by a spark or small flame, the combustion spreads from the ignition source to the adjacent layer of gas mixture; in turn, each point of the burning layer serves as an ignition source for the next adjacent layer, and so on. In this way, reminiscent of Christiaan Huygens' principle for the propagation of a light wave, a combustion wave (also called flame front, combustion zone) is formed which propagates through the gas mixture leaving in its wake hot burned gas. (See also COMBUSTION.) The mixture propagates a flame only above some minimum and below some maximum percentage of fuel gas. These percentages are called the lower and upper limits of inflammability. Mixtures of average coal gas and air, for example, will not propagate flame if the proportion of gas is less than about 5% or more than about 31%. For natural gas the limits are about 4% and 15%, respectively. If the mixture is enclosed in a small vessel, or if it flows through a narrow tube, the chilling effect of the wall of the vessel narrows the limits of inflammability; and below some critical diameter whose exact magnitude depends mainly upon the nature of the fuel gas and the temperature of the enclosure, flame is quenched altogether, even if the mixture ratio is the optimum for combustion of the fuel gas to carbon dioxide and water vapour.

The combustion wave travels against the unburned mixture at a definite velocity, called the burning velocity. This velocity depends upon the composition of the mixture, increasing from zero at the two limits of inflammability to a maximum at some intermediate percentage of fuel gas. It does not exceed 270 cm. per second for air and hydrogen (hydrogen, the fastest-burning gas, comprises about 50% of coal gas) and about 50 cm. per second for most other common fuel gases; it remains much less than 1,000 cm. per second for mixtures of fuel gases with oxygen, except under conditions of turbulence or detonation (see COMBUSTION). Close to chilling surfaces the burning velocity always drops to zero. The distance over which the chilling is effective, the "quenching distance," is a well-defined measurable quantity. It increases as the composition of the mixture changes from the optimum to either the lean or rich side and decreases as the temperature of the wall is raised. It does not exceed 2 mm. for common fuel gases and air, and drops to the order of 0.01 mm. for mixtures of oxygen and hydrogen or acetylene.

Depending upon the conditions of mixture formation and gas flow, several types of flame structure may be distinguished and are described below.

Diffusion Flame.—Consider a slow stream of fuel gas flowing from a tube into the open atmosphere. From the mouth of the tube upward air diffuses across the boundary of the stream toward the centre of the stream and forms an envelope of explosive mixture around a core of flowing fuel gas. This latter core diminishes with height until, at some distance above the tube, it has disappeared. It thus assumes the shape of a cone. Near the surface of the cone the mixture is overrich in fuel, and farther outward it becomes progressively leaner. On ignition a combustion wave rapidly spreads through the whole envelope of explosive mixture, pressing forward from the faster-burning outer layers to the slower-burning inner layers until it hugs the cone of fuel gas. The wave is now in a position of equilibrium, being unable to penetrate farther into the gas stream because oxygen necessary for combustion is lacking there, and also unable to detach itself because the increased burning velocity in the oxygen-enriched outer layers would drive it back again toward the cone. The combustion zone thus maintains itself as a hollow cone above the tube, while the gas stream passes continually through it, carrying with it fresh molecules of fuel gas and sweeping away the hot combustion products (water vapour and carbon dioxide) and the incombustible atmospheric nitrogen which remains after the oxygen is consumed. At the same time, fresh air is penetrating by diffusion into and against this stream of hot burned gas, to meet the fresh fuel gas in the combustion zone; and by the same process of diffusion a fraction of the burned gas, and also a fraction of the heat of combustion, penetrates into and against the inner cone of flowing fuel gas, diluting and heating it. Since common fuel gases contain hydrocarbons which at high temperature crack to form hydrogen and free carbon, the inner cone thus acquires a shell of hot, carbon-bearing gas adjacent to the combustion zone. This shell increases in thickness from the base of the cone upward. The hot carbon particles, being small, solid bodies, glow brightly and impart to flames of this type their characteristic luminosity. They burn in contact with oxygen at high temperatures. They accumulate readily on chilling surfaces; and when there is an oxygen deficiency in the stream, they cool below their ignition temperature and escape as soot into the atmosphere.

The combustion zone is visible as a faint bluish glow surrounding the inner cone. In a carbon-monoxide flame, which does not form free carbon and whose inner cone thus remains completely dark, the combustion zone is the only source of luminosity. This glow is chemiluminescent in character. The hot combustion products emerging from the zone emit no visible light but only infrared radiation of certain wave lengths.

In the flame of a candle or pocket lighter, liquid fuel is drawn into the wick by capillary suction and volatilized over the exposed length of the wick by heat supplied from the surrounding combustion zone. The quantity of streaming vapour, and therefore the height and volume of the flame, can thus be regulated by adjusting the length of the wick. In a candle the wick consists of braided cotton yarn in the form of a flat band which rises from a little pool of molten paraffin and curls over so that its tip projects into the air and burns. It thus remains constant in size. The wick material is chemically treated so that the ash residue is fusible and does not form a skeleton but collects at the tip in the form of a small bead. In the early days of straight-wicked tallow candles (the wick being merely twisted) the wick did not regulate itself and had to be cut from time to time ("snuffing the candle"). Irregularly shaped diffusion flames are also formed by burning wood, bituminous coal and other materials which give off combustible gases on heating.

When a gas stream issuing into the stagnant atmosphere has reached a certain height, it curls up into vortices which follow each other at more or less regular intervals. In large flames, vortices of combustion products may form around burning portions of the flame, shutting off the supply of oxygen, and the unburned core momentarily elongates, then contracts again as the vortex is carried away. This may repeat itself periodically, giving rise to the flicker of flames, sometimes accompanied by sooting. The regular rounded cone shape is lost.

If the flame is placed in an open, upright cylinder, the resulting chimney effect carries the air along with the burning gas; this eliminates the tendency to form vortices, and the flame is correspondingly steadied.

If air is added to fuel gas, the mixture still being above the upper limit of inflammability, the flame continues to burn by diffusion, though the combustion zone moves deeper into the core of fuel gas and less carbon is formed. The region of vorticity then is confined to the invisible burned gas well outside the luminous zone and a steady flame of regular rounded-cone shape results.

If sufficient air is added so that the mixture is below the upper limit of inflammability, an inner combustion zone is formed, surrounded by an outer mantle; the latter continues to burn as a soot-free diffusion flame as long as the volume of air in the stream is less than required for complete combustion (see below).

Flames of Turbulent Jets.—When a gas stream issuing from an orifice into the atmosphere exceeds a certain critical velocity, it breaks up into a turbulent jet which entrains the surrounding air and broadens out in the form of a cone. The flame in such a jet consists of a highly irregular interplay of vortices of gas and air mixture, forming transitory random patches of combustion waves throughout the jet, and no cohesive combustion surface exists. The hissing or roaring sound associated with turbulent jets is augmented by the combustion, and such flames are often very noisy. With common fuel gases the burning velocity is too low, and the flame readily blows off the jet, unless an effective pilot flame is provided at the base of the jet. A successful design consists in blowing a jet of oxygen from an orifice mounted concentrically in the mouth of a much wider tube, from which a comparatively slow stream of fuel gas flows. The oxygen jet entrains most of the fuel gas; however, some of the gas burns from the wide mouth as a slow diffusion flame that serves as a pilot for the jet flame.

Flames of Streams of Explosive Mixture.—Consider a mixture (*e.g.,* coal gas and air) of a composition well within the explosive range, flowing from a tube into the atmosphere. From some point of ignition, a combustion wave spreads out until it forms a continuous surface over the whole cross section of the stream. This surface can be distorted into various shapes by uneven gas velocities, but by the principle of wave propagation it maintains its continuity and propagates as a unit against the flow of unburned gas, in a contest between the burning velocity and the gas velocity. Three cases may arise: (1) if the gas velocity exceeds the burning velocity everywhere along the surface, the combustion wave blows off into the atmosphere and becomes extinct; (2) if the gas velocity is at any point smaller than the burning velocity, the combustion wave flashes back against the stream; and (3) if the gas velocity is maintained equal to the burning velocity at some point, though exceeding it everywhere else, the combustion wave becomes fixed in the gas stream and forms a stationary flame.

The gas velocity is zero at the boundary of the stream as a re-

FIG 2 —BURNING VELOCITY AND GAS VELOCITY ABOVE THE TUBE RIM. CURVES A. B, C, BURNING VELOCITY AT HEIGHTS A, B, C; CURVE 2, FLASH-BACK LIMIT. CURVE 3, STABLE FLAME; CURVE 4, BLOWOFF LIMIT: CURVE 5, BLOWOFF

sult of friction and rises steadily in the direction of the centre of the stream. Fig. 1 shows the conditions within the tube. The heavy curve shows the magnitude of the burning velocity near the wall. It is zero within the quenching distance, and beyond this distance it rises to a constant value. The other lines are curves of the gas velocity for three different gas flows. If the flow corresponds to curve 1, the gas velocity falls partly below the burning velocity, and the flame flashes back through the tube. If the flow corresponds to curve 2, the combustion wave can theoretically maintain itself at any position in the tube. In practice, however, it will not be possible to regulate the gas flow with the absolute accuracy required for this purpose. If the flow corresponds to curve 3, the gas velocity is everywhere larger than the burning velocity, and the flame is blown out of the tube.

In the latter case, as the combustion zone moves past the rim of the tube, it enters a region over which the chilling effect of the wall of the tube is gradually reduced, and consequently the curve of the burning velocity shifts toward the boundary of the stream. This is illustrated in fig. 2. Three burning-velocity curves are shown, corresponding to three heights, A, B and C, above the rim. At height A, close to the rim, the burning-velocity curve is about the same as in the diagram of fig. 1. At height B it has shifted toward the boundary. At height C the shift has become a maximum; here the chilling effect of the tube is small; nevertheless, the burning velocity drops to zero because the mixture is diluted by interdiffusion with air and because the adjacent air is carried along by the stream, thus forming an outermost boundary of nonexplosive gas. At greater heights the nonexplosive boundary layer broadens and correspondingly the burning-velocity curve recedes from the boundary; hence, if the gas velocity is as large as shown in curve 5, it exceeds the burning velocity everywhere and the flame blows off the tube. At any flow between limiting curves 2 and 4 the flame settles down to such a height above the rim that gas-velocity curve and burning-velocity curve meet each other tangentially. For example, let us suppose that the gas stream is adjusted to correspond to gas-velocity curve 3. If the combustion zone drops below height B, the burning-velocity curve shifts to the right, the gas velocity is larger everywhere, and the combustion zone lifts up again toward height B. If it should exceed this height, the burning-velocity curve shifts to the left, the gas velocity falls below the burning velocity at some distance from the boundary, and the combustion zone is driven back to its equilibrium position at height B.

The flame thus remains stable between a critical lower and upper gradient of the gas velocity at the stream boundary, represented by the slopes of curves 2 and 4 and corresponding to flash back and blowoff, respectively. For a flame burning in air, the blowoff gradient increases sharply as the mixture is enriched with fuel gas, because in this case the interdiffusing air increases the burning velocity at the boundary, and blowoff can occur only when an appreciable layer of outer air is carried along by the stream. Rich flames are therefore much more stable. However, if the surrounding atmosphere does not consist of air, but of some inert gas, such flames blow off readily.

The critical boundary velocity gradients are measurable, and by means of hydrodynamic equations of flow they permit calculation of the stability of flame at any flow for various burner tubes.

In a stable flame the combustion wave is thus anchored to the rim of the tube, while inside the stream—where the gas velocity exceeds the burning velocity—it is blown up to a cone which is clearly visible because of its bluish or greenish luminosity. The angle of the cone surface against the direction of the gas flow is everywhere such that the burning velocity equals the component of the gas velocity normal to the surface; this is the condition of equilibrium governing the shape of the cone. If the flow lines remained parallel to the stream axis and if the combustion wave were a very thin mathematical surface moving everywhere with constant velocity, the tip of the cone would be exceedingly sharp and pointed. However, at the tip the flow lines diverge in fanshape manner, and the combustion wave (being of not inconsiderable width) is disposed in a curve so that the various wave layers meet the above condition. Hence the luminous layer at the tip appears as a rounded dome.

The blowoff stability of a flame can be considerably increased by placing some solid object in the middle of the stream where dilution of the boundary by the surrounding air does not penetrate. The combustion wave anchors itself to such objects by the same process as described before, but the conditions within the stream favour stability at higher gas velocities than before. The principle of placing an obstacle inside the gas stream is widely used in flame-retaining devices and in grids for flame ports.

Flame Temperature.—The temperature in the luminous part of a candle flame and similar diffusion flames is generally lower than 1,500° C. In a flame of coal gas and air of optimum composition the temperature may be as high as 2,000° C., and in a corresponding natural-gas flame, 1,900° C. These figures increase if the gases are preheated before combustion. A gas-air flame cannot be used for welding and similar operations, although its temperature much exceeds the melting point of steel, because the heat is not delivered rapidly enough to overcome losses by radiation from the heated surface and conduction to colder parts of the metal. Oxygen-acetylene flames used for such operations are not only hotter but also deliver a much more rapid and concentrated heat flux as a result of the high burning velocity of such mixtures. The performance of gas-air flames is improved in blast lamps and blowtorches, which deliver rapidly a great volume of flame gas; such flames are used by glass blowers and plumbers.

Burners.—In air-injection gas burners used for domestic gas ranges and many industrial applications, the fuel gas issues from a small hole—the orifice—as a turbulent jet which entrains the surrounding air; the turbulent, fast-flowing mixture is then distributed to the flame ports by means of a Venturi duct (fig. 3). In this gradually expanding duct the gas motion decreases and a slight pressure is built up which forces the mixture uniformly through the portholes and thus permits any desired pattern of small flames on the burner head. The percentage of air in the mixture increases when the orifice is made smaller or the flame ports are enlarged. In the design of such burners, the tendency has been to keep the volume of entrained air noticeably below that required for complete combustion because in this way better flame stability is obtained; hence, a part of the fuel gas burns in the outer mantle by diffusion (see above). Air shutters are usually provided around the jet. The flame ports are spaced close together to form a grid, which further stabilizes the flame. Burners with closely spaced square grids are known as Méker burners.

In the ordinary Bunsen burner (*q.v.*) only a single flame is wanted; hence, a Venturi duct is unnecessary and the jet is passed into a short straight tube within which the turbulence subsides somewhat. The gas flow and air shutters are adjusted to produce a stable flame at the outlet of the tube. Enough turbulence usually persists to produce an unruly and slightly noisy flame. This is much more pronounced in the plumber's blowtorch; here a large jet of hot gasoline vapour burns partly in the zone of turbulent air entrainment. Such jet flames blow off readily and must be stabilized; this is accomplished by a perforated tube around the jet. The perforations near the jet base admit air and farther along

the tube serve as a grid for a flame attachment. The tube also passes enough heat back to the fuel line to vapourize the liquid fuel. The latter is usually delivered to the jet by air pressure from a hand pump. The blowtorch must be primed before use by heating the perforated shield and the fuel line with a flame; otherwise, liquid fuel spurts from the orifice and no vapour jet is formed.

Burners in which a jet of air or oxygen is passed into fuel gas are termed blowpipes or blast lamps. As mentioned above, the jet flame is stabilized by the surrounding slow-burning diffusion flame of the portion of fuel gas that is not entrained by the turbulent jet (fig. 3). By using jet nozzles of various orifice diameters, and adjusting the control valves, sharp flames of very small and very large size can be produced. Burners of this type are made as hand torches and desk burners and are widely used for glass blowing and soldering. For blowing quartzware, blast lamps burning hydrogen and oxygen are suitable. The mouth blowpipe, a conical brass tube curved at the small end and terminating in a small round orifice, was first adopted for testing minerals in the 18th century. A small jet flame is blown within an alcohol flame and directed against a small sample of the mineral on a piece of charcoal or some other support. The flame gas above the jet tip tends to reduce and, below, to oxidize the sample. A grain of lead ore is thus alternately reduced to a small globule of metal and oxidized to a characteristic red and yellow oxide. Other minerals give various other characteristic reactions.

Hand torches for welding are equipped with regulating valves, a mixing chamber and exchangeable nozzles for various sizes of orifices, depending on the thickness of the material to be welded. For oxyacetylene welding, which came into general use in 1900, an approximate 1:1 ratio of oxygen and acetylene is maintained because the resulting normal or neutral flame, as it is called. is the. one required in practically all welding operations. This neutral flame, characterized by a brilliant, white inner cone and a faint, blue outer envelope, also serves as a reference point for adjustment of gas composition to produce other types of flame. If the gas ratio is increased with respect to acetylene, the carburizing flame, which is easily recognized by its additional zone of luminosity, is obtained; flames of this type are employed in welding steel and in hard-facing processes. Similarly, an increase in oxygen concentration gives rise to the oxidizing flame, which differs slightly in appearance from the neutral flame by reason of its shorter inner cone and which finds its special application in the welding of brass and bronze.

The cutting of iron and steel, as distinguished from welding, consists in raising the material to its ignition temperature and continuously oxidizing it with a stream of oxygen. In addition to the chemical reaction. there is a mechanical eroding effect of the oxygen stream ahich assists in the cutting process by washing molten metal out of the cut. Hence the tip of a cutting torch contains a central orifice supplying the cutting jet of oxygen surrounded by several other orifices which deliver the oxyacetylene mixture necessary for the preheating flame. In practice the preheating flame must be maintained during the cutting to compensate for heat losses by conduction and radiation. Industrially, use of the oxyacetylene flame has taken precedence over that of the oxyhydrogen flame, since the maximum temperature of the former is more than 400° C. higher than the highest temperature achieved in the oxyhydrogen flame.

The atomic hydrogen flame and its mode of generation are basically different from all other oxy-fuel-gas flames. Thus, the arc welding torch bears little resemblance to the common gas welding torch. It consists principally of a pair of tungsten electrodes around which a stream of hydrogen gas is passed. The action of the electric arc produces a dissociation into atomic hydrogen, the formation of which is visible as a pink cone-shaped area above the electrodes. This is the characteristic colour of the Balmer series spectrum of atomic hydrogen. On recombination of the hydrogen atoms the heat of formation of molecular hydrogen is liberated, which is responsible for the attainment of the high flame temperature (about 3,800° C.). Aside from the development of temperatures higher than those of other arcs and gas flames, the hydrogen atmosphere excludes contaminating gases, such as oxygen and nitrogen, from contact with the weld.

Fluorine and hydrogen are distinguished by a very high heat of reaction and a low specific heat of the reaction product, hydrogen fluoride. These, coupled with the fact that hydrogen fluoride is very stable and thus dissociates very little, result in exceedingly high flame temperatures between 4,000° and 5,000° C.

FLAMEN (from *flare*, "to blow up" the altar fire), a Roman sacrificial priest. The flamens were subject to the pontifex maximus and were consecrated to the service of some particular deity. The highest in rank were the *flamen Dialis, flamen martialis* and *flamen quirinalis*, who were always patricians. When the number of flamens was raised from 3 to 15, those already mentioned were entitled *maiores;* the other 12, called *minores*, were chosen from the *plebs.* Toward the end of the republic the number of the lesser flamens diminished. The flamens were elected for life, but they might be compelled to resign for neglect of duty or on the occurrence of some ill-omened event during the performance of their rites. The characteristic dress of the flamens was the apex. a white conical cap; the *laena* or mantle; and a laurel wreath. The official insignia of the *flamen Dialis* (of Jupiter), the highest of these priests, were the white cap (*pileus, albogalerus*), at the top of which was an olive branch and a woolen thread; the *laena*, a thick woolen *toga praetexta* woven by his wife; the sacrificial knife; and a rod to keep the people from him when on his way to offer sacrifice. He was entitled to a seat in the senate and a curule chair. The sight of fetters being forbidden him, his house was a sanctuary for a prisoner, and a criminal who met him in the street was respited. He mas not allowed to leave the city for a single night, to ride or even touch a horse, to swear an oath, to look at an army. to touch anything unclean, or to look upon people working. His marriage, performed with the ceremonies of *confarreatio*, was dissoluble only by death, and on the death of his wife (called *flaminica Dialis*) he mas obliged to resign his office. The *flaminica Dialis* assisted her husband at the sacrifices and other religious duties which he performed. The main duty of the flamens was the offering of daily sacrifices; on Oct. 1 the three *maiores* drove to the capitol and sacrificed to *Fides Publica* (the Honour of the People).

Distinct from the above were the *flamen curialis*, who assisted the *curio* with the religious affairs of each *curia* (*q.v.*), the flamens of various sacerdotal corporations, such as the Arval Brothers (*q.v.*), and the *flamen Augustalis*, who superintended the worship of the emperor in the provinces.

FLAME PHOTOMETRY is the study of spectra emitted in flames. The atoms of each element exhibit characteristic spectra; the wave lengths of light which they emit or absorb are invariable for all practical purposes. These spectra are emitted readily when elements are exposed to the very high energies of an electric arc, spark or high-temperature flame. The light emitted is seen as discrete lines when viewed through a suitable spectroscope, and its intensity depends on the amount of the element energized. Measurement of the wave lengths and intensities of light emitted by the excited atoms therefore constitutes a convenient device for qualitative and quantitative analysis (see SPECTROSCOPY).

The principles of flame spectroscopy were established in the middle and late 19th century. The construction in 1945 of a photoelectric flame photometer employing filters placed its practical utilization on a firm basis. The instrument, called a flame photometer, proved extremely popular for the simple, sensitive and precise analysis of sodium and potassium. Since this time, the field of flame photometry has become of the greatest scientific, medical and industrial importance. Studies of large numbers of fuels, burners and photoelectric detection devices have extended the analytical applications to many elements contained in materials varying from rocks, alloys and metals to biological tissues. Very sensitive applications are limited to the elements of the first two groups and the first transition group of the periodic table (see PERIODIC LAW), but in particular to those which require relatively little thermal energy to emit light. The advent of very hot flames in the 1950s began to remove this limitation.

All substances are prepared for flame photometry by similar procedures. The sample is dissolved in a liquid which is then aspirated and sprayed into a flame. The emitted light enters a spectrograph which isolates the wave lengths to be measured by means of a filter, prism or grating. A photocell receives the light and converts it into electric energy which in turn is displayed by a meter. A millionth of a gram in one millilitre of fluid is readily measured with a precision of 1% to 2%. Modern instruments permit the simultaneous measurement of several elements—instead of one at a time—by the employment of multiple photoelectric receivers. Such instruments are called flame spectrometers. Flame photometry has brought about the development of completely new areas of knowledge. An example in medicine is the field of salt and water or electrolyte metabolism, which was virtually nonexistent prior to the advent of the flame photometer. This instrument has revolutionized the recognition and treatment of a wide variety of conditions.

FLAME THROWER. A military assault weapon that projects a stream of blazing oil or thickened gasoline against enemy positions. As used in World War II and the Korean war it consisted basically of one or more fuel tanks, a cylinder of compressed gas to supply the propelling force, a flexible hose connected to the tanks and a trigger-nozzle equipped with some means of igniting the fuel as it was spewed forth. The portable type, carried on the backs of ground troops, had a range of about 45 yd. and enough fuel for about 10 sec. of continuous "firing." Larger and heavier units installed in tank turrets could reach out more than 100 yd. and carried enough fuel for about 60 sec. of fire. To achieve maximum results, several short bursts were usually fired rather than one long blast.

Modern flame throwers first appeared in the early 1900s when the German army tested two models, one large and one small. submitted by Richard Fiedler. The smaller *flammenwerfer*, light enough to be carried by one man, used gas pressure to send forth a stream of flaming oil for a distance of about 20 yd. The larger model, based on the same principle, was cumbersome to transport, but had a range of more than 40 yd. and enough fuel for 40 sec. of continuous firing. Favourably impressed, the German army adopted these weapons and used them with surprise effect against Allied troops in 1915. The British and French soon countered with flame throwers of their own, but none of the World War I types had sufficient range or duration of fire to be satisfactory. Their chief effect seems to have been to terrorize the troops they were used against.

All major powers employed flame throwers in later years, both the back-pack type and the tank-mounted variety. Based on the same principle as Fiedler's early models, they incorporated technical refinements that made them far more effective, though still limited in range and duration of fire. British and U.S. flame throwers were fueled with napalm, a type of thickened gasoline that carried much farther than ordinary gasoline, burned with intense heat and clung like jelly to whatever it touched. These fearsome weapons were valuable for attacking enemy troops, burning away camouflage material and probing underbrush or the gunports of enemy positions. They were especially effective in World War II against the defensive-type warfare of the Japanese who stubbornly defended their caves and coconut-log bunkers on Pacific islands.

(See also CHEMICAL WARFARE; GREEK FIRE; NAPALM.)

(H. C. T.)

FLAMINGO, the name for six species of large water birds with remarkably long neck and legs, webbed feet and heavy ducklike bill bent abruptly downward. Related to herons (*q.v.*), they constitute the family Phoenicopteridae, in the order Ciconiiformes. They have black wing quills, and most are rosy-white with scarlet shoulders, but the American flamingo (Phoenicopterus ruber) is bright vermilion.

The American flamingo occurs on the Atlantic and gulf coasts of tropical and subtropical America, breeding locally in large colonies along mud flats in the Bahamas, Cuba, Haiti, Yucatán, Guiana and formerly the Florida Keys. They are gregarious birds; flocks numbering hundreds may be seen in long, curving flight formations and in wading groups along the shore. In feeding, the flamingo tramps the shallows, stirring up organic matter, especially small mollusks and crustaceans, which it strains from the muddy water by means of its sievelike lamellated bill. The nest is a truncated cone of clayish mud piled up a few inches in a shallow lagoon; both parents share 30 days incubating one or two chalky white eggs which are laid in the hollow of the cone. Downy-white young, with short legs and straight bills, leave the nests in two or three days and are fed by regurgitation on partly digested food of the adults.

Phoenicopterus *antiquorum* breeds in west-central Asia, northwest India, Caspian sea and Persian gulf, South Africa and the Cape Verde Islands. P. chilensis ranges from Peru and Uruguay to Tierra del Fuego. The smaller Phoenicoparrus *andinus* and P. jamesi live in Chilean and Argentine Andes, the latter to southern Peru. Phoeniconaias minor is abundant in the lake district of east Africa, also occurring in south Africa, Madagascar, northwest India and possibly Senegal.

Fossil forms have been found in France and Oregon.

FLAMININUS, TITUS QUINCTIUS (c. 228–174 B.C.), Roman general and statesman. He was military tribune under M. Claudius Marcellus, the conqueror of Syracuse. In 199 he was quaestor, and consul the next year.

Flamininus was one of the first and most successful of the rising school of Roman statesmen, the opponents of the narrow patriotism of which Cato was the type, the disciples of Greek culture and the advocates of a wide imperial policy. His personal charm, his knowledge of men and his intimate knowledge of Greek all marked him out as the fittest representative of Rome in the east. Accordingly, the province of Macedonia and the conduct of the war with Philip V of Macedon were assigned to him. Flamininus modified both the policy and tactics of his predecessors. He spent most of his first year in gaining control of Greece by diplomacy and force. Hostilities were renewed in the spring of 197, and Flamininus took the field supported by nearly the whole of Greece. At Cynoscephalae the Roman legion met the Macedonian phalanx for the first time, and defeated it. Philip lost all his foreign possessions. but retained his Macedonian kingdom almost entire; he was required to reduce his army, to give up all his decked ships except five and to pay an indemnity of 1,000 talents. All the Greek states which had been subject to the king became free and independent. Flamininus' last act before returning home was to ask the Achaeans to ransom the Italian captives who had been sold as slaves in Greece during the Hannibalic War. These were presented to him on the eve of his departure (spring 194) and formed the chief ornament of his triumph. In 192. on the rupture between the Romans and Antiochus III the Great, Flamininus returned to Greece as the civil representative of Rome. He secured the wavering Achaean states! cemented the alliance with Philip and contributed largely to the Roman victory at Thermopylae (191). In 183 he undertook an embassy to Prusias, king of Bithynia. to induce him to deliver up Hannibal, who took poison. Nothing more is known of Flamininus.

FEAMINIUS, GAIUS, Roman statesman and general, of plebeian family. During his tribuneship (232 B.C.), in spite of the determined opposition of the senate and his own father, he carried a measure for distributing among the plebeians the *ager Gallicus Picenus,* an extensive tract of newly acquired territory to the south of Ariminum (Cicero. De *senectute,* 4. *Brutus,* 14). In 223, when consul with P. Furius Philus, he took the field against the Gauls, who were said to have been roused to mar by his agrarian lam. Having crossed the Po to punish the Insubrians, he at first met with a severe check and was forced to capitulate. Reinforced by the Cenomani. he gained a decisive victory on the banks of the Addua. He had previously been recalled by the optimates, but ignored the order. The victory seems to have been due mainly to the admirable discipline and fighting qualities of the soldiers; the decree of the senate against his triumph was overborne by popular clamour. His name is further associated with two great works. He erected the Circus Flaminius on the Campus Martius for the accommodation of the plebeians. and continued the military road from Rome to Ariminum. which had hitherto only reached as far as Spoletium. He probably also instituted the "plebeian" games. In 218. as a leader of the democratic opposition, Flaminius was one of the chief promoters of the measure which debarred senators from commercial speculation (Livy xxi, 63). His support of this measure vastly increased his popularity with his own order and secured his second election as consul in the following year (217), shortly after the defeat of T. Sempronius Longus at the Trebia. He hastened at once to Arretium to protect the passes of the Apennines, but was defeated and killed at the battle of the Trasimene lake *(see* PUNIC WARS; TRASIMENUS, LAKE).

FLAMSTEED, JOHN (1646–1719), English astronomer and clergyman and first astronomer royal at the newly founded Greenwich observatory, was horn at Denby, near Derby, on Aug. 19. 1646. He was educated at the free school of Derby, but was forced to leave in 1662 because of bad health. During his illness he began to study astronomy, observing a solar eclipse on Sept. 12, 1662, and corresponding with several astronomers. His early studies were communicated to the Royal society in 1670 and were published in the *Philosophical Transactions,* gaining him general scientific recognition. In 1670 Flamsteed entered his name at Jesus college, Cambridge, and in 1674 took a degree of M.A. by letters-patent. He was ordained in 1675. He attracted the attention of Sir Jonas Moore whose influence with Charles II secured for him the position of astronomical observator upon the establishment of the Greenwich observatory in 1675. Except for a few gifts from Moore. Flamsteed supplied all of his own instruments from his salary of £100 a year and the income of the living of Burstow. Surrey, bestowed upon him in 1684 by Lord North. On the death of his father in 1688, a small inheritance provided Flamsteed with the means to construct a mural arc, with which he began systematic observations on Sept. 12, 1689. The latter part of Flamsteed's life passed in a turmoil of controversy regarding the publication of his results. He struggled to withhold them for presentation in completed form; but they were urgently needed. by Sir Isaac Newton and by Edmund Halley among others, for the testing of current theories. Newton. through the Royal society, led the movement for immediate communication, whence arose much ill-feeling between him and Flamsteed. In 1704 Prince George of Denmark undertook the cost of printing, and. despite the prince's death in 1708 and Flarnsteed's objections, the observations were printed. The *Historia coelestis,* embodying the first imperfect Greenwich star catalogue, was issued under Halley's editorship in 1712. Flamsteed denounced the production (400 copies) as surreptitious and later. when Newton's influence with the government declined, secured and burned 300 of them. Flamsteed died at Greenwich on Dec. 31. 1719. The preparation of his monumental work. *Historia coelestis Britannica* (3 vol. folio, 1725), was finished by his assistants Joseph Crosthwait and Abraham Sharp. The first two volumes included the whole of Flamsteed's observations, the third the *British Catulogue* of nearly 3,000 stars. The extent and quality of his work, which forms the basis of modern star catalogues, were the more remarkable considering his severe physical sufferings and straitened means.

See F. Baily, *Account of the Rev. John Flamsteed* (1835).

(O. J. E.)

FLANDERS, COUNTY OF, a powerful medieval principality in the southwest of the Low Countries, which occupied territories that are now divided between the French *département* of Nord, the Belgian provinces of East Flanders and West Flanders, and the Dutch province of Zeeland *(qq.v.).* The name appears in the 8th century and is believed to mean "flooded land." The pagus Flandrensis was at first an inconspicuous Frankish district, but a remarkable line of Flemish counts succeeded in erecting a quasi-independent state on the borders between the French and the German kingdoms out of French and German fiefs. As the treaty of Verdun (843) had made the Scheldt river the dividing line between West and East Francia. the count of Flanders came to be a vassal of the French king for what he held west of the Scheldt (Crown Flanders or Kroonvlaanderen, the most important part of his countship) and a vassal of the German king for what he held east of it (Aalst, etc.; collectively called Imperial Flanders or Rijksvlaanderen as part of the Holy Roman empire). Linguistically also Flanders mas a borderland, including Romance-speaking and Germanic-speaking peoples.

The Counts of Flanders in the Middle Ages. — In the Carolingian period the pagus Flandrensis was the region around Bruges. The rise of the Flemish dynasty began when the count or official administrator of the pagus, Baldwin I Iron-Arm or Ferreus, married the Frankish king Charles II the Bald's daughter Judith in 862 and mas established as count with control over a number of pagi between the North sea and the Scheldt. His son and successor, Baldwin II (count from 879 to 918). who married the English king Alfred the Great's daughter Xelfthryth, was the founder of the *de facto* autonomous county and reigned independently over a vast territory along the coast of the North sea; he fought the Danish raiders (invasion of 879–883). His son. Arnulf I the Great (918–965), continued the policy of independence and territorial expansion: extending the southern frontiers of Flanders to the Canche river: the main enemy at this time was Normandy. Arnulf's son Baldwin III. however. who had been associated with him as count from 959, died before him (962). and when Arnulf himself died an internal crisis broke out under the rule of his grandson Arnulf II (965–988); but authority was restored under the latter's son Baldwin IV (988–1035), who consolidated his internal position and resumed the expansionist policy. This count looked eastward, coveting imperial territory. and succeeded in conquering lands in the Scheldt estuary and also Valenciennes. an important town on the Scheldt; clearly he thought of the Scheldt as the natural frontier for Flanders on the east. His son Baldwin V (1035–67), an equally able ruler. continued the eastward expansion, adding imperial territories such as Aalst and Termonde. east of the Scheldt, to his dominions. His son and successor Baldwin VI (1067–70), by marrying Richildis, heiress of the neighbouring Hainaut *(q.v.)*, and thus becoming count of that principality himself, was the first to establish personal union between Hainaut and Flanders; but the succession of his son Arnulf III in 1070 was contested by Robert I the Frisian (d. 1093), another son of Baldwin V, who became count in 1071.

Robert the Frisian was a powerful ruler and a stern upholder of public order. who also took useful initiatives for the economic development of the county. His son Robert II, who had been associated with him as count from 1087, was succeeded in 1111 by his son Baldwin VII (d. 1119), called Baldwin with the Axe because of his repression of violence and crime. On his death the male line of the first dynasty of Flemish counts became extinct.

The next count, designated by Baldwin VII, was his cousin Charles, son of the Danish king Canute IV by Count Robert II's sister Adela. Surnamed the Good for his wise administration, Charles was assassinated at Bruges in 1127 and left no children. The French king Louis VI then intervened and had his candidate accepted as count: namely William Clito or the Aetheling, son of Robert Curthose, duke of Normandy (whose mother was a daughter of Baldwin V), and thus an enemy of Henry I of England, against whom the move was directed (1127). This intervention showed that the French crown was emerging from its period of weakness and consequently that Flanders would no longer enjoy undisturbed independence. William Clito, however, soon proved unacceptable to the Flemish population and on his death (1128) the county went to Thierry or Diederik (Dietrich) of Alsace, the son of Gertrude, another sister of Robert II. Thierry and his son Philip (1168–91) consolidated the counts' position and won great international prestige for the county, especially since Philip married Elizabeth of Vermandois and thus reigned over territories that stretched far south toward the region of Paris.

Philip's death without issue and the strong policy of Philip II Augustus of France brought Flanders to a perilous position, but the king failed to annex the county itself, to which Baldwin V of Hainaut, a brother-in-law of Philip of Alsace, succeeded as Baldwin VIII (1191–95), though considerable territory was lost in the south (Vermandois and Artois). Then Baldwin VIII's son Baldwin IX (VI of Hainaut), who became Latin emperor of Constantinople in 1204 (see BALDWIN I), was succeeded in 1205 by his five-year-old daughter Joan. The French king obtained custody of Joan and made her marry Ferdinand (Ferrand), a younger son of Sancho I of Portugal, in 1212, but in spite of his calculations Ferdinand took sides against him under Flemish pressure and joined the anti-French coalition formed by the emperor Otto IV and John of England. On the defeat of the coalition in the battle of Bouvines (*q.v.*) in 1214, Ferdinand was taken to Paris as a prisoner, but Joan was permitted to administer Flanders by the grace of the French crown. She died childless in 1244 and was succeeded in Flanders and Hainaut by her sister Margaret.

Margaret's reign (1244–80) was unfortunately marked by the struggle between the houses of Avesnes and Dampierre, the former being children of her marriage with Bouchard of Avesnes, which was annulled, the latter of her subsequent marriage with William of Dampierre (d. 1241). Finally Louis IX of France adjudged Flanders to Dampierre and Hainaut to Avesnes, but the rivalry between the two houses went on. It became rather dangerous for Flanders when the house of Avesnes obtained the county of Holland, on the northern flank of Flanders, in 1299, just when Margaret's younger son Guy of Dampierre, count of Flanders from 1278 to 1305, had to face a major crisis in Franco-Flemish relations. The French king Philip IV the Fair was in fact trying to bring Flanders directly under royal control and was finding support in the town oligarchies (such as the 39 *échevins* of Ghent), who were the count's political opponents. Guy, however, had the support of the rest of the population, especially in the towns, who felt themselves oppressed by the oligarchies. Against the French threat, Guy allied himself with Edward I of England (1294 and 1297), but when Edward had to withdraw his forces from Flanders in order to deal with the Scots the county was open to invasion. The French overran it in 1300 and took the old count prisoner. The people, however, detested the foreign rule, and on May 18, 1302, the French in Bruges were attacked by surprise and many of them killed (the "Matins of Bruges"). A powerful French army under Jacques de Châtillon then marched on Flanders for revenge, but the Flemings inflicted a disastrous defeat on it in the battle of Courtrai or battle of the Golden Spurs (July 11, 1302). This saved Flanders from French occupation, but the war dragged on till the treaty of Athis-sur-Orge (*q.v.*) in 1305. This treaty recognized Flemish independence, but imposed heavy financial burdens on Flanders and consequently led to considerable loss of territory in the south (Lille, Douai, Orchies) under the treaty of Pontoise (1312) between Philip IV and Guy's son and successor Robert of Béthune, now Robert III of Flanders (1305–22).

The 14th century brought a new political problem: the big towns, especially Ghent (about 50.000 inhabitants), tried to establish communal autonomy against the count and went far toward founding independent city-states. In consequence the counts looked for support to the king of France. Under Louis of Nevers, who succeeded his grandfather Robert of Béthune as count of Flanders in 1322, the outbreak of the Hundred Years' War led to another crisis: the count took the side of his suzerain, the king of France, but the Flemish towns, under the leadership of Jacob van Artevelde (*q.v.*), refused to follow him and took the English side instead, seeing as they did that English wool was indispensable for Flemish industry and prosperity. Louis of Nevers was killed fighting for the French in the battle of Crécy (1346). His successor Louis of Male (1346–84) established peace and followed an independent policy toward France, but his last years were obscured by the rising of Ghent under Philip van Artevelde (*q.v.*) and by the defeat of the Ghent militia by a French royal army in the battle of Roosebeke (West Rozebeke) in 1382.

The Burgundians and the Habsburgs.—Louis of Male left only a daughter, Margaret. Her first husband (1357), Philip of Rouvre, duke of Burgundy, had died in 1361, but in 1369 she had been married again, to Philip (*q.v.*) the Bold, brother of Charles V of France and, from 1363, himself duke of Burgundy. Thus when Louis died Philip the Bold succeeded to the county of Flanders. This was the starting point of an evolution that was to result in the unification of the Low Countries under the dukes of Burgundy and the house of Habsburg (see BURGUNDY). At first the Burgundians, Philip the Bold (count from 1384 to 1404), John the Fearless (1405–19) and Philip the Good (1419–67), acted as French royal princes and strove to play a role in French politics, taking sides against the Armagnacs and with the English. This changed under Charles the Bold (1467–77), who turned against France and attempted to build a Netherlandish-Burgundian realm between France and Germany and to give it strongly centralized institutions. On his death his young daughter Mary (*q.v.*), duchess and countess from 1477 to 1482, faced an internal and external crisis and found support by marrying Maximilian of Austria (see MAXIMILIAN I, Holy Roman emperor), thus bringing Flanders under the Habsburgs.

During the religious upheavals of the 16th century Protestantism won many adherents in Flanders, but the military occupation of the country by the Spaniards undid this development. The Counter-Reformation triumphed, and Flanders remained with the other southern provinces of the Netherlands under Spanish rule in the 17th century (during which it suffered severe territorial losses to the France of Louis XIV) and then under Austrian rule till it disappeared as a political entity in the course of the French Revolutionary Wars (see NETHERLANDS; BELGIUM: History). The title count of Flanders (comte de Flandre) remains in use, however, for princes of the Belgian royal family.

Institutions.— In the early middle ages Flanders shared the institutions of the Frankish kingdom. With the decay of these institutions under the later Carolingians the country became feudalized and was ruled by powerful princes—wealthy landowners—who sought to expand their territory by force of arms and to safeguard it by building castles. The population, though united under a common rule, was far from homogeneous. In the southernmost area it was mainly Gallo-Roman and Romance-speaking; farther north the Frankish settlement had been denser, so that the language was Germanic; and the coastal areas had been settled with people of Saxon and Frisian origin, of a less civilized way of life. The counts effectively united these peoples into one nation. An important new development set in from the 12th century onward, as the counts substituted for the old feudal structure an orderly administration and fiscal organization, with salaried officials (*baillis* instead of *châtelains* in the basic administrative circumscriptions), set up a centralized judicial system (using professional judges instructed in Roman law) and began extensive legislation. One of the main starting points of this development was the safeguarding of public order by the counts (pax comitis). The role of Philip of Alsace was capital in this field. He gave to a great number of towns charters (*keuren*), the contents of which varied little and which all went back to the charter of Arras of 1157–63. At the same time, but quite distinctly, there developed a powerful communal movement. For a full account of this development see COMMUNE (MEDIEVAL): Flanders. This led to the establishment in the numerous and wealthy towns of a town government with a considerable measure of independence. The towns were ruled by aldermen called in Flemish *schepenen* or in French *échevins* (Lat. scabini), who were administrators and judges at the same time. The constitutional history of Flanders is largely that of the struggle for supremacy between comital and communal authority. Finally the central authority was victorious and in the 16th century monarchical authority was firmly established. Representative institutions (estates) had grown up round the counts, especially from the 14th century onward; they were largely controlled by the three main towns of Ghent, Bruges and Ypres (see ESTATES-GENERAL).

Ecclesiastically, Flanders was divided between three bishoprics, none of which had its seat in an important Flemish city: Thérouanne and Tournai (in the metropolitan province of Reims) and Utrecht (in the metropolitan province of Cologne). In the 14th century Flanders was on the side of Rome against Avignon in the great schism of the papacy.

Economic Life.—At the outset the Flemish economy was agricultural, but there are very early signs of clothmaking of more than local importance. This was linked with the fact that the country raised large herds of sheep. Around the 12th century Flemish trade and industry became of real international importance. There also took place a crisis in the old manorial organization of agriculture and an expansion of money economy together with the rise of towns as centres of trade and industry. The role of the counts in fostering urban development was important. The cloth industry, which was soon working mainly with English wool and producing quality goods, had its largest centres at Ghent and at Ypres. International trade, however, was also very important. Till the 13th century the Flemish merchants conducted their trade abroad, especially at the fairs of Champagne (*q.v.*), but later merchants of all nations came to Flanders. The seaport of Bruges became a centre of world commerce. Flanders profited from its geographical situation, being an intermediary between the Mediterranean and the Scandinavian and Baltic countries and also between England and the Rhineland (especially Cologne). Toward the end of the middle ages the Flemish economy suffered for tuo main reasons: (1) the silting-up of the seaway to Bruges and the competition of Antwerp; and (2) the attempts by the towns to conserve artificially an industrial monopoly against normal development in the rest of the country. Even so, Flanders was a rich country whose contribution was of capital importance to the revenues of the Burgundian dukes.

Arts and Sciences.—Flemish architecture found its outstanding expression in civic buildings, belfries and town halls, though there were also some fine cathedrals (the Gothic style penetrated early in the 13th century). In literature, satire (for example Van den *Vos Reinaerde;* see REYNARD THE FOX) and the didactic genre (Jacob van Maerlant) flourished particularly. The names of the Flemish painters, the Van Eycks, Rogier van der Weyden, Hugo van der Goes, etc., belong to world art history (see PAINTING). For the sciences, the 16th century was very brilliant in the humanities, law and mathematics.

FLANDRIN, HIPPOLYTE (1809–1864), French academic painter, was born in Lyon. He was the second of three sons of a miniature painter, and all three brothers became prominent painters. Auguste (1804–1842), the eldest, passed the greater part of his life as professor at Lyon; Jean Paul (1811–1902) became a well-known landscapist. After studying for some time in Lyon, Hippolyte and Paul set out for Paris in 1829. They entered the atelier of J. A. D. Ingres, who became their model as well as their friend and patron. Ingres led Flandrin from his original interest in horses and soldiers toward history painting. In 1832 Flandrin received the Grand Prix de Rome for his canvas, the "Recognition of Theseus by His Father." He remained in Rome until 1838 and was greatly inspired by early Renaissance painting--especially Fra Angelico—during his stay in Italy. Turning toward religious painting, he developed a rather dry and cold pseudoclassic style related to that of the earlier German Nazarenes. Upon his return to France he received important church commissions for large-scale mural decorations. Most noteworthy among these are the murals in St. Séverin, St. Vincent de Paul, and St. Germain des Prés in Paris; St. Paul at Nismes; and St. Martin d'Ainay in Lyon. In mid-19th century he was also greatly in demand as a portraitist among the ladies of the second empire, but his portraits are rather imitative of Ingres, without his master's linear strength. Flandrin became an important teacher at the Academy and also inspired Dante Gabriel Rossetti and the English Pre-Raphaelites. In 1863 he returned to Rome where he died of smallpox the following year.

FLANNAGAN, JOHN BERNARD (1895–1942), U.S. 20th-century sculptor, one of America's most original "primitivising" sculptors. was born on April 7, 1895, in Fargo, N.D. Trained as a painter, he turned to sculpture a scant 17 years before his death, maturing his style during the last decade of his life despite many handicaps. Defining his sculpture as a species of occult fossil, Flannagan with a queer atavistic nostalgia dredged the subconscious for inspiration. Common fieldstone was the material he preferred for images which were only freed by an act of realization. "Jonah and the Whale" (1937), for example, was conceived as a rebirth motif, the fish being the symbol of the female principle. It was created with minimal modification of natural bluestone. The traumatic state of becoming was Flannagan's most effective poetic theme; it informed his major works. *e.g.,* "New One" (1935), "Triumph of the Egg" (1937 and 1941), "Not Yet" (1940), "Beginning" (1941), influencing mother and child subjects and perhaps even the tumid "Dragon" motifs or monster fantasies (1933 and 1941). Consonant with their iconography was a technique permitting the emergence of indwelling spirit from inert matter. Hence, in both formal and philosophical regards Flannagan was close to the artists of ancient India. He had broached new subjects and techniques in wrought bronze when he took his life on Jan. 6, 1942.

See Flannagan's *Letters* (1942); Dorothy C. Miller, *The Sculpture of John B. Flannagan* (1942). (J. S. BT.)

FLANNEL. A woolen stuff of various degrees of weight and fineness, made usually from loosely spun yarn. Baize, a kind of coarse flannel with a long nap, is said to have been first introduced to England about the middle of the 16th century by refugees from France and the Netherlands. The manufacture of flannel has naturally undergone changes and, in some cases, deteriorations. Flannels are frequently made with an admixture of silk or cotton, and in low varieties cotton has tended to become the predominant factor. Formerly a short staple wool of fine quality from a Southdown variety of the Sussex breed was principally in favour with the flannel manufacturers of Rochdale, who also used largely the wool from the Norfolk breed, a cross between the Southdown and Norfolk sheep.

In Wales the short staple wool of the mountain sheep was used and in Ireland that of the Wicklow variety of the Cottagh breed, but now the New Zealand, Cape and South American wools are extensively employed and English wools are not commonly used alone. Rochdale is the historic seat of the industry, and a good deal of flannel is now made in the Spen Valley district, Yorkshire. Blankets are largely made at Bury in Lancashire and Dewsbury in Yorkshire.

Welsh flannels have a high reputation, and make an important industry in Montgomeryshire. There are also flannel manufactories in Ireland

A moderate export trade in flannel is done by Great Britain and Australia.

FLANNELETTE, a descriptive term signifying a particular style of finishing and applied to an important class of cotton fabrics of simple texture. which have either one side only or, more usually, both sides formed with a short fleecy "nap" or fur. This nap is developed after weaving, by submitting the fabric to a finishing operation variously described as "teasling," "raising," or "perching," during which the fibrous filaments of cotton are scratched up and raised, thereby producing the short furry nap which is the distinctive characteristic of flannelette.

Flannelette is made in many different qualities ranging from comparatively coarse to fine textures that are used for a variety of domestic purposes, but mainly for clothing, and especially for undergarments and night attire, for which it is very suitable owing to its flannel-like and woolly character which imparts to the body a feeling of comfort and warmth. This attribute of flannelette results, of course, more especially from the presence of air in the short nap, which, being a poor conductor of heat, serves the more effectively to insulate the body, and thus prevents the radiation of heat, after the manner of the furry coats of animals.

It is this aerated property of flannelette which increases its susceptibility to ignition, for until the nap is formed on the surface it is no more inflammable than any other type of fabric, whether produced from cotton or other textile material. Flannelette does not possess the inherent properties of highly inflammable volatile and ethereal fluids of an explosive character, which are liable to ignition by a flame at some distance. Unless it comes into actual contact with fire, it is as immune from the risk of ignition as fabrics of any other textile material. Garments made of flannelette are in wide use, especially as night attire for children, but before the advent of central heating. children were often foolishly alloaed to crouch near the fire just before bedtime, or to go to bed with a lighted lamp or candle. These were the occasions when flannelette became a dangerous material, and therein lay the only risk of its use, not in any inherent property of inflammability. Indeed, it is highly probable that by providing a cheaper material for warm clothing, flannelette saved infinitely more lives than it destroyed. Nevertheless, so strong mas the prejudice of many people against the risk of fire incurred by using flannelette that it was, in some cases, submitted to chemical treatment to render it harmless. The additional cost of that process, however, prevented its becoming a commercial success.

There is no feature of special technical interest attaching to the manufacture of flannelettes, which are usually based on plain calico, three-end 1x2 twill, four-end 2x2 twill, or a similar weave structure, calculated to produce a relatively close and firm texture, free from long "floating" threads that would be liable to break during the operation of raising the nap. Also, since the nap is formed by raising the fibres composing the weft yarn. this is spun "soft," with less twist and of coarser counts than the warp yarn, which requires to be stronger than the weft.

Flannelettes are produced in a variety of different styles, as "plain," striped, checked, and sometimes printed with simple diapered figuring. (H. N.; X.)

FLARE. The term flare in pyrotechny is applied either to coloured fire composition burnt in a loose heap, or to a similar composition charged into a rolled paper case, thus ensuring longer and more regular burning Flares are used in pyrotechnic displays for the illumination of the surroundings and in a suitable setting, such as a background of trees and foliage, rocks or old buildings.

The flare, or light, in its present form can claim no greater antiquity than the early part of last century. when the introduction of chlorate of potash permitted the development of genuine colour composition (See FIREWORKS) Previous to this the only colour achieved. in addition to flame colour, had been the bluish-white light produced by a mixture of sulfur, saltpetre and orpiment. These blue lights, as they were called, were much used at sea for signaling and illuminating purposes.

Signal Flares and Lights. — The introduction of colours nhich could readily be recognized at a considerable distance opened up a much wider field for the use of flares at sea, and from the middle of the 19th century many patents were taken out; most of these had for their object a means of self ignition. The first of these inventions ignited the flare by breaking a hollow bead containing sulfuric acid which came into contact with a pellet of chlorate of potash. Subsequent inventions provided for ignition on the same principle as the modern safety match.

During World Wars I and II, a number of flares were developed for purposes such as battlefield illumination. target marking. aircraft identification and distress signals. Illuminating flares, dropped by airplanes or fired from artillery and naval pieces. were usually attached to parachutes, which prolonged the period of illumination over a greater surface area. (A. St. H. B.; X.)

FLAT: see APARTMENT HOUSE: LANDLORD AND TENANT.

FLAT (in music): see ACCIDENTALS.

FLATFISH is the common name of fishes of the order Pleuronectiformes (Heterosomata), which differ from all other fishes in having both eyes on one side. As adults they live on the bottom, with the eyed side uppermost; this side is coloured whereas the underside is usually white (but exposure of underside to light will cause some development of pigment). Nearly all flatfishes are marine. The have minute floating eggs. The larval flatfish. which is symmetrical, with an eye on each side, swims near the surface of the sea; but after a time one eye moves round over the top of the head to the other side, some of the fins change position and the fish, leaning over gradually on the eyeless side, sinks to the bottom. In most flatfishes the dorsal fin grows forward onto the head; in some species with a long larval life this happens before the eye "migrates," so that in pushing its way between the dorsal fin and the head. the eye seems to go through the head from one side to the other. Many flatfishes are remarkable for their power of changing colour to resemble the ground on which they lie, and it has been established experimentally that they must see the ground in order to imitate it. The eyes stand out from the head and can be turned independently in different directions looking sideways, or sometimes one looking forward and the other backward.

Certain variant types are known. Many albino (pigmentless) flatfish have been found. Some species. which have the underside coloured, tend to have the fin arrangement symmetrical. Another abnormality commonly found is to have the eyes on the reverse side from that normal for the species. In these individuals the optic nerves, which normally cross only once, may be "doubly crossed."

The most primitive genus, Psettodes, from west Africa and the Indo-Pacific has perchlike features (dorsal fin not extending on the head; symmetrical pelvic fins, nostrils and skull characters) and indicates the derivation of flatfishes from some percoid ancestor allied to the sea basses (Serranidae). The other flatfishes, numbering about 600 species, are generally called either flounders, when the lower jaw is prominent, or soles, when the rounded snout projects beyond the small curved mouth; each of these groups includes a family with the eyes on the right side and another with the eyes on the left. The family Pleuronectidae, or dextral (right-eyed) flounders. include the halibut. plaice and other important food fishes of northern seas. The Bothidae, or sinistral (left-eyed) flounders; include the turbot; some of the American species of *Paralichthys* are also valued as food. The Soleidae, or true soles, with eyes on the right side include the well-known common sole (*Solea solea*) of Europe. The Cynoglossidae, or tongue soles, with eyes on the left side. inhabit tropical and subtropical waters.

In the more specialized forms, which feed .exclusively on bottom-living invertebrates, the jaws of the blind side are more strongly developed than those of the eyed side, and have stronger teeth; in the soles the jaws of the eyed side are toothless. Most flatfishes grow to about one foot long. but the Atlantic halibut (*Hippoglossus hippoglossus*) may attain a length of 10 ft. and a weight of more than 500 lb. See also FISHES. (C. Hu.)

FLATFOOT is the term used in medicine to designate a depression of the arch of the foot. Usually associated with loss of the arch is a rolling outward of the foot and heel, resulting in a splayfoot position. Normally the arch is maintained by the shape of the bones and by the ligaments and muscles of the foot. Of these three, the muscles are most important. At an early stage the flat foot may be flexible and result from stretching of ligaments and weakness of muscles. At a later stage the shape of the bones may be altered and the deformity rigid.

Little is known regarding the causation of flatfoot. All infants have flat arches at birth. The normal arch does not appear until the infant begins to walk, thus developing muscle power. Failure of development of the arch may be a normal racial or familial characteristic; it is often seen, for example, in Negroes. In general, the problem is a disproportion between the weight to be borne and the muscles to bear it. In a few patients the deformity follows an injury.

Many symptoms have been attributed to flat feet—pain, swelling, muscular spasm, stiffness and awkward gait. Other vague symptoms in the extremities and back, sometimes considered as caused by flatfoot, probably are the result of the generalized muscle weakness which also produced flatfoot. Many persons with flat feet are entirely without disability or pain.

The aim of treatment is to secure proper position of the arch and heel by the use of adequate shoes. with or without supports, and to preserve that position by strengthening the muscles maintaining correction of arch and heel. Supports are indicated if pain is severe or fatigue excessive, but their prolonged use may weaken muscles and be harmful. Few persons have pain severe enough to require surgery. Rarely surgery is indicated for cosmetic reasons. (J. S. Ms.)

FLATHEAD (SALISH), a Salishan-speaking Indian tribe of western Montana whose territory extended from the crest of the Bitterroot mountains to the continental divide. centring on the upper reaches of the Clark fork of the Columbia river. Their tribal neighbours were: north, the linguistically unrelated Kutenai; east, the Algonkian Blackfoot; south, the Sahaptin Nez Percé; west, the Salishan Coeur d'Alene and Kalispel. Friendship prevailed with all but the Blackfoot, against whose raids the tribe frequently had to defend itself. Salish was the native name of the tribe, but Flathead is the customary designation in both popular and anthropological usage. Head flattening, however, was not practised. Flathead customs were typically those of the Plateau culture area, of which they were the easternmost representatives (*see* PLATEAU INDIANS). Political organization was tribal. Bison hunting was basic to the economy. Horses were plentiful. The Flathead were consolidated with the Upper Pend d'Oreille and Kutenai in the treaty which the three tribes signed with the U.S. on July 16, 1855. Since 1872 they have resided primarily on a reservation at Flathead lake, Montana. *See* also INDIAN. NORTH AMERICAN; SALISHAN. (V. F. R.)

FLATMAN, THOMAS (1637–1688), English poet and miniature painter, was educated at Winchester (1649–54) and New college, Oxford (1654–56). He left Oxford without a degree in 1657, having been made fellow of his college the previous year. In 1666 he was created M.A. of Cambridge by the king's letters. As a miniature painter he is highly esteemed by modern critics, but only a few of his poems have survived in anthologies. He died in London, Dec. 8, 1688. His collected works first appeared in 1674, as *Poems and Songs,* and an enlarged edition in 1686; many of his verses, however, were printed separately, the most notable being "A Thought of Death" (imitated by Pope); "Death, a Song"; and "Hymn for Morning." *Montélion's Almanack* for 1661 and 1662 and a mock romance, *Don Juan Lamberto,* have also been ascribed to Flatman by Wood.

See Anthony à Wood, *Athenae Ovonienses,* P. Bliss (ed.), vol. iv (1813–20); H Walpole, *Anecdotes of Painting* (1762–71, later ed. 1879); S. Redgrave, *Dictionary of Artists* (1878); F. A. Child, *Life and Uncollected Poems of T. Flatman* (1921).

FLATWARE is the term introduced toward the end of the 19th century to denote spoons, forks and similar articles such as fish knives, fish forks and serving utensils. Strictly speaking, it excludes knives, but in the U.S. the term flatware or flat silver is generally understood to include all table knives. This article is concerned with the manufacture of forks and spoons; for the manufacture of knives *see* CUTLERY. *See* also FORK; KNIFE; SPOON.

Flatware is made in a wide variety of designs in silver, silver plate, unplated nickel alloys, stainless steel and aluminum, tinned iron, brass and plastics; luxury services are made in gold. Wood is sometimes used for salad and spaghetti servers, mother-of-pearl for egg spoons and bone for mustard spoons. Handles, plain or ornamented, are either in one piece with the spoon bowl or the fork or fitted separately to tangs. Another wide range of spoons and forks is manufactured, usually in stainless steel, for use in cooking and preparing food.

Modern flatware is produced in all the cutlery centres of the world. During the 20th century the processes used in its manufacture developed to a high degree of mechanization. The metal, carefully refined, is cast into small ingots, each weighing (in the case of nickel alloys) about 40 lb. The ingots are reheated and rolled until sheets of the desired thickness are obtained; the sheets are then cut into strips of the required width. These processes involve the strictest control of metal behaviour and correct annealing to remove excessive strains. The strips are fed into machine "presses" to cut out each spoon or fork in its rough shape, one end being at first almost square for a spoon and rectangular for a fork. The ends of these "blanks" are rolled again in a direction at right angles to the centre line, thus reducing the thickness there without altering the thickness of the handle. The bowls of the more expensive spoons are at least half as thin as their handles. After being trimmed in another press, the blanks for spoons are ready for stamping in alloy steel dies that hollow the bowls and stamp a pattern on the handles. In the case of forks, slots are cut out to form the prongs, which are then stamped in dies to the required curvature, tapered and pointed on abrasive belts. These processes are approximately the same whatever metal is used, although in manufacturing the cheaper products, made from thinner sheets, cross-rolling can be omitted and the stamping can be done in one operation. In the early 1960s large quantities of these thinner types were being made in stainless steel.

Subsequent finishing processes vary according to the metal used. In the case of silver, successively finer stages of buffing prepare the surfaces for final polishing or satin finishing. In the case of alloys that are to be plated, the articles, after being buffed, are wired individually on frames; quantities of 100 or more can be immersed simultaneously in the series of cleaning baths and plating vats. The articles to be plated become cathodes in the vat, the metal to be deposited, *e.g.,* silver, being the anode. In most factories the complete frames of articles are transferred automatically from baths to vats and finally to washing and drying. Strict control is maintained of the composition, strength and temperature of the plating solutions as well as of the voltage and amperage of the direct current to ensure that the correct thickness of coating is deposited. (*See* ELECTROPLATING.) The thickness of deposit is increased by some makers at the places of maximum wear, for example, on the centre of the convex surface of spoon bowls. The deposit of silver is specified in grams or pennyweights per dozen pieces and sometimes in actual thickness in millimetres or thousandths of an inch; but the more popular method of indication is use of the terms "30 years," "25 years" or "20 years" plate. The designation A one (A 1) is satisfactory as a guarantee of the quality of the deposit provided it is given by a manufacturer of good repute.

When the pieces have been plated their surfaces are dull and require polishing. Hand polishing is done by holding the articles upon rapidly rotating mops dressed with an aluminum compound or rouge. In the case of silver and silver plate a little of the metal is removed; in the plating process allowance is made for this by depositing more silver than is called for by the specification, the makers guaranteeing a "finished deposit." Mechanical polishing is done by machines in which numbers of spoons or forks are secured in racks and applied en masse to rotating cylindrical mops.

The least expensive plating process is "bright plating," in which a very thin coating of silver or chromium can be deposited bright, thus eliminating the cost of final polishing. Such a coating does not last long and the process is therefore restricted to the cheaper grades of flatware.

Stainless steel is more difficult to polish than silver, silver plate or unplated nickel alloys. Techniques have been developed for stamping the cheaper varieties of stainless steel spoons and forks from prepolished sheet. In some countries electrolytic polishing of stainless steel has been satisfactorily developed.

Where cheapness and lightness are especially desired aluminum or plastics are employed in the making of flatware. Aluminum articles are stamped in one operation from metal sheets; plastic articles are molded.

In Europe, silver articles usually bear a hallmark (*q.v.*), which indicates that the metal contains a prescribed amount of silver. Other marks record the year of manufacture and the maker. United Kingdom hallmarks include the lion passant, which is the guarantee that the silver is not less than 92.5% pure; the assay office (town) mark; the monarch's head; the date letter recording the year of manufacture and the maker's full name, initials and/or trademark. In the United States the word "sterling" is accepted as a sufficient guarantee when used by a reputable supplier.

While well-proved 18th- and 19th-century patterns for flatware continue to be popular, the advent of new fashions in furnishings during the first half of the 20th century resulted in the introduction of many new flatware designs by all the manufacturing centres. Designs in stainless steel as well as in silver flatware are available to harmonize with any table appointments. furniture or room decoration. Although stainless steel articles need only to be washed after use there is still great demand for silver and silver plate flatware. (W. G. I.)

FLATWORM, a general name for members of the phylum Platyhelminthes (*q.v.*), including the flukes (*see* TREMATODES), tapeworms (*q.v.*) and certain free-living forms (*see* TURBELLARIA).

FLAUBERT, GUSTAVE (1821–1880), French novelist, whose work constitutes an epoch in the history of the art of fiction, was born in Rouen, Dec 12, 1821. His father. Achille Cléophas Flaubert (1784–1846), who came from Champagne, was one of Guillaume Dupuytren's most brilliant pupils and was chief surgeon and clinical professor at the Hôtel-Dieu in Rouen. His mother (Caroline Fleuriot), a doctor's daughter from Pont-l'Évêque, belonged on her mother's side to the Cambremer de Croixmare family, which had, produced a number of distinguished magistrates and was typical of the great provincial *bourgeoisie.*

Gustave Flaubert began his literary career in his school days in Rouen, his first published work appearing in a little review, *Le Colibri,* in 1837. He early formed a close friendship with the young philosopher Alfred Le Poittevin (1816–48), whose pessimistic outlook had a strong influence on him. No less strong was the impression made by the company of great surgeons and the environment of hospitals, operating theatres and anatomy classes with which his father's profession brought him into contact. It was, for instance, with Jules Cloquet, the most learned anatomist of his time, that Flaubert, on receiving his *baccalaurdat* in 1840, was sent by his father to visit the Pyrenees and Corsica. Later, on reading *Graziella,* Flaubert was to remark that Lamartine would have written a more powerful novel if he had had a doctor's eye.

Flaubert's intelligence, moreover, was sharpened in a general sense. He conceived a strong dislike of accepted ideas *(iddes reçues)*, of which he was to compile a dictionary for his amusement. He and Le Poittevin invented a grotesque imaginary character, called "le Garçon," to whom they attributed whatever sort of remark seemed to them most degrading. Flaubert came to detest the "bourgeois," by which he meant anyone who "has a low way of thinking."

In Nov. 1841 Flaubert was enrolled as a student at the faculty of law in Paris. At the age of 22, however, he was recognized to be suffering from a nervous disease which was taken to be epilepsy, although the essential symptoms were absent. This made him give up the study of law, with the result that henceforth he could devote all his time to literature. His father died in Jan. 1846. and his beloved sister Caroline died in the following March after giving birth to a daughter. Flaubert then retired with his mother and his infant niece to his estate at Croisset, near Rouen, on the Seine. He was to spend nearly all the rest of his life there.

On a visit to Paris in July 1846, at the sculptor James Pradier's studio, Flaubert met the poet Louise Colet (*q.v.*). She became his mistress, but their relationship did not run smoothly. Her jealousy made separation inevitable, angry scenes took place, and they parted in 1855.

In 1847 Flaubert went on a walking tour along the Loire and the coast of Brittany with the writer Maxime du Camp, whose acquaintance he had made as a law student. The pages written by Flaubert in their journal of this tour were published after his death under the title *Par les champs et par les grèves* (1886). This book contains some of his best writing; *e.g.,* his description of a visit to Chateaubriand's family home, Combourg.

So far it has been possible to deal chronologically with the events of Flaubert's life, but from this point the close interrelation between his works and his life, as well as his habit of recasting his books in his search for perfection, makes this difficult. It therefore seems more convenient to deal with the creation of each of his major works separately, linking with it the concomitant events of his life.

L'Éducation Sentimentale. — Some of the works of Flaubert's maturity dealt with subjects on which he had tried to write earlier. At the age of 16, for instance, he completed the manuscript of *Mkmoires d'un fou,* which contains elements that eventually appeared in *L'Éducation sentimentale* (2 vol., 1869; dated 1870). Before receiving its definitive form, however. this work was to be rewritten in two distinct intermediate versions in manuscript: *Novembre* (1842), and a preliminary draft entitled *L'Éducation sentimentale* (1843–45). Stage by stage, it was expanded into a vast panorama of France under the July monarchy — indispensable reading, according to Georges Sorel, for any historian studying the period that preceded the *coup d'dtat* of 1851.

At Trouville, where his family owned some property, the young Gustave Flaubert in 1835 had formed a sentimental friendship with one of his sister Caroline's friends, Gertrude Collier, a daughter of the British naval attaché in Paris. But in 1836 this was forgotten when he met Elisa Schlésinger (née Foucault; 1810–88), to whom he returned a coat that she had left on the beach. Eleven years older than he and married to a music publisher, this woman (the Marie Arnoux of *L'Éducation sentimentale)* inspired a devastating passion in Flaubert. She no doubt loved him too, but their love was never consummated. Readers of *L'Éducation sentimentale* may take the famous opening sentences of its last chapter but one as a true representation of Flaubert's feeling for her:

> He traveled.
>
> He came to know the melancholy of steamers, cold awakenings in the morning under canvas, the shock of landscapes and ruins, the bitterness of discontinued friendships.
>
> He came back.
>
> He associated with people and he had other love affairs. But the memory of the first one made them indifferent to him . . .

La Tentation de Saint Antohe. — The composition of *La Tentation de Saint Antoine* provides another example of that tenacity in the pursuit of perfection which made Flaubert go back constantly to work on subjects without ever being satisfied with the results. In 1839 he was writing *Smarh,* the first product of his bold ambition to give French literature its *Faust.* He resumed the task in 1846–49, in 1856 and in 1870 and finally published the book as *La Tentation de Saint Antoine* in 1874. The four versions show how the author's ideas changed in the course of time. The version of 1849 is influenced by Spinoza's philosophy and nihilistic in its conclusion. In the second version the writing is less diffuse, but the substance remains the same. The third version shows a respect for religious feeling that was not present in the earlier ones, since in the interval Flaubert had read Herbert Spencer and reconciled the Spencerian notion of the Unknown with his Spinozism. He had come to believe that science and religion, instead of conflicting, are rather the two poles of thought. The published version has the form of a catalogue of errors in the field of the Unknown (just as *Bouvard et Pécuchet* was to be a catalogue of errors in the field of science).

From Nov. 1849 to April 1851 Flaubert was traveling in Egypt, Palestine, Syria, Turkey, Greece and Italy with Du Camp. Before leaving, however, he wanted to finish *La Tentation* and to submit it to Du Camp and to his friend the poet Louis Bouilhet for their sincere opinion. For three days in Sept. 1849 he read his manuscript to them, and they then condemned it mercilessly: "Throw it all into the fire, and let's never mention it again." Bouilhet gave further advice: "Your Muse must be kept on bread and water or lyricism mill kill her Write a down-to-earth novel, like Balzac's *Parents Pauvres*. The Delamare story, for instance. . . ."

Madame **Bovary.**—Eugène Delamare mas a country doctor in Normandy who died of grief after being deceived and ruined by his wife, Delphine (née Couturier). The story is in fact that of *Madame Bovary* but it is not the only source of that novel. Another source is the manuscript *Mémoires de Mme Ludovica,* discovered by Gabrielle Leleu in the library of Rouen in 1946. This is an account of the adventures and misfortunes of Louise Pradier (née d'Arcet), the wife of the sculptor Fradier, as dictated by herself; and it bears a strong resemblance to the story of Emma Bovary. apart from the suicide. Flaubert, out of kindness as well as out of professional curiosity, had continued to see Louise Pradier when the "bourgeois" were ostracizing her as a fallen woman, and she must have given him her strange document. Even so, when inquisitive people asked him who served as model for his heroine, Flaubert replied. "Madame Bovary is myself." This was doubtless meant as a joke, but can be regarded as true if it is remembered that the idea nas already in his mind in 1837 when he was writing *Passion et vertu,* a short and pointed story with a heroine, Mazza. resembling Emma Bovary. For *Madame Bovary* he took a commonplace story of adultery and made of it a book that will always be read because of its profound humanity The Emmas of the 20th century do not take the stagecoach to rejoin their lovers but drive to them in their own cars, yet they pay the same price for their folly. While working on his novel Flaubert wrote: "My poor Bovary suffers and cries in more than a score of villages in France at this very moment."

Madame Bovary, with its unrelenting objectivity—by which Flaubert meant the dispassionate recording of every trait or incident that could illuminate the psychology of his characters and their role in the logical development of his story—marks the beginning of a new age in literature. It occupies the same position in the history of the novel as Claude Bernard's *Introduction à la médecine expérimentale* occupies in that of biology.

Madame Bovary cost the author five years of hard work. Du Camp, who had founded the periodical *Revue de Paris,* urged him to make haste, but he would not. The novel, nith the subtitle *Moeurs de province,* eventually appeared in instalments in the *Revue* irom Oct. 1 to Dec. 15, 1856 (new edition in book form, 1857). The French government then brought the author to trial on the ground of his novel's alleged immorality, and he narrowly escaped conviction (Jan.–Feb. 1857). The same tribunal found Baudelaire guilty six months later.

Salammbô.—To refresh himself after his long application to the dull world of the *bourgeoisie* in *Madame Bovary,* Flaubert immediately began work on *Salammbô,* a novel about ancient Carthage, in which he set his sombre story of Hamilcar's daughter Salammbô, an entirely fictitious character, against the authentic historical background of the revolt of the mercenaries against Carthage in 240–237 B.C. His transformation of the dry record of Polybius into richly poetic prose is comparable to Shakespeare's treatment of Plutarch's narrative in the lyrical descriptions in *Antony and Cleopatra.* The novel appeared in 1862 (dated 1863) and had a great and lasting success. A play, Le *Château des coeurs* (1863), was not printed until 1880.

Trois **Contes.**—The merits of *L'Éducation sentimentale,* which appeared a few months before the outbreak of the Franco-German War of 1870, were not appreciated, and Flaubert was much disappointed. Two more plays, *Le Sexe faible* and *Le Candidat* (both 1873), likewise had no success, though the latter was staged for four performances in March 1874. The last years of his life, moreover, were saddened by poverty. In 1875 his niece Caroline's husband Ernest Commanville, a timber importer, found himself heavily in debt. Flaubert sacrificed his own fortune to save him from bankruptcy. Flaubert found some consalation in his work and in the friendship of George Sand, Turgenev and his neighbour Edmond Laporte, and also in that of younger novelists—Émile Zola, Alphonse Daudet and, especially, Guy de Maupassant, who was the son of his friend Alfred Le Poittevin's sister Laure and regarded himself as Flaubert's disciple.

Flaubert temporarily abandoned work on a long novel, *Bouvard et Pécuchet,* in order to write *Trois Contes* (1877), which comprises the three short stories "Un Coeur simple," "La Légende de Saint Julien l'Hospitalier" and "Hérodias." This book, through the diversity of the stories' themes, shows Flaubert's talent in all its aspects and has often been held to be his masterpiece.

Bouvard et **Pécuchet.**—The heroes of *Bouvard et Pécuchet* are two clerks who receive a legacy and retire to the country together. Not knowing how to use their leisure, they busy themselves with one abortive experiment after another and plunge successively into scientific farming, archaeology, chemistry and historiography, as well as taking an abandoned child into their care. Everything goes wrong because their futile book learning cannot. compensate for their lack of judgment and because they have not had the general education that is a prerequisite of any intellectual activity. The profound meaning of this novel, which Flaubert left unfinished and which was published after his death (in the *Nouvelle Revue* from Dec. 15, 1880, to March 1, 1881; in book form. 1881), has been seriously misunderstood by critics who have regarded it as a denial of the value of science. In fact it is "scientism" that Flaubert is arraigning; *i.e.,* the practice of taking science out of its own domain, of confusing efficient and final causes and of convincing oneself that one understands fundamentals when one has not even grasped the superficial phenomena. Intoxicated with empty words, Bouvard and Pécuchet awake from their dream only when catastrophe overtakes their presumptuous efforts. Flaubert has been accused of presenting them as imbeciles, but in fact he expresses his compassion for them: "They acquire a faculty deserving of pity, they recognize stupidity and can no longer tolerate it. Through their inquisitiveness their understanding grows; having had more ideas, they suffered more." Flaubert's satire is thus to some extent the history of his own experience, told with a sad humour.

Flaubert died suddenly of an apoplectic stroke on May 8, 1880. He left on his table an unfinished page and notes for a second volume of his novel. Bouvard and Pécuchet, tired of experimenting, were to go back to the work of transcribing and copying that they had done as clerks. The matter that they chose to transcribe was the subject of the notes: it was to be a selection of quotations, a *sottisier,* or anthology of foolish remarks. There has been much controversy about this bitter conclusion, as the form that it was to take was leit undetermined.

Flaubert's Method of Composition.—Flaubert worked slowly and carefully, and as he worked, his idea of his art became gradually more exact. His letters to Louise Colet, written while he was working on *Madame Bovary,* show how his attitude changed. His ambition was to achieve a style "as rhythmical as verse and as precise as the language of science" (letter of April 24. 1852). In his view "the faster the word sticks to the thought, the more beautiful is the effect." He often repeated that there was no such thing as a synonym and that a writer had to track down *le seul mot juste,* "the unique right word," to convey his thought precisely. But at the same time he always wanted a cadence and a harmony of sounding syllables in his prose so that it would appeal not only to the reader's intelligence but also to his subconscious mind in the same way as music does and thus have a more penetrating effect than the mere sense of the words at their face value. Composition for him was a real anguish.

Flaubert sought objectivity above all else in his writing: "The author, in his work, must be like God in the Universe, present everywhere and visible nowhere." It is paradoxical, therefore, that his personality should be so clearly discernible in all his work, and that his letters, written casually to his intimates and full of disarming sincerity, delicate sensibility and even exquisite tenderness, should be considered by some critics as his masterpiece.

Editions and Translations.—The critical edition by René Dumesnil of Flaubert's novels, short stories and travel notes in 12 volumes (1938–46) provides a definitive text, with variant readings, as well as an introduction and annotations. For Flaubert's juvenile writings and for his plays, reference can be made to the 18-volume Conard edition (1910–28). This includes five volumes of *Correspondance,* but these were superseded by a new edition in nine volumes (1926–33), followed by the four-volume *Supplément à la correspondance générale,* edited by R. Dumesnil, Jean Pommier and Claude Digeon (1954).

Some of Flaubert's novels have been translated into English several times. The following versions may be cited: *November,* translated by F. Jellinek (1932); *Sentimental Education,* translated by Anthony Goldsmith (1941); *The First Temptation of Saint Anthony,* translated from the version of 1856 by René Francis, new ed. (1924); *The Temptation of Saint Anthony,* translated by Lafcadio Hearn, new ed. (1932); *Madame Bovary,* translated by Gerard Hopkins (1949); *Salambo,* translated by E. Powys Mathers, new ed. (1950); *Three Tales,* translated by Mervyn Savill (1950); *Bouvard and Pécuchet,* translated by T. W. Earp and G. W. Stonier (1936). There are selections of his letters in English translations by J. M. Cohen with an introduction by R. Rumbold (1950); and by F. Steegmuller (1954).

(R. Dl.)

FLAVIAN, SAINT (d. 449), patriarch of Constantinople, was an adversary of the Monophysite heresy (*see* MONOPHYSITES). He became patriarch in 446 and in 448 presided at a Constantinopolitan synod which condemned Eutyches (*q.v.*). Flavian's announcement of this evoked from Pope Leo I the famous *Dogmatic Letter* of 449. The "robber synod" of Ephesus, contrived by court intrigue, deposed and excommunicated him in 449; his opponents so maltreated him that he died three days afterward in Lydia. The Council of Chalcedon (451) vindicated him, however, proclaiming him a martyr and saint; both the Latin and Greek churches commemorate him on Feb. 18.

Three letters of Flavian to Pope Leo I and one to Emperor Theodosius II are preserved; they may be found in J P. Migne (ed.), *Patrologia Latina,* vol. 54 and *Patrologia Graeca,* vol. 65.

(Jn. Sr)

FLAVIAN I OF ANTIOCH (c. 320–404), bishop of Antioch from 381, was born probably at Antioch. With Diodorus of Tarsus. Flavian defended the Nicene faith against the Arian bishop Leontius. In the religious meetings they conducted, Flavian popularized the form of the lesser doxology that is derived from the baptismal formula, and he is believed to have originated the practice of antiphonal singing in church services. In 360 Meletius (*see* MELETIUS OF ANTIOCH), whom the Arians had ordained bishop of Sebaste, became bishop of Antioch, where his unexpected profession of the Catholic faith earned him several exiles. During these absences Flavian and Diodorus resumed the care of the faithful. Meanwhile, the Eustathians — Antiochenes who had separated from the Arian bishop after the banishment of the orthodox bishop Eustathius (331)—rejected Meletius and made Paulinus their bishop (*see* EUSTATHIUS, SAINT). The schism thus set afoot continued after Meletius' death. Flavian succeeded him in 381, and Paulinus appointed as his own successor Evagrius, the last bishop of the Eustathians. Recognition of Flavian as legitimate bishop of Antioch was at first withheld by the bishop of Rome, but it was secured in 399 through the intervention of John Chrysostom (q *v.),* patriarch of Constantinople, and the influence of the emperor Theodosius.

Flavian died in 404. Some Eustathians continued in schism until 414.

See F. Cavallera, *Le schisme d'Antioche* (1905); Herzog-Haupt, *Realencyklopadie.*

(J. A. P. B.)

FLAVIAN II OF ANTIOCH (d. c. 518), patriarch of Antioch probably from 498 to 512, mas chosen patriarch by the monophysitic emperor Anastasius I after he accepted the evasive Henoticon, the decree of union between the Monophysites (*q.v.*) and the Orthodox. In deference to orthodoxy, however, Flavian would not expressly repudiate the Council of Chalcedon. This equivocal policy only antagonized both sides, particularly the Monophysites. At the synod of Sidon (511) Flavian maintained his position, but soon afterward, under constant harassment by his enemies, he yielded finally to their demand for a rejection of Chalcedon. It was too late. He was forced to abdicate and was banished to Petra in Arabia. There he died, probably in 518. (Jn. Sr.)

FLAVIGNY, VALÉRIEN (d. 1674), French philologist primarily interested in technical questions of textual meaning in the Bible, was born near Laon, France, at the beginning of the 17th century. In 1640 he became professor of Hebrew at the Collège de France. His best-known work, *Epistolae IV de ingenti Bibliorum opere septemlingui* (1646–48), concerned Le Jay's polyglot Bible, over which Flavigny was engaged in a controversy with Abraham Ecchellensis. Flavigny also edited and published (1632) the works of Guillaume de Saint-Amour, 13th century French theologian. He died in Paris on April 29, 1674.

FLAVIUS, BLONDUS (*c.* 1388–1463), Italian historian, was born at Forlì. After acting as ambassador to Milan, where he discovered the manuscript of Cicero's *Brutus,* he was exiled to Venice from 1423–32. In the latter year he became secretary to Pope Eugenius IV. During his lifetime he was also secretary to three other popes, Nicholas V, Calixtus III and Pius II. He died in Rome in 1463.

Flavius wrote three encyclopaedias, *Romae Instauratae Libri Tres* (1482), *Romae Triumphantis Libri Decem* (1482) and *Italia Illustrata* (1474). The three included valuable material on 15th century Rome and Italy as well as on the ancient city and its inhabitants. These books formed the pattern on which many later works on Rome were based, and they continued to be consulted for hundreds of years after their author's death.

His collected works, including *Decades* and *De origine et gestis Venetorum* in addition to those listed above, were often printed in the 16th century, notably at Basle in 1531. B. Nogara edited *Scritti inediti e rari di B. Flavio* in "Studi e Testi" series, no. 48 (1927).

FLAVIUS, GNAEUS, Roman writer of the 4th century B.C., on legal procedure, was the son of a freedman but had a distinguished career which began when he was made secretary to Appius Claudius Caecus. Before Flavius' time, the technical rules of procedure in Roman law were known only to the patricians and pontiffs, part of whose power derived from the fact that they had to be consulted frequently on legal questions. Flavius, either by copying from a law book owned by Appius Claudius or by questioning the latter's friends, was able to work out the procedural system and published his findings under the title of *Jus Flavianum.* Thereafter he was immensely popular with the Roman people and was selected for a number of public offices. including that of senator. In 303 B.C. Flavius was made curule aedile (magistrate of public buildings and works) over the bitter protests of the nobles, with whom he was unpopular both because he had taken from them one of the sources of their power and because of his lowly parentage.

FLAVOUR is the total of the sensations perceived when a food or beverage is consumed; these sensations not only help a person identify substances but also furnish sources of enjoyment when eating and drinking.

Taste **and** Aroma. — The sensory organs involved in flavour perception are those of taste, smell and touch, with the nerve endings located in the nose and mouth.

Tasting occurs in the mouth, chiefly on the tongue through the taste buds. There appear to be only four basic receptor types responsible for the tastes—sweet, salty, sour and bitter. Examples of substances that induce the four basic tastes are sugar (sweet), salt (salty), lemon juice (sour) and quinine (bitter). Substances can be tasted only when they are in water solutions, and if a substance is not in solution when taken into the mouth it must be dissolved in saliva before it can be detected by the taste buds.

Smelling involves the olfactory nerve endings in the upper part of the interior of the nose. Aromas can reach these nerves either directly through the nostrils as in breathing or indirectly up the back passageway from the mouth. Because of their remote location, the olfactory nerve endings are best stimulated by "sniffing" through the nose or swallowing if food is in the mouth. Odours are smelled only when the material is in gaseous form: *i.e.,* a dispersion of molecules in air. While taste types are limited to four, the number of odours that can be identified is in the thousands. The trained flavour chemist is normally capable of distinguishing 10,000 different odours. Further, the sense of smell is extremely sensitive, requiring only minute quantities for detection; a few parts per million in air is sufficient for detection of many odours. The smell of brewing coffee or the cooking of onions, for instance, can be recognized at considerable distances. The sense of taste requires considerably higher concentrations of substances for detection, as much as several tenths of a per cent often being necessary to elicit a response. (See also SMELL AND TASTE.)

Touch sensations that contribute to taste originate in the nose, lips and throughout the entire mouth and throat. The many kinds of touch sensations are based on either the physical or chemical properties of the substance, or a combination of them. Physical properties of foods that produce touch sensations are particle size, texture, consistency and temperature; reactions induced by chemical properties include the coolness of peppermint, the "bite" of mustard and pepper, the warmth of cloves and the astringency of spinach. (See also TOUCH, SENSE OF.)

When a human consumes food, the simultaneous stimulation of the senses of taste, smell and touch create an immediate impression that causes the eater to accept the food and continue eating or reject and discard it. Many foods such as bananas, berries and other fruits, nuts, milk and a few vegetables have flavours that make them highly acceptable in their natural, uncooked state. Other foods derive their flavour through cooking, seasoning and flavouring or combinations of these. (See also NERVOUS SYSTEM: Sensory Endings (Receptors); SENSATION: Senses; FEELING, PSYCHOLOGY OF: *Theory* of Feeling.)

Flavour Development.—Roesting.—One of the earliest known and most impressive means of developing flavour is the cooking of meats and poultry over a fire. The high temperature caramelizes meat sugars, chars proteins and decomposes fats, resulting in development of highly aromatic roasted meat flavour. Wood fires, such as those made with hickory wood. may impart distinctive smoke aroma. Roasted meat flavour can also be produced by heat sources that use coke, charcoal, gas, electricity or any high-temperature fuel. To a lesser extent pan roasting, searing and pan frying also develop roasted meat flavour.

Flavour development by roasting is not confined to meat; for example, the flavours of coffee, cocoa and nut meats are developed by roasting. In the cooking of breads, cakes, cookies and pies, the outer crusts are often browned and have slightly burned, caramel flavour that is attributed to the roasting action of heat.

Baking, Boiling, *Steaming.*—Perhaps the simplest and best-known method of food preparation consists of cooking foods by placing them in boiling water or by allowing the steam produced by the water to heat the food. Meats, fish, cereals and vegetables are frequently cooked in this manner. While not usually thought of as such, baking, which is similar to roasting, is also a form of water cooking, involving the driving off of water in the form of steam from the baking food. During baking. boiling and steaming, the water will extract the volatile flavours and can carry them off; this extraction, if prolonged, can result in insipid flavour, as occurs when onions, carrots or parsnips are cooked too long. The effects of water extraction are not entirely adverse, however, and the method is used to prepare coffee, tea and other beverages.

For optimum flavour, vegetables should be boiled just long enough to produce tenderness. The food should be served immediately and not allowed to stand in the hot water. Some situations require lengthy boiling to develop flavour. as in the preparation of soup stock by boiling bones and meat to produce new aroma and flavour factors; but such situations are the exception to the rule.

As mentioned above, the outer crusts of breads. cakes and pastries are heated during baking to browning temperatures that are above the boiling point of water. Although the interiors of baked foods never reach browning temperature, the flavour changes produced in the interiors by baking greatly increase palatability. The most important change is brought about by cooking or bursting the starch cells to eliminate the raw starch taste and produce the full, mouth-filling flavour of cooked doughs.

Presumably by accident, man long ago found that the predecessor of modem bread could be made if a yeast were allowed to grow in the dough with subsequent conversion of sugars to alcohol, release of carbon dioxide gas and creation of a unique flavour. The highly attractive flavour of bread comes not only from the inherent flavours in the grain but also from by-products of yeast fermentation, which are alcoholic in odour, followed by the aromatic materials produced by baking.

Aging.—Some foods and beverages highly prized for their flavours owe these flavours to the development process of aging for long periods of time. Such aged foods include brandies, cheeses and pickles, to mention only a few. Brandy, for example, is first distilled and then the distillate is stored in wooden barrels for years to develop desirable brandy flavour. During this aging process components of the wood are slowly extracted by the brandy, and at the same time components of the brandy are absorbed or adsorbed by the wood. This gradual change in the brandy's flavour-producing ingredients produces a so-called "mellowing" or blending of flavours. Cured cheeses depend on a slow fermentation or ripening process to develop distinctive flavour characteristics. With some pickles, the action of sugar, vinegar, herbs and spices is allowed to take place over a long period of time to develop optimum flavour.

Seasoning.—Salt, sugar, monosodium glutamate (MSG) and certain spices such as pepper are examples of seasonings that make outstanding improvements in flavour. Their mode of action is not clearly understood; however, enough is known to indicate that seasoning is a highly complex phenomenon.

It is learned from early writings that man has always sought salt to make his foods more palatable and to help preserve them when stored. The continents of North and South America were discovered because of man's quest for new routes to the spice treasures of the orient. The optimum flavour contribution of salt occurs most often at a concentration below that which would give a distinct salty taste; best seasoning results are obtained by adding salt to foods prior to cooking.

Sugar and other sweeteners such as honey, sirups and molasses are useful at the seasoning level in gravies, stews and vegetables.

Monosodium glutamate, used for centuries in the orient in the form of a vegetable sauce to improve the palatability of a predominantly rice diet, has in recent years been introduced in North America and many countries of Europe. Like salt, it has found important use as a seasoner for improvement of flavour. Although it adds no flavour or aroma of its own, it has the ability to blend and zccentuate many flavour factors and makes important flavour contributions in soups, stews, meats, fish, poultry and vegetable dishes.

The spice pepper also belongs in the seasoning category, for it is used more often as a seasoning than as a flavouring agent. The demand for pepper has not diminished since the early caravans and explorers sought routes for procuring this highly prized substance. In early times, pepper no doubt did a great deal to improve the palatability of the unrefrigerated foods of the world. As a seasoning it is a blending agent, increasing the body of flavour and providing pleasant taste and aroma sensations.

Flavouring.—While the flavours of all natural foods are quite complex. the foods themselves are often made more appealing to the human palate by using them in combination with other foods, or by adding small quantities of highly aromatic flavouring agents such as spices. herbs and essential oils. The essential oils are the flavouring oils extracted from any natural product. Soaps and stews in which meat and vegetables are cooked together are examples of foods combined to give optimum appeal. Spreads such as butter, oleomargarine, jams and jellies when eaten on breads make for more eating enjoyment. Much use of flavouring agents is now made by food processors and home use continues to flourish in many instances; cinnamon and nutmeg are used in pastries, vanilla in baked goods, clove in hams and celery seed in soups and stews. (For descriptions of the most common herbs, spices and other seasoning agents and their use in cooking, see FOOD PREPARATION : Herbs and Spices. Also see individual articles on each agent.)

History has demonstrated that man has continually sought compatible combinations of foods and flavourings to relieve the monotony of eating. While sources of available foods have always governed eating habits to some extent, man often seeks flavour in preference to good nutrition. Although there is no one flavour that is appealing to all, certain widely accepted foods all seem to possess the following characteristics: (1) an early initiation of appropriate flavour; (2) rapid development of a full body of blended flavour; (3) pleasant mouth sensations; (4) absence of unpleasant characteristics in either the initial impression or aftertaste; and (5) usually a quick disappearance of flavour on swallowing. Cooking, aging, seasoning and flavouring all contribute toward these five desirable features.

Flavour Testing.—The techniques used for judging the flavour of foods can be grouped into several major categories: (1) ranking and scoring; (2) difference testing; (3) the flavour profile method, an analytical descriptive method of characterizing flavour; and (4) consumer acceptance testing.

Early flavour testing was carried out by experts who because of training, experience and familiarity with foods were believed to make sound judgments. While many judgments on flavour are referred to teams of trained workers known as flavour panels, single experts are employed in the coffee, tea and wine industries. Here the expert rates his product against product standards known to be acceptable to the consumer.

Ranking and Scoring.—One of the simplest techniques of flavour judgment is ranking, which requires flavour panel members to arrange a series of samples in ascending or descending order of intensity based on a specific flavour characteristic. For instance, panel members might be asked to rank sweetness of sugar solutions so that a correlation might be made between sweetness and strength. Panel members are trained to recognize the flavour factor under study and relate it to reference intensity standards. Ranking methods are useful in the food industry chiefly in quality control in large-scale production; however, the method lacks precision when flavour differences are small, and the information developed is limited to one flavour factor.

The scoring method was originally developed by the dairy industry to rate products such as butter, by numerical grade according to some predetermined standard; it is now widely used in the flavour appraisal of fruits and vegetables, as well as dairy products. Scoring is performed by panels previously trained in the particular qualities under observation. Many numerical scales are used, depending on the number of points considered convenient.

Difference Tests.—Difference tests were developed just prior to World War II as a means of introducing more precise measurement in the field of flavour testing. Many forms of difference tests are utilized, but all are intended to establish whether there is a detectable difference between two samples. The numbers of tasters and flavour samples evaluated are carefully controlled to meet a statistical model having a known theoretical distribution of responses based on chance. In the best known difference test, known as the triangle test, two of the three samples employed are identical, although all three are coded differently. The taster is asked to pick the odd sample. The chance probability of a taster picking the correct sample would be one out of three. Triangle tests for flavour are useful in production quality control to make sure each lot is as good as a standard.

Flavour Profile Method.—In the flavour profile method, panels of trained tasters describe the aroma and flavour of a food product in everyday language. Persons who have normal abilities to taste and smell and who are trained in sensory techniques of tasting and smelling are selected to work on flavour profile panels. They are also exposed to a number of flavour and odour situations in order to provide background experience for odour and flavour description. At least six months are required to train a panel member.

Panels first observe the total aroma of the food under test and then give their impressions of each of the detectable aroma factors as they occur, describing these in associative terms. The panel then tastes the food and makes similar observations on the flavour-by-mouth and on the aftertaste. Each aroma and flavour factor is appraised on the basis of intensity, using the scale of threshold, slight, moderate and strong. Aroma factors are the sensations perceived on sniffing and include odours as well as touch factors. Flavour-by-mouth sensations are those perceived by all of the flavour senses. including the basic tastes, touch factors in the mouth and throat, and odour and touch factors in the nose.

Individual observations recorded in tabular form on a response sheet are interpreted by the panel leader. Flavour profiles have been found useful in quality control of flavour, in guiding product development and in flavour research.

Consumer Acceptance Testing.—To determine the flavour acceptability of a food, it is often necessary to obtain information direct from the consumer. A number of methods have been employed to accomplish this, with variations occurring in the size and composition of the panel of tasters, the method of presenting the samples, the means of gathering information and the method of interpreting the data. Flavour is best evaluated by consumers who are potential users of the food; for example, a ready-to-eat cereal should be judged by those who normally eat this type of breakfast food. In consumer testing, it is important to have a panel large enough to furnish statistically significant information. Although much consumer testing is done on a single exposure, best judgments are made in the home under normal use conditions and over a short period of time. Data are collected either by questionnaire or by interview. Great care is taken to obtain factual information with respect to flavour, since most consumers are incapable of describing their reactions adequately.

Consumer panel results are interpreted by workers who are experienced in consumer testing and attempt to project the findings in terms of proposed market sales.

Witheridge, Odors: Physiology and Control (1949); Jean F. Caul, "The Profile Method of Flavor Analysis," from vol. vii, Advances in Food Research (1957–58). (L. B. SJ.)

FLAVOURINGS. Flavouring agents with the exception of common salt, are mostly obtained from plants, but some are derived from synthetics which resemble the natural products. The latter may be from any part of the plant; that is, leaf, stem, root or fruit. Though useful in helping to make certain foods palatable and easier to digest, condiments have no food value. Flavourings should always be blended with food in cooking and not served with the food. This rule should apply to salt and pepper but cus-. tom has largely prevailed to the contrary in this case. All condiments ought to be used sparingly and in such proportions that they do not spoil the natural flavours of other ingredients.

Pot Herbs.—This expression is usually applied to a particular set of flavouring herbs (parsley, thyme, bay leaf and marjoram) which is used in the form of a bouquet for stews, sauces, etc. A complete bouquet has other flavourings added such as lemon, celery, mace, tarragon, etc.

The term pot herbs is also familiarly given to onion, carrot and turnip added to stock.

Essences. — These are made by immersing a flavouring agent (*e.g.,* celery seed) in spirits of wine for several days to form a tincture; or, an essential oil, obtainable at a pharmacy (*e.g.,* oil of bitter almonds) is added to spirits of wine when the natural volatile oil cannot be obtained by ordinary methods of immersion and soaking. Examples of essences are cinnamon, nutmeg, lemon, ginger, etc. Vinegars are made by soaking some strong flavouring agent (*e.g.,* chilli) in ordinary vinegar.

Other Condiments. — Fresh herbs or those dried in leaf or powdered are used in making sauces, stews, etc. It is usual to classify them according to the part of plant to which they belong: (1) Leaves and stems. Among these are sage (for flavouring forcemeats, etc.); spearmint, commonly called mint and used in making mint sauce for mutton; bay leaf (bouquets); marjoram, thyme and sweet basil (bouquets); parsley, used as garnish as well as a popular flavouring agent; peppermint, principally used in confectionery. (2) Flowers and buds. Cloves; saffron (used chiefly for colour); capers (pickles, sauces, etc.). (3) Barks. Cinnamon. (4) Roots. Horseradish (grated in sauce or eaten au *naturel* with beef); turmeric (chiefly for colour and as an ingredient in curry preparations); ginger (puddings, cordials and jams); garlic (stews and sauces); these are the best known. (5) Seeds. Aniseed (pastry, cakes, cordial); caraway (cakes); fennel (cakes and liqueurs); mustard; nutmeg and mace; dill; cumin; coriander and various seeds used in curry preparations. (6) Fruits. In this class are certain fruits, such as allspice, capsicum and vanilla pods, ett. See FOOD PREPARATION.

FLAX. Flax (*Linum usitatissimum*), a crop plant grown on nearly 20,000,000 ac. annually in many temperate and subtropical countries for the production of linseed oil and linen fibre. Flax is an annual in temperate and cool climates, and a winter annual in warm climates. The plants grow to a height of 12 to 40 in., with a distinct main stem and a short taproot. Two or more basal branches may arise from the lower part of the main stem, and these, like the main stem, produce branches that bear the flowers. The lance-shaped leaves are borne alternately on the stems and branches. Each flower has 5 petals that are blue, white or pale pink, and 10 anthers that are blue or yellow. The flowers open in early morning and shed their petals by early afternoon. Daily blooming may continue for several weeks. The floaers are self-pollinated. The boll or capsule has 5 double-celled carpels and contains 10 seeds when all of them develop. The shiny, flattened seeds are brown or yellow, and from $\frac{1}{7}$ to $\frac{1}{5}$ in. long. A pound of flaxseed contains from 65,000 to 120,000 seeds. Fibre type varieties have long stems with few branches and seeds. The linen or bast fibres occur in the bark of the stem. Seed flaxes have short, much-branched stems and many seeds.

Origin and History. — Cultivated flax probably originated in the Mediterranean region from the wild flax (Linum *angustifolium*), the only species of wild flax with which it crosses readily. Several other species of Linum are grown as ornamentals. Flax was cultivated in prehistoric times, possibly at first for food. It was found in the ruins of the Stone Age lake dwellings of Switzerland, and the ancient Egyptians made linen cloth from flax fibres. Later flax cultivation spread through Europe, parts of Asia, and North Africa. It reached the United States during the colo'nial period where it was widely grown for fibre before the invention of the cotton gin in 1792 made cotton a cheaper fabric. The manufacture of linseed oil in the United States began in 1805.

Fibre Flax. — The world produces about 700,000 to 1,000,000 tons of flax fibre on from 2,000,000–3,000,000 ac. annually. Fully three-quarters of this is produced in the U.S.S.R. Other leading countries include Poland, Germany, France, Northern Ireland, Ireland. Rumania, Belgium and Holland; some is also produced in New Zealand, Australia, Japan, Argentina and Egypt. In the United States fibre flax is grown only in Oregon. Production there increased from a few thousand acres up to 18,000 ac. during World War II but declined to 1,000 to 2,000 ac. annually after 1950. Yields of fibre range from 300 to 800 lb. per acre in most countries, with still lower yields in the U.S.S.R. and much higher yields in Northern Ireland. The yield in the United States averages about $1\frac{3}{4}$ tons of straw or 400 lb. of fibre per acre. Flax is best adapted to medium loam or clay soils. Flax grown on soils high in nitrogen often has a low fibre content. Clean land, well-tilled to destroy weeds, is essential, and a smooth firm seed bed is desirable.

The crop is sown in early spring in most countries at a rate of 80–140 Ib. of seed per acre. Some hand weeding of the flax field may be necessary. Flax is harvested for fibre when about one-half of the seeds are ripe and the leaves have fallen from the lower two-thirds of the stem, which stage usually is reached about 80 to 100 days after sowing. Most of the crop is harvested by pulling the plants from the ground by hand, but pulling machines are available and all of the United States crop is pulled and bound by machine. After pulling, the bound stalks usually are set in shocks in the field for curing (drying). The dried stalks are deseeded by threshing, combing or beating the tops of the bundles. The seed, a by-product, is saved for sowing purposes, oil extraction or feed.

BY PERMISSION OF DR EUGEN KOHLER, "MEDIZINAL PFLANZEN"
FLAX (LINUM USITATISSIMUM) FROM WHICH LINEN IS MADE.

The deseeded straw is then retted (partly rotted) to dissolve the gums that bind the fibres to the woody portion of the stem. Both dew retting and water retting processes are practised but the latter provides uniformly better fibre. In dew retting. the common method in the U.S S.R., the straw is spread out evenly and thinly on the ground, usually on grassland, where it is subjected to weathering and to the action of soil-borne bacteria that are present on the straw. Retting is completed after 7 to 21 days, or more, when the bark of the stems is loosened so that it can be readily peeled from the woody core. The straw is then gathered, bound and again set in shocks to dry. In water retting, the common method in most countries, the straw is immersed in ponds, sluggish streams or vats, and allowed to steep until the bark is loosened. In vats the water is circulated to provide uniform retting. Water retting requires 6 to 8 days at a water temperature of 80° F., and up to 20 days when the water is cooler. The retted straw bundles are set in the fields in open shocks (wigwams) to dry. Chemical retting is also possible, but was not yet economically feasible in the 1950s.

The fibre is separated from the woody core by breaking and scutching. Breaking is accomplished by passing the straw between fluted rolls or by crushing it between slatted hand-breaking frames. This breaks the brittle woody portions of the stem into short pieces called shives while leaving the flexible fibres largely intact. Scutching is accomplished by passing the broken straw through revolving beaters that free the fibres from the shives. Some machines do both breaking and scutching. The scutched fibre is baled and shipped to spinning mills. At the spinning mill the fibre is hackled by machines that comb out the short, tangled fibres and remaining shives. The resultant long straight fibre, called line fibre, is further combed and then twisted into yarn on a spinning machine. Coarse yarns may be 8 lea or 2,400 yd. per pound. while the finest yarns are 120 lea or 36,000 yd. per pound.

The short or tangled fibres called tow may be carded to produce strands of parallel fibres which are then spun into coarse yarns, or the tow may be used for upholstering or padding. Fine yams are used in weaving high quality linen fabrics, such as laces, household linens and dress goods. Coarse yarns are used for crash or other coarse fabrics, or for making twine, cord or rope.

Seed Flax.—The world production of flaxseed (linseed) is about 130,000,000 bu. from more than 19,000,000 ac. About an eighth of this is obtained as a by-product from fibre flax and the remainder is produced by seed flax varieties. Seed flax yields are about twice those of seed from fibre flax under similar conditions. The United States, Argentina, the U.S.S.R., India, Canada and Uruguay are the leading countries in linseed production, but appreciable quantities are produced in 25 other countries on all continents. Production in the United States ordinarily averages more than 38,000,000 bu. on more than 4,000,000 ac., with a yield of 9.3 bu. an acre. North Dakota, Minnesota and South Dakota usually lead in total production but the highest yields are obtained on irrigated lands in Arizona and California.

The crop is grown from fall or early winter seeding in California, Texas and Arizona and other warm climates where it ripens about five months later. It is sown in the spring in northern Europe and in the northern half of the United States where it matures in 80 to 120 days. Flaxseed usually is sown with a grain drill, about 1 in. deep, at the rate of 30 to 50 lb. per acre. Flax is an excellent companion crop with which to sow meadow grasses and legumes. A clean seedbed, which is desirable, is best obtained when flax is preceded by an intertilled crop or a sod crop and the land is worked frequently before sowing the flax. Certain weedy grasses as well as broadleaved weeds in flax fields can now be controlled with suitable chemical herbicides.

Seed flax is harvested and threshed with a combine in the more advanced agricultural countries but simple harvesting and threshing machines or hand methods are still used on numerous small farms in many countries.

Flax is attacked by several diseases including wilt, rust, pasmo and anthracnose. These diseases are kept under fair control by chemical seed treatment or by growing resistant varieties that were developed by flax breeders. Before wilt resistant varieties were developed, flax could be grown on the same land for only a few years before the crop failed because the soil became infested with the fungus causing the wilt disease. This fact led to the popular misconception that "flax is hard on land." From colonial times until about 1920 flax production shifted westward to new lands that were not infested with wilt. Later, resistant varieties became available for all parts of the United States.

Linseed Oil.—Flaxseed contains from 30% to 40% oil and about 8% moisture. Large seeds are highest in oil content. Drought or temperatures above 90° F. when the seed is developing reduces the seed size and the oil content. A bushel (56 lb.) of linseed yields about 2½ gal. of oil in commercial crushing. Linseed oil contains three unsaturated fatty acids (oleic, linoleic and linolenic) that absorb oxygen and thus when used in paint cause the oil to form a hard film when the paint dries. The quality of a drying oil is measured by the iodine number, the grams of iodine absorbed by 100 g. of oil in a chemical test. The iodine number of linseed oil ranges from 160 to 195. In linseed oil mills the flaxseed is ground, steamed and then pressed to extract the oil. The residue or oilcake contains about 35% protein and 6% oil. It is used as a concentrated or conditioning feed for livestock. Linseed oil is used chiefly in paints and varnishes but also in making linoleum, oilcloth, printer's ink and patent leather.

Tow extracted from seed flax straw in the United States is used in making the domestic requirements for cigarette paper and Bible paper.

FLAXMAN, JOHN (1755–1826), English sculptor and draftsman, was born at York on July 6, 1755. His father was a modeler of plaster casts, and his early training was largely received at home. He was awarded a medal as a prize by the Society of Arts at the age of 12, and at 15 began to exhibit at the Royal Academy. At 20 he was working for Josiah Wedgwood as a modeler of medallions, portraits, vases, plaques, etc., and this activity accounted for much of his later fame. He continued to work for Wedgwood till 1787, developing into a sensitive neoclassicist with a manner of seeing which during his mature years was everywhere the fashion.

In 1782, Flaxman was married to Anne Denman. In 1787 they set out for Rome. Flaxman soon ceased modeling for Wedgwood himself, but continued to direct the work for other modelers employed for the manufacture at Rome. He had intended to return after a stay of a little more than two years, but was detained by a commission for a marble group of a "Fury of Athamas" from Frederick Hervey, earl of Bristol and bishop of Derry, and did not return until the summer of 1794, having in the meantime executed another commission (a "Cephalus and Aurora") for Thomas Hope, and having sent home models for several sepulchral monuments, including one in relief for the poet William Collins, in Chichester cathedral, and one in the round for Lord Mansfield in Westminster abbey.

But what gained for Flaxman in this interval a general and European fame were those outline designs to the poets, in which he showed his natural affinity to the ancients. The designs for the *Iliad* and Odyssey were commissioned by Mrs. Hare-Naylor; those for Dante by Hope; those for Aeschylus by Lady Spencer. All were engraved by Piroli, not without considerable loss of the finer and more sensitive qualities of Flaxman's own lines.

In 1797 Flaxman was made an associate of the Royal Academy. Every year he exhibited work of one class or another; occasionally a public monument in the round, more often memorials for churches, with symbolic acts of mercy or illustrations of Scripture texts, both commonly in low relief. In 1800 he was elected full academician. In 1810 he was appointed to a chair of sculpture specially created for him by the Royal Academy.

The most important works which occupied Flaxman in the following years were the monument to Mrs. Baring in Micheldever church, the richest of all his monuments in relief (1805–11); that for the Worsley family at Campsall church, Yorkshire, which is the next richest; those to Sir Joshua Reynolds for St. Paul's (1807); to Capt. Josiah Webbe for India (1810); to Captain Walker and Captain Beckett for Leeds (1811); to Lord Cornwallis for Prince of Wales's Island (1812); and to Sir John Moore for Glasgow (1813).

After his Roman period he produced for a good many years no outline designs for the engraver except three for William Cowper's translations of the Latin poems of Milton (1810). Other sets of outline illustrations drawn about the same time, but not published, were one to the ***Pilgrim's Progress,*** and one to a Chinese tale in verse, called "The Casket." In 1817 we find him returning to his old practice of classical outline illustrations and publishing the happiest of all his series in that kind, the designs to Hesiod, excellently engraved by the sympathetic hand of William Blake. Immediately afterward he was much engaged in designing for the goldsmiths—a testimonial cup in honour of John Kemble and following that, the great labour of the famous and beautiful though quite un-Homeric shield of Achilles. Almost at the same time he undertook a frieze of "Peace, Liberty and Plenty," for the duke of Bedford's sculpture gallery at Woburn, and a heroic group of Michael overthrowing Satan, for Lord Egremont's house at Petworth. He died on Dec. 3, 1826.

As a sculptor Flaxman was weakest when he was most ambitious and most inspired when he made the least effort. Of Flaxman's complicated monuments in the round, such as the three in Westminster abbey and the four in St. Paul's, there is scarcely one which has not something heavy and infelicitous in the arrangement. But when we come to his simple monuments in relief we find almost always a far finer quality. He did not thoroughly understand composition on the great scale and in the round, but he did thoroughly understand relief, and found scope in it for his remarkable gifts of harmonious design, and tender, grave and penetrating feeling.

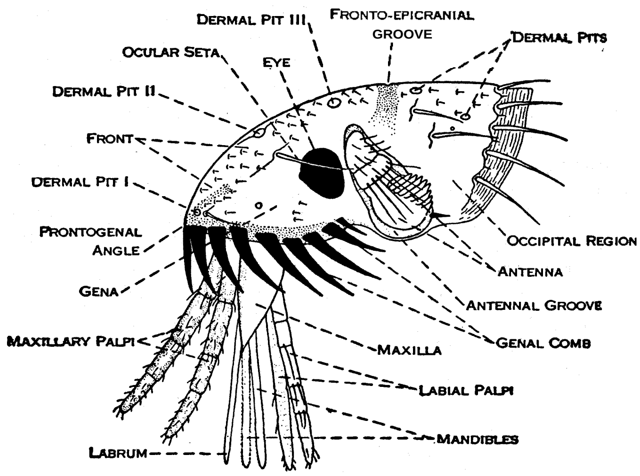
of Flaxman (1876); C. R. Leslie, *Life and Letters of Constable* (1896); *W. G.* Constable, *John Flaxman, 1755–1826* (1927). (A. K. McC.)

FLEA, the common name of a group of insects, known scientifically as the order Siphonaptera (or Aphaniptera), whose members are of economic importance because they are transmitters of human disease and because they are serious pests of man and animals. In the adult state they feed exclusively on the blood of birds and mammals, including man, but in the immature stages they are residents of the nest or habitation of the host and are not parasitic.

For the flea commonly known in the United States as "chigger," *see* JIGGER, CHIGGER or CHIGOE.

Structure and Life History.- leas are small insects, the largest ones being about one-fourth of an inch in length. They are wingless and have a greatly compressed body which is frequently provided with one or more combs of spines. Their well-developed legs give them remarkable powers of leaping, and they can jump a horizontal distance of about 13 inches—from 50 to 100 times their body length! As the adult subsists solely on blood, the mouthparts are adapted for piercing the skin of the host and sucking its blood. A penetrating beak is formed by the two mandibles and the labrum. From the accompanying illustration it will be seen that the mandibles are long, cutting blades with saw-toothed margins, while the labrum is flattened and needlelike. The drawing shows many other interesting features of the flea's head.



COURTESY OF U S. DEPARTMENT OF AGRICULTURE

HEAD OF A CAT FLEA *(Ctenocephalides felis)*, FEMALE. WITH THE DIFFERENT PARTS LABELED: DRAWING BY HENRY ELLSWORTH EWING

Among these are the simple eyes (degenerate or absent in some species), the short, stout antennae, and the genal comb of heavily pigmented spines, which is a conspicuous structure when it is present. The life history of the flea involves four distinct stages—the egg, the larva, the pupa and the adult. A number of eggs are laid by each adult female flea, commonly among the hairs or feathers of the host, from which they fall out into the nest or places where the animals roam or rest. The immature stages are therefore found in the situations frequented by animals. The cream coloured eggs hatch into small, yellowish, wormlike larvae which live in the organic debris of the resting place of the host. After a time, the larva transforms into the pupa which develops within a silken cocoon. ,The length of time necessary for completion of the entire life cycle is variable and depends upon the species concerned and upon various conditions; it may be from 17 days to more than a year.

Economic Importance and Control.—There are many known kinds of fleas. From North America and the West Indies, by the beginning of World War II, 209 species and 63 subspecies and varieties were recorded. How many occur in other parts of the world is difficult to ascertain, but certainly the number after World War II was in the vicinity of 500 known species. Only a few of these species affect man; the rest feed upon obscure wild birds and mammals, having strong preference for certain hosts. Nearly all species show this "host specificity." However, a few fleas are sufficiently versatile to feed upon man in the absence of their favoured hosts, and these are the ones of greatest importance, because they are capable of transmitting disease from animal to man.

Bubonic plague and murine typhus, a disease of increasing importance in the United States, are carried from rats to man by fleas. Two species are ordinarily involved in the transmission of these diseases, the oriental rat flea (*Xenopsylla cheopis*) and the European rat flea (*Nosopsyllus fasciatus*). The former is almost cosmopolitan in distribution but prefers particularly the warmer regions of the world. It is an efficient vector of disease because it bites humans freely. Plague is a disease which affects not only rats but also various wild rodents such as ground squirrels, chipmunks and even rabbits. Reservoirs of infection exist among these animals and are maintained by the fleas which carry the disease from one individual to another. Control of rodent fleas must be directed against the hosts, and this involves trapping, poisoning and fumigating as well as the ratproofing of buildings.

Fleas affect man not only as disease carriers but also as household pests. The principal ones which most frequently annoy man are: the dog flea *(Ctenocephalides canis)*, the cat flea (*Ctenocephalides felis)* and the human flea (*Pulex irritans)*. The United States department of agriculture recommends three steps in their control: (1) determine the source of the infestation. (2) treat or destroy the animal hosts, and (3) destroy the immature stages occurring in places where the hosts live. When fleas occur in human habitations they nearly always originate from animals which troop in and out or from the places where animals sleep or rest. To rid cats and dogs of fleas apply derris powder or pyrethrum powder to their skin and repeat the treatment every two weeks until the animal is free of the pest. When hogs are infested, their backs should be sprayed lightly with oil. If the fleas originate from cellars, outbuildings, porches, barns and beneath houses, spray the infested area with creosote oil. Should the use of creosote be objectionable, scatter flaked naphthalene over the floor, using enough to make the floor white in appearance.

The most injurious of the livestock-infesting species is the sticktight flea *(Echidnophaga gallinacea)* which causes damage to poultry. Its common name derives from the habit of attaching itself to the skin of the host. It attacks not only chickens but dogs, cats and man himself, as well as many other animals. Derris, powder or carbolated vaseline brought into contact with these fleas will control them.

The irritation caused by the bite of a flea in man is ordinarily not very serious. To assuage the pain a cooling lotion should be applied, such as mentholated ointments, carbolated vaseline, spirits of camphor, etc.

FLÈCHE, an architectural term which, in France, signifies any spire, but in English usage is limited to those small, slender spires which are placed on the ridge of a roof of a church and not upon a tower. The flèche is usually built of a wood framework covered with lead or occasionally copper and is generally of rich, light, delicate design, in which tracery, miniature buttresses and crockets have an important part. They are frequently of great height, that of Notre Dame, Paris, being nearly 100 ft. and that of Amiens, 148 ft. The fleche is usually placed at the intersection of nave and transepts. Reims cathedral had, however, an additional flèche at the summit of the apse. *See* SPIRE.

FLÉCHIER, VALENTIN ESPRIT (1632–1710), bishop of Lavaur (1685) and Nîmes (1687), one of the celebrated court preachers under Louis XIV, was born at Pernes near Avignon, June 10, 1632. He was admired as a man of letters rather than as a devout preacher, and his sermons were particularly relished by women, He wrote *Mémoires sur les Grands Jours tenus à Clermont en 1665.* In dealing with the Huguenots, he proved himself a wise and humane bishop. He died at Montpellier, Feb. 16, 1710.

FLECKEISEN, ALFRED (1820–1899), German philologist and critic, chiefly known for his work on Plautus and Terence, was born at Wolfenbuttel on Sept. 23, 1820. He was educated at the Helmstedt gymnasium and the University of Göttingen. After holding several educational posts he was appointed in 1861 to the vice-principalship of the Vitzthum'sches gymnasium at Dresden, which he held until his retirement in 1889. He died on Aug. 7, 1899. In the knowledge of Plautus and Terence he was unrivaled, except perhaps by F. W. Ritschl. his life-long friend. Fleckeisen's chief works are: *Exercitationes plautinae* (1842), one of the most masterly productions on the language of Plautus; *Plauti Comoediae,* i, ii (1850–51, unfinished); *P. Terenti Afri Comoediae* (new ed., 1898). His short treatise on orthography *Fünfzig Artikel* (1861) is considered most valuable. Fleckeisen was for many years editor of the *Jahrbücher fur classische Philologie.*

FLECKER, JAMES ELROY (1884–1915), English poet was born in London on Nov. 5, 1884. Desiring to enter the consular service, he went to Caius college, Cambridge. to learn oriental languages, and he was sent to Constantinople in June 1910. The same year his *Twenty-sin: Poems* was published. In September, having fallen ill, he returned to England and went to a sanatorium. He returned to his post. apparently cured, in March 1911, and was transferred to Smyrna in April. He fell ill again early in 1913, and went to Switzerland: *The Golden Journey to Sanzarkand* was published in this year. He died at Davos on Jan. 3, 1915. He belongs to no "school," though the Parnassians are known to have had some influence on him. Of his many themes the most recurrent are Greece, the east and England, and he has best portrayed himself in *Oak and Olive.* But at least it seems safe to conjecture that some of his lyrics, between the sculptured stillness of *A Ship, an Isle* and the movement, so expressive in utterly different ways, of *Saadilbad* and the *Dying Patriot* will not be forgotten. He left behind him at his death two unpublished plays, *Hassan* (Haymarket. 1923) and *Don Juan. Don Juan* is perhaps too slight and unequal to support a claim to dramatic genius. *Hassan* is rather a different matter. No one would call it faultless, but as a play to read. with its colour and its wit and its passion, its alternation of merriment and tragedy, and the strange beauty of its rhythms it is entirely fascinating. Flecker also wrote *The Grecians* (1910) and a novel, *The Kzng of Alsander* (1914).

Editions of his work are *Collected Poems,* with an introduction by J. C. Squire (1916); *Hassan* (1922); *Don Juan* (1925); *Collected Prose* (1920 and 1922); *Letters to Frank Savery* (1926).

See D Goldring, *J. E. Flecker* (1922); and the *Life* by Geraldine Hodgson (1925).

FLECKNOE, RICHARD (*c.* 1600–*c.* 1678), English poet, dramatist and traveler, whose writings evoked both praise and ridicule, was possibly a Jesuit of Irish extraction. The most authentic information about him is *A Relation of Ten Years' Travels in Europe, Asia, Affrique, and America* (1654?), a collection of letters to distinguished persons in England and abroad. He went to Flanders in 1640, attempted in 1645 to negotiate in Rome the marriage of Béatrix de Cusance to Charles IV of Lorraine, traveled in the Levant, visited Portugal, and in 1648 "merely on curiosity" went to Brazil. Although he appears vain and cocksure, his letters are interesting, particularly his account of Brazil.

Flecknoe's picture of himself as a popular ladies' man contrasts sharply with Andrew Marvell's account in his poem, "Fleckno, an English Priest at Rome," which ridicules his threadbare asceticism and bad verses. The unpopularity which greeted his return to England may have resulted from his disapproval of the licence of the stage, implicit in his *Short Discourse of the English Stage* (1664; reprinted in J. E. Spingarn's *Critical Essays of the 17th Century,* 1908), which he prefixed to the revised version of *Love's Dominion* (1654) the only one of his five plays to be publicly performed. This may also account for the hostility of Dryden, who lampooned him in *MacFlecknoe* (1682) as being "Throughout the realms of Nonsense, absolute." Neither his poems in *Epigrams of all sorts . . .* (1670) nor his prose sketches in *Enignzatical characters . . .* (1658) warrant such an attack and both Lamb and Southey attempted to restore his reputation; Lamb prefixed some of Flecknoe's lines to his essay, "A Quakers' Meeting." Flecknoe remains a contradictory personality who praised Cromwell in *The Idea of his Highness Oliver* (1659) and the Stuarts in *Heroick Portraits* (1660).

FLEET, NAVAL. The word fleet is used with several meanings, logically related but differing in their precise connotation. It is sometimes defined as the collective naval force of a country, and naval men frequently use it in this sense. For example, the first lord of the admiralty, in a statement to parliament in Feb. 1958 used a subtitle, "The Strength of the Fleet," followed by this explanation: "During the coming year the ships of the Fleet will be deployed as follows: (A.) Ships in the Operational Fleet. or preparing for service with it. (B.) Ships engaged on Trials and Training (C.) Fleet Support and Auxiliaries. (D.) Ships in all classes of Reserve or undergoing extended refit, modernization, conversion, etc.. during the course of the year." During and since World War II the Royal Navy has had a home fleet and a Mediterranean fleet, each with a commander in chief, besides a number of commands, forces, stations and flotillas responsible to the admiralty and not to either fleet commander. Thus the word fleet means a large group of naval vessels of many types under a single commander in chief, and usually assigned to one geographical area. In a loose sense, fleet is applied to a large number of ships, as a fishing fleet, the Cunard fleet or a fleet of oil tankers.

The U.S. navy did not employ the word fleet officially until 1907 when the Atlantic fleet, Pacific fleet and Asiatic fleet were established. Previously there had been a home squadron, a Pacific squadron and so on. After temporary disruption of this arrangement during World War I, it was restored in 1922. During the years that followed. the U.S. fleet consisted of a battle force, scouting force. submarine force and base force. Since World War II there have been Atlantic and Pacific fleets, each with an admiral as commander in chief; Atlantic and Pacific reserve fleets, under the commanders of the Eastern and Western Sea Frontiers; and four numbered fleets, 1st in the Pacific, 7th in the far east, both a part of the Pacific fleet; 2nd in the Atlantic and 6th in the Mediterranean, both belonging to the Atlantic fleet. Each of the six subordinate fleets had a vice-admiral as commander.

Administrative and Tactical **Groupings.**—In the U.S. navy each of the two major fleets had commanders in charge of the air force, cruiser force, destroyer force, submarine force, amphibious force and service force. These officers were called type commanders or administrative commanders; some were vice-admirals, others rear admirals. Three to six vessels constituted a "division" of aircraft carriers, cruisers, destroyers, submarines, transports, mine sweepers and other types. The division commanders were considered to be tactical commanders primarily. Frequently a force commander would also command a division of his own force. Two divisions of destroyers or of submarines constituted a squadron, and the squadron commander commanded one of the divisions. Three destroyer squadrons made a flotilla. Rear admirals usually commanded aircraft and cruiser divisions and destroyer flotillas. Service force and amphibious force squadrons, destroyer and submarine squadrons were commanded by captains. Divisions of destroyers, submarines, and mine craft were commanded by captains or commanders.

Fleet Tactical Training. — Although a fleet comprises ships of various types it will not be an effective fighting unit unless the ships are capable of working together as a team and can be controlled by the commander. This necessitates continuous tactical training and study. A new naval vessel, or one which has undergone an extensive reconstruction, runs a series of trials over a measured-mile course, or over a range which can be measured accurately by means of positions on a chart. By means of such trials, calibration scales are developed and the ship's engineer officer knows how many revolutions of his propellers normally produce a given speed. By further trials, in an area where precise positions can be fixed by cross bearings, the new ship determines the necessary rudder angle to turn through 90° or 180° at usual speeds. These two processes are necessary steps in preparing the ship to steam in formation with other vessels and to make turns while in formation. When a new ship has "standardized" her own steaming and her own turning she is ready to steam with others, beginning with vessels of her own type.

Fleet Tactical Formations. — There are three elemental formations involving a single line of ships. If all ships present steamed in single file, all on the same course, one astern of the other, they would form a straight line. The Royal Navy called this formation "line ahead." while the U.S. navy called it "column." If the ships were abreast of each other, the Royal Navy called it "line abreast" and the U.S. navy simply "line." Any other form of line was called "line of bearing," with the bearing designated by signal.

A large fleet would usually form a more complicated formation. For example. three squadrons of eight ships each might steam with each squadron in column or line ahead, while the three flagships leading their respective squadrons might be abreast of each other. In the U.S. navy this formation would be line of squadron columns; in the Royal Navy it mould be squadrons in line ahead. disposed abeam. More complicated formations presented no problems to ships accustomed to maintain position and distance in the elemental formations and to turn in standard turning circles on signal. Type commanders had the responsibility for developing tactical instructions for their own vessels so that these ships would conform to the standards of the fleet as a whole. Tactical commanders had the responsibility for insuring that their own ships could maneuver with the fleet without becoming a menace to their neighbours in formation. Proficiency in fleet maneuvers was possible only if the fleet systematically and regularly steamed together at sea, in bad weather as well as in good. The study of fleet tactical manuals helped to expedite the attainment of high standards, but practice at sea was indispensable. When a fleet was well trained it could pass from one formation to another without confusion or delay.

Battle Formations. — In the days of sail, the great sailing ships of the line-of-battle formed in a single line to fight the enemy with broadsides, keeping their frigates on the unengaged side of their line for the protection of these vessels and to use them for repeating signals. In World War I and earlier the battleships formed the battle line, and kept their cruisers and destroyers ahead and astern of this battle line.

In World War II the presence of the aircraft carrier completely changed fleet dispositions. All formations were circular, with the carriers in the centre, battleships and cruisers deployed in a circle outside the carriers, and destroyers on an outer circle. One large ship was designated as guide and all others kept their bearing and distance on the guide. The carrier task force in the Pacific in 1944–45 usually consisted of 4 carrier groups, each in its own circular formation with 3 to 5 carriers. 2 or 3 battleships. 4 to 8 cruisers, 10 to 18 destroyers. When the carriers of a group launched or recovered planes, the entire circular formation of that group headed into the wind by simultaneous ship turns. In these formations the carriers were allowed slightly more leeway than the other ships in their station keeping, but they had to remain close to their designated positions.

NATO Tactical Formations. — After the establishment of the North Atlantic Treaty organization (NATO) all of the participating navies combined to devise uniform tactical instructions, doctrine and formations for cruising and battle. All formations became circular. Thus the tactical practices of the Royal Navy and the U.S. navy merged in the common instructions governing the NATO navies.

TYPES OF VESSELS

Combatant vessels include the aircraft carrier; battleship; cruiser; submarine; frigate and other destroyer (*qq.v.*) types, including corvette and sloop; and escort and patrol vessels. All of these types are men-of-war. Gunboats. which vary considerably in size. armament and speed, submarine chasers and motor torpedo boats also belong to the combatant vessels classification, although their effectiveness is much limited in bad weather.

Mine craft and amphibious types are in a slightly different category. Mine layers and mine sweepers frequently enter enemy waters in wartime and have little or no defense against enemy attack. Vessels of the various amphibious types, including attack transports, attack cargo vessels. landing ships or fast transports, as well as the smaller landing craft and rocket launchers are all designed to enter enemy territory under fire and sustain enemy attacks, although they are extremely vulnerable. Command ships are subject to the same hazards.

During and since World War II, mine craft and amphibious craft have been considered combatant ships because of the nature of their normal employment in wartime, although they are obviously not fighting ships in the same sense as the types listed in the preceding paragraph.

Fleet auxiliary vessels are manned by officers and men of the navy and are built for the service of the fleet. The U.S. navy is proud of the fact that it pioneered in the development of destroyer and submarine tenders, fleet repair ships and fleet oil tankers. The tenders for destroyers and submarines were developed when vessels of these two types were much smaller than they were after World War II They supplied food, clothing, miscellaneous stores and repair facilities nhich were beyond the capacity of the destroyers and submarines themselves. Fleet repair ships were capable of many kinds of repair work which were impossible for the largest men-of-xar to execute with their own facilities. and they undertook jobs for which the tenders lacked equipment.

During World War II many repair ships were commissioned to specialize in particular types of repair work, such as the overhaul

of diesel engines, etc. Seaplane tenders served the large long-range patrol planes and furnished living quarters for their men, as well as repair facilities for the planes. Ammunition ships were partly improvised in World War II, but the U.S navy had a few that were designed for this duty; they were able to control temperatures and humidity in their ammunition and powder storage spaces to avoid any possibility of deterioration. The fleet oil tankers were equipped for fueling ships at sea while under way, and they had facilities for passing supplies across to the ships receiving fuel oil while the fueling was in progress.

Fleet supply ships were equipped to carry fresh meat and other refrigerated items, as well as what the navy calls dry provisions, meaning food in cans, barrels, sacks or packages; they also had stowage for potatoes and for miscellaneous ships' stores, including stationery, cleaning materiels, paints, etc. Fleet stores ships were fitted for carrying miscellaneous fleet supplies, including dry provisions, so arranged that particular items could be supplied to tenders and other ships which requested them. Submarine rescue vessels usually were seagoing fleet tugs fitted with some special equipment which would be especially useful in helping damaged vessels. including submarines. Salvage vessels varied in their facilities and equipment, but some of them were employed in the extensive work of clearing harbours after many ships had been sunk by gunfire or aerial bombs or both.

Service Squadrons in Advanced Areas.—Before World War II the fleet organization of the U.S. navy included a fleet base force. sometimes called the "fleet train," which became the service force during that war. A few squadrons of this force, notably service squadron ten, became especially well known for their effective and immediate service to vessels of the fleet in the forward areas in the Pacific. This squadron began operating in Majuro atoll in Feb. 1944, and afterward moved to Eniwetok, thence to Ulithi. The squadron had one or more of each of the types of fleet auxiliary vessels described in the preceding paragraph, plus many others.

Perhaps even more important than the ships available, the squadron equipment included three floating drydocks: one small one capable of lifting 1,000 tons, a medium dock to lift 3.000 tons and a gigantic sectional floating dock able to lift 80,000 tons, and thus able to take any ship of the fleet. A barracks vessel had quarters for 60 officers and 1,000 men. There were four repair barges besides the repair ships, four ocean-going fleet tugs, four harbour tugs, four rescue tugs and one salvage barge in addition to two salvage ships. There were also net tenders, net layers and a net cargo ship to keep the lagoon entrance closed to enemy submarines. Two floating cranes, a degaussing barge, water barges, picket boats and patrol boats completed the aggregation afloat in the lagoon. Later a dozen large concrete stores barges were brought to the atoll and these were used as floating storage. Some of them had refrigeration in some storerooms. Supply and stores ships discharged their cargoes into these barges and returned to the mainland for reloading.

Other service squadrons were established and located at other islands or atolls in the Pacific. It would be difficult to exaggerate the value of these service squadrons because they made it possible for a number of seriously damaged ships to be patched up sufficiently to return to the mainland for major repairs. The repair ships and tenders demonstrated that they could accomplish almost anything in the form of repairs, but there was so much to be done that it was necessary to send to the mainland for the big jobs rather than tie up all the repair facilities of the squadron.

The Royal Navy's fleet support and auxiliaries listed by the first lord in his report to parliament (mentioned above) included: destroyer depot ships, submarine depot and support ships, repair ships, deep diving vessels, mine layers, a coastal mine-sweeping headquarters ship, a survey ship, boom defense vessels and harbour accommodation ships.

The only noncombatant ships in the U.S. navy were hospital ships; the Royal Navy had none in commission. Under international law these vessels carry no arms of any kind. When they cruise at sea in wartime they show lights and keep the red cross on the funnel and on the ship's side illuminated at night. Hospital ships joined each of the service squadrons in the Pacific during World War II and while there, in anchorages where men-of-war were present, they showed no lights at night.

The U.S. navy had a few special types of vessels in operation in 1958, including surveying ships, icebreakers and ocean radar station ships. These latter remained on fixed cruising stations well off the coast and were in a position to report by radio concerning anything to be seen on their powerful radars.

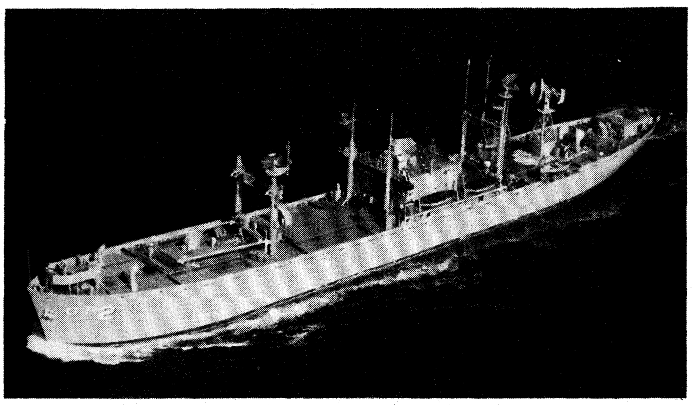
NAVY HOSPITAL **SHIP U.S.S.** "REPOSE"

Reserve Fleets.—Ships of the Royal Navy in reserve consisted of three groups. The operational reserve included ships in commission with reduced complements on board, which could put to sea fully manned and equipped within a very short period of time. It was a substantial force and included a number of escort vessels. The second part was called the supplementary reserve. It consisted of ships in very good condition. in a state of preservation called "moth-balling." Such ships would require a certain amount of time before they could be restored to active service. The number of destroyers and frigates in these first two reserve groups in 1958 was stated to be about the same as the number in the seagoing fleet. The vessels in this maintained reserve would be kept in that status until their useful lives had ended, unless their services were found to be required sooner.



BY COURTESY OF U.S. DEPARTMENT OF THE NAVY

OCEAN RADAR WARNING SHIP U.S.S. "LOOKOUT"

The third class was called the extended reserve. It consisted of ships of wartime design and construction which had not been modernized. The majority of the vessels had not had a refit for five years or longer These ships were tied up in an unattended condition; their maintenance cost was almost nothing, but under these circumstances they were deteriorating. They were cruisers 18 to 20 yr. old. destroyers 14 to 17 yr. old, ocean mine sueepers built in nartime and frigates 14 to 17 yr. old It mas stated explicitly that the five carriers in reserve could not be modernized; that even if they mere cut down to the waterline their hulls would not be satisfactory for modernization.

The reserve fleets of the U S. navy in the late 1950s were located on the two coasts. About 28 destroyers were in commission in reserve with partial crews and did some operating. About 34 destroyer escorts were assigned to naval reserve training and had full creus of reservists assigned on a mobilization basis. These vessels regularly made one week-end cruise per month and one annual cruise of 14 days, with their assigned complement of reserve officers and men.

A small number of reservists serving on active duty were the instructors for their shipmates, and these men were the shipkeepers between cruises. A number of submarines were assigned for reserve training, but these ships were partially moth-balled with their propellers removed. The reservists assigned to them made their training cruises in regularly commissioned submarines.

All other ships of the Atlantic and Pacific reserve fleets were in "moth balls," with the ships dehumidified and all their equipment and machinery in a state of preservation. Groups of ships in this status were berthed at piers on both the east and west coasts. The navy department planned to scrap some older battleships, aircraft carriers, cruisers and submarines but not destroyers or destroyer-type vessels from the reserve fleets.

(J. B. HN.)

FLEETWOOD, CHARLES (d. 1692), English soldier and politician, was admitted into Gray's Inn on Nov. 30, 1638. At the beginning of the Great Rebellion, he joined Essex's lifeguard. was wounded at the first battle of Newbury, obtained a regiment in 1644 and fought at Naseby. He had already been appointed receiver of the court of wards and in 1646 became member of parliament for Marlborough. He was said to have been the principal author of the plot to seize King Charles at Holmby, but he did not participate in the king's trial. In 1649 he was appointed a governor of the isle of Wight, and in 1650, as lieutenant general of the horse, took part in Cromwell's campaign in Scotland and assisted in the victory of Dunbar. Next year he was elected a member of the council of state, was entrusted with the command of the forces in England, and shared in the final triumph at Worcester. In 16jz he married Cromwell's daughter and was made commander in chief in Ireland, to which title that of lord deputy was added. During his administration (1652–55) he carried out ruthlessly the settlement of the soldiers on the confiscated estates. He showed great severity in the prosecution of the Roman Catholic priests, and favoured the Anabaptists and the extreme Puritan sects.

Fleetwood was a strong and unswerving follower of Cromwell's policy. In Dec. 1654 he became a member of the council, and after his return to England in 1655 was appoii red one of the major generals. On Cromwell's death, he was regarded as a likely successor. and it is said that Cromwell had in fact so nominated him. He, however, supported Richard Cromwell, but allowed subsequently, if he did not instigate, petitions from the army demanding its independence, and finally compelled Richard by force to dissolve parliament. His project of re-establishing Richard in close dependence upon the army met with failure and the Long Parliament was recalled. Fleetwood became a member of the committee of safety and of the council of state, and one of the seven commissioners for the armv: on Tune 4 he was nominated commander in chief. But on Oct. 11 parliament declared his commission void. The next day he assisted Lambert in his expulsion of the parliament and mas reappointed commander in chief. On Monk's approach from the north, he stayed in London and maintained order. The army on Dec. 24 restored the Rump, when he was deprived of his command and ordered to appear before parliament to answer for his conduct. At the Restoration he was included among the 18 who were punished only by perpetual exclusion from public office, and his public career therefore closed, though he survived until Oct. 4, 1692.

FLEETWOOD, WILLIAM (1656–1723), English divine, was born in the Tower of London on New Year's day, 1656. He was educated at Eton and King's college, Cambridge. About the time of the Revolution he took orders, and became bishop of St. Asaph (1708), then of Ely (1714). He died at Tottenham on Aug. 4, 1723. Fleetwood's opposition to the doctrine of nonresistance brought him into conflict with the Tory ministry of 1712 and with Swift, but he never entered into personal controversy.

His principal writings are: *An Essay on Miracles* (1701); *Chronicum preciosum* (an account of the English coinage, 1707); and *Free Sermons* (1712), containing discourses on the death of Queen Mary, the duke of Gloucester and King William. The preface to this last was condemned to public burning by parliament, but, as no. 384 of *The Spectator,* circulated more widely than ever. A collected edition of his works, with a biographical preface, was published in 1737.

FLEETWOOD, a municipal borough, seaport and holiday town in the North Fylde parliamentary division of Lancashire, Eng., at the mouth of the Wyre, 9 mi. N.N.E. of Blackpool. Pop. (1951) 27,537. It dates its rise from 1836 and takes its name from Sir Peter Hesketh Fleetwood (1801–66), who laid it out.

Fleetwood looks northward over Morecambe bay to the Lake district and has large sandy beaches. A market is held Tuesdays and Fridays. A ferry crosses the Wyre to Knott End-on-Sea. Rossall school, formerly Rossall hall and the seat of Sir Peter Hesketh Fleetwood, was founded in 1844 and incorporated by royal charter in 1890. It is a large fishing port, with extensive docks and fish docks and ancillary industries. Coastal and Irish trade shipping is carried on.

FLEGEL, EDWARD ROBERT (1855–1886), German traveler, who attempted to open up West Africa for the Germans, was born on Oct. 13, 1855 at Vilna, Russia. He was appointed to a post in Lagos, West Africa, in 1875 and in 1879 traveled up the Benue river about 125 mi. farther than the point previously attained by European travelers and was commissioned by the German-African society to explore the whole of the Benue country. In 1880 he went by way of the Niger to Sokoto and there obtained permission from the sultan for an expedition to Adamawa. This was undertaken in 1882 and on Aug. 18 he discovered the source of the Benue near Ngaundere. In 1883–84 he again explored on the Benue. After a short stay in Europe, Flegel returned to Africa in April 1885 with a commission to open up the Niger-Benue basins to German influence and so prevent the British from establishing themselves in that part of West Africa. He was unsuccessful and died at Brass (Guinea) in the Niger delta on

Sept. 11, 1886.

Flegel wrote Lose Blatter *aus* dem Tagebuch meiner *Haussa*-freunde (1885); Vom *Niger-Benuë;* Briefe aus Afrika, edited by K. Flegel (1890). (R. M. P.)

FLÉMAL (FLEMAEL), **BERTHOLET** (1614–1675), Flemish painter, a pioneer of the classicist movement in his country, was born at Liège, Belg.. on May 23, 1614. He studied under Henri Trippez and Gerard Douffet. He went to Italy in 1638, returning via Paris, where he decorated the churches of the Grands Augustines and the Carmes Déchaussés. He returned to Liège in 1663. In 1670 he was elected member of the Paris academy. and he painted the ceiling of the audience chamber in the Tuileries (destroyed in 1871). He is one of the most important masters of the later Flemish school. His style is modeled on that of Poussin. Most of his numerous religious pictures in the churches of Liège were destroyed and lost during the French Revolution. However, there are several works still extant in the cathedral and in the churches of St. Jean, St. Barthelemy and Ste. Croix. Others are in the museums of Likge, Bamberg, Brussels, Dresden, Fontainebleau, Cassel, Stockholm, Niort and in the Louvre, Paris. Flémal was also a distinguished portrait painter. His self-portrait was engraved by Jean Duvivier.

Flémal died at Likge on July 10, 1675.

FLÉMALLE, LE MAÎTRE DE: see CAMPIN, ROBERT.

FLEMING, SIR ALEXANDER (1881–1955), British bacteriologist and discoverer of penicillin and 1945 Nobel laureate in medicine! was born at Lochfield, Ayrshire, Scot. on Aug. 16, 1881. He was educated at Kilmarnock academy and St. hlary's Hospital medical school, University of London, winning academic distinction at both institutions. Following his graduation he did research work at St. Mary's under Sir Almroth Wright, pioneer in vaccine therapy, and became interested in bacterial action and antiseptics. During World War I Fleming served as a captain in the army medical corps (1914–18) and was mentioned in dispatches.

After military service?during which he was able to make further studies of the problems of infection and use of antiseptics, Fleming returned to laboratory work and teaching bacteriology at St. Mary's. In 1919 he was appointed Hunterian professor and in 1928 Xrris and Gale lecturer at the Royal College of Surgeons. In the laboratory Fleming's interest continued in antibacterial substances which would be nontoxic to animal tissues. The first fruit of his search was the discovery of the antibiotic lysozyme. His epochal discovery in 1928 of the antibacterial powers of the mold from which penicillin is derived was a "triumph of accident and shrewd observation." While he was engaged in research on influenza, mold had developed accidentally on a staphylococcus culture plate, and Fleming discovered that the mold had created a bacteria-free circle around itself. Experimenting further, he found that a liquid mold culture, which he named penicillin, prevented growth of staphylococci, even when diluted 800 times. He published his results in the Journal of *Experimental* Pathology in 1929.

Fleming was made fellow of the Royal society in 1943, was knighted and given the John Scott medal in 1944, and awarded the Nobel prize, with Sir Howard Walter Florey and Ernst Boris Chain (*qq.v.*) in 1945. He died March 11, 1955, in London. See also PENICILLIN.

FLEMING, PAUL (1609–1640), German poet, was born at Hartenstein in the Saxon Erzgebirge, on Oct. 5, 1609, the son of the village pastor. He studied at Leipzig until driven away by the troubles of the Thirty Years' War. He was attached by Duke Frederick of Holstein-Gottorp to an embassy (1634–39) to Russia and Persia, to which the famous traveler Adam Olearius was secretary. Fleming died at Hamburg on April 2, 1640.

Fleming's *Teutsche Poëmata* (pr. 1642) mere edited by J. M. Lappenberg, in the Bibliothek des litterarischen Vereins. 2 vol. (1863). a third volume (1866) contains Fleming's Latin poems. Selections by J. Tittmann are in Deutsche Dichter des siebzehnten *Jahrhunderts,* vol. ii (1870) and by H. Österley (1885).

See Rost, *Paul Fleming* (1909).

FLEMING, RICHARD. (c. 1360–1431), bishop of Lincoln, and founder of Lincoln college, Oxford, was born in Yorkshire and educated at University college, Oxford. He was made prebendary of York in 1406. Becoming an ardent Wycliffite, he incurred the censure of Archbishop Arundel. He afterward became one of Wycliffe's most determined opponents, and to him was entrusted the execution of the decree of the council for the exhumation and burning of Wycliffe's remains. Before 1415 he was rector of Boston, Lincolnshire, and in 1420 became bishop of Lincoln. In 1423 he attended the councils of Pavia and Siena, and on his return. the see of York being vacant, the pope conferred it on Fleming; but Henry V refused to confirm the appointment. In 1427 Fleming obtained the royal licence empowering him to found a college at Oxford for the training of disputants against Wycliffe's heresy.

Fleming died at Sleaford on Jan. 26, 1431.

FLEMING, SIR SANDFORD (1827–1915), Canadian engineer and publicist, was born at Kirkcaldy, Scot., on Jan. 7, 1827, but in 1845 emigrated to Canada, where he was from 1867 to 1880 chief engineer of the Dominion government. Under his control were constructed the Intercolonial railway and much of the Canadian Pacific. After his retirement in 1880, when the Canadian government handed over the construction of the latter to the Canadian Pacific Railway company, he devoted himself to the study of Canadian and imperial problems, such as the unification of time reckoning throughout the world. and the construction of a state-owned system of telegraphs throughout the British empire. He saw the first link forged in the chain. in the opening in 1902 of the Pacific cable between Canada and Australia. He advocated federation in 1864–67, and in 1891 attacked the Liberal policy of unrestricted reciprocity with the United States.

He received the C.M.G. in 1877 and the K.C.M G. in 1897. He died on July 22, 1915, at Halifax. Nova Scotia.

He published The Intercolonial: a historical sketch *1832–76* (1876); England and Canada (1884); numerous *brochures* and magazine articles.

See L J. Burpee, *Sandford Fleming, Empire-Builder,* with bibliography (1915).

FLEMISH LANGUAGE. In a narrow sense. Flemish (Vlaams) refers to the local dialects of the provinces of East and West Flanders (Oost- en *West-Vlaanderen*) in western Belgium and of the adjoining section of France to the west. In a broader sense. Flemish refers to the standard language and the various dialects of northern Belgium. This broader use of the term often leads to the belief that Flemish is a separate language, though this is not the case. Just as the standard language of southern Belgium is identical with that of France, so the standard language of northern Belgium is identical with that of the Netherlands. In place of Flemish (for northern Belgium) and Dutch (for the Netherlands). the single term Netherlandish (*Nederlands*) is generally used in scientific writings. At the level of local dialects, northern Belgium and the Netherlands (except the Frisian speaking province of Friesland) are part of the Netherlandish-German dialect area which stretches from the North sea to the Alps.

See NETHERLANDISH LANGUAGE; GERMANIC LANGUAGES.

(W. G. Ms.)

FLENSBURG (Danish, Flensborg), a seaport in the Land of Schleswig-Holstein, Germany, at the head of the Flensburg fjord, 20 mi. N.W. from Schleswig. Pop. (1959 est.) 97,055.

Flensburg was probably founded in the 12th century. It attained municipal privileges in 1284, was frequently pillaged by the Swedes after 1643 and in 1848 became the capital. under Danish rule, of Schleswig. In the plebiscite after World War I it voted itself in Germany. The principal public buildings are the Nikolaikirche (built 1390, restored 1894). uith a spire 295 ft. high and the Marienkirche. also a medieval church, with a lofty tower. Flensburg is the most important town in nhat was formerly the duchy of Schleswig. It possesses excellent wharves, does a large trade in coal, is famous for fish curing; it has shipbuilding yards. sugar, paper, glass, copper, soap factories and iron foundries. It engaged in the Greenland whale and the oyster fisheries,.

FLESH FLY, the name applied to any member of the family Metopiidae (or Sarcophagidae) of the order Diptera (*q.v.*), but more specifically to the genus *Sarcophaga*. The flies are usually blackish with a checkered abdomen and gray and black striped thorax. They deposit living maggots on carcasses, and often on fresh meat. Others are parasites of snails, grasshoppers, caterpillars, etc. *S. cistudinis* is a parasite of turtles in North America.

For North American Species *see* J. M. Aldrich, *Sarcophaga and Allies* (1916), for British species *see* C. J. Wainwright, "The British Tachinidae," in *Trans. Entomological Soc. London,* pp. 139–254, (1928). (C. H. CN.)

A TYPICAL FLESH FLY, SARCOPHAGA: THE FEMALES DEPOSIT LIVING LARVAE ON MEAT

FLETA, a treatise on the common law of England written about the year 1290. It is little better than an ill-arranged epitome of Bracton. The author also borrowed some information on husbandry from Walter of Henley. He is supposed to have written it during his confinement in the Fleet prison, hence the name. *Fleta* was first printed by Selden in 1647.

FLETCHER, ALICE CUNNINGHAM (1838–1923), U.S. ethnologist, a distinguished early student of American Indian life, was a pioneer in the study of Indian music and devoted much of her life to the improvement of Indian uelfare. She was born in Cuba (where her Bostonian parents were visiting) on March 15, 1838, and was privately educated. With the encouragement of F. W. Putnam of the Peabody museum at Harvard, Miss Fletcher studied the Plains and Prairie Indians, among whom she lived for a number of years. Together with her adopted Omaha son she wrote her major work, an ethnography of the Omaha tribe, which remains one of the best anthropological studies of its kind. Her description of a Pawnee ritual is equally outstanding as an intimate description and interpretation of a primitive ceremony. She was the first anthropologist to undertake a systematic study of American Indian music, for which she devised a system of notation.

Miss Fletcher served as special agent on problems of land allotment to the Omaha (1883–84), Winnebago (1887–89) and Nez Percé (1890–93) tribes, and initiated a system whereby the Indians secured loans for buying land and building houses. She was largely responsible for preventing the deportation of the Omaha from their Nebraska settlement to Indian territory in Oklahoma. In the early 1880s Miss Fletcher became associated with the Peabody museum, where she became an assistant in 1886 and held a fellowship from 1891 until her death in Washington, D.C., on April 6, 1923. She was elected vice-president of the American Association for the Advancement of Science (1896) and president of the Anthropological Society of Washington (1903) and of the American Folk-Lore society (190j).

Alice Fletcher's outstanding works are *The Omaha Tribe,* with Francis La Flesche, published as the 27th annual report of the Bureau of American Ethnology (1911); *The Hako: a Pawnee Ceremony,* 22nd annual report of the Bureau of American Ethnology (1904); *Indian Story and Song from North America* (1900). For a complete bibliography *see* W. Hough, "Alice Cunningham Fletcher" in *American Anthropologist* (April–June 1923).

FLETCHER, ANDREW, of Saltoun (1655–1716), Scottish politician. was the son and heir of Sir Robert Fletcher (1625–1664), and was born at Saltoun (Salton), East Lothian. He was a member of the Scottish parliament which met in 1681. Fletcher was a fearless and active opponent of the duke of Lauderdale's administration. He left Scotland about 1682. subsequently spending some time in Holland as an associate of the duke of Monmouth and other malcontents. He accompanied Monmouth to the west of England, but left the army after killing one of the duke's trusted advisers.

During the next few years he is said to have traveled in Spain, and he fought against the Turks in Hungary. Having in his absence from Scotland lost his estates and been sentenced to death, he joined William of Orange at The Hague. On William's accession his estates were restored to him; he soon became a leading member of the "club," an organization which aimed at reducing the power of the crown in Scotland, and an active opponent of the English government. In 1703, at a critical stage in the history of Scotland, Fletcher again became a member of the Scottish parliament.

The failure of the Darien expedition had aroused a strong feeling of resentment against England, and Fletcher and the national party seized the opportunity to obtain a greater degree of independence for their country. In the negotiations for the union of the two kingdoms Fletcher performed essential service. He got the act of security passed, which declared that the two crowns should not pass to the same head until Scotland was secured in its civil and religious liberties. Therefore Lord Godolphin was forced into the Union, to avoid a civil mar after the queen's demise.

After the passing of the Act of the Union, Fletcher retired from public life. He did a real, if homely, service to his country by introducing from Holland machinery for sifting grain. He died in London in Sept. 1716.

Fletcher was a fine scholar and a graceful writer. His chief works are: *A Discourse of Government relating to Militias* (1698); *Two Discourses concerning the Affairs of Scotland* (1698); and *An Account of a Conversation concerning a right regulation of Governments for the common good of Mankind* (1704), which contained his well-known remark, "I knew a very wise man so much of Sir Christopher's (Sir C. Musgrave) sentiment, that he believed if a man were permitted to make all the ballads, he need not care who should make the laws of a nation."

See *The Political Works of Andrew Fletcher* (1737); D. S. Erskine, 11th earl of Buchan, *Essay on the Lives of Fletcher of Saltoun and the Poet Thomson* (1792).

FLETCHER, GILES (*c.* 1548–1611), English poet and author and father of the poets Phineas and Giles Fletcher, who published an interesting account of his visit to Russia in *Of the Russe Common Wealth* (1591). The son of Richard Fletcher, the vicar of Cranbrook, Kent, he was born in 1548 or 1549 at Watford, Hertfordshire, and educated at Eton and at King's college. Cambridge. He was employed on diplomatic service in Scotland, Germany and Holland; and in 1588 was sent to Russia to the court of the tsar Theodore I, with instructions to conclude an alliance between England and Russia, to restore English trade and to obtain better conditions for the English Muscovy company. He returned to England in 1589, and in 1591 published *Of the Russe Common Wealth,* a comprehensive account of Russian geography, government, law, methods of warfare, church and manners. The Russian government was alarmed at the book's freedom and had it suppressed. In 1610 Fletcher was employed to negotiate with Denmark on behalf of the merchants of the Eastland company; he died in London in the following year and was buried on March 11, 1611.

Of the Russe Common Wealth was issued in an abridged form in Richard Hakluyt's *Principal Navigations, Voyages, Traffiques and Discoveries* (2nd ed., 1598); in *Purchas his Pilgrimes* (1625); and also as *History of Russia* in 1643. Fletcher also wrote *De Literis antiqzrae Britanniae* (1633); a treatise on "The Tartars," to prove that they were the ten lost tribes of Israel; Latin poems published in various miscellanies; and *Licia, or poems of love . . . Whereunto is added the Rising to the Crowne of Richard the Third* (1593). This series of love sonnets, followed by some other poems, was published anonymously. Most critics have accepted it as the work of Giles Fletcher on the evidence afforded in the first of the *Piscatorie Eclogs* (1633) of his son Phineas, who represents his father (Thelgon) as having "raised his rime to sing of Richard's climbing."

FLETCHER, GILES (*c.* 1584–1623), English poet principally knonn for his great baroque devotional poem. *Christs Victorie, and Triumph in Heaven, and Earth, over, and after death,* was the younger son of Giles Fletcher (c. 1548–1611; *q.v.*). He was born in London about 1584, and was educated at Westminster school and at Trinity college, Cambridge. After taking orders, he held a college living, and his sermons at St. Mary's were famous. Thomas Fuller states in his *Worthies* (1662) that Fletcher's prayer before his sermon was a continuous allegory. He left Cambridge about 1618, and soon after received the rectory of Alderton, Suffolk. He died in 1623.

The theme of Fletcher's masterpiece, *Christs Victorie* (1610), owes something to the *Semaines* of Du Bartas, but the devotion, the passionate lyricism and the exquisite vision of paradise are Fletcher's own. The poem is written in eight-line stanzas owing something to Edmund Spenser of whom, like his brother Phineas, Giles was a disciple. The first five lines rhyme a, b, a, b, b. and the stanza concludes with a rhyming triplet, resuming the conceit which nearly every verse embodies. Like most amateurs of the conceit, he is sometimes grotesque, but uhen he forgets his ingenuity he attains a depth of melody that delighted Milton, who followed him to some extent in *Paradise Regained* (1671).

Fletcher contributed a poem on the death of Queen Elizabeth I to *Sorrowes Joy* (1603), and in 1612 he edited *The Young Divines Apologie for his Continuance in the Universitie* of his cousin Nathaniel Pownoll. His last work was the prose *Reward of the Faithfull* (1623).

There is an unpublished manuscript by him in the library of King's college, Cambridge, *Aegidii Fletcherii versio poetica Lamentationum Jeremiae.*

Bibliography.—*The Poetical Works of Giles and Phineas Fletcher* were ed. by F. S. Boas, 2 vol. (1908–09). *See* also *H*. E. Cory, *Spenser, the School of the Fletchers, and Milton* (1912) and *A*. Esch, *Giles Fletchers "Christs Victorie and Triumph": Eine Studie zum Epenstil des englischen Barock* (1937).

FLETCHER, HARVEY (1884–), U.S. physicist who made notable contributions to the science of acoustics, was born in Provo, Utah, Sept. 11, 1884. He graduated from Brigham Young university in 1907 and received a Ph.D. *summa cum laude* in 1911 from The University of Chicago. He taught physics at Brigham Young until joining Bell Telephone Laboratories, Inc., in 1916, where he remained for 33 years, working primarily in the fields of speech, music and hearing. Fletcher appreciated the importance of precise measurement and the value of organizing fundamental information into useful relationships. Throughout the period, new instrumentation and techniques of measurement were under continuous development. The basic knowledge so obtained was fundamental to the rapid growth of the science of psycho-acoustics and its application to communications. Much of the work is described in Fletcher's book *Speech and Hearing in Communications* (1929).

On retirement as physical research director in 1949, Fletcher joined the staff of Columbia university and established a new department of acoustical engineering. In 1952 he returned to Brigham Young university as director of research and in 1954 became dean of the college of physical and engineering sciences.

(J. C. Sg.)

FLETCHER, JOHN WILLIAM (1729–1785), English divine, was born at Nyon, Switzerland, on Sept. 12. 1729, his original name being de la Flechere. He was educated at Geneva for the church, but went to Lisbon and enlisted. An accident prevented his sailing with his regiment to Brazil, and he went to England, picked up the language, and in 1752 became tutor in a Shropshire family. Here he came under the influence of the new Methodist preachers, and in 1757 took orders, being ordained by the bishop of Bangor. He often preached with John Wesley and for him. Refusing the wealthy living of Dunham, he accepted the humble one of Madeley, where for 25 years (1760–85) he lived and worked with unique devotion and zeal. Fletcher was one of the few parish clergy who understood Wesley and his work, yet he never wrote or said anything inconsistent with his own Anglican position. In theology he upheld the Arminian against the Calvinist position, but always with courtesy and fairness; his resignation on doctrinal grounds of the superintendency (1768–71) of the countess of Huntingdon's college at Trevecca left no unpleasantness. The outstanding feature of his life was a transparent simplicity and saintliness of spirit. Wesley preached his funeral sermon from the words "Mark the perfect man." Southey said that "no age ever provided a man of more fervent piety or more perfect charity, and no church ever possessed a more apostolic minister." It is said that Voltaire, when challenged to produce a character as perfect as that of Christ, at once mentioned Fletcher of Madeley. He died on Aug. 14. 1785.

Complete editions of his works were published in *1803* and *1836*. The chief of them, written against Calvinism, are *Five Checks to Antinomianism, Scripture Scales to weigh the Gold of Gospel Truth,* and the *Portrait of St. Paul. See* lives by J. Wesley (1786); L. Tyerman *(1882)*; F. *W*. Macdonald *(1885)*; J. Maratt (1902); also C. J. Ryle, *Christian Leaders of the 18th Century (1869).*

FLETCHER, PHINEAS (1582–1650), English poet best known for his religious and scientific poem *The Purple Island*, elder son of Giles Fletcher *(c.* 1548–1611; *q.v.)* and brother of Giles the younger *(c.* 1584–1623), was born at Cranbrook, Kent, and baptized on April 8, 1582. He was educated at Eton and at King's college. Cambridge. His pastoral drama, *Sicelides A Piscatory* (1631) was written in 1615 for performance before James I at King's college but only produced after the king's departure. Fletcher became chaplain to Sir Henry Willoughby, who presented him in 1621 to the rectory of Hilgay, Norfolk, where he spent the rest of his life. He had married Elizabeth Vincent of Risley, Derbyshire, in Aug. 1615. In 1627 he published *Locustae, vel pietas Jesuitica (The Locusts or Apollyonists*), two parallel poems in Latin and English attacking the Jesuits. An erotic poem, *Brittain's Ida* (1628), though bearing Spenser's name, is to be included in the Fletcher canon, since it appears in the unique manuscript preserved at Sion college, London, of his *Piscatorie Eclogs.* Entitled there *Venus and Anchises,* it bears additional stanzas which prove his authorship. In 1632 appeared two theological prose treatises, *The Way to Blessedness* and *Joy in Tribulation,* and in 1633 his magnum opus, *The Purple Island.* It included his *Piscatorie Eclogs and other Poetical Miscellanies.* He died in 1650, his will being proved on Dec. 13.

The Purple Island, or the Isle of Man, is a poem in 12 cantos describing in cumbrous allegory the physiological structure of the human body and the mind of man. The manner of Spenser is preserved throughout, and the chief charm of the poem lies in its descriptions of rural scenery. Some critics see in the allegorist of *The Purple Island* a link between Spenser and Bunyan. The *Piscatorie Eclogs* are pastorals, the characters of which are represented as fisherboys on the banks of the Cam, and are interesting for the light they cast on the biography of the poet himself (Thyrsil) and his father (Thelgon), and on Phineas' friendship with Cambridge men, such as the musician Thomas Tomkins (Thomalin). Phineas Fletcher's poetry has not the sublimity sometimes reached by his brother Giles. The mannerisms are more pronounced, the conceits more farfetched, but the verse is fluent and musical; his lyric poetry lacks neither colour nor ardour, as is seen in the "Epithalamium" of the Sion college manuscript.

Bibliography.—*Poems,* ed. by A. B. Grosart, 4 vol. *(1869)*; *Poetical Works of Giles and Phineas Fletcher,* ed. by F. S. Boas, 2 vol. (1908–09); *Venus and Anchises . . . ,* ed. by E. Seaton for the Royal Society of Literature *(1926). See* also *H. E.* Cory, *Spenser, the School of the Fletchers, and Milton* (1912), and *A.* B. Langdale, *Phineas Fletcher* (1937).

FLEURANGES, ROBERT III DE LA MARCK, Seigneur de (1491–1537), marshal of France and historian, was the son of Robert II de la Marck, duke of Bouillon, seigneur of Sedan and Fleuranges, whose uncle was William de la Marck, "the Wild Boar of the Ardennes." At the age of ten he was sent to the court of Louis XII, and placed in charge of the count of Angoulême, afterwards King Francis I. He served in Francis' Italian campaigns; and in 1512, the French being driven from Italy, Fleuranges was sent into Flanders to levy a body of 10,000 men, in command of which. under his father, he returned to Italy in 1513, seized Alessandria, but failed to take Novara. In 1515 he distinguished himself at Marignano, where the king knighted him with his own hand. He next took Cremona, and was there called home by the news of his father's illness. In 1519 he was sent into Germany to canvass the electors in favour of Francis I. Fleuranges fought at Pavia (1525), and was taken prisoner with Francis. The emperor, irritated by the defection of his father, Robert II de la Marck, kept him in prison in Flanders for some years. During this imprisonment he was created marshal of France. In his *Histoire des choses mkmorables advenues au règne de Louis XII et de François I, depuis 1499 jusqu'en l'an* **1521,** written in prison (ed. Lambert, 1735), also in the *Nouvelle collection des mkmoires pour servir à l'histoire de France* (edited by J. F. Michaud and

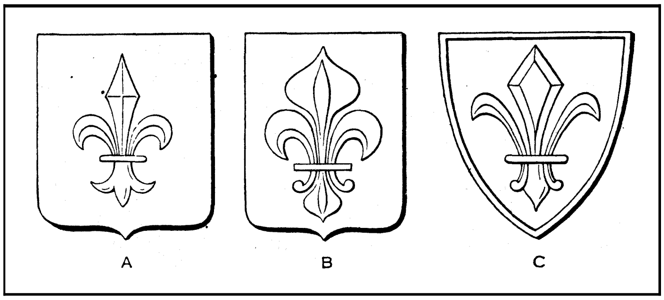
J. J. F. Poujoulat, series i, vol. v, 1836 *et* seq.), he gives many curious and interesting details of the events he had witnessed. He died at Longjumeau in Dec. 1537.

FLEUR-DE-LIS (Fr. "lilyflower"), a heraldic device, very widespread in the armorial bearings of all countries, but more particularly associated with the royal house of France. The conventional fleur-de-lis, as Littre says, represents very imperfectly three flowers of the white lily (Lilium) joined together, the central one erect, and each of the other two curving outwards. The fleur-de-lis is common in ancient decoration, notably in India and in Egypt, where it was the symbol of life and resurrection, the attribute of the god Horus. It is common also in Etruscan bronzes. It is uncertain whether the conventional fleur-de-lis was originally meant to represent the lily or white iris — the flower-de-luce of Shakespeare — or an arrow-head, a spear-head, an amulet fastened on date-palms to ward off the evil eye, etc. In Roman and early Gothic architecture the fleur-de-lis is a frequent sculptured ornament. As early as 1120 three fleurs-de-lis were sculptured on the capitals of the Chapelle Saint-Aignan at Paris.

The fleur-de-Iis was first definitely connected with the French monarchy in an ordonnance of Louis le Jeune (c. 1147), and was first figured on a seal of Philip Augustus in 1180. The use of the fleur-de-lis in heraldry dates from the 12th century, soon after which period it became a very common charge in France, England and Germany, where many a gentleman of coat-armour desired to adorn his shield with a loan from the shield of France, which was at first *d'azur, semé* de *fleurs* de *lis* d'or (blue, interspersed with gold lilies). In Feb. 1376 Charles V of France reduced the number of fleurs-de-lis to three — in honour of the Trinity — and the kings of France thereafter bore *d'azur, à trois fleurs* de *lis* d'or (blue, with three gold lilies).

Tradition soon attributed the origin of the fleur-de-lis to Clovis, the founder of the Frankish monarchy, and explained that it represented the lily given to him by an angel at his baptism. According to a more rationalistic explanation, it was a figure used instead of a sceptre at the proclamation of the Frankish kings.

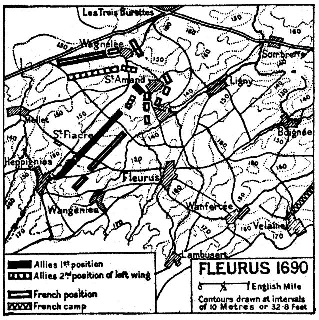
An order of the Lily, with a fleur-de-lis for badge, was established in the Roman states by Pope Paul III in 1546; its members were pledged to defend the patrimony of St. Peter against the enemies of the church. Another order of the Lily was founded by Louis XVIII in 1816, in memory of the silver fleurs-de-lis which the comte d'Artois had given to the troops in 1814 as decorations; it was abolished by the revolution of 1830.



THREE MODIFICATIONS OF THE FLEUR-DE-LIS
A. Middle Aaes B. 17th Century C. 18th and 19th Centuries

FLEURUS, a village of Belgium, in the province of Hainaut, 5 mi. N.E. of Charleroi, pop. (1955 est.) 7,206; scene of several battles. The first of these was fought on Aug. 19–29, 1622, between the forces of Count Mansfeld and Christian of Brunswick and the Spaniards under Cordovas, the latter being defeated. The second is described below, and the third. and fourth, incidents of Jourdan's campaign of 1794, under FRENCH REVOLUTIONARY WARS. The ground immediately north-east of Fleurus forms the battlefield of Ligny (June 16, 1815), for which see WATERLOO CAMPAIGN, 1815.

The second battle (for its strategic prologue see GRAND ALLIANCE, WAR OF THE) was fought on July 1, 1690, between 45,000 French under duke of Luxemburg, and 37,000 allied Dutch, Spaniards and Imperialists under George Frederick, prince of Waldeck. The latter had formed up his army between Heppignies and St. Amand in what was then considered an ideal position; a double barrier of marshy brooks was in front, each flank rested on a village, and the space between, open upland, fitted his army exactly. But Luxemburg, riding up with his advanced guard from Velaine, decided, after a brief survey of the ground, simultaneously to attack the front of the Allies' position, envelop their right flank and turn their left flank by a wide manoeuvre on to their rear, a boldness and breadth of tactical conception which was rare for the age, indeed for any age. The left wing of cavalry was to move under cover of woods, houses and hollows to gain Wangenies, where it was to connect with the frontal attack of the French centre from Fleurus and to envelop Waldeck's right. Luxemburg himself with the right wing of cavalry and some infantry and artillery made a wide sweep round the enemy's left by way of Ligny and Les Trois Burettes, concealed by the high-standing corn. At 8 o'clock the frontal attack began by a vigorous artillery engagement, in which the French, though greatly outnumbered in guns, held their own, and three hours later Waldeck, whose attention had been absorbed by events on the front, found a long line of the enemy already formed up in his rear. He at once brought his second line back to oppose them, but while he was doing so the French leader filled up the gap between himself and the frontal assailants by posting infantry around Wagnelée, and also guns on the neighbouring hill whence their fire enfiladed both halves of the enemy's army up to the limit of their ranging power. At 1 P.M. Luxemburg ordered a general attack of his whole line. He himself scattered the cavalry opposed to him and hustled the Dutch infantry into St. Amand, where they wera promptly surrounded. The left and centre of the French army were less fortunate, and in their first charge lost their leader, de Gournay, one of the best cavalry officers in the service. But Waldeck, hoping to profit by this momentary success, sent a portion of his right wing towards St. Amand, where it merely shared the fate of his Ieft, and the day was decided. Only a quarter of the cavalry and 14 battalions of infantry (English and Dutch) remained intact, and Waldeck could do no more, but with these he emulated the last stand of the Spaniards at Rocroi 50 years before. A great square was formed of the infantry, and a handful of cavalry joined them — the French cavalry, eager to avenge de Gournay, had swept away the rest. Then slowly and in perfect order, they retired into the broken ground above Mellet, where they were in safety. The French slept on the battlefield, and then returned to camp with their trophies and 8,000 prisoners. They had lost some 2,500 killed, the Allies twice as many, as well as 48 guns, and Luxemburg was able to send 150 colours and standards to decorate Notre-Dame. But the victory was not followed up, for Louis XIV. ordered Luxemburg to keep in line with other French armies which were carrying on more or less desultory wars of manoeuvre on the Meuse and Moselle.



PLAN OF THE SECOND BATTLE OF FLEURUS, JULY 1, 1690

FLEURY (ABRAHAM JOSEPH BÉNARD) (1750–1822), French actor, noted as a comedian, was born at Chartres on Oct. 26, 1750. He began his stage apprenticeship at Nancy, where his father was an actor at the court of King Stanislaus I. He went to Paris in 1778 and almost immediately was made a full member of the Comédie Franqaise, although the public was slow to recognize him as thegreatest comedian of his time. In 1793 Fleury was arrested in consequence of the presentation of the politically controversial play *L'Ami des Lois* by Jean Laya. When liberated, Fleury appeared at various theatres until, in 1799, he rejoined the rehabilitated Comédie Franqaise.

Fleury retired in 1818 and died on March 3, 1822.

FLEURY, ANDRÉ HERCULE DE (1653–1743), French cardinal and statesman, was born at Lodbve (Hérault) on June

22, 1653, the son of a collector of taxes. Educated by the Jesuits in Paris, he entered the priesthood, and became in 1679, through the influence of Cardinal Bonzi, almoner to Maria Theresa, queen of Louis XIV., and in 1698 bishop of Fréjus. Seventeen years later he became tutor to the king's great-grandson and heir, and in spite of an apparent lack of ambition, he acquired over the child's mind an influence which proved to be indestructible. On the death of the regent Orleans in 1723 Fleury, already 70 years of age, deferred his own supremacy by suggesting the appointment of Louis Henri, duke of Bourbon, as first minister. Fleury was present at all interviews between Louis XV. and his first minister, and on Bourbon's attempt to break through this rule Fleury retired from court. Louis made Bourbon recall the tutor, who on July 11, 1726, took affairs into his own hands, and secured the exile from court of Bourbon and of his mistress Madame de Prie. He refused the title of first minister, but his elevation to the cardinalate in that year secured his precedence over the other ministers. He was naturally frugal and prudent, and carried these qualities into the administration, with the result that in 1738–1739 there was a surplus of 15,000,000 livres instead of the usual deficit. In 1726 he fixed the standard of the currency and secured the credit of the government by the regular payment thenceforward of the interest on the debt. By exacting forced labour from the peasants he gave France admirable roads, though at the cost of rousing angry discontent. During the 17 years of his orderly government the country found time to recuperate its forces after the exhaustion caused by the extravagances of Louis XIV. and of the regent, and the general prosperity rapidly increased. Internal peace was only seriously disturbed by the severities which Fleury exercised against the Jansenists. He imprisoned priests who refused to accept the bull *Unigenitus,* and he met the opposition of the parlement of Paris by exiling 40 of its members.

In foreign affairs his chief preoccupation was the maintenance of peace, which was shared by Sir Robert Walpole, and therefore led to a continuance of the good understanding between France and England. But he reluctantly supported the ambitious projects of Elizabeth Farnese, queen of Spain, in Italy by guaranteeing in 1729 the succession of Don Carlos to the duchies of Parma and Tuscany. Fleury had economized in the army and navy, as elsewhere, and when in 1733 war was forced upon him he was hardly prepared. He was compelled by public opinion to support the claims of Louis XV.'s father-in-law Stanislaus Leszczynski, ex-king of Poland, to the Polish crown on the death of Frederick Augustus I., against the Russo-Austrian candidate; but the despatch of a French expedition of 1,500 men to Danzig only served to humiliate France. Fleury was driven by Chauvelin to more energetic measures; he concluded a close alliance with the Spanish Bourbons and sent two armies against the Austrians. Military successes on the Rhine and in Italy secured the favourable terms of the treaty of Vienna (1735–1738). France had joined with the other powers in guaranteeing the succession of Maria Theresa under the Pragmatic Sanction, but on the death of Charles VI. in 1740 Fleury by a diplomatic quibble found an excuse for repudiating his engagements, when he found the party of war supreme in the king's counsels. After the disasters of the Bohemian campaign he wrote in confidence a humble letter to the Austrian general Königsegg, who immediately published it. Fleury disavowed his own letter, and died a few days after the French evacuation of Prague on Jan. 29, 1743. He had enriched the royal library by many valuable oriental mss., and was a member of the French Academy, of the Academy of Science, and the Academy of Inscriptions.

FLEURY, CLAUDE (1640–1723), French ecclesiastical historian, was born at Paris on Dec. 6, 1640. Educated at the aristocratic college of Clermont (now that of Louis-le-Grand), he was nominated an advocate to the parlement of Paris in 1658, but nine years later, he turned to theology and by 1672 was in orders. The king entrusted to him the education of the princes of Conti and of the count of Vermandois, one of his natural sons, on whose death in 1683 Fleury received for his services the Cistercian abbey of Loc-Dieu, in Rhodez. In 1689 he was appointed sub-preceptor of the dukes of Burgundy, of Anjou and of Berry, and thus became intimately associated with Fénelon, their chief tutor. On the completion of the education of the young princes the king appointed him prior of Argenteuil, near Paris (1706), and he resigned that of the abbey of Loc-Dieu. Fleury, who had been made confessor to the young king Louis XV. in 1716, because, as the duke of Orleans said, he was neither Jansenist nor Molinist, nor Ultramontanist, but Catholic, died on July 14, 1723. His great learning was equalled by the modest simplicity of his life and the uprightness of his conduct.

His chief work, the *Histoire ecclésiastique,* which comes down to 1414 and was completed by others dcwn to 1684, has passed through many editions, the first being that of Paris, 20 vols., 1691, Partial Eng. trs., 1842 ff. His other works *include:* — *Histoire du droit françois* (1674, Eng. trs., 1724), *Moeurs des Israélites* (1681, Eng. trs., 1805); *Moeurs des Chrétiens* (1682, Eng. trs., 1698); *Traité du choix et de la me'thode des e'tudes* (1686, 2 vols.); *Les Devoirs des maîtres et des domestiques* (1688); his *Cate'chisme historique* (1679, Eng. trs., 1726) and the *Institution du droit ecclésiastique* (1687) were put on the Index. *See* C. E. Simonetti, *Der Character eines Geschichtsschreibers in dem Leben und aus den Schriften des Abts C. Fleury* (Gottingen, 1746); C. F. P. Jaeger, *Notice sur C. Fleury, considéré comme historien* (Strasbourg, 1847); Reichlin-Meldegg, *Geschichte des Christentums,* i.

FLEXNER, SIMON (1863–1946), U.S. pathologist, was born at Louisville, Ky., on March 25, 1863. After receiving his medical degree from the University of Louisville in 1889, he studied at Johns Hopkins university, Baltimore, Md., and at the universities of Strasbourg, Berlin and Prague and the Pasteur institute, Paris. He was associate professor of pathology (1895–98) and professor of pathological anatomy (1898–99) at Johns Hopkins and professor of pathology at the University of Pennsylvania, 1899–1903. Director of the laboratories of the Rockefeller Institute for Medical Research, New York, 1903–35, he was also director of the institute, 1920–35.

Flexner became widely known for his treatment of spinal meningitis (*see* MENINGITIS) with a curative serum. He published numerous monographs, including *Serum Treatment of Epidemic Meningitis* (1917); *Epidemic Poliomyelitis;* and *Epidemiology.* With James Thomas Flexner he wrote *William Henry Welch and the Heroic Age of American Medicine* (1941). He died in New York city on May 2, 1946.

His brother ABRAHAM FLEXNER (1866–) was secretary of the general education board, 1917–25, and director of the Institute for Advanced Study, 1930–39. He wrote *A Modern School* (1916); *A Modern College* (1923); *I Remember: An Autobiography* (1940); and works on medical education.

FLICKER, one of more than 100 names for ground-loving, ant-eating, North American woodpeckers *(Colaptes auratus),* 12 in. long, brownish-gray above barred black, brownish-white below washed yellow, black spots and crescent on breast, and black moustaches in the male. White rump and yellow under wings and tail are conspicuous in flight. A 13-18 in, nest is dug high in dead limb or stub where 5-9 white eggs incubate two weeks. The flicker ranges from the Atlantic to the Rockies and limit of trees to the Gulf coast. Red-shafted flickers (C. *cafer),* Rockies to Pacific and Alaska into Mexico, have brown crown, red under wings and tail, black moustaches in male. Gilded flickers (C. *chrysoïdes*) occur on Arizona-California-Mexican borders, other species in Cuba and southern Mexico. (G. F. Ss.)

FLIEDNER, THEODOR (1800–1864), German Protestant divine and philanthropist, was born on Jan. 21, 1800, at Epstein (near Wiesbaden), and studied at Giessen, Gottingen and Herborn. In 1821 he became pastor of the Protestant church at Kaiserswerth, on the Rhine. During a visit to England in 1823 he made the acquaintance of Elizabeth Fry. The German prisons were then in a very bad state. The prisoners were huddled together in dirty rooms, badly fed, and left in complete idleness. Fliedner applied for permission to be imprisoned for some time, in order to see prison life from the inside. This petition was refused, but he was allowed to hold fortnightly services in the Düsseldorf prison, and to visit the inmates individually. On June 18, 1826, the first Prison Society of Germany (Rheinisch-Westfälischer *Gefängnisverein*) was founded. In 1833 Fliedner opened in his own parsonage garden at Kaiserswerth a refuge for discharged female convicts. He then turned to the care of the sick poor, and he began a scheme for securing proper training for nurses. In 1836 he began the first deaconess house, and the hospital at Kaiserswerth, the institution which gave Florence Nightingale fruitful ideas on the provision of nursing. By their ordination vows the deaconesses devoted themselves to the care of the poor, the sick and the young; but their engagements were not final—they might leave their work and return to ordinary life if they chose. Fliedner also founded (1835) an infant school, then a normal school for infant school mistresses (1836), an orphanage for orphan girls of the middle class (1842), and an asylum for female lunatics (1847). He assisted at the foundation and in the management of similar institutions, not only in Germany, but in various parts of Europe.

In 1849 he resigned his pastoral charge, and until 1851 travelled over a large part of Europe, America and the east—the object of his journeys being to found "mother houses," which were to be not merely training schools for deaconesses, but also centres from which other training establishments might arise. He established a deaconess house in Jerusalem, and after his return assisted by counsel and money in the erection of establishments at Constantinople, Smyrna, Alexandria and Bucharest. He founded the Christian house of refuge for female servants in Berlin (connected with which other institutions soon arose) and the "house of evening rest" for retired deaconesses at Kaiserswerth. Fliedner died on Oct. 4, 1864, leaving behind him more than 100 stations.

His son FRITZ FLIEDNER (1845–1901), after studying in Halle and Tübingen, became in 1870 chaplain to the embassy in Madrid and founded several philanthropic institutions in Spain. He was also the author of a number of books, among which was an autobiography, *Aus meinem Leben, Erinnerungen und Erfahrungen* (1901).

See G. Fliedner, *Theodor Fliedner, kurzer Abriss seines Lebens und Wirkens*, 3rd ed. (1892). *See* also on Fliedner and his work *Kaiserswerth Deaconesses* (1857); J. S. Howson, *Deaconesses* (1862); E. C. Stephen, *The Service of the Poor* (1871); W. F. Stevenson, *Praying and Working* (1865).

a purchase of stock that is known by the buyer to be of a highly speculative nature, and by which he hopes to make a quick turnover at a profit, though realizing that there is also a great possibility of loss. *Taking a flier* is essentially a gamble and is so recognized.

(NATURAL). The flight of birds has been from time immemorial a riddle as well as a source of inspiration. In the Proverbs of Solomon it says "the way of an eagle in the air" is "too wonderful" for him; and for many centuries the paradox that a bird could for hours together maintain its motion without a flap of the wing or any appreciable expenditure of energy seemed hopeless of explanation. But though the upward gliding of a vulture until it is almost invisible, or the effortless sailing of an albatross for hundreds of miles over the ocean are obviously marvellous, the ordinary flapping flight of a swift or a pigeon is in reality almost as wonderful. For flapping flight involves a combination of a highly perfected mechanical design of the wings with a motive power of remarkable lightness; and, though men have carried on sailing flight in a motorless aeroplane for hours, a motor-driven flapping aeroplane has not been prodhced.

Gliding, Soaring or Sailing Flight.— For comprehension of the fundamental principles underlying nonflapping flight, we are indebted to the late Lord Rayleigh who in 1883 remarked that "wherever . . . a bird pursues his course for some time without working his wings we must conclude either (1) that the course is not horizontal, (2) that the wind is not horizontal, or (3) that the wind is not uniform." As we shall see these suggestions lead to the solution of the problem, which, as far as flight inland is concerned, may be exemplified by the behaviour of an ordinary vulture. He weighs about 10 lb., has wings each about 3 ft. long and 1 ft. wide, and, about an hour after sunrise, when he throws himself off the bough on which he has roosted, he gives the impression of being too heavily loaded for any but the clumsiest of flying. He flaps laboriously uphill, usually in a spiral path, until he has reached a height of 50 or 100 ft. and then a mysterious change begins to show itself; he flaps less and less hard and after a short time starts gliding steadily and majestically upward in his spiral. After reaching a considerable height, which may be between 500 and 2,000 ft., he has no need of further effort, and seems able to float at will in any direction and at any pace that he likes until he descends for food or because sunset is approaching.

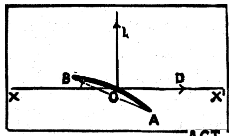

FIG. 1.—AIR FORCES ACTING ON 7 WING SHOWING HOW, WHEN MOVING HORIZONTALLY, THE WING EXPERIENCES A VERTICAL * BACK-

The details of his flight do not diminish our surprise; for the air in the plains is often so still that there is no suggestion of an upcurrent sufficient to support a 10 lb. weight, and with the plane of his wings inclined upward (the forward edge being higher than that in the rear) a vertical upcurrent would seem to drive him backward, not forward. His continued advance seems inexplicable.

Downhill Gliding Through Still Air.—If a bird is gliding horizontally through still air the resistance of the air must lessen his speed, and on the other hand if he glides steeply downhill he will gain in speed. There must be some slope for which he will neither gain nor lose speed and its inclination is called the "angle of descent." Much detailed information has been accumulated regarding the forces which act on wings of various cross sections and on elongated bodies when travelling at different speeds through the air (*see* AERONAUTICS); and if we have a wing of cross section AB (*see* fig. 1) travelling in the direction X′OX the air forces acting on it are equivalent to (1) a resistance or "drag" D backward in the reversed direction of motion. (2) a lifting force L at right angles to the direction of motion. For a "high velocity" section, the ratio of L : D may reach 17. So when our bird is gliding steadily downhill along a line inclined and to the horizon it is acted on by D, L and its weight W, and we must have

$$\frac{\quad}{\cos a} = \frac{\quad}{\sin \alpha} = W$$

Now it may easily be calculated from well-known data that if we construct an artificial bird with rectangular wings of standard section and a torpedo-shaped body all of approximately the actual dimensions, the total weight being that of the bird, its angle of descent will be about 4° or 5°. Further, we habitually see birds in the tropics gliding at a considerable height in all directions without any obvious descent; but we should not observe an angle of descent of 5° under these conditions, and for one who has been able to watch the gliding of kites from a hill it is impossible to believe that their angle of descent is as great as this. Hence, although past measurements of the forces acting upon stuffed birds in wind tunnels have indicated great inferiority by parison with aerofoils fitted to torpedo-shaped bodies, the ratio of lift/drag in the stuffed birds not exceeding 5, the failure must be explained by the difficulty of preserving the true shape of the wing. Preliminary experiments made at S. Kensington have confirmed this view and from measurements made on living birds in 1920 in Africa, P. Idrac found a lift/drag ratio of about 18.

Gliding When There Is an Upward Current of Air.—If a bird whose angle of descent is 1 in 12 is gliding through still air at 18 m.p.h. he will be descending at the rate of $\frac{18}{12}$ or $1\frac{1}{2}$ m.p.h.; and if there were a column of air ascending at more than $1\frac{1}{2}$ m.p.h. the bird would climb as long as he kept within it in a spiral path.

Now an ordinary observer has no evidence of such vertical air motion, for near the ground that motion must be negligible; but there is complete proof, both meteorologically and by direct measurement, of its existence. We know that in sunny weather. owing to the overheating of air near the ground, conditions in continental regions in summer in medium latitudes and in the tropics for much of the year are unstable; so that a mass of

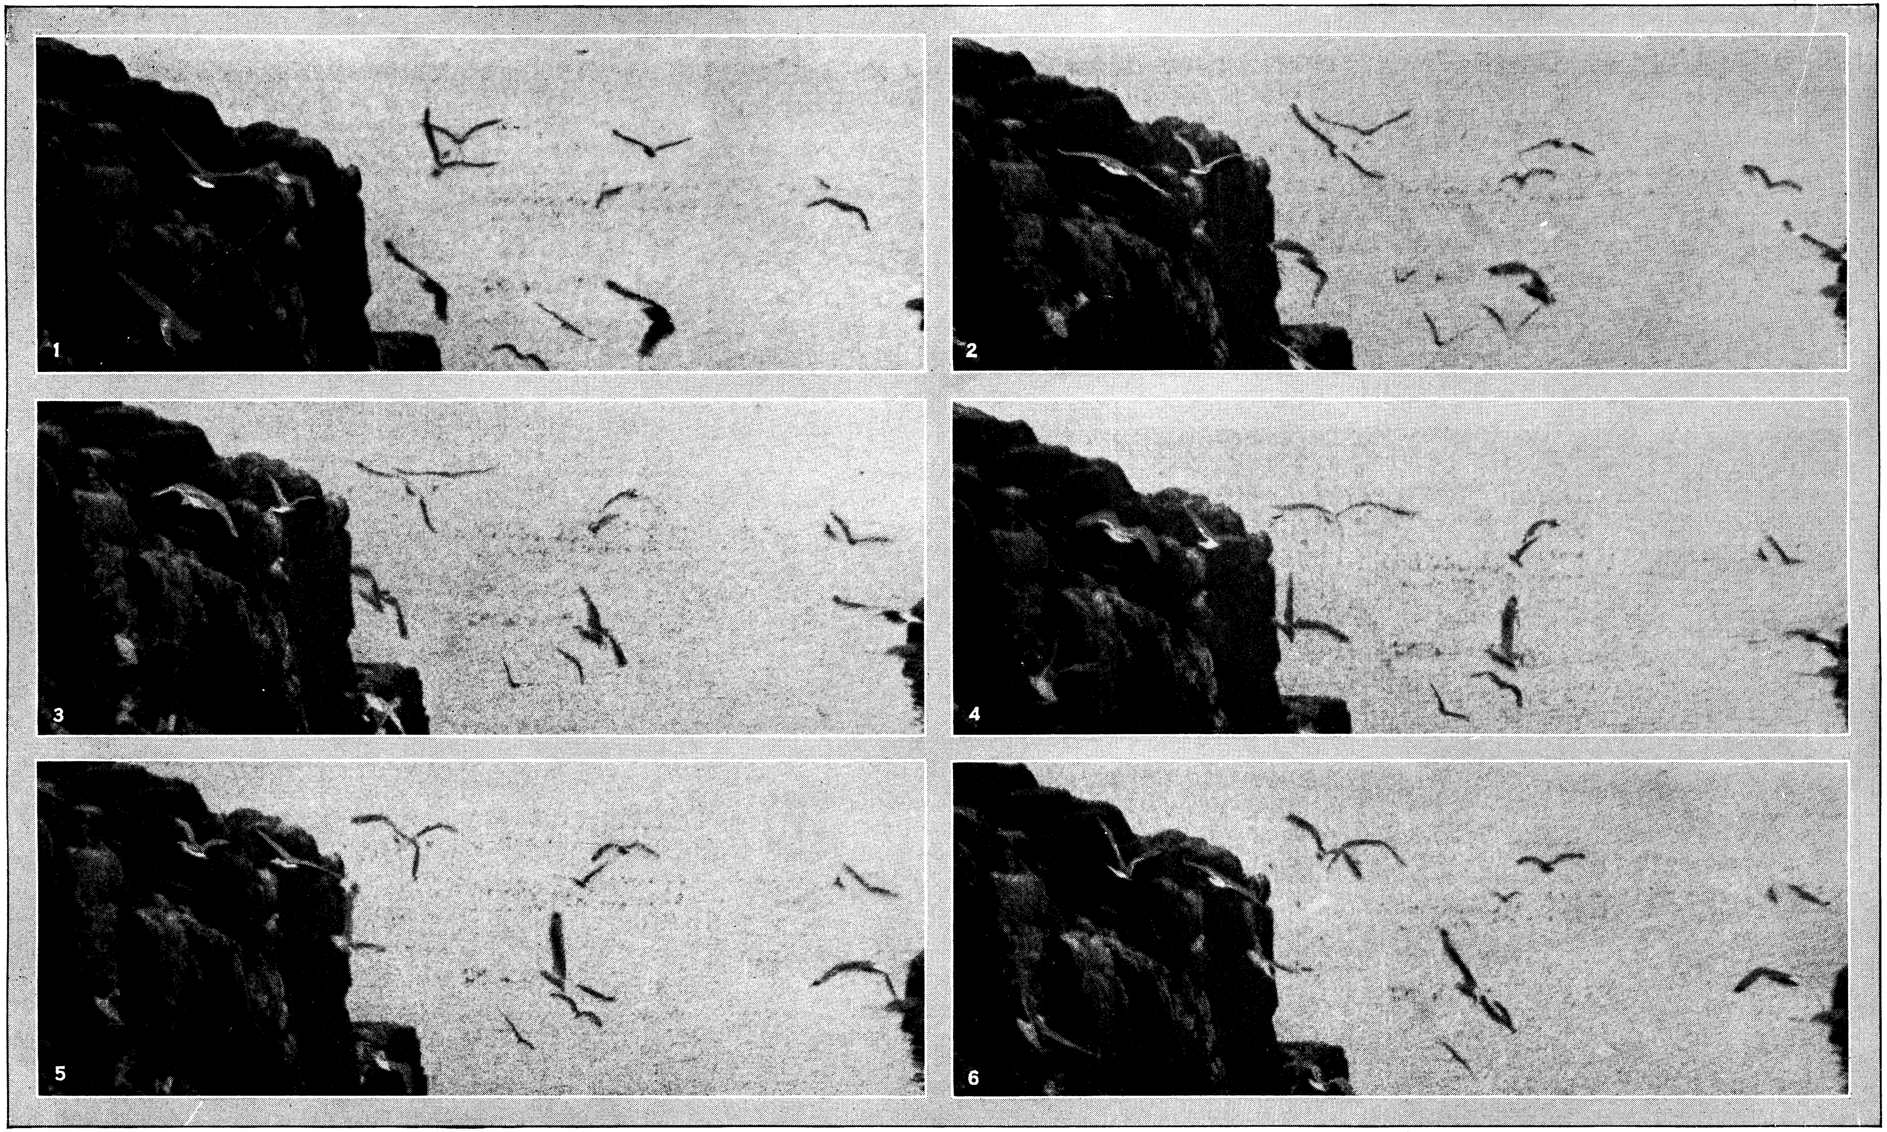
WILD SWANS IN STEADY FLIGHT

Series of cinema photographs, showing wing movements of birds in course of flight. The changes can best be observed by following the movements of the two birds at the top of the pictures. The wings are straightened at the end of the upward beat, curved at the end of the downward beat. At the beginning of the upward beat the wings are bent to avoid air resistance; at the beginning of the downward beat the wings are straightened to give maximum driving surface



BY COURTESY OF THE BRITISH INSTRUCTIONAL FILMS, LTD.

KITTIWAKE GULLS IN FLIGHT

The pictures in the series are timed at equal intervals. By observing the top gull against the dark cliff throughout the series a cycle or flap of the wings can be followed, ending in the rapid upward flick of the wings. 1, beginning of downbeat; 2, 3 & 4, movements in downbeat, showing twist or bend of wings; 5, 6, upbeat, wings raised in preparation for downbeat tips steeply inclined upward air rising above a heated rock will climb to a considerable height before it cools to the same temperature as the surrounding air and comes to rest. These local upward currents are experienced by meteorological kites and balloons, and their effects are described by aviators as "bumps"; in Egypt, for instance, they extend to heights of 4,000 to 10,000 feet. In addition to large currents there are "small vertical currents" whose bottoms can in many cases be detected "in the vicinity of a town by kites or hawks soaring," and whose vertical speed over hilly country is probably as much as 16ft. a second. The dependence of soaring flight on vertical currents is also completely confirmed by the observations of Idrac in Senegal.

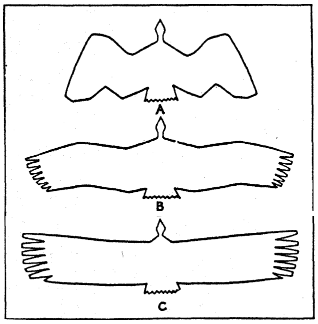


FIG. 2.—A VULTURE GLIDING ILLUSTRATING THE SHAPE OF WINGS WHEN (A) DESCENDING STEEPLY, (B) GLIDING EASILY AND (C) CLIMBING AS FAST AS POSSIBLE

When a bird of prey is "stooping" at a great speed he bends his wing considerably at the elbow and wrist joints as shown at (a) in fig. 2; when he is gliding and not troubling about climbing the bending is slight as at (b); but when he is trying to ascend all he can he straightens his wings and spreads out the primary quills (the pinions at the ends of his wings) so that they are separate from each other over a length of about a fifth of the wing, as at (c). Nature obviously attaches some importance to this feature for she employs a special device to increase the separation beyond that due to the mere fan-like spreading of the feathers; she deliberately leaves the primary quills of full width for about half their length and then steps down the width almost to half the previous amount for the outer half of the length of the quill. This feature, sometimes called the "notch" is apparently universal in birds of prey and the device, as a whole, strongly recalls the Handley-Page slotted wing which enables an aeroplane to climb at a much bigger angle of incidence. Thus G. T. Walker reports having seen vultures climbing on an upward current of about 12ft. a sec., their speed being about 25ft. a sec. up a slope of about 20°, the inclination of the wings also being 20°. If in fig. 3 OP=25 represents the velocity of the bird in space, PN the vertical rate of climb is about 8·5 f.s., so that if QP=12 represents the upward velocity of the air, the rate of climb through the ascending air is NQ=3·5 f.s. and OQ, the bird's path relation to the air, descends at about 8·5°, so that the real angle of incidence POQ is about 28.5°. At first sight it would seem as if the bird could not possibly maintain its forward motion against the resistance of the air. But if we consider the forces acting—the "lift" L (at right angles to the relative motion and so inclined forwards at 8·5° to the vertical) and the "drag" D—it is clear that the condition for maintenance of the forward motion is that the resultant of L and D shall be forward of the vertical, or that (since 8·5°=7·7) the lift shall exceed 7·7 times the drag; this condition is satisfied with a Handley-Page wing.

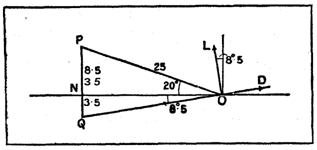

FIG. 3.—FORCES ON A BIRD GLIDING ON AN ASCENDING CURRENT SHOWING HOW THE BIRD IS DRIVEN FORWARD BY AN ASCENDING CURRENT ALTHOUGH THE UPWARD SLOPE OF ITS WINGS SUGGESTS A BACKWARD FORCE

When an aeroplane is losing pace the pilot is tempted to raise the nose of his machine so as to increase the angle of incidence of the wings and get an adequate lift; but this process checks his pace, and if he is still losing height, it may be that no further increase of the angle of incidence will support the aeroplane. The machine is thus said to "stall," control may be lost and a crash occur. Now at such times a Handley-Page slot is of great value in enabling control to be kept; and as a bird trying to climb fast is probably near the stalling angle very often, the slotted ends of its wings have probably the great advantage of enabling it to maintain control. Vultures when climbing may occasionally be seen to make sudden movement of the wings which ends in a short downhill path and probably indicates recovery from a difficult situation of this kind.

Gliding (or Sailing) When the Wind Is Not Uniform.—Lord Rayleigh indicated in general terms the mechanism by which the energy necessary to maintain flight could be derived from the variability of the wind. He pointed out that it is the velocity of the bird relative to the air, not its velocity relative to the ground, which determines the forces acting on it; and the bird can at any time by climbing upwards turn some of the energy of that relative velocity, with comparatively slight loss owing to air resistance, into energy of position; conversely he can with little loss by gliding downhill turn energy of position into velocity relative to the air.

Now if the bird is flying horizontally with relative velocity U, the potential height to which he could climb is $U^2/2g$, where g is the acceleration due to gravity; and if relative to the air he has an acceleration f in the direction of U, U^2 will after an extremely short interval τ become $(U \text{ and } f\tau)^2$ and will so increase at a rate 2Uf; hence the potential height will grow at a rate Uf/g. Also as the bird is moving horizontally L the "lift" must be equal to his weight; and if the ratio L/D is k, D will be the weight divided by k; so as the weight would produce a downward acceleration g, the backward acceleration due to the drag is g/k. Now if the wind is changing in any continuous manner it will have some acceleration where the bird is, which we can call f′, and by steering always so as to meet that acceleration he will secure an acceleration $(f'-g/k)$ through the air and will gain potential height at a rate $U(f'-g/k)/g$ or $U(f'/g-1/k)$. If the bird does not fly directly against the direction of f′ so that there is only a component —f″ along his path, f″ must replace f′ in this formula.

Now it has long been known that the velocity of the wind is in general far from steady and much light has been gained regarding the gustiness due to eddymotion of the air under various conditions. It has been estimated by Walker that in an ordinarily gusty wind of 22m. an hour the acceleration due to turbulence is in excess of 2fss. and for stronger winds proportionally higher. So for a bird with k=12, whose angle of descent would be 5°, we must have f/g not less than $\frac{1}{12}$ or f not less than $\frac{32}{12}$, *i.e.*, 25. Thus a wind averaging $22\times2\frac{2}{3}\div2$, or, say, 30m. an hour would enable a bird to keep up its velocity without flapping.

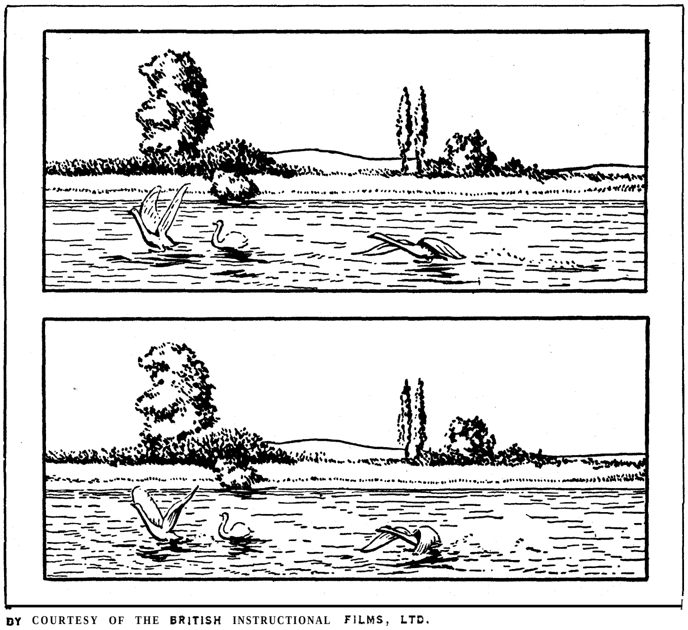
It may be noted that not only do some inland birds of temperate regions, such as rooks, and many sea-birds avail themselves of turbulence for sailing flight, but also tropical birds of prey who usually depend on convection currents. Thus on overcast days when there are not enough upward currents for kites and scavenger vultures to glide they usually remain in their trees; but occasionally a sudden change in the weather will start them gliding in all directions as if aimlessly, or for pleasure; and it would appear that turbulence afforded the explanation. Nonflapping flight is also possible when the wind, though steady, varies from place to place, as when a gull uses the screening of the wind by a vessel to describe circles near its stern.

The principle also has an important application to the gliding or sailing flight of albatrosses and other large sea birds in windy weather away from the influence of ships. It is known that the velocity of the wind must diminish down to the surface of the water owing to the influence of friction at the surface and of eddy-motion in the air; so by rising or falling a bird can get into a stronger or weaker current of air. If then he sails uphill against the wind, the air that he meets will be at increasing heights and will have an increasing velocity in the direction opposite to his motion, so that his rate of travel through it will not diminish as it would if the air were stationary; *i.e.*, he will gain potential height. Exactly the same happens if he sails downhill with the wind, which is then decreasing in speed and has an acceleration in the direction opposite to his velocity. The natural way to combine these effects is to describe circles in an inclined plane, always descending when moving to leeward and ascending when moving to windward. It is accordingly interesting that the results of a mission of Idrac to the south seas to study the problem entirely confirmed Rayleigh's ideas. He found (a) that such flight was only possible for very swift birds, the average speed of the albatross being 72 f.s. or 49 miles an hour; and (b) it needs a minimum wind of 17 f.s. close to the water.

Now the rate of increase of wind with height varies greatly with the conditions; and in the absence of detailed observations close to the surface of the sea we must utilize those over land made by the London Meteorological Office which agree with those at Nauen in giving an excess of 47% in the wind at 50 feet (5 metres) compared with that at $6\frac{1}{2}$ feet (2 metres) above ground. So corresponding to a speed of 24 f.s. at 7ft. we can deduce r, the velocity increase for 1ft. of height, as ·26 f.s. Further, it seems that over the sea in high latitudes the reduction of the velocity will not extend so high as over land, and r will be greater. We shall not be very far wrong in taking it as ·3 though Idrac's formula leads to only ·2.

If the albatross climbs a slope of 1 in 3 at 72 f.s. against the wind his rate of ascent is 24 f.s., so that the increase of the wind in a second is 7.2 f.s. If for simplicity's sake we may treat U as constant in the computation, the rate of gain of potential height $U\,(f/g - l/k)$ is 1·6ft. if $k=15$; so he would in 2 seconds of either climb against, or descend with, the wind gain enough energy to take him 116 yards before further thought was necessary. Of course, a greater rate of increase of wind with height, or a greater efficiency of design, would enlarge his powers, but a moderate rate would seem to give an albatross the ability to roam apparently at will. If he describes a circle inclined at 20° with the lowest point to leeward and say 5ft. above the sea, while the highest point is 50ft. above sea, Walker's approximate formula gives a gain of potential height of 13ft. on describing the circle. Reference may also be made to a letter to Nature by S. L. Walkden.

Flapping Flight.—Birds differ materially in the details of their flapping, the contrasts between the deliberate beat of a heron, the smooth silent flight of an owl, and the hurried whirr



BY COURTESY OF THE BRITISH INSTRUCTIONAL FILMS, LTD.

FIG. 4–5.— WILDSWANS RISING FROM THE WATER

In this series the swans are seen taking off from the lake. As greater driving power is needed than for steady flight, the wings are more rotated on the up beat and brought more forward on the down beat

of a partridge being conspicuous enough. But the general character of the wing movements is the same; and as there have been differences of opinion, mainly owing to the difficulties of observation, regarding the fundamental facts, it will be useful to refer to the twelve reproductions in Plate I. of wild swans derived from a "slow-motion" cinema film made by British Instructional Films, Ltd. In Plate I., fig. 1, the two top birds are marked (a) and (b), and in fig. 6 will be found diagrams (1) to (12) showing approximately the positions of the wings of bird (a) at instants corresponding with the figures of the plate. In them two features stand out prominently; (a) the time interval between successive pictures being constant, the time of a down beat is half as long again as that of an upbeat; and (b) though the wings are kept straight during positions 2–6 of a down beat, they are bent during 8–11 of the up-beat, the outer portions remaining almost at the same angle with the horizontal for the time 7–9, and being then lifted with a flick in the second half of the upbeat, 9–11. As may be readily seen in Plate I., the motion of the wings relative to the body consists of an up and down beat roughly in a vertical plane when the bird is in horizontal steady flight. The rotation, or twisting of the wing about its own long axis also is of importance as it affects the angle of incidence, *i.e.*, the angle between the direction of motion and the plane of the wing (between X'X and AB in fig. 1). It will be seen from Pl. I., fig. 3 that while the wings of b, during an upbeat, are inclined decidedly uphill, those of a, in a downbeat, are less clearly downhill; the same is true in figs. 6, 7 with a and b interchanged. If now the bird's body is describing from right to left an approximately straight line OQSU (fig. 7) a point in the outer portion of the wing will describe an undulating line OPQRSTU, with the upbeats steeper than the downbeats. So if we indicate the plane of the wing as shown in the film, clearly uphill at O and slightly downhill at Q, it will be seen that on the downbeat, as at Q, the angle of incidence is positive and the lift L is upwards at right angles to the path; while on the upbeat, as at S, the angle of incidence is negative, so that L is downwards and forwards. The drag D is always backwards along the path.

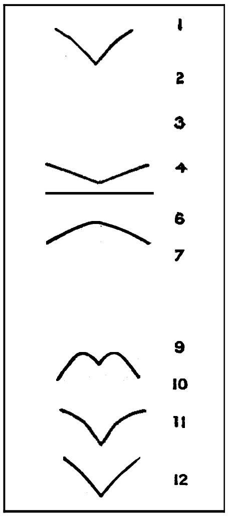


FIG. 6.—PROFILES OF WINGS DURING A DOWNBEAT AND AN UPBEAT MADE AT EQUAL INTERVALS SHOW THAT THE UPBEAT TAKES PLACE MORE THAN THE DOWNBEAT, THE OUTER PORTION OF THE WINGS BEING RAISED WITH A FLICK

It will be seen that the force L always tends to drive the bird forwards; and as it is much greater than D which tends to retard the forward motion, the outer portion of the wing contributes propulsion. Also both L and D have a downward tendency during the upbeat, though the tendency is upward during the downbeat; so this portion of the wing is of little avail for support. With the inner portion, however, the situation is quite different. Here the slight up-and-down motion is almost cancelled by the slight down-and-up motion of the bird's body, so that the flight is essentially non-flapping; the section of the wing must be adapted for high lift and the angle of incidence is positive so that there is lift all the time.

Reference to fig. 7 will show that the plane of the wing is twisted. Near the top of the upbeat, when the upward flick of the outer portion occurs, the plane of the outer portion at B will be inclined more uphill than of the inner portion at B_1, but this is not so in the early portion of the upbeat at A and A_1. And during the downbeat the outer portions of the wing will be inclined downwards but not the inner portion. These inferences may be verified in the illustration of Plate II. of Kittiwake gulls. In figs. 1, 2 of Pl. II., we have the downbeat of the marked bird with the downward inclined tips seen almost edge on. At the beginning of the upbeat in 15, the inner portions are inclined uphill more than the tips; but in 5, during the flick, the tips are inclined uphill more steeply than the inner portions.

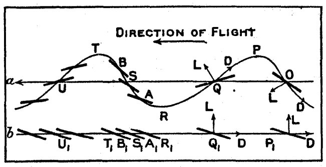

FIG. 7.— THE ROTATION OF THE WING: (A) OUTER THIRD, (B) INNER THIRD, ILLUSTRATING WHY THE INCLINATION OF THE INNER AND OUTER PORTIONS OF A WING IS DIFFERENT DURING THE FLAPPING FLIGHT

As will be seen from the reproductions, the swans (a) and (b) are ascending, so that their beats must be stronger than if they were flying horizontally; and it is worth while to see what modifications occur when a bird has to exert all his force. In the figures 4–6 we have some wild swans flapping hard to get into the air, that to left in 4 beginning his downbeat; that to right is beginning his upbeat. They have not yet acquired much pace, and are using their feet as well as their wings. It will be seen in 5, that, as far as rotation is concerned, the plane of the wings of one is inclined downhill, while that of the other is uphill, and the reason is that, with a speed insufficient for the inner portion to support the weight by mere gliding, the bird has to adopt an uphill path and aim at more propulsion; so he uses most of the wing as he previously used only the outer portion, and with marked rotation of the type indicated in fig. 8. At the lowest point (*see* fig. 5) the wings are rather forward, partly in order to avoid the water. but also in order to secure propulsion along a more upward direction.

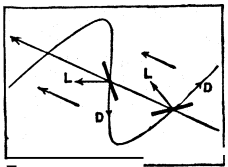

FIG. 8.—BIRD CLIMBING STEEPLY, SHOWING HOW THE WHOLE WING IS EMPLOYED IN PRODUCING FORWARD DRIVE

The question naturally arises whether a machine fitted with aerofoils of known properties as wings attached to a torpedo-shaped body would support and propel itself in the air if its dimensions and weight were those of a typical bird such as a rook; and the wings were flapped in approximately the same manner. To this Walker, as the result of an approximate computation with a "high lift" inner third of the wings for support and a flat outer third for propulsion, replies "Yes." He also finds that the power requisite compares not unfavourably with that necessary for a screw propeller driving a gliding bird with fixed wings.

Flight by Creatures Other Than Birds.—There is no evidence of the use by these of principles other than those described; and it will therefore suffice to indicate the chief types:—Bats, Flying Lemurs, Flying Squirrels, Flying Phalangers; Pterodactyles (extinct), Flying Lizards (or Dragons), the Flying Snake of Borneo; Flying-fishes, Flying-gurnards, American and African Fresh-water Flying-fishes; Insects.

See also AERONAUTICS and the long series of articles described under AERONAUTICAL ARTICLES.

FLINCK, GOVAERT (1615–1660), Dutch painter, was born at Cleves on Jan. 25, 1615. He first studied under L. Jacobszon in Leeuwarden and later entered Rembrandt's studio, becoming one of the master's most accomplished followers. As a painter of Biblical and allegorical subjects he at first modeled himself very closely on Rembrandt's style, as, for example, in his "Crucifixion" (1643?) in Basel, but later he developed a more florid and oratorical manner, in which he appears to have been influenced by Rubens, as in the allegory of 1654, "Amalia van Solms Mourning the Death of Her Husband. Prince Frederick Henry of Orange," in the Rijksmuseum, Amsterdam. Flinck's most successful genre was portraiture. In this, too, his earlier works are extremely close to his master, for instance the "Portrait of Rembrandt," signed and dated 1639, in the National gallery, London. which had passed (with the aid of a forged signature) as a self-portrait by Rembrandt himself. In later portraits his own individuality is more apparent, and he is especially successful in his groups, among which one may single out the portrait of "A Goldsmith and his Family" in Brussels, and the splendid large groups of "Civic Guards" in the Rijksmuseum. Flinck died at Amsterdam on Feb. 2, 1660. (R. E. W. J.)

FLINDERS, MATTHEW (1774–1814), English navigator, was born at Donington in Lincolnshire on Mar. 16, 1774, and entered the navy in 1789. He served in the "Bellerophon" at Ushant in 1794, and from 1795 to 1799 was engaged in exploration on the Australian coast, including the circumnavigation of Tasmania in 1798. On his return to England he was appointed to the command of an expedition for the thorough exploration of the Australian coasts. The sloop "Investigator" left Spithead on July 18, 1801, and reached Cape Leeuwin on Nov. 6. On his way round the coast he met the French exploring ship "Le Géographe" on Apr. 8, 1802, in what is now Encounter Bay. The narrative of the French expedition claimed discovery of most of the land west of the point of meeting, and the matter was not cleared up till the publication of Flinders' book in 1814.

Flinders reached Port Jackson on May 9, 1802. On July 22 he set out again to complete the circumnavigation of Australia. He examined the Great Barrier Reef and surveyed the gulf of Carpentaria, and then, finding the "Investigator" to be in a leaky state, sailed round the west and south of Australia back to Port Jackson, which he reached on June 9, 1803, after a voyage in which much suffering had been endured by everyone, particularly from scurvy. He left Port Jackson for England in the "Porpoise" which, together with the "Cato," was wrecked on a coral reef, about 800 miles out, on Aug. 17. The officers and men camped on a small sandbank, while Flinders returned to Port Jackson in a six-oared cutter to obtain relief. He got back and took them off on Oct. 8, and on the 11th sailed again in the "Cumberland." Putting in at Mauritius on Dec. 15, he found England and France at war, and his passport from the French government did not cover the "Cumberland." He was detained until June 1810, and reached England in October. His narrative, *A Voyage to Terra Australis*, was published on July 19, 1814, on which day Flinders died. This work contains very valuable scientific observations, especially with regard to magnetism, meteorology, hydrography and navigation. He seems to have been the first to discover, and correct for, the errors of the compass caused by iron in ships. He also wrote *Observations on the coast of Van Diemen's Land*, etc., and two papers in the *Phil. Trans.* in 1805 and 1806.

FLINDERS BARS, vertical bars of soft iron placed in front of or behind a ship's compass to compensate the disturbing magnetic effects due to the vertical soft iron parts of the ship. Other effects due to soft and hard iron in horizontal and vertical directions are also eliminated by bars or by spheres appropriately placed. *See* COMPASS.

FLINDERS RANGE: *see* AUSTRALIA.

FLINSBERG or SWIERADOW ZDROJ. a village in Lower Silesia region, Wroclaw province, southwestern Poland. It lies near the Czechoslovakian border at the foot of the Isergebirge on the Kwisa river about 18 mi. W. of Hirschberg (Jelenia Gora). Pop. (1946) 2,994. Flinsberg is a noted health and winter sports resort.

FLINT, AUSTIN (1812–1886), U.S. physician, was born at Petersham, Mass., on Oct. 20, 1812, and graduated in medicine at Harvard university in 1833. From 1847 to 1852 he was professor of medicine in Buffalo Medical college, of which he was one of the founders, and in 1852–56 he filled the same chair in the University of Louisville. From 1861 to 1886 he was professor of medicine in Bellevue Hospital Medical college, New York. He wrote many textbooks on medical subjects. among these are *Diseases of the Heart* (1859–70); *Principles and Practice of Medicine* (1866); *Clinical Medicine* (1879); and *Physical Exploration of the Lungs* (1882). He died in New York on March 13, 1886.

His son, AUSTIN FLINT (1836–1915), who was born at Northampton, Mass., on March 28, 1836, after studying at Harvard and at the University of Louisville, graduated at the Jefferson Medical college, Philadelphia, in 1857. He then became professor of physiology at the University of Buffalo (1858) and subsequently at other centres, his last connection being with the Cornell University Medical college (1898–1906). His *Text-book of Human Physiology* (1876) was for many years a standard book in U.S. medical colleges. He also published an extensive *Physiology of Man*, 5 vol. (1866–1874) and other valuable medical works. He died in New York city on Sept. 23, 1915.

FLINT, TIMOTHY (1780–1840), **U.S.** clergyman and writer, an important social historian of the early Ohio valley, was born near North Reading, Mass.. July 23, 1780. After graduation from Harvard in 1800 he served as a Congregational minister at Lunenburg, Mass., 1802–14. In 1815 he left for the Ohio valley, engaging in missionary work for a time and farming at St. Charles, Mo. Subsequently he visited Louisiana and was principal of a seminary at Alexandria. Plagued by ill health, he moved to Cincinnati, O., where he edited the *Western Monthly Review* (1827–30) and devoted himself to literary work. He served briefly as editor of the New York *Knickerbocker Magazine* (1833). Besides editorial work. Flint wrote history, biography and four novels. His *Recollections of the Last Ten Years* (1826) is a valuable account of early western life and manners. In 1826 he also published his best novel, *Francis Berrian: or the Mexican Patriot,* in which he utilized some of his own experiences. *A Condensed Geography and History of the Western States* appeared in 1828 (rev. ed., 1832), his edition of the *Personal Narrative* of the adventurer James O. Pattie in 1831 and his biography of Daniel Boone in 1833. *George Mason, the Young Backwoodsman* (1829) is a novel of Mississippi river life, and *The Shoshonee Valley* (1830) is a far western romance notable for its fantastic plot and lush description. He died at Reading, Mass., on Aug. 16. 1840.

See J. E. Kirkpatrick, Timothy *Flint* (1911), which contains a bibliography. (J. T. Fn.)

FLINT or FLINTSHIRE (*Sir-y-Fflint*), a county of north Wales, bounded north by the Irish sea and the Dee estuary, east by Cheshire, and south and west by Denbighshire. Pop. (1951) 145,279. Area 255.8 sq.mi. Included in Flint are the detached parish of Marford and Hoseley, lying 2½ mi. southeast of the main part of the county, and the hundred of Maelor, a separate rural district, lying 8 mi. southeast of the main part. Maelor is bounded by Cheshire, Shropshire and Denbighshire.

Physical Features. — The county is dominated by the Clwydian hills running south-southeast to north-northwest. Their western slope to the Vale of Clwyd is steep but the eastern slope over much of the county to the Vale of Dee is more gentle. The Clwydian hills are entirely of Silurian age; their highest point is Moel Fammau (1,820 ft.) on the Flint-Denbighshire boundary. The Silurian strata of the hills, all of Ludlow age, are faulted against the Triassic (Bunter) Red Beds in the Vale of Clwyd. On the eastern flank of the range the Silurian is overlaid by Carboniferous rocks which, for their economic value, are the most important rocks in the county. A band of Carboniferous Limestone passes from Prestatyn on the coast, forms the Halkyn mountain (943 ft.) and continues west of Mold to beyond the county boundary. Above these beds come the Holywell Shales while upon them lies the Gwespyr Sandstone. Farther to the east the Coal Measures extend from Talacre through Flint and Mold to Hope. A purple sandstone succeeds the Carboniferous Limestone in the neighbourhood of St. Asaph.

The Alyn enters the county near Moel Fammau and passes Cilcen and Mold with a section of underground drainage in the Carboniferous Limestone near Hesb-Alyn ("the drying up of Alyn") and bends south to Caergwrle, re-enters Denbighshire and joins the Dee. The Dee enters Flintshire near Overton and divides Maelor from Denbigh on the west, then passes Chester and forms the eastern boundary of the county on the northeast. It enters the Irish sea by means of a wide but shallow estuary. The northeastern part of Flintshire is a low-lying country bordering the Dee estuary which extends westward to the mouth of the Clwyd valley. This has been one of the great "ways" into Wales for many centuries. Short stretches of blown sand occur between Rhyl and Talacre.

History **and** Architecture. — The post-Roman centuries saw Flintshire under the influence of the Celtic saints, the Saxons and the Northmen. St. Beuno, who has been called the St. David of the north, is commemorated by legends in Flintshire. The lives of St. Kentigern ascribe to that long-lived Glasgow saint the foundation of the monastery of St. Asaph, later the cathedral city of the diocese. One of the few relics of ancient Christianity in the county is a late sculptured cross, Maen Achwyfan, in Whitford parish. The Anglo-Saxon occupation of the more fertile low-lying part of the county left its mark on place names as far north as Prestatyn. The famous earthwork, Offa's dyke, a poor defensive work with a gap of over 20 mi. between Pantasaph and Treuddyn, is backed by the shorter and better preserved Watt's dyke, which begins near Holywell and runs out of the county beyond Hope. Sir Cyril Fox in his standard work (*Offa's Dyke*, London, 1955) shows that the dykes start 12 mi. apart at Prestatyn and Holywell and that the lines almost converge at a point outside the county.

The Normans at first found north Wales an easy prey. A great castle and a borough were built at Rhuddlan. The twin lordship of Mold and Hawarden became the prize of the Montalt family, who had castles at both places. Flintshire was the easy road into north Wales and for 200 years. as Welsh resistance stiffened, nar in the county was almost unceasing. The earls palatine of Chester fought many of the early battles. Henry II suffered a decisive check (1156) in the forest of Ewloe. Henry III relied greatly on his favourite castle at Dyserth and struggled to defend it in a long war and through many truces. Edward I finally built a great castle and a borough at Rhuddlan on a new site, and a castle and bastide at Flint, and achieved a final conquest in 1284. The Welsh had revived notably under Owain Gwynedd and the two Llewelyns, and the result of this roo years' fighting was that Welsh influence penetrated almost to the walls of Chester.

Edward I in 1284 formed the county of Flint out of the northern cantred of Tegeingl, taken from the Welsh principality of Gwynedd; the hundred of Maelor, taken from the dowager of the Welsh princely line of Powys Fadog; and Hope and Hopedale, anciently part of Powys and taken immediately from the last Welsh prince, David. The county was in three detached portions. When Henry VIII suppressed the lordships of the march, in the Acts of Union (1536–42), he gave Moldsdale and Hawarden to Flintshire and so joined the cantred of Tegeingl to the land of Hopedale, leaving the county in two main portions, as it is still.

In the civil war of the 17th century, Flintshire was solidly royalist, and the castles. Hawarden, Flint and Rhuddlan, were garrisoned again to protect the communications between Chester and north Wales and Ireland. After the fall of Chester, the castles surrendered slowly and were slighted (dismantled) by order of parliament.

The county contains two mediaeval religious houses — Basingwerk abbey, near Holywell, a Cistercian house founded about 1131 and patronized alike by Welsh princes and Norman counts, and Rhuddlan priory (*c.* 1258), a house of Dominicans; its ruins were later incorporated in a farmhouse. The rise of the great Welsh religious denominations in the 18th and 19th centuries caused a profound change in the social life of Wales. Flintshire, especially on the English border in the Maelor district, had early associations with Puritanism. But the Calvinistic Methodism of the highlands of Denbighshire was not so marked in Flintshire, though the western section of the county was much affected. Holywell has always been a Roman Catholic centre.

In the second half of the 19th century. Daniel Owen (1836–95) of Mold, wrote a number of Welsh novels depicting the life of his times, and earned a permanent place in Welsh letters. The county has been influenced in its architecture as in its life as much from England as from Wales. In addition to the notable Edwardian castles — Flint, with an unusual plan, and Rhuddlan — there is the interesting castle of Ewloe, built by Welsh princes in imitation of Norman work. The prosperity of the county in the 16th and 17th centuries is shown by a large number of country houses of that period. such as Fferm, Gwysaney, Rhual, Golden Grove, Plas Teg, Vaenol. In the 18th century Leeswood hall was built from the profits of lead mining. The most elaborate church is perhaps the old Perpendicular church of St. Mary in Mold, built by the Stanleys in Cheshire style.

Archaeology. — Caves in the Lower Carboniferous rocks bordering the Vale of Clwyd have yielded plentiful remains of Pleistocene mammals, particularly Cae Gwyn and Ffynnon Beuno near Tremeirchion and the Gop cave, Newmarket, or Trelawnyd. Microliths found in the Gop cave suggest Mesolithic occupation and a Mesolithic site has also been recorded near the coast at Prestatyn. Few traces of Megalithic influence survive in the county, Neolithic occupation has been proved at Dyserth and Gwaenysgor in the north near the coast, and the Gop cave was used in Neolithic times for burial and shelter. The later Bronze Age was obviously an important time in the county's prehistory. Barrows are numerous especially on the Halkyn-Brynford plateau. Sir Cyril Fox's excavation of the earth circle and barrow at Lower Stables farm in a distant part of Ysceifiog parish is a notable piece of work. A gold ceremonial cope or tippet, now in the British Museum, London. was found at Mold in 1823. About the same time a gold torque was found somewhere in the large parishes of Caerwys or Ysceifiog, and a gold hoard just over the county boundary at Maesmaenan. The Caergwrle cup, in the National Museum of Wales at Cardiff, is probably of this period. A jet necklace of unusual type appeared in a barrow at Llong, which was under excavation in 1956. The impressive hill forts on the Clwyd range have yielded finds of Roman coins. A tribe known as the Deceangli held what is modern Flintshire as their territory. They were overrun by the Romans in an early campaign and the great legionary fortress at Chester must have kept them in subjection. Considering the nearness of Chester, the scarcity of Roman remains in Flintshire is a mystery. Some of the land may have been densely forested and uninhabitable. There were Roman smelting-works at Flint and pigs of lead have been found marked DECEANGL, the name of the Celtic tribe occupying what was later called Tegeingl in Welsh. A Roman bathhouse of legionary type has been found at Prestatyn and the important and ancient Talargoch lead mines are nearby.

Agriculture and Industries. — The Vale of Clwyd is well known for its pasture lands. Out of the 163,712 ac. of land in the county, 117,58j were, in the mid-1950s, under crops and grass, of which 21,704 ac. were in tillage crops. Oats, mixed corn and wheat are the chief crops. Milk production is the main enterprise, while pigs and poultry contribute materially to the farming economy. There is a high stock density, Friesians being a leading breed followed by Ayrshires and Shorthorns. Early lamb production was increasing in the mid-1950s, Welsh ewes being crossed with Border Leicester and Down rams.

Flintshire is, from an industrial point of view, one of the most important of the Welsh counties. It has been known from early times that the county was rich in mineral deposits as the Romans mined lead there, later copper and lead were worked and throughout the 19th and early 20th centuries a considerable quantity of coal was mined and there are still coal mines in the county. Copper and lead are no longer worked.

In the first half of the 19th century large industries sprang up with consequent substantial increase in the county's population and prosperity. The principal manufacturing industries include iron and steel, rayon, aircraft manufacture, chemicals, paper making, woollen textiles, cement, brick-making and quarrying in its various forms. Steel is manufactured on a large scale on Deeside. The principal product is steel sheet. There are large iron works producing mainly a manganese alloy of iron. In the Flint area are some of the largest rayon plants in Europe manufacturing rayon staple fibre by the viscose process, with distribution to Lancashire, Yorkshire and abroad. Rhyl and Prestatyn are attractive seaside resorts on the north coast.

Administration and Communications. — Flintshire is divided into 4 rural districts, 6 urban districts and the municipal borough of Flint (pop., 1951, 14,267). Between the census of 1931 and that of 1951 the population of the county increased by 32,219 chiefly because of industrial development. Flintshire is within the Wales and Chester circuit and the assizes are held at Mold; there is one commission of the peace. Considerable interest is taken in technical and agricultural education, the county council having provided a modern and extensive technical college and a horticultural college. The main part of the county is in the diocese of St. Asaph, but there is a small portion in that of Chester. The county returns two members to parliament, for East and West Flint.

The Chester-Holyhead main railway line runs along the east and north coasts of the county and a branch line from Chester to Mold and Denbigh serves the central area.

FLINT, a city of southeastern hfichigan, U.S., 62 mi. N.W. of Detroit; county seat of Genesee county. Pop. (1960) city, 196,940; standard metropolitan statistical area (Genesee county), 374,313. The city was named for the Flint river. The first settlement occurred at the Grande Traverse, where the Mackinaw trail crossed the river; there Jacob Smith, a Detroit fur trader, established an outpost in 1819, soon after the land passed from Indian control. The emigration of settlers from western New York led to the organization of the county, with Flint as the county seat, in 1836. Flint became the trading centre of the Saginaw valley farming area and was incorporated as a city in 1855.

For the next 30 years, Flint was one of Michigan's lumbering centres, but with the depletion of the pine stands in the 1880s, Flint's importance declined. The success of the two-wheeled road carts manufactured by the Durant-Dort Carriage company in 1886 opened its manufacturing era. By 1900 Flint was widely known as the "Vehicle city," with a population of more than 13,000 and a production of more than 100,000 horse-drawn wagons and carriages annually. The body, spring and wheel companies of the carriage industry became the suppliers for the rapidly expanding Buick Motor company, organized in 1903. Thereafter, the city's growth paralleled the business successes of William C. Durant and other former carriage makers. In 1908 Flint's major manufacturing resources were consolidated into the General Motors company. Flint's continued growth reflected the success of the automotive industry, and in the second half of the century it was the site of the largest single manufacturing operation of the General Motors corporation. Supplying the needs of that industry and other commercial activities are two railroads, the Grand Trunk Western and the Chesapeake and Ohio, and many trucking lines. Flint's retail trade area has a radius of 25 mi.

At mid-century, more than 90% of the total manufacturing labour force was engaged in some phase of the automotive industry. According to the 1950 federal census, more than 85% of Flint's population was native-born. By 1958, however, it was estimated that less than 20% of its population was born in Genesee county. The continued migration to the automobile factories, begun in 1904, had considerable influence on Flint's metropolitan population.

Flint adopted the commission-manager form of municipal government in 1929. A 1933 amendment established a nine-ward division of the city with a commissioner elected from each ward. The rapid growth of the metropolitan fringe area after World War II encouraged efforts to bring the whole area of 162 sq.mi. under a single government.

A new municipal centre, including a city hall, municipal court building, police department headquarters and health department building and auditorium, was completed in 1958 at a cost of more than $7,000,000.

In addition to its public school system. Flint's educational institutions include a publicly supported junior college; the General Motors institute, a private technical school; the Mott foundation (which offers a program in co-operation with the community schools); and the Flint college of the University of Michigan.

As part of Flint's $25,000.000 college and cultural development project, a combined campus for the city's two colleges was dedicated in 1954, and four years later a natatorium, art centre, planetarium and theatre were completed. A new public library was also opened in 1958. The city park system included three golf courses, four swimming pools, and over 1,750 ac. of parks.

(R. H. V. B.)

FLINT, a municipal borough in the East Flint parliamentary division of Flintshire. Wales, on the Dee estuary, 12 mi. W N.W of Chester by road. Pop. (1951) 14,267. Area 10.6 sqmi. At Pentre, along the coast, was a Roman settlement. Flint castle was built on an isolated rock by the river side by Edward I, whose architects laid out the town, geometrically, beneath the castle and who granted it the first charter in 1284. The castle held out against Owen Glendower; it was held for the king during the Civil War but taken, after siege, by the parliament, and finally dismantled in 1647.

First a market town and seaport, Flint became, in the 19th century, a coal-mining and lead-smelting town. The introduction of rayon manufacture, still the chief industry, brought it prosperity in the 20th century and other industries include paper mills at Oakenholt, iron and steel works at Shotton and aircraft manufacture at Broughton.

FLINT: see CHERT AND FLINT.

FLINT-LOCK: see SMALL ARMS, MILITARY.

FLINT RIDGE CAVE SYSTEM, in Mammoth Cave National park (*q.v.*) in Kentucky, is an integrated complex of caves and underground rivers. Thirty-five miles of passages are known. The integration of the system has been established by surveys and exploration and by an extensive series of dye tests conducted on the underground drainage. Flint Ridge is an erosional plateau of ten square miles, capped by layers of resistant sandstone and impervious shale and underlain by 275 ft. of relatively pure limestones, all bedrock being of Middle Mississippian (Carboniferous) Age. This unique stratigraphic sequence in a karst (*q.v.*) area is responsible for the unusual characteristics of this cave system.

Especially prominent, in addition to its great length, are the localized abundance of distinctive vertical shafts, many of which exceed 150 ft. in height; fantastic and extensive sulfate mineral decorations; sparse but attractive stalacto-stalagmite displays; the magnificent size of many of the cave passages; and archaeologic artifacts.

Individual caves which have played a part in the region's colourful history include Salts, Colossal, Unknown, Floyd's, Potato, Logsdon, Great Onyx and Blair. The hub and gateway of the system is Floyd Collins' Crystal cave, named after its discoverer (1917) nho also lost his life there (1925) trying to find a new entrance, and its Blind Fish river which issues as Pike spring on Green river (the base-leveling surface stream of the region), where all of the affected drainage converges. Much of the knowledge of this system is due to the efforts of attack teams of the National Speleological society and the Cave Research foundation.

(E. R. P.)

FLINTS. The term flints is popularly used to denote implements made by men of the Stone Age, since in Europe flint and flinty materials were frequently used for that purpose.

Flint is a hydrated silica containing a varying amount of water loosely held in combination. When pure it is translucent, but impurities render it opaque and coloured, commonly either black or brown. Irregular flint nodules occur native in horizontal bands in chalk. Their origin is not clearly understood. In some cases it is undoubtedly due to marine organisms, such as sponges which, requiring silica for their growth, secrete it from the water.

Under certain imperfectly understood conditions the water in the flint seems to dry out, leaving on the exposed surface a thin film of white silica; this is known as the patina. When thick it gives a quite white appearance; when very thin the colour of the unchanged flint underneath shows through, so that a black flint will have a blue appearance. Flint itself is impervious to moisture, but the patina is porous. Thus when patinated flint occurs in gravels containing iron salts a yellow staining, producing the well-known ochreous patina, results. Patinated flint embedded in peats also gets stained in a characteristic manner. Other varieties of staining called by fanciful descriptive names are often due to the patina occurring in patches; thus we have the "toad-belly" patina found in certain gravel pits in East Anglia. Originally the patinated surface is matt, but where the object has been rolled to some extent in soft sands or loams it becomes polished and lustrous. The thickness of the patina skin is partly a question of the length of time during which the weathering process has operated but it naturally depends on local conditions.

FLINT IMPLEMENTS OF THE OLD STONE AGE

The discovery of artificially chipped flint in soii belonging to the Palaeolithic epoch has enabled science to trace, with firmer conviction, the history of man back to that period

Flints are fractured easily and evenly in three ways, by percussion, by pressure, and by temperature changes.

Percussion Flaking. — If a lump of flint is struck with a sharp blow concentrated at a point it breaks in such a way that a sort of cap can be lifted off, exposing a double cone consisting of a broad angled cone resting on the truncated apex of another with steeper sides, there being a more or less sharply defined shoulder at the junction of the two. The cap which comes off naturally shows a hollow corresponding to these cones; this is known as the negative cone. If the blow is delivered on the margin of the block a flake comes off showing a swelling near the point of impact. This is the so-called bulb of percussion; it is a partially formed cone. Around this bulb curved lines often appear on the flake, the concavity being always toward the apex of the bulb. This is important. as it sometimes happens in the case of an implement that the bulb has been removed subsequently; but it is still possible to tell from these curved lines the direction from which the blow originally came. When the blow has been particularly intense, lines of fracture radiating from the point of impact also appear on the surface of the flake. They form radii to the curved lines. A small flake scar known as an *éraillure* is often seen on the surface of the bulb. This is not due to an attempt by prehistoric man to get rid of the bulb, but appears under certain conditions when a flake is struck off.

When a piece of flint is struck the force of the blow rapidly diminishes as it penetrates the dense medium. Should there be sufficient energy the fracture set up by the blow, especially if it is struck diagonally outward near the edge, will go right through the flint. a flake being removed. In this case the new flake-scar forms a clean angle where it meets the original surface of the flint. Should the blow be directed inward, however, and only penetrate a short way into the flint the shattering will cause a fragment to break off which leaves ridges where the two surfaces meet. The first method is known as "feather-edge" flaking, the second as "resolved" or "step" flaking. Both were used as secondary working to toughen an edge and it is important to differentiate between the two, as resolved flaking is especially common in certain prehistoric cultures. In nature percussion flaking takes place by torrent action, where materials are hurled together, the result being chipping in all directions (flint thus knocked about shows innumerable minute incipient cones of percussion); by sea action, where not only is beach material hurled by the waves against larger fixed rocks and so chipped indiscriminately, but also is sucked back by the waves, so that any chance lump of flint embedded in the beach becomes in time much chipped in one direction by the passing pebbles; by ice action in glaciated regions.

Pressure Flaking. — This method of flaking flint was employed by prehistoric man and is still used by many primitive peoples, such as the aborigines of Australia. The aborigine takes a flake and, using the sole of his foot as a tough anvil, presses off little flakes along the margin, wherever he requires a sharp edge or desires to remove material. When a large flake is thus removed a bulb of pressu-e corresponding to the bulb of percussion appears, but it is, as a rule, considerably flatter. Usually flakes removed by pressure are small and scalelike. The resulting flake scar shows a large number of curved lines like those round a bulb of percussion but generally rather flatter and closer together; the consequent reflection and refraction of light give a characteristic glassy or waxy appearance to an unpatinated pressure-flaked surface. In nature pressure-flaking results from the differential movement of gravels containing a large number of pebbles, such movement being often due to the slipping of a gravel bed down the side of a valley or the caving-in of a gravel bed owing to the solution of some underlying limestone deposit by underground streams. Thus pebbles get forced against one another; and in the latter case especially the pressure tends to come all from one direction, and so definite trimmed edges are produced.

OLD STONE AGE FLINTS FOUND AT LE MOUSTIER, FRANCE

Upper row: points, used for spears or arrows; centre: a hand ax; bottom row: side-scrapers

Temperature Changes.—Flint is a very poor conductor of heat but it expands with a rise of temperature. If then the exterior is rapidly heated accommodation with the interior has to take place and there results a series of fractures. In this case no bulb of any sort occurs, but the fractured surface is covered with irregular closed rings. This method has been rarely used by man; but thermal fractures. as they are often called. naturally caused by daily and seasonal changes in temperature, are of common occurrence. Frost action is especially characteristic. As a rule the surface of the flint becomes pitted and covered, as it were, with small hemispherical depressions. Under certain circumstances, too, prismatic bars of flint are found, the formation of these being analogous to that of the prismatic columns occurring in basalt. This is commonly known as "starch" fracture. At first sight these prismatic bars of flint might be taken for cores from which long narrow flakes had been removed. The complete absence of any bulb, coupled with an appearance characteristic of a thermally fractured surface but difficult to describe, at once distinguishes the two.

Mr. Reid Moir has attempted, by studying microscopically fractured surfaces of the flint, to distinguish between the various methods just described. With regard to the appearance of percussion and pressure-flaked surfaces, a rough analogy may be made respectively with the surface of an apple cut by a knife, which is smooth, and that of an apple broken between the two hands, which is rougher and more hackly. No results, of course, can be obtained where the surfaces have been subsequently patinated.

It has become desirable to find criteria which will demonstrate whether a chipped object has been fashioned by man or by nature. As noted previously, when nature chips flint, whether by percussion or pressure, the direction of the blow or pressure comes either from one or an infinite number of directions. What nature cannot do is to apply blows or pressure in two or three definite directions more or less at right angles to one another. Thus it is difficult for nature to knock off a flake and then trim one of the edges, an action involving two directions of blows; and it is almost impossible to invoke nature as the agent if we find a specimen showing also a "prepared" platform on which the blow making the original flake had been struck, thus involving blows from yet a third definite direction. Nor would it have been more possible for nature to achieve this result did we postulate, as might more probably be the case, that the direction of the blows remained constant and that the object itself was revolved once or twice through go° while receiving the blows.

Of course prehistoric man did not only make his tools of flint, chalcedony, chert, and other flintlike materials which furnish a sharp but brittle working-edge; any kind of fine-grained rock was utilized. In these latter materials the fracture phenomena are similar to those of flint but are far less in evidence and much more difficult to identify. Such rocks, too, fracture irregularly, and it was not till Neolithic man adopted a grinding and polishing technique that a sharp regular edge was obtainable which had the added virtue of being tough.

Typology (*q.v.*) enables the prehistorian to group the various tools of the Stone Age into families according to their purposes or significant characteristics. The following is a summary of the more important of these tool families.

Coups de **poing** (sometimes called hand-axes or bouchers).—Originally pear-shaped, boldly flaked, and with irregular edges; later they become flatter and finer. An oval form also develops. In the latter case the edge shows the "S" twist characteristic of the Acheulean culture, where the top part of the tool is, as it were, slightly rotated upon the bottom half. The coup de poing family is especially characteristic of Lower Palaeolithic cultures.

Scrapers.—The essential feature of the scraper is its sharp, convex edge. The chief varieties are side-scrapers, end-scrapers on blades or flakes, round-scrapers and core-scrapers. Side-scrapers generally show the characteristic "resolved" flaking and belong to the Mousterian culture: the other varieties are post-Mousterian. A special kind of core-scraper, in which the flakes removed are narrow and flat and rise fanwise to a well defined keel, is known as the keeled or tarti-scraper. It is a characteristic tool of the Middle Aurignacian culture, when such a fluting technique was common.

Awls.—A true awl has a point prepared by careful trimming all round. Pseudo-awls which have the point trimmed only halfway round, the under surface remaining a part of the general flake surface, are, however, common.

Points.—These form a varied family comprising a number of related types and others the connection of which is more obscure. Some types were doubtless used as lance-heads, *e.g.,* the Mousterian Point and the Solutrean Laurel and Willow leaves, others, such as an important series which grade from what are known as Xudi Points to Gravette Points were probably pointed knife blades. They have the side of the blade opposite the working edge blunted. This series enables us to subdivide the Aurignacian period into a number of stages.

Pigmy Tools.—The pigmy family includes several distinct types which are named, according to their shape, lunates, crescents, triangles, trapezes, and pigmy scrapers. They are linked together by the fact that they formed the sharp working edges of finished tools, being hafted in various ways into handles made from some other material. The chipping seen on them is generally intended to blunt the edge which is actually to be hafted lest it should cut into or split the haft. Pigmies are found all over the world during widely different periods; they do not necessarily all belong to the same culture.

Celts.—The Celt family is characteristic of Neolithic times, and a grinding and polishing technique is often employed in their manufacture. The original type when chipped only is not unlike the coup de poing at first view. But the carefully prepared sharp, convex working edge is at the broad end of the tool. Two evolutionary series can be determined—one North European, the other West European. In the former the sides of the tool become squared and finally the upper and under surfaces become flat, a section through the tool being rectangular. In the latter the round squat original type becomes flatter and more chisel-like.

Arrow-heads.—Many varieties of arrow-heads are known, some with wings and a central tang, others with wings or tang only; some again are lozenge or leaf shaped. Not only can an evolutionary series be to some extent determined, but certain types only occur commonly in definite areas.

Bone tools, found associated with stone tools during certain periods, can also be classed into families. Harpoons for example form an important evolutionary series, starting with a primitive form where the barbs are hardly detached from the stem and developing through the detached single-barbed varieties to the double-barbed specimens. This series is important for subdividing the Magdalenian culture. Other important bone families are lance-heads, needles, and polishers.

FLOATING DEBT: see DEBT, PUBLIC.

FLOATING DOCK: see DOCK.

FLOCK. 1. A word found in O.E. and O.Norw., from which come the Danish and Swedish words, and not in other Teutonic languages; originally a company of people, now mainly, except in figurative usages. of certain animals when gathered together for feeding or moving from place to place. For birds it is chiefly used of geese, and for other animals most generally of sheep and goats. It is from the particular application of the word to sheep that "flock" is used of the Christian Church in its relation to the "Good Shepherd," and also of a congregation of worshippers in its relation to its spiritual head.

2. Probably from the Lat. *floccus*, but many Teutonic languages have the same word in various forms; a tuft of wool, cotton or similar substance. The name "flock" is given to a material formed of wool or cotton refuse, or of shreds of old woollen or cotton rags, torn by a machine known as a devil, This material is used for stuffing mattresses or pillows and also in upholstery. The name is also applied to a special kind of wallpaper, which has an appearance almost like cloth or, in the more expensive kinds, of velvet. It is made by dusting on a specially prepared adhesive surface finely powdered fibres of cotton or silk. The word "flocculent" is used of many substances which have a fleecy or flocklike appearance, such as a precipitate of ferric hydrate.

FLODDEN or FLODDEN FIELD, near the village of Branxton, in Northumberland, Eng. (10 mi. N.W. of Wooler), the scene of a famous battle fought on Sept. 9, 1513, between the English and the Scots. On Aug. 22 a great Scottish army under King James IV had crossed the border. For the moment the earl of Surrey (who in King Henry VIII's absence was charged with the defense of the realm) had no organized force in the north of England. King James wasted much precious time among the border castles, and when Surrey appeared at Wooler, with an army equal in strength to his own, which was now greatly weakened by privations and desertion, he had not advanced beyond Ford castle. The English commander promptly sent in a challenge to a pitched battle, which the king, in spite of the advice of his most trusted counselors, accepted. On Sept. 6, however, he left Ford and took up a strong position facing south, on Flodden Edge. Surrey's reproaches for the alleged breach of faith and a second challenge to fight on Millfield plain were this time disregarded. The English commander, thus foiled, executed a daring and skillful march around the enemy's flank, and on Sept, 9 drew up for battle in the rear of the hostile army. It is evident that Surrey was confident of victory, for he placed his own army. not less than the enemy, in a position where defeat would involve utter ruin. On his appearance the Scots hastily changed front and took post on Branxton hill. facing north. The battle began at 4 P.M. Surrey's archers and cannon soon gained the upper hand, and the Scots, unable quietly to endure their losses, rushed to close quarters. Their left wing drove the English back, but Lord Dacre's reserve corps restored the fight on that side. In all other parts of the field, save where James and Surrey were personally opposed, the English gradually gained ground. The king's corps was then attacked by Surrey in front, and by Sir Edward Stanley in flank. As the Scots were forced back, a part of Dacre's force closed upon the other flank. and finally Dacre himself. boldly neglecting an almost intact Scottish division in front of him, charged in upon the rear of King James's corps. Surrounded and attacked on all sides. this, the remnant of the invading army, was doomed. The circle of spearmen around the king grew less and less: and in the end James and a few of his nobles were alone left standing. Soon they too died, fighting to the last man. Among the 10,000 Scottish dead were all the leading men in the kingdom of Scotland. and there was no family of importance that had not lost a member in this great disaster.

The "King's Stone," said to mark the spot where James was killed, is at some distance from the actual battlefield. "Sybil's Well," in Scott's *Marmion,* is imaginary.

FLODOARD (894–966). French chronicler. was born at Epernay. and educated at Reims in the cathedral school which had been established by Archbishop Fulcon (822–900). As canon of Reims, and favourite of the archbishops Herivaeus (d. 922) and Seulfus (d. 925), he occupied while still young an important position at the archiepiscopal court! but was twice deprived of his benefices by Heribert, count of Vermandois, because of his steady opposition to the election of the count's infant son to the archbishopric.

Upon the final triumph of Archbishop Xrtold in 947, Flodoard became for a time his chief adviser, but withdrew to a monastery in 952, and spent the remaining years of his life in literary and devotional work. His history of the cathedral church at Reims *(Histovia Remensis Ecclesiae)* is one of the most remarkable productions of the 10th century. Flodoard had been given charge of the episcopal archives, and constructed his history out of the original texts, which he generally reproduces in full: the documents for the period of Hincmar being especially valuable. The *Annales* which Flodoard wrote year by year from 919 to 966 are doubly important, by reason of the author's honesty and the central position of Reims in European affairs in his time.

Flodoard's poetical works are of hardly less historical interest. The long poem celebrating the triumph of Christ and His saints was called forth by the favour shown him by Pope Leo VII, during whose pontificate he visited Rome, and he devotes 14 books to the history of the popes.

Flodoard's works were published in full by J. P. Migne in *Patrologia Latina*, vol. CXXXV; a modern edition of the *Annales* is the one edited by P. Lauer (Paris, 1906). For bibliography *see* A. Molinier, *Sources de l'histoire de France,* no. 932.

FLOE, a sheet of floating ice detached from the main body of polar ice and of less extent than the field of pack ice; the latter is a compacted mass of greater depth, drifting frequently under the influence of deep currents, while the floe is driven by the wind.

FLOGGING was for a long time one of the most common methods of punishing criminals and of preserving discipline in the home, school, armed forces and prisons. In the Mosaic code flogging was a punishment for crime. Slaves were frequently flogged to death when they were sufficiently numerous to be of little value, but the flogging of Negro slaves in the southern states before the American Civil War was exaggerated in abolitionist literature: the fact was that these slaves were too valuable to have their efficiency reduced by severe punishment. Both soldiers and sailors received many lashes for their offenses, the latter being flogged at the mast or through the fleet, receiving a stipulated number of lashes on each ship. During the 19th century imprisonment gradually took the place of corporal penalties as a punishment for crime. The courts, however, retained the power of sentencing a prisoner to be whipped when convicted of crimes of violence. The situation was greatly changed in England, Scotland and Wales by the Criminal Justice act of 1948, by which the courts were deprived of the power to sentence a person to a whipping in many cases. However, except in Scotland, the power to inflict corporal punishment was retained in cases of mutiny, incitement to mutiny and gross personal violence to an officer of a prison when committed by a male person.

In the second half of the 20th century the flogging of certain criminals was still prescribed by law in Great Britain, Canada, some continental and Asiatic countries and in the state of Delaware in the United States, where public whippings might be administered at the discretion of the court for 25 different crimes. In 1953 Maryland repealed its law which had prescribed corporal punishment for wife beaters (*see* Robert G. Caldwell, *Red Hannah: Delaware's Whipping Post,* 1947).

The instruments and methods of flogging have varied. In maintaining discipline in the home and school, sticks, rods, straps, whips and other objects are used. Elsewhere the lash has been widely used, usually with ingenious refinements and elaborations. One of the most brutal of these is the cat-o'-nine-tails. This is constructed of nine knotted cords or thongs of rawhide attached to a handle. Even more effective in producing pain and ultimately death is the Russian knout. This is an instrument consisting of a number of dried and hardened thongs of rawhide interwoven with wire, the wires often being hooked and sharpened so that they tear the flesh.

A particularly painful, though not so deadly, type of flogging is the oriental bastinado, or blows delivered on the soles of the feet with a light rod or knotted cord or lash. Flogging was formerly executed with great brutality. The backs of the condemned were frequently lacerated and salt was poured into the wounds to increase the pain. (H. E. BAR.; P. E. L.; R. G. CL.)

FLOOD, HENRY (1732–1791), Irish statesman, son of Warden Flood. chief justice of the king's bench in Ireland. was educated at Trinity college. Dublin. and at Christ Church. Oxford. He entered the Irish parliament for Kilkenny in 1759, and immediately began the creation of an opposition in that corrupt body and the education of public opinion in the country. The English government was driven by his efforts to pass the Octennial bill! limiting the duration of parliament to eight years. and, during the viceroyalty of Lord Townshend. to mitigate the practice of allowing crown patronage to be dispensed by the owners of parliamentary boroughs. The growth of an independent spirit in the Irish house was shown in 1769. when a money bill was sent over by the privy council in London for acceptance by the Irish house of commons. It was rejected on the ground that the bill had not originated in the Irish house. Parliament was peremptorily prorogucd. and a recess of 14 months was employed by the government in securing a majority by the most extensive corruption. Nevertheless when parliament met in Feb. 1771 another money bill was thrown out on the motion of Flood; and the next year Lord Ton-nshend, the lord-lieutenant whose policy had provoked this conflict, was recalled. The struggle was the occasion of a publication, famous in its day, called *Baratariana,* to which Flood contributed a series of powerful letters after the manner of Junius. one of his collaborators being Henry Grattan.

Flood was now in a position such as no Irish politician had previously attained. Under parliamentary conditions that were exceedingly uniavourable and in an atmosphere charged with corruption. venality and subservience. he had created a party before which ministers had begun to quail and had inoculated the Protestant constituencies with a genuine spirit of liberty and self-reliance. Lord Harcourt. who succeeded Townshend as viceroy, saw that Flood must be conciliated at any price: accordingly, in 1775, he received a seat in the privy council and the office of vice-treasurer with a salary of £3.500 a year. The result was that the leadership of the national party passed from Flood to Grattan, who entered the Irish parliament in the same session that Flood became a minister. Flood continued in office for nearly seven years. During this period he necessarily remained silent on the subject of the independence of the Irish parliament. But in 1778 the creation of a volunteer force to defend Ireland against a possible invasion by France. which had become the ally of the revolted American colonies. changed the Irish situation. A volunteer convention, formed with all the regular organization of a representative assembly but wielding the power of an army, began menacingly to demand the removal of the commercial restrictions which were destroying Irish prosperity. The government gave way: the whole colonial trade was in 1779 thrown open to Ireland for the first time, and other concessions were also extorted. Flood now resigned his office to rejoin his old party. He found to his chagrin that he was eclipsed by Grattan. But though Flood had lost control of the movement for independence of the Irish parliament. the agitation. backed as it now was by the volunteer convention and by increasing signs of popular disaffection. led at last in 1782 to the concession of the demand. together with a number of other important reforms (*see* GRATTAN, HENRY). A question then arose—known as the Simple Repeal controversy — as to whether England. in addition to the repeal of the acts on which the subordination of the Irish parliament bad been based, should not be required expressly to renounce for the future all claim to control Irish legislation. This dispute led to the rupture of friendship between Flood and Grattan, each of whom assailed the other with unmeasured but eloquent invective in the house of commons. Flood's view prevailed — for a Renunciation act such as he advocated was ungrudgingly passed by the English parliament in 1783—and for a time he regained popularity at the expense of his rival. Flood next (Nov. 28, 1783) introduced a reform bill, after first submitting it to the volunteer convention." The bill, which contained no provision for giving the franchise to Roman Catholics — a proposal which Flood always opposed — was rejected. ostensibly on the ground that the attitude of the volunteers threatened the freedom of parliament.

In 1783 Flood purchased a seat for Winchester in the English house of commons from the duke of Chandos, and for the next seven years he was a member at the same time of both the English and Irish parliaments. He remained a firm opponent of Roman Catholic emancipation, even defending the penal laws on the ground that after the revolution they "were not laws of persecution but of political necessity": but after 1786 he does not appear to have attended the parliament in Dublin. In the house at Westminster. where he refused to enroll himself as a member of either political party, he disappointed the expectations aroused by his achievements in Dublin. At the dissolution in 1790 he lost his seat in both parliaments, and he then retired to Farmley, his residence in County Kilkenny. where he died on Dec. 2, 1791.

FLOOD, the rise of the waters of a natural stream above a level associated with the beginning of damage. Damage stage is usually reached when the stream is bank full; that is, when the channel is completely occupied. Beyond this, the flood plain is overflow. Flood plains range from a narrow marginal width in the confined, steeply sloped valley of mountainous country to one extending many miles from the river channel.

Four thousand years of recorded history tell of man's repeated failure to evade the destructiveness of floods. The fertile valleys of the Yangtze and Hwang-ho rivers in China have lured him back after each disastrous flood, only to drive him forth again as these rivers rechart their courses in unstable alluvial plains which to this day have defied man-made controls. In striking contrast, the floods of the Nile have been turned to a decided advantage, For thousands of years its orderly and controlled rise and fall have provided fertility and moisture for the fields within its flood plain. (*See* also NILE: Hydrology.)

Excessive rains caused floods of great damage in Paris in 1658 and 1910, Warsaw in 1861 and 1934, Frankfurt am Main in 1854 and 1930, and Rome in 1530 and 1557. The Darling river in Australia was reported to have flooded extensive areas in 1864 and 1886. In 1927 monsoon rains swelled the rivers throughout India to such extent that enormous property damage resulted. In 1099 a storm tide flooded the coasts of England and the Netherlands causing 100,000 deaths. In early 1953 disastrous storm tides flooded the coasts of England, the Netherlands and Belgium resulting in the loss of nearly 2,000 lives.

Records for the Danube, dating back to the 11th century, tell of serious floods in 1342, 1402, 1501 and 1830, resulting from ice jams during the spring rise. In 1824 St. Petersburg (Leningrad) and Kronstadt suffered an ice jam flood in the Neva in which 10,000 persons were drowned.

Lisbon in 1755 and Hilo, Haw., in 1946 experienced floods caused by sea waves of earthquake origin. Johnstown, Pa., was practically destroyed in 1889 by a flood following the failure of a dam behind which runoff from a moderate storm had been allowed to concentrate.

*Beginning of flood damage.

Lying athwart a zone in which dry, cold air masses from the arctic meet warm, moist air originating in the Caribbean and South Atlantic, the United States east of the 90th meridian is subject to storms and floods which extreme contrasts in temperature and moisture invariably bring about. Among the results are the spectacular floods of the Connecticut, Susquehanna and Potomac rivers in 1936, the Ohio in 1936 and 1937, and the Mississippi in 1884, 1927, 1937, 1943, 1947, 1951 and 1952.

The encroachment of industrial and community development on the natural channels of nearly all the larger rivers has contributed substantially to the extent of flood damage. Unless such encroachment is halted by some form of flood plain zoning, flood damage can become staggering. In certain eastern and western states flood danger is increased by the possibility that seasonal rains may combine with thawing of major snow accumulations.

Flood-producing storms of limited areal extent occur throughout the whole of humid United States. These storms are of the thunderstorm type, occurring as single or multiple convective "cells," and are capable of producing phenomenal downpours. Property damage and loss of life from floods created by this type of storm constitute an appreciable percentage of the total loss. The storm of July 1942 in Pennsylvania afforded an outstanding example of this type, more than 30 in. of rain in 12 hours having been observed at the storm centre.

With the exception of the arid southwest and the Great basin, no region of the United States is immune from floods in any month of the year. The primary cause of flood is rain concentrated within relatively short storm periods. However, protracted storms, such as that of January 1937, blanketed the whole of the Ohio basin and caused the greatest flood of record on that river. The great flood of 1937 took 137 lives and caused an estimated property damage of $417,700,000 in the Ohio and lower Mississippi basins.

Following a two-month period of above-normal precipitation, rains of unprecedented intensity over much of the state of Kansas in July 1951 resulted in the greatest flood in more than a century in the Kansas river basin and adjoining areas. Twenty-eight lives were lost and property damage amounted to nearly $1,000,000,000.

Hurricane rains of 1955 caused floods of record or near-record proportions in many streams in southern New England, southeastern New York, eastern Pennsylvania and New Jersey which took 180 lives and caused an estimated damage of $686,000,000.

Monetary loss from floods averages $300,000,000 annually in the United States. This figure would be much higher were it not for various means of flood control, such as protective levees, channel improvement, storage reservoirs and flood warnings.

Early precedent in protecting the fertile alluvial plains of the lower Mississippi valley at government expense established the policy of flood control under and by federal agencies, the principal one of which is the corps of engineers, United States army. The department of agriculture, with its soil conservation and forest services, carries out programs of soil and forest conservation that are in many cases the indirect means of retarding and absorbing storm runoff, thus reducing the height to which floods would otherwise rise.

The weather bureau, through its flood forecasting service, reduces flood damage by providing opportunity to remove goods and evacuate populations. Losses are still further reduced by the efforts of the American Red Cross, the army engineers and the coast guard in caring ior persons driven from their homes by floods.

Many sections of Asia and the far east frequently suffer severe floods. In India, for example, some parts are flooded every year with considerable damage. Floods of major importance occurred in many parts of India during 1952 to 1956. These started with the Brahmaputra and tributaries doing extensive damage with large loss of dwellings and cattle. Heavy southwest monsoon rain (June–September) caused the Godavari floods of 1953 which were unprecedented in 50 years. Southwest monsoon rain caused severe floods in all the south Indian states again in 1954 although less severe than those of 1953. Floods also occurred during this period in Assam, Bihar and West Bengal. Some of India's rivers reached the highest flood of record in 1955. The Mahanadi, Orissa's largest river, reached a record level and marooned 300,000 people. Severe floods also developed in the Jumna, the Beas, the Ravi and the Sutlej rivers in the northwest of India. The Ravi completely changed its course during this flood, swamping hundreds of villages on both sides of the Pakistan-India border. Floods continued in 1956 with the Jumna river reaching the highest level on record at Delhi, and with the Ganges river seriously affecting the states of Bihar, Uttar Pradesh and West Bengal. India's floods result primarily from rain, however snow melt makes a contribution from those rivers arising in the Himalayas. Nearly half the total population of (half a billion people) continually face the danger of floods.

Australia's largest rivers are the Murray, Darling, Fitzroy and

Burdekin which together comprise a drainage area of approximately 740,000 square miles or about one quarter of the continent. Flooding occurs periodically in these major rivers but even more frequently in the smaller eastern and southeastern streams.

Major floods occurred in New South Wales in 1955 on the Macquarie, Castlereagh. Namoi, Hunter and Gwydir rivers taking 50 lives and leaving nearly 40,000 homeless in 40 towns.

Some of the heaviest rains of history occurred in 1956 in southeastern Australia, flooding rivers, and forming a sea 40 miles wide between the towns of Hay and Balranald.

The British Isles occasionally are subjected to flooding irom abnormally heavy storms. Outstanding recent events were the Lymouth flood, causing 28 deaths, the Korth Devon, North Somerset and Sussex floods, all in 1952, the northern England and southwest Scotland floods of 1953, and the Weymouth flood of 195j which resulted from 11 inches of rain in less than 24 hours at Martinstown, Dorset. See also RIVER AND RIVER ENGINEERING.

Jarvis, tn-o papers which contain extensive bibliographies: *Supplementary Gleanings From the Field of Hydrology* (Sept. 1943), 67 reterences to floods, and "Floods in the United States," United States Geological Survey *Water Supply* Paper 771 (1936), 207 reiercnces irom American and European sources. Jarvis discussed fioods in Europe and Asia from the middle ages on, and the Nile floods since beginning of records about A.D. 620, in "Flood-Stage Records of the River Nile," *Transactions* of the American Society of Civil Engineers, vol. lxii, pp. 1012–71 (1936), 65 references. C. E. P. Brooks and J. Glasspoole, British *Floods and* Droughts (1928), discusses in detail floods in rivers anti along the coasts of the British Isles since A.D. 9. Lowell Thomas in *Hungry Waters* (1937) takes up in detail the great 1937 flood of the Ohio valley and gives an account of floods in Canada, Europe, Asia and other rivers of the U.S. prior to 1937. "Kansas-Missouri Floods of June–July 1951" (1952) and "Floods of April 1952—Upper Mississippi, Missouri and Red River of the Sorth" (1954) in Weather Bureau *Technical* Papers 17 and 23. (M. BD.; W. E. HT.)

FLOOD (IN RELIGION AND MYTH) is the name given to the cataclysm that was said to have covered most of the earth with an immense inundation and to have caused the death of all but a few of the human race. Most civilizations record a tradition about this event, which is best known from the account in the Old Testament and in the Gilgamesh myth.

Biblical Accounts.— The story of the flood in Gen. vi–ix is, as biblical criticism has shown, a fusion of two closely interwoven versions. one based on the 8th-century B.C. tradition known as "J" (Yahweh), the other on the 6th-century B.C. priestly tradition called "P," which represents a less primitive and more theological attitude (see GENESIS).

The J *Source.*—Yahweh has decided to destroy the human race, which is basically evil. save for one just man, named Koah. Yahweh warns Noah of the coming cataclysm. and commands him to go into the ark with his household and pairs of animals, seven of the clean and one of the unclean. in order to preserve the species. The waters cover the earth, and every living thing is destroyed except for those in the ark. Xfter the rain has ceased, Noah releases a raven. which returns to the ark because it can find nowhere else to rest. and a dove. which does the same. Seven days later the dove is released again. and returns with an olive branch in her beak. After a further seven days the dove does not return after her release. Noah then leaves the ark and makes a thank offering to Yahweh. who in his turn is reconciled with mankind. promising never again to smite every living thing.

The P *Source.*—Noah is an upright man in the midst of a perverse generation which God has decided to obliterate. He is commanded to make an ark of certain precise measurements which is to shelter him and his, together with two of each species of living things and provisions for them all. Noah is 600 years old when the flood begins: "all the fountains of the great deep burst forth, and the windows of the heavens were opened" (Gen. vii. 11). The ark carries its load while the waters rise for 150 days. Then comes a wind which brings calm, and the waters begin to sink. In the seventh month, on the 17th day of the month, the ark comes to rest "upon the mountains of Ararat." A further period of time. carefully measured, has to pass before Noah with his family and animals can leave the ark. God then blesses Noah and his sons. and makes a covenant that he will never send another flood on the earth.

Mesopotamian Accounts.— The Assyrian text of the epic of Gilgamech on cuneiform tablets discovered at Nineveh comes from the library of Ashurbanipal (7th century B.C.), but undoubtedly repeats an earlier original. (A fragment of a Babylonian version found at Nippur goes back to the 19th century B.C.)

Assyrian *Version in Cuneiform* Script.— Gilgamesh, king of Erech (Uruk), much distressed by the death of his friend Enkidu, realizes that his own life too must one day end. He remembers that only one human being, Ut-Napishtim ("Uta is my life"), has received eternal life. after surviving a flood which he has described in all its episodes. When the gods decided to destroy the city of Shuruppak, Ea advised his protégé Ut-Napishtim to build a vessel according to a specified plan and to bring into it his family. craftsmen. animals. gold and silver. Flood and storm are then unloosed. to the great dismay of the gods who have commanded them. The earth is submerged, and "mankind is turned into clay," Seven days later there is a lull, and the vessel comes to rest on Mt. Nisir. After another seven days a dove, a swallow and a raven are sent out. Only the last finds a place to alight. so does not return. The survivors come out of the ark and make a sacrifice upon which the gods descend. The wrath of Enlil is appeased, and after blessing Ut-Napishtim and his wife he grants them immortality.

There is also another cycle. parallel to the epic of Gilgamesh, in which the hero's name is Atrahasis ("the most wise"). The tablets on which it is found were excavated at Nineveh and at Sippar. These documents in Akkadian, like Hebrew a Semitic language. had been preceded by others written in Sumerian, which is not Semitic.

Sumerian Version From *Nippur.*—The gods, except for Inanna and Enki, have decided to send a flood "to destroy the seed of the human race." The king Ziusudra is saved in a giant ship which he has built in accordance with instructions from a god who takes pity on him. He makes a thank offering for his escape and ultimately receives an "eternal inspiration" and goes to live in the country of Dilmun.

Late Babylonian Version.—The latest Babylonian version of the flood story was written about 275 B.C. by Berossus. priest of Marduk (Bel) at Babylon. Xisuthros is commanded by Cronus to build a ship for his family, friends and animals. and load it with food. as a flood is imminent. The cataclysm is then unleashed. When it is over, Xisuthros releases birds in order to find out how far the water has sunk, and it is only after this has been done three times that they do not return. Xisuthros then leaves the ship with his wife. his daughter and the pilot, and makes a sacrifice to the gods. These four become invisible. and those left in the ship are begged to become virtuous and to return to Babylon, then to Sippar, where Xisuthros buried all existing writings before the flood. This is a long journey for them, as the ship has come to rest on the Corydaean mountains of Armenia.

Evidence for *the* Flood in *Historical* Sources.— Besides these more. or less legendary narratives. there are brief references to the flood as a historic fact. For instance. Weld-Blundel's prism (W.B. 444) mentions Ubar-Tutu, father of Ut-Napishtim according to the Gilgamesh epic. and then. after enumerating five cities and eight kings, it continues, "the flood came. Xfter the flood had come. kingship descended from heaven. The kingship was at Kish." A tablet (W.B. 62) mentions two kings of Shuruppak (the city of the flood) including Ziusudra (as in the Sumerian version of the story). For ancient historiographers, therefore, the flood marks a distinct break in the train of events.

Archaeological Evidence in Mesopotamia.— Excavations in Mesopotamia have revealed conflicting evidence about the flood. In strata dating from before 2000 B.C., when the first Sumerian narrative was probably written, flood layers have been found at levels which do not correspond stratigraphically. At Ur a deposit of clean water-laid clay whose depth varies from 3.7 to 2.7 m. appears to go back to between 3000 and 4000 B.C., whereas at Kish a similar deposit, only 0.3 m. deep, dates from about 2800 B.C. In Erech and Shuruppak the flood layers date from the same period

(c. 2800 B.C.), but differ in depth (1.55 m. and 0.6 m. respectively). Further, at Nineveh excavators found at a depth of between 21.1 and 21.3 m. a series of 13 alternate strata of mud and riverine sand, which show an important climatic change (c. 3000–4000 B.C.).

The conclusion to be drawn from these excavations seems to be that there was not merely a single flood but many. Probably one of these cataclysms brought such destruction in its train and made such a great impression that it became a theme of cuneiform literature. It was known as *the* flood, caused first by an unusually violent rising of the Tigris and the Euphrates (Iraq still suffers from such disasters, as witness the flood in the spring of 1954), augmented perhaps by torrential rain (cf. Gen. vii, 4, 12) if not also by a tidal bore (cf. Gen. vii, 11). Such violent upheavals of water could not fail to bring about almost total destruction of life in the area save for a few privileged exceptions.

Relationship Between the Biblical and the Mesopotamian Floods. — That the various accounts of the flood given above are connected is beyond all doubt, and it is equally clear that the biblical narrative enshrines the Israelite version of an earlier Mesopotamian tradition (extant in cuneiform texts) which was reshaped by the Hebrew writers of the 8th and 6th centuries B.C. This Babylonian tradition must have been brought from Mesopotamia by the patriarchs and later transferred to Canaan where there was no memory of such a flood, which is a specifically Mesopotamian disaster.

Religious Meaning of the **Biblical Flood.**—Into this story drawn from earlier sources the biblical narrative introduces new elements which reveal teaching about God and his purposes for mankind. The flood in Genesis is understood as an instrument of God's justice, which because of man's wickedness dealt out destruction on all save the righteous Noah and his family. The flood story also marks an important stage in the relationship of man to God, for God in his mercy then promised that such a cataclysm would never happen again and made the first of the covenants recorded in the Bible, that made with every living creature, whereby the earth should continue, with its ceaseless cycle of the seasons and the harvest.

In the New Testament the flood story is used as a "type" of the last judgment. Jesus Christ compared the unexpected coming of the last judgment to the flood, making the comparison a warning of the necessity for watchfulness (Matt. xxiv, 37 ff.; Luke xvii, 26 ff.). The story is used in II Pet. ii, 5 as a reminder that God punishes the ungodly while delivering the righteous. A further interpretation is found in I Pet. iii, 20, where the floodwaters are said to prefigure the saving waters of Christian baptism.

The Flood in Greek Mythology. — The story of the flood is first explicitly mentioned in Greek literature by Pindar (5th century B.c.). A full version is to be found in the mythological compendium called *Bibliotheca* wrongly ascribed to Apollodorus (2nd century B.C.). Zeus has decided to destroy the human race, but King Deucalion, advised by his father Prometheus, builds an ark in which he and his wife Pyrrha take refuge with a store of provisions. Zeus submerges Greece in torrential rain. so that only a few others are able to escape by climbing up into the mountains. The ark of Deucalion floats for nine days, after which it comes to rest on Mt. Parnassus. When the rain ceases Deucalion comes out of the ark and makes a sacrifice. Zeus, thus appeased. then sends Hermes to offer Deucalion anything he wants. Deucalion chooses to increase the human race; he throws over his shoulder stones which turn into men while those thrown by Pyrrha become women.

This legend about Deucalion was not the only flood story current in the Greco-Latin world. Dionysius of Halicarnassus (1st century B.c.) in his work on Roman antiquities refers to a flood in the reign of King Dardanus of Arcadia, and the church historian Julius Africaaus (c. A.D. 200) speaks of a flood in the time of Ogyges, king of Thebes in Boeotia. References to these floods are found in other sources, and by the 5th century A.D. the poet Nonnus in his *Dionysiaca* counts three floods, first Ogyges', then Deucalion's, then Dardanus'.

J. G. Frazer suggested that these various narratives are not based on actual events but were invented to account for certain obvious physical features of the Greek landscape: the formation of Lake Copais from overflow (flood of Ogyges), the rising in the valley of the Pheneus (flood of Dardanus) and the split in the mountains of Thessaly (flood of Deucalion).

The story of the flood of Deucalion was popular at Hierapolis on the Euphrates. A version in the De *dea Syria* wrongly ascribed to Lucian (2nd century A.D.) relates that after the flood all the waters disappeared into a cleft in the earth at Hierapolis, beside which Deucalion built a sanctuary to Hera. Twice a year thereafter, in memory of this miracle, worshipers brought sea water to the sanctuary and poured it into the cleft. Similarly, Pausanias (2nd century A.D) was informed that an offering of honey cakes was made annually at Athens at the cleft in the ground near the temple of Olympian Zeus where the floodwaters had drained away. It is worth adding that coins of the 3rd century A.D. from Apamea Cibotus in Phrygia (Asia Minor) show the ark, with the name Noah written on it. This is the first known instance of the iconography of the flood which later becomes so familiar, especially in Romanesque paintings and sculptured capitals.

Legends of the Flood in Other Traditions. — The flood is not mentioned in the Vedic hymns of ancient India (1500–1000 B C.), but in the Sanskrit Satapatha-Brahmana (6th century B C.) there is the story of Manu, who was informed by a small fish that a flood was to take place and advised to build a ship. Manu reared the fish until it grew big, and when the flood began it pulled him in the ship to a mountain, thus saving him alone from death. When the waters sank. Manu came out of the ship and offered a sacrifice of butter and milk, from which sprang a woman, to be the mother of the race of Manu; *i.e.,* mankind. Later variations of this legend are also known.

Legends of a flood are also found in southern Asia, the Indian archipelago (Sumatra, Borneo, Celebes). New Guinea, Australia, Melanesia, Polynesia and the American continents from Alaska to Cape Horn, as well as in the folklore of certain European countries—Wales, Lithuania and Rumania—and in eastern Russia. But in Africa, including Egypt. there is scarcely a trace of it. In most of these stories constant features are the saving in a vessel of a remnant (whether a single person, man and wife, brother and sister or a larger group), often with the help of a god, and the subsequent repeopling of the earth by natural or miraculous means.

Origins of the Legends. — It seems that the traditions of the flood fall into two groups, to one of which belong the cuneiform (both Sumerian and Akkadian) and Hebrew narratives. These may to some extent have inspired the Greek story of Deucalion, and just possibly that of Manu in Sanskrit literature Behind them would lie a historical flood of catastrophic proportions which inundated the Tigris-Euphrates basin. To the other group belong the rest of the legends nhich, having no necessarily factual basis, are to varying degrees mythical or legendary and are not connected with the first group

FLOOD CONTROL: *see* RIVER AND RIVER ENGINEERING; DAM; RESERVOIRS; LAND RECLAMATION.

FLOOD PLAIN, a plain made of sediment deposited by a river. When the gradient of a river becomes very slight, it is unable to carry all the material brought downstream. and consequently the lower valley becomes filled with alluvial deposits. In times of flood the river torrent tears off and transports an unusually large quantity of sediment; in the flooded lower valley the rush of water is checked. and the stream in consequence drops its extra load. Flood plains are sometimes of great extent. In the United States, that of the Mississippi below its confluence with the Ohio has an occasional width of 80 mi. with a total area estimated at 50,000 sq.mi.

Flood plains may be caused by a graded river's meandering from side to side and thus widening its valley and ultimately covering the nidened valley mith sediment. Any sudden increase in a river's velocity and volume or obstruction across its course may result in a flood plain, but flood plains are most commonly found in the lower reaches of such large rivers as the Rhine, Nile or Mississippi. The flood plain is usually bounded by levees (*q v*).

Sections of the Missouri river flood plain show a great variety of material of varying depth and of coarseness ranging from heavy gravel through fine sand to fine silt. It is probable that any section of such a plain would shou similar deposits.

The flood plain during its formation is characterized by marshes, meandering or anastomosing streams, oxbow lakes and bayous (*q.v*), and is occasionally completely drowned. When the drainage system is entirely diverted for any cause, the flood plain may become a smooth area of great fertility, similar in appearance to the floor of an old lake. from which it differs, however. in that it is not quite flat. It has a gentle slope along the original downstream course and also usually from the edges toward the centre. See also PLAIN.

FLOOR, the lower horizontal surface of an enclosure; used, also, almost interchangeably with "story," to designate different levels or planes of rooms, one above the other. The floor may be a prepared surface of the ground or an elevated area. In primitive buildings the leveled surface of the ground was covered with matting as a protection against dampness; in regions of heavy rainfall, a platform or floor set above the ground and supported on posts provided a protection from surface water.

In modern buildings the floor areas resting on the ground are insulated from moisture by replacing the top soil with coarse gravel or crushed rock, which leaves large volumes of voids to permit free drainage and cut off the capillary action which might otherwise penetrate the floor slab.

A floor area free of the ground is both a structure and a finished surface. The structure must have sufficient strength to carry loads. The upper surface should be protected by a covering or wearing surface capable of withstanding traffic. The underside may be exposed or covered, depending upon the aesthetic requirements or the need for protection against fire. The upper, or wearing surface is called the finished floor; the underside, either exposed or finished: is the ceiling.

Wood, steel, concrete or a combination of these materials may be used in the construction of the floor. The structure is similar to that of flat roofs of the same materials, except that the distances between supports are usually less to accommodate heavier loads.

For light wood construction in dwellings, the joists are supported by bearing partitions in the first and upper stories, or by beams and posts where the supporting partitions would not coincide with the locations of the walls of the rooms. In the basement story the bearing partitions and the first floor joists are usually carried on wood or steel girders supported on posts and the basement walls.

The finished floors are usually hardwood strips (oak or maple) having a $2\frac{1}{4}''$ face width! and tongue and grooved at the edges and ends. The strips are blind nailed through the tongue to the under floor using cut nails. The strips are laid at an angle with the under floor and parallel to the partitions or outer walls. The flooring strips are sanded when laid to remove any inequalities at the edges and to provide a smooth clean surface for the finish. The finish consists of a filler, followed by a built-up surfacing of wax properly polished.

The floors of multistoried industrial buildings carrying heavy loads (as well as those of commercial buildings and schools carrying relatively light loads) may be constructed of reinforced concrete slabs supported directly on columns or carried on concrete or steel beams attached to supporting columns. For lighter constructions steel panels or light steel joists supporting a light concrete slab or fill may be used.

For the finished floor wood, cork, linoleum, tiles, and masonry (*e.g.,* flagstone, marble, brick slate, granolith, terrazzo) have practical and aesthetic qualities. See ROOF; CARPENTRY.

(E. N. G.)

FLOOR COVERINGS.' Many materials are used as floor coverings; those considered in this article have been classed as smooth-surface floor coverings and include linoleum, rubber floor coverings. cork tile, asphalt tile, printed felt base and the many varieties derived from vinyl chloride resins. The use of these materials increased greatly after 1920; in the 1960s the extensive use of concrete flooring in homes and commercial buildings had further expanded the market.

Linoleum, the first smooth-surface floor covering to be used widely. was introduced about 1860. Frederick Walton invented the linoleum-making process, in which linseed oil is oxidized to produce the binder for cork and other fillers. He built the first linoleum factory at Staines. Eng.. and in about 1900 developed the straight-line inlaying machine, which greatly increased the variety of patterns that could be produced. Production of linoleum increased steadily until about 1950, after which it decreased, mainly because of competition from newer materials.

Printed felt base mas first manufactured in Erie. Pa.. about 1910. Production gradually increased until yardage became much greater than that of linoleum. But, like the output of linoleum. the production of this material is now decreasing although large volumes are still manufactured.

Cork tile has been made for many years and continues to be produced in large volume, although not in the volume of linoleum or the newer materials. Rubber flooring has been produced for many years, and the volume has shown a gradual increase. However, it is a relatively expensive material and the yardage produced is not a major portion of the total floor covering manufactured.

Asphalt tile was first produced about 1930. The volume of production has increased rapidly and in the 1960s it exceeded the yardage for linoleum. Vinyl floor coverings were first produced in the United States about 1945 and their use has expanded greatly. Vinyl coverings are made in a wide variety of types, and the total vinyl usage is about the same as that of linoleum.

Floor coverings are offered in a variety of forms. The flexible materials are available in roll form; the trend, however, is toward tile. and nine-inch square tile is most widely employed. The tiles are offered in a variety of thicknesses from $\frac{1}{16}$ to $\frac{3}{16}$ in., and in some cases the tile is even thicker. A backing of felt may be used.

These floor coverings, except those in which thin films are employed. are manufactured by mixing the plastic material with fillers and pigments to create a plastic mix that is rolled into sheets and then calendered to the desired thickness. If a backing is used the plastic sheet is calendered onto the backing.

A variety of decorative effects; including mottles, *jaspé* and spatter patterns, are obtained by blending in one or more other mixes of the same general composition as the base in sheet or chip or granule form. By controlling the extent of mixing a wide variety of these effects may be achieved. In some cases the added colour is mixed little, if at all, and it may be compressed rather than rolled into the sheet.

Linoleum.—In the original process for manufacturing linoleum. a thin film of linseed oil was allowed to oxidize. Since oxidation proceeds principally on the surface, fresh oil was continually applied to the surface of the oxidized film. The film was started on a light cotton scrim, and linseed oil was poured over the film while it was festooned in tall stoves or sheds. After weeks of exposure. during which the thickness of the oil film reached several inches, the oxidized oil was fluxed with a natural resin, such as rosin or kauri gum. Cork and other fillers, such as wood flour (pulverized dried wood) and whiting, were mixed with the blend of resin and oxidized oil.

The shed process was cumbersome and slow, and it was replaced by a faster method in which linseed oil is oxidized in large cylindrical kettles where the oil is stirred at elevated temperatures. The oxidization is continued until the oil barely flows at reaction temperature; then the oil is blended mith rosin in heated kettles equipped with agitators. Often the rosin is added to the oxidizing kettles while the air is blown into the mixture at elevated temperatures; a plastic material of high viscosity is then formed.

The mixture of oxidized oil and rosin is blended with wood flour and whiting. In modern practice cork is no longer widely employed as a filler. The use of cork declined largely because of both the trend to brighter colours and the scarcity and relatively high cost of cork.

The binder. fillers and pigments are mixed, then calendered in sheet form and applied to a backing. Burlap mas the principal material used for backing until World War II, but it became scarce during the war and was replaced by felt saturated with asphalt. Burlap is still used, however, for heavier gauges of linoleum Saturants of light colour are often used in place of asphalt to waterproof the felt.

The backed linoleum is hung in tall buildings or stoves, which are heated to harden the linoleum. The hardening process may take weeks. Linoleum tile is made by prolonging the heating until a much harder material is formed.

While the modern process described can be used to produce plain or solid patterns, many decorative effects are obtained by blending mixes of various colours. Marble effects are achieved by mixing blends of two or more colours. The degree of mixing must be controlled carefully to obtain the desired effect. Geometric patterns are produced by granulating mixes of various colours and applying the granules through stencils. Tile and textured effects are obtained in this same manner. The granules are integrated under pressure and then stoved. Spatter patterns are produced by adding granulated mixes in various colours and granule sizes to the surface of a calendered sheet and again calendering. At one time a printed surface was applied to linoleum, but this practice has long been abandoned.

Most linoleum is made in rolls 6 ft. wide, $\frac{3}{32}$ in. thick and with a felt backing. Some grades are offered in a thickness of $\frac{1}{8}$ in. and with burlap backing.

Felt Base.—This low-cost floor covering, often referred to as printed felt base, is produced by printing a heavy film of paint on felt that has been saturated with asphalt. Before the paint is applied, the felt is sealed nith one or two layers of coating to keep the asphalt from discolouring the paint and to level the surface; a backing coat also is applied at this time. A variety of paint vehicles have been employed; usually oleoresinous varnishes form the paint base, although alkyd resins have been used. The requirements for a satisfactory paint are rather severe since the paint must (1) have a low volatility when applied; (2) exhibit little tendency to flow; (3) dry readily in thick films much heavier than the usual paint film; and (4) produce a durable wearing surface with high gloss.

The paint is printed on the felt base from wooden blocks that are coated with paint and then applied to the surface of the felt. Many colours are applied in the usual printed pattern, and each colour is printed separately. The printed felt is then dried by heating in ovens, either in horizontal racks or in festoons. The paint must not flow if the festoon system is used. Maturing is finished in a few days. Printed felt base is available either in roll form or in rugs of various sizes and in several thicknesses.

Asphalt Tile.—Linoleum does not give good service when subjected to dampness or alkaline conditions, and a need arose for a floor covering that would perform well under these conditions. Asphalt tile met these requirements. It is comparatively low in cost and is available in tile form so that it can be installed easily by the homeowner.

The name "asphalt tile" is essentially a misnomer, since asphalt is used only in the very darkest shades of tile; lighter-coloured resins are used for most of the asphalt tile now on the market. The first tiles made from asphalt were quite dark in colour and were used mostly in industry. The name, however, has persisted.

The manufacture of asphalt tile is somewhat simpler than the manufacture of linoleum since the binder is thermoplastic and is not cured. Scraps, cuttings and trimmings can be reworked, and the tile can be packaged as soon as the calendered sheet has been cut and the tile has cooled.

Asphalt tile is made by mixing about 25 parts by weight of a resin and plasticizer with about 75 parts by weight of fillers and pigments. The filler consists of about 35% of asbestos fibres, 60% of ground limestone and up to 5% of pigments. The fillers and binder are premixed in some cases to shorten the mixing cycle.

Asphalt, gilsonite, dark-coloured coal tar and petroleum resins are used for dark-coloured asphalt tile while limed tall oil pitch is often used as the plasticizer for the darkest shades. For the lighter colours, coumarone-indene (coal-tar) resins were the first resins used. With the rapid increase in consumption of asphalt tile. however, petroleum resins came to be used, but the addition of polystyrene was required to make a suitable resin. Much of the tile on the market in the early 1960s contained some polystyrene, although the amounts used by various manufacturers varied considerably. Plasticizers for light-coloured tile also must be light in colour; limed tall oil is usually employed in combination with mineral oils or synthetic alkylated aromatic hydrocarbons. Since tall oil is saponifiable. the amounts in which it is used must be kept to a minimum in order to preserve the alkali resistance of the tile.

After the resin, plasticizer and fillers have been thoroughly mixed they are sheeted on mixing rolls and finally calendered to the thickness of the final tile, either $\frac{1}{8}$ or $\frac{3}{16}$ in. Mottle colours are usually added on mixing rolls, and the spatter colours are added in granular form just prior to calendering.

The sheet is then cut into nine-inch square tiles, cooled and packed. Originally the tile was offered in a wide variety of marbleized effects, but the spatter patterns have become more popular. In some cases the colour granules cover most of the surface of the tile; simulated cork surfaces are made in this way.

Vinyl Asbestos Tile.—Vinyl asbestos tiles are formed from vinyl chloride polymers or vinyl chloride-vinyl acetate copolymers. Copolymers are used more frequently than polymers because they are softer and more readily plasticized. (See also PLASTICS: Polyvinyl Chloride Resins)

Vinyl asbestos tile is made by mixing about 25 parts of a binder with about 75 parts of filler consisting of ground limestone, asbestos fibres and pigments. The binder consists of a vinyl chloride polymer or vinyl chloride-acetate copolymer, phthalate ester plasticizers and materials that stabilize the vinyl resin in heat and light. The asbestos content is usually lower than in asphalt tile, Mixing procedures are similar to those for asphalt tile although working temperatures may be somewhat higher. Mottle colours are added on the mixing rolls after the mix is blended and sheeted or just before it is calendered, depending on the type of decoration desired. The most popular thickness for vinyl asbestos tile is $\frac{1}{16}$ in.. although heavier gauges are offered. The material is offered usually as nine-inch square tiles, although other sizes are available. In addition to mottles, terrazzo and spatter patterns. tile is also decorated with bronze and aluminum flakes. Vinyl asbestos tile is somewhat more flexible than asphalt tile but often cracks on repeated flexing.

Vinyl Floor Coverings.—Rug-size floor coverings made from vinyl resins have proved popular and are now offered in a wide variety of forms. One variety is similar to printed felt; the paint coat consists of a vinyl chloride resin and a plasticizer. This is usually printed as a plastisol coating consisting of very finely divided vinyl chloride resin suspended in a plasticizer and pigmented. When heated, the resin dissolves in the plasticizer; no further curing is required.

Calendered vinyl floor coverings are also produced from calendered sheets on felt backing. These are offered in several different forms but usually in rolls or as tiles =&in, thick. Calendered vinyl sheets on felt backing are also offered in an alkali-resistant variety.

Homogeneous vinyl tile is made from vinyl chloride polymers plasticized with a phthalate ester. Fillers are employed but asbestos is not used in these flexible tiles. Pigments and stabilizers for the vinyl resin are used in the blend. The tile is produced in thicknesses of 0.08 to 0.125 in. and in 9-in. squares and in other tile sizes.

Some varieties are offered in translucent form. In this type little or no filler is used and the decoration consists of geometric shapes or metallic flecks throughout the tile. Many of these simulate the appearance of marble.

Rubber Flooring. — Rubber flooring for many years was made of natural rubber, but in recent years synthetic rubber, particularly the styrene-butadiene copolymer, has been employed in most rubber flooring. The rubber is mixed with resins to improve processing; fillers, pigments and curing agents are mixed, and the mix is then sheeted and cured in heated presses. Rubber tile is usually offered in plain or mottle patterns, in thicknesses of $\frac{1}{8}$ in. and $\frac{3}{16}$ in., in squares of 6 in., 9 in. and 12 in., and in rolls.

Cork Tile. — Ground cork has long been used to make floor coverings. When cork is heated at high temperatures the particles knit and form a resilient composition. Heating takes hours by conventional methods since heat is transferred through the cork very slowly. High-frequency heating (*q.v.*) reduces the heating time to minutes. Cork tile is offered in tan and dark brown colours, thicknesses of $\frac{1}{8}$ in., $\frac{3}{16}$ in. and $\frac{5}{16}$ in., squares of 6 in. and 9 in. and also in rectangular shapes.

Properties of Floor Coverings. — All of the floor coverings described in this article have found their own fields of application and each has properties that make it suitable or unsuitable for particular applications. Asphalt tile is lowest in cost, the dark shades of asphalt being the least expensive. Linoleum is next lowest in cost, followed by vinyl asbestos, cork and rubber. Homogeneous vinyl tile is the most expensive of all those described.

When comfort and quiet are essential, cork tile is superior; appearance and maintenance, however, are not strong points of cork. Linoleum has had a long history of successful performance, but it cannot be used below grade, as in basements, or in areas where high moisture or alkaline conditions prevail. Asphalt tile has been widely adopted under these conditions because it is resistant to water and alkali. Rubber flooring is used mostly in public buildings and has many excellent properties; it is not too easy to maintain, however, nor is it particularly resistant to grease. Vinyl flooring is offered in so many forms that generalizations are difficult. Homogeneous vinyl tile, however, offers good resistance to water and alkali, is grease resistant and has good colour stability.

FLOOR TRADERS, members of a (especially the New York) stock exchange who buy and sell securities for their own account and who do not conduct transactions for clients. They are to be distinguished from the commission brokers whose exclusive function is to trade for the accounts of clients. Floor traders are often known as room traders.

FLOQUET, CHARLES THOMAS (1828–1896), French statesman, was born at St. Jean-Pied-de-Port (Basses Pyrénées) on Oct. 2, 1828. He studied law in Paris, and was called to the bar in 1851. The coup *d'état* by Napoleon III in that year aroused the strenuous opposition of Floquet, who had, while yet a student, given proof of his republican sympathies by taking part in the fighting of 1848. He made his name by his brilliant and fearless attacks on the government in a series of political trials, and at the same time contributed to the *Temps* and other influential journals.

When the tsar Alexander II visited the Palais de Justice in 1867, Floquet was said to have confronted him nith the cry "Vive la Pologne. monsieur!" He delivered a scathing indictment of the empire at the trial of Pierre Bonaparte for killing Victor Noir in 1870, and took part in the revolution of Sept. 4 as well as in the subsequent defense of Paris. In 1871 he was elected to the national assembly by the *département* of the Seine.

During the Commune he formed the Ligue d'union républicaine des droits de Paris to attempt a reconciliation with the government of Versailles. He was imprisoned for a short time after the fall of the Commune. Floquet edited the *République française,* was president of the municipal council, and entered the chamber of deputies in 1876. He took a prominent place among the extreme radicals, and became president of the group of the "Union républicaine." In 1882 he held for a short time the post of prefect of the Seine. In 1885 he succeeded Henri Brisson as president of the chamber. This difficult position he filled with such tact and impartiality that he mas re-elected the following two years. Having approached the Russian ambassador in such a way as to remove the prejudice existing against him in Russia since the incident involving tsar Alexander II in 1867, he rendered himself available for office. On the fall of the Tirard cabinet in 1888 he became president of the council and minister of the interior in a radical ministry pledged to secure the revision of the constitution. Heated debates in the chamber during the Boulangist agitation culminated on July 13 in a duel between Floquet and Boulanger in which the latter was wounded.

In Feb. 1889 the government fell on the question of revision, and in the new chamber of November Floquet was re-elected to the presidential chair. Implicated in the Panamá scandals he lost the presidency of the chamber in 1892, and his seat in the house in 1893, but in 1894 was elected to the senate.

Floquet died in Paris on Jan. 18, 1896.

See *Discours et opinions de M. Charles Floquet,* ed. by A. Faivre (1885).

FLOR, ROGER DI, a military adventurer of the 13th–14th century, was the second son of a falconer in the service of the emperor Frederick II, who fell at Tagliacozzo (1268). When Roger was eight years old he was sent to sea in a galley belonging to the Knights Templars. He entered the order and became commander of a galley. At the siege of Acre by the Saracens in 1291 he was accused and denounced to the pope as a thief and an apostate, was degraded from his rank, and fled to Genoa, where he began to play the pirate.

The struggle between the kings of Aragon and the French kings of Naples for the possession of Sicily was at this time going on and Roger entered the service of Frederick, king of Sicily, who gave him the rank of vice-admiral. At the close of the war, in 1302, as Frederick was anxious to free the island from his mercenary troops (called *Almogávares*), whom he had no longer the means of paying, Roger induced them under his leadership to seek new adventures in the east, in fighting against the Turks, who were ravaging the empire. The emperor Andronicus II accepted his offer of service; and in Sept. 1303 Roger with his fleet and army arrived at Constantinople. He was adopted into the imperial family, was married to a granddaughter of the emperor, and was made grand duke and commander in chief of the army and the fleet.

After several weeks lost in dissipation, intrigues and bloody quarrels, Roger and his men were sent into Asia. and after some successful encounters with the Turks they went into minter quarters at Cyzicus.

In May 1304 they again took the field, and relieved Philadelphia, then invested and reduced to extremities by the Turks. But Roger determined to found in the east a principality for himself. He sent his treasures to Magnesia, but the people slew his Catalans and seized the treasures. He besieged the town, but was repulsed. Being recalled to Europe, he settled his troops in Gallipoli and other towns, and visited Constantinople to demand pay for the *Almogávares.* Dissatisfied with the small sum granted by the emperor, he plundered the country and carried on intrigues both with and against the emperor, receiving reinforcements all the while from all parts of southern Europe. Roger was now created Caesar, but shortly afterward the young emperor Michael Palaeologus, not daring to attack the fierce and now augmented bands of adventurers, invited Roger to Adrianople, and there contrived his assassination and the massacre of his Catalan cavalry (April 4, 1306).

His death was avenged by his men in a fierce and prolonged war against the Greeks.

See Moncada, *Expedicidn de los Catalanes* y *Aragones contra Turcos y Griegos* (1840).

FLORA, Italian goddess of the flowering of plants. Her worship at Rome, where she had her own priest (flamen), goes back to very early times. Her festival (*Floralia:* April 28–May 3) was instituted in 238 B.C. on the advice of the Sibylline books, and at the same time a temple was dedicated on the slopes of the Aventine near the Circus Maximus. The *Floralia* was accompanied by much indecency. Harlots considered this their special season, and the games included lewd mimes. Flora's head, distinguished only by a floral crown. appears on coins of the republic.

The term flora is used in botany collectively for the plant growth of a district.

FLORAL PARK, a residential village of Nassau county in southeastern New York, U.S., on Long Island, immediately east of the borough of Queens (New York city) and 4 mi. W. by N. of Hempstead. Although most residents of the village work in New York city, there are light manufactures which include the making of slippers, photographic equipment and aircraft parts. Flower cultivation, from which the village takes its name, is also carried on. Floral Park was incorporated in 1908. For comparative population figures see table in NEW YORK: *Population.*

FLOREAL. The name given to the eighth month of the year introduced into the French Republican calendar in 1793. It extended from April 20 to May 19.

FLORE AND BLANCHEFLEUR: see AUCASSIN AND NICOLETTE.

FLORENCE, WILLIAM JERMYN (BERNARD CONLIN) (1831–1891), U.S actor. whose greatest success was in Benjamin Woolf's *The Mighty Dollar,* which he is said to have performed over 2,500 times. He was born in Albany, N.Y., July 26, 1831, of Irish parents. Reared in New York city, he became a call bov at the Old Bowery theatre under F. S. Chanfrau. While working to support his mother and her seven younger children, he rehearsed plays at night. and in 1850 began to do dialect impersonations. In 1851 he married Malvina Pray, and thereafter the two generally appeared together on the stage.

Florence's first success was in *A Row at the Lyceum* (1851); following this. he established his reputation as Captain Cuttle in *Dombey and Son,* Bob Brierly in *Ticket-of-Leave Man* and Sir Lucius O'Trigger in *The Rivals.* His last appearance was with Joseph Jefferson, with whom he had maintained a successful partnership. He died in Philadelphia, Nov. 18, 1891. Florence was one of a select number of Americans to win the ribbon of the Société Histoire Dramatique. (S. W. H.)

FLORENCE (Ital. FIRENZE, Lat. FLORENTIA), capital of Tuscany, and the capital of the province of the same name, lies 145 mi. N.N.W. of Rome, Italy. Pop. (1957 est.) 411,962 (commune). Florence is very favourably situated where the Arno river, after leaving the undulating spurs of the Apennines and before flowing inta the level fertile plain, is at its narrowest and therefore easiest to ford and to bridge. Because of its position near the three Apennine passes, of which two lead to Bologna and one farther south to Faenza, Florence became one of the foremost centres of communication of central Italy. It has equally easy access to the Tyrrhenian seaboard since the embarking and draining operations have averted the danger of flooding from the intervening lower ranges of the river.

ancient times Tuscany stood out among the regions of peninsular Italy as the one endowed with the most varied natural resources and containing almost the entire mineral wealth of Italy. The surrounding hills and plain produce wheat, maize, olives, vines, fruit trees, etc. The chief nonfruit-bearing trees are the pine, cypress, ilex and poplar. Gardens and fields produce such an abundance of blossoms that Florence is known as *la cittb del fiore* ("the city of the flower"); the city's emblem is a flower which also was struck on the obverse of the Florentine gold coins (hence called *florins*).

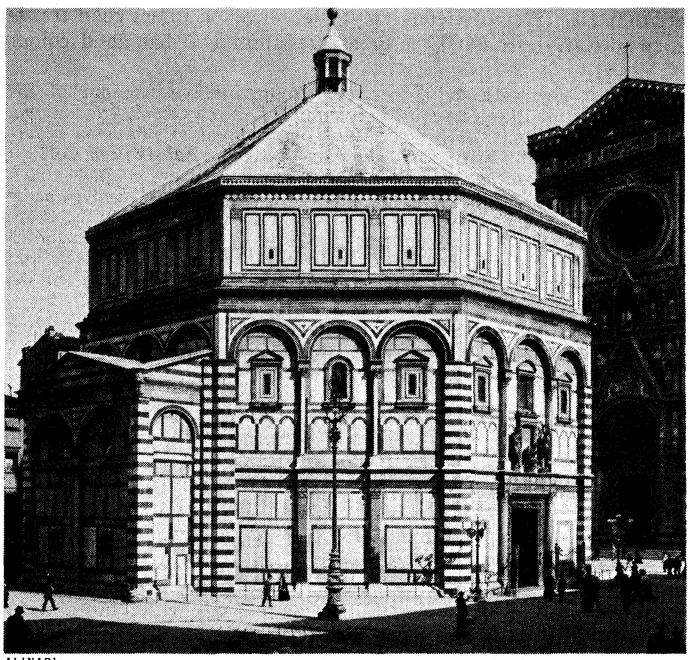
The soft yet precise outlines of the surrounding hills are one among the many attractions of the Florentine landscape. The rigour of the winter (minimum temperature 23° F.) and the heat of the summer (maximum 96.3" F. in July) do not last long: between the seasons the temperature is delightful.

Known as "the Athens of Italy," Florence is one of the foremost art centres of the world, second only to Rome for the wealth of monuments and art treasures; it equally used to be the seat of the oldest learned societies and academies. The Florentines have never lost their inborn sensitiveness for the fine arts nor their natural good taste; lively, quick in repartee, with a sharp, sometimes cynical sarcasm, they nevertheless cling to their traditional festive occasions and their charitable customs.

The artistic temperament of the Florentines accounts for their highly developed handicrafts, the best-known being statuettes (in marble and alabaster), gold and silver wares, the so-called Florentine "mosaic" (really *intarsio* of hard stones), cabinetmaking, artistic ceramic and terra-cotta wares, glass. wrought iron, embroidery, lace, tooled leather and the typical Florentine plaited straw goods. Later crafts have been added such as photographic reproduction of works of art. The latest manifestation of Florentine artistry is the fashion shows which. under the auspices of the Ente della Moda. take place periodically in the Palazzo Pitti: these occasions have grown into international exhibitions and attract people from the rest of Europe and from North America.

Florence has been spared the mechanization attending mass production. Except for a few flour mills, some glassworks. a nonferrous metal factory, a motor factory and an oil drilling equipment factory, there are hardly any large industries, though Florence is the centre of one of Italy's foremost firms producing precision instruments. There are porcelain works in the outskirts. (O. D. S.)

Architecture and Art.—The oldest surviving building in Florence is almost certainly the Baptistery, but it has never been satisfactorily dated. In the 14th and 15th centuries it was regarded as having been built by the Romans as a temple of Mars: modern guesses range from the 5th (or even 4th) century to the 11th or 12th. The present building is probably of the 11th or 12th centuries and very probably replaces a much earlier one. There are other churches of the Romanesque period in Florence, and



ALINARI

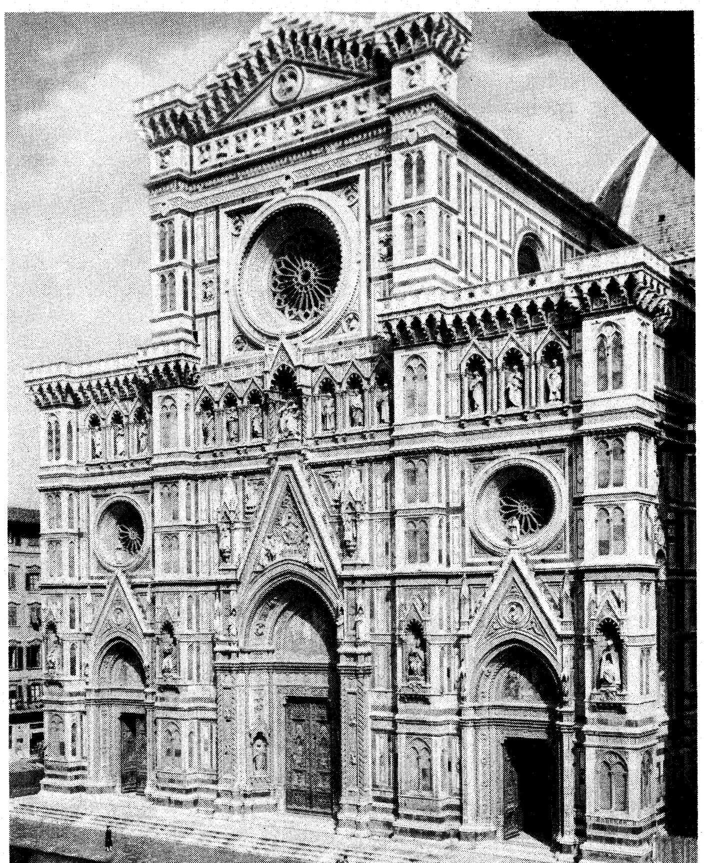
BAPTISTERY OF S GIOVANNI. PROBABLY THE OLDEST SURVIVING BUILDING IN FLORENCE, DATING IN ITS PRESENT FORM FROM THE 11TH OR 12TH one of the finest is S. Miniato al Monte, just outside the city, which goes back to 1018 or 1062, although most of it is somewhat later. These very classical buildings, with their peculiar striped appearance due to the decorative use of bands of ahite and dark grey-green marble, were one of the formative influences on the great outburst of architectural activity in Florence in the 13th, 14th and 15th centuries.

After the governmental reorganization of 1250 there was a wave of church-building, partly due to the great influence of the new mendicant orders of friars (Dominicans and Franciscans) and, at the same time, the strong civic sense of the Florentines asserted itself in several large public buildings and in the subsidizing of new churches, especially the great cathedral (begun in 1294 and not consecrated until 1436) which was regarded as a state enterprise. In the 14th century. there grew up two nuclei of building activity in Florence, one centred on the new cathedral and campanile just opposite the old Baptistery and the other nearer the river and centred on the Palazzo della Signoria (Palazzo Vecchio), or town hall, the great square in front of it, and the Loggia dei Lanzi, with the Bargello, the residence of the *podestà* or chief magistrate, a little way off.

The first great church to be built for one of the new orders was Sta. Maria Novella, the main Florentine church of the Order of S. Dominic, or Friars Preachers. This church is the one that shows the strongest influence of an entirely new style, conditioned by French Gothic (and particularly by the Cistercian forms of it), but with far less verticality and with a calm spaciousness due to the remembered forms of the classical and Romanesque churches. Some of the spacious effect is probably also due to the fact that churches for the new orders were designed to hold huge congregations who came to hear the preachers. The first plan of Sta. Maria Novella was made by 1246, but it is not certain how much (if any) of the existing church is of that date; and it has been argued that parts of Sta. Trinità antedate Sta. Maria Novella: whether or not this is so. it remains true that Sta. Maria was a new kind of church designed for a new religious purpose in a new, Italian, Gothic style. Sta. Croce, at the opposite end of the city. was the corresponding headquarters of the rival Franciscan order and, according to tradition, was designed by Arnolfo di Cambio from 1294–95. It is less ambitious architecturally than Sta. Maria Novella for it retains the traditional flat, openwork, timber roof where Sta. Maria has stone vaults. Sta. Croce is perhaps best known for the wealth of Trecento frescoes. including those by Giotto (*q.v.*) decorating two chapels, and for the Quattrocento and later tombs. Arnolio di Cambio is also credited with the Badia. a reworking of an older church. but his principal work was Sta. Maria del Fiore, the cathedral of Florence. where he is recorded as having worked in 1300 and consequently being exempt from taxation. He died soon afterward. and the plans he had established were much enlarged, though relatively little changed, by Francesco Talenti (1355–65).

Between the times when Arnolfo and Talenti held the surveyorship it passed to Giotto (1334–37) on the grounds of his fame as a painter rather than his architectural skill. He did not alter Arnolfo's plans hut instead began to erect the campanile, or bell tower, which stands at the side of the west front. The crowning feature of the cathedral, and the great landmark for miles around. is the huge ribbed dome which was added by Brunelleschi (*q.v.*) between 1420 and 1436—the lantern mas added later—and which was constructed entirely without centring. The opening is about $138\frac{1}{2}$ ft. across (slightly larger than St. Peter's. Rome, and much larger than St. Paul's. London). The engineering feat performed by Brunelleschi ensured his fame, quite apart from his other works in Florence, some of which are of greater aesthetic importance. The decoration of the cathedral occupied much of the 15th century and many of the finest sculptors worked on it, in particular. Donatello and Luca della Robbia who both worked there at the time when Ghiberti was occupied with his first and second bronze doors for the Baptistery (1403–52). The main front of the cathedral remained incomplete until 1875 when the present neo-Gothic design was made by E. de Fabris.

The major public buildings erected in the 14th century were the Bargello (now the National Museum of Sculpture) and the Palazzo della Signoria, which was the seat of government and was sufficiently fortified to withstand rioting and other disorders. The great bell tower, built out over the façade, carries the bell used



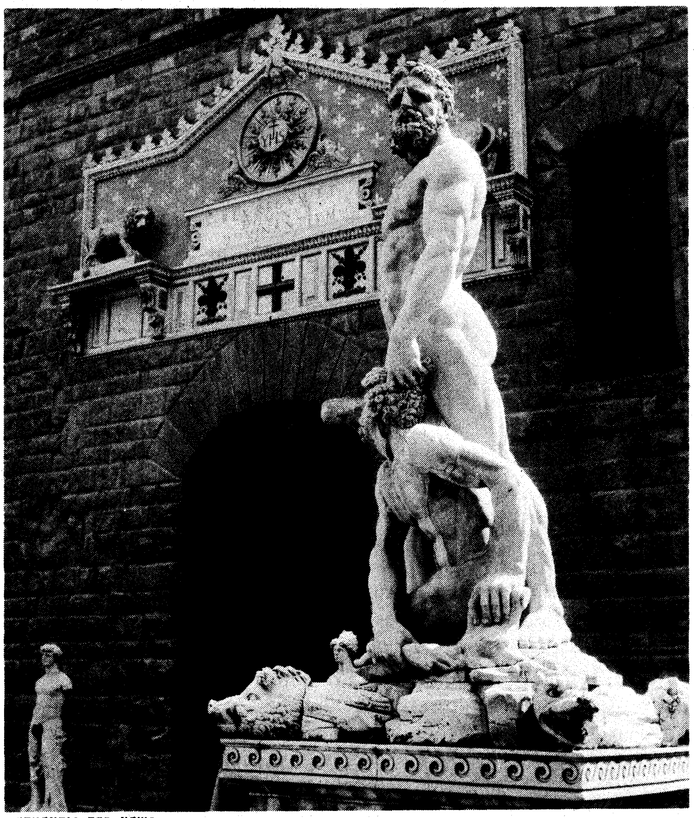
EWING GALLOWAY

FACADE OF STA. MARIA DEL FIORE. THE CATHEDRAL OF FLORENCE. BEGUN IN THE 13TH CENTURY, COMPLETED LATE 19TH CENTURY

as a city alarm. The Palazzo della Signoria is attributed to Arnolfo di Cambio, but there is no evidence for this although the dates, 1298 to 1314, would fit. Opposite the palace, the Signoria built an open loggia, generally known as the Loggia dei Lanzi, as a public meeting place. This was begun in 1376. Other more ar less public buildings include the church of Or San Michele, which was originally a grain store but became the church of the guilds, which formed the political centre of Florence. On the façades of Or San Michele are several niches holding statues of the patron saints of the various guilds; many of these figures are among the most important examples of early 15th-century Florentine sculpture, including Ghiberti's "St. John," "St. Matthew" and "St. Stephen," Donatello's "St. George" (now represented by a copy), Nanni di Banco's "Quattro Santi Coronati," and, among the later works, Verrocchio's "Incredulity of St. Thomas."

Perhaps the most important semipublic building in Florence is the loggia of the Spedale degli Innocenti (the Foundling hospital). Not only was this the first hospital of its kind but it is also an architectural landmark, since it was designed by Brunelleschi about 1419 and it, rather than the cathedral, is the first Renaissance building. It was finished by Brunelleschi's pupils and he himself turned his attention to church-building, his two main works being S. Lorenzo and Sto. Spirito. Both are Latin cross designs (derived from traditional models such as Sta. Croce), subjected to the rigorous classical discipline of mathematical proportion which was Brunelleschi's major contribution to Renaissance architecture. S. Lorenzo was the parish church of the Medici, and it was for one of this family that he first built the old sacristy at S. Lorenzo before working on the church proper. The old sacristy is the burial place of several Medici and is one of the first modern buildings to be constructed on the central plan system. It is built as a cube with a dome over it; the hemispherical dome is half the height of the cube. The decorations—which did not please Brunelleschi—were by his friend Donatello. A century later, beginning in 1520, Michelangelo built the new sacristy as another Medici chapel in a style which is clearly based on Brunelleschi's old sacristy opposite. Finally, the later Medici caused a still larger funerary chapel to be added behind the church choir and between the other two chapels: this is by Matteo Nigetti and was begun in 1605. It is one of the least successful of the few Baroque buildings in Florence. The cloister of S. Lorenzo contains the Biblioteca Laurenziana, also by Michelangelo and one of his most important works in architecture as well as one of the first Mannerist buildings.

On the other side of the Arno, in the poorer quarter Oltr' Arno Brunelleschi built Sto. Spirito, his last church design, which is



AUTHENTICATED NEWS

MARBLE STATUE OF HERCULES AND CACUS BY BACCIO BANDINELLI (1493–1560), OUTSIDE THE PALAZZO DELLA SIGNORIA (PALAZZO VECCHIO). FLORENCE

a revised edition of the ideas in S. Lorenzo. Additions were made later in the century by Giuliano da Sangallo and Il Cronaca, but the influence of Brunelleschi is paramount. The only other important church in this quarter is Sta. Maria del Carmine, which is of interest less because of its architecture than because it contains Masaccio's Brancacci chapel frescoes, the foundation of Quattrocento painting and the most important fresco cycle painted in Florence since Giotto's in the chapels of Sta. Croce a century earlier.

The only other major building on the south side of the Arno is the huge Pitti palace. begun in the mid-15th century by an unknown architect, traditionally, but improbably, said to be Brunelleschi. It was enormously enlarged by Ammanati (1558–70) as a residence for the Medici; various later grand dukes had further alterations and additions made. It became the usual residence after Cosimo I gave up living in the Palazzo della Signoria and for this reason it was connected with the Palazzo degli Uffizi (Vasari and others, 1560 onward), which housed the government offices, by a long corridor carried over the Arno on top of the Ponte Vecchio. The corridor was badly damaged during World War II, when the Germans destroyed all the old bridges save the Ponte Vecchio and also blew up much of the Por Santa Maria quarter at the approaches to the Ponte Vecchio. Two bridges have been built since the war: Ponte Santa Trinità, reconstructed according to the original plans, and Ponte Amerigo Vespucci, built of prestressed concrete. Behind the Pitti palace lie the Boboli gardens, smong the largest and most splendid of Italian formal gardens, sloping steeply up the hillside. At the top is the Fortezza di Belvedere, first opened to the public in 1957, from which a breathtaking panorama of Florence may be obtained.

The Pitti and Uffizi are now the two principal art galleries of Florence, containing an unsurpassed representation of Tuscan painting from the 13th to the 17th centuries and a fair representation of other Italian and foreign schools. Some early and less important works are also to be found in the Academy of Fine Arts, the chief treasure of which is Michelangelo's "David." The main collection of Tuscan sculpture is, however, housed in the Bargello. Most of the numerous churches of Florence contain interesting paintings, but two must be mentioned specifically: S. Marco and the SS. Annunziata. Both contain important frescoes; the convent of S. Marco is now a museum dedicated to its two most famous inhabitants, Savonarola and Fra Angelico, the latter of whom painted the splendid series of frescoes which adorn it, as well as the altarpieces now preserved there.

No account of the art history of Florence, however brief, could conclude without mention of the palaces which have formed many of our ideas of city living. The Florentines were among the first people to revive the classical idea of great houses which combined warehouses and shops on the ground floor with apartments on the upper ones. In most cases the palace was built by a wealthy merchant (not noble) family, which had offices on the ground floor and lived on the cool, spacious first floor (piano *nobile*); the upper floors, smaller and hotter, being let off or used for the accommodation of employees and relatives. Many such palaces are still in the possession of the families that built them and are still used for the same purposes. The Palazzo Davanzati, now a museum, is a splendid example, built at the end of the 14th century. The finest examples are from the 15th century: the Palazzo Medici, by Michelozzo (*q.v.*); the Rucellai, by Alberti (*q.v.*), which first used the classical orders on a house façade; later 15th-century ones like the Pazzi-Quaratesi and Strozzi; and, in the 16th century, one by Raphael himself, the Palazzo Pandolfini. This, though now within the northern boundary of the city, was then a suburban villa, and, as such, can perhaps hardly count in the evolution of what has always been a very urban city.

(P. J. MY.)

Libraries.—The Biblioteca Nazionale Centrale (Central National library) has the right to receive a copy of every publication issued in Italy and contains some 4,000,000 pieces divided into manuscripts, rare first editions, pamphlets, maps, engravings and autographs. The Biblioteca Marucelliana, founded in 1703, is chiefly remarkable for its collection of illustrated works and art publications. The Laurentian library was opened to the public by Grand Duke Cosimo I in 1571; it contains first editions and a collection of manuscripts, including richly ornamented missals, bibles and codices of great beauty. A famous international library is the Gabinetto Viesseux which now belongs to the commune of Florence and is on the ground floor of the Strozzi palace. (See LIBRARIES: Italy.)

University and Institutes.—The University of Florence is descended from "Studio Fiorentino" (later called *universitas scholarium*) founded in 1349, which Lorenzo de' Medici transferred to Pisa in 1472; there still remained in Florence the important study of medicine which was at the head of the scientific movement of the age, though the university was not legally constituted until 1923. There are numerous specialized and foreign academies.

(X.)

HISTORY

Florentia was founded considerably later than Faesulae (Fiesole), which lies on the hill above it. Tacitus mentions it, and

Florus describes it as one of the *municipia splendidissima.* A bishop of Florence is mentioned in A.D. 313. The first event of importance recorded is the siege of the city by the Goths. A.D. 405, and its deliverance by the Roman general Stilicho. We find the Longobards in Tuscany in 570, and mention is made of one *Gudibrandus Dux'civitatis Florentinorum,* which suggests that Florence mas then the capital of a duchy.

Guelphs and **Ghibellines.**—Under the Carolingian emperors, Tuscany was a march or margraviate, which, in 1054, passed to the famous countess Matilda, daughter of Boniface of Canossa. In the Wars of the Investitures Matilda was on the papal (Guelph) side against the emperor and the faction afterward known as Ghibelline *(see* GUELPHS AND GHIBELLINES), and she herself often led armies to battle. While she presided at the courts of justice in the name of the empire, she was assisted by a group of great feudal nobles, judges, lawyers, etc., who formed. as elsewhere in Tuscany, the *boni homines* or *sapientes.* The citizens found themselves in opposition to the nobility of the hills around the city, Teutonic feudatories of Ghibelline sympathies, who interfered with their commerce, and they began to form themselves into groups and associations, which were the germs of the *arti* or guilds.

After the death of Countess Matilda in 111; the *grandi* or *boni homines* continued to rule, but in the name of the people—a change which marks the foundation of the commune. After 1138 the *boni homines* began to be called *consules,* while the population was divided into the *grandi* or *delle torri; i.e.,* the noble families possessing towers, and the *arti* or industrial and merchant guilds. At first the *consules* were chosen by the *grandi* and assisted by a council of 100, in which the *arti* were predominant. In 112j Fiesole was sacked and destroyed, but the feudal nobles of the *contado* (surrounding country), protected by the imperial margraves, were still powerful.

The Florentines waged war against the Alberti family, whose castles they destroyed, and fought successfully against the powerful Counts Guidi. Frederick Barbaroisa. honever, elected emperor in 1152, made his authority felt in Tuscany, and appointed one Welf of Bavaria as margrave, and a *potestas* or *podestci* who resided at San Miniato was appointed to represent the emperor and exercise authority in the *contado.* From the end of the 12th century the *podestà* was always a foreigner. In the meantime Florence had already become an important industrial and banking centre.

The work of crushing the nobles of the *contado* and of asserting the city's position among rival communes continued. The tumults against the Paterine heretics (1244–45), among whom were many Ghibelline nobles, indicate a successful Guelphic reaction; but, when civil war broke out. Frederick of Antioch, imperial vicar in Tuscany, and natural son of Frederick II. entered the city with 1,600 German knights, the Ghibellines triumphed again, and in 1249 the Guelph leaders were driven into exile—the first of many instances in Florentine history of exile en masse of a defeated party.

Comune and **Popolo.**—The Ghibellines being unable to maintain their supremacy, the city came to be divided into two almost autonomous republics, the *comune* headed by the *podestci,* and the *popolo* headed by the *capitano* and militarily organized into 20 companies; the central power was represented by 12 elders. At this time the *podestci's* palace (the Bargello) was built, and the gold florin was first coined and soon came to be accepted as the standard gold piece throughout Europe. But, although greatly strengthened. the Guelphs were not wholly victorious, and in 1251 they had to defend themselves against a league of Ghibelline cities (Siena, Pisa and Pistoia) aided by Florentine Ghibellines. A Florentine army assisted by Guelphs of other towns was met by a Sienese army reinforced by Florentine exiles, and by the cavalry of Manfred of Sicily *(q.v.),* with the result that the Florentines were totally routed at Montaperti on Sept. 4, 1260. Count Giordano, acting for Manfred, entered Florence, appointed Count Guido Novello *podestà,* and began a series of persecutions against the Guelphs. The Ghibellines even proposed to raze the walls of the city. Their triumph, however. was short-lived: Charles I of Anjou *(q.v.),* descended into Italy as the champion of the papacy; Manfred was defeated and killed (1266), and Guido Novello and the Ghibellines were expelled and their property confiscated. But it was not the *popolo* who triumphed; the pope and Charles were the real masters of the situation. Nevertheless much of the old order was restored; the *podestci* who represented King Charles was assisted by 12 *buoni uomini,* and by the council of the 100 *buoni uomini del popolo,* but the constitution of the republic, although of very democratic tendencies, seemed designed to promote civil strife and weaken the central pouer.

While the constitution was evolving in a manner which seemed to argue small political ability and no stability in the Florentines, the people had built up a wonderful commercial organization. Each of the seven *arti maggiori* or greater guilds was organized like a small state with its councils, statutes, assemblies, magistrates, etc., and in times of trouble constituted a citizen militia. Florentine cloth especially was known and sold all over Europe, and the Florentines were regarded as the first merchants of the age. In 1279 Pope Nicholas sent his nephew, Cardinal Latino Frangipani Malabranca, to reconcile the parties in Florence once more. He succeeded to some extent, and was granted a kind of temporary dictatorship. He raised the 12 *buoni uomini* to 14 (eight Guelphs and six Ghibellines), to be changed every two months; and they were assisted by a council of 100. A force of 1,000 men was placed at the disposal of the *podestci* and *capitano* (now both elected by the people) to keep order and oblige the Guelph nobles to respect the law. After 1282 the signory was composed of the three (afterward six) *priori* of the guilds, who ended by ousting the *buoni uomini,* while a *defensor artificum et artium* replaced the *capitano;* thus the republic became an essentially trading community, governed by the *popolani grassi* or rich merchants.

The republic now turned to the task of breaking the power of the Ghibelline cities of Pisa and Arezzo. In 1289 the Aretini were completely defeated by the Florentines at Campaldino, a battle made famous by Dante's presence. Peace was made in 1293.

The Ordinamenti Della **Giustizia.**—The nobles, who had largely contributed to the victory, especially men like Corso Donati and Vieri de' Cerchi. were becoming more powerful, but new laws were passed to reduce their influence. These were reinforced by the *Ordinamenti della Giustizia* of 1293, by which all nho were not of the *arti* were definitely excluded from the signory. The leading spirit of this reform was Giano della Bella, a noble who by engaging in trade had become a *popolano;* the nobles strenuously opposed the new measures, and in 1295 a signory favourable to them enacted a law attenuating the *Ordinamenti.*

Charles of Valois and Henry of Luxembourg. — The nobles, however, had split into two factions, the *Neri* (Blacks), headed by the Donati, and the *Bianchi* (Whites) led by the Cerchi. The pope's attempt to unite them having failed, he summoned Charles of Valois to come to his assistance, promising him the imperial crown, and in 1301 Charles entered Italy with instructions from the pope to crush the Bianchi and the *popolo* and exalt the Neri. On Nov. 1 Charles reached Florence. He promised to respect the laws, but the new *podestci,* Cante dei Gabrielli of Gubbio, who had accompanied Charles, punished many of the Bianchi; among those whom he exiled mas the poet Dante (1302).

Corso Donati, who for some time mas the most powerful man in Florence, made himself many enemies by his arrogance, and the irritation against him resulted in a rising in which he was killed (1308). In the same year Henry of Luxembourg was elected king of the Romans, and with the pope's favour he came to Italy in 1310; the Florentine exiles and all the Ghibellines of Italy regarded him as a saviour and regenerator of the country, while the Guelphs of Florence regarded both him and the pope as dangerous to their liberties. In 1312 Henry was crowned emperor as Henry VII in Rome, but circumstances made him merely a German kaiser who tried to subjugate free Italian communes. He besieged Florence without success, and died in 1313.

The 14th Century. — In 1325 further constitutional reforms were enacted. The former councils were replaced by the *consiglio del popolo,* consisting of 300 *popolani* and presided over by the *capitano*, and the *consiglio del comune* of 250 members, half of them nobles and half *popolani,* presided over by the *podestà.* The *priori* and other officers were drawn by lot from among the Guelphs over 30 years old who were declared fit for public office by a special board of 98 citizens (1329).

From 1313 to 1338. the Florentines waged war with varying success against Pisa and Lucca. Finally. by the peace of 1339 they obtained a part of Lucchese territory. At the same time they purchased from the Tarlati the protectorate over Arezzo for ten years. But misfortunes fell on the city: Edward III of England repudiated the heavy debts contracted for his wars in France with the Florentine banking houses of Bardi and Peruzzi (1339), and this eventually led to their bankruptcy, shaking Florentine credit all over the world; Philip VI of France extorted large sums from the Florentine merchants and bankers in his dominions by accusing them of usury; in 1340 plague and famine wrought terrible havoc in Florence, and riots again broke out between the nobles and the *popolo.* To put an end to these disorders, Walter of Brienne, duke of Athens. was elected "conservator" and captain of the guard in 1342. An astute, dissolute and ambitious man, half French and half Levantine, he succeeded in getting himself acclaimed by the populace lord of Florence for life. But by his oppressive taxes; and his ferocious cruelty. he accumulated bitter hatred against his rule. On July 26, 1343, the citizens rose in arms, demanded the duke's abdication, and besieged him in the palace. Finally on hug. 1 he had to resign his lordship.

A *balia,* or provisional government. was appointed to institute reforms; new constitutional changes were introduced; the *Ordinamenti* were maintained, but in a somewhat attenuated form, and certain nobles as a favour were declared to be of the *popolo.* Florence became a thoroughly democratic and commercial republic, but Florentine democracy was limited to the walls of the city, for no one of the *contado* nor any citizen of the subject towns enjoyed political rights. which were reserved for the inhabitants of Florence alone, and not by any means for all of them.

Florence was, in the 14th century. a city of about 100,000 inhabitants. of whom 25,000 could bear arms; there were 110 churches. 39 religious houses; the shops of the *arte della lana* numbered over 200, producing cloth worth 1,200,000 florins. and Florentine bankers and merchants were found all over the world, often occupying responsible positions .in the service of foreign governments. It was already a centre of art and letters and full of fine buildings, pictures and libraries. But since the nobles had been suppressed politically, the lowest class of adventurer had come into prominence. thus paving the way for tyranny.

In 1347 the city was again stricken with famine, and in 1348 by a terrible plague. which carried off three-fifths of the population (according to Yillani). Yet in spite of these disasters the republic was not vanquished; it soon regained the suzerainty over many cities which had broken off all connection with it and purchased the overlordship of Prato. Giovanni Visconti, lord and archbishop of Milan, having purchased Bologna and allied himself with sundry Ghibelline houses of Tuscany with a view to dominating Florence. aroused Florentine anger and the city made war on him in 1351, and placed itself under the protection of the emperor Charles IV (13jj). This enabled the nobles who dominated the *Parte Guelfa* to enact stringent measures, punishing with death or heavy fines all who, being Ghibellines, held office, and to exercise a veritable reign of terror.

Italy at this time began to be overrun by bands of soldiers of fortune. The first of these bands with whom Florence came into contact was the Great Company. commanded by the count of Lando, which twice entered Tuscany but was expelled both times by the Florentine troops (1358–59). From 1362–64 Florence was again at war with Pisa and the latter called Sir John Hawkwood's English company to their aid. Peace was finally made with no advantage gained on either side.

The Parte **Guelfa.**—The tyranny of the *Parte Guelfa* continued unabated, and the *capitani* carried an enactment by which no measure affecting the *Parte* should be even discussed by the signory unless previously approved by them. This law. however, aroused so much opposition that some of the very men who had proposed it assembled in secret to discuss its abolition, and a quarrel between the Albizzi and the Ricci having weakened the *parte*, a *balìa* of j6 was agreed upon. Several of the Xlbizzi and the Ricci were excluded from office for five years. and a council called the Ten of Liberty was created to defend the laws and protect the weak against the strong.

In 1375 Florence became involved in a war which showed how the old party divisions of Italy had been obliterated. The papal legate at Bologna, Cardinal Guillaume de Noellet (d. 1394), although the Church was then allied to Florence. was meditating the annexation of the city to the Holy See; he refused a request of the Florentines for grain from Romagna, and authorized Hawkwood to devastate their territory. An alliance with Bernabò Visconti was thereupon concluded. war declared, and a *balia* of eight, the *Otto della guerra* (afterward called the "Eight Saints" on account of their good management) was created to carry on the campaign. Pope Gregory XI placed Florence under an interdict. but by 1378 peace was made, partly through the mediation of St. Catherine of Siena, and the interdict was removed in. consideration of the republic's paying a fine of 200.000 florins to the pope.

During the war the eight had been practically rulers of the city, but now the *Parte Guelfa,* led by Lapo da Castiglionchio and Piero degli Albizzi, attempted to reassert itself. Salvestro de' Medici, however, who had always opposed the *parte,* was elected *gonfaloniere* in spite of its intrigues (1378), and the people were anxious to break the power of the *parte* for good. *A* large body of wool carders gathered outside the city and conspired to subvert the signory and establish a popular government. Although the plot, in n-hich Salvestro does not seem to have played a part. was discovered. a good deal of mob violence occurred. and on July 21 the populace seized the *podestà*'s palace, which they made their headquarters. Once the people were in possession of the palace. a carder named Michele di Lando took the lead. Master of Florence for one day, he quelled disorder and pillage, and reformed the constitution. But to satisfy the people several of the nobies, including Piero degli Albizzi, were put to death on charges of conspiracy, and many others were exiled. Perpetual rioting and anarchy succeeded. until at last, in 1382, a reaction set in, and order was restored by the guild companies. Again a new constitution was decreed by which the *gonfaloniere* and half the *priori* were to be chosen from the greater guilds and the other half from the lesser. The demagogues were executed or forced to fly, Michele di Lando was exiled, and the Guelph families gradually regained much of their lost power.

Pisa.—In 1393 Maso degli Albizzi was made *gonfaloniere,* and for many years remained almost master of Florence. A severe persecution was initiated against the Alberti and other families, who were disfranchised and exiled. Disorders and conspiracies against the merchant oligarchy continued. and the exiles caused the republic much trouble by intriguing against it in foreign States. In 1397–98 Florence was at war with Gian Galeazzo Visconti, who, aspiring to the conquest of Tuscany. acquired the lordship of Pisa, Siena and Perugia; but just as the Milanese were about to march on Florence, Visconti died. His territories were divided between his sons and his *condottieri.* In 1404 the Florentines' attempt to capture Pisa single-handed failed, and Gabriele Maria Visconti. lord of Pisa, placed himself under the protection of the French king. The Florentines then made overtures to France, who had supported the antipopes all through the Great Schism, and suggested that they too would support the then antipope, Benedict XIII, in exchange for the sale of Pisa. With French support they purchased the city in 1405, but a few days later the citizens rose in arms and recaptured it from the mercenaries. There was great consternation in Florence at the news, and the Florentines attacked Pisa once more. After a six months' siege it surrendered on terms (Oct. 9, 1406), and Florence acquired a great seaport and was at last able to develop a direct maritime trade.

Except in connection with the Pisan question, the republic had taken no definite side in the Great Schism which had divided the church since 1378, but in 1408 it appealed both to Pope Gregory XII and the antipope, Benedict XIII, and suggested a council nithin its own territory. Gregory refused, but after consulting a committee of theologians who declared him to be a heretic, the council promoted by Cardinal Cossa and other independent prelates met at Pisa. The council deposed both popes and elected Pietro Filargi as Alexander V (June 26). But Ladislas of Naples still occupied the Papal States, and Florence. alarmed at his growing power and ambition, formed a league with Siena, Bologna and Louis of Anjou who laid claim to the Neapolitan throne, to drive Ladislas from Rome. Cortona, Orvieto, Viterbo and other cities were recovered for Alexander, and in Jan. 1410 Rome itself mas captured by the Florentines under Malatesta dei Malatesti. Alexander having died in May. Cardinal Cossa was elected as John XXIII, and Florence purchased Cortona from the pope.

Ascendency of the De' Medici

Giovanni de' **Medici.**—In 1421 Giovanni de' Medici was elected *gonfaloniere* of justice, an event which marks the beginning of that family's power. The same year the republic purchased Leghorn from the Genoese for 100,000 florins, and established a body of "consuls of the sea" to superintend maritime trade. Filippo Maria Visconti, who had succeeded in reconquering most of Lombardy, seized Forlì. The Florentines declared war on him. and through Venetian intervention, Visconti was finally defeated and forced to accept peace on onerous terms (1427).

The old systems of raising revenue no longer corresponded to the needs of the republic, and as early as 1336 the various loans made to the state were consolidated into one national debt (*monte*). Subsequently all extraordinary expenditure was met by forced loans (*prestanze*), but because of the general discontent a *catasto* or assessment of all the wealth of the citizens was made in 1427, and measures were devised to distribute the obligations according to each man's capacity, so as to avoid pressing too severely on the poor. The *catasto* was largely the work of Giovanni de' Medici, who greatly increased his popularity thereby. He died in 1429.

Cosimo de' Medid — An attempt to capture Lucca led Florence, in alliance with Venice: into another costly war with Milan (1432–33). The mismanagement of the campaign brought about a quarrel between the aristocratic party. led by Rinaldo degli Albizzi, and the popular party led by Giovanni de' Medici's son Cosimo (1389–1464). Rinaldo succeeded in getting Cosimo exiled, but his proposal for a coup d'état met with no response from his own party. and he failed to prevent the election of a pro-Medici signory in 1434. A revolution was only averted through the intervention of Pope Eugene IV. A *parlamento* was summoned, and the *balìa* appointed decreed the return of Cosimo and the exile of Rinaldo degli Albizzi and others. On Oct. 6, 1434, Cosimo returned to Florence, and for the next three centuries the history of the city is identified with that of the house of Medici.

Cosimo succeeded in dominating the republic while remaining nominally a private citizen. He exiled those who opposed him, and governed by means of the *balìa*, which, re-elected every five years. appointed all the magistrates and acted according to his orders. In 1437 Florence and Venice were again at war with the Visconti, whose chief captain, Niccolò Piccinino (*q.v.*), on entering Tuscany with many Florentine exiles in his train. was signally defeated at Anghiari by the Florentines under Francesco Sforza (1440); peace was made the following year. The system of the *catasto,* which led to abuses, was abolished, and a progressive income tax (*decima scalata*) was introduced with the object of lightening the burdens of the poor, who were as a rule Medicean, at the expense of the rich.

Lorenzo the Magnificent. — In 1464 Cosimo died and was succeeded, not without some opposition, by his son, Piero. who was very infirm. Various plots against him were hatched, but Piero's unexpected energy upset the schemes of his enemies. He died in 1469, leaving two sons, Lorenzo (1449–92) and Giuliano (1453–78). The former at once assumed the reins of government and established his domination by means of provisional governments consisting entirely of Mediceans, to be renewed every five years (1471). In 1472 a quarrel having arisen with Volterra, Lorenzo sent an expedition against the city. which was sacked, and many of the inhabitants massacred. As a result of a variety of causes an enmity arose between Lorenzo and Pope Sixtus IV, and the latter, if not an accomplice, at all events had cognizance of the Pazzi conspiracy against the Medici (1478). The result of the plot was that Lorenzo strengthened his position, and put to death or exiled numbers of his enemies. He was excommunicated by Sixtus, who, together with King Ferdinand of Naples, waged war against him.

Eventually the Florentines were defeated at Poggio Imperiale and the city itself was in danger. Lorenzo by his boldness in going to Naples succeeded in concluding a peace with the king, which led to a reconciliation with the pope (1479–80). He was received with enthusiasm on returning to Florence and became absolute master of the city. From that time until his death the city was free from party strife under a *de facto* despotism. Because of his .political activity Lorenzo had neglected the business interests of his firm, and in order to make good certain heavy losses he seems to have appropriated public funds. His foreign policy, which was magnificent but expensive, rendered further forced loans necessary.

An attempt by the Venetians to seize Ferrara led to a general Italian war. in ahich Florence also took part on the side hostile to Venice, and when peace was made in 1484, the republic gained some advantages. The following year a revolt of the Neapolitan barons against Ring Ferdinand broke out actively supported by Pope Innocent VIII; Lorenzo remained neutral at first. but he ended by giving Ferdinand assistance in spite of the king's unpopularity in Florence. Peace was made in 1486, and in 1487 Lorenzo regained Sarzana. which Genoa had taken from Florence nine years previously. The general disorders and ceaseless intrigues all over Italy required Lorenzo's constant attention. and he succeeded in making Florence "the needle of the balance of poner in Italy." At this time the Dominican friar, Girolamo Savonarola (*q.v.*), was in Florence, and aroused the whole city by his denunciations of ecclesiastical corruption and also of that of the Florentines. He opposed Lorenzo's government as the source of the immorality of the people, and to some extent influenced public opinion against him. Ill health now gained on Lorenzo. and Savonarola, whom he had summoned to his bedside, refused to give absolution to the destroyer of Florentine liberties. Lorenzo died in 1492.

Expulsion of the Medici, 1494.—He was succeeded by his son Piero, who had none of his father's capacity and made many blunders. When Charles VIII of France came to Italy to conquer Naples, Piero decided to assist the latter, but as soon as Charles had entered Florentine territory and captured Sarzana, Piero went to his camp and asked pardon for opposing him. The king demanded the cession of Pisa. Leghorn and other towns, which Piero granted, but on returning to Florence on Kov. 8. 1494, he was refused admittance to the palace, and the people began to shout "Popolo e liberta!" in opposition to the Medicean cry of "Palle, Palle!" (from the Medici arms). With a small escort he fled from the city, followed soon after by his brother Giovanni. That same day Pisa rose in revolt against the Florentines and was occupied by Charles.

The expulsion of the Medici produced some disorder, but Piero Capponi (*q.v.*) and other prominent citizens succeeded in keeping the peace. Charles entered Florence on Nov. 1 j at the head of 12.000 men. He was impressed with the wealth and refinement of the citizens, and above all with the solid fortresslike appearance of their palaces. But his demands by no means pleased the Florentines, and when the king began to hint at the recall of Piero de' Medici. whose envoys had gained his ear, the signory ordered the citizens to be ready to resort to arms. The proposal was dropped, but Charles demanded an immense sum of money before he would leave the city. The syndics refused to accept his insolent ultimatum, and the king said in a threatening tone, "Then we shall sound our trumpets," whereupon Capponi tore up the document in his face and replied, "And we shall ring our bells." The king. realizing what street fighting in Florence would mean, at once came to terms; he contented himself with 120,000 florins, agreeing to give up the fortresses he had taken and to keep the Medici in exile. But it was not until Nov. 28, after an exhortation by Savonarola, whom he greatly respected, that he left Florence.

Savonarola.—It was intended to re-establish the government on the basis of the old republican institutions, but it was found that 60 years of Medici rule had reduced them to mere shadows, and the condition of the government was utterly chaotic. Consequently men talked of nothing save of changing the constitution, but. unfortunately. there was no longer an upper class accustomed to public affairs. while the lower class was thoroughly demoralized. Savonarola. who had already made a reputation as a moral reformer. began his famous series of political sermons, and gradually a new government was evolved. each law being enacted as the result of his exhortations. A greater council empowered to appoint magistrates and pass laws was formed, to which all citizens who had paid their taxes, and *beneficiati* (*i.e.,* who had sat in one of the higher magistracies, or whose fathers, grandfathers or great-grandfathers had done so) were eligible. There were 3,200 such citizens. and they sat one-third at a time for six months. The greater council was to elect another council of 80 citizens over 40 years old; this body was to appoint ambassadors and commissaries of war, and deal with other confidential matters. The system of forced loans was abolished and a 10% tax. on real property introduced in its stead, and a law of amnesty for political offenders enacted. Savonarola also proposed a court of appeal for criminal and political offenses tried by the *Otto di guardia e balìa;* this too was agreed to, but the right of appeal was to be, not to a court, as Savonarola suggested, but to the greater council, a fact which led to grave abuses, as judicial appeals became subject to party passions. But in spite of Savonarola's popularity. there was a party called the *Bigi* (grays) who intrigued secretly in favour of the return of the Medici, while the men of wealth, called the *Arrabbiati*, although they hated the Medici. were even more openly opposed to the actual regime. The adherents of Savonarola were called the *Piagnoni,* or snivellers, while the *Neutrali* changed sides frequently.

A league between the pope. the emperor. Venice and Spain having been made against Charles VIII. the French king was forced to return to France. On his return journey he violated his promise by giving aid to the Pisans in their revolt against Florence, and did not restore the other fortresses. Piero de' Medici's attempt to seize Florence failed, but the conditions of the city were not prosperous; its resources were strained by the sums paid to Charles and by the war, its credit was shaken, its trade paralyzed; famine and plague visited the city, and the war to subjugate Pisa was proceeding unsatisfactorily. Worse still was the death, in 1496, of one of its ablest and most disinterested statesmen. Piero Capponi. The league now attacked Florence, for Pope Alexander VI hated Savonarola and was determined to destroy the republic, so as to reinstate the Medici temporarily, and prepare the way for his own sons; Venetians and Imperialists besieged Leghorn, and there was great misery in Florence.

All this decreased Savonarola's popularity to some extent. but the enemy having been beaten at Leghorn and the league being apparently on the point of breaking up, the Florentines took courage and the friar's party was once more in the ascendant. Numerous processions were held, Savonarola's sermons against corruption and vice seemed to have temporarily transformed the citizens, and the carnival of 1497 remained famous for the burning of the "vanities" (*i.e.,* indecent books and pictures and carnival masks and costumes). The friar's sermons against ecclesiastical corruption, and especially against the pope, resulted in Savonarola's excommunication. The party hostile to him gained ground with the support of the Franciscans, who disliked the Dominican order. The pope again and again demanded that the friar be surrendered to him, but, in spite of his threats of an interdict against the city, without success. In 1498, however, a signory of *Arrabbiati* having been elected, Savonarola was arrested and imprisoned. The commission appointed to try him on charges of heresy and treason was composed of his enemies; many irregularities were committed during the three trials. and the prisoner was repeatedly tortured. The outgoihg signory secured the election of another which mas of their way of thinking, and on May 22, 1498, Savonarola was condemned to death and executed the following day.

Piero **Soderini.**—The pope having been satisfied, the situation in Florence was less critical for the moment. But Cesare Borgia suddenly demanded the reinstatement of the Medici in Florence, and the danger was only warded off by appointing him captain-general of the Florentine forces at a large salary (1501). The weakness of the government became every day more apparent. In 1502, in order to give more stability to the government. the office of *gonfaloniere,* with the right of proposing laws to the signory, was made a life appointment. The election fell on Piero Soderini (1448–1522), an honest public-spirited man of no particular party, but lacking in strength of character. One useful measure which he took was the institution of, a national militia, at the suggestion of Niccolò Machiavelli (1505). Meanwhile the Pisan war dragged on until in 1509 the city was driven by famine to surrender and again became a dependency of Florence.

The Schismatic Council of **Pisa.**—In 1510 Pope Julius II, having seceded from the league of Cambrai, in which he had joined France and Spain against Venice, raised the cry of "Fuori i Barbari" ("out with the barbarians"), with a view to expelling the French from Italy. King Louis thereupori proposed an ecumenical council and demanded that it be held in Florentine territory. The republic agreed to the demand. and the council was opened at Pisa. whereupon the pope immediately placed Florence under an interdict. A Spanish army under Raymundo de Cardona entered the republic's territory and demanded 100.000 florins, the dismissal of Soderini, and the readmission of the Medici. Soderini offered to resign, but the greater council supported him and preparations for defense were made. In August the Spaniards took Prato by storm and committed hideous atrocities on the inhabitants; Florence was in a panic, a group of the nobles forced Soderini to resign and leave the city, and Cardona's new terms were accepted, viz., the readmission of the Medici, a fine of 150,000 florins and an alliance with Spain.

Return of the Medici, 1512.—On Sept. 1, 1512, Giuliano and Giovanni de' Medici. and their nephew. Lorenzo. entered Florence with the Spanish troops, and a constitution similar to that of Lorenzo the Magnificent was created. Giuliano became *de facto* head of the government, but he did not pursue the usual vindictive policy of his house. In 1513, on the death of Julius II. Giovanni de' Medici was elected pope as Leo X. In March 1514 Giuliano died. and was succeeded by Lorenzo. who was also created duke of Urbino. At his death, in 1519, Cardinal Giulio de' Medici took charge of the government. He did not rule badly and maintained at all events the outward forms of freedom. In 1523 he was elected pope, as Clement VII. and sent his relatives. Ippolito and Alessandro. both minors and bastards. to Florence under the tutorship of Silvio Cardinal Passerini.

Second Expulsion of the Medici, 1527.—Cardinal Passerini's regency proved most unpopular, and the city was soon seething with discontent. Revolts broke out and Passerini showed himself quite unequal to the situation. The nobles were mostly anti-Medicean. and when Filippo Strozzi. and above all his wife, threw their influence in the scales against the Medici, and the magistrates declared for their expulsion from power, Passerini. Ippolito and Alessandro left Florence (May 17, 1527). *A Consiglio degli Scelti* was summoned and a constitution similar to that of Savonarola's time was established.

The greater council was revived and Niccolò Capponi created *gonfaloniere* for a year. Rut Florence was torn by factions. Having been re-elected *gonfaloniere* in spite of much opposition in 1528, Capponi tried to make peace with the pope but his correspondence nith the Vatican resulted in a quite unjustified chargr of high treason, and although acquitted he had to resign office and leave the city for six months. Francesco Carducci was elected *gonfaloniere* in his place. and on June 29, 1529, the pope and the emperor concluded a treaty by which the latter agreed to reestablish the Medici in Florence.

Siege of Florence and Restoration of the **Medici.**—Carducci made preparations for a siege, but the majority of the people were against him, either from Medicean sympathies or fear, although the *Frateschi*, as the believers in Savonarola's views were called, supported him strongly. A body called the *Nove della Milizia*, of whom Michelangelo (*q.v.*) Buonarroti was a member, was charged with the defense of the city, and Michelangelo himself superintended the strengthening of the fortifications. A most unfortunate choice for the chief command of the army was the appointment of Malatesta Baglioni. In August an imperial army under Philibert, prince of Orange, advanced on the city. In September Malatesta surrendered Perugia, and other cities fell before the imperialists. All attempts to come to terms with the pope were unsuccessful, and by October the siege had begun. Although alone against papacy and empire, the citizens showed the greatest spirit and devotion, and were successful in many sorties. The finest figure produced by these events was Francesco Ferruccio (*q.v.*); by his defense of Empoli he showed himself a first-class soldier, and was appointed commissioner-general. But Malatesta was a traitor at heart and hindered the defense of the city. Ferruccio, who had recaptured Volterra, marched to Gavinana above Pistoia, to attack the imperialists in the rear; but in spite of his heroism he was defeated and killed (Aug. 3); the prince of Orange also fell in that desperate engagement. The signory, at last realizing that Malatesta was a traitor, dismissed him; but it was too late, and he now behaved as though he were governor of Florence; when the troops attempted to enforce the dismissal he turned his guns on them. On Aug. 9 the signory saw that all hope was lost and entered into negotiations with Don Ferrante Gonzaga, the new imperial commander. On the 12th the capitulation was signed; Florence was to pay an indemnity of 80,000 florins, the Medici were to be recalled, the emperor was to establish the new government, "it being understood that liberty is to be preserved." Baccio Valori. a Medicean who had been in the imperialist camp, took charge, and the city was occupied by foreign troops. A *parlamento* was summoned, the usual packed *balìa* created, and all opposition silenced. The city was given over to Pope Clement. who, disregarding the terms of the capitulation. had Carducci and Girolami (the last *gonfaloniere)* hanged, and established Alessandro de' Medici, the natural son of Lorenzo, duke of Urbino, as head of the republic on July 5. 1531. The next year the signory was abolished, Alessandro created *gonfaloniere* for life, and his lordship made hereditary in his family by imperial patent. Thus Florence lost its liberty. and came to be the capital of the duchy (afterward grand duchy) of Tuscany. (P. V.; L. V.)

The **Medici's** Grand Dukes.—Cosimo I, who succeeded Alessandro when he was slain by his brother Lorenzino. laid the foundations of the regional state. which took the place of the small Florentine republic. He established a strong centralized government and started a policy of territorial expansion which led to the conquest of Siena and its surrounding area. The loss of old civic liberties was the price that Florence paid for the political unification of Tuscany under the Medicean rule. Solemn recognition of the new princedom came when Pope Pius V conferred on Cosimo the title of hereditary grand duke in 1567, which in 1576 was confirmed by Emperor Maximilian II. Cosimo's successor, Francis I. is chiefly remembered for the establishment of Leghorn as the great modern port of Tuscany. The policy of the next grand duke, Ferdinand I, former cardinal and brother of Francis, was far more ambitious in scope, if not in achievement. With him Tuscany entered the arena of international politics, shaking off the traditional Spanish influence for a fresh alliance with France. This was sealed by the marriage of Maria, daughter of Francesco di Medici. with King Henry IV, newly converted to Catholicism. Special attention was given to maritime development, and even attempts at colonial conquests were made by sending an expedition to Brazil. The progress of agriculture was furthered by important works of land reclamation in the marshes of Valdichiana. Maremma and Pisa. But the Tuscan grand duchy soon degenerated after Ferdinand's death. The inefficient rule of the weak Cosimo II was followed by the regency period when the mother and grandmother of young Ferdinand II directed the home and foreign affairs of the state with worse results. The decline of the Medici family reached its nadir with the sickly and inept Cosimo III, who let foreign powers decide the fate of Tuscany. It was decreed at the treaty of London in 1718 that Don Carlos of Spain, upon the extinction of the native dynasty, should receive Tuscany. But, in fact, because of intervening changes in the international scene, upon the death of the last Medici—the childless Gian Gastone—the grand duchy was assigned in 1737 to Francis, duke of Lorraine, who became Francis II of Tuscany and, in 1745, the emperor Francis I.

The 18th Century.—As Francis, who was the husband of Maria Teresa of Austria. resided abroad, Tuscany was governed for almost 30 years by a series of foreign regents. The first duke of Lorraine to settle in Florence was Francis' son, Leopold I. who remained from 1765 to 1790, and proved one of the most capable and remarkable of the enlightened princes of the 18th century. He improved the administration of justice, suppressed torture and capital punishment. reduced mortmain, and introduced a system of free trade. Taxation was also reorganized on a basis of equality for all citizens. and the system of *mezzadria* (crop sharing) between landowners and tenant farmers was introduced in agriculture. Leopold's intervention in religious matters, inspired by the most progressive ideas of the "enlightened age," was equally effective in curbing the excessive power of the clergy and in rejecting its interference in economic and political affairs; but his attempt to modify internal ecclesiastical discipline, although supported by the bishop of Pistoia, Scipione de' Ricci, failed because of the condemnation of the pope. The appointment of Ferdinand III as duke of Tuscany when his father Leopold became emperor and removed to Vienna was followed in 1799 by a brief revival of republican government in Florence during the wars of the French Revolution. After the peace of Lunéville in 1801, Tuscany became the kingdom of Etruria under Louis, duke of Parma. *(See* also MEDICI, and for further history, TUSCANY and ITALY: *History.)*

FLORENCE, a city of northwestern Alabama, U.S., on the north bank of the Tennessee river, in the fertile Muscle shoals district; seat of Lauderdale county. Just upriver is the Wilson dam; across the river are important chemical and metallurgical plants and the Tennessee Valley authority's fertilizer-munitions centre. The city has several manufacturing industries. It is the seat of Florence State college, established in 1872, the oldest state teachers college in the south.

Florence was founded in 1818 by the Cypress Land company and chartered in 1826. It was named for Florence. Italy. An early property holder was Andrew Jackson. Among the distinguished ante-bellum homes are the Forks of Cypress, Mapleton, the Simpson-Irvine home and Rogers Hall. During the American Civil War the town was raided several times by the Federal forces. For comparative population figures *see* table in ALABAMA: *Population.* (B. CR.)

FLORENCE, a city of northeastern South Carolina, U.S., about 80 mi. E. of Columbia; the seat of Florence county. It is an important sales, distribution and manufacturing centre for the tobacco-rich Pee Dee section of the coastal plain. The Clemson college experimental station, a University of South Carolina extension centre and the state industrial school for boys are located there.

Sites of interest include a museum and library, the latter having extensive state historical material. There is a national cemetery and nearby is a Confederate prison stockade. Timrod park and the Henry Timrod School shrine display indigenous trees and flowers, and the Womack gardens and nursery are noted for azaleas and camellias. Florence was founded about 1856, chartered in 1871, incorporated in 1890. The city adopted the council-manager form of government in 1921. For comparative population figures *see* table in SOUTH CAROLINA: *Population.* (A. L. D.)

FLORENCE OF WORCESTER (d. 1118), English monk, usually accepted as the author of *Chronicon ex chronicis,* which is valuable for late Anglo-Saxon and early post-Conquest history. Its basis is the universal history (from the creation to 1082) compiled by Marianus Scotus, an Irish recluse at Mainz. The author of the *Chronicon,* like Marianus, was a careful annalist with a marked interest in chronology. He supplements Marianus' scanty treatment of English affairs by drawing on Bede. Asser, lives of English saints, laws, the Anglo-Saxon Chronicles and also on local records and traditions.

Under the year 1118 the *Chronicon* records the death of Florence (July 7), but it is continued without break to 1131 by a John of Worcester, who. later, added material up to 1140. On the interpretation of the notice under 1118 depends Florence's claim to authorship, but what Orderic Vitalis has to say of John's historical work at Worcester suggests that John's part in the whole *Chronicon* is more substantial than has been traditionally allowed. After 1131, the *Chronicon* was copied at other monasteries, in several cases continued and frequently used by chroniclers.

The standard edition is *Florentii Wigorniensis monachi Chronicon ex chronicis,* ed. by Benjamin Thorpe, English Historical Society, 2 vol. (1848–49), which excludes Marianus' text where possible and follows the *editio princeps* of 1592 by William Howard in printing the continuation to 1141. and adds a second continuation to 1295; translation of English material to 1295 by R. Forester in Bohn's *Antiquarian Library* (1854).

See *The Chronicle of John of Worcester,* 1118–1140, ed. *by* J. *R. H.* Weaver, *Anecdota Oxoniensia* (1908) ; *D.* Whitelock, *English Historical Documents,* vol. *1,* pp 113 ff, 121 (1955). (G. SD.)

FLORES, JUAN JOSÉ (1800–1864), autocratic first president and long-time dictator of Ecuador, was born in Venezuela on July 19, 1800. At 15 he enlisted in the forces fighting the Spaniards and fought practically continuously for the next ten years, becoming one of Simón Bolivar's trusted senior officers. In 1826 he became commanding general of the southern region of the federation of Gran Colombia. He fought brilliantly at the battle of Tarqui, where the Peruvian attempt to wrest territory from Colombia was thwarted. In 1830 he took the lead in establishing Ecuador as a separate country and became its first president. He held office from 1830 to 1834, crushing several revolutionary attemps to unseat him. Following four years as army commander he regained the presidency in 1839, relinquishing it in 1845 after a liberal revolution. Exiled first to Europe and later to Argentina and Chile, Flores spent the next 15 years plotting to return to Ecuador. He finally accomplished this through Gabriel Garcia Moreno. his son-in-law. who became president in 1861. Flores aided Garcia Moreno militarily during the latter's term, beating off Peruvian attempts to seize Guayaquil. Flores died on Oct. 1, 1864, while engaged in putting down a revolt against Garcia Moreno. His death closed a turbulent career, marked by revolution, invasion, corruption and oppression, characteristic of Ecuador's early years as an independent nation.

FLORES, a department in south-central Uruguay, named for Gen. Venancio Flores. leader of the Colorado party and president of Uruguay (1865–1868). Pop. (1954 est.) 41,081; area 1,982 sq.mi. Flores, like its neighbouring departments, is a great rolling pasture supporting concentrations of livestock—in the 1950s about 1,000.000 sheep and 250,000 cattle. Industrial crops, principally sunfloner seeds and flax, are grown. as well as cereals and forage. The departmental capital, Trinidad (est. pop. 24,000) is connected by railroad and highway to Durazno 29 mi. S.W. (M. I. V.)

FLORES, an island forming part of the Azores archipelago. Pop. (1950) 7,850; area. 55 sq.mi. Flores and the adjacent island of Corvo (pop. 731; area, 7 sq.mi.) constitute the westernmost group of the Azores, from the rest of which they are widely severed. It derives its name from the abundance of the flowers that find shelter in its deep ravines. Its capital is Santa Cruz das Flores. In 1591 Flores was the station of the English fleet before the famous sea fight between Sir R. Grenville's ship "Revenge" and a Spanish fleet of 15 vessels. *See* AZORES.

FLORES, one of the Lesser Sunda (Nusa Tenggara) islands, Indonesia, the last large island of the chain which extends eastward from Java, and lies between Celebes and Timor. Flores has an area of 6.622 sq.mi., is 224 mi. in length and 44 mi. in width.

Flores is a long narrow island extending from east to west, with several deep inlets, the chief being Maumere bay on the north coast, in the east, in which is Poelau Besar or Mangkure. On the north coast, too, are Terang bay, Sindeh bay and Hading bay; on the south coast, Aimere bay and the Gulf of Endeh; and on the east coast, Okka and Konga bays, tmo deep inlets, the former cutting through high mountains. The island is very mountainous, with the greatest heights in the western part where the peaks of the Mandasawu range reach more than 7,000 ft. There are ten active volcanoes in the central and eastern parts of the island, although the western section has a few which are in the fumarole stage. The interior, which is heavily forested, has been but little explored, but the existence of slates, chalk and sandstones, with eruptive rocks and volcanoes, indicates that geologically the island is similar in structure to others of the Lesser Sunda chain. The few rivers known run either northward or southward, and do not seem to be navigable, with the exception of the Reo river. for about a mile. In northern Manggarai, in the northwest where there is a considerable area of limestone. the rivers sometimes run underground. Little is known of the flora and fauna. but the former includes, in the forests, coconut palms. and the sapan, cinnamon and sandal tree. Most of the vegetation consists of either tropical deciduous forest or savanna. The population of Flores in 1956 was estimated at 894,826; mainly of a mixed Malay-Papuan type, the so-called Alfur type. In the west the Manggarese have more of the Malayan characteristics, while in the central and eastern parts the people are more Papuan in appearance. In addition to these there are settlers all round the coast from Macassar, Sumba, Sumbawa and the Solor isles; in Todo, Manggarai, are colonists said to be descended from Menangkabau Malays; and on the Endeh coast are descendants of shipwrecked Chinese. The indigenous population long remained heathen, but Christianity spread rapidly in modern times; almost all of the Christian population became Roman Catholic. The remainder is either Mohammedan, in the coastal areas, or still pagan. The people of Endeh and Manggarai are the most developed, those of Central Flores the most savage and warlike, but industry everywhere is at a low stage of development, and the people make their living mostly by fishing, hunting and simple agriculture. Maize is the chief food, though rice is also grown and coconuts are cultivated. copra forming the chief article of export. Other items are small amounts of coffee, sandalwood, cinnamon, tobacco, mother-of-pearl and trepang. Coffee is grown in the districts of Manggarai and Ngada, in the west, while cotton was for a time cultivated under Dutch supervision. Iron, sulfur, pumice stone and saltpetre are found. Horses, buffaloes, pigs. dogs and fowls are kept, but meat is little eaten except at festivals. *Baju* and *sarong,* or even trousers, are worn generally in the east and south, and often *sarong* only in the west; ceremonial garments are very elaborate, and many ornaments are worn. The form of house varies greatly. In Ngada houses are built on terraces. often on piles, and they are neat and regular in arrangement and are surrounded by a hedge of bamboo. In Manggarai they are conical in form, with a roof reaching to the floor; they are divided into separate rooms for different families. and a passage where unmarried men and strangers sleep. In the east the houses are smaller and inhabited by one family only, while in Endeh they are square, roomy and well-built. Each village has its barns and, generally, a *pemali* house. The ground is usually owned communally by the tribe, and the head man, *tuan tanah,* has great power. But hereditary tenure of the individual prevails in Ngada, and here a stranger may own the uncultivated land he breaks up, whereas in the remainder of the island he has no rights.

Dutch rule reached the people through their chiefs and weaned them gradually from a state of primitive culture to one of semi-civilization. which became apparent in most of the coastal districts. Endeh. Aimere, Reo and Labuan are ports of call for vessels. A fair-weather motor road traverses the entire island from west to east. There is an airfield at Reo on the northwest coast. Flores originally was tributary to princes of Celebes. including Macassar. and nhen their power was broken by the Dutch in 1667 the island became open to Dutch influence, though Larantuka, in the east, together with some of the neighbouring islands, was claimed by Portugal, and in 1818 a commission confirmed Portugal's right. In that year the Dutch stationed an official at Endeh bay to suppress piracy, but no impression mas made until 1838, when the place was bombarded and seven chiefs journeyed to Kupang, in Timor, to apologize for their piratical activities. A treaty was then made with these and other chiefs of Endeh. Trouble aith the Portuguese authorities in Larantuka and the island of Solor in 1848 led to negotiations with Portugal when, in return for the remission of certain debts, the Portuguese government renounced all claims to Larantuka and the neighbouring islands, and though the treaty embodying this was not ratified until 1859, Dutch troops were sent to garrison the ceded districts in 1851. Later the troops were withdrawn and a civil official appointed to reside at Larantuka; for many years afterward there was considerable trouble here and at Endeh. on account of slave raids and piracy. The rajah of Larantuka, a Christian, was the principal cause of annoyance, and his arrest and banishment in 1905 led to a peaceful state of affairs. A treaty was concluded in 1874 with one of the principal chiefs of central Flores, but attempts made in 1887, 1888 and 1889 to penetrate into the interior failed, and in 1890 two large military expeditions were compelled to withdraw, because of the hostility of the natives. Eventually, from Endeh as a base, a body of mounted police succeeded in penetrating and pacifying the whole of the inland region (1907), and civil government was established. Manggarai has always been associated with the Sultan of Bima, in Sumbawa. The Dutch only once interfered—to suppress a small rising in 1909. The other states of Flores all came under the "short declaration," which allowed them some measure of self-government under Dutch supervision. Flores was occupied by Japanese troops during World War II.

(E. E. L.; X.)

FLOREY, SIR HOWARD WALTER (1898–), Australian pathologist, born at Adelaide, South Australia, Sept. 24, 1898, was awarded the Nobel prize for physiology and medicine in 1945, together with Ernst Chain and Sir Alexander Fleming, "for the discovery of penicillin and its curative effects in various infectious diseases." He studied medicine at Adelaide and Oxford universities until 1924 and then undertook research work in Great Britain and the United States. After holding a fellowship and a lectureship at Cambridge (1927–31) and the professorship of pathology at Sheffield (1931–35), he became professor of pathology at Oxford from 1935 onward.

Florey's contributions to experimental pathology were mainly concerned with fundamental phenomena of inflammation and later also with secretion of mucus by mucous membranes. The study of mucus roused his interest in lysozyme, a bacteriolytic enzyme, and work on this was continued with his colleagues until the enzyme was purified and its substrate characterized. This led to plans for a wide survey of naturally occurring antibacterial substances, of which many were known.

In this survey, which started in 1939, penicillin soon showed so much promise that other studies were dropped and research was concentrated on investigating and producing penicillin and eventually on bringing it into clinical use.

In 1943 Florey went with a research team to north Africa to investigate the possibility of using the penicillin then available on the wounded. In 1943–44 he visited Moscow with an Anglo-American scientific mission. In 1944 he visited Australia and New Guinea at the invitation of the Australian army. Later he mas an adviser to the Australian National university in Canberra.

Florey was elected a fellow of the Royal society in 1941, and received many honours. He was knighted in 1944.

FLÓREZ, ENRIQUE (1702–1773), Spanish Augustinian monk, an outstanding historian and scholar, was born at Villadiego, July 21, 1702. A notable example of 18th-century erudition, his *España sagrada,* 29 vol. (1747–55; continued by others to 51 vol; index by A. González Palencia, 1918), embodies the results of tireless research in many archives on the origins and growth of religious foundations in Spain; for transcriptions of documents and study of secondary materials (coins, medals. inscriptions, legends) it is an essential sourcebook for the history of Spain. His biographical *Memorias de las reinas católicas* (1761) has charm. Flórez died at Madrid on May 5, 1773. (R. F. B.)

FLORIAN (FLORIANUS), **SAINT** (d. 304), a Roman army officer and martyr. He occupied an administrative post in Noricum. now part of Austria, and was martyred under Diocletian. His *Acta,* with little historical value. date from the end of the 8th century.

Florian is regarded as one of the patron saints of Poland, Linz and Upper Austria. His protection is often sought against fire, and his feast is kept on May 4.

See H. Thurston and D. Attwater (eds.), *Butler's Lives of the Saints,* vol. ii, pp. 230–231 (1956).

FLORIAN, JEAN PIERRE CLARIS DE (1755–1794), French poet and romance writer, was born at the château of Florian, near Sauve, in the department of Gard. His uncle and guardian. the marquis of Florian, who had married a niece of Voltaire, introduced him at Ferney and in 1768 he became page at Anet in the household of the duke of Penthièvre, who remained his friend throughout his life. He then studied at the artillery school at Bapaume and became a captain of dragoons. On the outbreak of the French Revolution he retired to Sceaux, but he was soon discovered and imprisoned; and though his imprisonment was short he survived his release only a few months, dying on Sept. 13, 1794.

Florian's first literary efforts were comedies; his verse epistle *Voltaire et le serf du Mont Jura* and an eclogue *Ruth* were crowned by the French academy in 1782 and 1784 respectively.. In 1782 he also produced a one-act prose comedy, *Le Bon Ménage,* and in the next year *Galatée,* a romantic tale in imitation of the *Galatea* of Cervantes. Other short tales and comedies followed, and in 1786 appeared *Numa Pompilius,* an undisguised imitation of Fenelon's *Télémaque.*

In 1788 he became a member of the French academy, and published *Estelle,* a pastoral of the same class as *Galatée.* Another romance, *Gonzalve de Cordoue,* preceded by a historical notice of the Moors, appeared in 1791 and his famous collection of *Fables* in 1792.

Among his posthumous works are *La Jcunesse de Flovian, ou Mémoires d'une jeune Espagnol* (1807) and an abridgment (1799) of *Don Quixote,* which, though far from being a correct representation of the original, had great and merited success.

Florian imitated Salomon Gessner, the Swiss idyllist, and his style has all the artificial delicacy and sentimentality of the Gessnerian school. Perhaps the nearest example of the class in English literature was afforded by John Wilson's (Christopher North s) *Lights and Shadows of Scottish Life.* Among the best of his fables are "The Monkey Showing the Magic Lantern," "The Blind Man and the Paralytic" and "The Monkeys and the Leopard."

An edition of Florian's *Oeuvres complètes* appeared in Paris in 16 vol. (1820); his *Oeuvres inédites* in 4 vol. (1824).

See "Vie de Florian" by L. F. Jauffret, prefixed to his *Oeuvres posthumes* (1802); A. J. N. de Rosny, *Vie de Florian* (Paris, year V); Sainte-Beuve, *Causeries du lundi,* t. iii; *A.* de Montvaillant, *Florian, sa vie, ses oeuvres* (1879); *Lettres de Florian à Mme. de la Briche,* published, with a notice by the baron de Barante, in *Mélanges,* published (1903) by the Société des bibliophiles français; G. Gaillard, *Florian, sa vie, son oeuvre* (1912).

FLORIANÓPOLIS, a city and port of southern Brazil, and capital of the state of Santa Catarina (*q.v.*), is located some 450 mi. S.W. of Rio de Janeiro, on the western side of Santa Catarina Island (Ilha de Santa Catarina) which is connected to the mainland by a steel bridge 2,788 ft. long. Pop. (1950) 48,264. This island city serves as the state administrative and commercial centre in spite of the difficulties involved in reaching the inland parts of the state from the coast. The Great Escarpment which marks the edge of the Paraná plateau is especially steep in Santa Catarina and the interior of the state is more closely connected to Pôrto Alegre and Curitiba than to the state capital. Florianópolis is linked with other coastal towns, such as Blumenau and Joinville, by all-weather gravel highways. There are air services to the interior.

The central part of Florianópolis consists mainly of wharves, warehouses and business establishments. This older harbour district is encircled by a modern residential garden section known as Praia de Fora built on the surrounding hill slopes.

The first European settlement on Santa Catarina Island was made in 1 j42 by the Spaniards under Alvar Núñez Cabeza de Vaca, n-ho proceeded to march inland over rugged terrain to Asunción in Paraguay. The Portuguese established their control of this southern part of the coast when they sent an espedition from São \-icente to occupy the island in 1675. The present city was established in 1700 as Desterro. In 1777 the island was occupied by a Spanish expedition, but it was returned in the same year to Portugal by treaty.

In 1893 the island was captured by revolutionists who opposed the government of Pres. Floriano Peixoto. When the revolution collapsed the city was named Florianopolis in honour of the president. (P E. J.)

FLORIANOPOLIS SUSPENSION BRIDGE, an eyebar suspension type with a main span of 1.113 It. 9 in.. was constructed (1923–261 for the state of Santa Catarina. Braz.. to carry a highway. electric railway and water supply to the capital city Florianópolis situated on an island off the Atlantic coast.

The structure, designed by Robinson and Steinman, consulting engineers. is the first example of a new form of suspension bridge whereby greatly increased economy and rigidity are secured simultaneously. Its distinctive ieature is the utilization of the cable to replace the middle half of the top chord of the stiffening truss and the consequent change from the conventional parallel chord truss to a stiffening truss of more effective outline, namely, with maximum depth near the quarter points of the span. These features combined yielded a structure four times as rigid as the previous conventional design! together with a saving of one-third of the steelwork.

Another departure from conventional practice was the adoption of rocker towers. which. eliminating the customary bending stresses. contributed a saving of 20% of the steelwork in the towers and permitted the main piers to be reduced to concrete cylinders. 16 ft. in diameter. The steel towers are 22 j ft. high. Instead of wire for the cables. eyebars were adopted. these were made of the newly developed. high-tension. heat-treated carbon steel. having a yield point exceeding 75,000 lb. per square inch and used with a working stress of 50,000 lb. per square inch.

In the foundation work for the main piers, novel construction methods had to be devised. By excavating and concreting successive test pits, the entire foundation area of one pier was carried down 20 ft. below the bottom of the cofferdam to bedrock at elevation —60. The concrete anchorages are of novel design. U-form in plan, for maximum efficiency. The island anchorage is on rock. the continent anchorage on piles. An entirely new method was developed for the erection of the eyebar cables and the suspended stiffening trusses, using overhead trolley, thus eliminating wooden falsework and working platforms. The bridge. nhich was more than three years in building. provided a 28-ft. roadn-ay. a metre-gauge electric railway, a 24-in. water main and a 9-ft. sidewalk. Its over-all length is 2.788 ft. (D. B.S.)

FLORIDA, officially the "Sunshine state" and often referred to as the "Peninsula state." lies at the extreme southeastern corner of. and is the most southern state of. continental United States. The peninsula is the visible part of the Floridian plateau that separates the depths of the Atlantic ocean from those oi the Gulf of Mexico; the submerged area is as large as the part above sea level. It is bounded on the north by Alabama and Georgia, on the east by the Atlantic ocean, on the south by the strait of Florida. n-hich separates it from Cuba. and by the Gulf of Mexico. and on the west by the Gulf and by Alabama. The total area of the state is 58.560 sq.mi., of which 4,308 sq.mi. are water surface; it ranks 22nd in size among the states. Florida was admitted to the union on March 3, 1845. as the 27th state. The state capital is Tallahassee. The state tree is the palmetto, or sabal, palm; the state flower, the orange blossom; the state bird, the mockingbird.

PHYSICAL GEOGRAPHY

Physical Features.— Florida is situated between 24° 30' and 31" N. and 80° and 87° 38' W. The topographical regions of the state include the coastal lowlands. which are generally less than 100 ft. above sea level; the higher, hilly western highlands; the Marianna lowlands; the Tallahassee hills: and the central highlands or the "ridge" of the peninsula proper. Islands, the Florida keys. stretch southward. like a string of beads. from Biscayne bay to Key West. The last group of keys. the Dry Tortugas Islands (*q.v.*), lie west of Key West. The state is 447 mi. long and 361 mi. wide at its northern boundary, but never more than 145 mi. wide below the panhandle.

The general coast line. which does not recognize all the details of indentations, is 1.197 mi. in length (Atlantic. 399 mi., Gulf of Mexico. 798 mi.). The shore line when all details of indentations —bays. sounds and other bodies of water to the head of tidewater—are included measures 8.426 mi. (Atlantic. 3.035 mi.; Gulf of Mexico. 5.301 mi.). No point in the state is more than 70 mi. from either the Atlantic ocean or the Gulf of Mexico. The coast lines are bisected by many rivers, some of which are navigable for long distances. The St. Johns on the east coast is one of the few rivers in North America that flows northward; it enters the Atlantic at Mayport, above Jacksonville. The large rivers in western Florida rise in Georgia and Alabama: the Perdido, Escambia. Choctawhatchee and Apalachicola were the chief arteries of trade in the steamboat era. The Suwannee rises in the Okefenokee swamp on the border of Georgia and Florida.

Water is one of Florida's major resources: the underground and surface supplies are exceeded by no other area of similar size on the continent. There are more than 30.000 natural lakes in the state and more than 1.400 in one county (Lake) alone; the largest is Lake Okeechobee, covering 700 sq.mi., the second largest (after Lake Michigan) body of fresh water in the U.S. The overflow of this lake every year spilled into the long inundated plain of the Everglades (*q.v.*) and gradually made its way 100 mi. southward to Florida bay. The overflow is now controlled (see OKEECHOBEE, LAKE). and the lake forms a part of the Intracoastal waterway and cross-state canal, connected on the eastern side by the St. Lucie canal and river and on the western side by the Caloosahatchee canal and river. Of the 75 largest artesian springs in the United States. 17 are located in Florida; among the best knon-n are Silver springs. Rainbow springs and Salt springs near Ocala and Wakulla springs near Tallahassee.
