Climate.— A mild climate is one of the state's greatest assets; in winter there is more sunshine than in any other state east of the Mississippi. The annual rainfall of about 53 in., most of which falls from April to November, tempers the warm temperatures of the summer season. Although the average temperature is near 70° F.. the state is subject to damaging cold waves. Hurricanes that form in the Caribbean sea frequently strike the state and cause great destruction of property and often loss of life.

Soil.—The soils of Florida vary from the highly fertile organic muck and peat of the Everglades to the poorest of sandy soils along the coastal dunes and beaches. The soils of the coastal lowlands and the western highlands are generally composed of sands of low fertility, except in the river bottoms and marshy areas where organic materials have been deposited. Much of the area of the Marianna lowlands and of the central highlands is underlain by Ocala limestone formations which, when mixed with the overlying sands, make fertile soils. The soils of the Tallahassee hills are generally the most fertile in the state and contain large amounts of red clay and organic matter.

Plant Life.—The high and low hammocks, sand and clay hills, beds of organic soils and salt- and fresh-water marshes of Florida provide excellent habitats for native and imported plants, from

VIEWS OF FLORIDA

BY COURTESY OF (BOTTOM LEFT) SARASOTA COUNTY CHAMBER OF COMMERCE. (BOTTOM RIGHT) FLORIDA STATE NEWS BUREAU; PHOTOGRAPHS, (TOP LEFT) EWING GALLOWAY, (TOP RIGHT) BUAGERT BROTHERS (CENTRE LEFT AUTHENTICATED NEWS large flowering trees to delicate orchids. Of the palms found in the U.S., 15 varieties are native to Florida, and they range in size from the small saw palmettos to the tall royal palms, the coconut palms and the sabal palmettos. There are more than 300 varieties of trees: pines. oaks, cypresses. palms and mangroves are the predominant native trees; magnolias, yews, hollies, and hickories are also native. The royal and coconut palms, mahogany and gumbo limbo trees are tropical; northern species that thrive in the state include the red maple, the sweet gum and the tulip tree.

The woods. prairies and marshes support more than 3,500 species of plants. Bladderwort, duckmeed, hyacinths and water lettuce grow in the marshes; pitcher plants, lilies, milkwort and cactus in the sandy soils: and coontie (comfortroot, from which the Indians made flour) flourishes in the rocky pinelands of the southeastern section of the state. Spanish moss streams from the trees: and more than 80 other air plants (epiphytes). 25 of which are orchids, have been identified in south Florida. Many plants and trees have been imported — more than 400 varieties of bougainvillaea. hibiscus. oleander: and croton for ornamental plantings and poinciana, poinsettia. jacaranda and mountain ebony.

Animal Life. — Eighty-four species of land mammals are found in Florida, including wildcat, gray fox, deer, panther and all of the smaller animals that are native to the southern states. Commercial trapping has reduced the number of otter and mink, and the tiny Key deer of the keys is almost extinct. The manatee or sea cow is occasionally found in coastal waters and in the rivers of the far southern part of the state. More than 400 species and subspecies of birds have been recorded, and the natural rookeries around Lake Okeechobee, in the Big Cypress swamp and in the Everglades are world famous. The first, national bird sanctuary, Pelican Island in the Indian river. was established by Pres. Theodore Roosevelt; since then 18 additional national sanctuaries have been created in the state. Among the water birds are gulls, pelicans. cormorants. ospreys and sandpipers found along the seacoasts; ibises, herons, egrets and gallinules (water hens) in the fresh-water marshes and surface waters. The snowy egret. roseate spoonbill and flamingo have become relatively rare. Land birds include almost all of the birds common to the southern states. Turkey, quail, dove and duck are the game birds protected by law except during the short hunting season in the fall of the year.

The alligator, long associated with Florida's lakes and rivers and hunted for sport and hide, is now protected from hunting by law. The crocodile is still found from time to time along the east coast from Biscayne bay to Cape Sable. Of the 40 species of snakes native to the state four are poisonous: the diamondback and ground rattlers: the coral snake and the moccasin. Lizards, land turtles, water turtles and frogs are plentiful. ;\lore than 700 species of fish have been identified: 300 species along the Gulf coast. 174 along the Atlantic and 290 around the Keys. The edible and commercially salable sea fish include mullet: drumfish, trout. mackerel, snapper, grouper and pompano; fresh-water fish that are edible include bass. bream, perch and catfish. For sport fishing the tarpon, sailfish and marlin of the deep waters and the bonefish of the shallows are eagerly sought.

Parks and Forests. — Florida was the first of the eastern states in which a national forest was created, the Ocala in 1908. The Osceola National forest was created in 1931 and the Apalachicola in 1936. The three national forests have a combined area of 1,100,000 ac. There are four state forests: Blackwater River near Milton, Myakka River near Sarasota. Pine Log near Panama City and Austin Cary near Gainesville. The Everglades National park in extreme south Florida attracts thousands of visitors as do the national monuments: Castillo de San Marcos at St. Augustine. Ft. Matanzas south of St. Augustine, Ft. Jefferson in the Dry Tortugas Islands. Ft. Caroline at Jacksonville and the De Soto memorial near Tampa. The Everglades National park contains the only tropical wilderness in the U.S., and is one of the few parks in the national park system established for the conservation of exotic plant, animal and marine life. A number of state parks and historical memorials protect plant and animal life, geological formations and historical landmarks. Pennekamp Coral Reef preserve, the world's first underwater park, is a state-controlled area of 75 sq.mi. (nautical) established (1960) in the Atlantic ocean off Key Largo by the federal and state governments to preserve a portion of the beautiful multihued coral formations of the area. There are also more than 20 public and private gardens and more than 200 public and private scenic attractions that are open to visitors.

HISTORY

The romance and the tragedies of the early history of Florida give it a unique place in the annals of the American states. Within 20 years after the first voyage of Columbus to the new world in 1492, an expedition was being organized to seek for a fabulous fountain of youth and for riches in the new and inviting land. This expedition was followed by others seeking wealth or seeking to establish the Christian faith among the savages. In turn these were followed by French Huguenots who sought a place of religious freedom. but the zeal of the Spaniards soon brought an unhappy end to their search. Florida also has the honour of containing the oldest European settlement within the bounds of the United States, as St. Augustine was founded in 1565, 42 years before the English were successful at Jamestown. The Spanish Council of Indies claimed that after 1510 fleets and ships had gone to Florida. and Florida is shown on the earliest known map of the new world, the Cantino map of 1502.

Spanish Exploration. — In 1513 Juan Ponce de León (c. 1460–1521), who had been with Columbus on his second voyage and who had later been governor of Puerto Rico, obtained a royal grant authorizing him to discover and settle "Bimini"—a fabulous island believed to contain a marvelous fountain or spring whose waters would restore to old men their youth or, at least. had wonderful curative powers. Soon after Easter day he came in sight of the coast of Florida, probably near the mouth of the St. Johns river. From the name of the day in the calendar. *Pascua* Florida, the country was named Florida. Ponce de León seems to have explored the coast, to some degree. on both sides of the peninsula, and to have turned homeward fully convinced that he had discovered an immense island. He returned to Spain in 1514 and obtained from the king a grant to colonize "the island of Bimini and the island of Florida." of which he was appointed *adelantado* (civil and military governor); in 1521 he made another expedition, this one for colonization as well as for discovery. He seems to have touched at the Dry Tortugas Islands, so named because of the large number of turtles found there, and to have landed at several other places, but many of his men succumbed to disease and he was wounded in an Indian attack, dying soon afterward in Cuba. Meanwhile, in 1516, another Spaniard, Diego Miruelo, seems to have sailed for some distance along the west coast of the peninsula. The next important exploration was that of Pánfilo de Narváez. In 1528 he sailed from Cuba with about 600 men (soon reduced to less than 400); he landed early in 1528, probably near the present site of Tampa. and for six months remained in the country, he and his men suffering terribly from exposure, hunger and fierce Indian attacks. In September, his ships being lost and his force greatly reduced in number; he hastily constructed a fleet of five boats, re-embarked, probably at Apalachee bay, and lost his life when his boat was blown out to sea while off the coast of Texas. Only four of his men. including Alvar Núñez Cabeza de Vaca, succeeded, after eight years of Indian captivity and of long and weary wanderings, in finding their way to Spanish settlements in Mexico. Florida was also partially explored by Hernando de Soto (*q.v.*) in 1539–40. In the summer of 1559 another attempt at colonization was made by Tristan de Luna. who sailed from Veracruz, landed at Pensacola bay and explored a part of Florida and (possibly) southern Alabama. Somenhere in that region he desired to make a permanent settlement, but he was abandoned by most of his followers and gave up his attempt in 1561.

French Huguenot Settlers. — In 1562, Jean Ribaut (c. 1520–65). with a band of French Huguenots, landed first near St. Augustine and then at the mouth of the St. Johns river, which he called the River of May, and on behalf of the king of France claimed the country. which he described as "the fairest, fruitfullest and pleasantest of all the world"; but he made his settlement on an island near what is now Beaufort, S.C. In 1564 René de Laudonnière (d. *c.* 1586), with another party of Huguenots, established Ft. Caroline at the mouth of the St. Johns, but the colony did not prosper and in 1565 Laudonnibre was about to return to France when (on Aug. 28) he was reinforced by Ribaut and about 300 men from France. On the same day that Ribaut landed, a Spanish expedition arrived in the Bay of St. Augustine. It was commanded by Pedro Menéndez de Avilés (1519–74), one of whose aims was to destroy the Huguenot settlement. This he did, putting to death almost the entire garrison at Ft. Caroline "not as Frenchmen but as Lutherans," on Sept. 20, 1565. The ships of Ribaut were soon afterward wrecked near Matanzas inlet; he and most of his followers surrendered to Menéndez and were executed. Menéndez then turned his attention to founding a settlement which he named St. Augustine (*q.v.*); he also explored the Atlantic coast from Cape Florida to St. Helena and established forts at San Mateo (Ft. Caroline), Avista, Guale and St. Helena. In 1567 he returned to Spain in the interest of his colony.

The news of the destruction of Ft. Caroline and the execution of Ribaut and his followers was received with indifference at the French court; but, according to a widely accepted story, Dominique de Gourgues (c. 1530–93), a friend of Ribaut but probably a Catholic, organized an expedition of vengeance, not informing his men of his destination until his three ships were near the Florida coast. With the co-operation of the Indians under their chief, Saturiba, he captured Ft. San Mateo in the spring of 1568 and on the spot where the Huguenots of Ft. Caroline had been executed, he hanged his Spanish prisoners and inscribed on a pine tablet the words: "I do this not as unto Spaniards but as to traitors, robbers and murderers." Feeling unable to attack St. Augustine, De Gourgues returned to France.

Spanish Settlements.— The Spanish settlements experienced many vicissitudes. The Indians were hostile and the missionary efforts among them failed. In 1586 St. Augustine was almost destroyed by Sir Francis Drake, and it also suffered severely by an attack of Capt. John Davis in 1665. Not until the last decade of the 17th century did the Spanish authorities attempt to extend the settlements beyond the east coast. Then, jealous of the French explorations along the Gulf of Mexico, they turned their attention to the west coast, and in 1696 founded Pensacola. When the English colonies of the Carolinas and Georgia were founded, there was constant friction with Florida. The Spanish were accused of inciting the Indians to make depredations on the English settlements and of interfering nith English commerce, and the Spanish were in constant fear of the encroachments of the English. In 1702, when Great Britain and Spain were contending in Europe, on opposite sides, in the War of the Spanish Succession (1701–14), a force from South Carolina captured St. Augustine and laid siege to the fort but, being unable to reduce it for lack of necessary artillery, burned the town and withdrew at the approach of Spanish reinforcements. In 1706 a Spanish and French expedition against Charleston, S.C., failed, and the Carolinians retaliated by invading middle Florida in various raids between 1702 and 1728. In 1740 Gen. James Edward Oglethorpe, governor of Georgia. supported by a naval force, made an unsuccessful attack upon St. Augustine; two years later a Spanish expedition against Savannah by way of St. Simon's Island failed, and in 1745 Oglethorpe again appeared before the walls of St. Augustine; but the treaty of Aix-la-Chapelle in 1748 prevented further hostilities. Pensacola, the other centre of Spanish settlement, though captured and occupied (1719–23) by the French from Louisiana, had a more peaceful history.

The Establishment of the Florida Provinces.— By the treaty of Paris in 1763 Florida was ceded to England in return for Havana. The provinces of East Florida and West Florida were now formed, the boundary of West Florida being 31° N. (when civil government was organized in 1767, the northern line was made 32" 28' N.), and the western boundary the Chattahoochee and the Apalachicola rivers, the Gulf of Mexico, Mississippi sound, Lakes Borgne. Pontchartrain and Maurepas, and the hlississippi river, A period of prosperity began. Civil in place of military government was instituted; immigration began; and Andrew Turnbull, an Englishman. brought over a band of about 1.500 Minorcans (1767), whom he engaged in the cultivation of indigo at New Smyrna. Roads were laid out, some of which yet remain; in the last three years of British occupation the government spent $580.000 on the two provinces. Consequently, the people of Florida were for the most part loyal to Great Britain during the American Revolution. In 1776, the Minorcans of New Smyrna refused to work any longer on the indigo plantations; many of them removed to St. Augustine, nhere they were protected by the authorities. Several plans were made to invade South Carolina and Georgia, but none matured until 1778, when an expedition was organized which co-operated with British forces from New York in the siege of Savannah, Ga. In the following year, Spain having declared war against Great Britain, Bernardo de Gálvez (1746–86), the Spanish governor at New Orleans, seized most of the English forts in West Florida and in 1781 captured Pensacola.

By the treaty of Paris in 1783 Florida reverted to Spain and, no religious liberty being promised, many of the British inhabitants left East and West Florida. A dispute with the United States concerning the northern boundary was settled by the treaty of 1795, the line 31° N. being established.

Acquisition by the **U.S.**—The westward expansion of the United States made it highly desirable to have American ports on the Gulf of Mexico: consequently, the acquisition of A'est Florida as nell as of New Orleans was one of the aims of the negotiations which resulted in the purchase of Louisiana in 1803. After the cession of Louisiana to the U.S., the people of West Florida feared that that province would be seized by Napoleon. They, therefore, through a convention at Buhler's plains (July 17, 1810), formulated plans for a more effective government. When it was found that the Spanish governor did not accept these plans in good faith, another convention was held on Sept. 26 which declared West Florida to be an independent state, and organized a government and petitioned for admission to the union. On Oct. 27, Pres. James Madison, acting on a theory of Robert R. Livingston that West Florida was ceded by Spain to France in 1800 along with Louisiana and was therefore included by France in the sale of Louisiana to the U.S. in 1803, declared West Florida to be under the jurisdiction of the United States. Two years later the U.S. congress annexed the portion of West Florida between the Pearl and hlississippi rivers to Louisiana (hence the so-called Florida parishes of Louisiana), and that between the Pearl and the Perdido to the hfississippi territory.

In the meantime war between Great Britain and the U S. was imminent. The U.S. government asked the Spanish authorities of East Florida to permit an American occupation of the country in order that it might not be seized by Great Britain and made a base of military operations. When the request was refused, American forces seized Fernandina in the spring of 1812, an action that was repudiated by the U.S. government after protest from Spain, although it was authorized in official instructions. About the same time an attempt to organize a government at St Mary's was made by U.S. sympathizers and a petty civil war began betneen the Americans. who called themselves "patriots," and the Indians, who were encouraged by the Spanish. In 1813 British troops landed at Pensacola to begin operations against the United States. In retaliation Gen. Andrew Jackson captured the place, but in a few days withdrew to New Orleans. The British then built a fort on the Apalachicola river, and from there directcd expeditions of Indians and runaway Negroes against the American settlements. These expeditions continued long after peace was concluded in 1814. In 1818 General Jackson, believing that the Spanish were aiding the Seminole Indians and inciting them to attack the Americans, again captured Pensacola. By the treaty of 1819 Spain formally ceded East and West Florida to the United States; the treaty mas ratified in 1821, when the United States took formal possession, but civil government was not established until 1822.

The New Territory and Statehood.— Indian affairs became the most serious problem of the new territory of Florida. Immediately after the cession of Florida to the United States, pressure was brought to bear upon congress and the president to have the Seminole Indians removed and the country thrown open to settlement. The Indians, who had been allowed to occupy their lands in peace by the Spaniards, could not understand why they should be forced to move to new lands west of the Mississippi; but they consented, by the treaty of Ft. Moultrie in 1823. to live within certain limits. Conflicts followed, however, as the population increased, and a new demand was made to have the Indians removed. By treaties made at Payne's landing in 1832 and Ft. Gibson in 1833 the Indian chiefs agreed to exchange their Florida lands for equal territory in the western part of the U.S. But a strong sentiment against removal suddenly developed, and the efforts of the U.S. to enforce the treaty brought on the Second Seminole War (1835–42), which resulted in the removal of all but a few hundred Seminoles whose descendants continue to live in southern Florida. In 1845 Florida became a state of the United States.

The **Civil** War and Reconstruction. — On Jan. 10, 1861, an ordinance of secession, which declared Florida to be a "sovereign and independent nation," was adopted by a state convention, and Florida became one of the Confederate States of America. The important coast towns were readily captured by Union forces—Fernandina, Pensacola and St. Augustine in 1862 and Jacksonville in 1863; but an invasion of the interior in 1864 failed, the Union forces being repulsed in a battle at Olustee on Feb. 20, 1864. In 1865 a provisional governor was appointed by Pres. Andrew Johnson, and a new state government was organized. The legislature of 1866 rejected the 14th amendment to the federal constitution. and soon afterward Florida was made a part of the 3rd military district, according to the Reconstruction acts of 1867. Negroes were now registered as voters by the military authorities, and another constitutional convention met in Jan. and Feb 1868. A factional strife in the dominant party, the Republican, threatened to break up the convention. but through the efforts of Gen. George G. Meade the differences were reconciled. A constitution was framed and ratified by the electors, and Florida passed from a quasi-military to a full civil government on July 4, 1868.

Before the American Civil War Jacksonville. St. Augustine and even Tampa had attracted tourists and invalids seeking respite from the colder winters of the northern states. but tourism only became a profitable business enterprise in the 1880s. Among later visitors were several northern capitalists who recognized possibilities for further development in Florida: Hamilton Disston, who bought 4,000,000 ac. of land in central Florida in 1881; Henry B. Plant who bought several short-line railroads and built them into the Atlantic Coast Line system through central Florida to the west coast; and Henry M. Flagler. who built the Florida East Coast line into Miami and over the seas into Key West. The railroads brought not only winter visitors, but settlers who grew winter truck crops, planted citrus groves and mined phosphate. The population of the state doubled between 1870 and 1890; by 1900 there were about 500.000 residents and in each succeeding 20 years the population almost doubled.

The 20th Century. — The history of the state in the 20th century has been that of rapid expansion and is quickly told in the rise in population in 60 years from about 528.000 in 1900 to more than 4,000.000 in 1960. The population, which had been swelled during World War II by thousands of members of the several branches of the armed forces sent to the state for training, continued to increase after the war. Many new industries located or relocated in the state, a number of them providing products and services associated nith the missile research and launching centre at Cape Canaveral. The annual state tourist influx approaches 10,000,000 persons. Agriculture remains an important part of the economy, but citrus crops and cattle raising have replaced field 'crops as the chief agricultural products. The growth of metropolitan and urban areas brought a decided shift of population and changed Florida's character from that of a rural state to that of a distinctly urban state. As in other states this shift resulted in a political fight on the part of the urban areas to secure better apportionment of representation in the state legislature.

Among the notable events in the 20th century were: the disastrous Jacksonville fire of 1901; the passage of legislation abolishing peonage (1909) and the convict lease system for prisoners (1923); the completion of the overseas railroad to Key West in 1912; the frantic land boom of the early 1920s; and the disastrous hurricanes of 1926, 1928, 1935 and 1960.

GOVERNMENT

The basis of Florida's government was laid in the constitution of 1885 (a document that was preceded by four earlier constitutions), to which about 100 amendments have been ratified. The amending process is simple. proposal by three-fifths of all of the members of both houses of the legislature and ratification by a majority of the voters casting their ballots for the proposed amendment at the next general election. The material that has been added by amendment comprises more than half of the constitution. There are a number of important constitutional prohibitions and tax exemptions, including prohibitions against an income tax, an inheritance tax and an ad valorem tax on real estate; the exemptions include three that relate to homesteads — immunity from forced sale unless alienated by the onner, $5,000 real-estate tax and $1.000 personal-property tax exemptions.

Governmental powers are divided between the legislative, executive and judicial branches with the usual system of checks and balances. Representation in the legislature is apportioned among the 67 counties on the basis of a senate composed of 38 members selected from districts comprising one or more counties; the house of representatives is composed of 95 members with three representatives from each of the five largest counties in population. two from the next 18 largest and one each from the remaining 44 counties. The constitution provides for reapportionment every 10 years, but the rapid population growth in the most populous counties has made this a difficult task. Regular sessions of the legislature are held biennially for 60 days; the sessions may be extended for 30 days by a three-fifths majority vote. Special sessions of 20 days may be called by the governor and the legislature itself may call a special session for 30 days by a three-fifths vote of the members. A legislative council, with a legislative reference bureau, was created in 1949; this agency, composed of nine senators and nine representatives, serves as an interim planning and study committee between sessions.

The executive power is vested in a governor and six elected administrative officers; these officers serve four-year terms, but a governor may not immediately succeed himself in office. Executive authority is highly decentralized among more than 150 officers, agencies. boards and commissions. The most important agencies are the 32 ex officio boards and commissions of which the governor and the six administrative officers (the so-called cabinet), in full or in part, are members. including the budget commission and commissioners of state institutions The administrative agencies, established largely by statute, are supervised by officials appointed by the governor, including 22 examining boards for professions and vocations. Several agencies are under the control of the governor: the road department. industrial commission, racing commission. beverage department and motor vehicle commission. The heads of these departments are referred to as the "little cabinet." The only elective executive agency is the railroad and utilities commission whose three members are selected for four-year terms.

The judicial branch is composed of a supreme court of seven justices elected for six-year terms; the office of chief justice rotates among the members of the court. There are three district courts of appeals composed of three judges each, elected for six-year terms. There are 16 circuits of the circuit courts, with one circuit judge for every 50,000 inhabitants or major fraction thereof. To relieve the burden of litigation on the circuit courts. a number of courts of concurrent jurisdiction have been established in the more populous counties There is a county judge in each county; lesser courts have been created in several counties.

Each county elects a board of five county commissioners and at least eight administrative officers. An amendment to the constitution in 1956 excepted Dade county (the southeastern county which includes the Miami resort area) which adopted a county charter and a plan of metropolitan government. Municipal gov-

*Populations are reported as constituted at date of each census. †Formerly Brownsville-Brent-Goulding. ‡Changed from River Junction in 1941. $Includes Fernandina and Fernandina Beach in 1950; previously known as Fernandina. ‖Pass-a-Grille Beach and St. Petershurg Beach consolidated since 1950; previously known as Pass-a-Grille Beach.

Note: Dash indicates place did not exist during the reported census, or data not available.

ernments, generally chartered by special acts of the legislature, are provided for 310 incorporated communities. Of the 617 units of government in Florida, more than 200 are special purpose or ad *hoc* district governments.

POPULATION

The population of Florida in 1850 (the first census after the state entered the union) was 87,445. Its population ranked 32nd among the 37 states and territories of the union and was classified as 100% rural. By 1900 the population had increased more than 500% to 528.542, ranked 33rd among the 48 states and territories and was classified as 79.7% rural. In the succeeding decades the population increased 42.4% from 1900 to 1910; 28.7% from 1910 to 1920; 51.6% from 1920 to 1930; 29.2% from 1930 to 1940; 46.1% from 1940 to 1950; 76.3% from 1950 to 1960. At mid-20th century the population ranked 20th among the 48 states and was 65.5% urban. By 1960 it ranked 14th among the 50 states and was nearly three-fourths urban. After mid-20th century the population increased by about 225,000 new inhabitants per year. Of this total, about 65.000 represent natural increase, the excess of births over deaths. The net annual immigration to the state is about 160,000 arrivals per year or more than 3,000 per week. The population per square mile in 1950 was 47.3, as compared with 49.9 for the nation as a whole. By 1960 the population per square mile had increased to 83.5 per square mile, as compared with 49.7 for the nation as a whole.

The five largest counties—Dade, Duval, Hillsborough, Pinellas and Broward (Fort Lauderdale) contain slightly less than one-half of the total population. The four metropolitan areas (Jacksonville, Miami, Orlando and Tampa-St. Petersburg) contain more than one-half of the total population. By 1960 50.1% of the population lived in these areas.

More than half of the population of Florida comprises migrants from other states, but there are very few foreign-born residents. The distribution by colour and nativity, according to the 1950 census was as follows: 73.7% native white; 4.4% foreign-born white; and 21.8% nonwhite. Practically all of the nonwhite population is Negro.

FINANCE AND TAXATION

The state derives more than half of its total income from taxation and about one-eighth from the federal government. State tax revenues are derived from the following sources: sales and use taxes, gasoline taxes, beverage taxes, motor-vehicle licences, pari-mutuel fees and taxes, cigarette taxes, unemployment compensation taxes and intangible property taxes. There is no state income tax and no state property ad valorem tax. Most of the state's revenue comes from the excise taxes. The state disburses more than half of its income for operating expenses and about one-third of its income goes for aid to counties and cities. State aid to counties includes about $160,000,000 for public schools and school debt.

EDUCATION

In 1947, Florida established a Minimum Foundation program for public schools which enables each county, with the potential help of state funds, to offer adequate educational opportunities to all children. The program provided that all schools have a term of 180 days, increased teachers' salaries and encouraged the training of new teachers. State educational scholarships for prospective teachers were doubled, provisions for kindergartens and junior colleges were made and many new school buildings were constructed. Almost 1,000,000 students were enrolled in public schools by mid-20th century.

The school program provides a broad program of adult education, of diversified co-operative training enabling the student to work part-time and of driver education. The state system of higher education is supervised by an appointive board of control subject to the ex officio state board of education. One institution, the University of Florida (founded in 1853), is located at Gainesville; two others are at Tallahassee—Florida State university (founded in 1857), and Florida Agricultural and Mechanical university (founded in 1887) for Negroes. These institutions are co-educational, and between them, enroll approximately 25,000 students. There is a medical college at Gainesville affiliated with the University of Florida.

The state also contributes to the support of the medical college of the Cniversity of Miami (founded in 1925), a private institution. Older private institutions of higher education include Rollins college at Winter Park (incorporated in 1879 and opened in 1885), Stetson university at DeLand (founded in 1883) and Florida Southern college at Lakeland (founded 1885).

HEALTH AND WELFARE

The public health program of Florida is directed by the state board of health and administered by 66 county health departments. Under the state program clinics are provided for mothers and children, and visiting nurses instruct in child care and nutrition; sanitarians guard and test water supplies and inspect food establishments and handlers.

Immunization programs are provided and many counties require certification as to health conditions before issuing building permits; many of the counties provide guidance clinics to assist in the solving of behaviour and mental problems.

The state maintains four hospitals for the treatment of tuberculosis, three hospitals for the mentally ill and a rehabilitation centre for alcoholics with out-patient clinics in several cities of Florida. Training of doctors is supported by the state at the medical colleges of the Universities of Florida and Miami. The crippled children's commission has developed programs which have attracted both public and private funds.

The public-welfare program of Florida generally follows the federal program of social security and public assistance. Florida spends about $70,000,000 annually for aid to aged persons, the blind, dependent children and the disabled. and smaller amounts for unemployment compensation and other aids and for administration. The state maintains training schools for delinquent boys at Marianna and Okeechobee and for girls at Ocala. Schools for the mentally retarded are operated at Gainesville and Fort Myers. Correctional institutions are operated at Apalachee for first offenders while the state penitentiaries for men are at Raiford and Belle Glade and for women at Lowell.

THE ECONOMY

About four-fifths of Florida's labour force are nonfarm workers. Of the total number of employees in nonagricultural establishments about 30% are engaged in retail and wholesale trade; about 15% each in government, services and manufacturing; about 10% in construction trades; and less than 10% in transportation, communication and public utilities; about 5% in finance, insurance and real estate; and about 1% in mining.

The geographical distribution of employment varies with the economy of each section according to the development of tourism, agriculture and industry: agricultural employment is well distributed in the farm and grove areas from Pensacola to Miami; businesses and trades that cater to tourism and hence employ food handlers. maids and porters are concentrated along the major highways on the east and west coasts. The pulp and paper industry is largely in the northern sections; food canning and preserving in the central citrus section; the apparel industry chiefly in the Miami area; printing and publishing in the largest cities; chemicals in and around Pensacola; and mining in Polk county.

The population increased 76.3% from 1950 to 1960. The per capita income of Floridans rose from $1,228 in 1950 to about $2.000 by 1960, approximating the average for the nation as a whole. Extractive, processing and fabrication industries contribute about 20% of the total personal income; trades, services and related industries contribute about 40%; federal, state and local governments about 20%; and unclassified sources, about 1 5 . More than half of the state's income is derived from aages and salaries. Proprietors' income and property income each amount to about 15%.

Agriculture. — Florida is one of the few states in which agriculture is an expanding industry. The refrigerated freight car made practicable the long-distance shipment of perishable truck and citrus crops; quick freezing and the wholesale marketing of frozen foods increased market demands. The successful control of insect pests and the introduction of cultivated pastures promoted beef production; livestock receipts amount to almost 25% of total farm receipts. More than 100 meat-packing plants process Florida cattle, most of the beef being bought in 30 livestock auction markets.

Citrus fruits account for almost 35% of the state's agricultural production; Florida accounts for about two-thirds of the total U.S. production. Vegetable production is important; 62 vegetables are grown commercially, mostly for winter trade. Part of the 23,000,000 ac. of forest land in the state is privately owned, and timber is cut for lumber and pulpwood mills. The number of commercial farms in the state increased after mid-20th century, while there was a decline in other states. The production, processing and distribution of agricultural products is one of the three major sources of income payments.

The perfection of manufacturing processes for the concentration of citrus juices through a "quick-freeze" operation resulted in a major new food industry which consumes more than half of the citrus production of the state. Commercial fishing is an important industry, the annual catch being valued at about $30,000,000.

Manufacturing and Industry. — The most significant economic factor in the growth of Florida has been diversification: in agriculture with new processing for crops, in tourism through expansion to a year-round business and in industry through over-all expansion and development. Florida's industrial growth began with the 20th century: between 1899 and 1933, the value added by manufacture increased at a rate of 3% each year; after 1933 the rate of growth was more than 7% annually. Florida is not, however, a major industrial state, accounting for only about 1% of total U.S. industrial employment.

The broadening of the industrial base is illustrated by the great increases in metalworking and fabricated metal production and the establishment of an electrical machinery industry. Industry groups which doubled their employment in 1950–60 include apparel. furniture, paper, chemicals, stone, clay and glass, and nonelectrical machinery.

Food processing, including canning and preserving, was the state's leading industry after mid-20th century; it was followed, in order, by pulp, paper and paperboard; cigars; ne spapers; and sawmills and planing mills. The most significant industrial development of the 1950s was the completion and opening of a natural gas line from Texas into the peninsula to serve all of the metropolitan areas. The state's leading power plants, industries and manufactured gas distributing systems were converted to the use of natural gas, assuring an ample supply of fuel for additional industries.

Beginning in 1956, several manufacturers of space missiles and jet engines established plants in Florida, and the national missile testing centre was established at Cape Canaveral. With nearby Patrick air force base, the centre employs 35,000 persons. There are more than 150 electronics manufacturers most of whom are located near Tampa and St. Petersburg.

Minerals. — Although the extraction of minerals from the earth in Florida is behind other states in volume, the state leads in the production of phosphate rock and fuller's earth. Both aluminum and uranium have been extracted from Florida phosphate, enough of the latter to warrant the establishment of a recovery plant by the Atomic Energy commission. Among the newer minerals extracted in the state are titanium. zirconium and hafnium; ilmenite and rutile are, in turn, processed from titanium. The chemical industries include the production of textile fibres by chemical synthesis. organic chemicals, fertilizers, inorganic chemicals and plastics and resins. A fourth of the nation's supply of turpentine and wood rosin is manufactured in Florida.

Tourism. — Agriculture, industry and tourism constitute a three-way economy for Florida. The equable year-round climate and nearness to centres of population have made it a leading vacation land. In 1927. about 1,800,000 visitors spent approximately $201,000,000. Three decades later, about 8,080,000 visitors spent approximately $1,323,000,000 on vacations in Florida. After mid-20th century tourism was one of the state's three largest business enterprises. Before 1920, the state was a rich man's vacation spot, but the automobile and better roads made the luxury of a former generation, a mass market.

Transportation and Communication. — There are more than 4,700 mi. of railroads. There also are 14,275 mi. of state-maintained paved roads and 28,145 mi. of paved roads maintained by counties and cities plus 20,000 mi. of improved but unpaved roads in Florida. International airports are at Miami and Tampa. Domestic and several foreign airlines operate from more than 100. commercial and municipal airports; there are more than 50 military airports and several private airports. The export-import trade through the state's 13 deep-water harbours regularly operating in foreign trade amounts to almost 10,000,000 tons, nearly balanced between imports and exports.

There are more than 40 daily newspapers and about 150 weekly newspapers; 130 radio stations, 16 commercial television and 6 educational television stations broadcasting in the state.

FLORIDABLANCA, JOSÉ MOÑINO Y REDONDO, COUNT OF (1728–1808), Spanish statesman, was born at Hellin, Murcia. on Oct. 21, 1728. He was the son of a retired army officer. He studied at Salamanca and practised as an advocate. After a successful embassy to Rome, Floridablanca succeeded Grimaldo as first minister to Charles III. He regulated the police of Madrid, reformed many abuses, projected canals, took measures for the improvement of trade and agriculture, and encouraged learning, science and the fine arts. The long-standing disputes with Portugal on the boundaries of the South American colonies were settled. An agreement signed at San Ildefonso (Oct. 1, 1771) was later followed by a treaty of alliance between the two powers signed at Pardo (March 24, 1778). At the outbreak of war between Great Britain and the North American colonies. Floridablanca advised a middle course, but Spain was drawn into the conflict in 1779. Floridablanca was much under the influence of French *philosophes* and economic writers. The French Revolution frightened him into reaction, and he advocated the support of the first coalition against France. He retained his office for three years under Charles IV; but in 1792, through the influence of the favourite Godoy, he was dismissed and imprisoned in the castle of Pampeluna. Here he was saved from starvation only by the intervention of his brother. He remained in seclusion till the French invasion of 1808. He was then nominated president of the central junta at Aranjuez. He died at Seville on Nov. 20, 1808. He left several short treatises on jurisprudence.

FLORIDOR (JOSIAS DE SOULAS, SIEUR DE PRIMEFOSSE) (*c.* 1608–1671), French actor, of whom De Visé wrote that he acted "like a gentleman . . . whose bearing and movements were so natural that even without speaking he inspired general admiration." He was born at Brie early in the 17th century. After about five years at the Marais theatre in Paris he joined the Hôtel de Bourgogne in 1643 and there rose to the position of manager and *orateur,* that is. the speaker who addressed the audience when the next play was to be announced. As an actor Floridor seems to have been better suited for parts that required more dignity than warmth. Robinet commented on his *"air charmant"* and *"noble manière,"* and Louis XIV held him in particular esteem. When Racine cast him in the role of Nero in *Britannicus* (1669), the spectators had difficulties in reconciling the irreproachable actor with the wicked part he had been assigned to play. (A. M. N.)

FLORIN, the name of several coins of the continent of Europe and of two coins struck in England at different times. The word comes through the Fr. *florin* from the Ital. *fiorino,* flower, Lat. *flos, florem.* Fiorino was the Italian name of a gold coin issued at Florence in 1252, weighing about 54 grains. This coin bore on the obverse a lily, from which it took its name of "the flower," on the reverse the Latin name of the city *Florentia,* from which it was also known as a "florence." "Florin" and "florence" seem to have been used in English indiscriminately as the name of this coin. The Florentine florin was held in great commercial repute throughout Europe, and similar coins were struck in Germany, other parts of Italy, France, the Netherlands (where the silver florin is still in use), etc.

The English gold florin was introduced by Edward III in 1343, half and quarter florins being struck at the same time. This gold florin weighed 108 grains and was to be current for six shillings. It was found, however, to be overvalued in proportion to the silver currency and was demonetized the following year. The florin did not reappear in the English coinage until 1849, when silver coins with this name, having a nominal value of two shillings (one-tenth of a pound) were struck. In 1887 a double florin or four-shilling piece was issued, but its coinage was discontinued in 1890. The design of the florin was altered in 1937. The reverse side consists of a rose, thistle and shamrock surmounted by a crown, surrounded by an inscription. *(See* also MONEY, MEDIAEVAL; NUMISMATICS; GULDEN.)

FLORIO, JOHN (GIOVANNI) (c. 1553–*c.* 1625), English teacher of Italian, lexicographer and translator of Montaigne. was the son of Michael Angelo Florio, a Protestant refugee of Tuscan origin. John, who was born in London about 1553, may have had some education at Tiibingen, and had returned to England by 1576. In 1581 he matriculated at Magdalen college, Oxford. At Richard Hakluyt's instigation he translated, as *Navigations and Discoveries* (1580), Giambattista Ramusio's account of the voyages of Jacques Cartier. Another translation, *A Letter lately written from Rome,* was printed in 1585. *Florio his Firste Fruites* (1578), consisting of a grammar and 44 lively dialogues in Italian and English, was followed by *Florio's Second Frutes* (1591), together with a collection of proverbs alphabetically arranged in *Giardino di Ricreatione.* Between 1583 and 1585 Florio was employed as tutor to the French ambassador's daughter. He was associated with

Giordano Bruno, whose works Florio used freely as a lexicographer. By 1594, and possibly some years earlier, Florio had been appointed tutor to the earl of Southampton. His Italian-English dictionary, *A Worlde oj Wordes* (1598), contains some 46,000 definitions, many amply informative, others racy and idiomatic. The second edition, *Queen Anna's New World of Words* (1611), was greatly enlarged.

In 1603 Florio produced his major translation, *The Essayes . . . of . . . Montaigne.* By modern standards of accuracy the freedom of this version is licentious; the style is uniformly elaborate where Montaigne is variously subtle or spare, but the book is rightly recognized as thoroughly good reading and was only temporarily displaced by Charles Cotton's version (1685). Florio revised it in 1613. From 1604 to 1619 Florio was groom of the privy chamber to Queen Anne. He was also her Italian tutor and probably taught Prince Henry. His last years were spent in poverty at Fulham, near London, still occupied with translations. Part I of *The New-Found Politicke* (1626) gives his rendering of Boccalini's *Ragguagli di Parnaso.* He died of the plague about 1625. His elaborate will is discussed by F. A. Tates, who identified two manuscripts in the British museum, *Gzardino di Ricreatione* and an Italian version of Ring James's *Basilikon Doron.* Florio left collections for the dictionary and ten dialogues which were apparently used by Torriano in his *Italian Tutor* (1640). *H.* G. Wright has made a good case for Florio's responsibility for the anonymous translation of the *Decameron* (1620). He is known to have had friendly connections with Sir Philip Sidney, Fulke Greville, Sir Edward Dyer, Matthew Gwinne, Barnabe Barnes, Nicholas Breton, Thomas Thorpe and Ben Jonson. He had his enemies too: John Eliot mocked him in *Ortho-Epia Gallica.* It has been supposed that Holofernes in *Love's Labour's Lost* was Shakespeare's gentler ridiculing of Florio's palpable pedantry and affectation; the most judicious consideration of this question is in F. A. Yates's *Study of Love's Labour's Lost* (1936). Florio was observant and critical of English manners and of the Elizabethan scene and indefatigably interested in words. He appears from his style as lively, learned, opinionated, fluent, industrious and, by his own epithet. the "Resolute John Florio."

FLORIS (originally DE VRIENDT), **CORNELIS** (1514–157j) and **FRANS** (*c.* 1518–1570), Flemish artists, the former an architect, sculptor and medalist, the latter a painter, were brothers from a talented Antwerp (Belg.) family. Frans studied under Lambert Lombard in Liège, Belg.; and early in the 1540s both brothers went to Rome, returning with their sketchbooks crammed with impressions. Those of Cornelis bore fruit in ornamental engravings (issued 1548–57) which introduced Netherlandish artists to an exuberant version of the Roman grotesque style. Of the drawings which Frans made from antique sculpture and from Michelangelo's paintings, many survive; he was one of the first northern artists to feel the impact of Michelangelo's "Last Judgment" (unveiled 1541).

Both brothers were soon at the head of flourishing workshops in Antwerp. Cornelis supplied, among other works, the choir screen of Tournai cathedral and the tombs of the Danish kings Frederick I at Schleswig, Ger., (1550–52) and Christian II at Roskilde, Den., (1568–75). Of his architecture, the most important example is Antwerp town hall (1561–65); its remarkable amalgamation of a Gothic gable front with a Florentine palace façade became the model for Netherlandish town halls. Indeed, the somewhat severe Renaissance style which Cornelis evolved dominated later 16th-century Netherlandish architecture, and its influence was felt in northern Germany, Denmark and around the Baltic coasts. He died in Antwerp, Oct. 20, 1575.

Frans's success was even more phenomenal, thanks to the fashionable modernity of his style, an astonishing facility of hand and the ability with which. like Rubens, he organized an efficient picture-producing factory. But his extravagant mode of life brought him into financial difficulties and he died (in Antwerp, Oct. 1, 1570) overwhelmed with debt. Paintings that bear his signature (a double or triple F) are in Antwerp, Arnstadt, Vienna, Brussels, Stockholm, Florence and other cities.

Frans Floris' brilliant natural gifts seem obscured by his ill-digested borrowings from classical antiquity and from Raphael, Michelangelo, Tintoretto and others. His genius is best revealed in small details of his pictures, in his studies of heads and in such portraits as those of a falconer and his uife (1558; Brunswick, Ger.; Caen. Fr.). Here the bravura of the brushwork plainly foreshadows the painting of the Baroque. (D. KG.)

FLORUS, PUBLIUS ANNIUS (late 1st and early 2nd century A.D.), historian of Rome and poet. is important as the first of a number of African writers who, in the 2nd century, exercised considerable influence on Latin literature; he was also the first of the "new-fashioned" poets of Hadrian's reign, whose special characteristic was the use of lighter and more graceful metres (anapaestic and iambic dimeters), which had hitherto found little favour. He compiled, chiefly from Livy. a brief sketch of the history of Rome from the foundation of the city to the time of Augustus. The work, which some manuscripts call *Epitome de* T. *Livio bellorum omnium annorum DCC libri duo,* is a rhetorical panegyric of the greatness of Rome. Though almost valueless historically, it was much used in the middle ages. In the manuscripts the writer is variously given as Julius Florus, Lucius Annaeus Florus or simply Annaeus Florus; but from certain similarities of style he has been identified with Publius Annius Florus, who was also known to be the author of a dialogue *Vergilius orator an poeta,* of which a fragment of the introduction has been preserved. This states that he was born in Africa, and at an early age took part in the contest of poets instituted by Domitian in honour of Capitoline Jove. Having been refused a prize owing to the prejudice against African provincials, he left Rome and set up at Tarraco in Spain as a teacher of rhetoric. But he must have returned to Rome, for it is agreed that he is the Florus who addressed the lines to Hadrian beginning "Ego nolo Caesar esse" ("I do not wish to be Caesar"). quoted with Hadrian's answer by Spartianus. Twenty-six trochaic tetrameters, *De qualitate vitae,* and five graceful hexameters, *De rosis,* are also attributed to him.

FLOTATION PROCESS: *see* METALLURGY; *ORE* DRESSING.

FLOTOW, FRIEDRICH, FREIHERR VON (1812–1883), German composer known for his opera *Martha.* Born on April 26, 1812, at Teutendorf, Mecklenburg, he studied under Antonin Reicha in Paris, where he established his reputation with *Le Naufrage de la Méduse* (1839), written in collaboration with Albert Grisar and Auguste Pilati. Between 1840 and 1878 he produced 19 light operas in France, Italy and Germany of which the best known is *Martha* (Vienna, 1847), in its original form a ballet given at the Paris Opéra in 1844. Introducing the Irish song, "The Last Rose of Summer," and appealing by its melodic charm, *Martha* won a place in the operatic repertory. Flotow also wrote ballets produced at Schwerin, where he was director of the court theatre, and incidental music for Shakespeare's *A Winter's Tale.* He died at Darmstadt, Jan. 24, 1883.

See R. Svoboda, *Friedrich von Flotows Leben* (1892).

FLOTSAM, JETSAM AND LAGAN, in common law, goods lost at sea, as distinguished from goods which come to land, which are technically designated wreck (*q.v.*). Jetsam (the same word as jettison) refers to the case when goods are cast into the sea and there sink and remain under water; flotsam where they continue floating on the surface; lagan where they are sunk in the sea, but tied to a cork or buoy in order to be found again. Flotsam, jetsam and lagan belong to the sovereign in the absence only of the true owner. Wreck, on the other hand (*i.e.*, goods cast on shore), was by the common law adjudged to the sovereign in any case, because it was said by the loss of the ship all property was gone out of the original owner. *See* WRECK.

FLOUNDER, a name given generally to flatfishes other than sole or halibut *(qq.v.)* and in England particularly to *Platichthys flesus,* which ranges from northern Europe to the Mediterranean. and often enters fresh water. The starry flounder *(P. stellatus)* of the Pacific coast of North America is a related species. In America the name is given to several species of flat fish: *e.g.,* winter flounder *(Pseudopleuronectes americanus)*, summer flounder *(Paralichthys dentatus)* and gulf flounder *(P. Albiguttus)*. *See* also FLATFISH.

FLOUR is defined as the fine, clean, sound product made by bolting wheat meal. The word is used in a less definite sense of other cereals and even noncereals or other substances in a finely powdered state, though in these cases it is usual to use such terms as bean, rice, potato or other flour. The term so defined is generic and covers a wide range of products differing by reason of the variety or form of wheat used in their manufacture, or by reason of certain qualities required for several purposes.

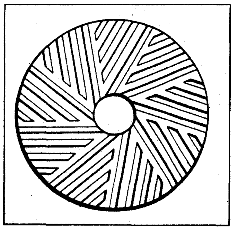

FIG. 1.—MILLSTONE FOR GRINDING WHEAT

Bread Flours.——As compared with wheat flour, all other materials used for making bread are of secondary importance. Rye bread is consumed in some of the northern parts of Europe and is popular in many parts of the United States: and breads commonly called corn pone, hoecake, johnnycake, made from corn meal, are largely eaten in the southern states and less generally throughout the corn belt. In southern Europe the meal of various species of millet is used and in India and China durra and other cereal grains are baked for food.

Buckwheat is employed in the U.S.S.R., the Netherlands and the United States, and in South America the meal of the tapioca plant; the flour of peas, beans and other leguminous seeds is also baked in cakes. But, excepting rye, none of these substances is used for making vesiculated or fermented bread, for only wheat and rye yield flours which, mixed with water, form doughs capable of satisfactory aeration or leavening.

Aside from its high nutritive value, due to its starch and gluten or protein content, and to a less degree to the mineral substances present, the most important characteristic of wheat flour is its capacity, when made into a dough, to enmesh gas, thus forming an open-textured, spongy, light bread. The gas formed either by the use of yeast as a leavening agent, or by the chemical reaction between an acid ingredient and bicarbonate of soda, is carbon dioxide (CO_2). Gas required for inflating the dough is produced by the growth of yeast. Yeast is a plant requiring food, and it must have sugar, nitrogenous matter and mineral salts in forms which it can assimilate; all flours contain some of these necessary yeast foods. They also contain certain enzymes. which may be called generically diastase. When dough is made these enzymes begin to operate on the starch of the flour, converting some of it, by stages, into sugar. The limiting factor in the quantity of gas evolved during panary fermentation is frequently a shortage of yeast-food; for example, the quantity of pre-existing sugar is insufficient, particularly if the proportion of yeast used is substantial and a prolonged fermentation is required. Therefore the yeast depends largely, and in the later stages of fermentation exclusively, for its saccharine food on the sugar produced in the dough by diastatic action. Modern bakery practice, in which all the operations between the mixing of the dough and the removal of the bread from the oven are performed to a definite time schedule, will not wait on the development of sugar in sufficient quantity to feed the growing yeast. Under certain conditions the addition of sugar or of special sugars made from corn starch is good practice. but it is preferable to use diastatic malt extract which produces sugar as the yeast uses it; in any case the yeast requires a sufficiently mixed food which includes some form of assimilable nitrogenous matter. *(See* BREAD.)

Baking Powder Leavening Agents.— Much of the bread baked in the home is of the hot bread or biscuit variety and is made by adding chemical leavening agents to the flour and water, or milk mixture. Baking powders are used in the production of biscuits, cakes and some forms of puddings, doughnuts, pancakes. etc. The formulas for baking powders vary somewhat, but all depend upon the release of carbon dioxide.

TYPES OF FLOUR

Self-raising **Flour.**—In relatively recent years millers added the chemical reagents necessary to the evolution of carbon-dioxide gas directly to their flour. The proportion of the alkaline body, bicarbonate of soda, is generally 1% to 1½% of the flour. Theoretically, a quantity of the acid body should be used just sufficient to neutralize the bicarbonate of soda: but in practice it is desirable and usual to use slightly more of the acid body (1¾% to 2¼%). The acid substance used in self-raising (called self-rising in the U.S.) flours is generally acid phosphate of lime. The manufacture of this chemical product has been greatly improved and it is excellent as to purity and constitution. When the finished self-raising flour contains 1½% of bicarbonate of soda, from 1½% to 2¼% of this phosphate should be used.

In the making of bread the growth of the yeast and the evolution of gas was a relatively long process, ranging from 3 to 20 hours. Modern practice, however, speeded up the fermentation process until the usual period of gas production was about seven hours. While these processes are proceeding, the flour as dough is being gradually rendered capable of easy distension and gas retention. It follows that the constitution and characteristics of the flour used must conform to the conditions as to time. temperature and proportion of yeast used so that there is no fixed standard of excellence in flour which can be always measured by any known factor, *e.g.,* the percentage of nitrogenous matter insoluble in water. On the contrary, widely differing characteristics are required, which the miller. as a specialist. must know and satisfy. So far as self-raising flour is concerned, he knows that the evolution of gas is rapid, and that the flour as dough must be capable of rapid distension and good gas retention. Therefore the wheats used in the manufacture of such flour differ substantially from those used for the manufacture of bread flours; and even in the manufacture of the latter regard must be paid to the conditions of time and temperature and to the sort and proportion of yeast used. These considerations led to many refinements of manufacture and to modern developments of milling.

Brown Bread Flours.— The consumption of brown bread or whole-wheat bread appears to have varied little in modern times, although more interest in whole-wheat breads was indicated. "Wheat meal" is not defined in Great Britain. It may be the entire product obtained by grinding cleaned wheat. and if designated whole-wheat meal it should be the 100% product; but it is usual and legitimate to describe as wheat meal either the 100% product or that from which bran equalling 5% to 10% of the whole has been abstracted. In the United States whole-wheat, entire-wheat and graham flour all mean flour containing all of the constituents of the cleaned grain. in their natural proportions.

Some persons benefit by the presence of bran or "roughage" in their food, and a proportion of whole-wheat bread is widely recommended. During World War I it was ascertained that brown flours formed 5% of the total flours consumed in Great Britain. This group of breadstuffs comprises certain well-known proprietary flours that are not whole-meal, and it is safe to say that wheat meals then formed only from 2% to 3% of the total flours consumed. There is no reason to think that this proportion was later substantially increased either in Great Britain or the United States.

Biscuit Flours.— For the manufacture of biscuits (crackers) certain types of flour are required, which differ materially from those used for bread. There are many kinds of biscuits, and specialization as to the types of flour required for them is carried to great lengths.

WHEAT

Wheat as Raw Material.— The embryo or germ from which the new plant originates forms from 1½% to 2% of the wheat berry. The endosperm is the food upon which the young plant lives till it is able to obtain its sustenance from the soil and air. The endosperm in its original form cannot, however, be assimilated by the embryo, and certain enzymes in the presenceof moisture gradually bring about the necessary changes. As a consequence the endosperm becomes liquid, and the bran functions as a container for it. This bran is very resistant to disintegration and can be found in the soil as an empty sac weeks or months after sowing.

The miller essentially divides wheat into two products, flour and offal, though there are several grades of each. The embryo or germ is sometimes regarded as a third product, but actually it goes into the two named. Until modern methods of milling were invented it was never obtained as a separate product. and even today it is impossible to separate more than about $\frac{1}{4}$ of the whole, that is to say, more than about $\frac{1}{4}$ of the 2% contained in the wheat berry. The germ, because of its oily nature, is particularly resistant to disintegration. Pressure applied either by millstones or rolls may flatten the particles and express some of its oil from the germ into the flour; but it is an error to suppose that flours manufactured by millstones contained the germ, and that those manufactured by modem methods do not. Formerly the germ aent mainly or wholly into the by-products; today some of it is extracted as substantially a separate product and is added, after cooking (which is necessary), to white flour to form certain special flours, *e.g.,* Hovis. a well-known English product. The remainder-goes mainly or wholly into the by-products of milling. Flours containing raw germ will not remain sound under trying conditions for long periods. The enzymes provided by nature to convert the endosperm into plant food reside mostly in or near the embryo or germ, and their activities have to be controlled or nullified in preparing the germ for use in bread; but ways have been devised whereby it can be included in certain flours.

Wheats and the Wheat Berry.—There are several races and very many varieties of wheat, some hard, some soft: some possessing so-called red bran, others white bran; some yielding white flours, others yellow flours; some growing and maturing rapidly, others slowly. On arrival at the mill their moisture content varies from 9% to 20%. Natural conditions of soil and climate enter into the selection of the varieties chosen for cultivation, and when a mill is situated in a great wheat-growing district the types of wheat available for its economic use may not differ widely; nevertheless, there are diversities in their constitution and character. But when, as in Great Britain, the wheats come from all parts of the world in an irregular supply, the miller must somehow manufacture flours of regular quality from raw material of very great diversity.

The miller divides the berry essentially into two products, flour and branny husk. The bran is made up of several layers. For present purposes it is unnecessary to deal with other than two of them. The outer skin (epidermis) is, to some extent. separated from the inner layers during the processes of milling, and is the principal constituent of the material known to millers as "bee's

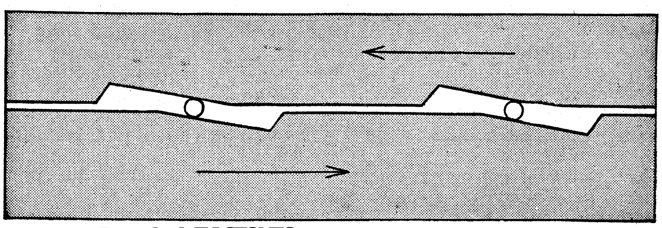

FIG. 2.—MILLSTONES: RUNNER AND BEDSTONE FACE

wing," a name indicative of its appearance. This bee's wing has a very high fibre content and is of low or little food value.

On the inner side of the bran there is a layer of rectangular cells known as the aleurone cells, of higher nutritive value than the bran. Theoretically wheat should yield much more flour than millers usually extract. Hence, if any attempt were made in commerce to increase the extraction, it is the inner side of the branny husk which should be attacked, not the outer one. When wheat was passed between millstones, it was principally the epidermis which was removed and passed as bran powder into the flour; the aleurone cells were left then, as they are now, on the finished bran. The addition of such powdered material to flour darkened it and had some effect in lowering its food value.

All wheats, moreover, have a crease. This greatly impedes an easy and satisfactory separation of wheat into its component commercial parts. It is also a receptacle for dust and dirt. In the early days of modern milling, millers attempted to split each berry down the crease and obtained a very dark product known as crease flour or crease dirt. This attempt proved to be a failure. A pair of fluted rolls, 60 in. long. grinds as a normal feed about 50,000,000 berries of wheat per hour, and it proved impossible to split each berry, or even most of them, in the desired way. Instead. wheat washing was introduced. The berry, furthermore, is furnished at one end with "hairs of beard" (which must not be confounded with the awns attached to the glumes), and these hairs have also to be removed by the miller.

Constitution of Flour.—The chemical constitution of flour may be stated as follows:

Starch	65 to 70%
Proteins	9 to 14%
Cellulose and fat	1%
Sugars	2½%
Mineral matter (ash)	4%
Water	13 to 15%

Actually, in exceptional cases, there are deviations beyond these limits. The principal proteins are gliadin and glutenin. When flour is made into a dough these two proteins constitute at least 80% of the material known as gluten. They are colloidal bodies and are of the greatest importance. It is wrong to say that very white bread is pure starch or relatively very starchy, for colour of crumb is largely due to the refraction and reflection of light, and the crumb of a loaf to be very white and bright must be well aerated; without a substantial or large proportion of these proteid bodies satisfactory aeration is impossible. Modern white bread is usually about 50% starch. The proportions of cellulose and ash present in flour are largely under the control of the miller. The cellulose is sometimes described as woody fibre, and by excluding particles of branny husk the proportion present of this indigestible matter is low. The ash consists principally of phosphates of potash and to a much smaller extent of phosphates of magnesia and lime, with traces of other constituents. The proportion of ash may be as low as 0.35% in the highest grades of flour or may rise to, say 1% in the commercially lowest grades. In no case is the presence of calcium salts of substantial significance, and this applies to wheat meals also. The form in which these constituents are combined in wheat has not been definitely ascertained. but if such salts may be divided into two groups, organic and inorganic, they are at that stage mainly or wholly organic, but become largely inorganic as a result of inorganic action during the milling and bread making processes.

MILLING PROCESSES

Milling processes may be conveniently divided into two stages: (1) the cleaning and conditioning of wheat; and (2) the separation of husk from kernel. Stated in these terms, milling may appear to be a simple process; actually it is a complicated one and, although modern milling developments have been in the direction of simplification, the diagram or flow sheet of a large modem mill would probably be unintelligible except to those trained in the techniques of milling. From the economic or technical point of view the amount added by milling to the value of the raw material is the measure of the merit of the work involved.

Wheat Cleaning and Conditioning.—The extraneous matter found in wheat consists principally of other cereals, seeds of many kinds. shapes and sizes, stones, chaff, straw, dust and dirt (earth). To extract these, many devices are employed. Sieves of perforated metal can extract substances either larger or smaller than wheat. But wheats differ so much as to size and shape of berry that better instruments than sieves are also necessary. Cylinders covered on their inner side with holes of varying sizes bored in zinc provide means of making more precise separations. Disks so bored rotating in a body of wheat are also employed. Ascending currents of air capable of precise regulation are passed through descending showers of wheat, and carry away particles which by reason of their shape or compactness of particle can be so separated. Wheat is scoured and brushed in various ways. One well-known machine consists essentially of a cylinder,, clothed on its inner side with emery; beaters revolving on a shaft serve the double purpose of scouring the wheat against the emery surface and of passing it through the length of the cylinder.

Conditioning is an English term; in the United States a somewhat similar operation is called tempering. Essentially it means that the physical condition of any given wheat is adjusted so that optimum separations of husk from kernel can be made. Sometimes water is added; sometimes it is abstracted. Adjustments must be made to suit the wheat under treatment. the conditions as to atmosphere and milling machinery subsequently used. and the flours to be produced. The factors employed are water, time and temperature. The methods of conditioning are still in the process of evolution. The results obtained by conditioning are mainly or wholly physical.

Grinding.— Roller mills are almost invariably employed for grinding today. When millers attempted at one operation to perform the whole of the grinding required, millstones were employed. This involved the use of friction, very great in amount and intensity: one passage between millstones involved at least 4 ft. of rough handling. Even when the wheats used were soft or mellow and therefore relatively resistant to disintegration, some of the husk of the wheat was reduced to powder. The Hungarians grew wheat of excellent quality, but the grain was hard and its skin friable. They therefore began. about 1870, to use roller mills. In other parts of Europe and in the eastern United States the wheats available were then mellow and the necessity for relatively gentle grinding mas not great. But when the states of the northwest and the western provinces of Canada were developed, the varieties of wheat found to be suitable were hard and had friable skins. Hence the American millers adopted the new Hungarian methods and British millers followed suit, for the ultimate users and consumers of flour would not accept flour or bread containing a large proportion of powdered husk. For these reasons gradual reduction by roller mills superseded the sudden death methods of grinding wheat by millstones.

A pair of cylindrical rollers, running at the point of contact in the same direction, nip and grind their feed at one point only in their circumferences. But a release of endosperm particles from the branny husk, and not mere crushing, being the object desired, the two rolls forming a pair are made to revolve at different speeds. This differential varies with the stage of milling. Furthermore, to effect optimum separations of husk from kernel it is necessary to obtain during the earlier stages of actual milling the endosperm particles in granular form. To effect this the rolls used in those stages are corrugated. The number and shape of these corrugations or flutes involve complicated technical points. The numbers range from 9 to 26 per inch of the roll's circumference. Still further to improve the separations the flutes are cut at varying angles in relation to the rolls' axes.

In conformity with the principle of gradual reduction, no attempt is made to obtain finished bran at one grinding; on the contrary, the wheat is broken down on the roller mills, known as the breaks, gradually by successive stages. These now number three, four or five; occasionally in some parts of the world six are used. Generally, millers aim to make as little flour as possible on the breaks, but some is made. The commercial product known as bran is separated from the stock, leaving the last break. The breaks as a stage of the milling process yield as finished products flour equalling from 8% to 18% of the original cleaned wheat and bran equalling from 10% to 15% of it. The remainder exists at that stage as granular products! known as middlings and semolina (*qq.v.*). These contain particles of pure endosperm, particles of pure husk and other particles consisting of endosperm with husk attached.

Ultimately, to resolve these intermediate products into finished flour and finished husk (known commercially in Great Britain as offals and in North America as feed) iurther grinding by rolls is required. These are known technically as reduction rolls or reductions, and generally have either smooth surfaces or very fine flutes ranging from 70 to 120 per inch of the roll's circumference. The speed and differential are adjusted to the work to be done, but the principle of gradual reduction is employed at these stages also. The central idea of such grinding is a release of endosperm particles from husk. In the case of particles consisting of endosperm only, it is desirable to reduce them in size by grinding. In no case should granular particles, however fine, be merely crushed.

Bolting.— This term in modern milling has a generic significance. In its simplest form it means separating by means of a sieve. Sieves are used largely in milling; they sort by size. Frequently several sieves are superimposed one above another to form the milling machine known as the plansifter. Though the principle of the plansifter is simple, it required a generation of experiment before a machine acceptable to millers generally was developed. Another form of bolting machinery is the octagonal, hexagonal or round reel mhich revolves at a slow speed. Here also separations are made according to size of particle. A framework is mounted on a central slightly inclined shaft. The framework is clothed with wire or silk cloth and the material to be separated is passed into the interior of the reel, whence it passes either through the cover or over the tail end of the reel. Another form of bolting is performed by the centrifugal. In this machine there is a reel or cylinder, generally hexagonal, revolving slowly and covered with silk or wire cloth. Inside are beaters revolving quickly mhich are set to throw the stock against the cover and to more it longitudinally. Primarily this also performs separations according to size of particle; but to some extent it sorts according to compactness of particle. The same thing can be said of the plansifter, but any such sorting depends on a nice adjustment of sieve space to the quantity of feed treated. After each grinding, whether by break or reduction rolls, some sort of separation by one or another of these bolting methods is performed, and the divisions and subdivisions of stock cause complexity. The meshes used vary from 10 to 140 per lineal inch.

PURIFYING, BLEACHING AND ENRICHMENT

Purifying.— In a technical sense purifying connotes separations of the granular products known as semolinas and middlings according to compactness of particle. For this purpose the machines known as purifiers have been designed and built. Before sorting by compactness of particle can be performed, sorting by size of particle is necessary, and must be carried out in great detail. There are various forms of this purification. Generally there is a sieve divided into a number of sections, each one having above it a separate air compartment. Through the sieve and each air compartment a current of air, under control as to intensity, is drawn. The best particles pass through the meshes of the sieve, some are held in suspension on the sieve and are floated over its end; others are caught in receptacles placed above the sieve.

Bleaching.— The principal colouring matter in flour is xanthophyll, with minor proportions of carotene and other unidentified colour pigments. As constituents of flour these seem to serve no useful purpose, and many consumers do not like bread which is even moderately yellow. These carotinoids are rendered colourless by oxidation and the flour then becomes nearly pure white in colour. This process occurs naturally when flour is stored for sex-era1 months, which permits the osygen of the air to react slowly with the colour pigments. Marked improvement in baking properties also occurs. Research on the reaction occurring in flour during storage led to the development of artificial bleaching which accomplishes in minutes what formerly took weeks. A current of air introduces the reactive substance to the flour stream before it goes to the packers.

Nitrogen peroxide, first employed in U.S. mills in 1904, is not extensively used at present. Nitrogen peroxide is made by passing a small current of air through a chamber in which flaming electrical discharges are produced intermittently. Flour thus treated may contain up to four parts per million of residual nitrites. Bleached flours must be so labelled if intended for sale in the Gnited States.

Nitrogen trichloride gas, produced by passing a stream of chlorine through a solution of ammonium chloride, matures as well as bleaches flour. At one time, 90% of U.S.-produced flour was thus treated. Criticism of flour bleaching with nitrogen trichloride, based on observations that it induced canine hysteria or running fits in dogs despite the fact that it has been shown that humans are not adversely affected and that dogs are not sensitive to amounts included in an average diet, led to its prohibition as a flour bleaching agent in the United States after Aug. 1, 1949. In Canada its use was discontinued May 1, 1949. The British government had not yet banned its use by the mid-1950s. Chlorine dioxide is generally accepted as an alternative flour bleaching agent in the United States and Canada. Intensive investigation showed it to be harmless.

Chlorine gas with 0.5% to 5% nitrosyl chloride is employed to some extent for soit-wheat cake flours and hard-wheat flours requiring very long fermentation. This agent affects the gluten strongly and the dosage must therefore be closely controlled. Traces of benzoyl peroxide will also bleach flour.

Enrichment.— Flour enrichment with thiamine, riboflavin, niacin and iron (optional, calcium and vitamin D) was made compulsory in the United States from Jan. 1943 to Oct. 1946 It mas made compulsory in a number of states, and the majority of US. bakers adhered to enrichment specifications, the program being supported by government organizations and nutritionists In Canada enrichment mas introduced in Feb 1953, though it was not made compulsory. In England, it was enforced in the 1950s for all flour of less than 80% extraction. However, the addition of *creta praeparata* was made compulsory for all flours. (See also GRAIN PRODUCTION AND TRADE; SEMOLINA; MIDDLINGS; etc.)

FLOUR BEETLE, a term popularly given to certain species of beetles (fam. Tenebrionidae) which are pests of broken grain and particularly of prepared cereal foods. The most important species belong to the genus *Tribolium;* of these, the confused flour beetle (T. *confusum)* and the rust-red flour beetle (*T. castaneum*) are the most serious pests found in flour mills. Originally these insects probably fed on broken grain in the fields; with the cultivation of grains by man, the beetles easily invaded stored supplies of whole grain and flours, which furnished an abundance of food and excellent breeding conditions. Remains of either T. *confusum* or *T. castaneum* have been found in a grain jar in a pharaonic tomb of the 6th dynasty, dating about 2500 B.C. The beetles have been spread throughout most parts of the world.

The life cycle of the various species of *Tribolium* is very similar. In T. *confusum* the adults are small, elongated, reddish insects about $\frac{1}{8}$ in. long. The females lay 400 to 500 small white eggs, which are dropped in the flour or grain. The larvae are slender and wormlike, white in colour, tinged with yellow, and pass through 6 to 11 instars, reaching an average length of $\frac{3}{16}$ in. before pupating. The life cycle may be completed in 4 weeks, but generally requires 40 days or longer, depending upon the food available and other conditions necessary for development.

In flour mills these pests are difficult to keep under control because of their small size and rapid development. According to R. T. Cotton and G. B. Wagner (U.S. Dept. Agric., Bur. Ent. and Pl. Quar., Mim. Ser. E-419, 1938), the mills generally become infested in six principal ways: (1) through entrance of the beetles with the grain stream; (2) from infested flour used in blending operations; (3) from infested flours returned to the mills from grocers, warehouses, etc; (4) from infested secondhand flour bags; (5) from infested secondhand machinery; (6) from infested feed stored in the mill near the milling machinery. The principal measures employed for control are fumigation or sterilization'of incoming grain, frequent repair of flour sifters, cleaning and fumigation of conveyors, and general fumigation of the mill with lethal gases such as hydrocyanic acid gas, chloropicrin and methyl bromide. Supplementary control measures consist of spraying neglected corners, woodwork, etc., with pyrethrum and thiocyanate sprays, rebolting of flour which is being reconditioned, diversion of infested returned stocks, proper handling and storage of finished flour and fumigation and proper construction of warehouses. The beetles are often a source of annoyance to the housewife. All dry foods should be kept in tight containers; if the food becomes infested, it may be sterilized in a hot oven. Heavily infested supplies should be destroyed.

Other common flour beetles are the broad-horned flour beetle (*Gnathocerus cornutus),* the small-eyed flour beetle (*Palorus ratzeburgi*) and the long-headed flour beetle *(Laetheticus oryzae*). These are widely distributed forms similar in habits to the species of *Tribolium.*

See R. *T.* Cotton, *Insect Pests of Stored Grain and Grain Products* (1941). (R. L. WL.)

FLOURENS. GUSTAVE (1838–1871), French revolutionary and one of the most romantic figures of the Commune, mas born on Aug. 4, son of Pierre Flourens *(see* below). Gustave was trained by his father to succeed him. and had a brilliant scientific career up till his father's death in 1867, when the Collège de France, to which his evolutionary theories and his republican opinions were equally objectionable, abruptly signified that it had no further use for his services. Flourens indignantly left the country and went to Crete, where he joined the ranks of the insurrection against Turkey. In this hard guerrilla warfare he gained his chief military experience, and acquired such prestige among the Cretans that he was chosen president of the delegation elected by Crete in 1868 to sit in the Hellenic parliament. Had it been admitted *(see* TURKEY: *History),* war between Greece and Turkey might well have resulted; the Greek government solved their difficulties by kidnapping Flourens and sending him to France, while they turned his colleagues back to Crete. He then carried on republican propaganda in Naples till he was imprisoned, and in France, where he was dangerously wounded in a duel with Paul de Cassagnac. At the funeral of Victor Noir (Jan. 12, 1870) he attempted with his usual impetuosity, to lead an insurrection, but was thwarted by Rochefort, Delescluze, and Blanqui (*qq.v.*): he did in fact attempt a rising on Feb. 7, which collapsed at once, and he was condemned to imprisonment in a fortified place. During the siege of Paris he was ardently patriotic and commanded, first five battalions raised in Belleville, then a corps of tirailleurs. Together with 23 other *chefs de bataillon* he overturned the government on Oct. 31, 1870, charging it with treachery, but as he received support from no politician but Blanqui, withdrew from the hotel de ville after negotiation. On the outbreak of the Commune (March 18, 1871) Flourens was elected for the 19th and 20th *arrondissements* and made a colonel. He attempted by a personal example of bravery and devotion to diminish the incoherence and disorder around him: he exposed himself too rashly at Rueil in the sortie of April 3, was captured, and killed while a prisoner by a sabre cut from an officer.

See the *Grand Dictionnaire, etc., Larousse* (1869 etc.) *s.v.*
(R. W. P.)

FLOURENS, PIERRE (1794–1867), French physiologist, was born at Maureilhan, near Béziers, on April 15, 1794. After taking his M D. at Montpellier, Flourens began physiological research in Paris and in 1822 published his *Recherches expérimentales sur les propriétés et les fonctions du systkme nerveux dans les animaux vertébrés,* in which he, from experimental evidence, sought to assign their special functions to the cerebrum, corpora quadrigemina and cerebellum. He was chosen by Cuvier in 1828 to deliver for him a course of lectures at the Collège de France. In 1832 a professorship of comparative anatomy was created for him at the museum of the Jardin. In 1833 Flourens, in accordance with the dying request of Cuvier, was appointed a perpetual secretary of the Academy of Sciences, and in 1838 was returned as a deputy for the arrondissement of Béziers. In 1840 he was elected, in preference to Victor Hugo, to succeed J. F. Michaud at the French Academy; and in 1846 he was created a peer of France. In 1847 Flourens directed the attention of the Academy of Sciences to the anaesthetic effect of chloroform on animals. At the revolution of 1848 he withdrew completely from political life, and in 1855 he accepted the professorship of natural history at the Colltge de France. He died at Montgeron, near Paris, on Dec. 6, 1867.

Besides numerous shorter scientific memoirs, Flourens published *Expériences sur le système nerveux* (1825); *Cours sur la génération, l'ovologie, et l'embryologie* (1836): *Analyse raisonnée des travaux de G. Cuvier* (1841); *Buffon, hirtoire de ses travaux et de ses idées* (1844); *Fontenelle, ou de la philosophie moderne relativement aux sciences pkysiques* (1847); *Oeuvres complbtes de Buffon* (1853); *De la longdvitd humaine* (1854), *Histoire de la de'couverte de la circulation du sang* (1854); *Cours de physiologie compare'e* (1856); *De la vie et de l'intelligence* (1858); *De la raison, du génie, et de la folie* (1861); *Examen du livre de M. Darwin sur l'Origine des Espèces* (1864). For a list of his papers *see* the Royal Society's *Catalogue of Scientific Papers.*

FLOWER, SIR WILLIAM HENRY (1831–1899), English biologist who greatly influenced museum display, was born at Stratford-on-Xvon on Nov. 30, 1831. He took his M.B at London in 1851, and went to the Crimea as assistant-surgeon. On his return he became a member of the surgical staff of the Middlesex hospital, London, and in 1861 curator of the Hunterian museum of the Royal College of Surgeons In 1870 he also became Hunterian professor, and in 1884 was appointed to the directorship of the Natural History department of the British museum at South Kensington. He died in London on July 1, 1899. He made valuable contributions to structural anthropology and to the comparative anatomy of mammals.

His chief publications are: *Diagrams of the Nerves of the Human Body* (1861); *The Osteology of the Mammalia* (1870); *Introduction to the Study of Mammals, Living and Extinct* (1891); *Essays on Museums and other Subjects* (1898).

See C. J. Cornish, Sir *W.* H. *Flower* (1904), and *R.* Lydekker, *Sir William Flower* (1906).

FLOWER, a term popularly used for the blossom of a plant, and so by analogy for the finest part or aspect of anything. Here it is dealt with only botanically. The flower is characteristic of the highest group of plants—the flowering plants (Phanerogams)—and is the association of more or less leaf-like organs which are concerned with the production of the seed. In modern botany the group is often known as the seed-plants or Spermatophyta (*see* ANGIOSPERMS and GYMNOSPERMS). Following pollination, a seed develops from the ovule; the essential structures for seed production are the *stamens,* which bear the pollen, and the *carpels,* on which the ovules are formed. In comparative morphology, stamens and carpels are known as *sporophylls* because they bear the microspores developed in the microsporangia, or the megaspore developed in the megasporangium. Following germination *of* the megaspores, these are known as pollen grains, and the microsporangia as pollen sacs. The megasporangium, together with an outgrowth of maternal tissue, the integument, constitutes the ovule. In the more primitive gymnosperms the micro- or megasporophylls are generally associated in separate cones, to which the term "flower" has been applied. But it is to more definite and elaborate structures in the higher angiosperms that "flower" generally refers.

Bracts.—Flowers are produced from flower-buds in the axils of leaves called *bracts;* "bract" is properly restricted to the leaf from which the primary floral axis arises, while leaves which arise between the bract and the flower are *bracteoles.* Their arrangement is similar to that of foliage leaves. In many cases, bracts protect the young flower, but they are sometimes undeveloped, and usually fall off early. Sometimes, especially with bracteoles, no flower-buds arise in their axils. At the base of the general umbel in umbelliferous plants is often a whorl of bracts, the *general involucre,* while *partzal involucres* or *involucels* are found at the base of the umbellules. In Compositae the involucre surrounds the heads of flowers (fig. 12). A sheathing bract or *spathe,* enclosing one or several flowers is common among monocotyledons and may, in some palms, reach 20 ft. in length and enclose 200,000 flo ers. The spathe may be coloured *(Anthurzum)* or white (arum lily, *Zantedeschia ethiopica*). In grasses, the outer scales (glumes) of the spikelet are sterile bracts. Bracts may be changed into leaves.

Inflorescence.—The arrangement of flowers on the axis is called the *inflorescence.* The primary axis of the inflorescence is the *rachzs;* its branches, when present, are *peduncles,* which in turn may give rise to *pedicels.* A flower having a stalk is pedunculate or pedicellate; one with no stalk is sessile. To obviate any confusion, it is common to speak of the rachis as the *primary* floral axis, the peduncles as the *secondary* floral axes, and so on. The peduncle may be simple, bearing a single flower, or branched. When it proceeds from radical leaves, it is a *scape.* The floral axis may be shortened, as in daisy and fig, or flattened, convex or concave in form and bearing numerous flowers, as in marigold or in fig. Adhesions occasionally take place between the peduncle and the bracts, as in the lime-tree (fig. 1). The termination of the part upon which the whorls of the flower are arranged is the *receptacle.*

Two general types of inflorescences are recognized. In one, the flowers arise as lateral shoots from a primary axis, which continues to elongate, and the lateral shoots do not exceed the length of the primary axis. The flowers are said to be *axillary* and the inflorescence is *indeterminate.* In the other type, the primary axis ends in a single flower, but lateral axes arise from the axils of bracts and repeat the process, the development of each lateral axis being stronger than that of the primary axis beyond its point of origin. The flowers are thus *terminal* and the inflorescence is *determinate.* In indeterminate inflorescences, the lower or outer flowers expand first *(centrzpetal)*: in determinate inflorescences, it is the upper or inner flowers that open first *(centrifugal).* In some inflorescences (*mixed*), the primary axis has an arrangement belonging to one type, the branches one of the opposite type.

The simplest indeterminate form is one in which a lateral shoot in the axil of a single foliage leaf ends in a single flower. In this case the flower is *solitary.* A more complicated inflorescence is commoner. Thus if the primary axis, as in fig. 2, is elongated and gives off pedicels ending in a single flower a *raceme* is produced, which becomes a *panicle* if the secondary axes branch. If the lower flower-stalks art? developed more strongly than the upper, and thus all the flowers are on a level, a *corymb* is formed, which may be simple (fig. 4) or branched. If the pedicels are wanting, so that the flowers are sessile, the result is a *spike.* If this bears unisexual flowers it is a *catkzn;* if it becomes succulent and surrounded by a spathe it is a *spadix,* which may be simple (fig. 7) or branched. A spike with female flowers only and covered with scales, as in the hop, is a *strobilus.* In grasses there are usually numerous sessile flowers in small spikes (*spikelets*); if these are borne not on the primary but on secondary axes, they form a *panzcle.*

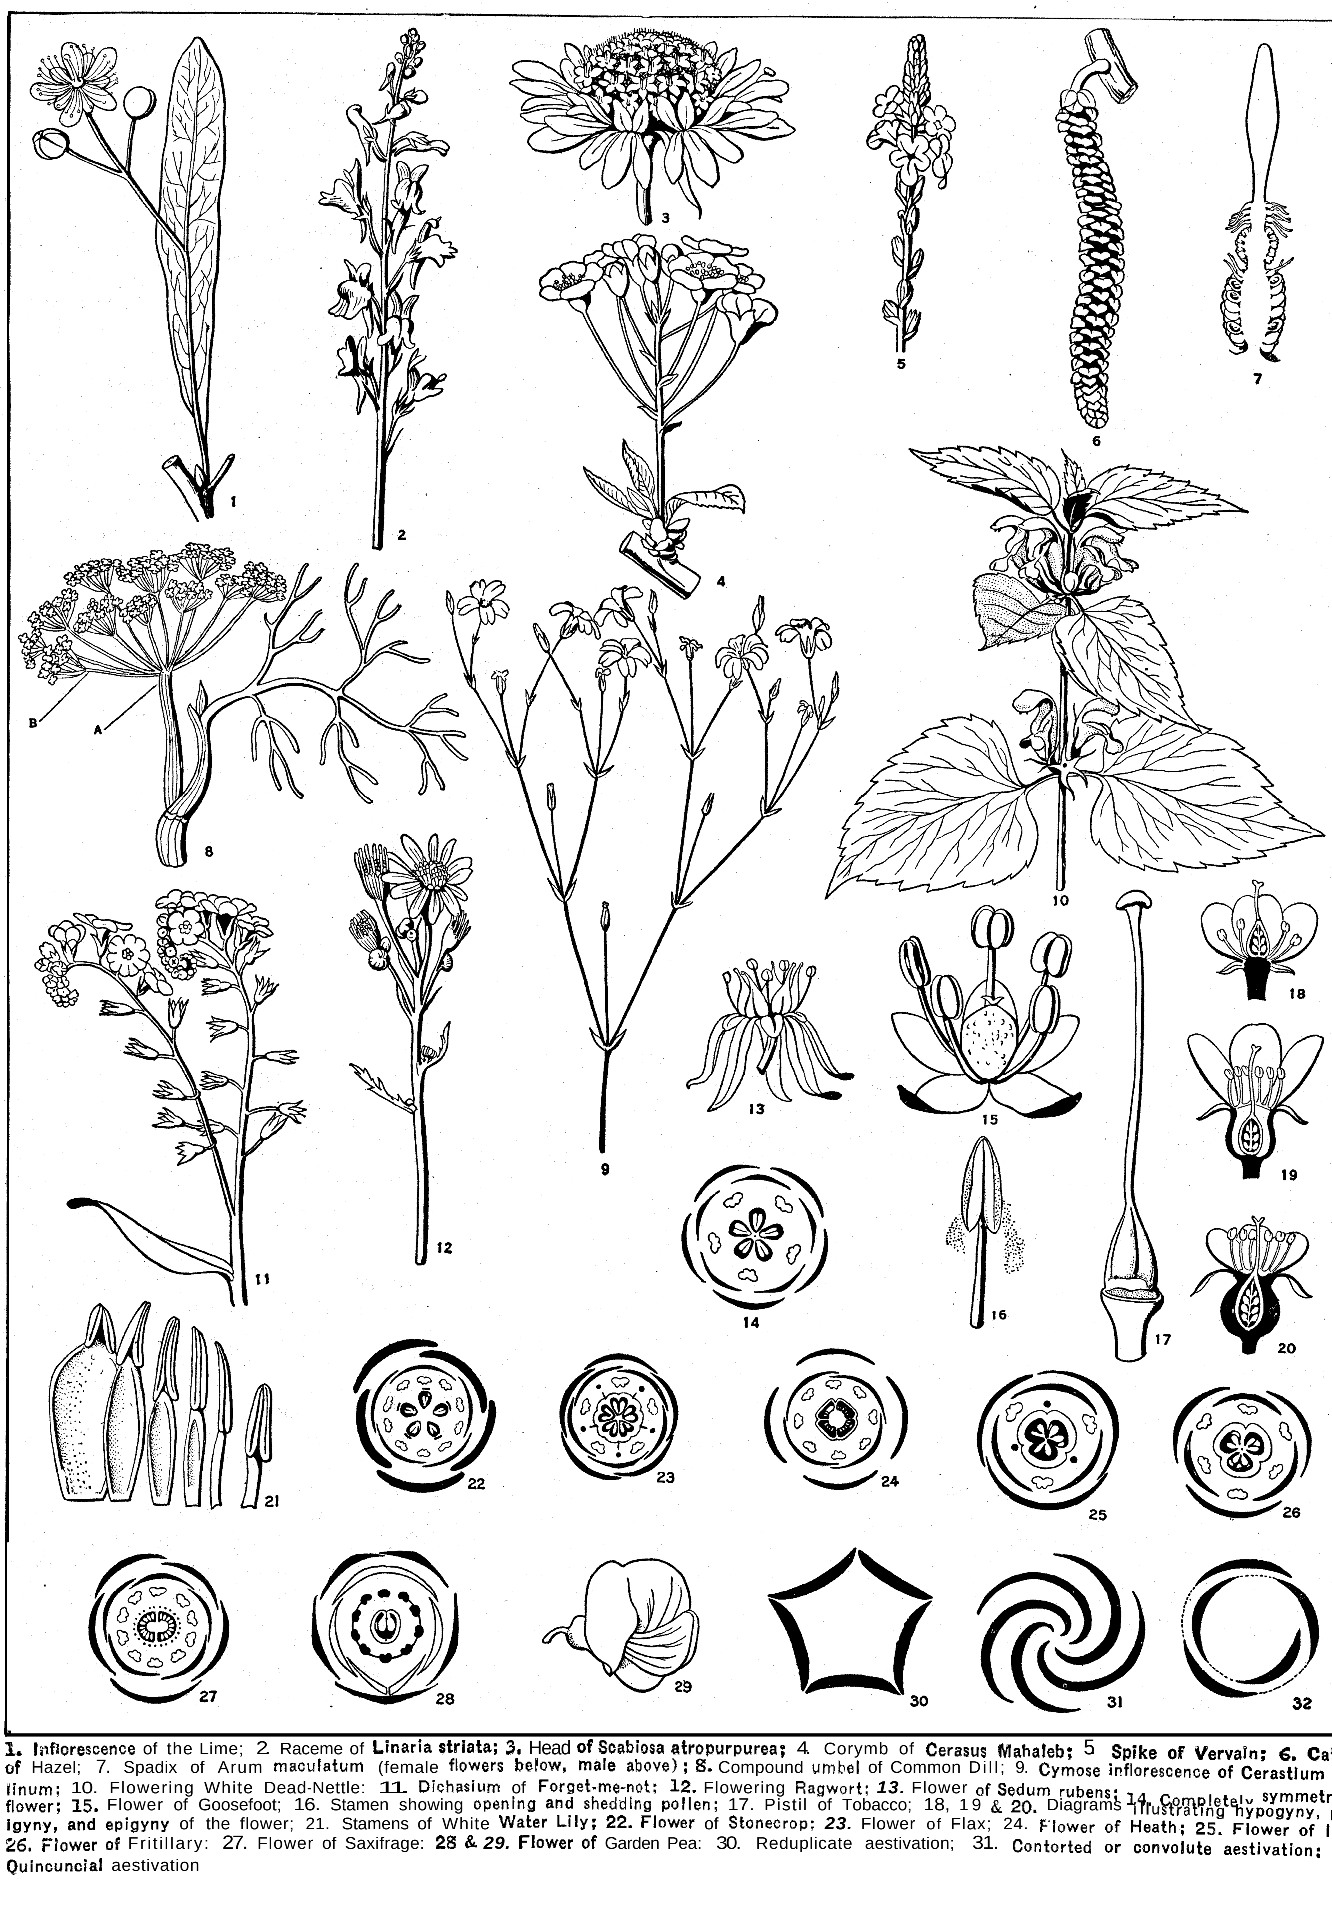
If the primary axis is contracted, other forms result. When it is so short that the secondary axes arise from a common point and spread out as radii of nearly equal length each ending in a single flower or dividing again similarly, an *umbel* (fig 8) is produced. If there are numerous flowers on a flattened, convex or concave receptacle, having short pedicels or none, a *capitulum* is formed, as in marigold and scabiosa (fig 3). If the margins of the receptacle are developed upwards, they may ultimately give rise to the *hypanthium* of the fig.

In compound indeterminate inflorescences, the lateral shoots, developed centripetally, bear numerous bracteoles from which floral shoots arise, which may have a centripetal arrangement similar to that on the mother shoot, or a different one. Thus we may have a group of racemes arranged in a racemose manner; compound umbels as in most Umbelliferae (fig. 8); a raceme of capitula; a raceme of umbels, as in ivy, and so on.

The simplest type of determinate inflorescence is where, as in *Anemone nemorosa,* the axis terminates in a single flower, no other flowers being produced on the plant This is a *solitary terminal* inflorescence. When the primary floral axis, before ending in a flower, gives off lateral unifloral axes which repeat the process, the result is a *cyme.* A cyme with two axes is a *biparous* cyme or *dichasium* (fig. 11); with one axis, it is *uniparous.* In the dead-nettle *(Lamzum)* the flowers arise in the axis of each foliage leaf and appear as if arranged in a whorl, but there is a central flower expanding first, and from its axis spring secondary axes bearing single flowers (fig. 10). The inflorescence is thus a dichasium and the clusters are called *vertzczllasters.* Where numerous lateral axes arise from the primary axis, a *cymose umbel* is produced. When these lateral axes grow strongly and develop irregularly, as in species of *Juncus,* the inflorescence is an *anthela.* In a uniparous cyme, the basal portion of the consecutive axes may become thickened and arranged more or less in a straight line, forming a false axis or *sympodium,* the inflorescence thus simulating a raceme. The uniparous cyme presents two forms; in a *scorpzoid* cyme the flowers are arranged alternately in a double row along one side of the sympodium, the bracts forming another double row on the opposite side (*e.g.,* Boraginaceae). In-a *helicoid* cyme, the flowers are in a single row and form a spiral round the false axis.

Compound definite inflorescences are by no means common, but in *Streptocarpus polyanthus* and in several calceolarias we probably have examples. Here we find *scorpzoid cymes of pairs of flowers,* each pair consisting of an older and a younger flower.

Both the determinate and indeterminate types are represented in mixed inflorescences. Thus in the ragwort (fig. 12) the *heads* of



1. Inflorescence of the Lime; 2. Raceme of Linaria striata; 3. Head of Scabiosa atropurpurea; 4. Corymb of Cerasus Mahaleb; 5 Spike of Vervain; 6. Catkin of Hazel; 7. Spadix of Arum maculatum (female flowers below, male above); 8. Compound umbel of Common Dill; 9. Cymose inflorescence of Cerastium collinum; 10. Flowering White Dead-Nettle: 11. Dichasium of Forget-me-not; 12. Flowering Ragwort; 13. Flower of Sedum rubens; 14. Completely symmetrical flower; 15. Flower of Goosefoot; 16. Stamen showing opening and shedding pollen; 17. Pistil of Tobacco; 18, 19 & 20. Diagrams illustrating hypogyny, perigyny, and epigyny of the flower; 21. Stamens of White Water Lily; 22. Flower of Stonecrop; 23. Flower of Flax; 24. Flower of Heath; 25. Flower of Iris; 26. Flower of Fritillary: 27. Flower of Saxifrage: 28 & 29. Flower of Garden Pea: 30. Reduplicate aestivation; 31. Contorted or convolute aestivation; 32. Quincuncial aestivation

flowers are developed centrifugally, while the *florets* open centripetally. Various combinations occur in different families.

Tabular View of Inflorescences

A. Indeterminate Centripetal Inflorescences.
- I. Flowers solitary, axillary, *Veronica hederifolia.*
- II. Flowers in groups, pedicellate.
  - i. Elongated form (Raceme), *Hyacinth;* (Corymb), *Prunus.*
  - ii. Contracted form (Umbel), *Cowslip.*
- III. Flowers in groups, sessile.
  - i. Elongated form (Spike), *Plantago.*
    - (Spikelet), *grasses.*
    - (Catkin), *Hazel.*
    - (Spadix), *Arum.*
    - (Strobilus), *Hop.*
  - ii. Contracted form (Capitulum), *Daisy.*
- IV. Compound Indeterminate Inflorescences.
  - *a.* Compound Spike, *Rye-grass.*
  - *b.* Compound Spadix, *Palms.*
  - c. Compound Raceme, *Astilbe.*
  - d. Compound Umbel, most *Umbelliferae.*
  - *e.* Raceme of Capitula, *Petasites.*
  - *f.* Raceme of Umbels, *Ivy.*

B. Determinate Centrifugal Inflorescences.
- I. Flowers solitary, terminal, *Tulip.*
- II. Flowers in cymes.
  - 1. Uniparous Cyme.
    - a. Helicoid Cyme.
      - (i) Elongated, *Alstroemeria.*
      - (ii) Contiacted, *Wittsteznra corymbosa.*
    - *b.* Scorpioid Cyme.
      - (i) Elongated, *Forget-me-not.*
      - (ii) Contracted, *Erodium.*
  - 2. Biparous Cyme (including Dichasium, Cymose Umbel).
    - *a.* Elongated, *Cerastium.*
    - *b.* Contracted (Verticillaster), *Dead-nettle.*
  - 3. Compound determinate Inflorescence. Many *Calceolarias.*

C. Mixed Inflorescences.
- Raceme of Scorpioid Cymes, *Horse-chestnut.*
- Scorpioid Cyme of Capitula, *Vernonia scorpioides.*
- Compound Umbel of dichotomous Cymes, *Viburnum.*
- Capitulum of contracted Scorpioid Cymes (Glomerulus), *Sea-pink.*
- Cyme of Capitula, *Rag-wort.*

Parts of the Flower.—The flower consists of the floral axis bearing the sporophylls (stamens and carpels) usually with protective envelopes. The axis is normally contracted, no internodes being developed and the portion beanng the floral leaves, the receptacle, is frequently a conical, flattened or hollowed expansion; rarely the axis is elongated and internodes are developed. Upon the receptacle the parts of the flower are crowded, usually forming a series of whorls, the parts of which alternate, but sometimes arranged spirally, especially if the axis is elongated. In a typical flower (fig. 22) there are four distinct whorls, an outer *calyx* of, *sepals;* within it, the parts alternating with those of the calyx, is the *corolla* of *petals;* next alternating with the parts of the corolla, the *androecium* of *stamens;* and in the centre, the *gynoecium* of *carpels.* Fig. 14 is a diagrammatic representation (*floral dzagram)* of such a flower, supposed to be cut transversely, the parts of each whorl being distinguished by a different symbol. The sepals are usually greenish, their function is mainly protective, shielding the delicate internal organs before the flower opens. The petals are usually showy. Sometimes (usually in monocotyledons) the calyx and corolla are similar; in such cases the term *periantlz* is applied, and the parts of the calyx are *petaloid.* In some cases the petals resemble sepals *(sepaloid).* In plants, as *Nymphaea alba* (fig. 21), where a spiral arrangement of floral leaves occurs, these tvhorls pass insensibly into each other. When both calyx and corolla are present, the plant is *dichlamydeous;* when one is absent, *monochlamydeous* (fig. 15). Sometimes both are absent *(achlamydeous),* as in willow. The stamens in their most differentiated form consist each of a stalk, the *filament,* and the *anther* (fig. 16) the latter composed of pollen sacs containing the powdery pollen which is ultimately discharged. The *gynoecium* or *pistil* terminates the floral axis. It consists of one or more carpels, separate or fused together (figs. 13, 17). The pistil is composed of the *ovary* (figs 17, 18), which contains the *ovules* destined to become seeds; the **stigma,** or receptive surface on which the pollen is deposited, and which is either sessile on the apex of the ovary as in the poppy or separated from it by a long *style.* The androecium and gynoecium are not present in all flowers. When both are present the flower is *hermaphrodite, perfect,* or *monoclinous,* and is represented by the symbol ☿. When only one is present the flower is *unisexual* or *diclinous,* and is either male *(staminate),* ♂, or female (*pistillate*), ♀. When all four whorls of organs are present the flower is *complete.* Usually the successive whorls of the flower, disposed from below upwards or from without inwards upon the floral axis, are of the same number of parts, or are a multiple of the same number of parts, those of one whorl alternating with those of the whorl next to it.

In the more primitive types of flower the receptacle is more or less convex, and the series of organs follow in regular succession, culminating in the carpels (fig. 18). This arrangement is *hypogynous,* the other series being beneath *(hypo)* the gynoecium. In other cases the floral organs spring from a cup around the ovary (*perigynous,* fig. 19). In some forms this is carried further and a cavity is roofed over by the carpels so that the outer members of the flower spring from the edge of a **cup** the rim of which is above the ovary (*epigynous,* fig. 20).

Symmetry of the Flower.—When a flower consists of parts arranged in whorls it is *cyclic,* and if all the whorls have an equal number of parts and are alternate it is *eucyclic* (figs. 14, 25). In contrast to cyclic flowers are those where the parts are in spirals *(acyclic).* Flowers which are cyclic at one portion and spiral at another (as many Ranunculaceae) are *hemicyclic.* In spiral flowers there is usually a gradual passage from sepaloid through petaloid to staminal parts (water lily, **fig.** 21). In some cases the parts of one whorl are opposite or *superposed* to those of the next. The superposition of the stamens on the sepals in the Caryophyllaceae is due to the suppression of the petals.

A flower is *symmetrical* when each whorl consists of an equal number of parts, or when the parts of any one whorl are multiples of that preceding it. Thus, a symmetrical flower may have five sepals, five petals, five stamens and five carpels (fig. 14) or the number of any of these parts may be a multiple of five. In the staminal whorl especially it is common to find additional rows. In fig 24 the parts are in fours; in figs. 25 and 26, in threes. The floral envelopes are rarely multiplied. Flowers in which the number of parts in each whorl is the same are *isomerous;* when the number in some whorls is different, the flower is *anisomerous.* It often happens that when fully formed, the number of parts in the pistillate whorl is not in conformity with that in the other uhorls. In such circumstances a flower is called symmetrical, provided that the other whorls are normal (fig. 27). A flower in which the parts are arranged in twos is *dimerous;* in threes, fours or fives, *trimerous, tetramerous* or *pentamerous* respectively. Trimerous symmetry is the rule in the monocotyledons, pentamerous the commonest in the dicotyledons, though dimerous and tetramerous flowers also occur in the latter group.

The various parts of the flower have a definite relation to the central axis. Thus in a tetramerous flower, one sepal may be next the axis (superior or posterior), another next the bract (inferior or anterior) and the other two *lateral* (fig. 24). *A* plane passing through the anterior and posterior sepals and through the floral axis is the *median* plane of the flower; a plane cutting it at right angles and passing through the lateral sepals, is the *lateral* plane; while the planes which bisect the angles formed by the lateral and median planes are *diagonat* planes In a pentamerous flower one sepal may be superior (Rosaceae and Labiatae) or inferior (pea family, figs. 28, 29); in the latter case the odd petal *(vexillum)* is then superior. In the Scrophulariaceae one of the two carpels is posterior, the other anterior, while in the Convolvulaceae the carpels are lateral.

When the different members of each whorl are alike, the flower is *regular;* differences in size and shape of the parts of a whorl make the flower *irregular* (fig. 28). When a flower can be divided by a single plane into two similar parts it is *zygomorphic* (as in Papilionaceae). Polysymmetrical flowers have a radial symmetry and can be divided by several planes into similar portions; such are all regular, symmetrical flowers. When the parts of any whorl are not equal to, or some multiple of, the others, the flower is asymmetrical. This alteration in the symmetrical arrangement has been traced to suppression or non-development of parts, degeneration or imperfect formation, cohesion or union of parts of the same whorl, adhesion or union of parts of different whorls, *multiplication* of parts and deduplicatzon (chorisis) or splitting of parts. Cultivation has a great effect in causing changes in the various parts of a plant. The changes in colour and form of flowers thus produced are endless.

As a convenient method of expressing the arrangement of the parts of a flower, *floral* formulae have been derived. The following is a simple mode: the whorls are represented by the letters S (sepals), P (petals), A (stamens), C (carpels) and a figure marked after each indicates the number of parts in that whorl. Thus $S5P5A5C5$ means that the flower is perfect; isomerous and pentamerous. The flower of Sedum (fig. 22) would be represented by $S5P5A5+5C5$, where $A5+5$ indicates that the staminal whorl consists of two rows of five parts each.

Aestivation. — The manner in which the parts are arranged in the flower-bud with respect to each other before opening is the aestivation, and distinctive names have been given to the different arrangements exhibited, both by the perianth members individually and in their relation to each other. As regards each perianth member of the flower, it is either spread out, as the sepals in the bud of the lime-tree, or folded upon itself (*conduplicate*), or slightly folded inwards or outwards at the edges, as in the calyx of some species of Clematis, or rolled up at the edges (involute or revolute), or folded transversely, becoming crumpled or corrugated as in the poppy.

When the parts of a whorl are in an exact circle, and are applied to each other by the edges only, without overlapping or folding, aestivation is *valvate*. The edges of each of the parts may be turned inwards (induplicate) or outwards (reduplicate). When the floral members overlap in the bud, two arrangements are found. In the convolute (contorted or twisted) condition, the parts may be rolled or wound together, covering each other completely, or the petals or other segments may cover each other partially, in which case the edge of one petal is overlapped by the one before it, while the other edge in turn overlaps the next segment. In imbricate aestivation an outer member overlaps the margins of the inner segments on both sides. When the parts are five, as in many dicotyledons, there may be two parts external, two internal and a fifth which partially covers one of the inner parts by its margin and is in turn partially covered by one of the external parts (quzncuncial), as in the calyx of Rosaceae. In the Leguminoseae, the vexillum is often large and folded over the others (vexillary) or the carina (the two anterior petals) may perform a similar office (carinal). Circular aestivation is generally associated with a regular calyx and corolla while spiral aestivation is connected with irregular as well as regular forms.

FLORAL ENVELOPES

Calyx. — The sepals are sometimes free or separate from each other, at other times united to a greater or less extent; in the former case, the calyx is polysepalous, in the latter *gamosepalous* or monosepalous. The divisions of the calyx are usually entire, but occasionally are cut (rose); rarely they are stalked Sepals are generally more or less oval, elliptical or oblong, with blunt or acute apices. They may be erect or reflexed, spreading downwards (divergent or *patulous*) or arched inwards (connzvent). They are usually greenish (herbaceous) but sometimes they are coloured (petaloid). The vascular bundles sometimes form a prominent mid-rib, at other times, several ribs. The venation is useful as pointing out the number of leaves in a gamosepalous calyx. A polysepalous calyx with three sepals is *trisepalous*, with five, *pentasepalous*, etc. The sepals are occasionally of different forms and sizes. The number of members in a gamosepalous calyx is usually marked by divisions at the apex, which may be simple projections or may extend down as fissures, the calyx being *trifid* (three-cleft), *quinquefid* (five-cleft), etc.; or they may reach nearly to the base, the calyx being tripartite, *quinque*-partite, etc. The union of the parts may be complete and the calyx entire or truncate. The cohesion is sometimes irregular; thus a two-lipped or labzate calyx arises. Occasionally certain parts of the sepals are enlarged to form a spur as in *Tropaeolum*, Viola and Pelargonium. Degeneration may take place so that the calyx becomes dry and scaly (Juncaceae) ; or hairy (Compositae); or a mere rim (madder), when it is obsolete or marginate. In Compositae, the calyx is attached to the pistil and its limb is developed into hairs (*pappus*). The calyx sometimes falls off before the flower opens, as in poppies (*caducous*, fig. 36); or with the corolla, as in *Ranunculus* (deciduous), or it remains after flowering (persistent) as in Labiatae, or its base only is persistent. Sometimes a persistent calyx encloses the fruit without being incorporated with it (accrescent); or it may become inflated or vesicular (Lychnis).

Corolla. — The corolla is the inner floral envelope, and usually the most conspicuous whorl. As a rule the petals are highly coloured, the colouring matter being contained in the cell-sap (blue and red flowers) or in *plastids* (chromoplasts) as in yellow flowers, or in both (orange flowers). Petals are generally glabrous, but in some instances hairs are produced. They often close the way to the honey-secreting part of the flower to small insects whose visits would be useless for pollination. Coloured hairs occur on the perianth of Iris. Normally thin and delicate petals occasionally become thick and fleshy (*Rafflesia*), dry (heaths), or hard and stiff (*Xylopia*) Each petal often consists of two parts, a lower narrow unguis or claw, and an upper, broad lamina or lzmb (fig. 38). The claw is often wanting (fig 39) and the petals are then sessile. The limb may be flat, concave or hollowed. In hellebore the petals become tubular (fig. 40); in aconite (fig. 42), some resemble a hollow-curved horn, supported on a grooved stalk; while in columbine and violet (fig. 41) one or all are prolonged as a spur. In *Antirrhinum*, the spur is short and the petal is gibbous or saccate. These spurs, tubes and sacs serve as receptacles for nectar.

A corolla is *dipetalous*, *tripetalous*, etc., according as it has two, three, etc., separate petals; the general name *polypetalous* is given to corollas with separate petals, while those in which the petals are united are *monopetalous*, gamopetalous or sympetalous. This union generally takes place at the base and extends towards the apex. In the vine, the petals are separate at the base, adherent at the apex. In a sympetalous corolla the lower portion usually forms a tube, the upper parts a common limb, the point of union being the throat. The number of parts is determined by the divisions (teeth, fissures, etc.), or when, as rarely, the corolla is entire, by the venation. The union may be equal, or some parts may unite more than others.

Among regular polypetalous corollas may be noted that of the Rosaceae, usually composed of five petals; the *caryophyllaceous* corolla, in which there are five clawed petals;' the cruciform, having four petals in the form of a cross, as in the wallflower. Of irregular polypetalous corollas, the most marked is the *papilionaceous* (fig. 28–29), in which there are five petals — one superior next to the axis, usually larger than the rest; the *vexillum* or *standard;* two lateral, the alae or wings; two inferior, often united slightly to form a single keel or *carina*, which embraces the essential organs.

Regular sympetalous corollas may be campanulate or *bell*-shaped (*Campanula*); *hypocrateriform* or salver-shaped (Primula, fig 43) tubular (comfrey); rotate or wheel-shaped (forget-me-not) ; urceolate or *urn-shaped* (bell-heath). Some of these forms may become irregular as a result of certain parts developing more than others; thus in the foxglove there is a slightly irregular campanulate corolla. Other irregular sympetalous corollas include the labiate or lipped, having two divisions of the limb, the upper usually of two, the lower of three, united petals, separated by a gap. When the upper lip is much arched, and the gap is distinct, the corolla is *ringent;* when the gap is reduced to a chink, as in snapdragon, personate. In Calceolaria the lips become much hollowed out. When a tubular corolla is split to

form a strap-like process on one side, it is *ligulate* or *strap* shaped (fig. 44), as in many Compositae.

Petals are sometimes suppressed and at times the whole corolla is absent. In *Amorpha* there is only a single petal. In the Ranunculaceae some genera (e.g., *Ranunculus*) have both calyx and corolla, while others (e.g., Anemone) have only a coloured calyx.

The term *nectary* includes those parts of a flower which secrete a honey-like substance, as the glandular depression on the petal of Ranunculus (fig. 39). The honey attracts insects, which convey pollen to the stigma. The horn-like nectaries under the galeate (hollow and vaulted) sepal of Aconitum (fig. 42) are modified petals, as are the tubular nectaries of hellebore (fig. 54).

Petals are attached to the axis usually by a narrow base. When this attachment is by an articulation, the petals fall off either immediately after expansion (*caducous*) or after fertilization (deciduous). A corolla continuous with axis, as in *Campanula,* may remain in a withered state while the fruit is ripening. A sympetalous corolla falls off in one piece.

ESSENTIAL ORGANS

As a stamen represents a leaf developed to bear pollen or microspores, it is spoken of in comparative morphology as a microsporophyll; similarly the carpels which make up the pistil are the megasporophylls (see ANGIOSPERMS). In plants with hermaphrodite flowers, self-pollination is often provided against by the structure of the parts or by the period of ripening of the organs For instance, in Primula (fig. 43), some flowers (thrum-eyed) have long stamens and a short styled pistil, others (pin-eyed) short stamens and a long-styled pistil; these are dimorphic. In some plants the stamens are perfected before the pistil (*proterandrous*); more rarely, the pistil is perfected first (*protogynous*). Plants in which protandry or protogyny occur are dichogamous. When the same plant bears unisexual flowers of both sexes it is *monoecious* (hazel); when the male and female flowers are on separate plants, the plant is *dioecious* (hemp); when there are male. female and hermaphrodite flowers, it is polygamous.

Stamens.—The stamens, collectively constituting the androecium, arise from the receptacle within the petals, with which they generally alternate, forming one or more whorls. Their normal position is below the pistil (inferior), but they may be above (superior) or, as in Saxifragaceae, half inferior or half superior. Sometimes they adhere to the petals (*epipetalous*), or to the pistil, so as to form a column (*gynandrous*). These arrangements are important in classification. Stamens vary in number from one to many, even hundreds. In acyclic flowers there is often a gradual transition from petals to stamens, as in the white water lily (fig. 21). When there is only one whorl the stamens are usually equal in number to the sepals or petals. The additional rows of stamens may be developed in centripetal order or interposed between the pre-existing ones or placed outside them, *i.e.,* be developed centrifugally (geranium). When the stamens are fewer than 20, they are determinate; when more, indeterminate, represented by the symbol ∞. A flower with one stamen is *monandrous,* with two, diandrous, with many, *polyandrous,* etc.

The function of the stamen is the development and distribution of the pollen, which is contained in the anther. If the latter is absent, the stamen cannot perform its functions. The anther is developed before the filament, which may be absent (*e.g.,* mistletoe), when the anther is sessile.

The Filament.—The filament is usually thread-like and cylindrical, or slightly tapering towards its summit. It may, however, be thickened and flattened in various ways. The length sometimes bears a relation to that of the pistil, and to the position of the flower. Though usually of sufficient rigidity to support the anther in an erect position, the filament is sometimes (e g., grasses) delicate and hair-like, so that the anther is pendulous (fig. 68). It is generally continuous, but sometimes is bent or jointed (geniculate), or spiral (*e.g.,* pellitory). In Fuchsia it is red, in *Adamia,* blue; in Ranunculus *acris,* yellow. The filament is usually articulated to the receptacle and the stamen falls off after fertilization, but in Campanula, the stamens remain in a withered state. The filaments may cohere to a greater or lesser extent, the anthers remaining free. Thus, all the filaments may unite to form a tube round the pistil (*e.g.,* mallow), the stamens being *monadelphous,* or they may be arranged in two bundles (*diadelphous*), as in the pea, where nine out of ten unite, the posterior one being free (fig. 45).

The Anther.—The anther consists of lobes containing the minute pollen qrains, which, when mature, are released through an opening. There is a double covering to the anther—the outer exothecium resembling the epidermis and often bearing stomata; the inner *endothecium* formed by a layer or layers of cellular tissue, the cells of which have thickened walls. The endothecium generally becomes thinner towards the part where the anther opens out, and there disappears. The anther appears first as a simple protuberance of meristem, upon which indications of two lobes soon appear. Cpon these projections rudiments of the pollen-sacs, usually four, two on each lobe, are seen. In each differentiation takes place in the layers beneath the epidermis, by which an outer small-celled layer surrounds an inner one of larger cells. These central cells are the pollen mother-cells, the outer cells forming the endothecium while the exothecium arises from the epidermis.

When all four pollen-sacs remain permanently the anther is quadrilocular (fig. 46). Sometimes, however, the sacs in each lobe unite to give a bilocular anther. Further fusion of the lobes or the abortion of one of them (*e.g.,* hollyhock) leads to a *unilocular* anther. Occasionally there are numerous cavities in the anther (*e.g.,* mistletoe). The lobes are generally more or less oval or elliptical. The division between them is marked on the face of the anther by a furrow, and there is usually a suture indicating the line of dehiscence. Stamens may cohere by their anthers becoming syngenesious (*e.g.,* Compositae).

The Connective.—The anther-lobes are united by the connective which is either continuous with the filament or articulated with it. When the filament is continuous and prolonged so that the lobes appear to be united throughout their length, the anther is adnate or adherent. When the filament ends at the base of the anther, the latter is innate or erect. In these cases the anther is fixed. When, however, the attachment is narrow and an articulation exists, the anthers are movable (versatile) as in grasses (fig. 68). The connective is sometimes extended backwards and downwards (*e.g.,* violet) to form a nectar-secreting spur.

Anther *Dehiscence.*—The opening or dehiscence of the anthers to discharge their content takes place by clefts, valves or pores. When the anther-lobes are erect, the cleft is along the line of suture—longitudinal dehiscence (fig. 16). In other instances the opening is confined to the base or apex, each loculus opening by a single pore (e.g., *Solanum,* fig. 48); in the mistletoe there are numerous pores. In the barberry (fig. 49) each lobe opens by a valve on the outer side of the suture (valvular). Anthers dehisce at different periods during the process of flowering, sometimes in the bud but more commonly when the flower is expanded. They may dehisce simultaneously or in succession. These variations are connected with the arrangements for the transference of pollen. Introrse anthers dehisce by the surface next the centre of the flower, extrorse anthers by the outer surface; when along the sides (e.g., Iris) they are laterally dehiscent.

Stamens occasionally become sterile by non-development of the anthers and are then called *staminodes.* Some stamens are enclosed within the tube of the flower (included), others are *exserted, i.e.,* extend beyond the flower (e g., Plantago); sometimes they are exserted in early growth, but become included later (e.g., Geranium *striatum*). When there is more than one whorl, the stamens on the outside are often longest (*e.g.,* many Rosaceae), but sometimes the reverse is the case. When the stamens are in two rows, those opposite the petals are usually the shorter. In some flowers the stamens are *didynamous,* only four out of five being developed and the upper pair longer than the lateral (e g., Labiatae, Scrophulariaceae). When there are six stamens, four may be long and two short (tetvadynamous), the latter alternating with the pairs of long ones (*e.g.,* Cruciferae, fig. 50).

Pollen.—The pollen-grains consist of small cells, developed from the large, thin-walled mother-cells in the interior of the pollen-sacs. Two divisions (reduction divisions) occur in each mother cell to form four cells which are the microspores. The pollen grain results from the division of the microspore nucleus (germination), followed by an increase in size and differentiation of the cell wall into an outer exine and an inner *intine.* The mature grains commonly form a powdery mass. Then the walls of the mother-cells are absorbed and the grains float freely in the fluid of the pollen-sacs. The fluid gradually disappears and the mature grains form a powdery mass. In most Orchidaceae and Asclepiadaceae the pollen-grains are united into masses (pollinia, figs. 51, 52) by viscid matter. Each of these has a stalk (*caudicle*) which adheres to the prolongation at the base of the anther (rostellum) by a viscid gland (retinaculum). Gynostemzum is sometimes applied to the part of the column in orchids where the stamens are situated. The number of pollinia varies.

The exine is a firm membrane which defines the contour of the pollen-grain and gives it colour (generally yellow). The exine is either smooth or covered with projections and is often covered with viscid or oily matter. The intine is uniform, thin, transparent and extensible. In some aquatics (e.g., *Zostera*) only one covering exists.

Pollen-grains vary in diameter from $\frac{1}{300}$ to $\frac{1}{700}$ in. or less. They are most commonly ellipsoidal, but may be spherical, cylindrical and curved, polyhedral (Compositae) or nearly triangular in section. There are rounded pores varying in number from one to fifty, and through one or more of these the pollen-tube is extruded in germination. In monocotyledons there is usually only one; in dicotyledons, where they may form a circle round the equatorial surface, they number from three upwards. Within the pollen-grain is granular protoplasm with oily particles and occasionally starch. The mature pollen grain usually contains a vegetative cell, and a generative cell which later divides to form the two male cells, or sperms. (*See* ANGIOSPERMS; GYMNOSPERMS.)

Pollination.—When the pollen-sacs are ripe, the anther dehisces and the pollen is shed. In order that fertilization may be effected, the pollen must be conveyed to the stigma of the pistil. This pollination (*q.v.*) is promoted in various ways, the whole form and structure of the flower being adapted to the process. In some plants (*e.g.,* pellitory) the mere elasticity of the filament is sufficient; in others (*anemophilous*) pollination is effected by the wind (*e.g.,* grasses) and in such cases enormous quantities of pollen are produced; but the common agents of pollination are insects. To attract them to the flower the odoriferous secretions and gay colours are produced, and the position and complicated structure of the parts of the flower are adapted to the perfect performance of the process. It is comparatively rare in hermaphrodite flowers for self-pollination to occur and the various forms of dichogamy, dimorphism and trimorphism prevent this.

Disk.—Under the term disk is included every structure intervening between the stamens and the pistil. It presents great varieties of form, such as a ring, scales, glands, hairs, petaloid appendages, etc., and often contains nectar. The disk frequently arises by degeneration or transformation of the staminal row. In the Cruciferae, it consists of tooth-like scales at the base of the stamens. The enlarged receptacle covering the ovary in Nymphaea may be regarded as a disk.

The Pistil.—The pistil or gynoecium occupies the centre or apex of the flower and is surrounded by the stamens and floral envelopes when these are present. It constitutes the innermost whorl, which after flowering is changed into the fruit and contains the seeds. The ovary contains the ovules attached to the placenta. The pistil consists of one or more modified leaves, the carpels (megasporophylls). When a pistil consists of a single carpel, it is simple or *monocarpellary* (fig. 53); when composed of several carpels, it is compound or *polycarpellary* (fig. 54). Each carpel has its own ovary, style (when present) and stigma and may be regarded as formed by a folded leaf, the upper surface of which is turned inwards, towards the axis; the lower outwards, while the ovules develop from the margins. A pistil is usually formed by more than one carpel. These may be arranged at the same height in a whorl, or at different heights in a spiral. When they remain separate and distinct (*e.g.,* hellebore, fig. 54) the pistil is *apocarpous;* when they unite (*e.g.,* pear) it is syncarpous. A flower with a simple pistil is monogynous; with two carpels, dzgynous, with three, *trigynous,* etc.

The union in a syncarpous pistil is not always complete; it may take place by the ovaries alone (fig. 58), when the organ becomes a compound ovary; or by ovaries and styles; or by stigmas and the summits of these styles. Various intermediate states exist; the union is usually most complete at the base.

The ovary is usually spherical or curved, sometimes smooth on its surface, at other times hairy and grooved. The grooves usually indicate the divisions between the carpels. When the ovary is on the centre of the receptacle, free from the outer whorls, so that its base is above the insertion of the stamens, it is superior (e.g., *Primula,* figs. 43, 67). When the floral parts are inserted above the ovary, the ovary is said to be inferzor (e.g., *Fuchsia*). In many Saxifragaceae there are intermediate forms (*half-*inferzor).

The nature of the inferior ovary has long been a disputed question, and two chief interpretations have been proposed. The first, based chiefly upon ontogenetic studies, is that the tube to which the floral parts are attached is receptacular in nature, produced by the upgrowth of the receptacle around the gynoecium or by the invagination of the tip of the floral axis. Following invagination or upward growth the receptacle in many forms became fused to the ovary wall. This may be termed the "receptacular" theory and has been widely advocated. The second, or "calyx tube" theory, supported by evidence from vascular anatomy, conceives the perianth tube or calyx tube to be the product of the bases of the sepals, petals and stamens; from an evolutionary viewpoint these have become progressively fused to each other and then to the ovary wall. It is also possible that in some forms (Rosa) the lower portion of the calyx or floral tube is receptacular (*axile*), the upper portion derived from floral structures. In some forms (Darbya, Santalaceae) the inferior ovary has undoubtedly resulted from invagination and fusion of receptacle and ovary. In most forms investigated by the anatomical method, however, the tissues surrounding the ovary are appendicular and composed of the fused bases of the floral organs. This is true of most Rosaceae and Ericaceae; in the apple, for instance, around which controversy has raged, the outer part of the flesh is appendicular, not receptacular.

The Placenta.—The ovules are attached to the placenta, through which the vascular bundles pass. The placenta is usually formed on the edges of the carpellary leaf (marginal *placentation*). But often the placentas arise from the axis (*axile* placentation) and are not connected with the carpellary leaves. In marginal placentation, the placenta is borne on the inner or ventral suture, corresponding to the margin of the carpellary leaf, the outer or dorsal suture corresponding to the mid-rib. As the placenta is formed on each margin of the carpel, it is essentially double. When the pistil is simple, the inner margins unite and usually form a common placenta. When the pistil is apocarpous, there are generally separate placentas at each margin. In a syncarpous pistil, however, the carpels are so united that the edges of each of the contiguous ones, by their union, form a septum or *dissepiment,* and the number of these septa consequently indicates the number of carpels in the pistil. When the septa extend to the axis, the ovary is divided into cells (locules), being *bilocular, trilocular,* etc., according to the number, each cell corresponding to a single carpel. In these cases, the marginal placentas meet in the axis and unite to form a single central one. When the carpels of a syncarpous pistil do not fold inwards, the ovary is *unilocular* and the placentas are parietal (e.g., Viola). Often the margins of the carpels which fold in to the centre split there into two lamellae, each of which is curved outwards and projects into the locule, dilating at the end into a placenta. In some cases cohesion proceeds so far that the placentas of a single carpel are fused to form one (*e.g.,* Cucurbitaceae, fig. 63). Cases occur (Caryophyllaceae, Primulaceae) in which the placentas are not connected with the walls of the ovary (free *central* placentation, figs. 64, 65). It was formerly considered that such a placenta was a prolongation of the axis; anatomical evidence has shown, however, that the placenta is composed chiefly of the fused margins of the carpels, the septa having degenerated. Some residual axile tissue may be present, especially at the base of the placenta.

Occasionally divisions take place in ovaries which are not formed by the edges of contiguous carpels. These spurious *dissepiments* are often horizontal and develop only after fertilization. In Cruciferae, however, they are vertical and arise from the prolongation of the placentas.

The Style.—The style proceeds from the summit of the carpel (fig. 67) and is traversed by a narrow canal, a continuation of the placenta. The canal may be lined by a transmitting tract, or filled, at least in part, with specialized transmitting tissue. The tract or tissue is continuous with the stigma. In some cases, owing to more rapid growth of the dorsal side of the ovary, the style becomes lateral (fig. 66); this may be accentuated so that the style appears to arise from the base (basilar); but it still indicates the organic though not the apparent, apex of the ovary. Several basilar styles may unite (*e.g.,* Boraginaceae) to form a single gynobasic style. The style is usually cylindrical, filiform and simple; sometimes it is grooved on one side, or flat, thick, angular, compressed or even petaloid (e.g., Iris). It may bear hairs, which aid in the application of pollen to the stigma (collecting hairs, e.g., *Campanula*). The styles of a syncarpous pistil, when separate, alternate with the septa; when united, the style is simple (fig. 67). The style of a single carpel may be divided. The length of the style depends upon the relation which should subsist between the position of the stigma and that of the anthers to allow proper application of pollen.

The Stigma.—The stigma is the termination of the conducting tissue of the style and is usually in direct communication with the placenta. It consists of loose cellular tissue and secretes a viscid matter to which the pollen grains adhere. The stigmas alternate with the septa of a syncarpous pistil, *i.e.,* correspond to the back of the loculi; but in some cases half the stigma of one carpel unites with half that of the next, the stigmas being thus opposite the septa (*e.g.,* poppy). The divisions of the stigma usually mark the number of carpels in the pistil, but sometimes (*e.g.,* Gramineae) the stigma of a single carpel divides. It may be terminal or lateral and may present sensitive laminae which close when touched (e.g., Mimulus). It may be globular, umbrella-like, ovoid (e.g., Fuchsia), radiating, as in the poppy, where the true stigmatic rays are attached to a shield-like (peltate) body. The lobes of the stigma may be flat and pointed, fleshy and blunt, smooth, granular or feathery (*e.g.,* many grasses, fig. 68). In Orchidaceae, the stigma is on the anterior surface of the column beneath the anthers.

The Ovule.—The ovule is usually produced on the margin of the carpellary leaf, but sometimes ovules arise all over the surface of the leaf, or from a basal placenta (Polygonaceae) or laterally (*e* g., Primulaceae). The ovule is usually contained in an ovary and is *angiospermous;* but in the Coniferae and Cycadaceae it has no proper ovarian covering and is naked or gymnospermous. It is attached to the placenta either directly (sessile) or by a funicle (figs. 71, 72, 73) which may become much elongated after fertilization. The ovule is attached to the placenta or funicle by its base or *hilum,* the opposite end being its apex.

The ovule first appears as a small projection from the placenta. The cells multiply and assume an enlarged ovate form constituting the nucellus (megasporangium). This nucellus may remain naked and alone form the ovule, as in some parasitic families; but in most plants it becomes surrounded by integuments, which appear first as rings at the base of the nucellus, which gradually spread over its surface. In some cases (*e.g.,* Compositae), only one covering is formed, but usually another is developed subsequently, covering the first completely except at the apex, where neither integument invests the nucellus, but leaves an opening, the micropyle. In most angiosperms a single megaspore 'mother cell is differentiated within the nucellus. Most commonly two divisions (reductional) occur to form an axial row of four megaspores. One megaspore, usually that farthest from the micropyle, develops into a megagametophyte (embryo sac); the other three disintegrate. Only vestiges of the nucellus remain when the ovule has developed into a seed.

The point where the integuments are united to the base of the nucellus is the chalaza, which is often coloured, is denser than the surrounding tissue and is traversed by vascular bundles from the placenta. When the chalaza is at the hilum and the micropyle is opposite, there being a short funicle, the ovum is ortlzotropous (fig. 72). When by more rapid growth on one side than on the other, the nucellus and integuments are curved on themselves so that the micropyle approaches the hilum, the ovule is *campylotropous* (*e.g.,* Cruciferae, fig. 71). In an inverted or anatropous ovule (fig. 73), the commonest form in angiosperms, the apex with the micropyle is turned towards the point of attachment of the funicle to the placenta and the funicle coalesces with the ovule to form. the *raphe.* The ovule thus curves from the point of origin of the integuments and if a second integument is formed, it does not extend to the side adherent to the raphe. Forms intermediate between these types occur. When there is a single ovule with its axis vertical, it may be attached to the placenta at the base of the ovary (basal placenta), when it is erect (*e.g.,* Compositae) ; or it may be inserted a little above the base on a parietal placenta (ascending); or it may hang from an apical placenta at the summit of the ovary, its apex being directed downwards (inverted or pendulous); or from a parietal placenta near the summit (*suspended, e.g.,* Euphorbiaceae). Sometimes a long funicle arises from a basal placenta, reaches the summit of the ovary and there, bending over, suspends the ovule (*e.g.,* sea-pink); at other times the hilum appears to be in the middle and the ovule is horizontal. When there are two ovules in the same cell they may be side by side (collateral) ; or one erect and the other inverted; or one above the other, as is the case in ovaries containing a moderate number of ovules. When the ovules are determinate (*i.e.,* uniform and can be counted) their attachment usually forms a good character for classification. When very numerous (indeterminate) and the placenta little developed, their position shows great variation and their form is altered by pressure into various polyhedral shapes.

Fertilization.—When the pistil has reached a certain stage in growth, the egg is ready for fertilization. The pollen-grain having reached the stigma in angiosperms, or the summit of the nucellus in gymnosperms, it is detained there, and a pollen-tube protrudes through a pore in the grain. The pollen-tube (or tubes) passes down the canal (fig. 69), through the conducting tissue of the style, when present, and thence to the micropyle of the ovule, one pollen-tube going to each ovule. Frequently the tube has to pass some distance into the ovary to reach the micropyle, being guided by hairs, grooves, etc. In gymnosperms the pollen-grain resting on the apex of the nucellus sends off its pollen-tubes which at once penetrate the nucellus. Ultimately the apex of the tube perforates the tip of the embryo-sac, the male cells are discharged into it, and fertilization is effected. Consequent upon this, after a longer or shorter period, those changes begin in the embryo-sac which result in the formation of the embryo plant, the ovule being converted into the seed, the ovary enlarging to form the fruit, often incorporated with which are other parts of the flower (receptacle, calyx, etc.). In gymnosperms the pollen-tubes, having penetrated a certain distance down the tissue of the nucellus, are arrested in growth for a period, sometimes nearly a year. See ANGIOSPERMS: Flower; FRUIT; SEED.

PHYLOGENY OF FLORAL ORGANS

The writings of Goethe (1790) and de Candolle (1813) are chiefly responsible for what has come to be known as the "classical" theory of the fundamental nature of the flower. According to this, the flower is a highly modified and abbreviated shoot, determinate in growth, and the floral parts are homologous with leaves. The sepals are held to be modified foliage organs, and the carpels greatly reduced and infolded leaves bearing ovules along their margins. Differences of opinion have been expressed concerning the nature of the petals; on the one hand they have been considered modified sepals, on the other metamorphosed and sterile stamens. The latter point of view has been more generally accepted. The classical theory has been almost universally adopted as an instrument of description in taxonomic and morphological studies. An important modification of the classical theory was suggested by A. Arber in 1937 In the attempt to understand what is meant by the term homology, it was suggested that the carpel, for example, should not be regarded as an infolded foliage leaf, but that the essential organs, carpel and stamen, together with the leaf, should be viewed as the products of parallel evolution.

A further explanation of the ultimate origin of the leaf and floral organs has been found in a theory which derives the carpels and stamens on the one hand, and leaves on the other, from dichotomous branch systems such as existed in ancient and extinct plants of the Palaeozoic. Certain areas of the terminal branchlets of such systems are assumed to have been nonsporogenous, and to have given rise to primitive foliar organs following webbing and fusions Similarly, other and sporangium-bearing areas became webbed and fused to form carpels. The modern stamen, likewise, came into being as the result of extensive reduction of a fertile branch system or portion of such a system. Thus carpel and stamen were never primarily photosynthetic organs; the carpel is not an infolded leaf, for it never passed through the leaf stage in evolution, and both sporophylls and leaves are the end products of parallel evolution from branch systems of different categories. Support for this viewpoint has been supplied by anatomical and ontogenetic studies; in these latter (1941–43), it was shown that carpel and stamen are reduced axes, differing in their earlier development from that of perianth parts and foliage leaves, but showing the same mode of development as that of a shoot. Beginning about 1925 a number of other theories bearing on the phylogeny of the flower have been proposed, but none of these met with general acceptance.

(C. L. WN.; X.)

COMMERCIAL FLOWER GROWING

Europe.—Until the outbreak of World War II in Sept. 1939, flower growing for the wholesale markets was a truly great industry in several European countries, particularly in Great Britain, France and the Netherlands and, to a lesser extent, in Belgium, Germany and Italy. France had an extensive flower production area in the south, much of the produce being exported to England and other parts of Europe. Vast numbers of bulbs of Lilium candidum, white Roman hyacinths and paperwhite narcissi were also produced for export to England and elsewhere, the bulk of *Lilium* candidum reaching the United States.

The Netherlands, prior to 1939, was a large producer of cut-flowers under glass, quantities being exported, but the even more Important phases of her horticultural industry were the production of nursery stock—trees, shrubs and other ornamental plants—and bulb growing. The Dutch bulb industry was gigantic, the estimated area being 15,000 ac. Much of the land devoted to these cultures had been reclaimed from the sea. Several hundred million tulips, daffodils, hyacinths, lilies, irises and other bulbs were exported, Great Britain being the heaviest buyer with the United States a moderately good second. What were not exported or planted for the succeeding year's crops were forced in greenhouses around Boskoop and Haarlem, many of the cut flowers being shipped to the great auction market at Aalsmeer and from there sent to the leading cities of Europe.

England.—Prior to 1940, England alone devoted fully 6,000 ac. to outdoor crops of flowers, largely for cutting, independent of almost as much devoted to the production of ornamental plants for sale. This area included flowering bulbs, at least 2,000 ac. being devoted to daffodils, tulips and numerous other hardy kinds. The major proportion of all the named daffodils in commerce originated in England, where daffodil breeding had been carried on since the 19th century.

But of even greater importance was the glasshouse production of cut-flowers. Some areas in England, particularly around Cheshunt, Hampton and Worthing, are literally covered with glass, the major pre-1940 crops consisting of carnations, roses and chrysanthemums, with forced bulbs a special feature during the winter and early spring, before the outdoor blooms become available. From chrysanthemums alone the annual income was around £250,000, and, including ornamental plants in pots, the total yearly income from greenhouses was close to £1,500,000, while the entire flower production income was at least £2,000,000. Added to the glasshouse income was that derived from forced tomatoes, cucumbers and sundry fruits, quantities of which were produced in greenhouses that were not entirely devoted to flower crops throughout the year.

The necessity of food production after the outbreak of war in 1939 compelled curtailed production of flowers, and, at the end of 1943, British growers' flower production was limited to 10% of what it had been in 1939, while outdoor cultures of cut-flowers, bulbs and other ornamentals were limited to 25%. The provision for 10% under-glass production was primarily for the purpose of reserving stocks for future propagation.

United States.—Floriculture in the United States made its greatest progress after the close of World War I. The general prosperity that followed caused a tremendous expansion in glasshouses which, because of climatic conditions, are essential to flower growing, especially in the northern states. The 1930 federal census of horticulture showed that there were nearly 174,000,000 sq.ft. covered with greenhouses in the United States, the receipts of the growers being nearly $110,000,000. Their investment in land, buildings and equipment was almosr $222,500,000. The number of firms making reports, on which these figures were based, was 14,982, and the area they controlled, including open-ground cultures, was nearly 50,000 ac. In the succeeding years up to 1941, the area devoted to outdoor flower crops increased by 15,000 to 20,000 ac. because of the great development in commercial flower growing in California, Florida and the Carolinas. However, a shortage of labour and the necessity of growing more food caused considerable reduction in 1943 and 1944.

The major greenhouse flower crops at the time of the outbreak of World War II had changed somewhat from what were the recognized leaders at the close of World War I. Roses, as always, were in the lead, with carnations and chrysanthemums almost as important as seasonal crops. Snapdragons (Antirrhinums) had far outstripped sweet peas, while violets had fallen to a comparatively minor position, stocks (Mathiola) being a far more important late winter and early spnng crop. Orchids and gardenias, formerly classed as aristocrats, had become more or less commonplace, the production of these flowers throughout the year having multiplied at least tenfold without seriously lowering the market prices, except at certain times of the year.

In the same period, 1920–40, the production of outdoor or field grown flowers also vastly increased. California had developed a great flower shipping industry and, until the eastern growers successfully hastened the flowering of chrysanthemums by shading with black cloth for a certain number of hours daily during July and August, California blooms ruled most markets during September and October Other flowers grown on a vast scale in California for fall and winter shipping include asters and other annuals. Around 1930 Florida, Virginia and North Carolina became important cut-flower producers, gladiolus production in Florida becoming a big industry. Millions of spikes of these flowers reached all the northern markets and won such popularity that they became standbys from November to April, the Florida stock being followed by stock from Virginia and North Carolina. As a consequence, greenhouse men in the north practically ceased growing gladiolus as an early spring crop.

Florida also took up the production of early crops of delphinium and various annuals, and, as a result of Quarantine no. 37, a regulation which forbade the entry of all narcissus bulbs into the United States, Florida after about 1925 produced practically all the paperwhite narcissus bulbs required by the U.S. trade. Florida also became the largest producer of amaryllis and caladium bulbs in the world. North Carolina, besides growing gladiolus for cut blooms on a large scale, also shipped to all parts vast quantities of bulbous ins and daffodil flowers.

In the more northern regions the peony likewise took on great importance as a cut-flower for the wholesale markets, literally carloads being shipped to all points, particularly from Indiana and Illinois, while many other states began to produce great quantities for the neighbouring markets. The delphinium, after the introduction of the strain known as Pacific Giants around 1930, also became a highly important cut-flower, vast quantities of these flowers being grown for the New York, Philadelphia and Boston markets and to a lesser extent for other large city flower markets.

The narcissus embargo also brought about the development of a large daffodil growing industry, the major production of bulbs being in the states of Washington and Oregon, where the climate is especially suitable. Long Island and Virginia also produce goodly quantities of hardy narcissus bulbs. The total output probably exceeds 40,000,000, all of them sold in the United States, perhaps two-thirds of the supply used by florists for cut-flowers. Iris bulbs of the Dutch hybrid and tingitana hybrid types also are grown on an enormous scale in the northwest, millions of bulbs being shipped east mainly for forcing during the winter and spring by florists. Tulips and hyacinths also are successfully gromn in the northwest, the cultures of these being greatly increased after the invasion of the Netherlands in 1940 stopped all exports from that country. In 1943 the harvest of tulip bulbs in the northwest and Long Island probably exceeded 12,000,000.

The U.S. production of hyacinth bulbs is comparatively small, but the quality is sufficiently good to prove that such bulbs can be successfully grown as well as various other so-called Dutch bulbs. California, too, became a great producing centre of the more tender flowering bulbs. For many)ears all the freesia bulbs required by florists have been raised in California, the output running to many millions, and practically all the varieties in a wide range of colours have been originated there by careful breeding. Other bulbs grown on a big scale and imported before World War I include anemones, ranunculus, tuberous begonias, gloxinias, etc.

Indeed, it can be saiely said that practically all the flowering bulbs which commercial cut-flower growers and retail merchants require are produced on U.S soil with the exception of lilies for forcing. The so-called Easter lily (*Lilium longiflorum*), prior to 1940, was largely a Japanese monopoly, the only other source for U.S. forcers being Bermuda, which ior many years had supplied the U.S. trade with only a small proportion of its needs. However, from the close of World War I the U.S. department of agriculture experiment stations and various commercial growers had continually experimented with lily bulb production. More bulbs of the fine garden lily, *Lilium regale*, are grown in the United States than anywhere in the world.

Gladiolus bulb production in the United States was established as an industry shortly before World War II, and after that time the production multiplied many times, the annual sales of bulbs for commercial and garden purposes probably being not less than 100,000,000. The chief gladiolus bulb farms are in the northwest and in Michigan, but in almost every state, except in the south, gladiolus bulb farms are to be found, though for the most part the producers of bulbs are not interested in the cut-flower business.

Another phase of the U.S. flower industry is the production of azaleas, rhododendrons and numerous other plants for forcing, which prior to 1925 were largely imported in the dormant or resting stage. After a period of scarcity, resulting from the embargo regulations of Quarantine No. 37, nurserymen in the east began turning out azaleas as fine as ever came from Belgium, although the fact that the plants had to be carried over at least two winters in frost-free glass structures naturally increased the cost until the producers reached mass production. One New Jersey firm after a few pears never had less than 1,000,000 azalea plants on hand. Production costs were further lowered when the southern states took up azalea propagation on a large scale, and until 1941 the sale of azalea plants in flower from Christmas until spring was many times greater than in the heyday of inexpensive European plants. To a great extent this was due to the fact that the small-flowered Japanese Kurume azaleas, introduced into the United States around 1916, gained great popularity among commercial growers because they force readily and can be propagated from cuttings as easily as the hardy garden sorts, whereas the Indica varieties have to be propagated by graiting, a process that calls for greater skill and special greenhouse facilities. Another type of azalea that also helped to popularize this race of plants for commercial forcing is known as the Rutherfordiana, a race of hybrids originated by a New Jersey nurseryman through crossing various types. These hybrids are larger flowered than the Kurumes, very floriferous and force readily, but are not fully hardy

U.S. plant breeders have been highly successful in raising special strains or varieties of plants suited to U.S. conditions under glass. The first truly perpetual flowering carnations for fall, winter and spring blooming were developed in the United States, and only rarely after 1900 did foreign varieties make good under U.S. conditions, whereas many of the most popular varieties grown under glass in Europe were of U.S. origin. The forcing roses did not prove to be so international, ior only in rare instances were European varieties successiul in the United States or vice-versa, but nevertheless most of the principal iorcing roses in the U.S. were the result of interbreeding between European and U S. sorts.

U.S. seedsmen likewise were successful in breeding varietal strains of flower seeds suited to U.S. glasshouse conditions Winter flowering sweet peas were first developed commercially in New Jersey and aiter 1910 became an increasingly important winter and early spring crop under glass. The winter flowering snapdragon after 1930, however, gained an even greater popularity than the sweet pea, and it is probably a fact that among cut flowers raised from seed the snapdragon by 1943 was by iar the most important subject grown under glass, millions of spikes being shipped into the various markets. All the varieties of greenhouse snapdragons are of U.S. origin. Stocks, specially suited for greenhouse work. were of even later introduction. U.S. breeders developed remarkably fine types from European varieties. Calendulas, which under U.S. culture also became important flowers for winter, lost some favour with the advancement of snapdragons and stocks, though the marigold, a near relative, gained some attention aiter 1935; under U.S. hands a winter blooming type developed. U.S. breeders also gave considerable attention to flowering pot plants raised from seed, including cinerarias, calceolarias and cyclamens, so that the cutting off of the noted German strains of these flowers during World War II did not seriously inconvenience the American florists.

Bulb Forcing.—The general system of forcing bulbs into flower is practically the same in all countries, but in the United States some of the larger growers erect special bulb cellars instead of burying the pots or flats (shallow wooden boxes) outdoors. Daffodils, tulips and hyacinths, being truly hardy, must, after they are planted in pots or boxes in September, October or November, be kept cool and in the dark for at least two months to induce rooting. They are either placed in cool, dark cellars or buried under eight inches of soil outdoors and later protected by straw to prevent freezing. When well rooted, the flats or pots are given a greenhouse temperature of about 50° F. When the top growth is sufficiently advanced more heat is given, usually about 60° F. By special pre-cooling treatment prior to planting, the bulbs can be flowered several weeks earlier. The leading yellow trumpet daffodil is King Alfred. Probably more of this variety are forced in the United States than all other varieties put together. Other varieties forced in considerable quantities are Sir Watkin, The First, Tresserve, Springglory, Glory of Sassenheim, Early Surprise, Cassandra, Helios, Laurens Koster and Vanwaveren's Giant.

Tulips for earliest forcing are the so-called single earlies, such as Thomas Moore, Prince of Austria, De Wet, Couleur de Cardinal, Keizerskroon, Risingsun and White Hawk, but the Darwin type is much more favoured in the United States because the stems are longer and much more suitable for cutting. Popular forcing varieties are Allard Pierson, Wm. Pitt, Wm. Copland, Rose Copland, Pride of Haarlem, Bartigon and Carrara. Intermediate types, known as Mendels and Triumphs, are crossbreeds between the very early sorts and the Darwins, these forcing more readily than the latter with longer stems than the earlies.

Hyacinths are very responsive to forcing, provided they are kept cool and the flower buds are out of the neck of the bulb before above 50° is given. Generally speaking, daffodils and hyacinths are in bloom 3 to 4 weeks after being given warm treatment. Tulips are more variable according to their natural blooming habits, and extreme forcing for Darwins is not advisable, though from pre-cooled bulbs flowers are obtained in early January.

Other **Types** of Flowers.—Carnations.—The general cultural practice for carnations is to root cuttings in sand between December and March, grow in pots or flats and plant out in the field in late April. The plants are lifted in July and benched in the greenhouse in well prepared soil. By repeated pinching back until the plants are brought inside, well-branched, bushy plants are obtained. If early blooms are not wanted. pinching is continued until September. The major aim is to secure a heavy crop in December and on through the succeeding months until late June when the plants are usually thrown out, though some growers successfully carry the plants through a second season, as is the custom in Great Britain. In some areas the growers do not plant in the field but bench in the late spring, this method being helpful in controlling stem and leaf diseases. Carnations thrive best in a cool temperature with abundant ventilation. Expert growers never allow the night temperature to exceed 50° during the fall and winter.

Roses *Under* Gtnss—While numerous small growers successfully handle carnations in a greenhouse partly devoted to other crops, roses need a house to themselves and in the main are grown by specialists on a large scale solely for the wholesale markets, some of the largest producers growing as many as 1,000 000 plants in giant houses 40 to 50 ft. wide and from 300 to 800 ft. long. A steady night temperature of around 60° F. is maintained. The plants are either propagated by grafting in heat on Manetti stocks early in the year and benched in June, or semidormant budded plants are planted in April These budded plants are mostly budded in the field by Pacific coast growers specially for eastern forcers. High humidity, steady warmth and skilful pinching enable growers to start cutting quality flowers from September on, the two big cropping periods being Christmas and Easter, though generally roses from under glass are available every day in the year. Nowhere in the world are such fine roses produced in midwinter as in the eastern United States. On the other hand, outdoor roses in the eastern United States cannot compare with those grown in England, where the summer temperature is much lower.

The most popular of all forcing roses in the U.S. is Better Times, light red. In many areas, probably more of this variety is grown than of all other varieties together. Other varieties largely grown are: pink—Briarcliff, Peters' Briarcliff, Hapny Days, Pink Delight, Rapture, Hollywood, Queen Mary; red—Peerless, Rome Glory, Chieftain; yellow—Mrs. F. D. Roosevelt, Lestra Hibbard, Joanna Hill, Golden Rapture; yellow-red—Talisman; white—White Killarney Improved, Snow White, Starlight, American Pride.

Lilies.—As stated above, Japan used to supply the bulk of the forcing lily bulbs, the varieties being Giganteum for all-year-round cold storage, and Erabu for storage until spring. Both are forms of *Lilium longiflorum,* Giganteum doing best at a steady 60° F. temperature, while Erabu can be grown at a much lower temperature. With these lilies unavailable, American growers after 1940 had to depend upon the Bermuda-grown Harrisi and Howardi and the domestic grown Floridi from Florida, Creole from Louisiana and Croft from the northwest. A newer source was Mexico, whence goodly numbers of bulbs first arrived in 1942. All these lilies are also forms of *Lilium longiflorum.* Only at Easter time are lilies in pots called for in large numbers.

The usual practice is to plant Bermuda-grown bulbs in early fall and, for Easter on, other types after a period in cold storage, successive batches being planted from late December on. The bulbs are planted either in pots, boxes, raised benches or ground beds, and temperature control and careful watering are the major factors for success.

Chrysanthemums.—The culture of chrysanthemums in the United States is carried on on a tremendous scale, both for the wholesale markets and by retail growers for their local trade. In California they are grown on scores of acres in the open with cheesecloth covering, but in other sections all except certain early types are grown entirely under glass. Cuttings are rooted from early March until late May, planting on benches or ground beds being done up to late June. The large flowered sorts are usually kept to one to three stems, each producing one bloom. The small-flowered spray or pompon types are pinched to induce several stems, each carrying a spray of flowers, the quality of which is improved oy partial disbudding. While in California chrysanthemums start blooming in early September or before, good quality flowers in the east can be had at this date only by the shading method. Midseason or October bloomers, when shaded with black cloth each day from 4 P.M. until 7 A.M. during July and August, are induced to set flower buds and bloom several weeks earlier. In the reverse way, by using electric lights nightly during late summer the plants are delayed in flowering.

Chrysanthemums require cool treatment from fall onward and need much attention to keep them free from insect pests and good support to prevent crooked stems. Greenhouse culture throughout the season is favoured because the stems are then softer; grown outdoors the stems become woody and when cut do not take up water freely and the flowers therefore do not keep as well. The spray varieties are perhaps more largely grown than the large flowered kinds. They are sold by the bunch, while the large blooms are marketed by the dozen. Literally hundreds of varieties are grown by florists in different parts of the country. The small flowered varieties. grown under type headings as pompons, singles and anemone flowered, are legion, some thriving better in some sections than others. (T. A. W.)

FLOWERLESS PLANTS: see ALGAE; BRYOPHYTA; FERNS; FUNGI; LIVERWORTS; MOSS.

FLOWER PAINTING. Broadly speaking, flower painting may be divided into two big classes: that of the East, and that of the West. In the East, flower painting very early attained to a high state and became an individual, extremely beautiful art in China between the 7th and 17th centuries. Japanese painters, adopting many of the traditions of Chinese art, created a phase of flower painting which rose to superb heights in the 16th and 17th centuries. In the West, flower painting proceeded slowly from Egyptian, Grecian and Roman days, on through the Italian Renaissance, until, mainly in the north of Europe, again in the 16th and 17th centuries, almost with one bound, it reached a distinctive and highly developed form of painting in the Netherlands, and from there spread to nearly every country of Europe. The two schools grew under conditions so separated that each remained until recent times quite untempered by the other.

Flower painting of modern times is something of a heritage of both these divisions, but mainly of the Western group, to which has been added a richer and fuller sense of colour, finer and more subtle effects of light and atmosphere resulting from the greater development of visual perception and the delving into the realms of science, as developed by the French impressionists. The manner of painting flowers has followed the changes that have taken place in painting generally, whether of the East or of the West. In method, in the West, the early form was fresco, then oil; now water-colour and pastel are employed in addition. With the Chinese and Japanese, except in wall painting, it has always been a phase of water-colour painting, and their marvelous use of the brush on silk or paper has given a character found nowhere else in the world of art. In the Western world, flowers have been associated for the most part with man. They have appealed to his finer feelings; they have graced his life. He has used them as symbols, decorations, adornments, offerings and as enrichments to his home and his surroundings, while in the East they have always been thought of as a beautiful part of the great order of things in the universe, a part of nature of which man himself is likewise but a part. Flower painting, therefore, has developed along a far different line in the East from what it has in the West. In the East it has always been approached from a contemplative, philosophic and poetic point of view, while in the West it has been, for the most part from an objective one. In the West, we find flowers used in the early days only as accessories in the art of painting. At first they are painted as symbolical and decorative adjuncts. Later they assume a realistic phase in their conjunction with the religious and mythological subjects. But not until about the 16th century do they appear as subjects for paintings for their own beauty. In the East, however, they have formed a very distinct branch of painting for over a thousand years. The Chinese divided their paintings into four general subjects: landscape, man and objects, flowers and birds, plants and insects. Three of these main divisions deal directly in the broad field of nature; the third and fourth divisions are closely related, and being based on much the same conceptions as their landscape painting, follow it as a natural development.

THE ART IN CHINA AND JAPAN

The close observation and contemplation of nature by the artists of the East have produced in their work a rare character and charm. Their flower paintings vibrate with life and force; they are beautifully rhythmic. Their lilies nod and sway on delicate stems; lotus flowers vigorously grow from earth and water into light and sunshine. Their vines hang and sway in the breeze, their peonies unfold, their plum blossoms spread their petals and gently float away in the breeze almost as they open. Flowers in their paintings are associated with the passing of the seasons and the moods of nature. Generally they are painted with the birds of the seasons naturally associated with them at the time of flowering, in their natural habitat, and always with a great understanding of their life and growth. The Chinese artists ever communed with nature. It is said of Chao Ch'ang, of the early 11th century, that "every morning he would walk round the gardens and examine some flower carefully, turning it over and over in his hand. Then he would paint." Of I Yuan-chi, it is said that "he laid out a garden, planted it with bamboos and rushes, and kept there a variety of water fowl, so as to be able to watch them in movement and repose." Kuo Hsi writes about this same time: "Those who study flower painting take a single stalk and put it into a deep hole and then examine it from above, thus seeing it from all points of view. Those who study bamboo painting take a stalk of bamboo, and on a moonlight night project its shadow on to a piece of white silk on a wall."

Of the early Chinese flower paintings few remain to the present day, but of those known, the earliest are of the T'ang dynasty (A.D. 618–907) and show an art that must have been highly developed through many earlier centuries. Pien Luan. of the late 8th century, was noted for his paintings of birds and flowers. Hsiao Yiieh of the same century painted the bamboo exclusively. Hsii Hsi, of the early 10th century, was famous for his painting of flowers. "Peonies in the Wind" and "Ducks in a Lotus Pond" are typical titles. In his time he was considered an artist of the front rank, and has been called "the father of bird and flower painting.': He was famous for his paintings of the lotus flowers which were the inspiration for many painters in later times both in China and Japan. Huang Ch'uan and his son Huang Chu-ts'ai were noted painters of flowers of this same century. Two pictures, "Fowls" and "Peonies," in the British Museum are attributed to the father, while there is record of a large number of paintings of birds and flowers by the son.

The three centuries of the Sung dynasty (960–1279) saw flower painting advanced to a great art. It was a period of intense nature study, a period where a passion for flowers was common, a period when flowers were associated with nature and with every mood of nature. Many flower painters flourished, and their paintings are filled with an elusive poetic quality, combined with accurate form and rhythmic beauty of. growth. In this phase of Chinese art, the Sung artists are pre-eminent. Hsü Ch'ung-ssŭ was a painter of flowers and insects, and is accredited with being the first to paint directly without first sketching the subject. Chao Ch'ang, who followed something of his methods, attained great fame. It is said of him that he "not only produces an accurate resemblance, but hands over to you the very soul of the flower" also. Ch'êng T'ang was famous for his paintings of bamboo, as was Chou Shun. Li-Ti excelled as a flower painter, Chao-Mêng-Chien delighted in painting the plum and narcissus, while Cheng Ssŭ-hisao devoted himself to the painting of orchids.

In the Yüan period, 1279–1368, there are few outstanding flower painters. Ch'ien Hsiian, born in the earlier dynasty, was noted, and Li Kan achieved great fame as a painter of the bamboo. In the Ming dynasty, 1368–1644, though a decline had set in, much of the tradition of the golden age of the Sung period was carried on, and a number of flower painters are found. Mr. Fenollosa claims for Lin Liang first place of all Ming artists. Lu Chi painted his flowers and birds with a landscape background. Sun K'an specialized in the painting of the chrysanthemum. Other flower painters of this time were Ch'ên Shun, Kao Ku, Sun K'o-hung, whose paintings were noted for beauty of movement in flowers, and Chou Chih-mien, also noted for the rhythm and spirit he attained. In the Ch'ing or Manchu dynasty, 17th to the 20th century, though no new vigour has been added, and marked signs of decadence are seen, many of the traditions in flower painting of the earlier Sung and Ming periods were maintained with vitality, at least to the beginning of the 18th century.

In Japan, flower painting, inspired greatly by the Chinese masters of the T'ang, Sung and Ming periods, possess many of their characteristics, grafted often on to the traditions of their own Japanese native schools of painting.

The most impressive periods were the Ashikaga period (1335–1573) and the Tokugawa, from about 1600 into the 19th century. The first strongly upheld traditions of the Sung painters. The native Japanese tradition slumbered, and a sort of Chinese renaissance in Japan took place. The gorgeous coloured scrolls, which had been typical, were replaced by bold simple ink paintings of birds and flowers and landscape. It was the philosophic, contemplative art of earlier Chinese painters. So far as flower painting was concerned, it was the interpretation of the life and growth of the flowers and their association with nature. Sesshiu and Kano Masanobu, the first of the great Kano school, both of whom had great influence and many followers, painted flowers in the classic Chinese style. Utanosuke, son of Kano Masanobu, achieved a great reputation for his distinguished painting of flowers and birds He died in 157j. About 1600 began the Tokugawa period of Japanese art. Chinese ideals were developed along with the Japanese tradition for rich colour and sumptuous decorative effects. Artists with great skill and understanding vied with each other in producing a phase of flower painting, combining all the beauty of the growing flower with superb design and gorgeous colour, that remains unique in the entire field of painting. The three outstanding masters of flower painting of this period are Koyetsu (1557–1637), the leader in this movement, Sotatsu, considered by Japanese critics as the greatest of flower painters after Utanosuke, and Korin (*c.* 1657–1716) who "is perhaps the most Japanese of all the artists of Japan." Their influence carried forward to recent times, but there are few, if any artists since who have inherited their skill or genius.

OCCIDENTAL FLOWER PAINTING

In the West, as has been said, the earliest painted flowers are only to be found as symbols or as decoration. The blue water-lily of the Nile, symbolizing a full harvest, is constantly found in the painted decoration of the Egyptians. Flowers repeatedly appear in the religious paintings of the Renaissance. The lily, emblem of purity, is painted in almost every picture of the Annunciation and of the Madonna. In Roman times garlands and festoons of flowers were painted as decorations. Fine examples, in excellent preservation, are those painted in fresco on the walls of the house of Livia on the Palatine. Crivelli and Mantegna continually in their pictures echo much of this festive decorative floral and fruit painting of the Romans. Flowers form a part in many of the pictures by Botticelli, and though generally introduced for their symbolism, or decoration, they show close observation of growing flowers and a delight in painting flowers for their own beauty, and are rapidly assuming an objective, or realistic character. They slightly suggest those found in some, of the paintings of the late Ming period in China. Botticelli died in 1515, and this century witnessed an unprecedented interest in flowers and gardens. The Italians and Dutch both developed the making of gardens to a fine art. Merchants brought new and beautiful flowers from every corner of the earth to enrich them. In Holland this collecting of rare flowers became the fashion, and collectors of both Italy and Holland employed artists to paint them.

From 1550 to 1650 numerous painters in Italy, Spain and the Netherlands painted flower pictures for the beauty of the flowers themselves. Many of them attained great reputations, and a few were great masters. They exercised an influence that was immediately felt throughout Europe, and which has continued even to the present day. Jan Bruegel (1568–1625) is generally acclaimed as one of the first to develop this manner of painting to a fine art, and, since he introduced flowers as decorative elements in religious painting something in the manner of the early painters of the Italian Renaissance, and later painted flower pictures, he may be considered as the most important link in the chain which leads to the highest point of flower painting in the West. Caravaggio (1569–1609), an Italian, as a young man made many paintings of flowers and fruit while in Rome. He did much to advance solidity and light and shade in painting, and his influence was felt both in Spanish and Dutch painting From then on this feeling for light and shade and third-dimension was a markedly noticeable addition to painting. This phase, observed with greatest understanding, was almost scientifically accurate, and showed direct observation and study from nature. Daniel Seghers (1590–1661) painted in something of the same manner as Bruegel, whose pupil he was. He, too, used flowers in conjunction with religious subjects, but they seem rather to be painted as offerings to the Madonna and saints than as garlands of enrichment. As paintings of flowers, they are very beautiful, with much of the charm of their form, looseness and grace of growth, and delicacy of texture. Individual flowers are masterpieces of close observation and painted with feeling for and knowledge of the flowers themselves.

The painting of garlands and festoons as accompanying decorations to other subject matter led in turn to separate flower paintings. Jan D. van Heem (1606–1684) developed this phase of flower painting to an amazing degree. His technique was masterly. His composition, colours, arrangements, lighting and feeling for the forms of flowers, which he generally painted against a simple dark background, produced a most finished and unified result. As an objective painter, he advanced flower painting to a point far in advance of what had gone before. He has seldom been surpassed. He achieved a great and deserved reputation, and is one of the real masters of this art. His influence was unmistakable, not only among the Dutch and Flemish painters, but throughout Europe. Almost simultaneously, we find groups of artists painting flower pictures in various countries, much in the manner of de Heem. In Italy, there were many, the most noted among which were: Giovanni Battista Ruoppoli (1600–59); Mario Nuzi da Fiori (1603–73) (a pupil of Cavaliere Tommaso Salini's [1570–

1625], who was a contemporary of the Italian Caravaggio and the Flemish painter Jan Bruegel, and who is claimed by Lanzi to have been "the first that composed vases and flowers accompanying them, with beautiful groups of foliage"); and the Roman, Michelangelo de Campidoglio (1610–70). In Spain, various members of the Arellano family painted in the van Heem and Caravaggio manner, the most famous being Juan de Arellano (1614–1672) whose flower paintings, generally painted in pairs, are greatly prized throughout Spain.

Later a German, Abraham Mignon (1639–1697), pupil of de Heem's, who worked in Holland, made for himself a reputation second only to his master. He, in addition to painting grouped flowers and fruit, painted growing flowers but with little of their rhythmic beauty of growth and no sense of their envelopment by air and light. Andrea Belvedere (1646–1732), a Neapolitan, is another painter, of this later time, with something of the Dutch tradition, much of Ruoppoli and something of Juan de Arellano's. Like him his flower paintings are often in pairs. His pictures are crowded but there is much, as in Arellano's, of the easy free growth of the flowers. The crowning point of this kind of flower painting was reached by Jan Van Huysum (1682–1749), who painted well into the 18th century. His flowers are masterly in the drawing of their exquisite and beautiful forms, superb in their third-dimensional quality, and in their delicate and gracious contours. His combinations of colour, his contrasting of light flowers against dark and his design of the wealth of blossoms portrayed, produced gorgeous decorative effects and place him without question as one of the greatest masters of flower painting. Yet his paintings lack a feeling for the living flower and do not possess that quality of growth so superbly grasped by the artists of the East. They lack, too, the beauty of transmitted light and translucent colour that gives so much of the ethereal quality to flowers. These qualities were to come later in the painting of the French school of the 19th century. However, in his time his pictures were unequalled for exquisiteness and grace of form, and were masterpieces of faultless finish. Rachel Ruysch (1664–1750) painted in a similar manner and is by some critics considered his equal. Van Huysun's influence was considerable; and flower pictures in his manner continued to be painted on into the 19th century. They are not as sumptuous, have not the same perfected finish and have not usually the same beauty of form. Often they have an increased harshness.

In France there is an evidence of greater concern for the living character of the flower, a sense of its lightness and delicacy, or, its heaviness, on its stem—a sense for the frailness of flowers that makes Huysum's seem almost moulded from thin metal. Such a painter as Laurent Melaine (1745–1809) gives evidence of this, as does Francois Pret, of whom there seems to be no existing biography or even dates, but, whose robust and richly painted flowerpiece in the Prado, places him as a master, and moves the art of flower painting a step forward. It is in France, in the second part of the 19th century that flower painting reveals a new and glowing character. The changes brought about in painting by the French painters of this time are well known. The naturalistic trend of Courbet; Manet's aesthetic interest in colour and his admiration of Japanese art, tending to rich vivid masses of pure colour; Monet's interest in light, and colour in light—all these had their influence on flower painting.

France produced, adding these new phases to those of the Dutch school, a group of flower painters that is unsurpassed. In the decade between 1830 and 1840 were born Edouard Manet (1832–83), Antoine Vollon (1833–1900), Fantin-Latour (1836–1904) and Claude Monet (1840–1926). Manet and Monet were the real influences for added characteristics of painting, but Fantin-Latour was the great painter of flowers. In Manet's flower painting rich arrangement of colour in a bright and surrounding light gives a sumptuous quality. His flowers are painted with great gusto, freshness and luminosity. His influence is perhaps stronger on the painters of flowers of to-day than that of any other painter; but Monet's influence has been of an unmeasurable quantity also. He made the world see colour in light, pure colour of a vibrating, iridescent quality. In his pictures he has perhaps painted flowers rather more as a medium by which to express this feeling for pure colour in light and in space than because of the beauty of the flowers in themselves. Latour, on the other hand, understood flowers, their delicacy of form, growth and colour, and painted them for their own great beauty, but, in doing so, combined the qualities of his two great contemporaries. His pictures are beautiful arrangements of form and colour with all the living vibrating, if passing, qualities of: the flower, placed in full light with atmosphere surrounding them, and they mark to the present time the high spot of Western flower painting.

Between the realistic Dutch period and the French impressionistic, William Henry Hunt (1790–1864) in England, painting in a method quite his own, produced flower pictures in water colour that, ungracious as they generally are, had much of the exactness of floral structure with a suggestion in colour, that was slightly related to what the French later developed to such a supreme degree. Later still, Francis E. James (1849–1920) developed in water-colour a crisp delightful phase of flower painting. Contemporary with the great French impressionists, John La Farge (1835–1910) in America was a true flower painter, and the forerunner of a number of flower painters in this country.

Abbott Thayer, Wilton Lockwood, Maria Oakley Dewing, Charles Demuth and Laura Hills are artists who have found in flowers subjects for their paintings, and each has added something to the art. (See also PAINTING: WATER-COLOUR PAINTING.)

(G. W. D.)

FLOWERPECKER or midget, common names for many species of tiny, often brilliantly coloured song birds of the family Dicaeidae. Their greatest centre of abundance is in the Indo-Malayan region, extending east to the Solomon Islands and south across Australia. They are mainly three to four inches long, with short tails and fairly short wings. The male is usually more brilliantly coloured than the female, often with crimson or orange, black or dull blue, and gray. The bill is rather thick, short, triangular, slightly down-curved, and finely serrated at the tip. Flowerpeckers feed in tree tops and bushes along forest borders and gardens, on tropical mistletoe berries and tiny insects and spiders.

The nest, with four or five white eggs, may be a tiny cup of fibres and down suspended from a twig, or may be placed in a natural cavity of a tree or tunneled burrow in the ground. The nest of the species known as pardalotes, or diamond birds, confined to Australia, is in the ground, one species even digging its burrow in the desert plains of the southwest interior. (G. F. Ss.)

FLOWERS, ARTIFICIAL. Imitations of natural flowers are sometimes made for scientific purposes (as the collection of glass flowers at Harvard university, which illustrates the flora of the United States), but more often as articles of decoration. A large variety of materials have been used in their manufacture by different peoples at different times—painted linen and shavings of stained horn by the Egyptians, gold and silver by the Romans, rice-paper by the Chinese, silkworm cocoons in Italy, the plumage of highly coloured birds in South America, wax, small tinted shells, etc. At the beginning of the 18th century the French, who originally learned the art from the Italians, made great advances in the accuracy of their reproductions, and towards the end of that century the Paris manufacturers enjoyed a world-wide reputation. About the same time the art was introduced into England by French refugees and soon afterwards it spread also to America.

The industry is now a highly specialized one and comprises a large number of operations performed by separate hands. Four main processes may be distinguished. The first consists of cutting up the various fabrics and materials into shapes suitable for forming the leaves, petals, etc. This may be done by scissors, but more often stamps are employed which will cut through a dozen or more thicknesses at one blow. The veins of the leaves are next impressed by means of a die, and the petals are given their natural rounded forms by goffering irons of various shapes. The next step is to assemble the petals and other parts of the flower, which is built up from the centre outwards; and the fourth is to mount the flower on a stalk formed of brass or iron wire wrapped round with suitably coloured material, and to fasten on the leaves required to complete the spray.

FLOYD, JOHN (1572–1649), English Jesuit, was born in Cambridgeshire. When at Rome in 1592 he joined the Jesuits, and by 1606 was a missionary priest in England. He had considerable fame as a preacher and teacher, and was frequently arrested. His last years were spent at St. Omer where he died on Sept. 15, 1649. His works are listed in Fellow's *Bibl. Dict. Eng. Caths.* (1885).

FLOYD, JOHN BUCHANAN (1807–1863), American politician, was born at Blacksburg, Va., on June 1, 1807. He was the son of John Floyd (1770–1837), governor of Virginia, 1830–34. In 1826 he graduated from South Carolina college, after which he practised law in Virginia and in Helena, Ark. He was a representative in the Virginia legislature, 1847–49, and governor of Virginia, 1849–52; afterward he was again returned to the state legislature. In 1857 President James Buchanan appointed him secretary of war.

When Maj. Anderson on Dec. 26, 1860, transferred his forces in Charleston harbour from Ft. Moultrie to Ft. Sumter, the move that resulted in the outbreak of hostilities in the Civil War, Floyd claimed that the act was contrary to his orders. When the president and a majority of his cabinet upheld and defended Anderson's move, Floyd resigned and returned to his Virginia home, becoming a secessionist in his sympathies. A few days previous to his resignation President Buchanan had requested a resignation because of certain financial irregularities in Floyd's department due to extremely careless administration. Whether the request had reached Floyd at the time he resigned and the Ft. Sumter incident merely furnished him with a pretext for a more honourable exit is not known. Charges made later that he used his office to furnish arms to the south in anticipation of war were disproved by an investigating committee of the house of representatives Jan. 1861. He was commissioned a brigadier general in the Confederate service and employed first in operations in western Virginia. In Feb. 1862, he became commander of the Confederate forces at Ft. Donelson. When resistance seemed useless he escaped with part of his forces, leaving Gen. S. B. Buckner to surrender to Gen. U. S. Grant. For this President Jefferson Davis relieved him of his command. He died at Abingdon, Va., Aug. 26, 1863.

See P. G. Auchampaugh, *James Buchanan and his Cabinet on the Eve of Secession* (1926); J. F. Rhodes, *History of the United States, 1850–77*, vol. iii; R. M. Hughes, "Floyd's Resignation from Buchanan's Cabinet," *Tyler's Quarterly*, vol. v (1923).

FLUDD or **FLUD, ROBERT** [ROBERTUS DE FLUCTIBUS] (1574–1637), English physician and mystical philosopher, son of Sir Thomas Fludd, treasurer of war to Queen Elizabeth in France and the Low Countries, was born at Milgate, Kent. After studying at St. John's college, Oxford, he travelled in Europe for six years, and became acquainted with the writings of Paracelsus. He subsequently returned to Oxford, became a member of Christ Church, took his medical degrees, and ultimately became a fellow of the College of Physicians. He practised in London with success, although it is said that he combined a good deal of faith-healing with purely medical treatment. Following Paracelsus, he endeavoured to form a system of philosophy founded on the identity of physical and spiritual truth. The universe and all created things proceed from God, who is the beginning, the end and the sum of all things, and to Him they will return. The act of creation is the separation of the active principle (light) from the passive (darkness) in the bosom of the divine unity (God). The universe consists of three worlds: the archetypal (God); the macrocosm (the world); the microcosm (man). Man is the world in miniature; all the parts of both sympathetically correspond and act upon each other. It is possible for man (and even for the mineral and the plant) to undergo transformation and to win immortality. Fludd's system may be described as a pantheistic materialism, which, allegorically interpreted, he put forward as containing the real meaning of Christianity, revealed to Adam by God himself, handed down by tradition to Moses and the patriarchs, and revealed a second time by Christ. The opinions of Fludd had the honour of being refuted by J. Kepler, P. Gassendi and M. Mersenne. Though rapt in mystical speculation, Fludd was a man of varied attainments who did not disdain scientific experiments. He was an ardent defender of the Rosicrucians, and Thomas De Quincey considered him to have been the immediate, as J. V. Andrea was the remote, father of freemasonry. Fludd died in London on Sept. 8, 1637.

See J. B. Craven, *Robert Fludd, the English Rosicrucian* (1902), where a list of his works is given; A. E. Waite, *History of the Rosicrucians* (1887); Thomas De Quincey, *The Rosicrucians and Freemasons*; J. Hunt, *Religious Thought in England* (1870). His works were published in 6 vols., Oppenheim and Gouda, 1638.

FLÜGEL, JOHANN GOTTFRIED (1788–1855), German lexicographer, was born at Barby near Magdeburg, on Nov. 22, 1788. He was originally a merchant's clerk. Emigrating to the United States in 1810, he made a special study of the English language. He returned to Germany in 1819, and in 1824 was appointed lector of the English language in the University of Leipzig. In 1838 he became American consul, and subsequently representative and correspondent of the Smithsonian institution at Washington, D.C., and several other leading U.S. literary and scientific institutions. He died at Leipzig on June 24, 1855.

The fame of Flügel rests chiefly on the *Vollstandige Englisch-Deutsche und Deutsch-Englische Worterbuch*, first published in 2 vols. (Leipzig) in 1830, which had an extensive circulation not only in Germany but in England and the U.S. In this work he was assisted by J. Sporschil, and a new and enlarged edition, edited by his son Felix Flügel (1820–1904), was published at Brunswick (1890–92). Another edition, in two volumes, edited by Prof. Immanuel Schmidt and S. Tanger appeared (Brunswick, London and New York) in 1906. Among his other works were *Vollstandige Engl. Sprachlehre* (1824–26); *Triglotte, oder Kaufmannisches Wörterbuch in Drei Sprachen, Deutsch, Englisch und Franzosisch* (1836–40); *Kleines Kaufmannisches Handwörterbuch in Drei Sprachen* (1840); and *Praktisches Handbuch der Engl. Handelcorrespondenz* (1827, 9th ed. 1873). All these passed through several editions. In addition, Flügel also published in the English language: *A Series of Commercial Letters* (Leipzig, 1822), a ninth edition of which appeared in 1874 under the title *Practical Mercantile Correspondence* and a *Practical Dictionary of the English and German Languages* (2 vols., Hamburg and Leipzig, 1847–52; 15th ed., Leipzig, 1891). The last was continued and re-edited by his son Felix.

FLUID MECHANICS: *see* MECHANICS, FLUID.

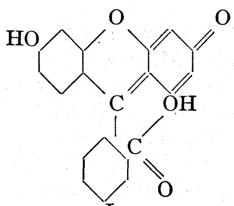
FLUKE, a name given to several kinds of fish, flat in shape, especially to the common flounder; also to a trematode worm, resembling a flounder in shape, which infects the liver and neighbouring organs of certain animals, especially sheep, and causes liver rot. The most common is *Fasciola hepatica* (*see* TREMATODES). The name is given to a species of kidney potato; to the holding plates, triangular in shape, at the end of the arms of an anchor; and to the triangular extremities of the tail of a whale. The use of the word as a slang expression seems to have been first applied in billiards to an unintentional scoring shot.

FLUORESCEIN, a synthetic colouring matter, was discovered in 1871 by A. von Baeyer who prepared it by fusing together phthalic anhydride (*q.v.*) and resorcinol (*q.v.*) at temperatures between 180° and 200° C. The chemical formula of fluorescein is $C_{20}H_{12}O_5$. Its name follows from the fact that the deep-red solutions of its sodium or potassium salt exhibit an intense yellowish-green fluorescence so strong that it can be seen in dilutions as high as 1:40,000,000.

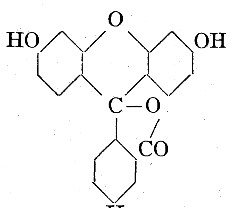
Because of its very high tinctorial power, the sodium salt of fluorescein, a dyestuff sold under the name of uranine, is used as a water tracer and a water marker. Millions of pounds of the product were used during the years of World War II for marking spots on the surface of the ocean. Eosine. a bright scarlet dyestuff, used mostly for the manufacture of a brilliant red pigment, is made by brominating fluorescein to its tetrabromo derivative.

Likewise erythrosine, somewhat bluer in shade than eosine, is tetraiodofluorescein. Rose Bengal, once an important colouring matter for dyeing wool and silk in rich. dark-red shades, was made by condensing tetrachlorophthalic anhydride with resorcinol and then iodinating the resulting tetrachloro fluorescein The product, no longer of commercial importance. was tetraiodotetrachloro fluorescein.

Structure and Preparation. — Fluorescein is resorcin phthalein. and is usually considered to have the quinoid structure I. although there is positive evidence that in solution it consists of an equilibrium mixture of I and the benzenoid form II. Moreover, derivations of both forms have been made, particularly the esters and ethers.



I



II

Commercially, fluorescein is of considerable importance and is made by heating resorcinol, phthalic anhydride and zinc chloride together at temperatures between 180° and 190° C.. the latter agent hastening the reaction between the other two compounds. The melt is extracted with hot water whereby most of the zinc chloride is dissolved out. The remaining mass is then dissolved in dilute caustic soda, the solution is filtered and the fluorescein is precipitated with acid. By repeating the extraction and precipitation process several times, fluorescein can be obtained in a comparatively pure form. It is a yellow amorphous powder. insoluble in water. but soluble in alcohol from which it crystallizes in dark-red nodules. (J. H. Ss.)

FLUORESCENCE: *see* LUMINESCENCE.

FLUORINE is the most electronegative and most reactive of all known chemical elements. The applications of its compounds range from the use of sodium fluoride as a water additive to the process by which uranium hexafluoride separates and concentrates uranium isotopes in atomic energy installations.

Fluorine is a pale greenish-yellow gas with an irritating odour resembling that of hypochlorous acid. Inhalation of the gas is dangerous except in very low concentration. In the liquid state. fluorine is clear yellow and the solid becomes colourless at −252° C.

Fluorine stands at the head of the halogen family in the periodic table (atomic weight 19. atomic number 9, chemical symbol F). There is only one stable and naturally occurring nuclear species of fluorine, F^{19}, but radioactive isotopes with mass numbers 17 (half life 70 sec.), 18 (112 min.) and 20 (10.7 sec.) have been prepared. Additional properties are listed in the table. The element was first isolated in 1886 by H. Moissan who obtained it by the electrolysis of anhydrous hydrogen fluoride containing dissolved potassium fluoride. He used a U-shaped platinum apparatus including an anode made of platinum iridium alloy, and this classical research brought final success to 75 years of scientific effort.

Numerical Properties of Fluorine

Molecular formula	F_2
Outer electron configuration	$2s^2, 2p^5$
Boiling point	−188° C.
Melting point	−223° C.
Density relative to air	1.32
Density of liquid	1.108 g. per c.c.
Atomic volume of solid	14.62 c.c.
Ionization potential	17.42 v.
Electron affinity	4.13 ev
Covalent radius	0.72 Å
Radius F^- in crystals	1.36 Å
Standard potential $F^- \rightleftarrows \frac{1}{2}F_2 + e$	2.85 v.

The chief source of fluorine is the mineral fluorspar or calcium fluoride, CaF_2, which is widely distributed geologically. It also occurs in cryolite, Na_3AlF_6, fluorapatite, $CaF_2.3Ca_3(PO_4)_2$, as well as in sea water, bones, nails and teeth in small amounts.

When fluorspar is distilled with concentrated sulfuric acid, essentially anhydrous hydrogen fluoride is liberated, which boils at 19.5° C. and dissolves in water to form hydrofluoric acid. Hydrogen fluoride is available in large commercial quantities, and is used widely as a solvent, as a versatile catalyst in organic chemistry and as a reagent for the replacement of chlorine by fluorine in organic compounds.

Elementary fluorine is prepared both commercially and in the laboratory by electrolysis of solutions of potassium bifluoride, KHF_2, in anhydrous hydrogen fluoride. The electrolytic cells or generators are constructed of steel or monel metal with especially treated carbon anodes and usually operate at moderate temperatures (about 100° C.). The process is efficient and the product, which is also available in cylinders under pressure, is of high purity. However, a jet of fluorine under pressure can be dangerous, since it instantly inflames organic matter, many metals and numerous other substances. Both hydrogen fluoride and the corresponding acid. which attacks glass and is used for etching, are corrosive and toxic.

In inorganic chemistry, the highly reactive fluorine combines readily with nearly all the other elements except the inert gases. It reacts with all metals forming a large number of single, double and complex salts, and also with most of the nonmetals. Because of the small size of the fluoride ion, it forms many stable complexes with positive ions; for example, $SiF_6^{=}$, $AlF_6^{\equiv}$.

Elements having variable valences usually show their several oxidation states in combination with fluorine; *e.g.*, the sulfur fluorides S_2F_2, SF_2, S_2F_{10}, SF, and SF,, the latter being the most stable. Many of these compounds have found significant use in the laboratory or in industry.

Boron fluoride. BF_3, and antimony fluoride, SbF_3, as well as hydrogen fluoride are important catalysts for organic reactions; cobaltic fluoride, CoF_3, and chlorine trifluoride, ClF_3, are good fluorinating agents; sulfur hexafluoride, SF,, is used as a gaseous insulator; and uranium fluoride, UF_6, to separate uranium isotopes. Also sodium fluoride. NaF, is used in the treatment of dental caries, and is often added to otherwise deficient water supplies (fluoridation) to reduce tooth decay in children *(see* DENTISTRY).

In the field of organic chemistry fluorine has become increasingly important. On account of the small size and great reactivity of the fluorine atom. elementary fluorine reacts with hydrocarbons to form corresponding fluorocarbons in which all hydrogen has been replaced by fluorine. These may be regarded as the parent substances from which a large number of completely fluorinated, or perfluorinated, organic compounds may be considered to be derived. These compounds are usually characterized by great stability, chemical inertness, high electrical resistance and other valuable physical and chemical properties. They may also be prepared by treating organic compounds with cobaltic fluoride, as well as by the new commercial process of electrolyzing their solutions in anhydrous hydrogen fluoride.

Unsaturated fluorocarbons and their derivatives readily yield polymers and plastics such as Fluon or Teflon $(CF_2CF_2)_x$ and Fluorothene or Kel-F $(CF_2{=}CFCl)_x$, which' are highly resistant and have found considerable commercial application. Closely related substances have found usage as resistant incombustible water-repellent lubricants and coatings. Fluorocarbon chemistry has come to be regarded as a significant subdivision in the organic field.

Another method for introducing fluorine into organic compounds consists of the replacement of nonaromatic chlorine, bromine or iodine by fluorine through the action of hydrogen fluoride, antimony fluoride or other inorganic fluorides as the fluorinating agents. These reactions have been extensively studied, and perhaps the most important commercial application is the large-scale production of dichlorodifluoromethane, CF_2Cl_2 (Freon), the stable nontoxic coolant used in most household refrigerators. A whole series of related substances (Freons, Genetrons) are also widely used as refrigerants and propellants, while the nontoxic compound CF_3Br is an excellent fire extinguisher.

Trifluoroacetic acid. CF_3COOH, can be made from the corresponding chlorine compound by this method as well as by the electrolytic process, and is available in commercial quantities along with related perfluorinated acids, which are also the source of many derivatives.

The stable $-CF_3$ group has been introduced as a side chain into aromatic compounds, and fluorine may be substituted directly on the aromatic nucleus by the diazo reaction. Such products have found use in the dye and pharmaceutical industries and also as insecticides. Finally, the $-CF_3$ group has been combined with many other elements, both metallic and nonmetallic, such as magnesium, nitrogen, phosphorus, arsenic and sulfur, and the products have been employed in organic synthesis and in other ways.

(L. A. B.)

FLUORITE or fluorspar is a common mineral composed of calcium fluoride, and the principal fluorine mineral. The name is derived from its low melting point and its use in metallurgy as a flux and comes from the Latin *fluere*, "to flow." The term fluorescence was derived from the behaviour of fluorite. Most varieties fluoresce strongly under ultraviolet light or other radiations. It may phosphoresce upon heating or after exposure to ultraviolet light. A variety called chlorophane emits a green light upon heating. (See LUMINESCENCE.)

Fluorite is used as a flux in the manufacture of open-hearth steel and in the making of aluminum fluoride and artificial cryolite, used in the production of aluminum (*q.v.*). It is used in opalescent glass, iron and steel enamelware, in the production of hydrofluoric acid, in the refining of lead and antimony and as a catalyst in manufacturing high-octane fuels (see also FLUORINE). Clear colourless fluorite of optical quality is used for apochromatic lenses because of its low index of refraction and low dispersion. A variety known as Blue John from Devonshire, as well as other types, have been used for ornamental vases and other articles.

Fluorite is common in hydrothermal veins, sometimes being the chief mineral, and sometimes the gangue mineral with various metallic ores, such as silver, lead and copper. It is found in pneumatolytic deposits associated with cassiterite, topaz, tourmaline and quartz. It is also found in sedimentary rocks such as limestone and dolomite.

A few of the important occurrences are at Cumberland, Yorkshire, Derbyshire and Cornwall in England; Saxony and Hartz mountains, Germany; the Austrian, Italian, Swiss and French Alps; northern Norway and the Kola peninsula, Russia (yttrium variety); Ontario and British Columbia, Canada; and in the United States in Illinois, Kentucky, Montana, New Mexico and Colorado.

Fluorite crystallizes in the cubic system. The commonest form is the cube, but octahedrons are sometimes found. Composite crystals have been found, made up of an aggregate of tiny cubes in the shape of an octahedron. Penetration twins of two cubes are common.

The octahedral crystals, usually light coloured, have been attributed to high-temperature formation, and the darker cube forms to low-temperature formation. Twinned crystals in the form of interpenetrating cubes are common. A large number of additional forms have been observed in combination, including those with crystal indexes of 110, 210, 310, 211, 311, 221, 331, 123 and 124 (see CRYSTALLOGRAPHY).

The structural arrangement of fluorite consists of calcium ions at the corners and face-centres of the cubic cell, with the fluorine ions at the centres of the eight small cubes into which the unit cube may be divided by the principal planes of symmetry.

Fluorite is no. 4 in Mohs' scale (*q.v.*) of hardness. It has an excellent octahedral cleavage. It is usually in crystals or in cleavable masses, but it is rarely columnar or fibrous. The specific gravity is 3.18, but it may be as high as 3.5 for yttrium and cerium varieties. It is usually transparent or translucent, with a vitreous lustre.

There is a wide range of colours; when pure it is colourless and clear. but commonly it is green, blue, yellow, purple, brown or blue-black; rarely pink or red. The colour may vary irregularly, and sometimes is in zones parallel to crystal faces. There may be a difference in the colour of the transmitted and the reflected light.

The formula is CaF_2, and it is usually quite pure. In certain localities it is found with the rare earths yttrium or cerium replacing calcium in amounts up to 15% to 20%. Dark coloured fluorite from Bavaria contains free fluorine and calcium ions released by radiation. When ground to a powder, this gives an odour of hydrogen fluoride and ozone.

Fluorite may contain minute cavities filled with water, bituminous matter or gas. Inclusions of tiny chalcopyrite crystals are sometimes found. (L. S. RL.)

FLUSHING (Dutch *Vlissingen*), in the province of Zeeland, Netherlands, on the south side of the island of Walcheren, at the mouth of the estuary of the western Scheldt, 4 mi. S. by W. of Middelburg, with which it is also connected by tramway and canal. Pop. (1957 est.) 28,148 (mun.). An important naval station and fortress up to 1867, Flushing later became a packet station. In 1872 the railway was opened which, in conjunction with the boat service to England (Queenborough and Harwich), formed one of the main routes between England and the continent. In 1873 the harbour, docks and canal works were completed. Yet the navigation of the port remained far behind that of Rotterdam or Antwerp.

As a summer resort Flushing acquired considerable popularity. It possesses a town hall, containing a collection of local antiquities, a theatre, an exchange, an academy of sciences and a school of navigation.

The Jakobskerk, founded in 1328, contains monuments to Admiral de Ruyter (1607–76) and Jacob Bellamy (1757–86).

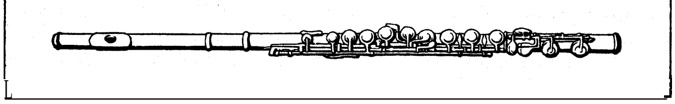
The chief industries are connected with the shipbuilding yards and packet service. The chief imports are ordinarily colonial produce and wine, wood and coal; exports, agricultural produce, shrimps and meat.

Flushing was occupied by Germany in 1940.

FLUSHING, former township and village of Queens county, N.Y., U.S., on Long Island, at the head of Flushing bay; after 1898 a part of the borough of Queens, New York city. Settled in 1644 by English nonconformists who had probably been living at Flushing, Holland, it uas the country seat of many rich New Yorkers and colonial officials before the American Revolution. Flushing Meadow park was the site of the 1939–40 New York world's fair and from 1946 to 1949 served as temporary headquarters for the United Nations general assembly.

FLUTE, in music, is a general term applied to wood-wind instruments consisting of a pipe pierced with lateral holes and blown directly through the mouthpiece without the intervention of a reed. The flute family is classified according to the type of mouthpiece used. *i.e.*, (1) those with the simple lateral mouth-hole or embouchure which necessitates holding the instrument in a transverse position; (2) those nith the whistle or fipple mouthpiece which allows the performer to hold the instrument vertically in front of him; (3) those having no mouthpiece of any sort, in which the column of air is set in vibration by blowing obliquely across the open end of the pipe, as in the ancient Egyptian nay, and the pan-pipe or syrinx (*q.v.*).

Of these the transverse flute has now entirely superseded, not only the obsolete third class, but also the whistle flute, which has



BY COURTESY OF CARL FISCHER, INC.
THE BOEHM FLUTE. MODELLED BY THEOBALD BOEHM

survived only in the so-called penny whistle, in the "flute-work" of the organ (*q.v.*), and in the French flageolet.

The Transverse *Flute* or *German* Flute includes the concert *flute*, known both as flute in C and as flute in D, the piccolo (*q.v.*) or octave flute, and the fife (*q.v.*), and consists of a tube open at one end and nominally closed at the other by means of a plug or cork stopper. Virtually, however, the tube is an open one giving the consecutive harmonic series of the open pipe or of a stretched string.

The compass of the modern flute is three octaves with chromatic semitones from middle C upwards. The sound is produced by holding the flute transversely with the embouchure turned slightly outwards, the lower lip resting on the nearer edge of the embouchure, and blowing obliquely across, not into, the orifice. The flat stream of air from the lips, known as the air-reed, breaks against the sharp outer edge of the embouchure. The current of air, thus set in a flutter, produces in the stationary column of air within the tube a series of pulsations or vibrations caused by the alternate compression and rarefaction of the air and generating sounds of a pitch proportional to the length of the stationary column, which is practically somewhat longer than the length of the tube. The length of this column is varied by opening the lateral finger-holes.

The bore of the early flute with six finger-holes was invariably cylindrical throughout, but towards the end of the 17th century a modification took place, the head joint alone remaining cylindrical while the rest of the bore assumed the form of a cone having its smallest diameter at the open end of the tube. The conical bore greatly improved the quality of tone and the production of the higher harmonics of the third octave. Once the conical bore had been adopted, the term flute was exclusively applied to the new instruments, the smaller flutes, then cylindrical, used in the army being designated fifes (q v.). At the present day in England, France and America, the favourite mode of construction is that introduced by Theobald Boehm, and known as the "cylinder flute with the parabolic head." though the conical type is still usually employed in military bands

The quality of tone depends somewhat on the material of which the flute is made. Silver and gold produce a liquid tone of exquisite delicacy suitable for solo music, cocus-wood and ebonite, a rich mellow tone of considerable power suitable for orchestral music. The tone differs further in the three registers, the lowest being slightly rough, the medium sweet and elegiac, and the third bird-like and brilliant. The proportions, position and form of the stopper, and of the air chamber situated between it and the embouchure are mainly influential in giving the flute its peculiar slightly hollow timbre. due to the paucity of the upper partials of which, according to Helmholtz, only the octave and twelfth are heard.

The technical capabilities of the flute are practically unlimited to a good player who can obtain sustained notes diminuendo and crescendo, diatonic and chromatic scales and arpeggios both legato and staccato, leaps, turn, shakes, etc., with the greatest facility

Instruments of the flute type appear to be of very ancient origin The Hindus, Chinese and Japanese all claim to have had them from time immemorial. the like applying to the Egyptians, and also to the Greeks and Romans.

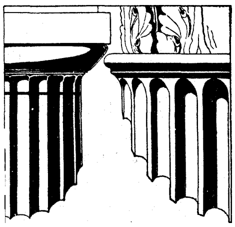
The first essentially western European trace of the transverse flute occurs in a German ms. of the 12th century, the celebrated *Hortus deliciarum* of the abbess Herrad von Landsperg, in which Fol. 221 shows a syren playing upon an instrument of this type, which Herrad explains in a legend as a *tibia.*

According to Quantz, it was in France, and about the middle of the 17th century, that the first modern modifications were introduced in the manufacture of the flute, including the abandonment of the cylindrical bore in favour of a conical one, and the introduction of keys. But no maker had as yet devoted his attention to the rational division of the column of air by means of the lateral holes, and it was left for Theobald Boehm, a Bavarian maker, to embody this and many other improvements in the completely remodelled instruments which he brought out in 1832 and in 1846.

The old English *fipple flute* or *flute à bec* is described under the headings RECORDER and FLAGEOLET. (X.)

In architecture flute describes vertical channels or curved sinkages used in a series for decorative purposes, especially when employed upon the shafts of columns. Flutes may be separated from each other by a sharp edge or ridge known as an arris, or by a small, vertical flat surface known as a fillet. The earliest known flutes occur in Egyptian columns. where they are obviously the result of the attempt to decorate simply the piers of a rockcut tomb If the corners are cut off a square pier. an octagonal pier results: if its corners are in turn cut off, one of 16 sides Such piers are common in the tombs at Beni Hassan (12th dynasty). In many, the sides are made slightly concave in order to emphasize the vertical lines at the corners The result is a fluted pier. In the temple at Karnak (c. 1400 B C), and that of Queen Hatshepsut, at Deir-el-Bahri (c. 1500 B C.), similar fluted supports appear. Such piers are sometimes known as Proto-Doric.

Whether borrowed from the Egyptians or developed independently. flutes became universal in Greek Doric building. In early examples they are segmental in plan, but later a section approximating an elliptical curve, or one formed with three centres, was the most common type as such a curve gave greater emphasis to the line of the arris, without too great depth in the flute itself. In columns of the Ionic and Corinthian orders the flutes are separated by fillets and here, more than ever, an elliptical section is necessary. in order to bring the edges of the flute as nearly parallel to a column radius as possible. In general, flutes separated by fillets are deeper than flutes separated by arrises, varying from one quarter of the width, as in the Ionic columns in the cella of the temple at Bassae (c. 450 B C), to one half the width, as in the Erectheurn. The number of flutes varies from 16 to 24 in Doric examples. with 20 as the most common number. In Ionic and Corinthian columns, the number of flutes is usually greater, averaging 24, but in the archaic temple of Artemis at Ephesus (*c.* 500 B C) there are 52. Similarly in the Persian palace columns of Susa and Persepolis, obviously influenced by Greek work, the number of flutes is great, varying from 30 to 52. Roman columns mostly followed Greek precedent, but with less refinement and a general substitution of semicircular and segmented flutes. in place of the refined Greek ellipses. In some of the smaller Roman examples, particularly in domestic work, the lower portions of the flutes are filled either with a convex moulding known as reeding or by merely filling them to a flat surface in an effort to preserve the arrises and fillets from damage. Tnisted, helical or spiral flutes are found occasionally in Roman work, are frequent in mediaeval Italy and were spasmodically used during the high Renaissance and Baroque, as in Sammichele's Bevilacqua palace at Verona (1530). Except where there was direct imitation of Roman work, as in much of the Romanesque of Burgundy and Provence, fluting was not used in mediaeval work outside of Italy.



FLUTE

Flutes are frequently used to decorate horizontal bands. especially the coronas, or flat projecting portions of the Corinthian cornice, and also in friezes. as in much English and American late Georgian work. Fountain basins and sarcophagi are also often fluted, in many cases with flutes not vertical, but taking an S curve. Fluting occurs in mediaeval work only in styles where there was much imitation of Roman work, as the Romanesque of Burgundy and Provence. (T. F. H.)

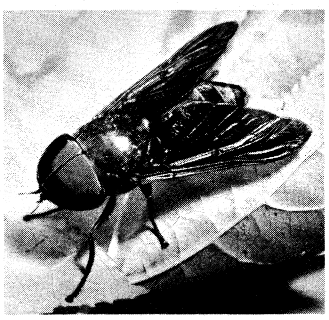
FLUX, in metallurgy, a substance introduced in the smelting of ores to promote fluidity, and to remove objectionable impurities in the form of a slag. The substances in commonest use are: —lime or limestone, to slag off silica and silicates, fluorspar for lead, calcium and barium sulphntes and calcium phosphate, and silica for removing basic substances such as limestone. Other sub. stances are also used, but more commonly in assaying than in metallurgy. Sodium and potassium carbonates are valuable for fluxing off silica; mixed with potassium nitrate, sodium carbonate forms a valuable oxidizing fusion mixture, "black flux" is a reducing flux composed of finely divided carbon and potassium carbonate, and formed by deflagrating a mixture of argol with quarter to half its weight of nitre. Borax is very frequently employed; it melts to a clear liquid and dissolves silica and many metallic oxides. Potassium bisulphate is useful in the preliminary treatment of refractory aluminous ores. Litharge and red lead are used in silver and gold assays, acting as solvents for silica and any metallic oxides present. The word is derived from Lat. *fluxus,* a flowing, and retains this meaning in medicine, etc.

FLUXIONS, a form of the calculus developed by Sir Isaac

Newton (*q.v.*), beginning in 1665. The word "fluxion," as used by him, denoted the rate at which a variable (flowing quantity, fluent) increases or decreases at a given instant of time. If x and y were taken to be the flowing quantities (fluents) $y = x^3$, then it could be shown that $\dot{y} = 3x^2\dot{x}$. In the alternative differential notation we should have $dy = 3x^2dx$. See CALCULUS. DIFFERENTIAL AND INTEGRAL.

FLY, a common name used in a restricted sense by entomologists for any two-winged insect belonging to the order Diptera (*q.v.*), and more loosely as part of the common names of many other insects that are not true flies. Thus, stone flies belong to the order Plecoptera; green fly, black fly, white fly and lantern flies to Hemiptera, suborder Homoptera; May flies to Ephemeroptera; dragonflies and damsel flies to Odonata; alder flies to Neuroptera; scorpion flies to Mecoptera; caddis flies to Trichoptera; butterflies to Lepidoptera; sawflies and ichneumon flies to Hymenoptera; and fireflies to Coleoptera.

The name fly is also used to distinguish the winged adult stage of many insects; *e.g.*, ant lions are voracious larvae whose winged adults are called ant lion flies. It may also be applied to any small. abundant, probably noxious insect, as in the farmers' name turnip fly for the turnip flea beetle. Flies used in fly-fishing (see FISHING) are designed to imitate the aquatic insects that have bred in the water and that are snapped at by fish when they hatch out as winged adults at the surface (mostly May flies, stone flies and caddis flies).



JOHN H. GERARD

FIG. 1. — BLACK HORSEFLY (TABANUS ATRATUS); ABOUT NATURAL SIZE

Without other qualification "fly" popularly indicates the housefly (*q.v.; Musca* damestica) or other true flies of generally similar build (fig. 1). "Fly" used as a collective noun ("the horses went down with fly") refers to disease-carrying. biting flies, and especially to attacks by the tsetse fly (*q.v.; Glossina*). "Fly-blown" means contaminated with the eggs and larvae (maggots) of blowflies; figuratively, it has also come to mean in a state of chronic neglect. The true flies, Diptera, are the subject of this article; for information on other so-called flies see titles under their common names, as ALDER FLY; BLACKFLY; CADDIS FLY; DRAGONFLY ; etc.

INTRODUCTION

Importance of Flies. — Estimates of the total number of known species of true flies in the world range from 60.000 to 85,000. Nearly every study of any group results in the discovery of new species and often of new genera. Probably most completely known are the tsetse flies, confined to tropical Africa. The mosquitoes. of the family Culicidae. have attracted many more workers than any other group of insects, yet even in this family there are groups, of no special medical importance, that are comparatively poorly known (see MOSQUITO). The pomace fly or small fruit fly, *Drosophila melanogaster,* has been laboratory bred for many years and intensively used in genetics studies (see DROSOPHILA).

Flies probably affect human welfare in more different ways than any other insects. These may be summarized as follows: direct transmission of specific diseases such as malaria, where the fly (in this case the mosquito) is an essential link in the chain; fortuitous or mechanical transmission, for example, through the contamination of food by houseflies; myiasis, or invasion of the human body by larvae of certain flies; similar infections or infestations of farm stock or draft animals; damage to cultivated plants by the feeding of the larvae of flies. (See ENTOMOLOGY: Applied *Entomology.*)

Characteristics. — The true flies are among the most highly evolved insects, and share a common ancestry with the orders Neuroptera. Mecoptera, Trichoptera and Lepidoptera, forming the so-called Panorpoid complex of R. J. Tillyard. The two most characteristic features of true flies are the modification of the hind wings into balancing organs and the structure of the proboscis in relation to feeding habits.

Wings of Flies. — True flies never have more than one pair of wings, which are on the second thoracic segment (mesothorax), and which correspond to the forewings of butterflies and to the elytra, or wing covers, of beetles. The hind wings, on the third thoracic segment (metathorax), have become modified into stalked organs like drumsticks, known as halteres, which are used to maintain stability in flight. The halteres vibrate in a fixed plane, and if the fly pitches. rolls or yaws in flight, nerve cells at the bases of the halteres are excited, producing impulses that affect the musculature in such a way as to make the necessary corrections in balance. This is similar in principle to the automatic pilot of an airplane.

The veins, or stiffening ribs, of the wing follow a definite pattern, which is remarkably constant in each genus and even in each species and thus proves of great value in classification. All flies have strong veins supporting the leading edge of the wing, as is shown in the examples illustrated in fig. 2. Some, like the horseflies (*Tabanus*), have most of the veins that were present in the hypothetical primitive insect; others, as shown, have fewer and weaker veins over much of the wing. These variations undoubtedly affect the functioning of the wing in flight, but exactly how remains to be explained. Also to be determined is whether a correlation exists between wing venation and observable differences in flight among flies.

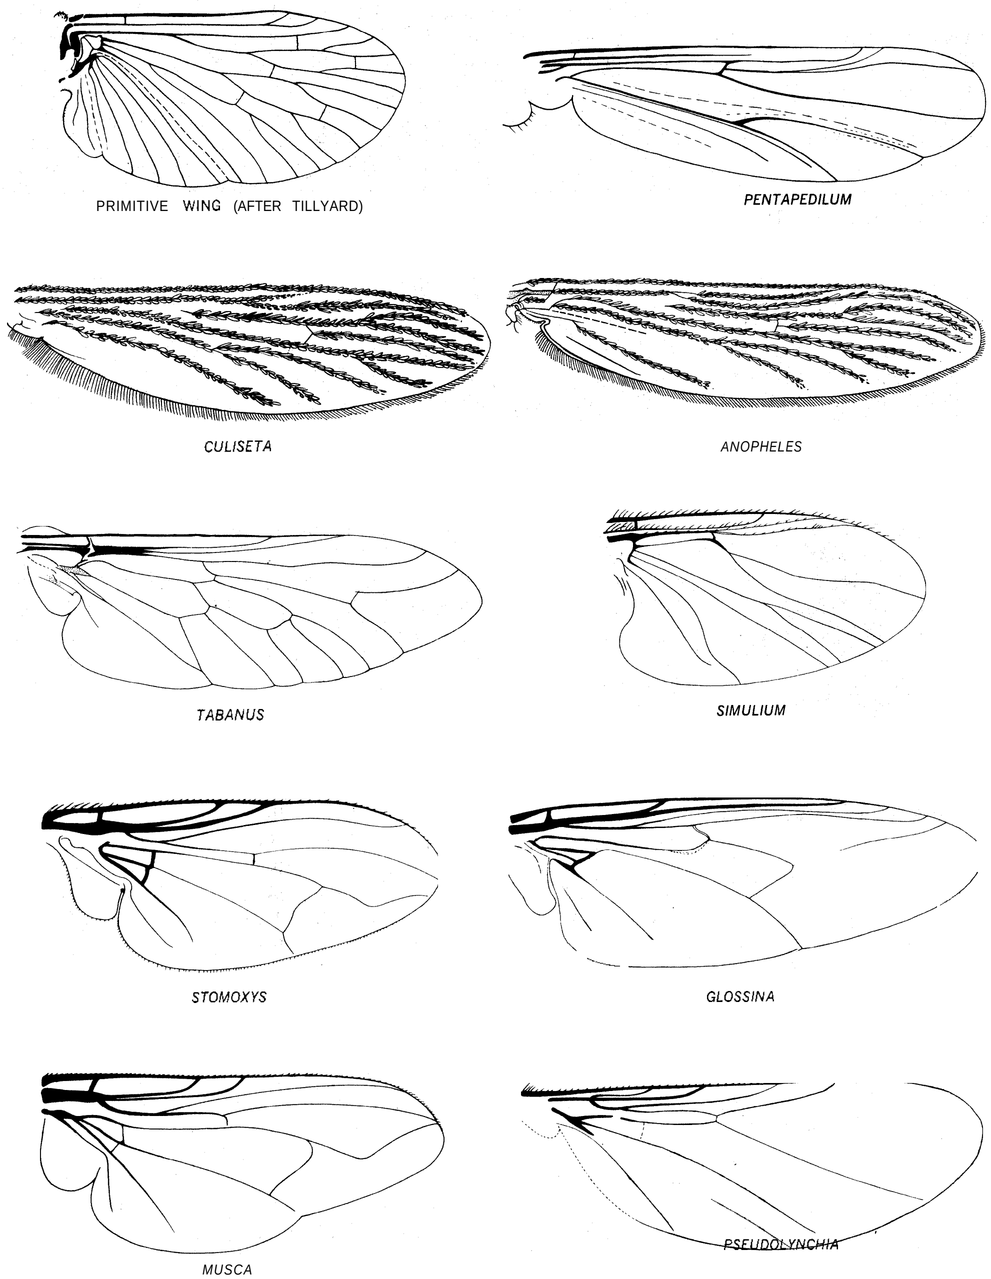
There are many flightless flies in which the wings are reduced in size, peculiar in shape, or missing altogether. A few species have functional wings that are used for the nuptial flight, after which they are broken off near the base. Flightlessness in certain flies may generally be associated with a parasitic life or with isolation on a remote island, on a high mountaintop, in a cave or in any habitat that is so restricted that a winged insect might easily stray and be unable to make its way back again. Yet this is not the whole story: the family Nycteribiidae, parasitic on bats, are all wingless; the family Streblidae, equally restricted to bats, are mostly fully winged. Flightless flies occur sporadically in many different families and, while some advantage can usually be seen in the loss of wings, it would seem that other flies can live in the same situation and still retain their powers of flight.

Despite the reduction or absence of wings, wingless flies can be recognized as belonging to the Diptera by the structure of the thorax, which always retains some of the modifications suited to the possession of one pair of wings. The dorsal, or upper, aspect of the thorax consists mainly of the dorsally enlarged middle segment, or mesothorax, which has evolved to accommodate the huge muscles of flight; the prothorax and metathorax, by comparison, are insignificant. The lower, or ventral, aspect of the thorax is much more equally divided into three segments, to each of which a pair of legs is attached.

Mouth Parts and Feeding Habits. — Adult flies feed upon fluids, which they draw up through a tubular proboscis. The component parts of the proboscis, when they are all present, are the same as those of grasshoppers or of beetles, which masticate solid food: labrum, or upper lip; a pair of mandibles; a pair of maxillae, with maxillary palps; a hypopharynx; and a labium, the lower lip. In flies these mouth parts are combined in various ways to form two distinct tubes (fig. 3), saliva being expelled through one and liquid food drawn in through the other.

Flies can be broadly divided into those that "mop-up," or sponge, liquid food from an exposed surface and those (erroneously called biting flies) that pierce the skin of another insect or of a vertebrate animal in order to suck blood.

Flies With Spongelike *Mouth Parts.*—The basic food of both sexes of most flies is carbohydrates. mostly in the form of nectar and pollen, and, of course, water and perhaps mineral salts. To get these substances. flies frequent flowers, pools of water, fresh dung, and most damp, rotting or fermenting matter. The great majority of living flies do not pierce skin or suck blood, but satisfy themselves with liquid food mopped up by the labium. The tip of the labium is divided into two lobes, called labella, the inner faces



FROM HERMS, "MEDICAL ENTOMOLOGY"; BY PERMISSION OF THE MACMILLAN CO., PUBLISHERS

FIG. 2.— WINGSOF DIPTERA

of which are lined with tiny, branching, open tubules, the pseudotracheae (fig. 3).

In normal use these tubules act as a fine sieve, allowing only liquids and the most minute solid particles to enter the proboscis, They are modified in various ways to suit the feeding habits. In many flies the labella has become a huge, spongelike organ, as in the housefly (fig. 4).

Flies With Piercing *Mouth* Parts. — The basic carbohydrate diet suffices to provide the adults of most flies with energy for flight and mating, but the females of some species need proteins to provide nourishment for the eggs. The habit of bloodsucking. interpreted as a way of obtaining this extra protein, was therefore primitively confined to female flies. This situation persists in such families as mosquitoes (Culicidae), black flies and buffalo gnats (Simuliidae), sand flies (Psychodidae), biting midges (Ceratopogonidae) and horseflies (Tabanidae).

At least some of these bloodsuckers can lay one batch of eggs without a blood meal. but all require blood before they can ripen a second batch. According to J. A. Downes (1958) the ancestral flies were apparently bloodsuckers. The mandibles and maxillae are drawn out into lancet blades, or stylets, which, by means of a combination of sharpened edges and backwardly projecting teeth, are suited for piercing the skin of vertebrates and lacerating capillaries. The released blood is drawn up into the food channel of the proboscis.

Some flies that earlier evolved spongelike mouth parts, losing the stylets, have secondarily developed piercing adaptations, associated with the return of these species to a bloodsucking habit. Thus robber flies (Asilidae) and dance flies (Empididae) have the hypopharynx, which bears the salivary duct, sharpened at its tip, and usk it like a bradawl against their insect prey. Many flies with big, spongy labella are able to turn these back to expose a pair of prestomal "teeth," with which they can rasp through the skin of other insects (*e.g.,* in Dolichopodidae) or even vertebrates and man (in *Musca crassirostris*).

The really efficient bloodsuckers of this group. such as the tsetse fly (*Glossina*), its relative the stable fly (*Stomoxys*) and the parasitic Hippoboscidae, Nycteribiidae and Streblidae have hardened the labium and reduced the spongy labella. while retaining prestomal teeth, so that the proboscis becomes a sort of miniature hollow drill In all flies that have redeveloped the bloodsucking habit this modification of the proboscis has been adopted by both sexes.

STRUCTURE

Size. — Flies have a tremendous range of size. The smallest midges are about 1 mm. long, and are difficult to see, except when a swarm is caught by sunlight and appears as a cloud of dancing specks. The largest robber flies (Asilidae) may be almost 3 in. (75 mm.) long, with a 2- to 3-in. wing span; the bulkiest flies, Pantophthalmidae, and some Asilidae, are not quite so long, but may be about 50 mm.. their bulk exceeding that of the tiny midge by about 125.000 times.

Shape.—Flies vary from slender. elongate insects, like the crane flies (fig. 5), to thickset, bristly flies like the housefly and bluebottle. Nearly all have a large, mobile head, a great part of which is occupied by the compound eyes. Male flies of many species are holoptic, the eyes meeting in the middle line and almost obliterating the rest of the head; females are almost invariably dichoptic, the eyes being separated by a strip called the frons. Where this difference is present, the sexes are easily distinguished, but in Xsilidae and in many families of the Acalypterae (see below) both sexes have separated eyes. In the family Diopsidae and in a few genera in other families, the eyes, held far apart at the end of long stalks, have the appearance of some sort of range finder.

Simple eyes, ocelli, believed mainly to perceive intensity of light rather than to make an image, are found in many flies as a group of three at the top of the head (vertex). Ocelli are clearly not essential, since flies without them seem in no way handicapped.

Body Parts.—The relative size and shape of the eyes and antennae among various families of flies vary considerably (fig. 6). As in other insects the antenna is composed of three parts: the basal segment, or scape; the second segment, or pedicel; and the remaining end portion, called the flagellum, which though superficially subdivided is one long compound segment. The long-horned flies, suborder Nematocera (literally, "thread-horn"), are so-called because nearly all the members have a long, threadlike flagellum consisting of a number of similar divisions. In the rest of the Diptera, the short-horned flies, the flagellum is much shorter, and constitutes a complex third segment that is variously modified but generally carries some of its divisions in the form of an appendage called either a style or an arista, according to its length and point of attachment.

The mouth parts have already been discussed. The maxillary palps are generally prominent, but only rarely take on a distinctive shape.

The thorax is always remarkable for the great development of the middle segment (mesothorax), but otherwise does not vary very greatly. Occasionally it bears spines of unknown function (*e.g.,* in Stratiomyidae and some Diopsidae). The posterior section of the mesothorax is the scutellum, a shield-shaped structure that seems to play an important part in flight mechanics. Occasionally the scutellum is enlarged: in Thyreophoridae it is abnormally long and triangular, and in Celyphidae it covers the abdomen dorsally, making these flies look like bee-tles.

FIG. 3.—THE TWO TYPES OF PIERCING MOUTH PARTS OF BLOODSUCKING FLIES (GREATLY MAGNIFIED)

(Above) Mouth parts of a horsefly (*Tabanus*), showing bladelike maxilla and mandible, and spongelike labella; (below) mouth parts of a stable fly (*Stomoxys*), showing the reduced maxilla and mandible, the palps and the thin, hard labium and labella produced as the piercing organ

The legs have all the segments well developed: coxa; trochanter; femur; tibia; and five-segmented tarsus. The legs are generally bristly. and in predaceous flies (*e.g.,* Asilidae, Empididae, Ephydridae) the femur and tibia of one or more pairs are often enlarged and equipped with strong spines or bristles that aid in seizing prey. Often the male may have the legs specially adapted to grip the &- male during pairing, and in some species (notably in Dolichopodidae) the tarsus and sometimes the tibia are broad and bear conspicuous tufts of hair or scales white or brilliantly coloured, which are used in a courtship display. The tip of the tarsus ends in a pair of claws, particularly strongly developed in parasitic flies; beneath each claw there is generally a pad called a pulvillus and centrally an empodium, which may be either a similar pad or a fine bristle.

The abdomen may be long and cylindrical or short and barrel-shaped, but nearly always the segmentation is clearly shown. Usually from four to seven segments are clearly visible, and constitute the abdomen proper. or preabdomen; the eighth to eleventh segments make up the postabdomen, which provides the organs of copulation in male flies and the ovipositor, or egg-laying apparatus, in females. The male postabdomen is very flexible and may be rotated round its longitudinal axis through anything up to 360°, in correlation with differences in the attitudes of the two partners during pairing. The shape and structure of the ovipositor of the female is directly adapted to the method of egg laying. If the eggs are merely dropped onto the ground, the ovipositor is very simple, but if they are laid inside the heads of grasses and in similar places, the ovipositor may be a bladelike organ. Flies that penetrate plant tissue, including fruit flies (Trypetidae or Tephritidae) that pierce the rind of young fruit, have a telescopic ovipositor; those laying eggs in sand or loose earth may have spiny or bristly ovipositors that assist in excavation.

FIG. 4.—HEAD AND MOUTH PARTS OF A FLY OF THE FAMILY **MUSCIDAE** (GREATLY MAGNIFIED)

LIFE HISTORY

Early Stages.—Flies are holometabolous insects; that is, they hatch from the egg as a larva that is quite different from the adult insect in shape and in habitat. At the end of larval life the insect passes through a quiescent pupal stage during which a complete metamorphosis occurs, the larva being transformed at one step into the adult fly, which emerges from the puparium in its final form. After a few hours the newly emergent adult has hardened fully and developed its full size and colour (fig. 7, 8). Contrary to popular belief, small flies never grow into big ones.

Egg.—The eggs of most flies are spindle-shaped and smooth (only rarely with external structures) : the eggs of some anopheline mosquitoes are supported in water by air floats, whereas the eggs of some Drosophilidae and some Muscidae have respiratory "horns" or lobes that, according to H. E. Hinton (1959), ensure a supply of oxygen to such eggs, which are liable to be submerged in rain water. The egg-laying female nearly always lays eggs where the larvae will be able to find its food at hand.

Larva.—The larvae of a very large number of flies feed upon decaying matter, either of vegetable or animal origin. That is why this order of insects has acquired an unsavoury reputation, though in fact these larvae are doing an invaluable service in breaking down organic material and redistributing its elements. Thus compost heaps and all natural media of this nature, including leaf mold, rotting seaweed and the like, are the breeding places of great numbers of flies. Other fly larvae live in carrion and in animal flesh of varying stages of decay. Dead bodies pass through a sequence of stages as the processes of putrefaction go on, and there is a corresponding succession of larvae, each group of flies laying its eggs at such a time that their larvae appear when conditions of temperature, humidity and acidity are best for that species. Larvae living inside growing plant material and causing damage and loss of crops include those of gall midges (Cecidomyiidae), frit flies (Chloropidae) and large fruit flies (Trypetidae).

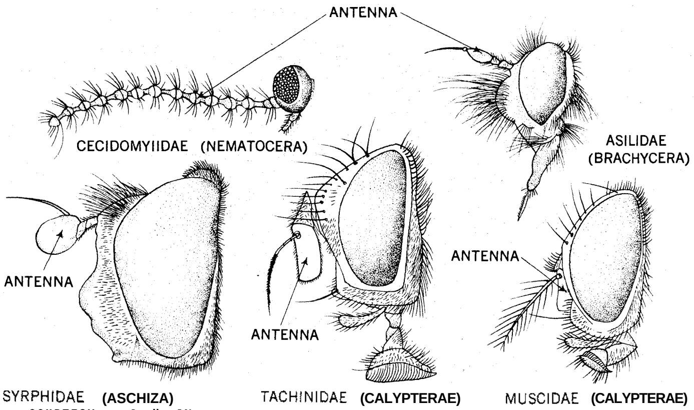
FIG. 5.—CRANE-FLY (TIPULA FULVIPENNIS); ABOUT NATURAL SIZE

As among larger animals there are herbivores and carnivores



BY COURTESY OF C H CURRAN

FIG. 6 — HEADS OF FLIES OF CERTAIN FAMILIES, SHOWING DIFFERENT TYPES OF ANTENNAE (MAGNIFIED)

or their equivalents. In a mass of dung. for example, there are larvae that feed upon the dung itself or upon the molds that grow on it; these are the primary feeders. which themselves are preyed upon by other dipterous larvae. According to D. Keilin, many Muscidae begin life in the first group. but as the larvae become larger and more rapacious they start to prey on their fellows. On vegetation. in the soil and in rotten wood are carnivorous larvae. notably of Syrphidae, Tabanidae and Stratiomyidae, that apparently roam about devouring anything they come upon Many of them live in wet soil or in mud beneath water The truly aquatic dipterous larvae also are divided into primary and secondary feeders.

Simuliidae. most Chironomidae, mosquitoes (Culicidae) and some Syrphidae feed on minute organisms, nhich they sweep into their mouths nith mouth brushes: some mosquitoes. Stratiomyidae. Tabanidae and Ephydridae have exclusively carnivorous aquatic larvae. Larvae of Ephydridae may lead a predaceous existence in most inhospitable media, including brine pools and even pools of crude petroleum round oil wells (the "petroleum fly" of California).

Dipterous larvae never have true. segmented legs such as are seen in, say, larvae of beetles. They often have other appendages, however: gills for breathing under water: telescopic siphons for reaching to the open air; prolegs, or fleshy swellings with spines, which are used to get a purchase when crawling or for clinging to underwater vegetation; or lateral fringed processes that may increase the surface area and help to keep the larva from sinking in a very liquid medium.

Larvae of the more primitive families of the suborder Nematocera generally have a well-developed head. with chewing mouth parts and conspicuous mandibles. Their bodies, usually rather elongate and often with spiracles or breathing apertures on the thorax and on each abdominal segment (*e.g.*, fungus gnats, or Mycetophilidae), have a fairly characteristic form in each family. In the more advanced families, especially in the Cyclorrhapha (see below), the larvae are either grublike or maggotlike; they have no head capsule, and their mouth parts are "mouth hooks," visible through the transparent skin.

The head end of a maggot is pointed, and the posterior end is bluntly truncate; there is one pair of inconspicuous spiracles on the prothorax and a larger. more obvious pair at the posterior end. The shape of these larger spiracles is often the only good structural character that can be used for identification of various larvae.

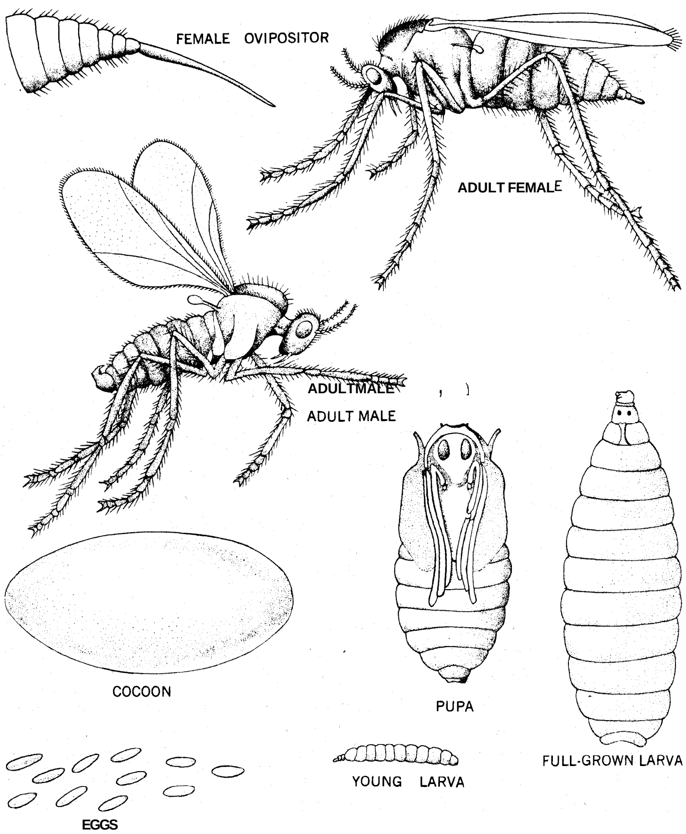
The larvae of Nematocera can usually be named to the family and sometimes, as in mosquitoes. even to the species; among the maggotlike larvae of the higher Diptera such a small proportion have ever been matched with their adults. and the differences between them are so slight. that identification becomes inspired guesswork, based as much upon where the larva was found as upon its systematic characteristics.

The length of larval life varies very considerably. The flies that are of practical importance as medical or agricultural pests are generally those that have several generations a year, and so are able to multiply rapidly during a favourable season. Such flies require about three weeks to proceed from egg to adult, of which time the egg may occupy about two days and the larva and pupa about nine days each. This duration, however, is much affected by temperature and humidity, and larval life may be greatly prolonged under unfavourable conditions. In cold weather a housefly may spend a much longer time as a larva, and many flies have only one generation a year, passing the winter either as larvae or as pupae.

A few flies may have a larval life of two years or even longer. This is particularly true of larvae of Tabanidae. which are predatory on other soil-living insects and which must often go for long periods without meeting any suitable prey.

Pupa.—Most larvae of flies leave their food material when they are fully fed and ready to pupate. Some aquatic groups. notably mosquitoes and the rat-tailed larvae of Syrphidae. have an aquatic pupa that remains in the water: but other groups. such as horseflies (Tabanidae), move to the muddy margins of ponds or streams to pupate. Most larvae that feed either in plant tissues or in rotting materials move out to pupate in the soil or in a dry, sheltered place, often some distance from their larval habitat.

The pupae of the more primitive families reveal externally the structures — head, antennae, legs. wings, etc.—of the developing adult (fig. 7). In addition they may have other structures peculiar to the pupal stage, *e.g.*, the powerful spines in Asilidae and Bombyliidae, which are used by the pupae to move to a more convenient place before the emergence of the adult. The pupae of the Cyclorrhapha are entirely enclosed in a puparium. a protective case formed from the skin of the last larval stage. Such puparia are barrel-shaped and generally brown, red or black. The structures that show through the puparium are anterior and posterior spiracles and bands of spicules of the larvae; no adult structures can be seen externally. A cocoon, on the other hand, is a pupal shelter made from extraneous materials such as soil, sand, silk, etc.



BY RE OF THE S PA EN A R T RE

FIG 7 — LIFEHISTORY OF THE ROSE MIDGE (DASYNEURA *RHODOPHAGA*) (ALL VIEWS GREATLY MAGNIFIED)

Cocoons occur sporadically throughout the Diptera, when the circumstances of pupation call for extra protection.

CLASSIFICATION

True flies fall into three suborders. which are usually referred to as Nematocera. Brachycera and Cyclorrhapha. There have been two lines of evolution from the ancestral Diptera, one of them leading to the Nematocera, which first appear in Upper Triassic deposits (about 170,000,000 to 180,000,000 years ago); along the other line, those families that have remained fairly primitive from the Lower Jurassic (beginning about 160,000,000 years ago) onward constitute the Brachycera, whereas those of the Tertiary (beginning about 70,000,000 years ago) are the most advanced flies, the Cyclorrhapha, and appear to be in active evolution at the present time. Although there are about 90 families of flies, it is relatively easy to place almost any adult specimen in its family. Identification of larvae, as has been noted, is much more difficult.

The following outline is one of several taxonomic schemes applied to the Diptera:

Suborder Nematocera
" Brachycera
" Cyclorrhapha
Series Aschiza
" Schizophora
Section Acalypterae
" Calypterae

Suborder **Nematocera.**—As mentioned earlier the name refers to the threadlike flagellum of the antenna, composed of a number of similar divisions that are inaccurately called segments. The maxillary palps also have several segments, and droop instead of projecting forward. Flies of this suborder might collectively be called the midges and gnats. Most of them are tiny or fragile, or both.

Tipulidae are the slender-bodied crane flies (sometimes called "daddy longlegs" because of their resemblance to the spider so called), with long, thin legs that are easily broken off. The familiar crane flies are fairly big, but the majority of the family are small and not often noticed. About 10,000 species have been described. The larvae live in moist situations where there is plenty of decaying vegetable matter. Some are pale and fleshy, like many larvae that live inside food material that they need never leave; others, which feed at the roots of plants (including grasses) and which come out on the surface at night, have a tougher skin and are known as leatherjackets (*q.v.*). A few tipulid larvae are carnivorous.

Closely related are Tanyderidae, a small, primitive family; Ptychopteridae, which have an aquatic larva with a respiratory "tail"; Trichoceridae, the winter gnats, which prefer cool, shady places in summer, and which come out on quite cold days in winter to dance in the sunlight; and Xnisopodidae (Rhyphidae), which have similar habits, but also breed in damp places indoors and often appear on windows.

Psychodidae are small, hairy midges, which are divided into the bloodsucking and the nonbloodsucking groups. The former, the Phlebotominae, are the true sand flies, though the name is often used for the Ceratopogonidae (*see* below). They occur in the drier tropical and subtropical areas, and transmit a number of diseases (*see* ENTOMOLOGY: *Medical and Veterinary Entomology*). The nonbiting Psychodinae, the moth flies, have broad wings covered with hair and scales. They breed in damp places in organic matter, and are common round drains and sewers. The larvae of some species are abundant in the filter beds of sewage works, where they play an active part in breaking down the sludge. Most houses have a few of them about.

Chironomidae are the familiar midges that dance over the water on summer evenings. Their larvae are mostly aquatic, and some that live in stagnant conditions have hemoglobin in their bodies and are called bloodworms. The adult midges are fragile, elongate flies, usually pale green; the males often have very bushy antennae. The behaviour of the swarms in relation to air currents and to moving objects is an interesting field of study.

Ceratopogonidae are tiny, bloodsucking relatives of the Chironomidae, and are called biting midges, and also "punkies," "noseeum's" and often, inaccurately, sand flies. *Culicoides* is the best-known genus. The larvae live in damp, decaying vegetation. The adults bite most intensely early and late in the day. Some genera attack other insects, sucking fluid from the wing veins.

Blepharoceridae are an aquatic family, the larvae of which have special suckers with which they cling to boulders in rapid streams; the adults have a characteristic network of fine wing veins. Deuterophlebiidae are closely related. Thaumaleidae (Orphnephilidae) are another aquatic family, with larvae similar to those of Chironomidae.

Simuliidae are the black flies, turkey gnats or buffalo gnats, the last name aptly describing their humpbacked appearance. The adult flies suck blood from man and other mammals and from birds. They cause extreme annoyance to and loss of blood from their victims: and in some tropical countries carry onchocerciasis, a disease caused by a nematode worm that parasitizes the flies. Many cases of blindness arise from this infection. The larvae of Simuliidae live in water that is rich in oxygen, either rapidly flowing water or water supporting a great deal of aquatic vegetation. The larvae attach themselves to rocks or plants by a posterior sucker and filter food from the water with mouth brushes. The pupae are also aquatic, and have respiratory filaments.

Bibionidae are shining flies, mostly blackish, with a hairy covering and the legs armed with elaborate spurs. *Bibio marci*, St. Mark's fly, is conspicuous about the Feast of St. Mark (April 25), while *Dilophus febrilis* (undeservedly called a "fever fly") often occurs in great numbers, especially on blossoms, in spring. The larvae are sometimes found in great numbers at the roots of plants, which they may damage. Scatopsidae are superficially very similar but have no tibial spurs, and the eyes form a bridge over the antennae. They breed in decaying material and excrement, and sometimes appear on windows.

Mycetophilidae, or fungus gnats, are very small, fragile, dull black insects, soft-bodied and with filamentous antennae. They are common in all cool, moist places. and their larvae are believed to feed on molds and fungus growths. Some breed directly in fungi and may be a pest to growers of mushrooms. The Sciaridae used to be placed in the same family, but are now separated: they have the eyes meeting in a bridge over the antennae, like the Scatopsidae. The larvae of some Sciaridae, which migrate in columns, are called army worms.

Cecidomyiidae, gall midges, are very fragile flies that are little-known as adults. Many of their larvae live in plants and cause them to form galls, but a number are free living in decaying materials or are predatory or parasitic on other small insects. The larvae are remarkable among Nematocera in having no head capsule, and indeed almost no structure, except for a clove-shaped "breastbone" that is a useful aid to recognition. The larva of the Hessian fly, *Phytophaga destructor*, causes the stems of winter wheat to break. The genus *Miastor* is able to reproduce by paedogenesis; *i.e.*, its larva may be seen to be filled with a mass of daughter larvae, which consume their parent before she has metamorphosed toward the adult stage.

Finally, the family Culicidae comprises three subfamilies. The largest of these is the subfamily Culicinae, the mosquitoes (*q.v.*); the other two subfamilies are much smaller. Chaoborinae are much like mosquitoes as adults. but their larva is different. The phantom larva of *Chaoborus* (*Corethra*) has two conspicuous air sacs that help to adjust the larva's density to match the water in which it lives; it is carnivorous. The Dixinae have adults rather like small crane flies, but their larvae are like those of anopheline mosquitoes.

Suborders Brachycera and **Cyclorrhapha.**—With very few exceptions, all flies other than Nematocera are "Brachycera" in the sense that they have shorter antennae. with the divisions of the flagellum fused into a compound third segment. They can be divided into Brachycera-Orthorrhapha. in which the adults emerge irom the pupa by making a straight or a T-shaped slit; and Brachycera-Cyclorrhapha, in which a circular slit opens a cap in the puparium. It is convenient to shorten these terms to Brachycera and Cyclorrhapha respectively, particularly since the shape of the slit is not a characteristic that can be used in practical identification. In practice all the families are placed in a generally accepted order, starting with the most primitive. M. L. Aczél (1954) proposed the names Orthopyga and Campylopyga for these two suborders. This scheme, based upon the position of the post-abdomen with regard to the preabdomen, is controversial; its chief interest is that it moves the family Dolichopodidae from the Brachycera to the Cyclorrhapha (see below).

Brachycera.—The first group of the Brachycera is the Homeodactyla, with three equal pads (pulvilli) on the foot and no strong bristles between them. Stratiomyidae, the soldier flies, are flower-loving flies, brightly coloured, generally found near water; they often have aquatic, carnivorous larvae. The discal cell (large cell at the base of the wings) is greatly contracted.

Rhagionidae (Leptidae) are primitive in most structures except antennae, and much resemble Anisopodidae of the Nematocera. The adults are furtive (*e.g.,* the downlooker fly). A few suck blood. The females of Atherix ibis and A. variegata die in clusters over their eggs on waterside vegetation. Larvae of the subfamily Vermileoninae live in pits like ant lions.

Tabanidae include horseflies, gadflies, clegs and deer flies. All male tabanids, and the females of some genera, feed from flowers, but females of the best-known genera, especially of Chrysops, *Tabanus* and *Haematopota,* are fierce bloodsuckers. Their larvae live in moist earth, wet sand or mud, and many, but not all, are carnivorous.

Allied to these three families are a number of primitive genera that lie close to the stem of evolution of the Brachycera: various families have been proposed for these, such as Coenomyiidae; Xylophagidae;. Xylomyiidae; Rhachiceridae; Pelecorrhynchidae and Pantophthalmidae. The last-named family includes giant flies (2- to 3-in. wing span), confined to tropical America; their larvae live in wood. Nemestrinidae, with complex wing venation, have larvae that parasitize beetles. Acroceridae (Cyrtidae) are globular little flies whose larvae parasitize spiders.

The group Heterodactyla have only two pulvilli on the foot, with a bristlelike empodium between them. Scenopinidae, window flies, are small and smooth-bodied but have a relatively large carnivorous larva, like a small worm, which is often found in carpets.

Therevidae are hairy, dusty-looking flies, with a larva very much like that of *Scenopinus.* Asilidae, robber flies, are a big family of fiercely predaceous flies; armed with a strong proboscis and protected by many bristles, they will attack even wasps bigger than themselves, catching them in flight and sucking them dry. Apioceridae and Mydaidae are related families, smaller and little-known.

Bo byliidae, bee flies, are covered with hairs and scales, and hover over flowers like bees, or dart in flight like wasps (*Systropus*). Many have a long proboscis. Their larvae are parasites or scavengers in the nests of bees and wasps; they also parasitize the egg pods of locusts and the larvae of moths.

The Empididae are a large family of predaceous flies which are rather like the Asilidae but are recognized by the more spherical head, sharper proboscis and different wing venation. They seem to replace the Asilidae in temperate regions. Males of *Hilara* spin silk from glands in the fore tarsi, and make a bundle: with or without prey, which they offer to the female during mating.

Dolichopodidae, long-legged flies, are bristly and usually metallic blue or green; they are abundant on damp vegetation, and prey on other insects, which they envelop in the labella of the proboscis and tear open by means of prestomal teeth. These mouth part's foreshadow those of Cyclorrhapha and support the view of Aczél, who excludes the Dolichopodidae from the Brachycera; yet the larvae cannot be certainly distinguished from those of Empididae.

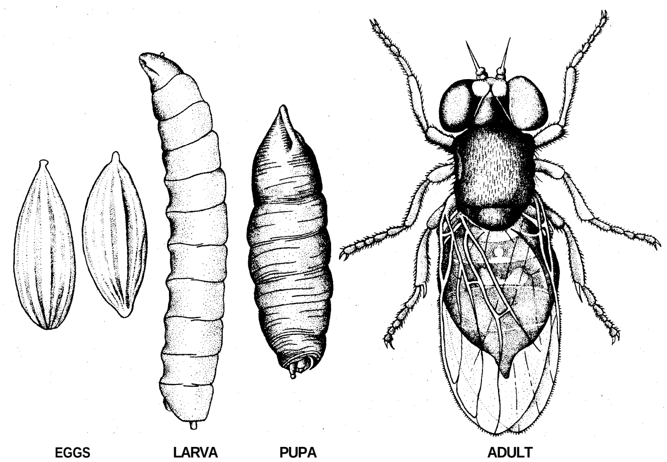
Cyclorrhapha.—*Series Aschiza.*—The first division, series Aschiza, have the small frontal lunule shown in fig. 4 but no frontal suture dividing the frons from the face. The five families included are highly individual, and seem to be evolutionary offshoots at the base of the Cyclorrhapha.

Syrphidae (hover, or flower, flies) are a large family of conspicuous insects. They are smooth, bristleless, shining flies, often large and bulky, with an amazing ability to hover in one place with very rapidly beating wings. Nearly all adult Syrphidae feed from flowers, but the larvae inhabit, almost every kind of possible food material. The beneficial ones devour aphids. The rat-tailed larvae live in stagnant water and have a telescopic breathing tube.

Platypezidae, with peculiar flattened tarsi, live as larvae in fungus; Pipunculidae, with a curious almost spherical head, have larvae parasitic upon plant bugs. Phoridae are tiny black flies with a characteristic wing venation: one or two strong veins near the leading edge and the rest weak and running parallel to each other across the wing. The larvae live in almost any decaying animal matter in a dry or even mummified state. Some live with ants or with termites, and are sometimes separated as a family, Termitoxenidae. Lonchopteridae, in contrast, are small flies with pointed wings; only a few species exist.

Series *Schizophora.*—Cyclorrhapha of this group have a frontal suture, or more properly ptilinal suture, from which is pushed out an inflated sac, called a ptilinum, when the adult fly is breaking out of the puparium, making its way out of the soil. The air in the ptilinum is used to inflate the crumpled adult body to full size, the ptilinum being drawn into the body in the process. The series is divided into two sections, the Acalypterae and the Calypterae.

Section Acalypterae are so-called because the calypter, a flap at the base of the wing, is small and inconspicuous. This is a complex assemblage of species, nearly all small ($\frac{1}{4}$–$\frac{1}{3}$ in.), that appear to be in active evolution, since so few clearly defined groups exist. Conopidae are an exception; they are large flies, wasplike, with larvae that are parasitic on adult bees, wasps and Orthoptera. Among other conspicuous families are Trypetidae, the large fruit flies, which include the Mediterranean and the Queensland fruit flies, and others that are dangerous enough to have legislation directed against them (see FRUIT FLY). Like the related Otitidae the large fruit flies often have patterned, or "pictured," wings. Chloropidae (fig. 8) include the frit fly (*q.v.*) of oats and the gout fly of barley as well as the eye gnats that carry conjunctivitis and the yellow swarming fly that invades houses in autumn. Agromyzidae include many species with leaf-mining larvae that tunnel in leaves and sometimes damage ornamental shrubs. Drosophilidae are world-famous for the intensive research into the laws of heredity that has been carried out on several species including Drosoph-



FROM ESSIG, 'COLLEGE ENTOMOLOGY", BY PERMISSION OF THE MACMILLAN CO , PUBLISHERS

FIG. 8.— LIFESTAGES OF A CHLOROPID FLY (HIPPELATES PUSIO)

ila melanogaster. Many Ephydridae, shore flies, are powerful predators both as adults and as larvae; some are equipped with raptorial legs for this purpose. The petroleum fly, previously mentioned, belongs to this family. In all, there are more than 40 families of Acalypterae, of which a majority breed in many kinds of decaying materials.

Section Calypterae.—These are structurally the most advanced of all flies. Representative of this group are the housefly and the bluebottle — short. stout, bristly, active flies. They generally have large calypters, except in the Cordyluridae. They also have a characteristic cleft in the second antenna1 segment. The species are very numerous and difficult to classify, especially the females, since often the only obvious differences are in the male genitalia.

Only a few large families are recognized, and even these are subject to dispute. Oestridae are parasitic as larvae in the skin and in head cavities of mammals; the sheep nostril fly, *Oestrus ovis,* and the warble fly of cattle, *Hypoderma,* are well-known. These flies have virtually no mouth parts, and during their short adult life they do not feed.

The other Calypterae are divided according to the presence or absence of bristles on a chitinous plate (sclerite) on the side of the thorax, the hypopleural bristles: the families Muscidae and Cordyluridae have none; Calliphoridae and Tachinidae have them present. Cordyluridae, predatory flies with small calypters, are exemplified by the yellow dung flies that may be seen rising in a cloud from cow dung. Muscidae includes the housefly (*q.v.*) and its many allies, most of which feed on fluids by mopping them up. A number, however, including the tsetse fly, *Glossina,* and the stable fly, *Stomoxys,* have a hardened proboscis that can pierce skin.

Tachinidae are very bristly flies with larvae that are parasitic in a number of other insects, and consequently they rank as beneficial to mankind. Calliphoridae differ from Tachinidae in not having a strong convexity of the postscutellum, a chitinous plate of the thorax, and in their habits. Typically they breed in carrion, like the bluebottle, *Calliphora,* and play a useful part in disposing of animal remains. From this feeding habit many have progressed to infesting open wounds, then to attacking living tissues.

The sheep maggot fly, *Lucilia sericata,* and others, cause much distress to and loss of sheep. The Congo floor maggot, *Auchmeromyia luteola,* seems to be a specific parasite of man in its larval stage, whereas *Callitroga macellaria,* the secondary screwworm fly, causes a great loss of tissue and mutilation in man and other animals. *Sarcophaga* and its allies are the flesh flies, remarkable for their habit of producing living larvae, which can begin to feed at once; they are sometimes placed in a separate family, Sarcophagidae.

Disputed Groups. — There remain a few groups of Cyclorrhapha, the position of which is in dispute. *Braula coeca,* a tiny, wingless, beetlelike fly clings to worker honeybees, and its larva lives on the wax of the honeycomb. According to A. D. Imms (1942 j it is placed next to Chamaemyiidae in the Acalypterae.

Adults of Gasterophilidae have reduced mouth parts, and their larvae live as parasites in the intestines of mammals; *Gasterophilus,* in horses and zebra; *Gyrostigma,* in rhinoceroses; *Cobboldia,* etc., in elephants. Although this group seems so like the Oestridae, some authors have suspected mere convergence and removed them to Acalypterae; but F. Zumpt *(1957)* put them back next to the Oestridae.

Finally, there are three families of flies that are parasitic and bloodsucking as adults: Hippoboscidae, on mammals and birds, and Nycteribiidae and Streblidae, on bats. Adult females of these families nurture the larva until it is fully fed and drop it when it is ready to pupate. They have thus long been grouped together as the section Pupipara, and in spite of some criticism this still seems to be the best way to treat them. All Nycteribiidae are wingless, and so are some Hippoboscidae, including the sheep ked, *Melophagus ovinus.*

For a discussion of basic anatomy, function and evolution of flies and other insects *see* INSECT; for economic importance and control *see* ENTOMOLOGY. *See* also separate entries on various flies under their common names, and references under "Fly" in the Index volume.

BIBLIOGRAPHY.—Most of the literature on flies is specialized, dealing either with individual species, families, etc., or with regional dipteran fauna. Few popular works of a comprehensive nature exist.

General: D. J. Borror and D. M. DeLong, *An Introduction to the Study of Insects,* ch. 27, "Order Diptera: Flies"; L. S. West, *The Housefly* (1951); J. Smart, *Insects of Medical Importance* (1943, and later revisions); J. R. Busvine, *Insects and Hygiene* (1951).

Advanced: E. Lindner, *Die Fliegen der Palaearktischen Region* (Eurasian Diptera) (1924, with periodic revisions); P. Wytsman, *Geneva Insectorum,* has many parts on families of Diptera, over a long period: notable examples are F. W. Edwards on Culicidae, and E. Séguy on Muscidae; E. Kertész, *Catalogus Dipterorum hucusque descriptorum* (1902–lo), covers Nematocera, Brachycera and Aschiza, and can be brought up to date by using the *Zoological Record;* Willi Hennig, *Die Larvenformen der Dipteren,* 3 vol. (1948–52), has most comprehensive keys, giving detailed references to published illustrations; Alvah Peterson, *Larvae of Insects: an Introduction to Nearctic Species,* part ii, *Diptera,* etc. (1948–51); E. Séguy, *La Biologie des Diptères Encyclopédie entomologique,* xxvi (1950), provides an exhaustive analysis of the published information on flies. For feeding habits of flies, with a complete bibliography, *see* J. A. Downes in *Annual Review of Entomology,* vol. 3, pp. 249–266 (1958).

Regional: Some of the works listed below can be used with care in other regions, especially those marked with an asterisk (*).

North America: C. H. Curran, **Families and Genera of North American Diptera* (1934), is a valuable general guide that can be used to some extent in most other regions; C. T. Brues, A. L. Melander and F. M. Carpenter, "Order Diptera," in *Classification of Insects, Bull. Harvard Mus. Comp. Zool.,* 108:305–543 (1954).

Europe: C. N. Colyer and C. O. Hammond, **Flies of the British Isles* (1951); F. W. Edwards, H. Oldroyd and J. Smart, *British Bloodsucking Flies* (1939); *H.* Oldroyd, *Diptera: Introduction to the Families* in the series "Handbooks for the Identification of British Insects" (1949–); E. B. Basden, *The Distribution and Biology of Drosophilidae in Scotland, Trans. Roy. Soc. Edinb.* lxii, pp. 603–654 (1954); W. Lundbeck, *Diptera Danica* (1907–27); *E.* Séguy, "Diptera," part 28, in *Faune de France* (1934).

Other Continents: For the other continents there are no really comprehensive guides to the flies, but some information can be found in sections on insects in the various faunal series: for Asia, *The Fauna of British India: Fauna of U.S.S.R.;* for Oceania *see* R. A. Harrison, *Acalyptrate Diptera of New Zealand* (1958); for Africa *see* parts of the *Ruwenzori Expedition 1934–5* (1939 *et seq.)*; *Exploration du Parc National Albert* (1959 *et seq.)*; for South America see *Diptera of Patagonia and South Chile* (1935 *et seq.)*; for Hawaii *see* D. E. Hardy, *Fauna of Hawaii,* "10. Diptera: Nematocera, Brachycera" (1960). (H. OL.)

FLYCATCHER, the name for songbirds of the family Muscicapidae, a large group numbering nearly 100 genera and many hundreds of species of small birds found only in the old world, where they are distributed throughout Europe, Asia, Africa, Australia, the Malays and the Southwest Pacific islands. They are closely related to the thrushes and old world warblers. They are mostly 5 to 7 in. long. Some are dull-coloured, like the common pied and spotted flycatchers (*Muscicapa*) of Europe, the former grayish, the latter black and white; some are very dark, like the black flycatcher (*Meleanornis*) of Africa. Some are bright, with breasts of orange or yellow or chestnut, or with earwattles of emerald, turquoise, purple, or red among African species. Bright breasts are also found in the yellow robins (*Eopsaltria)* of New Caledonia and the scarlet robins *(Petroica)* of Australia and the Southwest Pacific. The blue fairy flycatcher *(Erannornzs)* is bright light blue with a long fan-tail. A great many species known as fantails *(Rhipidura),* found throughout oriental-Malay-Australian-Southwest Pacific areas. are coloured with gray, brown, rufous or white. The paradise flycatchers *(Tchitrea)* of Africa and tropical Asia, are black and chestnut or white, which also make striking patterns for the long tail streamers. Flycatchers inhabit tree tops or undergrowth in forests, or borders and open moods, both in lowlands and mountains, where they dart from a perch to catch insects on the wing.

The name is also applied to an entirely different family of songless (but not voiceless) perching birds, the Tyrannidae, or tyrant flycatchers, including some four score genera and 400 species confined to the new world and widely distributed from Patagonia to northern Canada and Alaska, though only *11* genera and *31* species occur north of the Mexican border. These include the well known kingbirds *(Tyrannus)* and scissor-tailed flycatchers (*Muscivora*), phoebes *(Sayornis)* and peewees (*Myiochanes*), the noisy crested flycatchers (*Myiarchus*) and the inconspicuous greenish least flycatcher and its relatives *(Empidonax),* as well as the gorgeous vermilion flycatcher *(Pyrocephalus).* They are found wherever there are trees, from which they dart forth to snap their flattened, hook-tipped bills and catch insects on the wing, as do the true flycatchers of the old world. In the cooler parts of their range, flycatchers are migratory, due to winter shortage of flying insects. *See* KINGBIRD; PEEWEE; PHOEBE. (G. F. SS.)

FLYING, COMMERCIAL: *see* AVIATION, CIVIL; TRANSPORT: *Air Transport.*

FLYING BOAT: *see* SEAPLANE.

FLYING BRIDGE, a type of ferryboat propelled by the resistance of a rope or chain attached to a fixed buoy acting against the forces of the stream. The rudder is fixed obliquely which causes the boat to move at right angles toward the buoy. See also FERRY.

FLYING DOCTOR SERVICES comprise a method for supplying medical service by airplane to areas where doctors are few and communications difficult. The plan for the first such service was conceived in 1912 by the Rev. John Flynn, superintendent of the Australian Inland mission of the Presbyterian Church. The large, isolated areas of the Australian outback which lacked highways, railroads and wire or wireless facilities for sending messages were imposing formidable hardships and retarding white settlement. Flynn's dream dawned into reality in May 1928 when the first base of what is now the Royal Flying Doctor Service of Australia began operating at Cloncurry, Queensland, under Dr. K. St. Vincent Welch. Flynn recruited an Adelaide electrical engineer, A. H. Traeger, to develop a low-powered, portable. pedal-driven! Morse radio transmitter-receiver with a range of 300 mi. This "transceiver," with the use of airplanes, made possible the world's first system of regular long-distance medical consultations and the flying of doctors to patients in emergencies. By 1962, 13 bases, run by state branches, covered two-thirds of the Australian continent and part of Tasmania. St. Vincent Welch traveled 20,000 mi. and attended 255 patients in his first year; by the 1960s doctors flew 500,000 mi. a year in 1,600 flights and conducted 10.500 radio consultations with patients at 1,300 outposts; the service also handled 250,000 radio messages annually. The Australian state governments contribute one-third of the finances; the rest comes from voluntary and outpost subscriptions and message charges. The flying doctor service is free.

Other parts of the world regularly use aircraft for the assistance of the isolated sick. In Canada the Saskatchewan Air Ambulance service was inaugurated in 1947; by the end of 1961 it had flown more than 15,000 patients to city hospitals. Newfoundland operates from the International Grenfell association at St. Anthony an air ambulance service, likewise begun in 1947, covering north Newfoundland and Labrador. The Royal Canadian Air Force operates a search and rescue service for Eskimos and Indians in the Arctic.

In east Africa the African Medical and Research foundation, established in 1957 by joint British and American enterprise, was enabled in 1961 to begin a flying doctor service with a single airplane provided by private United States benefaction. In collaboration with this body, the Flying Doctor Service of Africa, Ltd., registered in the United Kingdom, planned a pilot scheme to be based on Gusau, northern Nigeria. (E. A. BE.)

"FLYING DUTCHMAN," a spectre ship believed to haunt the waters around the Cape of Good Hope. Its appearance is considered by sailors ominous of disaster. The commonest legend declares that the captain, Vanderdecken, was condemned for blasphemy to sail round the cape forever, unable to "make" a port. This legend was adapted by Wagner in his opera *Der fliegende Hollander* (produced 1843).

A German form of the legend alleges that the captain, called Von Falkenberg, is condemned to sail forever round the North sea, in a ship without helm or steersman, playing at dice for his soul with the devil. Sir Walter Scott's version, in *Rokeby,* is that the vessel was laden with bullion. A murder was committed on board and the plague broke out among the crew and closed all ports to the ship. The story has frequently been used in literature.

See G. Kalff, *De Sage van den Vliegendea Hollander. Naar behandeling, Oorsprong en zin Onderzocht* (1923).

FLYING FISH, the name generally given to fishes of the family Exocoetidae, in which the pectoral fins are greatly enlarged. The lower lobe of the caudal fin is very long and, with strong strokes of the tail, these fishes emerge rapidly from the water and, with the pectoral fins outspread, sail through the air at a great speed, for distances up to 200 yd. It is probable that the flight is an effort to escape from large piscivorous fishes, such as bonitos. There are numerous species of Exocoetidae, all of them from warm seas.

The so-called flying gurnards *(Dactylopterus)* are not related to the flying fishes. They have relatively larger pectoral fins than *Exocoetus,* but appear to be less efficient fliers, perhaps because the caudal fin lacks the long lower lobe. There are three or four species from tropical seas.

Pantodon, a little African fresh-water fish, has large pectoral fins and is said to fly; but perhaps the most interesting flier is *Gastropelecus,* a Characin of the rivers of South America, a deep-bodied fish nith a large rounded, sharp-edged ventral keel, formed by the greatly expanded coracoid bones, which serve for the attachment of the enormous muscles of the pectoral fins.

This fish has been seen by Eigenmann to progress by rapid beats of the strong pectoral fins, uith the keel just cutting the surface of the water, and finally to emerge in a true, but not prolonged. flight.

The Catalina flying fish (*Cypselurus californicus*) of southern California waters. sometimes 18 in. long, one of the largest known species, is a strong flier, with enlarged ventral as well as pectoral fins.

FLYING FOX or **FOX BAT,** the name applied to the fruit-eating bats of the genus *Pteropus,* which contains more than half the family Pteropidae. This genus is confined to the tropics of Asia, Madagascar, Australia and east to Samoa. It comprises numerous species, a considerable proportion of which occur in the islands of the Malay Archipelago. The flying foxes are the largest of the bats, the kalong of Java *(Pteropus vampyrus)* measuring about a foot in length, and the wings measuring 5 ft. across. Flying foxes are gregarious, nocturnal bats, suspending themselves during the day head downward from the branches of trees with their wings wrapped about them. They are good eating. something like hare. Toward evening these bats fly off in companies to the village plantations, where they feed on all kinds of fruit, doing much damage.

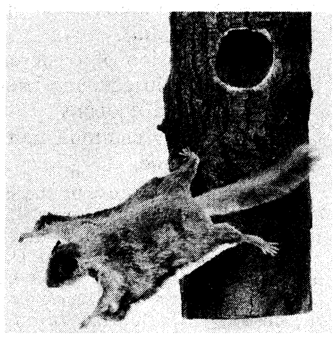
FLYING FOX (PTEROPUS GIGANTEUS)

The flying fox of India (P. *giganteus)* is a smaller species, but is found in great numbers wherever fruit is to be had in the Indian peninsula.

FLYING LEMUR, a name for two species of Cynocephalus (*q.v.*) or Galeopithecus. belonging to the primitive mammalian order Dermoptera, found only in the Australian region. They are called Colugo by the natives.

FLYING SQUIRREL, the name applied to two very different groups of nocturnal, tree-dwelling rodents, in both of which a parachute-like expansion of the skin of the flanks enables them to take long gliding leaps. They all have large, dark-adapted eyes, and are omnivorous, berries, seeds, nuts and insects being the chief diet.

The first group, allied to the true squirrels (Sciuridae), comprises about 11 genera forming the subfamily Petauristinae and occurs from Scandinavia to Japan and the Malay region, and in North America from northern Canada to Honduras. The greater number of species occur in the Indian and Malayan regions; here some, *Petaurista* species, reach large size, more than a yard in total length and may be foxy red, red spotted with white, or black in colour. The gliding membranes of these large species are more extensive than those of smaller forms; a fold connects the hind limbs with the tail. Flying squirrels glide from a position high on one tree to a lower level on another tree or log, sometimes covering 200 ft. or more in a glide. Species of the North American genus *Glaucomys* are



BY COURTESY OF CHICAGO NATURAL HISTORY MUSEUM

NORTH AMERICAN FLYING SQUIRREL (GLAUCOMYS VOLANS) smaller buff-coloured sciurids (*see* RODENTIA).

The second group, more correctly called scaly-tailed squirrels,. is African and consists of certain members of the family Anomaluridae, some of which, however, have no parachute. The flying species differ from those of the last group in that the membrane is supported by a bone at the elbow joint instead of by a cartilage at the wrist. There are two flying genera, *Anomalurus* and *Idiurus,* each containing several species. They are all similar in habits to the previous group and, like them, are very squirrel-like in appearance.

The term "flying squirrel" is also applied to certain marsupials but these are more properly called flying phalangers. *See* PHALANGER; MARSUPIALIA. (J. E. HL.; X.)

FLY RIVER, a large stream in southern New Guinea, the largest in Papua. It rises in the Victor Emanuel mountains near the centre of the island and flows first south and then southeast into the Gulf of Papua. It is more than 700 mi. in length and is navigable with a steam launch for a distance of more than 500 mi. from its mouth. For approximately 100 mi. it forms the boundary between Papua and Netherlands New Guinea. The Fly river enters the Gulf of Papua in a great estuary nearly 50 mi. across which is filled with a series of low shifting mud islands. The largest, Kiwai, lies in the centre of the estuary and is inhabited. The effect of the tide is felt for a distance of 150 mi. up the river, and at the point where it ceases the stream is 600 yd. wide and averages 39 ft. in depth. About 300 mi. from its mouth the Strickland river, a tributary as large, and perhaps larger, than the Fly, enters from the north, having its source also in the Victor Emanuel mountains. About 500 mi. from the mouth another large tributary, the Alice, comes in from the right. Perhaps 550 mi. from the mouth the Fly river divides into two nearly equal branches, the one from the left, named the Palmer, being regarded as the tributary. There are no white settlements in the whole vast extent of territory drained by the Fly river, and for the last 400 mi. of its course the land is too low and unhealthy for white occupation, though the natives are fairly numerous. The low country is inundated annually. The first hills are found about 480 mi. up the river, and from here on nights are cool and the climate healthier. Despite its great navigable length the river is commercially unimportant.

The mouth of the Fly river was discovered by Capt. Blackwood in 1842 and named after one of his ships. It was first explored by Macfarlane and D'Albertis in 1875–76.

FLYSCH is a term long used by geologists to denote a particular formation of Tertiary age (1,000,000 to 70,000,000 years) occurring in the northern Alpine region. The term is now commonly applied to similar deposits of other ages and other places.

Although flysch is said to mean "slippery earth" in the local Swiss-German dialect, it is applied by geologists to a sequence of gray shales rhythmically interbedded with thin, hard, dark gray sandstones of graywackelike character. The total thickness is commonly many thousands of feet; the individual beds, however, are thin, a few inches to a few feet in thickness. Fossils, notably rare, indicate marine deposition. The flysch facies is now generally believed to have accumulated in moderate to deep (up to 1,000 fathoms) marine waters. The deposition of coarse angular sands, commonly graded-bedded and locally conglomeratic, is attributed to turbidity flow — catastrophic incursions of debris-laden muddy waters. The extraordinary coarse conglomeratic mudstones found in some flysch are thought to be a product of submarine mudflows.

Flysch deposits characterize many ancient geosynclinal accumulations. Such deposits occur in old Pre-Cambrian formations of Canada. in the Lower Paleozoic of the Caledonian geosyncline in Great Britain, in the Late Paleozoic of the Armorican geosyncline of Europe and in the late Ordovician and in the later Devonian of the Appalachians, in the Alpine Tertiary, in the Tertiary of the Caucasus and the Himalayas and in the Tertiary'beds of the Carpathian geosyncline.

For identification and discussion of periods, formations and terms *see* GEOLOGY.

FLYWHEEL, a relatively heavy rotating wheel attached to a shaft, whose principal purpose is to store kinetic energy while there is more energy coming onto the shaft than is departing, and to give up some energy when the energy leaving the shaft is greater than that received.

The amount of kinetic energy which can be stored in a flywheel or any rotating body is a function of the moment of inertia of the body and its angular speed. Thus a given flywheel stores energy only as its speed increases; it gives up energy as it slows down. Almost all reciprocating machines (for example, automotive engines) need a flywheel in order to run smoothly. This can best be understood by considering the operation of a single-cylinder engine. In a two-stroke cycle engine for a lawn mower or outboard motorboat. for example, the explosion occurs and the high gas pressures result in work being done as the piston moves down. Most of the work is done during the early part of the stroke and the amount gradually decreases. hioreover, on the return stroke of the piston, not only is no work done by the shaft but work has to be done on it to drive the piston to compress the gases for the next explosion. Since the law of conservation of energy says that energy is indestructible, the energy to compress the gases must be supplied from somewhere. This "somewhere" is the kinetic energy of the flywheel (and other rotating parts), and the flywheel got it from the excess work done while the pressure of the burned gases was high. Thus, the speed and energy of the flywheel increase while excess engine work is done; then, while the engine is not producing enough energy to do the job, the flywheel supplies the necessary additional energy, slowing down in the process. This speeding-up and slowing-down is ordinarily not noticeable because it happens so quickly.

If a two-cylinder engine is used, so that the explosion occurs in one cylinder while compression takes place in the other, the work done is more uniform. but not constant. In this case, a somenhat smaller flywheel (same speed, speed variation, and power) will do the same job as before. The impulses overlap still more in an eight-cylinder engine, but a flywheel is nevertheless needed.

The size and weight of the flywheel depend not only on how constant the rate of work is but also upon the amount of speed variation that is permissible. If the speed must be nearly constant, as in driving an electric generator, a larger flywheel for a reciprocating engine is required than in most other situations. The larger and heavier the flywheel, the less will be the speed variation.

In such machines as punches and shears, the major part of the work. that is, the actual punching and shearing, is done in only a small fraction of an operating cycle. If a flywheel is used, the machine not only runs with less speed variation but the peak requirement of power from the motor is reduced. In these machines, the motor may be so small that the major source of energy during the cutting operation is the kinetic energy of the flywheel. (V. M. F.)

FOÀ, EDOUARD GEORGES (1862–1901), French 'explorer whose travels increased the knowledge of west and central Africa, was born at Marseilles on Dec. 17, 1862. In 1886–89 he explored the interior of Dahomey, and in 1891–93 made two extended journeys in Nyasaland and the lower Zambesi valley. Finally in 1894–97 he crossed Africa from the Zambesi mouth to Libreville on the Atlantic coast, covering unexplored ground in the upper Congo basin. He died at Villers-sur-Mer, Calvados, on June 29, 1901. His works include *Le Dakomey* (1895); *Chasses aux grands fauves pendant la traversée . . . du Zambèze au Congo Français* (1899; Eng. trans. F. Lees, 1899); and *De l'Océan indien a l'Océan Atlantique* (1900).

See *Résultats scientifiques des voyages en Afrique d'Edouard Foà* (1908). (R. L. HL.)

F.O.B., a contraction for "free on board," an expression used in commerce to denote that a price quoted is inclusive of all costs of carriage and delivering the goods on board the ship or other medium which is to take them to their destination.

FOCA, a town of Bosnia and Hercegovina, Yugoslavia, occupied by Italy in 1941. Pop. (1953) 3,992. It is famous for its silver filigree work and inlaid weapons. The soil produces excellent walnuts. Close to the frontiers of Novipazar and Montenegro, Foca (Chocha) was the scene of almost incessant border warfare during the middle ages. No monuments of this period are left, except the Bogomil cemeteries and the beautiful mosques which are the most ancient in Bosnia. Foca was a trading station of the Ragusans in the 14th century, if not earlier. In the 16th century it was the residence of the governor of Hercegovina. It was captured by the Montenegrins in World War I.

FOCH, FERDINAND (1851–1929), French marshal, was born at Tarbes on Oct. 2, 1851. His father's family had long been settled in the south of France, leaving the district of Ariège in the 17th century to establish themselves as woollen manufacturers in the small town of Valentine where they took a prominent part in municipal affairs. On his mother's side, Marshal Foch came of a race of soldiers, his maternal grandfather having been a gallant officer of the Grand army. His father was a lawyer at Tarbes (Hautes-Pyrénées) who later became a revenue official, and he was frequently transferred from place to place, taking his son with him. The future marshal thus received his education successively at the Lycées at Tarbes and Rodez, the seminary at Polignan and the Jesuit college at St. Étienne.

It was not long before his teachers were struck with his "geometrical mind," and it was decided that he should enter the École Polytechnique, to prepare for which he was sent to St. Clement's college at Metz. After a few months there, however, the war of 1870 interrupted his studies. He enlisted in the infantry but the armistice came before he saw any fighting, and he returned to Metz to finish preparing for his examination. One of his fellow students has described how, in the midst of a lesson, they learned on March 11, 1871, by the booming of the German guns, that the treaty of peace had made Metz a city of the German empire. None could foresee that the young student was destined, as marshal, to restore the city to France.

He sat for his examinations at Nancy, which was still occupied by Edwin von Manteuffel's troops, and was admitted to the École Polytechnique, where he made his mark. In 1873 he was commissioned and served successively at Fontainebleau, Tarbes and Rennes. He then passed into the École Supérieure de Guerre where, after a tour of duty on the general staff, he was appointed a professor on Oct. 31, 1894. His lectures soon made a sensation. both by the evident soundness of the matter and the originality of the form. Even thus soon his pupils bore witness to the excellent qualities of their professor, who presently became one of the leaders in military doctrine, The lessons given between 1894 and 1900, collected in volumes, constitute the chapters of Foch's great works: De la conduite de la guerre and Des *principes* de la guerre, which appeared in 1897 and 1899.

In teaching six batches of staff college students Foch fortified his own military science as well; his years at Paris were, in fact, of capital importance in the higher development of his intellect. When he vacated his post no one doubted that he would return ere long in another capacity. After holding two regimental commands of artillery and spending a year on the staff of the 5th corps, he was, so to say, imposed on the government by the opinion of the whole army as the fittest selection for the command of the École de Guerre that he had made famous. It was Georges Clemenceau—at that time prime minister—who made the appointment, giving him the rank of general, and from that day began the cordial relations between the great statesman and the great soldier which were to be revived later under memorable conditions.

The general held his post as head of the école for four years, during which time he threw himself with untiring zeal into the work of this famous centre for military study, giving it a permanent stamp and forming a whole new generation of picked officers. When, in 1911, he was nominated to the command of the 13th division at Chaumont, Foch was one of the very few outstanding figures of the army, and it was not surprising that after a brief period in command of the 8th corps the wish of everyone acquainted with the higher military personnel brought him to the head of the splendid 20th corps, stationed about Nancy, which was accounted one of the best elements of the "couverture." Thus in 1913 he entered, to the sound of trumpets, the town where he had passed his examinations to the tune of the German army fifes and whence, before long, he was to march out for World War I.

General Foch, who had married Mlle. Julie Bienvenue, had at that time three children—two married daughters and a young son who was destined to be one of the first to fall in the war. Although still attached to his Pyrenean home, the general spent his holidays on a small estate that he had acquired at Trofeunteniou in Brittany. In the summer of 1914 France was so far removed from any idea of attacking Germany that Foch had left Nancy to spend a month in far-away Brittany. A week later events led to his recall.

The **Outbreak** of War.—He was then a man of 63, but his rare moral: intellectual and physical vigour kept him singularly young. Foch was a man of thought and also, above all, a man of action. Gifted with an intelligence which was never allowed to be idle, ever widening the scope of his knowledge, reflective and delighting—to use his own striking phrase—to "phosphoresce," the great soldier was even stronger in will than in intellect. "Victory = Will. . . . Victory goes always to those who deserve it by the greater force of will. . . . A battle won is a battle in which one will not acknowledge oneself beaten"—these are but a few of the maxims found in his books, in which the word will occurs on every page. And in truth, although his gray eyes sparkled with intelligence, the forehead and, even more, the mouth revealed that will which he was able to communicate to all those who came in contact with him in the course of war. It was this will which gave such solidity to his character and protected it from all weaknesses. What is more, it stimulated both conscience and intelligence. He spoke of "these natures, hungry for reponsibility, which alone turn out great men," and his own was one of these natures that no sentimental considerations could either divert or check. For the rest, his clarity of mind translated itself by a realistic and somewhat ironic common sense. "What is it about?" was a favourite phrase of his in all circumstances, for he believed in clear vision before direct action.

The 20th corps formed part of the and army and Foch was therefore one of the commanders of Gen. Edouard de Castelnau's army, which, on Aug. 19, 1914, was thrown into annexed Lorraine. It will be remembered that this army, after some successes, met formidable resistance in the region of Morhange and failed with heavy losses. Foch had had no part in forming the plan. which met with so cruel a check; he was but one of the executants. He had thrown his army corps resolutely at Morhange and, when repulsed, was still able to organize with perfect coolness its retreat on the solid positions of the Couronne de Nancy. Not content to await the enemy there he resumed the offensive and, on Aug. 20, threw himself on the German regiments which were waiting to attack in the "gap of Charmes," and in overthrowing them prepared the victory in Lorraine. He was preparing to take his part there when he was called to the Grand Quartier Général, where Gen. Joseph Joffre entrusted him with the command of an army.

At that time the French were retiring in good order from Belgium and the Ardennes toward the region of the Marne. As a gap tended to open between the 4th and 5th armies. Joffre gave Foch the mission of forming a new army (the 9th) between them, co-ordinating his action with theirs. He was on the ground before the corps entrusted to him had arrived. In a few days he forged out of them a solid and supple little army which was already well in hand when the celebrated order of Sept. 4 arrested the retreat and prescribed the battle which was to lead to the victory of the Marne.

Foch, after passing the marshes of St. Gond, established himself on the heights which dominate the Petit Morin and of which Fere Champenoise marks the crest. It was thought that his role would be limited to supporting Franchet d'Esperey's army on his left. But when the German armies, which instead of turning the left of the French armies as they had expected, were themselves turned on the right, they tried to penetrate the allied centre precisely in this region of Fere Champenoise and Foch had therefore suddenly to support the main strain of the battle, and that with troops inferior in number. The heights were for a moment carried by the Germans from Mondemont to Fère Champenoise. It was then that, by a clever manoeuvre, Foch rapidly transferred the 42nd division from his left to his centre and thus was able to gain the upper hand and force the enemy back. The extreme fatigue of his troops prevented him from pushing his successes, but he hung on to the retreating Germans and entered Chalons-sur-Marne behind them. His part in the victory of the Marne was capital and it was recognized by a glorious citation in general orders. *(See* MARNE, 1ST BATTLE OF.)

His reputation was so increased after this great crisis that Joffre immediately entrusted him with a new mission—this time one without parallel. Scarcely had the operations of the Marne terminated when, the two armies mutually trying to outflank one another, the "race to the sea" set in from the Oise to the Flemish coast which was only to be closed by the arrival of the Belgian army and the formation of a continuous front right to Nieuport. The British corps, for their part, had been moved into the region of Ypres, while Joffre detached from the now stable front between the Oise and the Vosges all the forces that he could spare to meet a great attack between the Oise and the sea.

To co-ordinate the action of the heterogeneous troops hurriedly thrown into these regions, a leader of great authority was wanted at once to take the higher direction of the operations of the French armies and to co-operate harmoniously with the Allied armies so as to assure the co-ordination necessary to victory. On Oct. 4, Foch was sent to the Nord to fulfil this mission with the title of deputy to the commander-in-chief.

He did not limit himself to giving the French armies, from Picardy to Flanders, the most energetic orders but put himself in close and cordial relations with Field-Marshal Sir John French and King Albert I, and established the essential liaison between the Allied armies. Ceaselessly finding the necessary reinforcements and dispatching them to the aid of the hard-pressed British and Belgian corps, he was able by his friendly and generous activity to impose his own resolute ideas and so make himself the soul of the battle of Flanders that, after the fierce fighting of the Yser and of Ypres, ended in mid-November by the definite check of the German invasion for the year 1914. In all this Foch had not merely confirmed his prestige as a strategist but had won for himself the friendly admiration of his Allies so completely that, even then, it could be foreseen that if, one day, circumstances required unity of command there could be no better choice for it than Foch. Did not David Lloyd George say: "He could not have done more for us had he been one of our own generals."

Foch was left therefore in contact with the British and Belgian corps in the capacity of general commanding the Group of Armies of the North. He held the post for two years and thus presided over the two Artois offensives of May and Sept. 1915 and the battle of the Somme (*q.v.*) in the summer of 1916 which the German attack on Verdun prevented from assuming the amplitude and decisive character that had been intended.

After brilliant initial successes the Somme battle seemed to sink in the autumn mud. The disappointment that it caused led to a movement of dissatisfaction with the higher leaders who had presided over it. Joffre having been relieved of his command, Foch was deprived of his also and relegated to Senlis for a mission of inspection. The story was that he was fatigued. This was hardly the case, but he accepted this semidisgrace with resignation and his valuable advice was always at the disposal of Gen. Louis Lyautey, who had become minister of war.

When, in May 1917, Gen. Henri Pétain was called to the chief command, he himself suggested to the government that Foch could be usefully employed in the post of chief of the general staff. Having been sent into Italy on the morrow of Caporetto to establish a much-needed understanding with Gen. Luigi Cadorna's headquarters, and having remained in constant and cordial relations with Field-Marshal Sir Douglas Haig, there was little doubt that when the time came Foch mould appear as the single commander that so many people desired by the end of 1917. When, in March 1918, the Germans launched their first grand offensive and the Allied line threatened to break, the necessity of this command became obvious to everybody. It was at Doullens that Foch, on March 29, received from the representatives of the French and British governments that mission of higher co-ordination that on April 14 became more precise in the form of the chief command of all the Allied armies fighting in France. Already he had grasped this command with a firm hand. As a result of the close cooperation of the Allies he stopped the Germans at the gates of Amiens, and thereby brought about the final failure of their attempt to break the Anglo-French front and penetrate to the channel.

Henceforward his whole energies were directed toward assuring this fruitful co-operation. Thus he brought strong French reinforcements to help the British armies, attacked in March and April, and engaged British and U.S. divisions in the battle of the Aisne in May, twice checking German offensives that for a moment were triumphant. And when the Germans came to a standstill in the pockets that they had driven into the Allied front, he prepared the counteroffensives which, when the hour struck, were to shake and crumple the German front.

The counteroffensive was on the point of being launched against the flanks of these pockets, from the Aisne to the Marne, when, on July 15, a new German offensive took place *(see* MARNE, 2ND BATTLE OF). This met with a partial check which had the effect of deepening the pocket in which Foch intended to grip the enemy. The victorious attack of July 18 on the enemy's flanks forced him to retire and gave the signal for the grand Allied offensives.

Foch was now determined to halt no more. He realized that the German armies were beginning to be exhausted but that if they were to be overthrown, the blows must fall thick and fast. The great offensive of Aug. 8 in the region of the Somme which, as it gradually spread and became more violent, forced the Germans to retire on to the Hindenburg line, was almost immediately followed by the new offensive against that strong position where French and English vied with each other in valour. Once the line had been forced, Foch launched his famous directive of Sept. 3 which was in fact the program of the general attack. The stages of this semiconcentric attack are well known. It stretched from the Meuse into Flanders and was designed to draw the enemy from all parts back on to the region of the Ardennes where Foch hoped to pin them and grasp them. The directives, which issued from the headquarters of Bombon (and later, Senlis), are clear, resolute and pitiless. At this point Pétain, Haig and Pershing worked in closest harmony with their French colleague. The directives of Oct. 10 and 19 were followed by successes—hard won and unequal, it is true, but which on Nov. 5 culminated in the general retreat of the beaten and exhausted German armies.

Foch, following them closely, had already prepared an operation on a large scale to make an end of them. While the Germans were to be thrown back into the difficult Ardennes region, a huge group of armies under the orders of Castelnau, with Gen. Charles Mangin as principal executant, were to attack on the Moselle and the Sarre and. reaching the Rhine, were to bar the line of retreat from the encircled Germans. It was at this point that the Germans asked for the Armistice. On Nov. 8 Foch, who had been engaged in drawing up the conditions for three weeks past, received the German plenipotentiaries at Rethondes and by his masterful attitude brought them to accept all conditions on Nov. 11, obtaining with the occupation of the left bank of the Rhine the results which he had expected to gain from the supreme battle.

The career of Foch was not at an end. Europe acclaimed him as the leader who had secured the victory. Marshal of France since Aug. 7, he now became a British field-marshal and later a marshal of Poland. He was elected a member of the *Acade'mie française,* which body, emulating the *Acade'mie des sciences,* gave him a wonderful reception, and at Paris, on July 14, 1919, he passed under the *Arc de triomphe de l'e'toile* at the head of the victorious troops. From New York to London and from Brussels to Warsaw he passed from triumph to triumph. He was not, however, content with a parade role, and, as president of the Inter-Allied military commission. he was repeatedly called upon to take measures in support of the action of the Allied governments. In Jan. 1929 the marshal was taken ill and after a long wasting illness, he died suddenly on March zo. He lay in state beside the grave of the Unknown Soldier at the Arc de Triomphe, and was then laid to rest at the Invalides near the tomb of Napoleon. *(See* WORLD WAR I.)

FOCŞANI, a town of Rumania, in the region of Galatz; on the Milcov river, which formed the ancient frontier between Moldavia and Walachia. Pop. (1956) 28,244. The chief buildings are the prefecture, schools, synagogues, and many churches, including those of the Armenians and Protestants. It is a commercial centre of some importance, the chief industries being oil and soap manufacture and tanning. A large wine trade is carried on, and corn is shipped in lighters to Galatz. The annual fair is held on April 29. The vicinity is rich in iron, copper, coal and petroleum. Near Focşani the Turks suffered a severe defeat from the Austrians and Russians in 1789.

FOCUS, a point at which converging rays meet, toward which they are directed or from which diverging rays are directed; in the latter case it is called the virtual focus (see LENS; MICROSCOPE; TELESCOPE). In geometry the word is used to denote certain points, such as the focuses of an ellipse or the focus of a parabola *See* ANALYTIC GEOMETRY; CONIC SECTION; ELLIPSE; HYPERBOLA; PARABOLA; PERSPECTIVE.

FODDER: *see* FEEDS, ANIMAL.

FOG. A cloud in contact with the ground, fog is usually the result of a condensation process taking place in air near and at the earth's surface, but at mountain-summit stations it may be merely the result of clouds formed in the free air and drifted onto the mountain slopes by the winds. (See CLOUD.)

Physical Characteristics.—A fog is a cloud of particles, usually water droplets (water fog) but sometimes of ice crystals (ice fog). There is no essential distinction between fogs and free-floating clouds in the atmosphere. Fogs seldom produce precipitation, if any at only very small rates; in this respect they are similar to many of the free clouds seen in the sky that are not giving precipitation. Fogs and those clouds which do not tend to develop precipitation are said to be colloidally stable; that is, there is no marked tendency within them for the size of some of the droplets to grow rapidly at the expense of the other drops. Clouds (fogs) of this type are characterized by relatively small-sized drops, predominantly much less than 100 μ in diameter (rain drops are 400–1,000 μ), and also their drop-size spectrum (more or less bellshaped in general) has a smaller range than found in colloidally unstable or precipitating clouds. But the size distribution, median and modal size, etc., in fogs vary greatly from case to case, according to the method of formation, history of the fog, its age, the wind, temperature and radiation conditions, thickening or thinning tendency, admixture of smoke or other "foreign" aerosols, effects of rain or snow falling into it from above, etc. Theory and certain experiments suggest that initially a fog formed by a simple adiabatic expansion should have a fairly uniform drop size, assuming sufficient uniformly effective condensation nuclei are present (often the case in nature). Since observations on fogs rarely show this uniform size, it must be assumed that considerable coalescence of droplets takes place with time, through collisions because of turbulence and the faster falling of the resulting larger droplets.

Normally water fogs form and persist at relative humidities of 100%, but many cases are reported with humidities between 95% and 100%, presumably because special nuclei effective somewhat below 100% are present, or because of pollution. However, NaCl particles deliquesce at about 70% relative humidity and this effectprobably explains the fogs and hazes sometimes reported at sea with humidities from 75% to 95%.

The concentration of droplets in fog rarely exceeds 100 per cubic centimetre, and the liquid water contents are usually of the order of hundredths of a gram per cubic metre and less (whereas rain and many warm, unstable clouds have 0.1 to 3 g. per cubic metre.) Fogs, however, often appear to be denser than any clouds, because a large number of small drops is a more effective light-absorbing medium than a smaller number of larger drops.

Various theories of scattering and transmission of light have been applied to fogs, with conflicting results. Measurements show that the transmission is greatest in the visible spectrum, and the difference in transmission of visual colours is trivial.

There is a tendency for the climatological probability of fog formation to decrease at low temperatures, largely because of the very low water content of cold air masses and the unfavourable effects of snow cover and atmospheric circulation conditions where very low temperatures prevail. Fogs of water drops become rare at temperatures below 15° F., and well inland practically none occur between —15° F. and —28° F. Below —28° F., however, ice-crystal fogs frequently appear in the vicinity of towns and airfields where there is moisture given off from combustion of hydrocarbon fuels, and over water surfaces through evaporation. Ice fog has become a serious problem at some airfields in Alaska and northern Canada, where very low temperatures prevail for months each year. Otherwise in the polar night only a very thin frost haze can form; it persists widely over the arctic ice pack in winter.

The visual range in fog has been analyzed as an integral part of the general problem of visibility (*q.v.*) which has defied both satisfactory theoretical analysis and measurement. It is noteworthy that the routine observation of fog as a meteorological element has been confined, in all weather services and observatories, to recording (1) the observer's opinion as to whether or not true fog exists at or in sight of the station at the time of observation, and (2) the observer's estimate of the horizontal visual range, in general or in each direction, in terms of the distance to the remotest object that can just be distinguished. The latter is given in miles, yards, metres or in International Visibility or other code numbers. Until the 1929 International Meteorological code was generally adopted, many different codes for reporting the types and intensities of fog were in use, and as a result the older statistics given in terms of dense, thick, moderate or light fog, mist, haze, days with fog, etc., are often useless for climatological comparisons between stations or countries that used different codes. Significant distinctions have long been observed in some countries between ground fog, high fog, stratus, steam fog, ice-crystal fog, smoke, dust, etc. These morphological categories are of meteorological value, particularly nowadays in connection with forecasts for air navigation, and most of them have been embodied as hydrometeors in the International Meteorological code. The code in the 1950s still defined various intensities of fog in terms of visual range. Careful observers will not file weather reports in which the hydrometeor indicated under "weather" is inconsistent with that indicated under "visibility." Nevertheless, it is a manifestly difficulttask, often requiring arbitrary considerations, for an ordinary observer to decide whether he is enveloped in a thin water fog, or a light haze (British "mist"), or a light obscuration by smoke or dust. Even the dense fog reported in cities may be caused as much by smoke as by water (called a smog). Therefore, a good deal of circumspection is in order when analyzing fog-frequency and fog-intensity statistics. The use of estimated visual range as some kind of a measure of the density and constitution of a fog can be misleading, for the visual range, according to accepted approximate "laws," depends on the liquid water or solid-particle content, the size distribution, the type of particle, the type and intensity of illumination, the background contrast, the observer's eyes, etc. (*See* VISIBILITY.)

Meteorology of Fog.—The treatment of fog phenomena from the point of view of synoptic meteorology or weather forecasting has proceeded along lines largely independent of the study of the physical or chemical constitution of fog. Observations of fog formation and morphology in relation to the wind direction and speed, pressure and temperature distribution, topographical relations, antecedent weather, etc., long ago revealed the basic processes which lead to saturation or fog dissipation. Sverre Petterssen has given the best summarization of the fog processes in the following table:

Fog-producing Processes

1. Evaporation from:
   a. Rain that is warmer than the air (rain-area fog or frontal fog)
   b. Water surface that is warmer than the air (steam fog)
2. Cooling because of:
   a. Adiabatic upslope motion (upslope or orographic fog)
   b. Flow of air across the isobars toward lower pressure (isobaric fog): effect negligible
   c. Falling pressure (isallobaric fog; unimportant)
   d. Radiation from the underlying surface (radiation fog)
   e. Advection of warmer air over a colder surface (advection fog)
3. Mixing:
   a. Horizontal mixing unimportant by itself, and strongly counteracted by vertical mixing

Fog-dissipating Processes

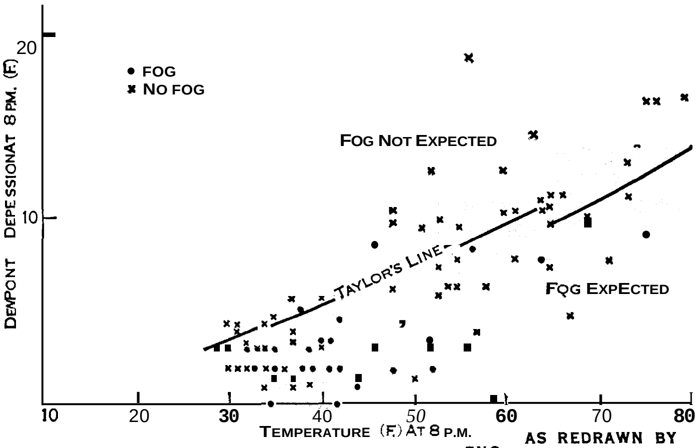
1. Sublimation or condensation on:
   a. Snow with air temperature below freezing (excepting ice-crystal fogs)
   b. Snow with air temperature above freezing (melting snow)
2. Heating because of:
   a. Adiabatic downslope motion
   b. Flow of air across isobars toward higher pressure (effect negligible)
   c. Rising pressure (unimportant)
   d. Radiation absorbed by the fog or the underlying surface
   e. Advection of colder air over a warmer surface
3. Mixing:
   a. Vertical mixing (important in dissipating fogs and in producing stratus clouds)

Source: Sverre Petterssen, *Weather Analysis and Forecasting*, McGraw-Hill, 1940.

It has been the fashion to classify fogs into types each identified with a single process supposed to produce it. While the logic and clarity of such a scheme has obvious advantages for didactic purposes, it is difficult to apply that sort of classification in a strict way to real cases or in the practice of weather forecasting, because several of the processes enumerated are commonly operating together at the same time. The relative importance of the processes varies from case to case and with time in a given case; no two fogs are conditioned by precisely the same combination of factors. Thus, the forecaster, must apply a great measure of judgment, acquired as much by experience as by theoretical understanding of the processes. There are in the standard textbooks many useful generalizations about the characteristics and favourable processes and antecedents for advection fogs, radiation fogs, upslope fogs, frontal fogs, etc., based on the general impressions of forecasters and a few detailed analyses. But it has remained for the studies of Joseph J. George and collaborators to show fully how complex the fog forecast-analysis problem is and how strikingly it differs from one air terminal to another. Previous studies were usually restricted to detailed analyses of isolated single cases and did not provide sufficient material for quantitative generalization. George's method—taking a cue from early work of G. I. Taylor—is to analyze a large number of past fog situations at each station, classifying them according to combinations of processes acting along the previous trajectory of the air fogging the terminal; probability diagrams are constructed to show the critical limits of the most dangerous combinations of factors. The general picture may be similar for all stations in a meteorologically homogeneous region, but for practical use by the forecaster the data must be worked up at each station, since the numerical values may differ considerably. George also showed that for aviation-forecasting purposes it is infeasible to attempt to distinguish between low stratus and fog, especially for the fog types (common to the southeastern U.S. where he worked) in which the ceiling gradually lowers to the ground during the development of the fog situation. He proposed what appears to be the first (but partial) classification of fog types that is practical for use by forecasters: (1) prewarm frontal and postcold frontal fog; (2) orographic (upslope) fog; (3) advection fog; (4) radiation fog; and (5) radiation-advection fog.

The preparation of a statistical (or so-called objective) system of fog forecasting for a given airfield or station involves the careful selection of the important parameters that will predict fog formation (or dissipation).

This is done a *priori* on basis of experience, known general principles, and detailed analysis of past cases. The forecasting relationships of these parameters to the combined visibility and ceiling (*i.e.*, fog) conditions of aviation-operational concern are then determined by means of scatter diagrams. Pure radiation fogs are most amenable to such an approach, since usually only dew-point depression and temperature preceding clear nights need be considered, as illustrated by the use of Taylor's well-known fog-prediction diagram (see figure). In case of the other types of fog, wind speed, trajectory of the air coming to the station, terrain and weather conditions along that trajectory: etc., must be added to the equation, and then a series of diagrams is required to express the prediction relationships. Forecasting by means of such procedures alone is not always sufficiently successful to justify their use; it is suggested by some workers that the inclusion of the vertical gradients of wind and moisture content may improve the results. There are limitations to the statistical method imposed by inadequacies of the weather observations available. Nevertheless, the application and development of this approach to fog forecasting is steadily gaining ground in the leading weather services. Only the complex California type of coastal stratus, which is involved in



AS REDRAWN BY ENG., TAYLOR'S FOG PREDICTION DIAGRAM FOR KEW, MOOK (*Bull. Amer. Met. Soc.*, JUNE 1950)

The points plotted show all cases during 1900–05 when the wind at 8 p.m. was less than 5.5 m.p.h. and the sky was clear; if fog occurred by the next morning a dot was plotted, if no fog a cross. The line divides roughly the dots from the crosses. Below the line the chances were about equal that fog would form or not form if the line was used to forecast (for Kew)

a seabreeze sort of air movement from the cold shore waters onto the coastal plains—formed at sea as advection fog and reinforced by nocturnal radiation over the land—has generally proved quite refractory to statistical attempts.

The geographical and seasonal distribution of fog is determined by the relative occurrences of each process or type of fog at given points over the earth. In general, the oceans of middle and high latitudes have a large maximum frequency of fog in the summer because of advection of warm air over cold water. A few advection fogs appear over the cold lands in winter. The continents are the home of radiation fogs, which tend to have a maximum frequency in autumn or winter in middle latitudes, in summer in high latitudes and in the rainy season in the tropics. Superimposed on these regimes characteristic of land *v.* sea, is a tendency for frontal fogs to occur in the circumpolar belt of cyclonic storms, which pass through the middle latitudes in winter shifting to higher latitudes in summer. The annual march of fog frequency at most places in the world can be explained by one of or some combination of these basic fog-type regimes, as R. G. Stone demonstrated in a study of fog distribution in the U.S. The advection fogs are individually apt to be widespread, dense and deep, especially over the colder ocean waters. Radiation fogs are usually shallow though dense; the sky is often visible (ground fog)—and they generally are restricted in coverage to valleys, marshes and low ground. However, the high (radiation) fogs of California and western Europe are extensive: deep, dense and persistent for days, whereas ground (valley) radiation fogs are usually nocturnal only. The frontal fogs with cold fronts are brief and infrequent, but the type formed under a warm front by falling rain is apt to be deep and extend for hundreds of miles, one of the most troublesome of all weather conditions hindering aviation.

Artificial Fog Dissipation.—Under discussion and experiment for many years, no practical use was made of artificial fog dissipation until World War II. Many proposed methods were unscientific or not practical. The feasible methods are of two basic types: (1) to evaporate the drops by heating the foggy air, or by injecting a drying agent into it, and (2) to remove the drops physically by some means of inducing their precipitation. A practical heating method (Fido; Fog. Intensive. Dispersal of) was developed by the British during World War II and was successfully used to clear aerodromes in England. Oil was burned in rons of jets arrayed around the field. The amount of heat required depends on the latent heat needed to evaporate the water in a unit volume of the fog and the amount of foggy air to be cleared in a specified time. Even with a moderate wind, the equipment used cleared a large field up to 100 ft. or more above the runways in a few minutes. Under windy conditions the equipment must have much more rapid heat output and a more flexible burner system so that the centre of heating can be shifted rapidly to the windward. Such developments were improved and further tested after the war but high installation and operating costs prevented their general use. Henry G. Houghton and William H. Radford successfully demonstrated the precipitation of fog by means of a vertical curtain of fine salt spray through which the wind drifted the fog, leaving a small runway clear to the lee. The use of chloride or chemically active agent may be precluded for airfields because of destructive effects on the aircraft and the installations, soil, etc. Precipitation by means of dropping electrified particles, or passing the fog through an electrostatic (Cottrell) precipitator, or coalescing the drops by intense high-frequency sound, have been demonstrated in laboratory experiments but appear to be impractical for large-scale use. Meanwhile air navigation interests place much faith in development of radio and radar beacons and powerful lights to make landing and take-off feasible and safe in fog. On the basis of successes in dissipating clouds by seeding with dry ice or silver iodide, it was suggested that some types of fog might be economically cleared from certain airports in this manner.

FOGAZZARB, ANTONIO (1842–1911), Italian novelist who opposed to the literary realism of his time an idealism stressing romantic feeling and minute analysis of psychological problems. Born at Vicenza, March 25, 1842, he was a pupil of the priest and poet Giacomo Zanella, whose religious spirit continued to inspire his work. A poetic romance *Miranda* (1874) was his first published work; *Malombra* (1881), *Daniele* Cortis (188j), *Il mistero* del poeta (1888) established his reputation as a novelist. Popularity came with the great success of Piccolo *mondo antico* (1895), which was acclaimed. even by critics unsympathetic to his religious and philosophical ideas, as the best Italian novel since Manzoni's I *Promessi sposi* (1827). It tells the story of the contrasted love of Franco and Luisa and of the pathetic death of their little daughter, against a background of the struggle in Lombardy between the Italian nationalists and the Austrians. An even greater sensation was caused by *Il santo* (1906), condemned as unorthodox and placed on the Index for its presentation of a mystical modern reformer of the church and its satire of the clerical world of its time. Other successful novels were Piccolo *mondo moderno* (1900–01) and Leila (1911). Fogazzaro also wrote short stories: plays and poems. He became a member of the Italian senate in 1896 and died in Vicenza, March 7, 1911. Many of his novels have been translated into English.

Although Fogazzaro's literary importance lies in his idealistic portrayal of virtue and feeling. and his interest in the psychological problems of his characters, which was strongly opposed to the realism (*verismo*) of other writers of his time, he owed his contemporary popularity to his talent for describing domestic interiors in aristocratic society and his intimate studies of the conflict between religious aspirations and sensual appetites. A liberal Catholic, he derived from Antonio Rosmini his sincere desire to revive the church (see ROSMINI-SERBATI, ANTONIO). This sometimes led him to accept modernist ideas, which he reluctantly abandoned in obedience to the church's condemnation. His position is made clear in La *parola* di Dolt *Giuseppe Flores* (published posthumously in 1920). A critical edition of Fogazzaro's works by P. Nardi was published in 14 volumes (1930–41).

BIBLIOGRAPHY.—E. Donadoni, *Antonio Fogazzaro* (1913); T. Gallarati-Scotti, *La vita di Antonio Fogazzaro* (1920); P. Nardi, *Fogazzaro* (1930). (F. DI.)

FOGBOW, a white rainbow, about 40° in radius. It has a reddish outer margin and an inner margin of bluish tinge, but the whole of the middle of the band is uncoloured. It occasionally accompanies fogs (*q.v.*) and its origin resembles that of the normal rainbow, but the smallness of the water drops (under 0.05 mm.) causes the colours to be mixed and the resulting band to be nearly white. See HALO.

FOGELBERG, BENEDICT (or BENGT) **ERLAND** (1786–1854), Swedish sculptor. was born at Gothenburg on Aug. 8, 1786. His father sent him in 1801 to Stockholm, where he studied at the school of art. He then studied in Paris, first under Pierre Guérin, and afterward under the sculptor Bosio. for the technical practice of sculpture. In 1820 Fogelberg went to Rome, where the greater part of his remaining years were spent. He died at Trieste on Dec. 22. 1854. The subjects of Fogelberg's earlier works are mostly taken from classic mythology. Of these, "Cupid and Psyche." "A Bather" (1838), "Venus and Cupid" (1839) and "Psyche" (1854) may be mentioned. His "Odin" (1831), "Thor" (1842), and "Balder" (1842), though influenced by Greek art. are of greater interest. His portraits and historical figures, as those of Gustavus Adolphus (1849), of Charles XII (1851). of Charles XIII (1852), and of Birger Jarl, the founder of Stockholm (1853), are faithful and dignified works.

FOGGIA, a town and episcopal see of Puglia, Italy, capital of the province of Foggia, 243 ft. above sea level, in the centre of the great Apulian plain 201 mi. by rail S.E. of Ancona and 123 mi. N.E. by E. of Naples. Pop. (1957 est.) 120,628 (commune). The name is perhaps derived from the pits or cellars under the pavement slabs of the open spaces (foveae) in which the grain of the neighbourhood is stored. The town is the medieval successor of the ancient Arpi. 3 mi. N.; the Normans, after conquering the district from the Eastern empire, gave it its first importance. The date of the erection of the cathedral is 1172; it retains some fine Norman architecture but was much altered after the earthquake of 1731. Only one single gateway of the palace of the emperor Frederick II (1223, by Bartolommeo da Foggia) is preserved. There died his third wife. Isabella, daughter of King John of England. Charles of Anjou died there in 1285. After his son's death, it was a prey to internal dissensions and finally came under Alfonso I of Aragon, who converted the pastures of the Apulian plain into a royal domain in 1445, and made Foggia the place at which the tax on the sheep was to be paid and the wool to be sold. It remained a great wool market. During World War II the city was occupied by British troops in Sept. 1943.

Foggia is a railway centre, on the main line from Bologna to Brindisi, where this is joined by the line from Benevento and Caserta. There are also branches to Rocchetta S. Antonio (and from there to either Avellino, Potenza, or Gioia del Colle), to Manfredonia and to Lucera.

See R. Caggese, *Foggia e* la *Capitanata*, well illustrated (Bergamo, 1910); A. Haseloff, *Bauten der Hohenstaufen in Unteritalien*, i, 67 ff. (Leipzig, 1914).

FOG SIGNALS are employed for the purpose of guidance or warning when visual marks or signals are obscured by fog or their visibility is materially reduced by atmospheric conditions. Permanent fog-signals intended for the guidance of the mariner are usually established in conjunction with coast and harbour lighthouses and lightships. Fog signals are used in railway working to narn engine drivers when the ordinary signals are obscured by fop: these commonly consist of detonators, fixed on the rail, which are exploded as the leading wheel of the engine passes over them.

Coast fog-signals are of three kinds: (1) aerial-acoustic; (2) submarine-acoustic, including submarine bells and oscillators, which are usually established on light-vessels as an auxiliary to aerial-acoustic signal; and (3) wireless or radio fog-signals. Aerial-acoustic signals may be divided into three classes; first, those sounded by compressed air. such as sirens, diaphones and reed-horns; second, explosive signals, including nitrated-gun-cotton charges, guns and rockets. the last two seldom used; and third bells and gongs. The use of wireless fog-signals has been largely extended since 1921 nhen the first permanent coast signal of this description was established, and they are of great importance to aerial as well as to marine navigation. Aerial-acoustic signals are audible at greatly varying distances and, under certain atmospheric conditions, may be heard at a considerable distance though at the same time wholly inaudible in intervening areas. Wireless and submarine signals, on the other hand, are unaffected by the atmospheric conditions which impair the audibility of aerial sound-signals. (*See* also LIGHTHOUSES: *Fog Signals;* RULE OF THE ROAD AT SEA.) (N. G. G.)

FÖHN, a warm, relaxing wind experienced on the northern side of the Alpine range most frequently in winter and early spring. Similar local winds occur elsewhere; *e.g.,* Norway, Greenland and North America. In the last case it is known as the chinook (*q.v.*) and descends the Rocky mountains to the western prairies as a warm, dry wind which evaporates a great deal of the winter snow.

The fohn approaches the ridge from the south, is cooled during its ascent, and moisture may be condensed from it, giving rain or snow. It descends the northern slope by some process still obscure, during which it becomes warmed and dried. and has important local effects with reference to human activities.

See also WINDS. MOUNTAIN AND LOCAL. (ML. FE.)

FOIL. 1. A leaf (from Lat. *folium*); so used in heraldry and in plant names (*e.g.,* the trefoil clover) and hence applied to anything resembling a leaf. In architecture the word appears for the small leaflike spaces formed by the cusps of tracery in windows or panels, and known, according to the number of such spaces, as quatrefoil, cinquefoil, etc. The word is also found in counterfoil, a leaf of a receipt or cheque book, containing memoranda or a duplicate of the receipt or draft kept by the receiver or drawer as a counter or check. Foil is particularly used of thin plates of metal, resembling a leaf, not in shape as much as in thinness. In thickness foil comes between leaf and sheet metal. In jewellery a foil of silvered sheet copper, sometimes known as Dutch foil, is used as a backing for paste gems, or stones of inferior lustre or colour. This is coated with a mixture of isinglass and translucent colour, varying with the stones to be backed, or, if only brilliancy is required, left uncoloured but highly polished. From this use of foil, the word comes to mean, in a figurative sense, something which by contrast or by its own brightness served to heighten the attractive qualities of something else placed in juxtaposition. The commonest foil is that generally known as tinfoil. The ordinary commercial tinfoil usually consists chiefly of lead, and is used for the wrapping of sweetmeats, tobacco or cigarettes. A Japanese variegated foil gives the effect of damaskeening. Many thin plates of various metals, such as gold, silver and copper, together with alloys of different metals are soldered together in a particular order. a pattern is hammered into the soldered edges and the whole is hammered or rolled into a single thin plate, the pattern then appearing in the order in which the various metals were placed.

2. An old hunting term, used of the running back of an animal over its own tracks to confuse the scent and baffle the hounds (from O. Fr. *foler,* to tread). It is also used in wrestling, of a throw. Thus comes the common use of the word, in a figurative sense, with reference to both these meanings, of baffling or defeating an adversary, or of parrying an attack.

3. As the name of the weapon used in fencing the word is of doubtful origin.

FOIL FENCING: *see* FENCING.

FOIX, COUNTS OF. The counts of Foix were a distinguished French family which flourished from the 11th to the 15th century and during the 13th and 14th centuries were among the most powerful of the French feudal nobles. Living on the borders of France and having constant intercourse with Aragon, they were in a position peculiarly favourable to an assertion of independence.

The title of count of Foix was first assumed by Roger, grandson of Roger I, count of Carcassonne (d. 1012), when he inherited the town of Foix and the adjoining lands which had hitherto formed part of the county of Carcassonne. Roger died about 1064 and was succeeded by his brother Peter, who died six years later and was succeeded by his son, Roger II. This count took part in the crusade of 1095 and was afterward excommunicated by Pope Paschal II for seizing ecclesiastical property; but subsequently he appeased the anger of the church by rich donations. When he died in 1125 he was succeeded in turn by his son, Roger III, and grandson Roger Bernard I. The latter's only son, Raymund Roger, accompanied the French king, Philip Augustus, to Palestine in 1190 and distinguished himself at the capture of Acre. He was afterward engaged in the wars of the Albigenses and, on being accused of heresy, lost his lands to Simon IV, count of Montfort. Raymund Roger, who came to terms with the church and recovered his estates before his death in 1223, was a patron of the Provençal poets and counted himself among their number. He was succeeded by his son, Roger Bernard II. called the Great, who assisted Raymund VII, count of Toulouse, and the Xlbigenses in their resistance to the French kings and was excommunicated on two occasions. Roger Bernard II died in 1241. His son, Roger IV, who followed, died in 1265 and nas succeeded by his son, Roger Bernard III, who, more famous as a poet than as a warrior, was taken prisoner both by Philip 111 of France and by Peter III of Aragon. This count married Margaret, daughter and heiress of Gaston VII, viscount of Béarn (d. 1290). This union led to the outbreak of a long feud between the houses of Foix and Armagnac, which was continued by Roger Bernard's son and successor, Gaston I, who became count in 1302 inheriting both Foix and Bkarn. Becoming embroiled with the French king, Philip IV, Gaston was imprisoned in Paris; but quickly regaining his freedom he accompanied King Louis X on an expedition into Flanders in 1315. He died on his return to France in the same year. His eldest son. Gaston II, became reconciled with the house of Armagnac and died at Seville in 1343. He was succeeded by his son, Gaston III (1331–91), surnamed Phoebus on account of his beauty, the most famous member of the family. Like his father he assisted France in its struggle against England, being entrusted with the defense of the frontiers of Gascony; but when the French king, John II, showed a marked preference for the count of Armagnac, Gaston left his service and went to fight against the heathen in Prussia. Returning to France about 1357 he delivered some noble ladies from the attacks of the adherents of the *Jacquerie* at Meaux and was soon at war with the count of Armagnac. In 1362 the latter was defeated and compelled to pay a ransom; peace was made in 1377.

Early in 1380 the count probably was appointed lieutenant of the king in Languedoc, but when Charles VI became king later in the same year this appointment was cancelled. Gaston refused at first to heed the royal command and was supported by such towns as Toulouse; but as early as Sept. 1381, he abandoned the struggle against John, duke of Berry, who had been chosen as his successor. Left without legitimate sons, Gaston was easily persuaded to bequeath his lands to King Charles VI. who thus obtained Foix and Béarn when the count died at Orthez in 1391. Gaston was very fond of hunting but was not without a taste for art and literature. Several beautiful manuscripts are in existence which were executed by his orders and he himself wrote *Déduits de la chasse des bestes sauvaiges et des ozseaulx de proye.* Froissart gives a graphic and enthusiastic description of his court and his manner of life.

Almost immediately after Gaston's death King Charles VI granted the county of Foix to Matthew, viscount of Castelbon, a descendant of Count Gaston I. Dying without issue in 1398. Matthew's lands were seized by Archambault, count of Grailly and *captal* of Buch, the husband of his sister Isabella (d. 1426), who became count of Foix in 1401. Archambault's eldest son, John (*c.* 1382–1436), who succeeded to his father's lands and titles in 1412 and married Joan, daughter of Charles III, king of Navarre, played an important part in the wars of his time, supporting at different periods the kings of Aragon, France and England. The next count was John's son: Gaston IV, who married Leonora (d. 1479), a daughter of John, king of Aragon and Navarre. In 1447 he bought the viscounty of Narbonne and, having assisted King Charles VII in Guienne, was made a peer of France in 1458. In 1455 his father-in-law designated him as his successor in Navarre, and Louis XI of France gave him the counties of Rousillon and Cerdagne and made him his representative in Languedoc and Guienne. But these marks of favour did not prevent Gaston IV from joining a league against Louis in 1471. His eldest son, Gaston, the husband of Madeleine, a daughter of Charles VII of France, died in 1470; and when Gaston IV died two years later, his lands descended to his grandson, Francis Phoebus (d. 1483), who became king of Navarre in 1479 and was succeeded by his sister Catherine (d. 1517), the wife of Jean d'Albret (d. 1516). Thus the house of Foix-Grailly was merged in that of Albret and subsequently in that of Bourbon; and when Henry of Navarre became king of France in 1589 the lands of the counts of Foix-Grailly became part of the French royal domain.

BIBLIOGRAPHY.—At mid-20th century there was still no good history of the dynasty of Foix. *See* C. de Vic and J. J. Vaissète, *Histoire générale de Languedoc*, 16 vol., new ed. (Toulouse, 1872–1905); B. Nabonne, *Gaston Phébus Seigneur du Béarn, 1331–1391* (Paris, 1936), to be used cautiously; L. Flourac, *Jean Ier, comte de Foix, vicomte souverain de Béarn . . . , 1398–1425* (Paris, 1884); H. Courteault, *Gaston IV comte de Foix, vicomte souverain de Béarn, prince de Navarre, 1423–1472* (Toulouse, 1895).

FOIX, PAUL DE (1528–1584), French prelate and diplomatist, was ambassador to England from 1561 to 1565. He was then sent to Venice, and returned a short time afterward to England to negotiate a marriage between Queen Elizabeth and the duke of Anjou. He fulfilled several important missions during the reign of Henry III of France. In 1577 he was made archbishop of Toulouse, and in 1579 was appointed ambassador to Rome, where he died on May 15, 1584.

There is some doubt as to the authenticity of *Les Lettres de Messire de Paul de Foix . . .* (1628). See *Gallia Christiana* (1715 *et seq.*); "Lettres de Catherine de Médicis," edited by Hector de la Ferrière (Paris, 1880 *et seq.*) in the *Collection de documents inédits sur l'histoire de France.*

FOIX, a town of southwestern France, in the middle ages capital of the counts of Foix, and now capital of the *département* of Ariège, 51 mi. S. of Toulouse, on the Southern railway from that city to Ax. Pop. (1954) 6,093. It stands at the confluence of the Arget with the Ariege. Foix probably owes its origin to an oratory founded by Charlemagne, which later became an abbey, in which were laid the remains of St. Volusien, archbishop of Tours in the 5th century. The county of Foix included roughly the eastern part of the modern *département* of Ariege; *i.e.,* the basin of the Ariège. During the later middle ages it consisted of a number of small lordships subordinate to the counts of Foix, with a share in the government of the district. Protestantism early entered the county, and severe religious struggles ensued. The *états* of the county can be traced back to the 14th century. The old town is dominated by an isolated rock crowned by the castle (12th, 14th and 15th centuries). St. Volusien is a Gothic church (14th century). The town is the seat of a prefecture, a court of assizes and a tribunal of first instance, and has a chamber of commerce. Iron-working is carried on.

FOKINE, MICHEL (1880–1942), Russian-U.S. choreographer who exerted a profound influence on the theatrical dance of his time. Born April 26, 1880, in St. Petersburg, he trained in the Russian Imperial ballet, graduating in 1898. He entered the ballet of the Maryinsky theatre and quickly established a reputation as an excellent dancer in such classic ballets as *Raymonda* and *The Sleeping Beauty.*

Dissatisfied with the rigid classic tradition enforced there by Marius Petipa, Fokine believed that in ballet the dancing, mime, music, scenery and costumes should all contribute toward the dramatic expression of the theme.

For charity performances and pupils' recitals he staged his early ballets *The Vine* (1906), *The Animated Gobelins,* later titled *Pavillon d'Armide* (1907) and *Chopiniana* (1908), revised as *Les Sylphides* The latter, an evocation of the romantic ballet, is recognized as one of the finest works in dance repertoire. *The Dying Swan* (1905), composed for Pavlova, is another well-known early work.

As principal choreographer of the Diaghilev Ballet Russe, Fokine had the opportunity to put his theories into practice, creating such distinguished works as *Petrushka, The Firebird, Prince Igor* and *Scheherazade.* For Vaslav Nijinsky and Tamara Karsavina, brilliant interpreters of his work, he created *Le Spectre de la Rose.* His wife, Vera Fokina, danced in many of his ballets.

From 1919 Fokine taught in New York city, continuing to create new ballets and revive old ones for various companies. He died in New York city, Aug. 22, 1942.

See Cyril W. Beaumont: *Michel Fokine and His Ballets,* new ed. (1942). (LN. ME.)

FOKKER, ANTHONY HERMAN GERARD (1890–1939), Dutch-U.S. airman and pioneer aircraft designer and manufacturer, was born at Kediri, Java, on April 6, 1890. He was educated at Haarlem, Neth., and began his aviation career at the age of 20, obtaining his international pilot's certificate in 1911. As the Netherlands offered insufficient opportunities, he went to Germany and established a small aircraft factory at Johannisthal near Berlin in 1912, in which year he participated in a competition for the design of military aircraft at St. Petersburg. The German government became interested in his designs and he received orders for aircraft and a three-year contract for the training of pilots.

Shortly before World War I Fokker set up a factory at Schwerin, Mecklenburg, and many aircraft of his design played a part in that war. He perfected the interrupter gear which made it possible to fire a machine gun straight ahead through the propeller. After the war he left Germany and established the Fokker works at Amsterdam. He also founded aircraft construction firms in the United States, where he became a naturalized citizen. During the later years of his life, he concentrated on the design and development of commercial aircraft. He died in New York city on Dec. 23, 1939. His autobiography *The Flying Dutchman* was published in 1931. (D. CR.)

FOLARD, JEAN CHARLES, CHEVALIER DE (1669–1752), French soldier and writer on tactical theory, was born at Avignon on Feb. 13, 1669. His military ardour was first awakened by reading Caesar's *Commentaries,* and he ran away from home and joined the army. He was almost continuously on active service, in Italy, in Flanders and, in 1714, under Charles XII of Sweden. Charles XII he regarded as the greatest captain of all time, and it was at Stockholm that Folard began to formulate his tactical ideas in a commentary on Polybius. On his way back to France he was shipwrecked and lost all his papers, but he set to work at once to write his essays afresh, and in 1724 appeared his *Nouvelles Découvertes sur la guerre dans une dissertation de Polybe,* followed (1727–30) by *Histoire de Polybe traduite par . . . de Thuillier avec un commentaire . . . de M. de Folard, Chevalier de l'Ordre de St. Louis.*

Folard spent the remainder of his life in answering the criticisms provoked by the novelty of his theories. He died friendless and in obscurity at Avignon in 1752.

Folard's military writings contain a great number of independent ideas, sometimes valuable and suggestive. The central point of his tactics was his proposed column formation for infantry. Struck by the apparent weakness of the thin line of battle of the time, he desired to substitute the shock of a deep mass of troops for former methods of attack, and further considered that in defense a solid column gave an unshakable stability to the line of battle. Controversy at once centred itself upon the column. While some famous commanders, such as Marshal Saxe and Guido Starhemberg, approved it and put it into practice, the weight of military opinion throughout Europe was opposed to it. History justified this opposition, even though the French Revolutionary armies won several victories with infantry columns.

FOLD. In geology, folds are undulations or waves displayed by the stratified rocks of the crust of the earth. Stratified rocks are generally formed by the accumulation of material in horizontal and nearly horizontal sheets. Some stratified rocks are of sedimentary origin, deposited in rivers, lakes and seas; other stratified rocks are of volcanic origin, deposited as lava flows or as layers of fragmental explosive material. In many places the sheets or strata. as they are more appropriately called, are no longer horizontal hut have been thrown into folds. Some folds are so gentle that the inclination of the strata is barely perceptible; other folds are so pronounced that the strata of the two flanks may be essentially parallel, either steeply inclined as in isoclines (see fig. 4) or lying nearly flat as in recumbent folds (see fig. 2).

Folds show a wide range in magnitude; some are miles or even hundreds of miles across; others, a few feet across, are visible in single outcrops; still others may be perceived only under the microscope. The tops of the large folds have almost invariably been removed by erosion so that only the truncated inclined strata can be seen (fig. 3).

For discussion of the significance of folds in the occurrence of oil and gas and in petroleum geology the reader is referred to the article MINE PROSPECTING AND DEVELOPMENT.

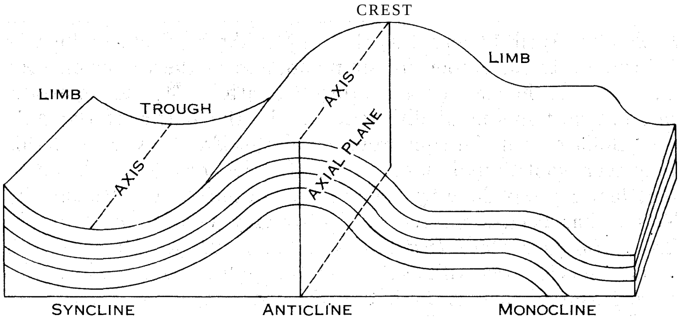

FIG. 1.—DIAGRAM ILLUSTRATING THREE FORMS OF FOLDS. WITH GENERAL DESCRIPTIVE TERMS

Origin of Folds.—The long linear folds, so characteristic of mountainous regions, are believed by many to result from compressional forces acting parallel to the surface of the earth and at right angles to the fold. Whether compressional forces are due to contraction of the crust of the earth or to the drag of subcrustal convection currents or to some other cause is not known. Some geologists believe that many folds are the result of strata sliding, under the influence of gravity, from a vertically uplifted area. The large folds that are essentially circular in plan are due to vertical forces of unknown origin. Many smaller domes, those one-half mile to two miles in diameter, are caused by the rise of masses of rock salt (salt domes) or by the injection of mushroom-shaped masses of magma (laccoliths). (See SALT DOME; LACCOLITH.)

The push exerted by an advancing glacier may throw weakly consolidated rocks into folds. The compaction of sedimentary rocks over buried hills results in gentle folds.

Geometry of Folds.—The axial plane or axial surface of a fold is the plane or surface that divides the fold as symmetrically as possible (fig. 1). The axial plane may be vertical, horizontal or inclined at any intermediate angle (fig. 2). An axis of a fold is the intersection of the axial plane with one of the strata of which the fold is composed (fig. 1, 2).

Although in the simpler types of folds the axis is horizontal or gently inclined, it may be steeply inclined or even vertical. The angle of inclination of the axis, as measured from the horizontal, is called the plunge. The folds illustrated in fig. 3 are plunging away from the reader at an angle of about 20°. The portion of

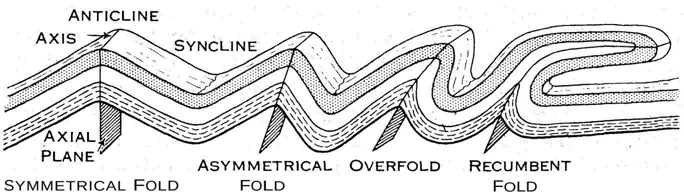

FIG. 2.—FOLDS. PROGRESSIVELY DECREASING FROM LEFT TO RIGHT IN THE INCLINATION OF THE AXIAL PLANE

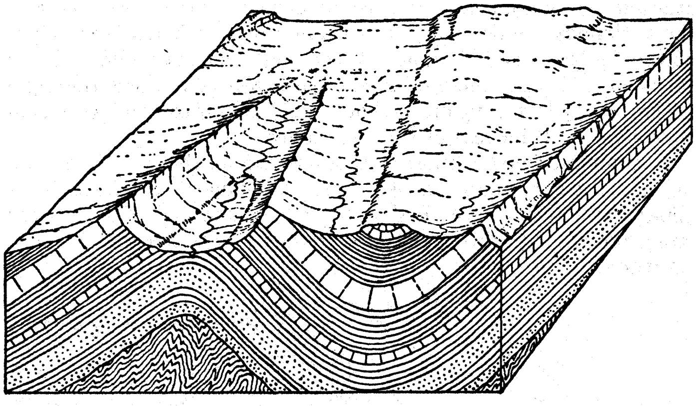

FIG. 3.—PLUNGING ANTICLINES AND SYNCLINES

the fold between adjacent axes forms the flanks, limbs or slopes of the fold (fig. 1).

An anticline is a fold that is convex upward (fig. 1). A syncline is a fold that is concave upward. An anticlinorium is a large anticline on which minor folds are superimposed. A synclinorium is a large syncline on which many minor folds are superimposed. A symmetrical fold (fig. 2) is one in which the axial plane is vertical. An asymmetrical fold (fig. 2) is one in which the axial plane is inclined. An overturned fold or overfold has the axial plane inclined to such an extent that the strata on one limb are overturned (fig. 2). A recumbent fold is one in which the axial plane is essentially horizontal (fig. 2). Isoclinal folds have the two limbs essentially parallel to each other and thus approximately parallel to the axial plane (fig. 4). In an area where the strata are generally horizontal, they may locally assume a steeper dip; a fold of this type, with only one limb, is called a monocline (fig. 1).

Many folds are distinctly linear; that is, their extent parallel to the axis is many times their width. But some are not linear and are more or less circular in plan. A dome is such a fold that is convex upward (fig. 5); this means the strata dip outward from a central area. A basin is such a fold that is concave upward; that is, the strata dip inward toward a central area.

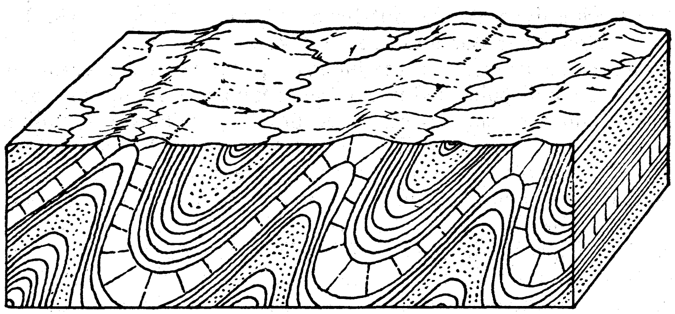

FIG. 4.—STEEPLY INCLINED OR ISOCLINAL FOLDS

Examples.—Folded strata are characteristic of many of the mountain ranges of the world. In the Appalachian valley and ridge province of eastern North America, extending in a southwesterly direction from Albany, N.Y., to central Alabama, the folds are symmetrical folds, asymmetrical folds and overfolds (fig. 2); the axial plane dips southeasterly. Only the eroded stumps of these folds are now preserved (fig. 3, 4). The distance from the crest of one fold to the next is from one to ten miles, and the height of the folds—the difference in altitude of the same bed in the trough of a syncline and on the crest of an anticline (fig. 1)—is two to five miles.

Many of the folds in the Rocky mountains of western North America are similar to those in the eastern United States. But in the southern and central Rockies of Colorado and Wyoming the distance from the crest of one major anticline to the crest of the next is 10 to 50 mi.

The Jura mountains of Switzerland and France offer a classic example of symmetrical and asymmetrical folds. The crests of the anticlines are one-half to two miles apart, whereas the height of the folds is one-half mile. When they were being folded, the rocks of the Jura mountains slid northwesterly along the rigid basement, just as a rug on the floor might fold if one end were held stationary and the rest of the rug moved.

Recumbent folds, similar to those shown on the right-hand end of fig. 2, are common in the Alps. In places many recumbent anticlines and synclines are piled on top of one another. Some of the larger recumbent folds in the Alps are many miles across. *See* also GEOLOGY.

FOLENGO, TEOFILO (GIROLAMO) (1491–1544), the most important of the Italian macaronic poets. who used an Italian vocabulary treated according to Latin rules of form and syntax, was born in Mantua, Nov. 8, 1491. In 1509 he entered the Benedictine order (taking the name Teofilo, by which he is known) and lived in the convents of Brescia, Mantua and Padua until he was 33. In 1525 he left the order, to which he was readmitted in 1534 after having lived as a hermit for a time near Sorrento. He died in a convent near Bassano. Dec. 9, 1544.

Folengo's masterpiece is the *Baldus,* a poem written in macaronic hexameters and published under the pseudonym of Merlin Cocai. Four versions of this poem (in 20 books) are known, published in 1517, 1521, 1539–40 and 1552 (mod. ed. by A. Luzio, Le *Maccheronee,* 1927–28). It narrates the adventures of Baldo, a descendant of Roland's cousin Rinaldo, in a comic style which avoids parody. The first 11 books deal realistically with the popular world of Cipada (birthplace of Baldo, near Mantua), while the last books contain a number of episodes which reveal the author's rich vein of fantasy. Folengo uses macaronic Latin in a masterly way, revealinga sound humanistic education, besides his familiarity with his native dialect. His minor works are of little literary value. The *Moschaea,* inspired by the *Batracomiomachia,* deals with the war between the flies and the ants; the *Zanitonella* describes the love of two peasants; the Italian poem *Orlandino* (1526) and the *Caos del Triperuno* (1527; written in Italian, Latin and macaronic language, partly in verse and partly in prose) have only autobiographical interest. Folengo wrote also two poems on Christ's life (La *Humanità del Figliuolo di Dio* and *Palermitana*) and a *sacra rappresentazione* (*Atto della Pinta*), of which only a very corrupt version is known. Of his three tragedies only the titles are known. Folengo's *Opere italiane* were edited by U. Renda in three volumes (1911–14).

See G. Billanovich, *Tra don Teoflo Folengo e Merlin Cocaio* (1948); E. Bonora, Le *Maccheronee di T. Folengo* (1956). (G. A.)

FOLEY, JOHN HENRY (1818–1874), Irish sculptor, was born at Dublin on May 24, 1818. He studied at the schools of the Royal Dublin society and the Royal academy, London. He began to exhibit at the academy in 1840, and in 1844 was commissioned to do the statues of John Hampden and Selden for the houses of parliament. He became A.R.A. in 1849, and R.A. in 1858. He executed many commissions in London and Dublin, and for India. He was responsible for the symbolical group "Asia," as well as the statue of the prince himself, for the Albert memorial in Hyde park; and "Stonewall Jackson," in Richmond, Va. The statue of Sir James Outram at Calcutta is probably his masterpiece. Foley died at Hampstead on Aug. 27, 1874.

See W. Cosmo Monkhouse, *The Works of J. H. Foley* (1875).

FOLEY, SIR THOMAS (1757–1833), British admiral, entered the navy in 1770, and served under Admiral (afterward Viscount) Keppel and Sir Charles Hardy in the Channel, and with Rodney's squadron was present at the defeat of De Lángara off Cape St. Vincent in 1780, and at the relief of Gibraltar. Still under Rodney's command, he went out to the West Indies, and took his part in the operations which culminated in the victory of April 12, 1782. In the Revolutionary War he was engaged from the first. As flag-captain to Adm. John Gell, and afterward to Sir Hyde Parker, Foley took part in the siege of Toulon in 1793, the action of Golfe Jouan in 1794, and the two fights off Toulon on April 13 and July 13, 1795. At St. Vincent he was flag-captain to the second in command, and in the following year was sent out in command of the "Goliath" (74), to reinforce Nelson's fleet in the Mediterranean. In the battle of the Nile the "Goliath" led the squadron round the French van, and this maneuver contributed not a little to the result of the day. Whether this was done by Foley's own initiative, or intended by Nelson, has been a matter of controversy (see *Journal of the Royal United Service Institution,* 1885, p. 916). His next important service was with Nelson in the Baltic. The "Elephant" carried Nelson's flag at the battle of Copenhagen, and her captain acted as his chief-of-staff. From 1808 to 1815 he commanded in the Downs. Sir Thomas Foley, who rose to be full admiral and knight grand cross of the Bath, died while commander in chief at Portsmouth in 1833.

FOLGER, HENRY CLAY (1857–1930), U.S. lawyer and capitalist, was born in New York city on June 18, 1857. He attended Amherst college, Amherst, Mass., graduating in 1879, and studied law at Columbia university, obtaining his LL.B. in 1881. As a student he was employed by Pratt and company, a part of the Standard Oil group, and later became a director of the company. In 1908 he became a director of Standard Oil Company of New York and in 1911 became its president. The firm prospered under his direction and in 1923 he became chairman of the board. A devoted Shakespearean scholar, Folger built a fine Shakespearcan collection and erected a library to house it in Washington, D.C. (H. J. SG.)

FOLGORE DA SAN GIMIGNANO, a 14th-century Italian poet, of whose life little is known. Some of his anti-Ghibelline political sonnets, and a few of his sonnets on the pleasures of the months and the days of the week, were translated by D. G. Rossetti and by J. A. Symonds.

FOLIES-BERGÈRE. This Parisian music hall, variety-entertainment theatre, destined to become one of the major tourist attractions of France, opened in a new and spacious theatre on May 1, 1869, located in the rue Richer. Its designation was taken, after litigation over the originally chosen name of Folies-Trévise, from the nearby rue Bergère. The opening performance included two operettas, a pantomime featuring the famous Paul Legrand as Pierrot, and a variety of specialty numbers. During the siege of Paris the theatre became a hall for political meetings but at the conclusion of the war opened again under the management of Leon Sari. By the last decade of the 19th century, its repertory resembled that of a vast circus but without the equestrian numbers. Vaudeville sketches, playlets, musical numbers in great variety, ballets, eccentric dances, acrobats and balancing performers, tightrope walkers, magicians and sleight-of-hand artists, trained animal acts, elaborate choral numbers, spectacular and mechanical effects on a vast scale, operettas and musical comedies attracted Parisians and tourists alike. For other patrons the pursuit of gallantry, intrigue and affairs of love in the promenades and the refreshment rooms was the chief attraction.

Under the management of the Lallemands, their nephew, Edouard Marchand, introduced the first "girls" to the Folies. In 1894 the vogue of the strip tease seized the music halls of Paris and the Folies took it over and elaborated it to the extent that, in the 20th century, its reputation for *les girls* overshadowed its many other beautiful performances. During the period of World War I the exhibition of feminine pulchritude in the nude became and continued to be the most sensational aspect of a Folies show.

Most of the great entertainers and music-hall artists of France have played at the Folies. The list includes, among many others, Fernandel, Colette, Yvonne Printemps, Raimu, Yvette Guilbert, Colette Fleuriot, Yvonne Menard, Maurice Chevalier, Mistinguett of the beautiful and highly-insured legs and Josephine Baker. Charlie Chaplin began his career at the Folies in 1902 at the age of 14. By the mid-20th century the elaborate shows at the Folies required 10 months of planning and preparation, about 40 different sets, 1,000 to 1,200 individually designed costumes, in addition to the elaborate electrical and mechanical effects. The large and splendidly equipped stage, complete with elaborate machinery and extensive lighting apparatus, allows the management to stage sumptuous and grandiose spectacles.

Through touring the Folies-Bergère became widely known throughout France and in many other European and South American cities.

See Paul Derval, *The Folies-Bergère,* trans. by Lucienne Hill (1954).
(H. C. Hr.)

FOLIGNO, a town and episcopal see of Umbria, Italy (anc. Fulginiae), 771 ft. above sea level, province of Perugia, from which it is 25 mi. S.E. by rail. Pop. (1951) 19,707. The cathedral has a Romanesque south façade of 1133. In the same piazza as the south façade is the Palazzo Trinci, completed in 1407. (Both buildings were damaged during World War II but were later repaired.) There are a number of notable Renaissance churches and buildings, and several churches contain paintings by Umbrian masters. Raphael's "Madonna di Foligno," now in the Vatican, was originally painted for the church of S. Anna.

Foligno changed hands often during the 13th century, and was destroyed by Perugia in 1281. From 1305 to 1439 it was governed by the Trinci family as deputies of the Holy See, until owing to the defection of one of them, Corrado II, Pope Eugene IV sent a force against Foligno, to which the inhabitants opened their gates, and Corrado was beheaded. Until 1860 Foligno belonged to the states of the church. It suffered from a severe earthquake in 1832. Foligno is an industrial centre. Products include textiles, paper and leather goods.

FOLIO, a term in bibliography and printing, with reference either to the size of paper employed, or of the book, or to the pagination. In the phrase "in folio" it means a sheet of paper folded once, and thus a book bound up in sheets so folded is a book of the largest size and is known as a folio. Similarly, folio is one of the sizes of paper adapted to be thus folded. In bookkeeping the word is used for a page in a ledger on which the credit and debtor account is written; in law writing, for a fixed number of words in a legal document, used for measurement of the length and for the addition of costs. In Great Britain a folio is taken to contain 72 words, except in parliamentary and chancery documents, when the number is 90. In the United States 100 words form a folio.

FOLIUM: *see* CURVES, SPECIAL.

FOLK DANCE. Folk dance began with primitive man when it served as his first and only means of communication. Through dance, he endeavoured to understand, as well as to control by means of magic, his supernatural world. He employed dance, therefore, as a medium of understanding and of bringing about the solicitation and placation of his gods, the driving away of evil spirits, the destruction of enemies, the changes in the seasons, the rising and setting of the sun, the waning and waxing of the moon, the pursuit of his various occupations, precipitation and other factors conducive to the fertility of vegetation, animals and human beings, and the initiation of his youth into adulthood.

G. Stanley Hall has stated that, whenever members of alien primitive tribes sought closer acquaintance with each other, they asked a single question in sign language: "What do you dance?" And as these respective members performed their dances, each was acquainted with answers to the innumerable questions that might have been posed. In the process of time, primitive tribes evolved into the separate nations which comprise the modern world. Each nation then developed its particular folk dances stemming from this common heritage of primitive man. *See* also FOLKLORE.

The folk dances of contemporary countries fall into two main categories: those which have retained their ritualistic origins and are therefore performed by smaller selected groups or individuals on special, commemorative occasions; and those which are distinctly recreational in nature, evolved for general participation in much the same manner in which ballroom or social dancing is engaged in by persons of all ages. The folk dances of all countries, therefore, share a common heritage and reflect the same basic thematic sources developed first by primitive man. They are distinctive, however: with respect to the inevitable changes and adaptations related to religious, historical, geographical, topographical, climatic, sociological and other factors which have proved the determining influences in the development of the specific folk dances of a particular time and place.

Folk dances may be defined as the authentic, traditional dances of a given country, handed down from generation to generation in the manner of all traditions, customs, beliefs, superstitions and folkways without alteration except that which has occurred unconsciously through such repetition. In other words, the genuine folk dances of all countries are those which have not been altered deliberately. National dances, by the same token, are those traditional folk dances which are the most widely known and popular in all sections of a country regardless of geographical barriers and local variations. Not every country acknowledges a so-called national dance. Illustrative, however, are the tarantella of Italy, the *Hambo* of Sweden, the *Csárdás* of Hungary, the *Kolo* of Serbia and the Balkans, the *Schuhplattlers* of Bavaria and the *Jarabe tapatio* of Mexico. Ethnic, or ethnologic, dances differ from traditional and authentic folk and national dances in that they result in art forms emanating from the folk dances of a certain country, but representing a highly specialized development of skill and subsequent theatricalized presentation. The ethnic dances of a country are presented as spectacles with distinctive audience appeal rather than as communal experiences in which all participate. Such countries as China, Japan and Spain have both folk dances in which various groups participate as well as ethnic dances for theatre purposes.

Illustrative folk dances of various countries are examined briefly.

Great Britain.—Dances of England may be classified into three main categories: (1) Sword dances, of a ritualistic nature) and originating from ancient pagan fertility rites, are performed traditionally between Christmas and the New Year, commemorative of their association with the presentation of sword plays during this particular season of each year. Death and resurrection are symbolized in recurring figures in such traditional sword dances as "Sleight's," the "Flamborough" and the "Beadnell." (2) Morris dances are performed with both handkerchiefs and sticks and originated from the more ancient sword dances associated with primitive sacrificial rites. The morris dances are linked with the season of Whitsuntide as a spring agricultural festival, and are related to primitive fertility rites in that they celebrate the conquest of spring over winter and the purging of fields and villages from evil spirits. Morris dances are both processional and stationary in design and include such well-known examples as "Tideswell Processional," "The Blue-Eyed Stranger," "Bean-Setting" and "Shepherd's Hey." (See MORRIS DANCE.) (3) Country dances are the recreational, social, general dances which evolved, no doubt, from the more ancient sword and morris dances of England but developed into folk dances for recreational purposes reminiscent of such expressions as "dancing on the green" or that particular centre of each English village upon which groups gathered to celebrate any festive occasion. English country dances are performed in circular, square and line formations. They include such popular dances as "Rufty Tufty." "If All the World Were Paper," "The Ole Mole:" "The Black Sag." "Gathering Peascods" and "Row Well. Ye Mariners." English sword, morris and country dances are performed in the 20th century in many villages, towns and cities on those occasions with which they are associated traditionally.

The folk dances of Scotland may be classified into four main categories: sword dances: flings, reels and schottisches. Both the sword dance and the Highland fling may be traced to war as a basic theme. The sword dance was performed on the eve of battle; around swords and scabbards crossed upon the ground. and the touching of either portended evil for the ensuing encounter. The Highland fling. however. was originally a dance of victory performed vigorously and exultingly on the scene after a successful battle. Both the sword dance and the Highland fling arepopular among modern competitive dance events in many Scottish folk festivals and Highland games. While the sword dances and flings are primarily solo dances, the schottisches and reels are popular group dances for recreational purposes, arranged in formations for two or more couples. All Scottish folk dances are highly stylized. They are executed with exactness in timing, sharpness of line and excitement of spirit. The precise use and contours of arms, legs, and feet are suggestive of a much later development of the classical ballet.

The folk dances of Ireland are variations of three main types—jigs, reels and hornpipes. They are primarily step dances, so called because of the rapid, exact and nimble movement of the feet and the subsequent production of rhythmic patterns as they touch the floor with great speed and dexterity. Irish folk dances are recognized as one of the antecedents of contemporary tap dance. The folk dances of Ireland are danced in the form of solos, duos and group dances for two or more couples. They are stylized to preclude any distraction from the intricate rhythms of the feet and are danced with erect bodies. a minimum of movement and the absence of posturings and affectations which might detract from the effectiveness of their primary characteristic — the rhythmic patterns of the feet.

Continental Europe. — The folk dances of Scandinavia and of countries comprising the European continent are too great in number and too diversified in type to permit more than a few cursory generalizations. These countries share such common folk dance forms as the polka, the schottische, the waltz, the *varsovienne,* the march and the two-step. They share, also, the same thematic bases for their origins augmented by other influences which arose in the process of regional development into separate nations. The folk dances of Norway, Sweden, Denmark and Finland reflect the cold climate of these countries through the vigorous style of their execution as well as the legends and superstitions that are a part of their respective cultures. Many of the folk dances of the Slavic countries are characterized by sharp changes in dynamics and tempo consonant with racial temperaments. Those of Switzerland are both delicate and robust in style and execution and suggestive of a serenity of spirit.

The folk dances of France vary from the simple, rollicking, follow-the-leader type of the farandole and the exuberant *branles* and *voltas* (which led to the waltz) to the more ordered gavottes, *rigaudons, contredanses* and cotillions. Illustrative are the *Branle Gascon,* the *Pont-Aven* and the *Quimper* gavottes. Countryfolk of various nations have attributed special significance of religious origin to bridges, associating them with the spanning between this world and the hereafter. Commemorative of this association is such a simple popular French folk dance as *Sur le Pont d'Avignon* and the frequent recurrence of *pont,* meaning "bridge," in other folk songs and dances.

Mexico. — The folk dances of Mexico and of other Latin-American countries are distinguished by the influences of their heritages, with styles reflective of subtle, romantic temperaments, and of the climatic conditions of the countries themselves. Those of Mexico fall into two main categories reflective of the history of this country. One group reveals distinctly the early Aztec culture and is Indian in character. the other reflects the influences of the Spanish conquest. Illustrative of the Indian influence is *Los Matlanchines,* an impressive ceremonial dance performed either in couples or by men only, depending upon the locale in which it appears; indicative of the Spanish influence are the *Zapateados* or step dances which include the *Jarabes,* the *Jaranas* and the *Huapangos,* danced in a variety of regional versions.

United States. — The folk dances of such areas as Hawaii reveal diversity directly traceable to the different lineages of the somewhat cosmopolitan inhabitants. Most widely known, however, is the hula with its many variations from the religious and ceremonial of ethnic import to those for popular entertainment.

Although the ultimate origin of the hula is somewhat obscure, it is fairly well established that it stems directly from ancient fertility rites. since fertility of plant. animal and human life was a primary theme of all dances of antiquity. Now a general term for all the folk dances of Hawaii. the hula was originally regarded as a sacred and religious dance and was safeguarded from desecration through the observance of tabus and through the performance of priestly rites.

The art of gesture was highly developed in the hula, through the movements of the hands and arms pantomiming the story of the accompanying song. while the movements of the feet and hips sustained the basic rhythm of the dance.

Aside from Hawaii, the United States is thought by some to possess no indigenous folk dances except those of the early North American Indians who comprised its first inhabitants. However, there has been a constant interchange of folkways from decade to decade, peoples from each country developing their own distinctive folk dances in the process of their specific growth and development. Folk dances of the United States, therefore, may be traced to those of other homelands. They have evolved ultimately into four distinctive types, which may be designated as play-party games, round dances for individual couples, group dances in parallel lines, and circular formations and square dances for four or more couples. Play-party games are those simple folk dances stemming from early Puritan days when both dancing and the use of musical instruments were denounced. Ingenious pioneers found a way to dance. therefore, by calling their dances "games" and by supplying vocal accompaniments. "Paw-Paw Patch" and "Shoo Fly" are only two dances illustrative of a great wealth of American folk dance literature devoted to this particular type of dance for recreational purposes.

Round dances in the United States reveal their kinship with those of other countries in that they include polkas, schottisches, waltzes, *varsoviennes,* two-steps and marches. but they reflect. also, distinctive adaptations in steps, style and manner of execution with respect not only to their performance in the United States as a whole but in the various sections, as a logical outcome of different periods in development. For example, the *varsovienne* of the early settlements in Virginia is very different from the "Put Your Little Foot" of Texas and the southwest, and yet both are U.S. variations of a folk dance form common to many countries. One of the earliest group dances performed in both circular and line formations is the "Virginia Reel," which may be traced directly to the English "Sir Roger de Coverly." The latter is illustrative of innumerable dances brought to America by early English settlers in Virginia. where the dances underwent many changes and adaptations so that they now bear but a faint resemblance to their progenitors. "Hull's Victory" is illustrative of an American folk dance with war as a basic theme.

Square dances are of two basic types: those that first evolved in the early settlements of New England and in some of the southern states. and those that were developed later in the southwestern and western sections. Although sharing many of the identical steps and figures, the former have retained the quiet, smooth, dignified: conservative and uniform style of some formal English country dances and French quadrilles, while the latter reflect the kind of rugged individualism that prompted later generations of pioneers to explore and develop new sections of the country. Marked differences in these two versions of the square dance include the substitution of "patter calls" of a homespun nature for simple. shouted "prompt calls," and a much freer and more boisterous type of movement, permitting the individual dancer to "cut didoes" in interpolating improvised steps within the general framework of the orderly figures of a particular square dance.

The list of American square dances is reflective of the particular section in which they have developed. as "The Texas Star." "Life on an Ocean Wave,'! "Tennessee Running Set" and "Birdie in a Cage."

The dances of the North American Indians, the first inhabitants of the Cnited States. present a sharp contrast to the dances evolved by those who settled later in the country. Their themes and purposes were those of primitive peoples everywhere. These primeval tribal dances provide for the folklorist one of the most authentic links with the past in those pueblos in New Mexico. Arizona and other southwestern states in which they are performed today in conjunction with rituals as old as the tribes themselves. Although the various tribes developed dances unique with respect to their history and mores, all shared such common ceremonial dances as those pertaining to war, solicitation for rain, fertility of crops and success in the pursuit of game, placation of gods, purging of evil spirits. etc.

Many tribes, therefore, developed and still dance today their Eagle, Buffalo and Deer dances commemorative of prowess in hunting; Corn dances in which high jumps were sought to ensure tall growth of the corn; Snake dances in which live and poisonous snakes were handled and then released to ensure rainfall after a long drought; and innumerable fertility dances in which fruits, vegetables, pine branches and phallic symbols were all used either as part of the costume or carried in the hands. Although there were solo dances on the part of the medicine men and others of distinction. the majority of the dances of the North American Indians were communal. A circular formation was deliberately employed to achieve unity and cohesiveness.

In schools and colleges, folk dance is incorporated in the curriculum and taught, properly, as a folk art rather than as a medium of exercise only. Such an approach presupposes its presentation with all of the associated learnings such as origins, beliefs, customs, legends. costumes and festivals. It is used, therefore, as a means of promoting understanding and appreciation of peoples of other times and places. as well as a means of gaining skills, knowledge and wholesome recreation.

Good courses of study, therefore, include both ceremonial and ritualistic dances along with those that are purely social and recreational.

Private folk dance organizations, civic and recreation centres and church groups also sponsor folk dancing. Cities as well as villages in all countries of the world incorporate folk dancing in the commemoration of special holidays and events.

See also DANCE and under names of various dances. (A. S. D.)

FOLKESTONE, a municipal borough, seaport and seaside resort in the Folkestone and Hythe parliamentary division of Kent, Eng., 17 mi. S.E. of Canterbury by road. Pop. (1951) 45,203. Area 6.3 sq.mi. Folkestone is an important port of the continental passenger service to Boulogne. The older part of the town lies in a small valley which opens steeply to the Dover strait. To the north, the town is sheltered by hills 400 to 500 ft. high, on one of which, Castle hill, is an ancient earthwork. Along the cliff west of the old town a broad promenade with lawns and flower beds. nearly 2 mi. long, called the Leas. extends west to Sandgate and is connected with the shore road and gardens below. On this cliff stands the parish church of St. Mary and St. Eanswith. mainly Early English, built to receive the relics of St. Eanswith. The original church, attached to a priory, was founded near the site of a convent built by Eadbald, king of Kent and father of Eanswith, in A.D. 630. for his daughter The town contains a public library and museum, a technical school, the Leas Cliff hall (a musical centre). a repertory theatre and the Royal Victoria hospital, built in 1889–90 and several times enlarged.

William Harvey, discoverer of the circulation of the blood, was a native of Folkestone and is commemorated by a memorial on the Leas. Sir Eliab Harvey, his nephew, founded the grammar school in 1674. Folkestone has its own court of quarter sessions.

Folkestone harbour has a deep-water pier, which, before World War I, was lengthened to 1,480 ft. and has berths for eight steamers, with a railway platform and lighthouse. The area of the inner and outer harbours is a little over 12 ac. There is a fishing industry, and in addition to passenger traffic a large general trade is carried on

The railway line to Dover (7 mi.) passes through a series of cuts and tunnels in the chalk cliffs, by way of the Warren (on the east of the town overlooking East Wear bay) and Abbot's and Shakespeare's cliffs. In 1915 a serious landslide in the Warren closed the railway for four years. In 1920 the earl of Radnor presented the Warren and East cliffs to the town and they have been developed as parks. The remains of a large Roman villa were excavated near the East cliff in 1924.

Folkestone (Folcantan) was among the possessions of Earl Godwine when he was exiled from England; at the time of the Domesday survey it belonged to Odo, bishop of Bayeux. From early times it has been a member of the Cinque Port of Dover, and had to provide one out of the 21 ships furnished by that port for the royal service. It shared the privileges of the Cinque Ports, whose liberties were exemplified at the request of the "barons" or burgesses of Folkestone by Edward III in 1330. The corporation, which was prescriptive, was entitled the mayor, jurats and commonalty of Folkestone. In 1629 the inhabitants obtained licence to erect a port.

By the end of the 18th century the town had become prosperous by the increase of its fishing and shipping trades, and by mid-19th century it was one of the chief health and pleasure resorts of the south coast. In 1805 the threat of invasion by Napoleon caused three Martello towers to be built, east of the town. It was an important embarkation point during World War I and one of the ports permitted to civilians. In World War II, 7,000 houses were damaged by enemy air raids.

FOLKLAND (folcland). This term occurs three times in Anglo-Saxon documents. In a law of Edward the Elder (c. i. 2) it is contrasted with bookland in a way which shows that these two kinds of tenure formed the two main subdivisions of landownership: no one is to deny right to another in respect of folkland or bookland. By a charter of 863, King Aethelbert exchanges five hides of folkland for five hides of bookland which had formerly belonged to a thane, granting the latter for the newly-acquired estates exemption from all fiscal exactions except the threefold public obligation of attending the fyrd and joining in the repair of fortresses and bridges. Evidently folkland was not free from the payment of gafol (land tax) and providing quarters for the king's men. In Ealdorman Alfred's will the testator disposes freely of his bookland estates in favour of his sons and his daughter, but to a son who is not considered as legitimate five hides of folkland are left, provided the king consents.

Two principal explanations have been given to this term. J. Allen thought that folkland was the common property of the nation (folc), out of which the king could carve dependent tenures for his followers more or less after the fashion of continental *beneficia.* These estates remained subject to the superior ownership of the folk and of the king: they could eventually be taken back by the latter and, in any case, the heir of a holder of folkland had to be confirmed in possession by the king.

Another theory was proposed by Sir Paul Vinogradoff in 1893. It considers folkland as landownership by folkright—at common law, as might be said in modern legal speech. In opposition to it bookland appears as landownership derived from royal privileges. The incidents recorded in the charters characterize folkland as subject to ordinary fiscal burdens and to limitations in respect of testamentary succession. Conversely, "bookland," land held under a royal charter, was normally free from fiscal dues and could be bequeathed at its holder's will. This view of the matter was accepted by the chief modern authorities. (P. VI.)

FOLKLORE. The word was coined by the English antiquarian W. J. Thoms in 1846 to denote the traditions, customs and superstitions of the uncultured classes in civilized nations. The meaning of words, however, is prescribed not by definition but by usage. and the scope of folklore came to include what was deliberately excluded in the early definition. popular arts and crafts. *i.e.*, the material as well as the intellectual culture of the peasantry. Mainly as the result of the work of the English anthropologists, Sir Edward Tylor, Sir James Frazer, and others, who directed attention to the use of the analogies presented by the practices and beliefs of the primitive cultures to illustrate and explain the superstitions and traditional customs of the European peasantry, no sharp boundaries were drawn in practice between the field of folklore and that of social anthropology (*q.v.*).

The Study of Folklore.— Interest in the traditions, ballads, stories and superstitions of the common folk is no novelty of recent date. One has only to think of the Caroline antiquaries such as John Aubrey whose manuscript notes upon the *Remaines of Gentilisme and Judaisme* were written in 1687, though first printed in their entirety in 1881. or of the renewed interest in popular poetry in the 18th century as evinced by such works as Thomas Percy's *Reliques of Ancient English Poetry,* an interest which reached its literary zenith under the influence of Sir Walter Scott in the early part of the 19th century. The customs of the folk no less than their songs attracted the attention of the 18th-century antiquary. John Brand's *Observations on the Popular Antiquities of the British Isles* was first published in 1777; in the early 19th century W. Hone's *Everyday Book* (1826) and *Year Book* (1829) deserve mention. But the work of the German Grimm brothers, whose *Kinder- und Hausmärchen* was published in 1812 and *Deutsche Mythologie* in 1835. laid the foundations for a study of folktales and popular superstitions upon a more scientific basis and envisaged its problems from a wider point of view than that of the local antiquarian or literary romantic.

The collections of material from different parts of Europe, which were the fortunate consequence of the example set by the Grimms. revealed that, as Aubrey had already noticed, there were many popular beliefs and practices to which parallels could be found in the records of classical antiquity. and that there was a large stock of tales! customs and beliefs which was common to all European countries. For a time speculation, which was led astray by a mistaken philological theory and by a belief, later proved erroneous, that the *Vedas* represented a primitive stage of "Aryan" culture, attempted to derive this common stock from the original ancestors from whom the various peoples who now speak languages belonging to the Indo-European family were thought all to have been descended. A prominent feature of the theories of this school, of which Max Müller was the protagonist, was the view that mythology and folktales were vestigial relics of an allegorical religious literature connected with the worship of natural phenomena. But the work of Tylor. followed by that of Frazer, whose *Golden Bough* extended to the primitive cultures the results of J. W. Mannhardt's researches into the agricultural customs of the peasantry of Europe, and made popularly effective by the adroit pen of Andrew Lang, demolished these theories by demonstrating that analogies to these supposed survivals of "Aryan" religion among the European peasantry were to be found also among primitive peoples in all parts of the world. Popular superstitions in Europe, it was later suggested, were not debased remnants of an elaborate archaic religious system, but vestiges of the stages of culture which the higher strata of civilized society had passed through but had outgrown. The world-wide distribution of similar or identical customs was explained by the hypothesis that the normal reactions of the human mind at similar stages of its development to similar conditions of environment will everywhere produce similar results.

Of the trend of the study of folklore in modern times two features may be noticed. First its materials were greatly enriched by the systematic collection and recording of data, particularly in the smaller countries of Europe. There the strong revival of national sentiment among the smaller nationalities supplied an effective stimulus, and the opportunities for collection proved exceptionally rich where the conditions of European civilization had been introduced relatively recently into what were previously peasant societies. Second. with greater knowledge the complexity of the material was more adequately appreciated, and a more cautious and more historical approach to its problems was general.

The acceptance of Tylor's doctrine of survivals led for a time to an exaggerated emphasis upon similarities, which were sometimes superficial, to the neglect of differences, which were often fundamental. Survivals, it was held, could not be dated; it might therefore be assumed that they belonged uniformly to an infinitely remote antiquity, and since no individual originator could be traced or named, some held that all popular songs, ballads and stories were "collective creations of the folk." How a ballad, or indeed any work of art, could actually be evolved by this committee process was never satisfactorily explained, but the view, which possessed a certain sentimental attraction, received some support from the works of the French school of sociologists, Emile Durkheim and his pupils, who endeavored to interpret the data of folklore and social anthropology in terms of contemporary theories about the psychology of crowds.

The modern tendency was to recognize that the survivals of which the material of folklore consists are not all of equal antiquity. Difficult though it undoubtedly is, the main task of the student is that of analysis and stratification. Many of the general ideas which find expression in popular customs and superstitions are doubtless the product of simple psychological reactions to environment! which are common to human nature in all parts of the world, but an examination of the detailed forms in which they have been given expression often reveals substantial differences. The distribution and, where possible, the chronological development of these specific forms demand the most careful attention. Only thus can the data be disentangled. For, if much is very old, much is relatively recent. Culture is affected by foreign contacts of all kinds, whether peaceful or warlike, and within a single society, the learning of one generation has a way of becoming the folklore of another. Much that is handed down eventually by oral tradition, perhaps in a debased and distorted form, has its origin in literature. The satisfactory analysis, therefore, of folklore material demands the use of every available instrument, historical, literary and philological, as well as that of comparative analogy.

What is quite certain is that in this, as in other fields of scientific enquiry, there is no master key which will unlock all secrets with a single simple formula.

Folktales and Popular Stories.— The fields of folklore and social anthropology as mentioned above are not rigidly separated. Thus it is not uncommon to find in a scientific monograph upon the social and religious customs of some primitive people a chapter devoted to their folklore. This will usually be found in practice to contain legends, stories, riddles and proverbs. Neither the storytelling faculty nor the ability to give forcible expression to moral and social truths or prejudices in picturesque apothegms are limited to any section of the human race. Though in particular cases a proverb may have been borrowed by one people from another, the generic similarity of many proverbs which have a wide distribution (*e.g.,* "one swallow does not make the summer") may well be due to the coincidence of independent invention.

The problem of stories is more complicated. Popular stories fall into three main categories; myths, legends and stories which are told primarily to provide entertainment. As distinct from these last, myths have a purpose. They are essentially aetiological, or, as R. Kipling would say, *"Just-So Stories."* Their object is to explain (1) cosmic phenomena (*e.g.,* how the earth and sky came to be separated); (2) peculiarities of natural history (*e.g.,* why rain follows the cries or activities of certain birds); (3) the origins of human civilization (*e.g.,* through the beneficent action of a culture-hero like Prometheus); or (4) the origin of social or religious custom or the nature and history of objects of worship. It will be obvious that myths which fall into the first three categories are likely to present resemblances which may be explained as coincidences, identical questions having provoked similar replies, whereas the myths of our fourth class are likely to differ as widely as the particular customs or local deities which they seek to explain.

Legend may be said to be distorted history. It contains a nucleus of historical fact the memories of which have been elaborated or distorted by accretions derived from myths or from stories of our third kind. In so far as they are historical the similarities between the legends of different peoples must be due to coincidences of real circumstance; in so far as they are fiction? the similarities will be of the same kind as those of myths or fairy stories from which they have really been borrowed.

The majority of the recorded stories of primitive peoples, with the possible exception of the animal tales to which the African peoples are peculiarly addicted, fall into the categories of myth or legend, perhaps because disinterested or unmotived flights of the inventive imagination and fancy, which are rare or rudimentary among primitive peoples, are essentially products of a relatively advanced civilization. But the problems presented by stories, which are neither myths nor legends, cannot be restricted to Europe; for there is a large stock both of incidents and of plots which is common to all countries between Iceland and India. Is this to be accounted for by the coincidence of independent invention or by diffusion? Theodore Benfey, whose *Pantschatantra* was published in 1859, maintained that India had provided the great reservoir of stories from which European folktales were derived. In Germany the work of Köhler and in England the writings of Clouston helped to elucidate the debt of western Europe to oriental story books, and in France Emmanuel Cosquin devoted great learning to the maintenance of the extreme view that all European folktales had their prototypes in India.

If we are unable to accept the Indianist position, we may be grateful for definite gains which these scholars achieved. First, they established the fact that certain kinds of similarity can only be accounted for by diffusion. While it is conceivable and often probable that a general idea or an isolated incident may have occurred independently to story tellers in different countries, it is to ask too much of coincidence to suppose that the same plot, *i.e.,* an identical series of incidents arranged in the same logical order of interest, could be independently invented more than once. Second, they proved that an undoubted influence had been exerted upon the folktales of Europe by the big literary collections of Indian stories, which passed through Persian and Arabic translations to the west. Factors in promoting this influence were the pilgrimage to Jerusalem, the crusades and the medieval contacts between eastern and western civilization which were occasioned by the material and intellectual expansion of Islam. In medieval Europe translations of oriental story books like the *History of the Seven Wise Masters* provided entertaining literature for the cultured, and eastern tales were collected in preachers' handbooks of *exempla,* as they were called, in order to enliven and adorn popular sermons. Popular satire, again, as represented by the *fabliaux* of France and Germany adapted this material to its purpose. It was later used again by the writers of *novelle* who presented it in some cases but little altered (*e.g.,* G. Straparola and Basile) or in others (*e.g.,* Boccaccio) transmuted by genius into the gold of literature.

Thus from the middle ages onward there was constant interchange of stories over the whole area, and there are some, though fewer, instances of a common property which goes back to classical times and even to the 5th century B.C. But it is difficult to believe that Indians have had a monopoly of invention, or that stories have not been spread mainly by exchange. The arguments which postulate a necessarily Indian origin for stories which are recorded only in modern oral tradition in India are unsound. For there is no guarantee of their antiquity upon Indian soil, and indeed there are other reasons to suppose that many of them entered India with Islam.

Further there exist particular plots, the distribution of the variants of which suggests that they have traveled from west to east, and not from east to west.

See also FOLKLORE (AMERICAS INDIAN); NEGRO, AMERICAN; FOLK DANCE; SOCIAL ANTHROPOLOGY. (W.R. H.; X.)

See M. Leach (ed.), *Funk and Wagnalls Standard Dictionary of Folklore, Mythology and Legend,* 2 vol. (1949).

FOLKLORE (AMERICAN INDIAN). Indian folklore exhibits a wide range of topics touching every aspect of traditional life and including secular and religious myths, folk tales and historical legends, as well as a rich folk science in star, plant and animal lore. Much of it is sheer art, expressing the love of telling stories, posing riddles and playing games—the joy of poetry, music and the dance that may accompany ritual. The folklorist has been interested in the kinds of tales. how and when they are told. where found and what forms they take. This article is concerned only with the myths and folklore of North American tribes.

Plains Indians themselves distinguish two classes of tales: the supposedly real or historical and the fictional. Such differences map be noted from lead lines: "A tribe was settled. . . ," "Spider was traveling. . . ." The eastern woodlands Indians distinguish among events "which truly happened" (myths); adventures with supernaturals ("they-went-to-hunt-for-meat tales"); and tribal history. Animal stories are virtually universal. Perhaps the most striking aspect of Amerind literature is the wide distribution of the tales of creation. the deluge, the "trickster" cycle, contest or ordeal stories, twin-hero and other myths.

Tales were traditionally told during the winter period of quiet "when the earth sleeps"; the storyteller filled an educational role, recounting night after night animal stories and trickster cycles to children. Creation myths and the origins of ceremonies were recited mainly in public to adult audiences. Definite rules governed the telling of stories—the host put up a feast. the narrator chose the topics and he continued so long as the children listened, stopping at the first sign of drowsiness. Myths and tales were widely disseminated from village to village and tribe to tribe. Warriors brought back "news" and captured bards from distant peoples. To this day, stomp-dance songs composed in Oklahoma reach New York and Ontario and the pan-Indian gatherings in the southwest have spread the modern "hoop dance" to metropolitan Indians of Chicago and New York.

Remarkable concordances of language, myths and geographical region mark off certain folklore areas as follows: Eskimoan; northeast Xlgonkian: Iroquoian of the Appalachian uplands; and southeastern. The Plains, the far west and the southwest are more complex. however. Certain tales are common to the north Pacific and Arctic coasts, another series spans the territory between the north Atlantic and the middle Pacific coast and a third extends along the Rocky mountains. The tale of the animal bringing up the earth from the bottom of the water is told over an enormous area; though at home in the watershed of the Great Lakes, its distribution includes the Mackenzie basin, the middle and south Atlantic coasts and a few isolated spots on the Pacific coast. An early connection has been inferred for the beautiful allegory of the loon's necklace, or the man who recovered his eyesight, which occurs both in Greenland and Oregon. Likewise, close relations obtain between Algonkian tales and those of the Pacific coast. Stories of the rabbit that tried to rival the ways of other animals are told of Longfellow's *Hiawatha* (Schoolcraft's "Nanabush"), and in Alaska they are told of the raven.

A story continental in distribution, lacking only in California and on the Arctic coast, is that of the bungling host—a person who is fed by the magic powers of his host but fails ignominiously to imitate him. Legends of the stars have followed trade routes from the Great Plains up the Ohio and westward to the Pacific. An appealing plot is that concerning "Thrown-Away," an outcast orphan boy who is brought up magically to become a hero. Characteristically western are themes involving "Eye Juggler," an animal that plays ball with his eyes and finally loses them; an ascent to the sky by means of a ladder of arrows; and the contest between beaver and porcupine in which beaver invites porcupine to swim and porcupine invites beaver to climb. Migration legends form another pattern of distribution in the southwest and the Mississippi river basin.

A series of complicated Xmerind tales has old world counterparts. Among the Samoyed of Siberia, as on the northwest coast of North America, children escape a pursuing cannibal by a magic flight. In Siberia a thrown whetstone becomes a ravine, a flint cast away is transformed into a mountain and a comb becomes a thicket; in America the whetstone becomes the mountain. a bottle of oil a lake, and the comb a thicket. Indian lore was enriched by contact: the French *voyageurs* traded oral literature nith the ax and gun across Canada, and the Negro slave in the southeast introduced fairy and animal tales from Africa.

Material collected in different parts of the continent presents marked differences as to themes, actors, plot and formal structure. It is not the selection of themes or even the actors that permits recognition of certain types of stories as characteristic of certain areas, but rather the fundamental ideas underlying the plots and composition or style. Elaboration of the tale may be extremely variable but the constant element is always some plot—such as "Thrown-Away" or the twins; "Turtle's War Party"; "Wisahka and His Brother" or "Tar Baby"—that characterizes the mythology of a particular area.

The majority of North American "test tales" have human heroes in a human setting and refer to social phenomena. In the southwest the quest for "long life" is a consistent theme of Apache mythology—an example that M. E. Opler cited in applying such themes to a characterization of the culture. In the trickster mythology, P. Radin saw the presence of a personage and motif having a permanent appeal and an unusual attraction from the beginnings of civilization, possibly reflecting universal psychic experiences of mankind. In part, the animals that appear in tales are determined by the particular fauna of each habitat. The same stories are told of all these creatures. Raven, the hero of a cycle in the northwest, is replaced farther south by the mink and then by the blue jay; the coyote ("Old Man Coyote") is the pornographic trickster on the plateau; the rabbit replaces him on the Plains and the spider in the southwest; a human trickster prevails among the Iroquois and Algonkin of the east. These tricksters are not to be equated with either animals or human beings but regarded, in Jungian terms, as the workings of a mythological imagination depicting man's struggle with nature and with himself.

Most Amerind origin myths deal with the transition from a mythological period to the modern age, usually brought about in a series of disconnected incidents by the act of a particular culture hero. Usually, the universe is assumed to be already present, and the plot is concerned with the discovery of elements, seasons, plants and animals that already exist or have been released on the earth for the use of mankind. Chaos does not precede the origin of the world. Four types of origin tales are noted: (1) accidental happenings (far north); (2) a decision by a council of animals (Plains and woodlands); (3) a contest between two beings, good and evil (California and east); and (4) the culture hero who travels about over the earth setting things right (east and northwest coast).

An absence of moralizing is offset by a high incidence of explanatory elements in the tales, particularly on the western plateau. Among the southern Caddoan tribes, an explanation of the stars predominates; on the plateau, animal behaviour is stressed; the Iroquois, Blackfoot and Kwakiutl have numerous tales relating to ceremonies; and the southern tribes tell a great number of cosmogonic tales.

Grouping of the tales into long episodes is characteristic and deliberate. The disconnected tales of the northwest present a striking contrast to such long and systematic origin myths of the east as the Iroquois myth of the holder of the Heavens (the cosmology) and the Deganawidah epic (the origin of the Iroquois political systemj. The structure of southern Plains, Navaho and Pueblo myths is similarly complex and is built around the idea of emergence from the ground. Unlike the southeastern tribes, the northern Iroquois, and also the Cherokee, lack extensive migration legends such as the *Walam Olum* of the Delaware.

Such historic sources as the *Jesuit Relations* record fragments of cosmogonic myths, journeys to the land of the dead and legends of the origins of supernatural power, which establish the tales as pre-Columbian. But the absence of written documents relating to the trickster cycle throws the investigation back on methods of inferring history from distribution. Efforts to describe tribal culture from folklore sources, first on the northwest coast, then on the Plains and later in the southwest, demonstrated that myths are not always exact tribal autobiographies and quite often novelistic tales outweigh realism. But in the pueblos of the Rio Grande dependence on tilling the soil, the necessity of irrigation and authoritarianism are mirrored in the tales which afford instances of disciplinary action consistent with modern political organization. Cases in which individuals have introduced new rituals and myths in postcontact times are found; *e.g.,* among the Navaho, in the history of the ghost dance (*q.v.*) and in the careers of the native prophets.

Interest has been increasing in the contributions of the Indian to American folk culture. Storytellers are still found among older reservation Indians and the growth of mythology continues in the beliefs held regarding tribal history, particularly treaties and relations with the federal government. Such traditions sometimes can be verified.

Music, poetry and the dance that comprise Indian ceremonialism have been collected since the mid-19th century. Musical scores have been printed and recordings are available on disks and tape for most areas. There is at least one successful attempt to render the native texts into English poetry. The choreography, which is inseparable from the songs and the ritual poetry, has been arranged according to the technique of Rudolf von Laban by modern students of the dance. The collected literature on the subject—much of it in native texts—is immense, but a comprehensive program of tape recording might yet rescue from oblivion style lost in transcription.

FOLK-SONG. Any art if it is to have life must be able to trace its origin to a fundamental human need. Such needs must prompt expression among people even in their most primitive and uncultivated state. To this rule the art of music is no exception; Parry has pointed out that the universal law of evolution demands that we should be able to trace even the most elaborate compositions of Beethoven or Wagner back to some primitive germ. This primitive, spontaneous music has been called "Folk-song," a rather awkward translation of the German word "Volkslied," but nevertheless a word which stands for a very definite fact in the realm of music.

It has been said that if me did not know by experience of the existence of folk-song we should have to presuppose it theoretically to account for the art of music.

Fortunately theory is borne out by practice. We find that unlettered and untravelled people have both the desire and the power to express themselves musically and these attempts at musical expression are not mere clownish nonsense, nor are they, as we are sometimes told, degraded reminiscences of "cultured" music, but are something *sui generis;* moreover, among these spontaneous expressions are to be found melodies which are the most treasured possessions of our art—such melodies as "Searching for Lambs" (England), "Ca' the Yowes" (Scotland), "The Londonderry Air" (Ireland), "Innsbriick Ich musz dich lassen" (Germany), "Magali" (Provence), are ample proof of this, and these are only a few examples out of hundreds.

Moreover, as we have already seen, the folk-song must of necessity bear within it the seed of all the future developments of the art. Such a tune as "The Lady in the Dark," from Playford's *Dancing Master*, exhibits in miniature the same ground plan as many a movement from a Beethoven Symphony: indeed this tune has been described as a "Symphony eight bars long."

Folk-music has, of course, its limitations. To start with, folk-music like all primitive art is an applied art, the vehicle for the declamation of a ballad or the stepping of a dance, and it is, therefore, bounded by the structure of the stanza or the dance-figure. Secondly, folk-music (at all events that of the Teutonic and Latin races) is non-harmonic; there is nothing but the melodic line.

But these limitations have their compensating advantages. A tune which is only eight bars long, and which has to be repeated as often as 20 times to accompany a ballad or a dance, must have certain peculiar qualities if it is not to become wearisome; and we find that the best folk tunes only show their true quality after several repetitions.

Again, the purely melodic character of traditional song gives it a wide range of outline, impossible to melodies which are bound by the progressions of underlying harmonies. Melodies of an harmonic nature are almost always in the major or minor modes, but in folk-song other modes, chiefly the Dorian or Mixolydian, are frequent.

The fact that these modes are also to be found in another great body of purely melodic music, namely the plain-song of the Roman Church, has led to the assumption that "modal" folk-songs must be "ancient," or even derived from mediaeval church music. On the propriety of dubbing a folk-song "ancient" or "modern" more will be said later; as to the supposed derivation from plain-song, surely the simple explanation is that folk-song and plain-song, being purely melodic, are based on the same principles; surely no similarity except that of mode can be traced between such tunes as "Seventeen come Sunday" and "Jesu dulcis memoria."

A further and very important limitation of folk-song must be mentioned, namely that it survives by purely oral tradition. By our hypothesis the inventors and disseminators of folk-music are unlettered, and are therefore unable to stereotype their inventions by means of reading and writing. It is on this that the whole nature of folk-song and all questions of its origin and development depend.

It is sometimes held that the word "folk-song" should be used in what is called a "broad" sense so as to include not only genuinely traditional music, but all those songs of a popular character which are habitually sung by the people of a country. But, in fact, the difference between these two classes of music is a real and scientific one, which is properly recognized by the Germans in their distinction between a "Volkslied" and a "Volksthümlicheslied." What common denominator can be found which will cover, on the one hand, such a song as "Tom Bowling" and, on the other, the "Lazarus" tune in *English County Songs?* In the one case we can judge the date and even guess at the composer; but who can date a folk-song? Indeed, a folk-song is neither new nor old; it is like a forest tree with its roots deeply buried in the past but which continually puts forth new branches, new leaves, new fruit.

Collectors are often asked by would-be intelligent enquirers as to the age of some folk-song, as if the question of age were either important or relevant. Others (sceptics) suggest that the traditional singer "made it up himself." The answer to this, of course, is that quite possibly he did to some extent "make it up himself," although this in no way adds to, or takes away from, its scientific or artistic value. It is not the question of age or authorship that is important in a folk-song but that of spontaneity and beauty. When a collector nowadays hears a song sung by a traditional singer he may be pretty sure that, if the singer is a true artist, he will have unconsciously added something of his own to what he sings. A folk-song then is always grafting the new on to the old. This is the answer to the question: "How old is that folk-song?" A folk-song is neither new nor old because it is continually taking on new life; it is an individual flowering on a common stem.

This brings us to the vexed question of the "communal growth" of folk-song; and here it may be pointed out that much useless derision has been wasted over a supposed theory of "communal origin." No one has ever laid it down as an indisputable proposition that folk-song has a communal origin, though even this is not so impossible an idea as some people suppose. No one insists that some individual must have invented every word of our language. Who invented "father" or "plough" or "sun" or any other of the words that belong to primitive life? If we admit communal authorship in our language, is it not even more probable in such an intangible matter as music?

However, it is not necessary to prove the communal origin of folk-song in order to argue in favour of its communal growth. It is yell known that when a rumoured fact or story becomes spread about it soon is circulated in various altered forms and this in spite of the fact that everyone who repeats the story is anxious to repeat it correctly. How much more then will a song become altered by oral repetition when each new singer is bound only by his artistic predilections? If he thinks he can improve the song, why should he not do so? If he finds it too difficult why should he not simplify it? Thus a folk-song evolves gradually as it passes through the minds of different men and different generations.

Nor will this gradual change ever be a process of deterioration, because those versions of the tune which are distasteful to others will die a natural death. Here then is a clear case of the survival of the fittest. A tune which has been handed down from father to son through many generations will represent the united imaginations of thousands of men and women through hundreds of years of evolution.

This then is the much discussed "communal growth" theory, and it is borne out by the facts. Collectors know well that numerous variants of the same tune have been found in different parts of the country and, conversely, that tunes have been found which are quite distinct from each other, but at the same time have features that point to a common stock. Thus Grimm's famous apophthegm "a folk-song composes itself" is not, after all, a piece of misty emotionalism but represents the hard common-sense facts of the case. (R. V. W)

Cowboy Songs.—The ballad spirit, common to all peoples and particularly active in European nations and their descendants, survived until recent years and under exceptionally friendly conditions in the section of the United States lying west of the Mississippi river. Here a fairly large group of men, almost all of Anglo-Saxon descent, were removed from easy contact not only with printed matter but with entertainment of any sort. Each man spent many hours entirely alone when on night herd or when range riding, engaged frequently in work that absorbed only a part of his attention; and he and his small group, about the chuck wagon or in going up the trail, spent long terms with only such social amusements as they could provide for themselves. Situated thus. the ballad-making instinct revived. with the result that there came into being a considerable body of folk-songs which have been preserved and perpetuated by oral tradition, and have been designated loosely for present purposes *Cowboy Songs*.

These songs are interesting chiefly as human documents, for the light that they throw on the conditions of frontier life. and for their reflection of the old time cattle baron and his crew. The whole cycle of the cowboy's experience—its monotony, its fun, its heroes. its love affairs, its dangers. and the epics of the long drives overland from Texas to Montana—is set forth in the songs made and sung by the men themselves. Further, the material offers to students of folk literature a picture of folk-songs in the process of manufacture and transmission. In a strict sense the songs of the cowboys are not ballads, yet, in the method of production. preservation and distribution. they show points of kinship to the accepted ballads of the Child collection. For example, the refrain of the ballad form is often present, adapted at times to common cattle cries: there are occasional instances both of simple and incremental repetition; some songs are introduced by the stereotyped "Come all ye." Also, a majority of the songs are without known authorship; some of them bear indication of communal composition, probably around the evening camp fires or the larger gatherings of the general roundups or in song contests, where the champion of one ranch "sang down" the champion of another ranch by the process of singing a greater number of songs. Some are adaptations of songs already well known, changed to fit a new environment; all, of whatever origin, existed for a number of years in oral literature, each singer feeling the freedom of an author, introducing his personal experiences, amending the phrasing, and giving that breath of real life that is present in true folklore.

During the time of their highest popularity these songs were not in print except in an occasional newspaper, but later a few small books, now out of print, appeared containing the words of some of the songs along with original verses by the local poet sponsoring them.

The best known of the real cowboy songs were widely distributed over the entire western United States, with 30 versions of the same song coming into the hands of a single collector from locations as far removed from each other as Idaho, California and Texas. In all, some hundreds of genuine cowboy songs were current among the frontiersmen, springing up as naturally, as unobtrusively, as did the prairie grass; and destined, except for the interest of scholars, to perish as noiselessly and as completely. As might be expected some of the cowboy's best poetic effort was expended on songs not suitable for publication.

FOLLEN, AUGUST (or, as he later called himself, ADOLF) **LUDWIG** (1794–1855), German poet, was born at Giessen on Jan. 21, 1794, the son of a district judge. He studied at Giessen and Heidelberg, and after leaving the university edited the Elberfeld *Allgemeine Zeitung*.

Suspected of being connected with radical plots, Follen was imprisoned for two years in Berlin. On his release in 1821 he went to Switzerland, where he lived until his death at Berne on Dec. 26, 1855.

Besides a number of minor poems Follen wrote *Harfengrüsse aus Deutschland und der Schweiz* (1823) and *Malegys und Vivian* (1829), a knightly romance after the fashion of the romantic school. The series of sonnets entitled *An die gottlosen Nichtswüteriche,* aimed at the liberal philosopher Arnold Ruge, started a violent literary quarrel.

Follen's best-known work is a collection of German poetry entitled *Bildersaal deutscher Dichtung* (1827).

FOLLEN, KARL (1795–1840), German poet and patriot, brother of A. L. Follen, was born at Romrod, Hesse-Darmstadt, on Sept. 5, 1795. He studied at Giessen, and after a year's service in the army (1813) began the study of jurisprudence, and in 1818 established himself as *Privatdocent* ("unpaid but official lecturer") of civil law at Giessen. Suspected of political intrigues, he removed to Jena, and thence, after the assassination of Kotzebue, fled to France. After the political murder of the duc de Berry (Jan. 14, 1820), Follen was regarded as suspect, and took refuge in Switzerland; but the Prussian authorities imperatively demanding his surrender, he sought in 1824 the hospitality of the United States. There he taught German at Harvard in 1825, and in 1830 was appointed professor; but he forfeited his post in 1835 by his antislavery agitation, and became Unitarian minister at Lexington, Mass. (1836). He perished at sea on the night of Jan. 13–14, 1840.

Follen was the author of several celebrated patriotic liberal songs. The best is perhaps *Horch auf, ihr Fürsten! Du Volk, horch auf!* It was published in A. L. Follen's collection of patriotic songs, *Freie Stimmen frischer Jugend.*

His wife Elisa Lee (1787–1860) published after his death his lectures and sermons, with a biography written by herself (5 vol., Boston, 1836).

FOLSOM, an early American Indian culture named after the town of Folsom, N.M., near which the first artifacts were found. There, in 1926, a stone point was discovered in direct association with the remains of a giant extinct bison *(Bison antiquus figginsi,* at that time classified as *Bison taylori)* by an expedition from the Colorado Museum of Natural History, led by J. D. Figgins. The acceptance by archaeologists and paleontologists of this association of Folsom culture remains with an extinct Pleistocene bison required a new interpretation of the problem of the peopling of the new world. Previously the earliest Americans were thought to have arrived three or four millenniums prior to European contact. Early estimates of approximately 10,000 years for the age of the Folsom culture (which, however, by no means represents the earliest culture in the new world), based primarily on geological dating methods, are supported by later estimates based on the radiocarbon analysis of bone and shell samples from a site near Lubbock, Tex., containing Folsom artifacts.

The single type of artifact most characteristic of the Folsom culture is a thin lanceolate stone projectile point with a deeply concave base and a long narrow flake removed lengthwise from its two flat surfaces. This gives the Folsom point a fluted or "hollow-ground" appearance. Folsom points seem to represent a relatively late refinement of the fluting technique, which may have been in use in North America as early as 12,000 years ago. They are believed to have been used on a thrusting spear.

The Folsom culture is best known from excavations by a Smithsonian institution field party in 1934 and 1935, under the direction of F. H. H. Roberts, Jr., at the Lindenmeier site in northeastern Colorado. There a deeply buried Folsom campsite had been partially exposed by erosion. Excavation of the uneroded portion yielded an extensive inventory of nonperishable tools associated with hearths and the remains of extinct bison and camel. Characteristic stone tools from the Lindenmeier site include snub-nosed scrapers, end scrapers, side scrapers, drills, gravers and various types of knives. There are also sandstone shaft polishers and rubbing stones, some bone punches or awls and several bone fragments of problematical use decorated with engraved lines. The kinds of tools and the condition of the animal bone at the Lindenmeier site indicate that the Folsom people subsisted primarily by hunting large bison, and that they were not dependent to any great extent on wild plant foods. While Folsom remains have been found in localities as widely scattered as southern Alberta, Can., and southern Texas, the centre of activity of the Folsom culture was the southern high plains region, particularly the eastern portions of what are now Colorado and New Mexico. The distinctive culture of the Folsom hunters appears to have been replaced by the Plano hunting cultures before 8,000 years ago. *See* also ARCHAEOLOGY: *Prehistory: The New World Prior to Urban Civilization;* INDIAN, NORTH AMERICAN: *Prehistory.*

FONBLANQUE, ALBANY WILLIAM (1793–1872), English journalist, was born of a French Huguenot family. His father was an Equity barrister and M.P. for Camelford. Fonblanque began journalistic work in 1812, and attracted attention by the boldness of his opinions and the superiority of his style to the ordinary work of the day. In 1830 he became editor of *The Examiner,* and remained in control until 1847. Fully maintaining the level of political independence set by the Hunts, he inspired the admiration even of his opponents by his wit, and *The Examiner* was the standard of literary merit in the journalistic world.

See the *Life and Labours of Albany Fonblanque,* ed. by his nephew, Edward Barrington de Fonblanque (1873).

FOND DU LAC, an industrial city, seat of Fond du Lac county, Wis., U.S., is located at the south end of Lake Winnebago in a dairy farming and resort region, 150 mi. N.W. of Chicago.

Platted by speculators in 1835, Fond du Lac attracted many German immigrants. Sawmills and wood product manufacturing prospered before the pine forests were removed. The town was incorporated as a village in 1847 and chartered as a city in 1852. A council-manager form of government mas adopted in 1957. (For comparative population figures *see* table in WISCONSIN: *Population.*)

Principal products include machine tools. refrigerators and outboard motors. Recreation centers on the lake where motorboat races attract entries from many states. The Episcopal Cathedral Church of St. Paul, with its wood carvings from Oberammergau, is a famous institution. One-third of the children attend parochial schools. A vocational school and an extension of the University of Wisconsin provide education beyond high school. (W. D. W.)

FONDI, a town of Lazio, Italy (anc. *Fundi*), province of Latina, 12 mi. N.W. of Formia, and 69 mi. S. of Rome by rail. Population (1957 est.) 21,529 (commune). It lies 25 ft. above sea level at the north end of a plain surrounded by mountains, which extend to the sea. It occupies the site of the ancient Fundi, a Volscian town, belonging later to *Latium adjectum*, on the Via Appia, still represented by the modern high road which passes through the centre of the town. It is rectangular in plan, and portions of its walls are preserved. The gate on the northeast still exists, and bears the inscription of three aediles who erected the gate, the towers and the wall. In the neighbourhood are remains of ancient villas. and along the Via Appia still stands an ancient wall of opus *reticulatum*, with an inscription. in large letters, of one Varronianus, the letters being at intervals of 25 ft.

The modern tonn is still enclosed by the ancient walls. The castle on the south-east side has some 15th-century windows with beautiful tracery. Close by is the Gothic church of S Pietro (formerly S. Maria), the cathedral until the see was united with that of Gaeta (1818). In the Dominican monastery the cell which St. Thomas Aquinas sometimes occupied is shown.

The ancient city of Fundi in 338 B C. (or 332) received (with Formiae) limited, and in 188 B.C. full citizenship, because it had always secured the Romans safe passage through its territory. This was strategically important for the Romans, as the military road definitely constructed by Appius Claudius in 312 B.C., still easily traceable by its remains, and in part followed by the high-road, traversed a narrow pass. which could easily be blocked, between Fundi and Formiae. The family of Livia, the consort of Augustus, belonged to Fundi During the Lombard invasions in 592 Fundi was temporarily abandoned, but it came under papal rule by 754. Pope John VIII ceded it with its territory to Docibile, duke of Gaeta, but sometimes it appears as an independent countship. though held by members of the Caetani family, who about 1297 returned to it. In 1504 it was given to Prospero Colonna. In 1534 Khair-ed-Din Barbarossa tried to carry off Giulia Gonzaga. countess of Fondi. and sacked the city. In 1721 it was sold to the Di Sangro family, in nhich it still remains. Its position as a frontier town between the papal states and the kingdom of Naples, just in the territory of the latter—the Via Appia can easily be blocked either north-west at the actual frontier called Portclla or south-east of it—affected it a good deal during the French Revolution and the events which led up to the unification of Italy.

The Lago di Fondi, in the middle of the plain, and the marshes surrounding it, compelled the Via Appia to make a considerable détour. The lake was also known in classical times as *lacus Amyclanus,* from the town of Amyclae or Amunclae, founded, according to legend, by Spartan colonists, and probably destroyed by the Oscans in the jth century B.C.; the bay was also known as *mare Amunclanum.* The ancient Speluncae (mod. *Sperlonga*) on the coast also belonged to the territory of Fundi. Here was the imperial villa in which Sejanus saved the life of Tiberius, who was almost crushed by a fall of rock. Considerable remains of it, and of the caves from which it took its name, still exist 1 m. S.E. of the modern village. Wine of the *áger Caecubus,* the coast plain round the Lago di Fundi, was praised by Horace. The plain of Fondi is the northernmost point in Italy where the cultivation of oranges and lemons is regularly carried on in modern times.

See T. Ashby, in *English Historical Review,* xix. (1904) 557 *seq.* for a notice of Italian works on the subject. (T. A.)

FONSAGRADA, a town of N.W. Spain, in Lugo province; 38 mi. E.N.E. of Lugo by road. Pop. (1950) 14,584 (mun.). Fonsagrada, over 3.000 ft. above sea level, is the market for the agricultural and dairy produce of the fertile valleys in the surrounding mountains, but its trade is mainly local, owing to the lack of communications beyond the Lugo-Rivadeo road. Insurgents captured the town early in the civil war of 1936–39.

FONSECA, MANUEL DEODORO DA (1827–1892), professional soldier and first president of Brazil. was born in Alagoas (Marechal Deodoro) on Aug. 5, 1827. The son of an army officer. Fonseca s-as trained from childhood for a military career. He distinguished himself for personal valour and military prowess in the Paraguayan war (1864–1870) and rose rapidly in the army thereafter. His rise to prominence occurred during a period of increasing political activity by army officers. many of whom favoured a republic. Although Fonseca was not an ardent republican, he defied the emperor, insisting that his fellow officers had the right to express their political views publicly even when they opposed the empire. The imperial government, severely weakened by other problems, could not withstand the direct military challenge to its authority. On Nov. 1j. 1889, Fonseca led the bloodless *coup d'état* that toppled the empire and set up the republic. He served as provisional president until Feb. 1891, when he was elected president by the constituent assembly. Arbitrary and autocratic. Fonseca lacked the capacity for political compromise. Unable to work harmoniously with his ministers or the congress, he resigned in Nov. 1891 and retired from public life. He died at Rio de Janeiro on Aug. 23, 1892.

Despite Fonseca's personal limitations as a political leader. his short regime established the institutional framework within which the republic functioned for nearly 40 years. Under his leadership a constitution patterned somewhat after that of the United States was issued (Jan. 1891); the highly centralized government of the empire was replaced by a federal system in which the states enjoyed almost complete political and economic autonomy; and the army was confirmed as a major element in the Brazilian political process. (R. E. P.)

FONSECA, GULF OF (GOLFO DE FONSECA), a sheltered inlet of the Pacific ocean in Central America, shared by Nicaragua on the south, by Honduras on the east and northeast and by El Salvador on the north and northwest. The gulf is about 50 mi. long and about 30 mi. wide at the mouth between Amapala and Cosigiiina points; it is regarded as one of the world's finest natural harbours, being protected from the winds and waves of the Pacific by the islands of Conchagüita, Meanguera and the rocky Farallones. It is surrounded by volcanic shores with huge sugarloaf islands, some of which are under cultivation, dotting the surface, and receives the Choluteca. Goascoran and Estero Real rivers and the Rio Negro. The chief ports are La Unión (*q.v.*), Amapala and Puerto Morazán (on the Estero Real. Nicaragua). The Gulf of Fonseca was discovered in 1j22 by Gil Gonzalez de Avila and was named by him after his patron, Archbishop Juan Rodriguez de Fonseca, persecutor of Columbus. Under the Bryan-Chamorro treaty (1916) with Nicaragua, the U.S acquired a perpetual option to the site of an interoceanic canal in Nicaraguan territory; at this time Nicaragua also granted the U.S. the right to establish a naval base on Corn Island if and when the Nicaraguan canal should be constructed. However, both Honduras and El Salvador protested to this latter grant, asserting that the waters of the gulf were not open sea but the joint property of El Salvador, Honduras and Nicaragua. (L. WE.)

FONT, the vessel used in churches to hold the water for Christian baptism. In the apostolic period baptism was administered at rivers or natural springs, Lat. *fons* (cf. Acts viii. 36), and no doubt the primitive form of the rite was by *immersion* in the water. *Infusion*—pouring water on the head of the neophyte—was early introduced into the west and north of Europe on account of the inconvenience of immersion, as well as its occasional danger; this form has never been countenanced in the Oriental churches. *Aspersion,* or sprinkling, was also admitted as valid, but recorded early examples of its use are rare *(see* BAPTISM). These different modes of administering baptism have caused corresponding changes in the receptacles for the water. After the cessation of persecution, when ritual and ornament began to develop openly, special buildings were erected for administering the rite of baptism. This was obviously necessary, for a large *piscina* (basin or tank) in which candidates could be immersed would occupy too much space of the church floor itself. These baptisteries consisted of tanks entered by steps (an ascent of three, and descent of four, to the water mas the normal but not the invariable number) and covered with a domed chamber *(see* BAPTISTERY).

By the 9th century, however, the use of separate baptisteries had generally given place to that of fonts. The material of which these were made was stone, often decorative marble; as early as 524, however. the council of Lerida enacted that if a stone font were not procurable the presbyter was to provide a suitable vessel, to be used for the sacrament exclusively. which might be of any material. In the Eastern Church the font never became an important decorative article of church furniture.

Few if any fonts older than the 11th century survive. These are all of stone, except a few of lead; much less common are fonts of' cast bronze (a fine example, dated 1112, exists at the Church of St. Barthelemy, Liege). The most ancient are plain cylindrical bowls, with a circular—sometimes cruciform or quatrefoil—outline to the basin, either without support or with a single central pillar; occasionally there is more than one pillar. The basins are usually lined with lead to prevent absorption by the stone. The church of Efenechtyd, Denbigh, possesses an ancient font made of a single block of oak.

Fonts early began to be decorated with sculpture and relief. Arcading and interlacing work are common; so are symbol and pictorial representation. A very remarkable leaden font is preserved at Strasbourg, bearing reliefs representing scenes in the life of Christ. At Pont-8-Mousson on the Moselle'are bas-reliefs of St. John the Baptist preaching, and baptizing Christ. Caryatides sometimes, take the place of the pillars, and sculptured animals and grotesques of strange design not infrequently form the base. Most remarkable is the occasional persistence of pagan symbolism; an interesting example is the very ancient font from Ottrava, Sweden, which, among a series of Christian symbols and figures on its panels, bears a representation of Thor *(see* G. Stephens' brochure, *Thunor the Thunderer*).

In the 13th century octagonal fonts became commoner, and in the 14th and succeeding centuries they became the rule. In England no fonts can certainly be said to date before the Norman conquest, although it is possible that a few very rude examples, such as those of Washaway, Cornwall and Denton, Sussex, are actually of Saxon times; of course we cannot count as "Saxon fonts" those adapted from pre-Norman sculptured stones originally designed for other purposes, such as that at Dolton, Devonshire. On the other hand, Norman fonts are very common, and are often the sole surviving relics of the Norman parish church. They are circular or square, sometimes plain, but generally covered with carving of arcades, figures, foliage, etc. Some of the best examples of "Norman" fonts in England (such as the notable specimen in Winchester cathedral) were probably imported from Belgium. Fonts of the Perpendicular period are very common, and are generally raised upon steps and a lofty stem, which, together with the body of the font, are frequently richly ornamented with panelling. It was also the custom during this period to ornament the font with shields and coats of arms and other heraldic insignia, as at Herne, Kent.

In 1236 it was ordered by Edmund, archbishop of Canterbury, that baptismal fonts should be kept under lock and key, as a precaution against sorcery. The ordinary position in the church was and is near the entrance, usually to the left of the south door.

FONTAINE, PIERRE FRANÇOIS LÉONARD (1762–1853), French architect and decorator, who supervised work on the Louvre for many years. was born at Pontoise on Sept. 20, 1762, and died in Paris on Oct. 10, 1853. Several of his family were distinguished architects.

In 1779 Fontaine went to Paris to study under Peyre the younger, and won the second Grand Prix de Rome in 1785. With this grant he went to Rome. After the French Revolution he was employed by Napoleon for the restoration of the palace of Malmaison, and thereafter executed the principal architectural works in Paris for Napoleon I. Louis XVIII and Louis Philippe. He was employed with his collaborator. Charles Percier. on the arch of the Carrousel, the restoration of the Palais-Royal. the grand staircase and several wings of the Louvre and the project for the union of the Louvre and the Tuileries.

The neoclassical Expiatory chapel (1815–26) in Paris is considered by many authorities the outstanding work of Percier and Fontaine. Together they published *Palais, maisons, et autres édifices de Rome moderne* (1802); *Descriptions de cérémonies et de fêtes* (1807 and 1810); *Recueil de décorations intérieures* (1812); *Choix des plus célèbres maisons de plaisance de Rome et des environs* (1809–13); *Le Parallèle des principales residences des soverains d'Europe* (1833).

A history, *L'histoire du Palais Royal,* was published by Fontaine alone.

See M. Fouché, *Percier et Fontaine* (1905).

FONTAINEBLEAU, a town of northern France, capital of an *arrondissement* in the *de'partement* of Seine-et-Marne, 37 mi. S.E. of Paris by rail. Pop. (1954) 17,218. It stands in the forest of Fontainebleau, nearly 2 mi. from the left bank of the Seine. The Tambour mansion, and a portion of the cardinal of Ferrar's house, both of the 16th century, are still preserved. Fontainebleau is the seat of a subprefect and has a tribunal of first instance.

The town has quarries of sand and sandstone, sawmills, and manufactories of porcelain and gloves. It is a summer resort, and the president of the republic frequently resides in the palace, one of the largest of the royal residences of France, situated to the southeast of the town.

The exact origin of the palace and of its name (Lat. *Fons Bleaudi)* are unknown, but the older château was used in the latter part of the 12th century by Louis VII. Francis I caused most of the buildings of the Cour Ovale to be erected. After Francis I. Fontainebleau owes most to Henry IV, Louis XIII, Napoleon I, Louis XVIII, Louis Philippe and Napoleon III. The park covers about 200 ac. and is traversed by a canal dating from the reign of Henry IV. On the north it is bordered by a vinery producing white grapes.

The forest of Fontainebleau is one of the most beautiful wooded tracts in France, and has been for generations the haunt of landscape painters. It covers 42,200 ac., with a circumference of 56 mi. Nearly a quarter of this area is of a rocky nature, and the quarries of sandstone supplied a large part of the paving of Paris. Oak, pine, beech, hornbeam and birch are chief trees.

FONTAN, LOUIS MARIE (1801–1839), French man of letters, was born at Lorient. He wrote a number of plays, of which *Perkins Warbec* (1828), written in collaboration with Halévy and Drouineau, was the most successful. He was repeatedly in trouble with the authorities under the Restoration and spent some time in prison before the revolution of 1830 brought him release.

Fontan's *Jeanne la folle,* performed in the same year, gained a success due perhaps mainly to sympathy with the author's political principles. A drama representing the trial of Marshal Ney, written in collaboration with Charles Dupenty, *Le Procès d'un maréchal de France* (printed 1831), was suppressed on the night of its production.

Fontan died in Paris on Oct. 10, 1839.

A sympathetic portrait oi Fontan as a prisoner, and an analysis of his principal works, are to be found in Jules Janin's *Histoire de la littérature dramatique,* vol. i.

FONTANA, DOMENICO (1543–1607), Italian architect who worked on St. Peter's cathedral and other famous buildings of Rome and Naples, was born at Melide (Mili) on Lake Lugano in 1543, and died at Naples in 1607. For Cardinal Montalto (afterward Sixtus V) he erected a chapel in the church of Santa Maria Maggiore and the Villa Negroni, Rome. On the election of Sixtus V, Fontana became his chief architect.

Among his works were the Laleian palace, the palace of Monte Cavallo (the Quirinal), the Vatican library and other buildings, executed in the baroque style. With Giacoma della Porta he completed the dome of St. Peter's cathedral (1585–go) from Michelangelo's model.

In the course of building an aqueduct, Fontana came across remains of the ancient city of Pompeii (*q.v.*), which was excavated many years later. His most famous undertaking was the removal of the Egyptian obelisk (brought to Rome in the reign of Caligula) from its place in the circus of the Vatican and its erection in front of St. Peter's in 1586.

Fontana was accused of misappropriating public money, and was dismissed from his post in 1592 by Clement VIII. He then became architect at Naples to the viceroy, the count of Miranda, and built the royal palace.

Fontana's projected new harbour and bridge were carried out after his death.

FONTANA, LAVINIA (1552–1614), Italian portrait painter, was the daughter of Prospero Fontana (*q.v.*). She was greatly employed by the ladies of Bologna, and, going then to Rome, painted the likenesses of many illustrious personages. She enjoyed the patronage of the family (Buoncampagni) of Pope Gregory XIII. The Roman ladies, from the days of this pontiff to those of Paul V, elected in 1605, showed no less favour to Lavinia than their Bolognese sisters had done. In her subject pictures she was not so successiul.

Examples of her work are to be seen at Bologna, Rome, Florence, Venice! Milan; the "Virgin Lifting a Veil From the Sleeping Infant Christ," in the Escorial, Madrid; and the "Queen of Sheba," a group of the Mantua courts, in the Dublin museum. Two self-portraits are at the Pitti, Florence, and one in the Academy of St. Luke, Rome.

Her husband, whose name is given as Paolo Zappi Giovanni of Imola, belonged to a distinguished family. He studied painting with Lavinia's father, and is said to have painted the draperies in many of Lavinia's pictures.

She was elected into the Academy of Rome, and died in that city in 1614.

FONTANA, PROSPER0 (1512–1597), Italian painter of the Mannerist school, was born in Bologna, and became a pupil of Innocenzo Francucci da Imola. He later worked 'for Giorgio Vasari and Perino del Vaga in Genoa, Florence and Rome. He has left a large quantity of work in Bologna where he lived after 1540. A representative work of his early period is the "Entombment" in the Bologna Pinacoteca, painted under the influence of his first master and comparatively careful in execution. To his later period belongs the "St. Alessis Distributing Alms," in S. Giacomo Maggiore at Bologna (1576), with many figures in architectural setting, in the mannered style of Vasari's pupils. He died in Bologna in 1597.

In portraiture Fontana was outshone by his daughter and pupil, Lavinia Fontana (1552–1614; *q.v.*). She was greatly employed in Bologna and in Rome. She enjoyed the patronage of the family of Pope Gregory XIII and painted the likenesses of many illustrious personages.

FONTANE, THEODOR (1819–1898), German poet and novelist, was born at Neu-Ruppin on Dec. 30, 1819. He made repeated visits to England, interesting himself in old English ballads, and as the first fruits of his tours published *Ein Sommer in London* (1854); *Aus England, Studien und Briefe* (1860) and *Jenseit des Tweed, Bilder und Briefe aus Schottland* (1860), and a volume of ballads *Männer und Helden* (1860). Fontane ranks with Uhland as one of the great ballad writers of the 19th century. He drew his material from English, Scottish and above all Prussian sources; sometimes, as in *Die Brück'am Tay* from contemporary events. Among the most famous are *Archibald Douglas, Schloss Eger,* and one on "der alte Dessauer." Fontane was particularly attached to his native Mark of Brandenburg: the fascination which it had for him may be seen in his delightfully picturesque *Wanderungen durch die Mark Brandenburg* (1862–82, 4 vols.). In 1870 he was for three months a prisoner of war at Vaucouleurs. His fine historical romance *Vor dem Sturm* (1878) was followed by a series of novels of contemporary life: *Irrungen, Wirrungen* (1888); *Stine* (1890); *Unwiederbringlich* (1891); *Effi Briest* (189j); *Der Stechlin* (1899), in which Fontane adapted the realistic methods and social criticism of contemporary French fiction to the conditions of Prussian life. He died on Sept. 20, 1898 at Berlin.

Fontane's other works include: *Kriegsgefangen, Erlebtes 1870* (1871); *Drr Krieg gegen Frankreich 1870–71* (1874–76). Fontane's *Gesammelte Romane und Erzählungen* were published in 12 vols. (1890–91, 2nd ed., 1905). For his life *see* the autobiographical works *Meine Kinderjahre* (1894), and *Von Zwanzig bis Drrissig* (1898), also *Briefe an seine Familie* (1905). *See* also monographs *by* F. Servaes (1900), Zillman (Stuttgart, 1919), Wandrey (Munich, 1919), and K. Hayens (London, 1920).

FONTANES, LOUIS, Marquis de (1757–1821), French poet and politician, was born at Niort (Deux Sevres) on March 6, 1757. He wrote a number of poems, including a version of Pope's *Essay on Man.* Fontanes drew up the protest of the citizens of Lyons against Collot d'Herbois, and was for some time in hiding. On the fall of Robespierre he was made professor of literature in the *École Centrale des Quatre-Nations,* and he was one of the original members of the Institute. He was exiled by the Directory and made his way to London, where he was associated with Chateaubriand. He soon returned to France, and his admiration for Napoleon, who commissioned him to write an *éloge* on Washington, secured his return to the Institute and his political promotion. He was president of the legislative chamber from 1804 to 1810. Fontanes has been accused of servility to Napoleon, but he remonstrated with him on the judicial murder of the duc d'Enghien, and as grand master of the university of Paris (1808–1815) he supported monarchical principles. He was made a marquis in 181j. He died on March 17, 1821, in Paris.

See his *Oeuvres* (2 vols. 1839), ed. Sainte-Beuve.

FONTENAY-LE-COMTE, town of western France, capital of an *arrondissement* in the *département* of Vendée 30 mi. N.E. of La Rochelle by rail. Pop. (1954) 7,995.

Fontenay existed in the time of the Gauls. The affix of "comte" was added when it was given to the count of Poitou, under whom it became capital of Bas-Poitou. Ceded to the English by the treaty of Bretigny in 1360 it was retaken in 1372 by Bertrand du Guesclin. It sufiered repeated capture during the Religious Wars of the 16th century, was dismantled in 1621 and was occupied both by the republicans and the Vendeans in the war of 1793. From 1790 to 1806 it was capital of the department of Vendée. A straggling town, it is situated on both banks of the Vendée, at the head of navigation. The church of Notre Dame (15th–18th cent) is rich in sculpture, and there are several old houses. The Hôtel de Terre Neuve (1595–1600) contains collections of furniture and tapestry. The Fontaine des Quatre-Tias, given to the town by King Francis I., commemorates the birth of many prominent men. Fontenay-Le-Comte is the seat of a subprefect and has a tribunal of first instance. It manufactures felt hats, oil and soap; timber-sawing, flour-milling and tanning are also carried on. There is trade in grain, fruit, horses, mules, timber, etc.

FONTENELLE, BERNARD LE BOVIER DE (1657–1; 57), French scientist and man of letters, described by Voltaire as the most universal mind produced by the era of Louis XIV. Fontenelle was born at Rouen on Feb. 11, 1657, of middle-class parents. his father being an advocate and his mother a sister of Pierre and Thomas Corneille; he was educated at the local Jesuit college. proceeded to study law. made an unsuccessful start as a barrister and thereafter devoted himself to literature and philosophy. Two of his early publications mere libretti for tragic operas (*Psyché,* 1678; *Bellérophon,* 1679), and despite later preoccupations he still nrote occasionally for the theatre in the 1730s and

1740s. Though he visited Paris in his youth he did not settle there until he had passed 30, by which time he had become famous. His literary activity during the six years 1683–88 won him a great reputation. The *Lettres galantes* (1683; expanded edition 1685) contributed to this, but the *Nouveaux Dialogues des morts* (1683; 2nd part, 1684) enjoyed a greater success and are more interesting to a modern reader. Conversations, modeled on the dialogues of Lucian, between such figures as Socrates and Montaigne, Seneca and Scarron, serve to place in circulation new philosophical ideas. The work of popularization was carried further by the *Histoire des oracles* (1686; critical edition by L. Maigron 1908; reprinted 1934), based on the Latin treatise *De oraculis ethnicorum* of the Dutch writer Anton van Dale (1683). Here Fontenelle uses a technique later to become popular with the 18th-century *philosophes:* it is to make criticisms of pagan religions in such a way that the reader will inevitably turn them against Christianity. The same antireligious bias is seen in his amusing satire *Relation de l'ile de Bornéo* (published in the Dutch periodical *Nouvelles de la République des Lettres,* 1686), where the civil war between the anagrammatic princesses Mréo and Eénegu symbolizes the dissensions between Catholics (Rome) and Calvinists (Genève-Geneva).

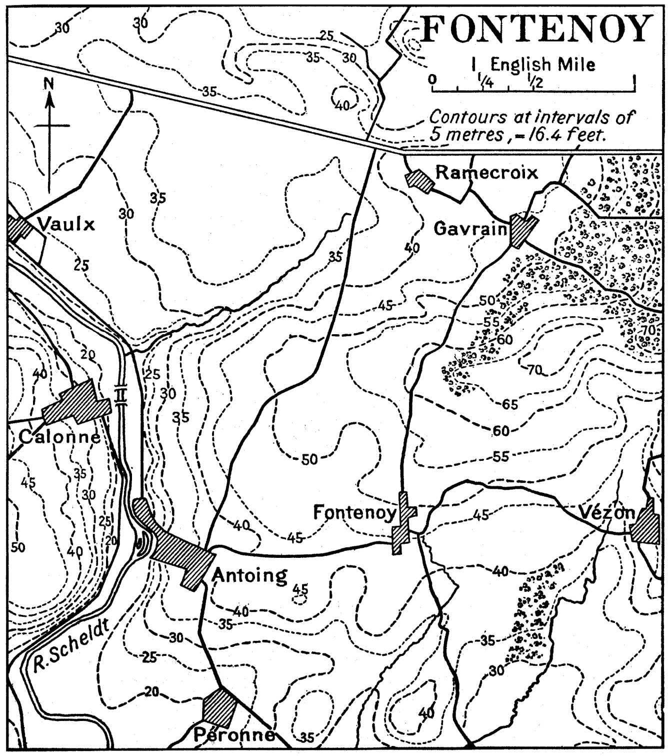
Fontenelle had not abandoned belles-lettres. His *Poksies pastorales* (1688) contains an interesting "Digression sur les anciens et les modernes," in which he shows himself an unashamed supporter of the moderns even to the extent of regarding many of Descartes's ideas (though not his method) as superseded. It was as a nholehearted Cartesian, however, that Fontenelle had published his most famous work, the *Entretiens sur la pluralité des mondes* (1686; critical edition by R. Shackleton, 1955). It is not an exaggeration to say that these charming and sophisticated dialogues were more influential than any other work in securing popular and fashionable acceptance of the Copernican system, still far from commanding universal support in 1686. Fontenelle's basis of scientific documentation was meagre: his main authority nas Bishop John Wilkins' *The Discovery oj a World in the Moone* (1638), and some of his figures were wildly erroneous even by the standards of his own day. He was unfortunate in the moment of his publication: the Cartesian theory of vortexes, on which his nork was based, was refuted the next year in Newton's *Principia.* But the *Entretiens* were nevertheless exceedingly successful. Their author was elected to the Académie Française in 1691 and became perpetual secretary to the Académie des Sciences in 1697. He was also elected to the Académie des Inscriptions in 1701.

The secretaryship of the Académie des Sciences became in Fontenelle's hands a highly influential office and afforded him his main occupation for the rest of his life. It mas his duty to publish the memoirs presented to the academy and to write its history, nhich he did (sometimes tendentiously) in his *Histoire de l'Académie royale des sciences,* covering the years from 1699 to 1740 in a series of volumes that appeared annually from 1702. His account of the earlier years, from the foundation of the academy in 1666, did not appear in the series till 1733; but his *Histoire du renouvellement de l'Académie* nas published separately in 1708. Initially quite undistinguished as a scientist, he later became highly competent, though without ever being original. He frequently revised and amended his *Entretiens;* he kept abreast of new developments in all branches of science and corresponded with scientists in most European countries. He developed his talent for lucid popular exposition so that in some of his obituary notices read to the academy (notably those of Newton and Leibniz) it reached almost the point of genius.

Fontenelle lived meanwhile a gay social life. Having knonn the salon of Madame de Sévigné, he lived to grace that of Madame Geoffrin. He was a close friend of Montesquieu, whom he introduced into Parisian society. He was well knonn to Voltaire, who mocked him in his *Micromégas.* He was witty, good-humoured, inclined to cynicism and exceedingly cautious, perhaps as a result of having been denounced to Louis XIV's government as an atheist after the publication of the *Relation de l'ile de Bornéo.* Many of the characteristic ideas of the Enlightenment are found in embryonic form in his works. His most original contribution is in his approach to historiography, shown in his *De l'origine des fables* (1724; critical edition by J. R. Carré. 1932), where he argues for the polygenesis of fables and tentatively addresses himself to comparative religion. He attended a ball at the age of 98 and died on Jan. 9, 1757. a month short of his century.

Bibliography.—The most serviceable collected editions of the *Oeuvres de Fontenelle,* 3 vol. (1818), and 5 vol. (1825), do not include the *Histoire de l'Académie royale des sciences.* *See* also L. Maigron, *Fontenelle, l'homme, l'oeuvre, l'influence* (1906); J. R. Carré, *La Philosophie de Fontenelle, ou le sourire de la raison* (1932). (Rt.S)

FONTENOY, a village of Belgium, province of Hainaut, 4 mi. S.E. of Tournai, pop. (1955 est.) 684; the scene of the battle of Fontenoy, in which on May 11, 1745, the French army under Marshal Saxe defeated the Anglo-Allied army under the duke of Cumberland. The object of the French (*see* also Austrian Succession, War of the) was to cover the siege of the then important fortress of Tournai; that of the Allies, who slowly advanced from the east, to relieve it. Informed of the impending attack, Louis XV., with the dauphin, came with all speed to witness the operations, and by his presence to give Saxe, who was in bad health and beset with private enemies, the support necessary to enable him to command effectively. Under Cumberland served



PLAN OF THE BATTLE OF FONTENOY. MAY 11TH, 1745

the Austrian field-marshal Konigsegg, and, at the head of the Dutch contingent. the prince of Waldeck.

The right of the French position (*see* map) rested on the river at Antoing, which village was fortified and garrisoned; between Antoing and Fontenoy three square redoubts were constructed; and Fontenoy itself was put in a complete state of defence. On the left rear of this line, and separated from Fontenoy by some furlongs of open ground, another redoubt was made at the corner of the wood of Barry and a fifth towards Gavrain. The infantry was arrayed in deployed lines behind the Antoing-Fontenoy redoubts and the low ridge between Fontenoy and the wood; behind them was the cavalry. Marshal Saxe himself, who was suffering from dropsy to such an extent that he was unable to mount his horse, slept in a wicker chariot in the midst of the troops. At early dawn of May 11, the Anglo-Hanoverian army with the Austrian contingent formed up in front of Vézon, facing towards Fontenoy and the wood, while the Dutch on their left extended the general line to Péronne. The total force was 46,000 against 52,000 whom Saxe could actually put into the line of battle.

It was resolved that the Dutch should attack the front Antoing-Fontenoy, while Cumberland should deliver a flank attack against Fontenoy and all in rear of it, by way of the open ground between Fontenoy and the wood. A great cavalry attack round the wood was projected but had to be given up, as in the late evening of the 10th the Allies' light cavalry drew fire from its southern edge. Cumberland then ordered his cavalry commander to form a screen facing Fontenoy, so as to cover the formation of the infantry. On the morning of the 11th another and most important modification had to be made. The advance was beginning when the redoubt at the corner of the wood became visible. Cumberland hastily told off Brigadier James Ingoldsby to storm this redoubt which, crossing its fire with that of Fontenoy, seemed absolutely to inhibit the development of the flank attack. At 6 A.M. the brigade moved off, but it was irresolutely handled; and after waiting as long as possible, the British and Hanoverian cavalry rode forward and extended in the plain, becoming the target for a furious cannonade which drove them back. Thereupon Sir John (Lord) Ligonier, whose deployment the squadrons were to have covered, let them pass to the rear, and pushed the British infantry forward through the lanes, each unit on reaching open ground covering the exit and deployment of the one in the rear, all under the French cannonade. This went on for two hours, and save that it showed the magnificent discipline of the British and Hanoverian regiments, was a bad prelude to the real attack.

It was now 9 A.M., and while the guns from the wood redoubt battered the upright ranks of the Allies, Ingoldsby's brigade was huddled together, motionless, on the right. Cumberland himself galloped thither, and under his reproaches Ingoldsby lost the last remnants of self-possession. To Ligonier's aide-de-camp, who delivered soon afterwards a bitterly formal order to advance, Ingoldsby sullenly replied that the duke's orders were for him to ad ance in line with Ligonier's main body. By now, too, the Dutch advance against Antoing-Fontenoy had collapsed.

But on the right the cannonade and the blunders together had roused a stern and almost blind anger in the leaders and the men they led. Ingoldsby was wounded, and his successor, the Hanoverian general Zastrow, gave up the right attack and brought his battalions into the main body. Meantime the young duke and the old Austrian field-marshal had agreed to take all risks and to storm through between Fontenoy and the wood redoubt, and had launched the great attack, one of the most celebrated in the history of war. The English infantry was in two lines. The Hanoverians on their left, owing to want of space, were compelled to file into third line behind the redcoats, and on their outer flanks were the battalions that had been with Ingoldsby. A few guns, man-drawn, accompanied the assaulting mass, and the cavalry followed. The column may have numbered 14,000 infantry. All the infantry battalions closed on their centre, the normal three ranks becoming six. (If the proper distances between lines were preserved, the mass must have formed an oblong about 500yd. × 600yd.).

The duke of Cumberland placed himself at the head of the front line and gave the signal to advance. Slowly and in parade order, drums beating and colours flying, the mass advanced, straight up the gentle slope, which was swept everywhere by the flanking artillery of the defence. When the first line reached the low crest, the fire became a full enfilade from both sides, and at the same moment the enemy's horse and foot became visible beyond. A brief pause ensued, and the front gradually contracted as regiments shouldered inwards to avoid the fire. Then the French advanced, and the Guards Brigade and the Gardes Françaises met face to face. Captain Lord Charles Hay, lieutenant of the First (Grenadier) Guards, suddenly ran in front of the line, took off his hat to the enemy and drank to them from a pocket flask, shouting a taunt, "We hope you will stand till we come up to you, and not swim the river as you did at Dettingen," then, turning to his own men, he called for three cheers. The astonished French officers returned the salute and gave a ragged counter-cheer. Whether or not the French, as legend states, were asked and refused to fire first, the whole British line fired one tremendous series of volleys by companies. Fifty officers and 760 men of the three foremost French regiments fell at once, and at so appalling a loss the remnant broke and fled. Three hundred paces farther on stood the second line of the French, and slowly the mass advanced, firing regular volleys. It was now well inside the French position, and no longer felt the enfilade fire that swept the crest it had passed over. Spasmodic counter-attacks on its flanks were repelled but these gained a few precious minutes for the French. It was the crisis of the battle. The king, though the court meditated flight, stood steady with the dauphin at his side—Fontenoy was the one great day of Louis XV.'s life—and Saxe, ill as he was, mounted his horse to collect his cavalry for a charge. The British and Hanoverians were now at a standstill. More and heavier counter-strokes were repulsed, but no progress was made; their cavalry was unable to get to the front, and Saxe was by now thinking of victory. Captain Isnard of the Touraine regiment suggested artillery to batter the face of the square, preparatory to a final charge. The nearest guns were planted in front of the assailants, and used with effect. The infantry led by Löwendahl, fastened itself on the sides of the square. On the front, waiting for the cannon to do its work, were the Maison du Roi, the Gendarmerie and all the light cavalry. The left wing of the Allies was still inactive, and French troops were brought up from Antoing and Fontenoy to support the final blow, about 2 P.M. In eight minutes the square was broken. As the infantry retired across the plain in small stubborn groups all attempts to close with them were repulsed by the terrible volleys, and they regained the broken ground about Vézon, whence they had come. Cumberland himself and all the senior generals remained with the rearguard.

The losses at Fontenoy were exceedingly severe in the units really engaged. Eight out of nineteen regiments of British infantry lost over 200 men, two of these more than 300. The Hanoverian regiments suffered as heavily in proportion. The total loss was about 7,500, that of the French 7,200.

Fontenoy was in the 18th century what the attack of the Prussian Guards at St. Privat was in the next. a *locus classicus* for military theorists. But the technical features of the battle are completely overshadowed by its epic interest.

FONTEVRAULT-L'ABBAYE (Lat. *Fons Ebraldi*), a town of western France, in the *département* of Maine-et-Loire, 10 mi. S.E. of Saumur by road, near the confluence of the Loire and Vienne. Pop. (1954) 1.296. The interest of the place centres in its abbey, which in 1811 became a convict prison. The church (12th century) has a beautiful nave formerly covered by four cupolas destroyed in 1816. There is a fifth cupola above the crossing. In a chapel in the south transept are the effigies of Henry II of England, of his wife Eleanor of Guienne. of Richard I of England and of Isabella of Angoulême, wife of John of England—Eleanor's being of oak and the rest of stone. Cloister, refectory and chapter-house date from the 16th century. The second court of the abbey contains the Tour d'Évrault (12th century), long called *chapelle funéraire,* but in reality the old kitchen. Details and diagrams will be found in Viollet-le-Duc's *Dictionnaire de l'architecture*. There are three stories, the whole being surmounted by a pyramidal structure.

The *Order of Fontevrault* was founded about 1100 by Robert of Arbrissel. The establishment was a double monastery, containing a nunnery of 300 nuns and a monastery of 200 monks, separated completely so that no communication was allowed except in the church; there were, moreover, a hospital for 120 lepers and other sick, and a penitentiary for fallen women, both worked by the nuns. The basis of the life was the Benedictine rule; the abbess ruled the monks as well as the nuns. At the beginning the order had a great vogue, and at the time of Robert's death, 1117, there were several monasteries and 3,000 nuns; afterwards the number of monasteries reached 57, all organized on the same plan. The institute never throve out of France; there were attempts to introduce it into Spain and England: in England there were three houses—at Ambresbury (Amesbury in Wiltshire), Nuneaton, and Westwood in Worcestershire. The nuns in England as in France were recruited from the highest families, and the abbess of Fontevrault, who was the superior-general of the whole order, was usually of the royal family of France.

Orden und Kongregationen (1907); the arts. "Fontevrauld" in Wetzer and Welte, *Kirchenlexicon* (ed. 2), and in Herzog-Hauck, *Realencyklopadie* (ed. 3); Edouard, *Fontevrault et ses monuments* (1875); for the later history *see* art. by Edmund Bishop in *Downside Review* (1886).

FONTEYN, MARGOT (DAME MARGOT FONTEYN DE ARIAS) (1919–), English prima ballerina of the Royal Ballet. London, was born at Reigate, Surrey, on May 18, 1919. She studied as a child in Hong Kong and later in London with Serafima Astafieva and at the Sadler's Wells school. Her debut was with the Vic-Wells ballet in 1934. The following year she took over many classical roles from Alicia Markova, among them *Giselle*. In 1939 she danced Aurora in a revival of *The Sleeping Beauty*. Apart from the classical repertoire she created many roles in ballets by Frederick Ashton, among them *Horoscope,, Symphonic Variations, Daphnis and Chloe, Ondine,* and has given outstanding performances in revivals of Fokine's *Firebird* and Petrouchka. Her dancing stands out for its exceptional musical quality; she is able to combine minute detail into a perfectly integrated whole. In 1955 she married Roberto Emilio Arias. Panaman ambassador to Great Britain. She was created dame of the British empire in 1956, and had become president of the Royal Academy of Dancing in 1954.

(A. L. HL.)

FOOCHOW (FU-CHOU, MINHOW), former treaty port and capital of Fukien (*q.v.*) province, China. Pop. (1953) 553,000; (1957 est.) 616,000. It is 35 mi. above the mouth of the Min Chiang near the head of a narrow delta, on the north bank of the river. The Min is the largest of the many Fukien drainage basins, and Foochow is the natural outlet for the area. The hinterland is rough and hilly with no good passes through its ranges and the Min is navigable by small boats only. Foochow is thus oriented to the sea, with a long history of coastal and foreign trade. The Foochow dialect is not intelligible beyond the Min river valley.

Foochow was one of the original five treaty ports and was opened in 1861. It became the chief centre of the China tea trade during the mid-19th century. and exported the noted black bohea tea which was grown inland. The former foreign settlement of Nan-t'ai was established on an island in the river. and is linked to the south commercial riverside suburb by the Wanshow ("ten thousand ages") and Kiangnan bridges. The decline of the tea trade. after 1880. commenced the decline of Foochow as an international port. Later the decrease in lacquerware exports and the loss of a good share of the camphor trade caused a further weakening of Foochow's commercial position.

Sand bars at the mouth of the Min Chiang prevent entry of large ships and shallows below the city caused the port proper to be located about 10 mi. downstream at Pagoda anchorage. Foochow remains a significant coastwise trading centre, but it cannot compete with deepwater ports having a large hinterland. Foochow's trade patterns continue to revolve around the exports of tea, timber products, lacquerware and leather products.

A rail connection to the Amoy–Ying-t'an line was under construction in the late 1950s, and Foochow is a highway transport centre for the Fukien region. The Chinese Communists, after 1952, began developing major industrial activities in Foochow, augmenting existing manufacturing. (J. E. SR.)

FOOD, the general term for what is eaten by man and other creatures for the sustenance of life. The scientific aspect of human food is dealt with under DIET AND DIETETICS; NUTRITION. *See* also FOOD PREPARATION and the different staple foods dealt with under their own headings; also the articles which follow.

FOOD, CARE AND STORAGE OF (IN THE HOME). The prevention of food spoilage has always been one of man's major problems. Effective food care is based on recognition of the two primary causes of food deterioration: decomposition brought about by bacteria, molds and yeasts; and chemical changes within the food resulting from the action of enzymes normally present. Efficient methods of food care begin with the judicious selection of food. after which must be provided environmental conditions that will maintain optimal food qualities for as long as possible.

Temperature is the cardinal factor influencing the storage life of food, all deteriorative changes being decreased by lowered temperatures. Home refrigerators maintain temperatures of approximately 50° F., a temperature at which food storage life is almost tripled as compared with that at 70° F. Moisture content also is a critical factor. It is necessary to exercise extreme care to keep microbial contamination to a minimum. Air around stored food should be kept to the minimum, to reduce chemical changes. Foods whose pigments are sensitive to light should be held under light-restricted conditions. Fresh fruits and vegetables are best stored under refrigeration. Thorough washing (with clean water) of leafy and firm-textured vegetables and fruits is essential. These should be placed in moistureproof containers or bags and stored in the refrigerator. Berries should be spread out and held at cool temperatures; they should not be washed until just before using, since they are subject to mold growth.

Newly purchased meat cuts such as steaks, chops and poultry should be wiped with a clean, damp cloth, loosely rewrapped in a nonmoisture-absorbing material and refrigerated. The more extensive the area of cut surface, the shorter the length of storage life. Raw ground meat should not be held longer than one to two days in a refrigerator; thick roasts and steaks refrigerate well for six to eight days. Fresh fish should be cleaned, wrapped in a moistureproof, vapourproof covering and refrigerated. Storage of fresh fish or shell fish should not exceed two days.

Butter should be refrigerated in a vapourproof container to prevent the absorption of odours from other foods. Milk and cream are best stored in the delivery containers, kept covered and held at 40°–50° F. Cheeses should be kept in tightly covered containers in the refrigerator.

Shell eggs should be cleaned, if necessary, placed large end up in a covered container and stored in the refrigerator.

Frozen Foods.—The initial freezing of food is carried out at temperatures of 0° to −10° F.; after the food is frozen it should be stored at 0° or lower. Fluctuation of temperature in the freezer cabinet should be avoided. Packaging materials for frozen foods are designed to be as nearly moistureproof and vapourproof as possible. Aluminum foil. or the plastic films which are moistureproof, vapourproof and adhere tightly to food, provide protective covering.

Frozen fruits and vegetables may be stored in the freezer as purchased, in their original containers, for up to one year. In storing meats, poultry and fish it is essential to use moisture and vapour-resistant packaging material that adheres tightly to the food. Vacuum sealing is desirable, since it greatly retards the development of rancidity. Butter may be wrapped in nonpenetrative wrappings, frozen and held in frozen storage for six to eight months. Firm cheeses, packaged in moistureproof cartons, may be held in freezer storage for one to two years.

Canned and Bottled Foods.—Transparent glass containers should be stored in a darkened area. Canned food is best stored in a cool. darkened room at temperatures of 4j° to jj° F. If the entire contents of a can or bottle are not needed at one time, the unused portion may be saiely left in the container at refrigerator temperatures.

Baked Foods and **Leftovers.**—Maintenance of good quality in baked products is dependent upon retaining the moisture in the food. These products should be carefully wrapped in moistureproof wrappers, such as aluminum foil, and kept at cool temperatures.

Leftover dishes containing vegetables, eggs, cheese, milk, meat or fish require fastidious care. They should be carefully covered in tight containers, held at refrigerator temperatures and stored for only short periods of time.

FOOD AND AGRICULTURE ORGANIZATION. The FAO. first of the permanent specialized agencies of the United Nations to be founded after World War 11. came into formal being in Oct. 1945 with the signing of its constitution at a conference held in Quebec, Que. The immediate factor leading to its foundation, was, the Conference on Food and Agriculture convened at the request of Pres. Franklin D. Roosevelt at Hot Springs, Va., in 1943.

The ideas underlying foundation of the new organization came from two sources. First was the International Institute of Agriculture (*q.v.*), founded in Rome in 1905, a forerunner whose functions FAO took over soon after its first conference. The IIA was designed to protect farmers against the effects of sudden slumps and gluts, thus being concerned with information about market trends and agricultural statistics. Second was the League of Nations, which in the period immediately before World War II had been interested in problems of nutrition and their relationship to health. Both the IIA and the League, however, had been principally concerned with the more advanced countries, whereas in the foundation of the FAO several of the new and so-called "underdeveloped" countries took great interest and played an active part.

Since FAO was in part an answer to the question of feeding vast populations in the countries whose economies had been seriously disrupted by World War II, it was natural that the first few years should be devoted to trying to help bring about a rapid increase in the world's over-all supplies of food (see also FOOD SUPPLY OF THE WORLD). At the same time, the member countries had an eye on the possible emergence of surpluses of some commodities in certain countries, should the distribution system break down or should needy governments not be able to pay for the food they required. Finally, an appreciation of the rapid rise in population in virtually all parts of the world in the immediate postwar period added urgency to the organization's work.

Sir John (later Lord) Boyd-Orr of Great Britain was the first director-general of FAO, 1945–48. His proposal, for a world food board of wide powers, though not accepted by governments, resulted in establishment in 1947 of the Council of FAO, originally seen as a World Food Council, which subsequently became an interim governing body of 24 governments elected by the conference. During the following administration of Norris E. Dodd (U.S.), 1948–53, a proposal for an international commodity clearinghouse failed of approval. Dodd was followed by Philip V. Cardon (C.S.), 1953–1956, and following his resignation for ill health, by B. R. Sen (India).

In 1951 the organization was transferred from its temporary headquarters, Washington, to a permanent seat provided by the Italian government in Rome. A regional office for North America remained in Washington; other regional offices were set up in Cairo (for the near east); Bangkok (far east), with a suboffice in New Delhi; and Santiago (Chile), Rio de Janeiro and Mexico City (for western, eastern and northern Latin America respectively). There was also a suboffice in Geneva, principally concerned with economics and forestry work, and an office in New York for special liaison with United Nations headquarters.

In its early years FAO sent advisory or exploratory missions to such countries as Poland, Greece and Venezuela. Certain funds and related agricultural projects remaining from the operations of UNRRA were handed over to FAO, including campaigns for the introduction of American varieties of hybrid corn (maize) into Europe, and for the eradication of rinderpest in Ethiopia. The hybrid maize campaign in particular was regarded as one of FAO's notable successes; it was eventually handed over, except for central co-ordination, to the various member countries.

With the creation of the United Nations Special Fund for Technical Assistance, further extrabudgetary sums became available for FAO's field operations and from 1950 onward an increasing number of countries received technical assistance from FAO under the terms of that fund. The range of projects covered all of FAO's activities in agriculture, nutrition, forestry, fisheries and economics.

Most of the experts working under the technical assistance program were on individual assignments, advising governments concerned on specific problems. FAO also helped its member governments through regional projects, including widespread plant and animal disease control schemes, such as the desert locust control program in the Arabian peninsula; projects for the eradication of rinderpest already referred to; and creation of a European commission for the control of foot-and-mouth disease. A broad educational program was also in continual operation, with training centres and seminars in many subjects and a fellowship program run in connection with the assignment of technical assistance experts.

These programs were implemented by various publications and reports of a technical nature. including the Plant Protection Bulletin, comprising the work of a world reporting service on plant diseases and quarantine regulations. A parallel informational service for animal diseases included an annual over-all summary of developments in the subject field as well as periodical reports. The FAO-sponsored monthly bulletin of agricultural statistics and allied yearbooks on production and trade in agriculture, fisheries and forest products were standard works in their fields.

Member nations met in full conference every second year, when the budget for the following two years was decided on. To this sum was added FAO's share of the UN technical assistance fund, varying from year to year but being of the same order of magnitude as the regular budget, the latter amounting to $17,000,000 for the biennium 1958–59. (P. B. Cs.)

FOOD POISONING, BACTERIOLOGICAL. The concept that illness may result from eating spoiled and putrefying food is an old one. To explain this concept numerous theories have been formulated (for example, that of ptomaine poisoning propounded by Francesco Selmi in 1870). Spoilage and putrefaction are not in themselves harmful. Instead, they often enter into the making of cheese, wines and sauerkraut and the aging of meat. It is equally clear, however, that illness may result from eating food containing any of a number of harmful agents. Such agents may be inorganic chemical substances, poisonous plants and animals, certain animal parasites and microorganisms, including bacteria, or their toxic products. Of these agents, bacteria and their products are undoubtedly responsible for the greatest proportion of food poisoning. The resulting diseases, nhich comprise several different types of illness, may conveniently be divided into tno classes: (1) infections, in that living bacteria are necessary for the development of disease. and (2) intoxications, in that products produced by the bacteria are responsible.

FOOD POISONING CAUSED BY LIVING AGENTS

Salmonella.—Salmonella is a generic name applied to a group of bacteria, of more than 200 types or species, commonly known as the paratyphoid bacteria. Some of these organisms were implicated in outbreaks of food poisoning as early as 1888. The bacteria comprising the salmonella group resemble the typhoid bacterium in size, shape. staining properties. physiology. immunology and habitat in the intestine. They are not limited to man but live and grow in the intestinal tracts of animals as well.

Some of the salmonella group produce a typhoidlike febrile disease in man which can be diagnosed only by isolating the specific organism. Others commonly produce the more usual gastroenteritis. It is knonn that they have to be living to cause either of these diseases, since bacteria-free filtrates of cultures or heat-killed organisms have failed to produce illness when fed to human volunteers. Typical food poisoning is initiated within 7 to 72 hours after ingesting the organisms and is characterized by nausea, vomiting, abdominal pain and diarrhoea. It may start with a headache and a chill or with varying degrees of abdominal pain accompanied by diarrhoea. Therefore. the stools are usually foul-smelling and may be watery. In severe cases the temperature rises, prostration, muscular weakness, faintness and thirst are present, and the white blood cell count Increases. The severity of the disease differs in different outbreaks and among various individuals in the same outbreak. Convalescence usually is rapid and may vary from a few hours to a neek.

Salmonella food-poisoning outbreaks have been described in civilized countries throughout the world. The number occurring annually cannot be estimated since all are not reported. The foods involved are often derived from infected animals or are contaminated during their preparation or storage by infected animals or men. Contaminated foods have no abnormal odour or flavour.

Salmonella infections may be treated with such antibiotics as streptomycin and chloromycetin. Care must be used in administering the latter drug since a few cases of aplastic anaemia have followed its use. Meat from animals ill with salmonella infection is condemned by government inspection at abattoirs in the United States where meat is sold in interstate commerce. Milk from infected cows may be rendered safe by adequate pasteurization, which kills salmonellae. Uncooked animal products may be contaminated with salmonellae, since healthy animals may be carriers. The salmonellae are probably present only in small numbers under such circumstances, and if food is properly refrigerated and cooked. no ill effects follow. Foods should be stored in places inaccessible to mice and rats, which may carry salmonellae.

Streptococcus **Faecalis.**—An alpha-type streptococcus was implicated in outbreaks of food poisoning in 1924 and was occasionally reported thereafter. If it were more generally sought in specimens of food during outbreaks, it might possibly be found more often. This streptococcus, identified as *Streptococcus faecalis,* is a bacterium commonly found in the intestinal tracts of healthy humans and animals. On the surface of blood agar plates it produces pin-point colonies surrounded by a greenish-coloured zone caused by chemical changes in the haemoglobin of the blood. Whether other related streptococci produce food poisoning still remained undetermined in the early 1950s.

The symptoms of this type of food poisoning are usually mild. They are characterized by nausea and sometimes by vomiting, colicky pains and diarrhoea, which begin within j to 18 hours after eating the contaminated food. Recovery usually occurs within 24 hours.

Experimental animals, with the possible exception of cats, are usually not affected after being fed living cultures. Human volunteers, on the other hand. have been made ill by living cultures but not by heat-killed cultures or sterile filtrates from unheated cultures. The foods involved are numerous and include dairy products, meats, poultry and cream-filled bakery goods. In some outbreaks. the contaminating bacteria were found to have had time to grow because the food was stored at warm temperatures for several hours. No specific treatment had been found at mid-20th century. The control of streptococcus food poisoning requires sanitary methods in handling foods and adequate refrigeration of perishable foods.

Other Infectious Agents Transmitted by **Food.**—Many infectious agents may occasionally and more or less accidentally cause food poisoning by being transmitted in food. These include the causative agents of typhoid fever, bacillary dysentery, amoebic dysentery, scarlet fever, diphtheria, brucellosis, trichinosis, Weil's disease, infectious hepatitis. poliomyelitis and a number of other animal parasites. *Clostridium perfringens* and *Bacillus cereus* have been found in large numbers in foods implicated in outbreaks where the symptoms were mild, resembling those for *Streptococcus faecalis.* In addition, many bacteria have been incriminated possibly as the cause of food poisoning because they have been found in the stools of patients, but convincing proof of their role is lacking.

FOOD POISONING CAUSED BY TOXINS OF MICROORGANISMS

Staphylococcus.—Staphylococci are common in the air, in soil, on the skin and in the nose and throat. These small. spherical bacteria grow in grapelike clusters. and the toxin produced by some of them is responsible for the food poisoning.

Staphylococci multiply under conditions which tend to kill such bacteria as typhoid bacilli. For example. they grow abundantly in concentrations of salt and sugar which kill or prevent the growth of typhoid bacilli. Therefore, a food partially preserved with a curing solution containing salt and other ingredients may not be a good medium for spoilage germs but may be an excellent one for food-poisoning staphylococci. The growth of staphylococci in food nith or without the production of toxin is not detectable by taste or smell.

Newspaper accounts of outbreaks of staphylococcus food poisoning usually refer to them as "ptomaine poisoning" outbreaks. This. however, is a meaningless term because the word "ptomaine" does not represent a chemical entity. Staphylococcus food poisoning is probably the most frequent type of food poisoning (nearly every adult has suffered attacks of nausea and vomiting), but no reliable statement of its prevalence may be made because: (1) it may not be reported because it is mild or affects only one or a few persons; (2) it may be erroneously attributed to other causes.

The foods involved have increased in number. Those already incriminated are milk, cheese and other milk products, custard-filled bakery goods. gravies and meats. including cured meats. The symptoms usually appear suddenly within one to five hours after eating contaminated food. They may begin and end with nausea, vomiting, abdominal cramps and diarrhoea. In severe cases the patient is weak and prostrate. his vomitus or stools may contain blood and he may even go into shock. Only rarely does a patient die, and ordinarily recovery occurs in a few days. There is usually no fever or other sign of infection such as occur in salmonella food poisoning. A few resistant persons do not become ill after eating food contaminated with staphylococci.

The toxin responsible for staphylococcus food poisoning is formed in food before it is eaten. Under experimental conditions toxin has withstood boiling for as long as 30 minutes. Food has to be subjected to the following conditions to become contaminated: (1) to be contaminated with a toxin-forming staphylococcus; (2) to contain favourable nutritive requirements, such as the proper amount of moisture and degree of acidity or alkalinity; (3) to be maintained at a temperature suitable for growth of the staphylococci; and (4) to be kept under these conditions long enough to permit the organisms to grow and form toxin.

The treatment of severe staphylococcus food poisoning is important. Since vomiting and diarrhoea are present, it is unnecessary to remove unabsorbed poison from the gastrointestinal tract by emptying the stomach or by giving cathartics; but saline solutions should be given subcutaneously or intravenously because of the acute prostration and symptoms of shock with loss of fluids and disturbances in salt balance. No specific drug or serum therapy is of value. Prevention of staphylococcus food poisoning depends upon adequate refrigeration of perishable foods since contamination itself cannot be prevented. Staphylococci do not grow at temperatures maintained in mechanical refrigerators, but grow slowly at room temperature (68° F.) and rapidly at body temperature (98.6° F.). In the cold months of the year they can grow in heated kitchens and buildings. In five hours on a summer day (82°–86° F.), they produced sufficient toxin to cause illness in human volunteers.

Botulism. — This disease is caused by the production of a toxin in food by the botulinum microorganism. *Clostridium botulinum.* This organism is rod-shaped and ordinarily lives in the soil. It will not grow in the presence of free oxygen on agar surfaces which support the growth of many bacteria and! hence, is called anaerobic. It produces spores that are resistant to heat, so that they succumb only to prolonged boiling. Five types (A, B, C. D and E) of *Cl. botulinum* have been described. Each type produces a specific toxin but causes similar symptoms in man or animals or both. Antitoxins which are usually specific may be produced by immunizing animals. For example, type A antitoxin will neutralize only type A toxin and not any of the other types. Types A and B, rarely type E, *CL. botulinum* have been found in outbreaks of food poisoning involving man. Type C has been found in naturally occurring outbreaks in wild waterfowl and in outbreaks on mink farms, and type D has been associated with poisoning in horses and mules in South Africa. The outbreaks of type E botulism in man have been associated with canned fish products. The toxin for type A *Cl. botulinum* has been crystallized and is a protein. The toxins are readily inactivated by heat and are destroyed in less than one minute at the temperature of boiling water (212° F.).

In the United States, underprocessed canned foods are responsible for outbreaks. The commercial canning industry early recognized the dangers of botulism and took steps to control its processing of foods to avoid this disease. By mid-20th century there had not been an outbreak of botulism from this source since

1925. Most botulism in the United States is caused by home-canned foods, usually by the cold-pack method, in which the processing time and temperature have been inadequate to destroy the spores of *Cl. botulinum.* The pressure-cooker method, on the other hand, if operated according to the directions which come with the cooker, successfully destroys the spores and is especially recommended for preserving low-acid foods.

Of 483 outbreaks of botulism occurring between 1899 and 1949, 98 outbreaks were traced to string beans, of which only 3 were commercially packed in the United States. Next in importance were corn (49 outbreaks), spinach or chard (24) and beets (24). With regard to meat products, there were five outbreaks from ham, six from sausage and five from other meats. Fish and sea foods resulted in seven outbreaks from tuna, eight from salmon, five from clams and four from sardines. Five outbreaks were attributed to home-canned cheese and two to commercially packed canned milk. In the U.S.S.R. outbreaks have been reported from eating salt herring, salt salmon, smoke-dried herring, dried sturgeon and smoked sturgeon. Shallots raised and canned in Naples, It., were responsible for some cases of botulism in the United States, where the food was marketed.

Most outbreaks of botulism are dramatic in that symptoms may appear suddenly and progress rapidly to death. Symptoms usually appear within 12 to 36 hours after ingesting the toxin, although as short a period as 2 to 4 hours is mentioned in the literature. In one outbreak one individual was active for eight days before hospitalization and died on the tenth day. Typical symptoms, involving the nervous system, are double vision, difficulty in swallowing and in speech, and laboured breathing. Death usually results from respiratory paralysis. In addition, patients may develop acute digestive disturbances with nausea and vomiting. These disturbances may be related to the degree of spoilage and to the amount of contaminated food consumed.

Experimental work has shown that spores of *Cl. botulinum* heated to destroy the toxin may be fed to susceptible animals without producing ill effects. Apparently spores living in the soil are toxin-free, since soil and dust contaminating fresh fruits and vegetables with their content of botulinum spores cause no ill effects when eaten by man.

The treatment of botulism is unsatisfactory. Damage done by the toxin, which is evident when symptoms are well advanced, cannot be repaired by the administration of antitoxin. It is advisable, however, to give combined type A and type B botulinum antitoxin to all patients to prevent further damage to the tissues. Antitoxin should also be given to those who have eaten food containing the toxin, even though they may not have developed symptoms, when the disease is discovered in others. The mortality varies for different outbreaks but the average is 65%.

The control of botulism obviously rests on adequately processing canned foods to destroy the spores of *Cl. botulinum.* Fortunately, foods in which *Cl. botulinum* has grown have an abnormal odour and taste and the cans containing it are sometimes swollen. Foods, therefore, which exhibit these characteristics or are in swollen containers should be discarded. *(G. M. DK.)*

FOOD PREPARATION. Persons using recipe books printed on the other side of the Atlantic should note that, while the British pint is equal to 20 fluid oz., the U.S. pint is only 16 fluid oz. Since American recipes usually give amounts by volume and British recipes give amounts by weight, knowledge of these differences is important. Also, the same word may have a different meaning (*e.g.,* biscuit) and, in some instances, there' are considerable differences in the type of ingredients used or in the methods of preparation (*e.g.,* cake making), or both.

METHODS OF COOKING

Boiling and Simmering.—Water is the principal cooking medium in boiling and simmering. Boiling is cooking in water in which bubbles rise continually and break on the surface. At sea level, water boils at 212° F. (100° C.), but at higher altitudes water boils at lower temperatures, the decrease in boiling temperature being approximately 1 degree C. for each 1,000 ft. Water-soluble substances, such as sugar and salt, raise the boiling point of the water. Simmering is cooking in a liquid somewhat below the boiling point, 180°–211° F., when bubbles form slowly and break below the surface.

Steaming.—Steaming, or cooking in steam, may result from added water or from water present in the food itself; in the latter case, the term waterless cooking sometimes is applied. The temperature of steam is equal to that of the liquid from which it is evolved. If the steam is confined, as in pressure cooking, the temperature rises and, at sea level, temperatures of 228°, 240° and 250° F. are possible in a pressure saucepan or cooker at pressures of 5 lb., 10 lb. and 15 lb. respectively.

Broiling and Baking.—Air is the principal cooking medium in broiling and baking or roasting. Broiling is cooking by direct heat; the term grilling sometimes is applied to the same procedure. Baking is cooking by dry heat, as in an oven; roasting is the same process as baking but the term usually is applied specifically to meats. Nearly all oven cooking is done at temperatures between 250" and 500° F., 350° F. being referred to as a moderate oven temperature

Frying.—Fat is the cooking medium in frying. The amount of fat varies from a small amount in sautéing or pan-frying to enough to cover the food in deep-fat frying. The cooking temperature is not limited by a boiling point but by the smoking temperature of the fat; *i.e.,* the temperature at which the fat decomposes and fumes become visible. Because the decomposition is irreversible and reduces the usefulness of the fat, heating a fat to its smoking point is best avoided. Temperatures of 350°–390° F. are used in deep-fat frying.

Braising.—In braising, food such as meat is first browned in a small amount of fat in an open pan, then is cooked further, often on a bed of vegetables, with the pan covered. A small amount of liquid may be added after the browning is completed. The term fricasseeing may be applied to the making of a stew by braising small pieces of poultry, rabbit or veal. The braising of a large piece of meat sometimes is called pot-roasting.

Electronic Cooking.—In electronic cooking, radiant energy in the form of high-frequency radio waves causes molecular activity which generates heat within the food. Because the heat is produced within the food itself, rather than being transferred from a warmer source, interior heating is complete before exterior browning and crust formation occur. Many electronic ranges combine this rapid type of heating with a final browning under a broiler unit.

Other Heating Processes.—Some processes involve heating but are not in themselves methods of cooking. These include:

Blanching, a boiling-water or steam treatment followed by plunging into cold water, used to preserve the colour of vegetables and white meats, to remove excess salt and to aid in removal of skins from nuts and fruits.

Blazing, pouring an alcoholic beverage over a food and igniting it.

Caramelizing, heating sugar until a brown colour and characteristic flavour develop.

Glazing, treatment of the surface of a food to present a lacquerlike finish

Parboiling, boiling a food until partially cooked, preliminary to completion of cooking by another method.

Rendering or trying or trying out, heating a fatty food to separate the free fat from the other tissue.

Scalding, either heating milk or other liquid to just below the boiling point or pretreatment of vegetables with boiling water before freezing.

Scalloping, baking pieces of food with a sauce or other liquid and a topping of crumbs.

Steeping, allowing a substance to stand in liquid below the boiling point in order to extract flavour, colour or other components.

Toasting, browning by direct heat.

APPETIZERS AND SOUPS

Appetizers.—Small portions of highly seasoned food served before a meal to stimulate the appetite are called appetizers; *e.g.,* fruit or vegetable juices; fruit cocktails consisting of various combinations of fruit; and sea food cocktails in which pieces of shellfish are served with a sauce. Hors d'oeuvres and canapés are also served as appetizers. An hors d'oeuvre can be selected from a large number of dishes, typical examples being various kinds of cold dressed vegetables, anchovies, sardines, smoked herrings, cubes and balls of cheese, stuffed eggs and other dainty relishes.

Canapés, which are eaten with the fingers, consist of small crackers or pieces of bread, either plain, toasted or fried, spread with various combinations of butter, cheese, smoked meats and fish, etc., and decorated and glazed.

SOUPS.—The foundation of all good soups, whether thick or thin, should be a well-made stock, the basic ingredients being meat and/or meat bones, vegetables, seasoning and water. White stocks are made without first frying the ingredients, brown stocks by frying before adding the liquid. Bouillon is a plain clear soup, usually unclarified beef broth, while a consommé is a clear soup which has been clarified by the use of egg white. Consommé can be served hot or chilled, in the latter case usually jellied.

Thick soups range from plain vegetable purée soups to rich cream soups. Vegetable purée soups are made from fresh or dried vegetables and may be served with or without additional thickenings. Flour or some other starchy material, such as rice flour, is used for thickening soups and may be added at the beginning of the process, with butter or other fat, or toward the end, when it is blended with milk or other liquid. Potato and lentil soups are examples of thickened vegetable soups. Thickened meat soups include kidney, oxtail and some curry soups such as mulligatawny. Cream soups are made by adding cream or egg yolk and thin cream to the soup just before serving. Some cream soups tend to curdle, particularly those with a relatively high acid or tannin content, such as tomato and onion respectively, but the presence of starch and precautions taken when adding the milk help to prevent this occurrence. Tomato, mushroom and chicken are examples of popular cream soups.

Many soups are served with appropriate garnishes, the most usual being croutons (small cubes of bread either toasted or fried), tiny dumplings, grated cheese, lemon slices, shredded nuts, chopped hard-cooked egg, sieved egg yolk, cooked egg custard, thin strips or cutouts of vegetables and tiny meat balls.

ENTREES

Meat.—The animal flesh consumed by man consists largely of muscle tissue A muscle is made up of bundles of fibres, each fibre, bundle of fibres and muscle being surrounded by connective tissue, the amount and kind of which influences the method of cooking a piece of meat. Fat is deposited around, between and within muscles and produces a mottled effect, called marbling, which contributes to juiciness and flavour of the cooked meat. The term cut or joint is applied to a piece of muscle tissue with the accompanying fat and bone. The large wholesale cuts into which a carcass is first divided are subdivided into the retail cuts which the consumer buys. In general. divisions are made in such a way as to separate tender from less tender parts. Composition of meat varies, with protein constituting 15%–20% of the edible portion and fat 5%–30%. The carbohydrate content is not appreciable.

During cooking most of the constituents of meat are changed. Pigments are decomposed, causing a change in colour. Proteins in the muscle fibres are coagulated by heat, causing a progressive increase in firmness. Some of the connective tissue, collagen, is changed to gelatin, allowing easy separation of muscle fibres. Another type of connective tissue, elastin: is relatively unchanged. Fat melts and some liquid evaporates which, together with changes in protein, causes shrinkage. Flavour is changed through volatilization of some constituents of meats and through changes in others because of surface browning.

Tender cuts, those containing a minimum amount of connective tissue, may be cooked by dry heat, less tender cuts by moist heat. Dry-heat methods include roasting, broiling or grilling, pan-broiling and frying. Roasting is cooking by radiated heat in an uncovered container in an oven or, less commonly, on a spit over a source of heat, and is used for relatively large cuts. A layer of solid fat may be placed on top of a very lean roast to prevent drying, or strips of fat (larding) may be forced into the muscle. Salt may be added either before or after the cooking. If a meat thermometer is used, the bulb should be centred in the largest muscle. A temperature of 300°–350° is usual, as higher temperatures cause excessive shrinking and toughening. Searing or sealing, the use of a preliminary high temperature to "seal in" meat juices, has been found to increase, rather than decrease, cooking losses, but the method is still preferred by some because of the additional flavour and crispness produced.

The time required for roasting depends upon oven temperature, the initial temperature, weight, shape and composition of the meat and the desired degree of doneness. The most accurate means of determining doneness is measurement of internal temperature with a meat thermometer, but time-weight tables are useful guides in scheduling meal preparation. Broiling is a dry-heat method in which smaller tender cuts, such as steaks and chops, 1–2 in. thick, are cooked by direct heat, as under an electric unit or a flame (grills). Pan-broiling is cooking in a hot, uncovered heavy skillet or frying pan and pouring off the fat as it accumulates. Cuts which are less than an inch thick are frequently either pan-broiled or fried. Moist heat methods include braising and cooking in water. Braising is used for large, less tender cuts; pot roasts; and for smaller cuts, such as chops. The meat may be floured or coated with egg and crumbs prior to browning if a thick crust is desired, and the liquid added after browning may be water, milk, cream, meat stock, tomato juice or sour cream. Cooking is continued until the meat is tender. Overcooking in a moist atmosphere may change so much connective tissue to gelatin as to cause the meat to fall apart into stringy fibres. For cooking in water, more water is used than for braising. Stews are made by this method, and the meat may be browned before the liquid is added if a brown stew is desired. After the liquid is added, cooking is continued at a simmering temperature because boiling causes stringiness of the meat, which is usually either from a less tender cut or from a thin irregular piece of meat. A relatively large amount of liquid is used in the preparation of clear soups or in the cooking of certain cured meats as corned beef.

Differences in methods of preparing meats from different animals are due to their distinctive characteristics. Beef is roasted or broiled to rare, medium or well done (internal temperatures of 140°, 160° and 170" F., respectively). Veal, obtained from the calf, is treated somewhat differently because of its lack of fat and relatively high proportion of connective tissue; in order to prevent excessive drying and to soften connective tissue, braising, rather than broiling, is recommended for small pieces. Fat from another source may be added to roast veal to compensate for the fat deficiency and to supplement the mild flavour. Long, slow cooking is especially important in order to soften the connective tissue and, for this reason, veal is roasted at a temperature not exceeding 300° F. and is not served rare. Fresh pork is cooked well, both for sterilization and for development of the full flavour. Although sufficiently tender and low in connective tissue to be broiled, small cuts are more successfully braised because slow cooking develops more flavour than does rapid cooking. Cured pork can be cooked to a somewhat lower internal temperature than fresh pork. Because of the tenderness of lamb, parts of the carcass which for other kinds of meat are cooked by moist heat may be cooked by dry-heat methods. Lamb roasts and chops are prepared either well or medium-cooked. The fell (the paperlike membrane covering the lamb carcass) usually is left on a leg during roasting. Mutton is stronger in flavour and less tender and moist-heat methods are therefore preferable.

Such special parts of the animal as edible organs and glands, oxtail and pigs' feet are termed variety meats or offal. Brains and sweetbreads, which are particularly tender, are precooked in acidulated water for increased firmness. Heart and tongue, the least tender of the variety meats, are simmered in water for relatively long periods. Most liver is tender enough to be fried or broiled and also may be braised.

For meat pies and puddings, *see* below, *Desserts*.

Poultry **and** Game.—Fowl or poultry may be cooked by all the methods described above. A large bird may be eviscerated, stuffed and roasted, provided it is not old and tough. Halves or quarters of very young chickens may be broiled. Pieces of young birds frequently are fried. Braising is used for pieces of practically any fowl. Large. less tender birds may be cut into pieces and simmered for stew or for stock.

Wild game also is cooked by the same methods. Venison, a dry meat which needs to be prepared with added fat, is improved by marinating, and braising is preferable to broiling. Rib and loin cuts may be roasted, provided they are from a rather young animal and the roast is overlaid with fat. Ducks and geese usually are stuffed and roasted. Pheasant and quail have a tendency to be dry-fleshed and frequently are braised. Squabs and partridges are broiled, roasted or braised.

Fish.—Fish are classified as to source, fresh water or salt water; as to general type, finfish or shellfish; as to oiliness of the flesh; or alternatively as roundfish, flatfish, crustaceans, mollusks and miscellaneous. In nonoily fish. fat is localized in the liver rather than scattered throughout the flesh as in oily fish. Because of extreme perishability, fresh fish should be chilled as quickly as possible after being caught and kept cold until used, which should be as soon as possible.

Finfish.—Fresh finfish can be purchased whole, in large unboned, unskinned pieces, in crosswise slices (steaks) and in boned lengthwise pieces (fillets). Because the connective tissue of fish is readily softened, tenderness is characteristic and cooking periods should be short. Cooking methods are substantially the same as those described in the section on meat. Broiling or grilling can be used for pieces of any type, except large, whole fish, the distance from the surface of the fish to the source of heat being varied according to the thickness of the piece. Fish is so easily broken that it is commonly broiled in a flat container rather than on a broiler rack and need not necessarily be turned during cooking. Baking is particularly satisfactory for a whole medium-sized fish or for pieces of large fish, as these may be stuffed. It is advisable to remove the backbone before stufling the fish to facilitate serving, and the open edges of the fish can be sewn or held together with toothpicks. Fillets can be stuffed by spreading and rolling and then baked, or they can be cooked in an uncovered baking dish together with suitable ingredients such as sliced onion or other vegetables, sour cream and wine. Small, whole fish are frequently fried and pieces of large fish can be dipped into milk or egg and coated with flour or bread crumbs, or dipped into a batter mixture before frying, if a thick crust is desired. Marinating fish in French dressing before frying provides additional flavour. Cooking fish by poaching involves gently simmering in salted water or in a court bouillon, which should be prepared before the fish is placed in it. In its simplest form it consists of sufficient water to cover the fish, a tablespoon of white wine or wine vinegar, a bay leaf, a sprig of thyme, a little parsley, an onion pierced with a clove and a carrot sliced in two. These ingredients are simmered together for $\frac{1}{2}$ to 1 hr. and strained before use. Because of the tendency for the fish to fall apart, it can be wrapped in cheesecloth or held in a frying basket or in a special rack during poaching. Steaming is similar to poaching except that the fish is held out of the water and cooked by circulating steam. Planking is a variation of either baking or broiling when the fish is cooked on an oiled hardwood plank and, during the last few minutes of cooking. may be surrounded by mashed potatoes.

Shellfish.—Shellfish, like finfish, are toughened by overcooking. Lobsters are purchased alive, dropped into boiling, salted water and then simmered until the lobster is just tender. The cooked lobster is then split through the centre from head to tail and the intestinal tract removed. The meat can be removed and combined with other foods in a variety of dishes or it can be served hot in the shell with melted butter. Lobsters also can be split and broiled. Hard-shelled or mature crabs arc cooked and used similarly; soft-shelled crabs are broiled or fried. Clams and oysters often are served raw, with sauces: as well as cooked in a variety of ways. Oysters can be fried in deep fat, cooked in milk. baked with crumbs and butter or broiled in the shell, while clams can be steamed in the shell. New England clam chowder contains chopped clams, together with potatoes. onions, milk. fat and seasonings; Manhattan clam chowder contains no milk but consists of clams. tomatoes or tomato juice and celery and spices. Scallops are fried frequently or broiled or stewed and served in a cream sauce. Fresh shrimp can be cooked in the shell but the black intestinal vein running the length of the body is most easily removed before the shrimp is cooked. Shrimp can be simmered, fried in deep fat or sautéed.

Lemon butter, wedges and butterflies of lemon, parsley sauce and tart sauces, such as hollandaise and tartare, are common accompaniments for fish.

Stuffings and Gravies.—Variety can be introduced into everyday meals through the use of stufiings containing interesting combinations of ingredients. Stuffings may be classified most conveniently according to their basic ingredients, of which bread is the most commonly used. Bread stufiings contain crumbs or small pieces of dry bread, seasonings, liquid and fat. Ingredients such as chopped celery, onions, sausage, bacon, oysters, giblets, mushrooms, nuts and fruits commonly are used and corn bread is a modification. Bread stuffings are used for poultry, game birds, fish and thin pieces of meat which are rolled with stuffing, such as flank steak and breast of mutton. Rice, brown or white, may form a basis for a stuffing for green peppers or various rolled meats. An excellent stuffing for game birds is of wild rice and mushrooms, and chestnut stuffing, either with or without bread, is a favourite for turkey. Mashed potato stuffings are sometimes used for goose. Mixtures containing meat may be used for stuffing vegetables, such as marrow, squash and tomatoes, as well as for accompanying other meats. These mixtures usually are called forcemeats.

Gravies are served with meat and potatoes and are made from meat drippings, added liquid and thickening. Gravy is best made in the pan in which the meat has been roasted, provided the drippings have not been allowed to burn and excess fat is removed. The amount of liquid used depends upon the drippings available for flavour, and the amount of thickening depends upon the kind of meat the gravy is to accompany; *e.g.*, thin gravies are served with beef and thicker gravies with mutton and lamb. Fat and flour: approximately equal in amount, are blended with the drippings and allowed to brown if a dark gravy is desired. Browned flour has slightly less thickening power than unbrowned flour. The liquid, preferably meat stock or vegetable water, is then stirred in gradually and boiled for several minutes to cook the flour and dissolve the hardened meat drippings. Separation of fat from a gravy indicates too high a proportion of fat to liquid. If separation is caused by excessive evaporation of water, it may be corrected by replacement of the water.

Sauces. which often are served instead of gravies, are rich and concentrated in flavour and are usually thickened. The liquid used may be milk. cream. sour cream. stocks and/or wine. Mushrooms, herbs and other seasonings can be added to give a variety of flavours.

VEGETABLES AND SALADS

Vegetable **Cookery.**—Vegetables are cooked primarily to make them more digestible and more palatable. Softening of the cellulose and modification of the starch granules and pectic substances cause a change in texture; and collapse of the cellulose causes a decrease in the bulk of green leafy vegetables. Succulent vegetables containing a high proportion of, water require very little added water, a-hereas vegetables which tend to absorb water, such as those with relatively high starch content, require a larger amount of added water.

Pigments in vegetables may be green, yellow, white or red. Since a vegetable may contain more than one pigment, the cooking method which best preserves the colour depends upon the pigment which predominates. The yellow pigments are insoluble in water and relatively stable under ordinary conditions of cooking: thus. the colour of carrots is retained easily. Red pigments. which predominate in red cabbage and beetroots, are red in an acid solution and blue to blue-green in an alkaline solution; they are very water soluble. Red cabbage can be cooked with a slice of apple for preservation of the colour. White pigments become yellow in an alkaline medium but remain white in an acid solution: the addition of a small amount of cream of tartar or other acid to the cooking water helps to preserve the colour of. *e.g.*, onions and cauliflower. The predominating pigment in green vegetables is not water soluble, but is intensified in alkaline solution and changed to olive green in an acid solution. In spite of the effect of alkali on the green colour, bicarbonate of soda (baking soda) should not be added to green vegetables during cooking as it adversely affects texture, flavour and nutritive value.

Excessive loss of aromatic compounds through volatilization and loss through solubility in the cooking water of other flavour components causes a general weakening of flavour. Sulfur-containing aromatic compounds responsible for the distinctive flavours of strong-flavoured vegetables, such as cabbage, decompose during cooking, with a strong disagreeable flavour resulting when these vegetables are overcooked. The sulfur compound in onions and leeks merely volatilizes during cooking, with a weakened flavour resulting.

Preparation before cooking varies according to the type: root vegetables are washed and usually peeled or scraped; green vegetables are washed and crisped in the refrigerator if necessary and frequently shredded; the others are prepared variously.

Suitable methods for cooking vegetables are boiling, steaming, baking, panning and frying. The following are general rules for boiling vegetables: (1) The smallest possible amount of water should be used; an exception is the occasional recommendation that a larger amount of water be used for strong-flavoured vegetables. (2) The salted water should be brought to the boil before the vegetable is added. (3) Green vegetables should be cooked in fast-boiling water and cooked only till tender and not oversoft. Root vegetables should be cooked in gently boiling water, as these tend to break up rather easily. As a rule the pan should be covered to promote rapid cooking and minimum loss through volatilization. Desirability of cooking vegetables whole rather than in pieces depends upon the type, upon the amount of water and whether this is used later. The advantage of smaller pieces is that cooking time is shortened, thus canceling out the disadvantage of increased surface area from which loss of soluble nutrients could occur. Steaming is suitable for cooking root vegetables and some of the miscellaneous group, but not for green vegetables, as the colour will be affected adversely. A steamer made for the purpose has a lower portion for the boiling water and one or more perforated upper portions for the food. Alternatively steaming may be carried out in a saucepan with a rack. Steaming at a high temperature in a pressure saucepan shortens cooking time and is very useful for vegetables which require a relatively long cooking period and are not susceptible to undesirable colour changes, such as potatoes. In baking, water-soluble nutrients are well retained, but the relatively long cooking period required is damaging to the colour of green vegetables. Potatoes and squash are particularly satisfactory for this method. A few vegetables such as potatoes and parsnips are suitable for roasting. Panning is cooking in a small amount of fat in a tightly covered pan. Finely shredded green vegetables. such as cabbage, can be cooked by this method, since the very short cooking time required does not permit development of a strong flavour. The conservative method is similar, except that a little liquid is added as well and the cooking may be in a pan on top of the stove or in a casserole in the oven. Root vegetables are either sliced or shaped in small pieces when cooked by this method. Sautéing is a quick method using a little fat, but usually without covering the pan; mushrooms are frequently sautéed. A few vegetables are fried, the most popular being potatoes, which when deep-fat fried are called chips. Tomatoes are sometimes shallow-fat fried and are one of the few vegetables which can be broiled.

All vegetables should be seasoned carefully with salt and sometimes pepper. Depending upon the method of cooking, some vegetables can be served without any further additions, but others are improved by the addition of butter or other fat. A few vegetables are served with or in white sauce. while others can be served with such sauces as hollandaise or cheese sauce.

Salads. — A salad may occupy any one of four positions in a meal. It can be served as the first course, in which case it functions as an appetizer. This type of salad is frequently a fruit salad and sharp in flavour, fresh fruit being preferable to canned fruit. As a main dish, a salad can be served for both luncheon and supper: it is frequently served with or contains pieces of cold meat, fish, hard-cooked egg or cheese, together with raw or cooked vegetables. A salad served as an accompaniment to the main course is smaller and less substantial than a main-dish salad and should emphasize tartness of flavour rather than sweetness. Such salads often are tossed in a French dressing. A dessert salad is made from a selection of fruits.

Great variety is possible in salad making. Green salads can be made with lettuce, water cress, fresh spinach, escarole or chicory, endive and other suitable ingredients, either singly or in combination, and usually are tossed. Other raw vegetables frequently used are: cabbage, carrots, cauliflower, celery, cucumber, onions, peppers, radishes and tomatoes. A typical mixed salad has a basis of lettuce with spring onions, radishes, cucumber, tomatoes and cooked beetroot. Single items, such as tomato, or a combination of two or three, for example, tomato and chicory, can be sliced and dressed. Besides beetroot, cooked vegetables commonly used in salads include: asparagus, beans, carrots, cauliflower, peas and potatoes. Potato and Russian salads are made predominantly from cooked vegetables with the addition of suitable dressings. Fruits used in salads may be fresh, frozen or canned. Both fruits and vegetables can be combined with gelatin mixtures and molded, while fruits occasionally are used in frozen salads.

Many dressings can be made to add to and accompany salads, most of them being variations and modifications of two classical recipes, French dressing and mayonnaise. The basic ingredients of French dressing are oil, wine vinegar, salt and pepper, while in mayonnaise oil is emulsified with egg yolk, and vinegar and seasonings added to taste.

BREADS

Yeast Breads. — The dough for yeast breads requires a fermentation or rising period prior to baking, during which the yeast cells grow and produce the leavening gas. Essential ingredients are flour, liquid and yeast: flour provides structure and enzyme activity; liquid assists the flour in the development of structure, holds other material in solution and makes possible the best consistency for yeast growth; and yeast provides the leavening agent. Salt is an important additional ingredient, as it helps to control fermentation and contributes to the production of an acceptable flavour. A small amount of sugar often is added as it slightly shortens fermentation time, and shortening, when added, has a tenderizing effect and improves keeping quality, but these are not essential. Characteristics of yeast breads may be varied through the use of flours other than refined wheat flour, *e.g.,* whole-wheat, soy, rye; through the use of different liquids, *e.g.,* water or milk or a mixture of the two; by use of different forms of sweetening, such as molasses or honey; and through the addition of nonessential ingredients, *e.g.,* eggs, caraway seeds. dates and raisins. Variations in the handling of the dough also affect the characteristics of the final product.

During the mixing or kneading, protein in the flour is hydrated by the liquid and forms the elastic network which gives structure and permits retention of the leavening gas. The dough then is set aside until double in volume, at which stage the dough is punched down or knocked back to expel excess gas and to equalize distribution of yeast cells and their food. In the making of loaves of bread, one further fermentation period is usual before shaping the loaves. Yeast rolls can be shaped after either the first or the second fermentation. After shaping the dough, another fermentation or proving period completes the preparation for the oven. During baking. the gas expands, protein is coagulated by heat, thus giving a permanent structure. the yeast cells are destroyed. the starch is cooked and the surface of the product is browned.

Temperature is important throughout the entire breadmaking process. Care must be taken during mixing to prevent premature destruction of yeast cells by excess heat, and for satisfactory fermentation the dough should be kept in a slightly warm place, about 80° F.. free from draughts. The optimum baking temperature varies with the ingredients, ranging from 400° to 475° F.

Biscuits (American), Scones and Other Quick Breads. — All these use a source of leavening other than yeast. Most are leavened by carbon dioxide produced chemically from baking powder or baking soda and a form of acid, but popovers are leavened by the action of steam.

Biscuits.—American biscuits are made from flour, shortening, liquid, salt and baking powder. The dough for rolled biscuits frequently is lightly kneaded in order to increase the volume, develop a cylindrical shape and a "flaky" or layered interior. After it is rolled, the dough is cut as desired and baked at 425°–450° F. Dough for drop biscuits contains more liquid than that for rolled biscuits and is simply dropped on a baking sheet.

Scones.—These are the English equivalent of the American biscuit and are very similar. They usually are slightly sweetened and are better if not kneaded after mixing. Seedless raisins (Sultanas), dates or cheese are added for variation.

Other Quick Breads.—Other quick breads are corn bread, griddle cakes, muffins, popovers and waffles, all of which are quickly made and often served hot.

DESSERTS

Cakes.—Cakes are of two general types, shortened and unshortened, the former containing fat.

American cakes usually are made by one of three methods. In the conventional method the sugar and fat are creamed together, the egg added and a mixture of flour, salt and baking powder mixed in alternately with the liquid, beginning and ending with dry ingredients. In the quick, dump or one-bowl method, all the ingredients except the leavening agent are put into a bowl and mixed vigorously, preferably with a power mixer, the leavening agent added and mixing completed. As a modification of the method, the eggs and part of the milk may be added as a separate stage. The muffin method involves adding the combined liquid ingredients to the combined dry ingredients but, although rapid and easy, this method unmodified produces a cake which tends to be coarse-textured and to have poor keeping quality. Chiffon cake is made by a modification of the muffin method in which the egg white is beaten separately and blended with the other mixed ingredients. Shortened cakes made by these methods can be baked in flat layer pans, in loaf pans or in individual cups and can be baked at oven temperatures of 350°–400° F.

English cake recipes using fat are of two main types. The rubbing-in method can be used for most mixtures where the amount of fat is not more than half the amount of flour by weight: the fat is rubbed into the sifted flour, salt and leavening agent until the mixture is like fine bread crumbs; sugar and other dry ingredients such as dried fruit are added next, followed by beaten eggs together with any other liquid in the recipe. The ingredients must be mixed thoroughly without beating or overmixing for satisfactory results. The creaming method is used when the proportion of fat to flour is half or more by weight, thus producing rich cakes: the fat and sugar are creamed well together, the egg beaten into this mixture and the sifted flour and salt, together with raising agent if necessary, folded carefully in, followed by dried fruit and any iiquid in the recipe. Baking temperatures vary from 290° F. for very rich fruit cakes to 425° F. for small buns.

Spongecake and angel food cake are examples of unshortened mixtures. These cakes depend largely upon incorporated air for leavening and, unless modified recipes are used, chemical raising agent is not necessary, sufficient air to produce a light product being incorporated by whisking the eggs. In angel food cake, only the white of egg is used, beaten with cream of tartar, which is acidic and tends to stabilize the egg white foam; the blended flour, sugar and salt then are gently folded in and the desired flavouring added. A portion of the sugar may be beaten with the egg whites. When making spongecakes, two methods are possible: in the first, the unseparated eggs are whisked with the sugar and any flavouring and the sifted flour is then cut and folded into this thick light mixture; in the second, the egg yolks are beaten with lemon juice and all or part of the sugar and the egg whites are beaten separately with or without part of the sugar, the flour and salt being added to the yolk mixture and the whole combined with the beaten whites. Baking temperatures for unshortened cakes range from 300° to 450° F. .the higher temperatures being used for thin products such as Swiss rolls. Cake or pastry flours give lighter, finer-grained and more tender cakes than do stronger flours, which are used for breadmaking.

Cookies (English Biscuits).—These usually are mixed by the creaming, quick-cake or rubbing-in methods and are of four general types. Drop cookies are made from a dough that is too soft to be rolled out on a board and is therefore dropped on to a baking sheet by spoonfuls. These cookies tend to be somewhat cakelike in texture. Rolled cookies are made from a stiffer dough which can be rolled out, cut and transferred to a baking sheet. This type of cookie tends to be crisp. Refrigerator cookies are made from a stiff dough formed into a cylindrical shape and chilled to facilitate slicing. These mixtures produce very crisp cookies. Bar cookies are made from mixtures which are baked in a continuous thin layer and cut into bar-shaped pieces after baking. Cookies are baked at temperatures of 350°–400° F.

Shortbread.—Shortbread is sufficiently distinctive to stand in a class by itself. The ingredients—butter, fine sugar and flour or a mixture of flour and rice flour—are worked together without addition of any liquid and the result, if correctly made, is a very short product.

Pastry and Pies.—Pastry.—Plain pastry (similar to short-crust pastry) is made of flour, shortening (fat), salt and liquid. The fat is cut into the dry ingredients in pieces, or cut and rubbed in until the mixture looks like fine bread crumbs. The liquid then is blended gradually either into all the mixture, with a minimum of mixing, or into a part of the mixture; this paste is blended in turn with the remaining fat and flour. If liquid fat is used, it is added to the dry ingredients with the other liquid. Soft flours, such as pastry and cake flours, give a shorter pastry than the stronger, all-purpose flour. Shortness is directly proportional to the amount of fat used and indirectly proportional to the amount of water added and the amount of manipulation involved. Flakiness is an internal layering obtained by leaving the fat in pieces and by using the maximum amount of water possible without producing toughness; the use of a minimum amount of water or the use of oil or melted fat tends to produce a pastry which is short but mealy rather than flaky. After the dough is mixed, it is rolled until gentle pressure with the fingers dents it only slightly and then placed in position with care to avoid stretching; otherwise the crust will shrink during baking. Pastry which is to be baked as a single shell for later filling is pricked with a fork before baking so that steam can escape. Plain and short-crust pastries can be modified by the addition of egg yolks, sugar and ingredients such as sesame seeds and chopped nuts.

The making of flaky and puff-type pastries, in which the proportion of fat to flour is high, involves special methods for the incorporation of the fat. In order to obtain the maximum amount of flakiness and rise, most of the fat is added to the dough during the rolling process, thus forming alternate layers of fat and dough. Careful manipulation and cool conditions are essential for good results. Hot-water crust is made by boiling the fat and water together and nhipping this mixture into the flour. The action should be as quick as possible as the paste must be molded while it is soft. Strong flours should be used for flaky, puff and hot-water pastries.

Dessert Pies.—Pies for dessert are of two general types. single-crust and double-crust. A single-crust pie frequently consists of a baked pastry shell filled with a starch-thickened mixture and topped with meringue: the crust is baked at a temperature of 425°–450° F. until dry and slightly bronned. and the cooked filling is added to the cooled shell. Typical fillings are chocolate, lemon and vanilla flavoured mixtures. A meringue, consisting of beaten egg white, sugar and flavouring, is then spread over the filling and browned slightly in the oven. Another type of single-crust pie has an uncooked filling, in which case a baked shell is filled with a mixture containing some gelatin and the pie chilled until the mixture has set. These mixtures frequently contain fruit. Chiffon pies are those filled with gelatin mixtures to which whipped cream or beaten egg white has been added. Custard and pumpkin pies are examples of single-crust pies in which crust and filling are baked simultaneously. For minimum soaking of the crust, baking of such pies is begun at a relatively high temperature, *e.g.*, 425° F., and then finished at a lower temperature, 350° F. Single-crust pies also can be made in a deep dish with a top crust. Raw fruit, the filling generally used, is put into the dish with layers of sugar, a little water is added and the whole covered with short-crust pastry. The pastry is pricked or slit to allow steam to escape and then baked. Such pies usually are served with a sprinkling of sugar on the crust, added after cooking. In two-crust (usually fruit) pies an unbaked shell is filled with fruit, a thickening agent, sugar and spices or other flavouring; a flat piece of pie dough then is laid over the filling and the two crusts are sealed together. The top is pricked to allow for the escape of steam during baking. If this is not done, sufficient internal pressure may develop during baking to cause the fruit juice to boil out. A lattice-work of pastry strips may be used in place of the continuous top crust.

Pies can be made with a single crumb crust in place of pastry. Crumbs of crackers or cookies or breakfast cereal are mixed with butter, pressed into a piepan and either baked or chilled. Starch-thickened or gelatin mixtures are typical fillings. Crumbs also may be used to add variety as toppings for fruit pies and in deep-dish desserts, such as apple crunch or crumble.

In Great Britain, a dish with a bottom layer of pastry, with or without a top crust, is usually called a tart. Specific examples are apple, with a double crust; jam, which is baked open or nith a lattice finish; and bakewell tart, which has a cake mixture-type filling.

Meat Pies. — Meat pies are either deep-dish or raised. In both cases, the pastry has to withstand a comparatively long cooking period, and flaky pastry and hot-water crust are the two most commonly used. Flaky pastry is used for deep-dish meat pies, such as steak and kidney, veal and ham, and chicken pies. The usual procedure is to put the pie into a moderately hot oven to cook the pastry and then to cover the pastry with wet greaseproof paper, lower the oven temperature and continue cooking until the meat is cooked. If cooked meat is used, as in chicken pie, the pie should be ready when the pastry is cooked. These pies can be served hot or cold. A raised pie is a meat or savoury pie in which the filling is encased with pastry without requiring a dish for support. Hot-water crust is suitable for these pies, since it can be molded by hand if used quickly after making. Pork and game are well-known examples of such pies, usually served cold. With both types of pie, it is usual to decorate with pastry leaves and glaze with egg before cooking.

Puddings. — Most of the products which can be classified as puddings have a farinaceous substance as one of the main basic ingredients and are oftener served hot than cold. The majority are suitable for the dessert or sweet course of a meal, but a few are not sweet and are served as or with the main course. Puddings can be subdivided into four main classes: those made with (1) suet as the form of shortening; (2) milk and eggs; (3) a cake mixture; and (4) cereal and milk. Depending upon the type, puddings are baked, boiled or steamed.

Suet puddings are of two main kinds: those with a suet crust and a filling, usually fruit, and those made of a suet mixture. The crust is made of flour, suet, salt, leavening agent and water rolled out and used to line a pudding basin. Uncooked, prepared fruit is then packed into the basin with layers of sugar and the top covered with a remaining piece of rolled dough. The pudding is steamed 2–3 hr. and turned out onto a dish. Puddings with suet crust and dried fruit sometimes are baked. The second type of suet pudding, in which all the ingredients are mixed together, ranges from the very rich variety such as Christmas or plum puddings to plain leavened mixtures which are served with sauces, such as treacle or ginger puddings. Bread crumbs often are used instead of flour to give a light product. Long cooking is essential for these mixtures, which usually are boiled or steamed in basins.

Puddings made primarily from eggs and milk include batter puddings, which can be served with fruit or jam; pancakes and various fruit fritters; and custard-based dishes such as queen of puddings and bread-and-butter pudding. Most of this group are baked or fried.

A wide variety of puddings are made with a cake-mixture base and frequently are cooked with jam, syrup and/or fruit; *e.g.,* steamed jam pudding, pineapple upside-down pudding and Eve's pudding. Usually steamed or baked, many are served with sauces.

Milk puddings vary from very plain recipes containing just milk, sugar, cereal and flavouring, to quite elaborate dishes which may have eggs and cream added and be topped with meringue. The richer puddings usually can be served hot or cold, while the plain varieties frequently are served hot with stewed fruit or jam. These puddings can be cooked in a double saucepan or baked.

Meat puddings are of the suet crust type and are made in the same way as fruit puddings, beefsteak and kidney being the most common filling. Dumplings, cooked and served with boiled beef and some soups, are made from a plain suet mixture and Yorkshire pudding is made from a batter and baked, usually as an accompaniment to roast beef.

Cold Sweets. — Fruit desserts are those predominantly or wholly composed of fresh or cooked fruit; *e.g.,* mixed fruit compote, fruit salad, stewed fruit and fresh fruit. Gelatin, an important ingredient in many well-known desserts, *e.g.,* jellies of fruit juice and fruit, and cream mixtures, such as bavaroise, is also often added to such desserts as cold souffles, mousses and ice cream to give additional structure and smoothness. Eggs are used both as a thickening agent in custards and creams and as a foaming agent to give lightness in soufflés and similar dishes. Custard, a mixture of egg, milk, sugar and flavouring, may be either a stirred sauce or baked or steamed to form a set dish, caramel cream or custard being a well-known example of the latter. Egg whites often are used separately; *e.g.,* in hard meringues, which consist of beaten egg whites, sugar and flavouring, baked very slowly until dry and then filled with fruit and/or cream.

Starch of various kinds is an important thickening agent in many desserts and blancmange, made from cornstarch, milk, sugar, butter and flavouring, depends entirely on starch for its structure. Starch-thickened mixtures, or mixtures thickened with both starch and egg, are also used as fillings for cream puffs and eclairs, while whole grain cereals such as rice can be creamed and served with fruit or other flavouring.

Many popular desserts are combinations of several individual items, trifle and charlotte russe being good examples.

Chilled Desserts. — Many of the types of desserts mentioned above can be chilled to advantage. Whipped cream, beaten egg whites and gelatin are common constituents of such desserts, but various combinations of fruits, nuts, coconut, cookie crumbs and other ingredients also can be used. In frozen desserts, firmness is produced by ice crystals; smoothness and other characteristics, by the ingredients and the method of preparation. This group consists mainly of ices. The simplest form is the water ice consisting of fruit juice or other flavouring, water and a sweetening agent. A sherbet is modified by the addition of gelatin or beaten egg whites to give increased smoothness of texture and may have milk or cream substituted for water. A sorbet (frappe in the U.S.) is a soft water ice with fruit or liqueur flavour and only half frozen. The usual basis of an ice cream is either cream or custard or a mixture of the two; flavouring, such as fruit purée or chocolate, sugar and often a little gelatin (to give additional smoothness) are added. A half-frozen ice cream is usually known in Great Britain as a frappé. Both ices and ice creams are stirred during the freezing process. Desserts that are frozen without stirring are mousses, parfaits and cold souffles, which are light ice cream preparations made from custard, cream, fruit or sirups, whisked egg whites and flavouring. *Bombes* and ice puddings are combinations of at least two different frozen mixtures packed in a mold and refrozen.

Confections. — Homemade candies or s eets are of two general types, crystalline (*e.g.,* fondant and fudge) and noncrystalline or amorphous (*e.g*., caramels, taffy, brittle and all kinds of toffee).

Crystalline. — In the making of crystalline candies, sugar in crystalline form is dissolved in excess water, combined with chocolate or other ingredients and cooked until properly concentrated. The degree of concentration may be checked either by taking the temperature of the sirup or by testing the sirup in cold water. During cooling of the concentrated sirup, the amount of sugar that can remain in solution decreases. Thus, at a temperature only slightly higher than body temperature, beating initiates recrystallization of so much of the sugar that a solid mass is formed. Vigorous beating during crystal formation tends to keep the crystals small and the texture of the candy smooth. Certain added ingredients also contribute to smoothness by interfering with crystal formation, *e.g.,* cream of tartar and other materials that act chemically; if used to excess or if allowed to act too long, as in very slow cooking, acids may interfere with crystallization to such an extent that the candy fails to harden. Butter and other fats and corn sirup act mechanically to keep crystals small. If a crystalline candy is cooked to or beaten at too high a temperature, a grainy product is likely to result, but this can be redissolved in water, cooked to the proper end point and finished satisfactorily.

Noncrystalline.—Noncrystalline candies are cooked at higher temperatures and the sugar solidifies so rapidly during cooling that crystals are not formed. These candies are not beaten and high proportions of substances which interfere with crystallization are sometimes added, *e.g.,* caramels are not agitated after cooking and have a high proportion of fat and of milk solids. Taffy is pulled when it is cool enough to be handled and this incorporates air, thus lightening the colour. Brittles are not manipulated except that they are sometimes stretched during cooling in order to make them as thin as possible.

Other confections include glazed apricots, prepared by cooking dried apricots slowly in a heavy sirup, glazed nuts, similarly prepared, and marzipan, a sweetened, flavoured paste of ground almonds frequently tinted and shaped for use as a decorative confection. Fondant can be used, with or without nuts, as stuffings for dates, prunes and apricots and also can be shaped and dipped in a special chocolate coating. It also can be melted, flavoured and tinted and either poured out in small amounts to form flat, round mints or used as a dip for balls of firm fondant.

BEVERAGES

Coffee.—Coffee is available in four forms: powdered, frozen liquid concentrate, whole bean and ground. Powdered coffee and the frozen concentrate are dissolved in hot or boiling water; coffee beans are ground and then used as ground coffee. The beverage may be prepared from ground coffee by several methods but, regardless of the method used, the aim in coffee-making is extraction of the desirable flavouring substances with a minimum amount of the tannins and other bitter-tasting substances. Subboiling temperatures are preferable to boiling because (1) the desirable flavour constituents are volatile and thus easily lost during boiling and (2) the bitter components of coffee are increasingly soluble in water as the temperature rises. Caffeine, the stimulating substance in coffee, is soluble in hot water and therefore extracted with the other constituents, but decaffeinated ground coffees are available. There are three general methods of making coffee. Steeping requires no specialized equipment, the coffee being heated with water in a coffeepot or a covered saucepan and kept just below boiling point until the desired strength is obtained. In a percolator a small amount of water is forced upward through a tube and then filtered downward through the coffee grounds; the process is repeated until enough water-soluble material has been extracted to give the desired strength and colour. In the drip method boiling water is poured onto the grounds and allowed to filter through the coffee into a serving pot. Fineness of grind is important in this method as the water is in contact nith the grounds only once and for a short time. In vacuum-type coffee-makers, coffee is made by a variation of the drip method or by a method in which the extraction takes place as steam is forced up through the grounds. Automatic electric coffee-makers are either percolator or vacuum in type. After-dinner coffee usually is served very strong in a small cup called a demitasse.

Teas.—Green, black and oolong teas differ because of their different treatment during processing. Black tea is subjected to a fermentation process not used for green tea, resulting in a mildness of flavour as compared with the pungent flavour of green tea. Oolong is partially fermented and its flavour compromises between those of green and black teas. Terms such as pekoe and orange pekoe are grade designations based on size of leaf, the smaller leaves being graded higher. The only general method for making tea is steeping: boiling water is added to the tea leaves, which are allowed to steep for approximately three minutes, after which the tea bag or ball is removed or the infusion is poured off the leaves. If a very strong beverage is desired, it is best obtained by using more tea leaves rather than by steeping for a longer time, as longer steeping results in the undesirable extraction of more tannin. Iced tea is made by pouring freshly made tea over ice: because of the dilution by melting ice, a particularly strong infusion of tea is used. However, if the infusion is too strong or if it is prepared by long steeping, the chilled product may become cloudy because of precipitation of tannins, which are less soluble in cold than in hot water. The stimulant in tea, theine, is the same as caffeine in coffee and is found in green and black tea in similar amounts.

Milk Beverages.—Cocoa and chocolate beverages contain milk and usually are served hot. Since cocoa contains starch, the mixture should be cooked for several minutes at some stage in the preparation, unless the precooked variety is used, in order to avoid a raw flavour and a sediment in the finished product. Cocoa and chocolate contain theobromine, a stimulant similar to caffeine.

Other milk beverages include *café* au *lait,* a mixture of strong coffee and hot milk, and numerous cold mixtures of milk and fruit juices.

CHEESE, EGGS AND FRUIT

Cheese.—Characteristics of various cheeses, the most pronounced of which are caused by differences in moisture content and methods of ripening, affect their use in food preparation. Moisture content may be as high as 75% for a soft cheese, as cottage cheese, or as low as 30% for a hard cheese, as Parmesan. Ripening may be brought about by acid-forming bacteria, as in Cheddar, by gas-forming bacteria, as in Gruyère, or by mold, as in Roquefort, and it is during ripening that the characteristic flavour and texture develop and that the cheese becomes easier to blend with other ingredients in cooking.

When cheese is heated, the fat melts and, as the temperature increases, the protein coagulates and the fat tends to separate; heating above 160° F. tends to toughen the protein and cause stringiness. In the preparation of a cheese sauce, grated cheese is mixed into a white sauce which has been cooled to approximately 125° F.; if the cheese fails to melt, the sauce may be heated over hot water until the cheese is blended. In the preparation of baked cheese mixtures, such as macaroni and cheese, high temperatures and overcooking should be avoided.

Eggs.—In addition to adding colour, flavour and nutritive value, eggs also contribute thickening, as in custards; structure, as in chou paste (cream puffs) and to some extent cake mixtures; leavening, as in angel food cake and sponges; emulsification, as in mayonnaise; and binding, as in croquettes and meat loaves.

Eggs are frequently used alone, either poached, fried, scrambled or cooked in the shell. Poached eggs are broken into simmering water and cooked until the white coagulates; fried eggs are broken into a skillet and cooked in fat. For scrambling, the eggs are broken and slightly beaten, a little milk and seasoning added and the mixture heated slowly with a little butter and stirred gently until just coagulated. Boiled eggs are cooked in the shell in simmering water until the required degree of coagulation is obtained. The formation of a dark ring around the yolk can be prevented by not overcooking and by immediately placing hard-cooked eggs in cold water.

The changes which occur during the cooking of eggs are largely due to the coagulation of protein at relatively low temperatures, 140°–160° F. in the case of undiluted egg and a little higher with diluted egg mixture, such as custards. Overcooking eggs causes overcoagulation, with the result that the protein is toughened and liquid and solid separate in custards or other mixtures in which liquid has been added.

Fruit.—The changes which occur during the cooking of fruits affect texture, flavour and colour. Alterations in texture are due to several factors: softening of cellulose, the substance of which plant cell walls are composed; changes in the pectic substances which bind the cells together; cooking of the starch which is present in some fruits; and changes in moisture content. Flavour is due to the presence of sugar, organic acids, aromatic compounds and mineral salts, and the loss of aromatic compounds through volatilization is an important problem of fruit cooking. Losses of sugar, acid and salt are mainly the result of their solubility in cooking water.

The colour of fruits is due chiefly to a group of yellow pigments, carotenoids, and to red pigments, anthocyanins: the yellow pigments are so stable that their preservation during cooking is no problem, but the red pigments, although maintaining their colour in the presence of acid, are water-soluble and tend to leach out into the cooking water and, in some cases, to form blue or black compounds with tin and iron. Another group of compounds, tannins, also found in fruits but not classified as pigments, may react with iron to form dark-coloured compounds and therefore iron knives and pans of tin, iron or chipped enamel should not be used in the preparation of fruits.

Fruits can be cooked in water or a sugar solution, baked, broiled or fried. The amount of water used in cooking fruit depends upon the kind used; *e.g.,* berries require less added water than apples since they have a higher natural water content. Cooking fruit in a sugar solution tends to make it lustrous but, if the sugar solution is too concentrated, sufficient moisture may be drawn from the fruit to cause shriveling; on the other hand, if the sugar solution is very dilute or no sugar is added to the cooking water the fruit may become mushy. If the fruit is to be sieved, as for applesauce, it should be allowed to become mushy by cooking in water and the sugar, if needed, added after sieving, but if the fruit is desired for garnish, as in the case of coloured and spiced pieces of apple, a sugar sirup should be used. Fruits cooked in a sugar sirup are usually referred to as stewed or coddled fruits. Fruits which are sometimes baked include apples, bananas and pears: apples are frequently cored, stuffed with a mixture of sugar, butter, seasonings, raisins and nuts and baked whole; bananas and pears are halved, dotted with butter and sprinkled with fruit juice and cinnamon or other seasoning. Some fruits can be broiled; *e.g.,* grapefruit, canned and fresh pineapple rings and canned peach halves. Apples and bananas are sometimes fried and also made into fritters.

Cooked fruit can be used in a variety of ways during a meal: as an appetizer, *e.g.,* broiled grapefruit; as part of the main course, *e.g.,* fried apples; as a garnish, *e.g.,* cinnamon apples; or as dessert, *e.g.,* baked fruits and various fruit puddings.

The principal goal in the cooking of dried fruits is the replacement of water removed during drying. Rehydration can be achieved satisfactorily by slow cooking of the fruit in water or by a short soaking period followed by slow cooking. Sugar, if needed, should be added when the fruit is nearly done. Long soaking of the fruit prior to cooking tends to produce an undesirably watery product.

HERBS AND SPICES

Seasoning is an extremely important part of food preparation: real skill in the seasoning of foods requires experience, imagination, discrimination and restraint, for overseasoning can be even more serious than underseasoning. Herbs and spices provide an endless means for enhancing the natural flavours of food.

Herbs. — Herbs are plants with succulent, distinctly flavoured leaves, which can be used fresh or dried, preferably in a finely divided form and always in small amounts. Meat dishes, vegetables, salads, soups, sauces, fish, poultry and egg dishes may all benefit from additions of herbs. The following are some of the more commonlv used herbs.

Basil, an aromatic potherb whose leaves have a strong flavour resembling cloves, is always included in the making of turtle soup.

Bay leaves, from a species of laurel tree, are used in soups, with meats and fish and one or part of a bay leaf is always included in the *bouquet garni* and in court bouillon.

Chervil, whose delicate flavour resembles both parsley and fennel, is used in salads, soups, sauces and meat dishes and sometimes in the fresh green state.

Chives, related to onions and similar in flavour, are used in salads and soups.

Dill is commonly used in pickling as well as in meat and vegetable dishes, soups, salads and sauces; the leafy tops are used as well as the dried fruit, usually known as dill seed.

Fennel, related to the parsley plant and with a flavour similar to aniseed, is commonly used for flavouring fish sauces, soups and salads.

Marjoram is one of the sweet herbs which, when dried, are included in mixed herbs for flavouring stews, meat dishes and soups, etc.

Mint is mainly used when fresh but sometimes in a dried form; the serving of mint sauce with lamb, hot or cold, is an English custom, as is the addition of mint leaves to the cooking of new potatoes and green peas.

Oregano is widely used in meat dishes, with eggs, beans, cheese dishes and fish, and is essential to Latin cookery.

Parsley, a lacy green herb with a slightly sharp flavour, is used as a garnish, in sauces and salads, can he fried and is used fresh to a greater extent than dried.

Rosemary is a mint-flavoured herb used with lamb and other meats and in stuffings.

Sage, a commonly used seasoning in bread stuffings for poultry and other meats, is also used in soups and sauces.

Sorrel is an essentially French herb used for making sorrel soup and for flavouring omelets and sauces.

Tarragon is used fresh in salads and for flavouring in chicken dishes, omelets, sauces and stews, as well as in tarragon vinegar.

Thyme, a pungently flavoured herb widely used in stuffings, sauces, soups and meat dishes, is traditionally used in the preparation of jugged hare.

Mixtures of herbs can be bought, such as poultry seasoning with sage usually predominating and mixed herbs, usually consisting of thyme, sage, marjoram and parsley.

Spices. — Spices are aromatic parts of plants, mostly tropical, which are dried and used in food preparation either whole or in a pulverized form. A spice may represent the root, bark, fruit, flower, bud or seed of the plant.

Allspice is the dried fruit of the pimento tree, its name being derived from the similarity of its flavour to that of a mixture of cinnamon, cloves and nutmeg and is used primarily in baked cakes and cookies.

Anise (aniseed) is an extremely small seed, the oil of which is used in confections, sauces, creams, sweet puddings and cakes, as well as pickling.

Whole *caraway* seeds are used in breads, cakes, meat dishes, salads and in some cheese.

Cardamon seeds resemble anise in flavour and are used similarly, and in curry.

Celery seeds are used in pickling and in soups, as well as in fish and meat dishes.

Cinnamon, the bark stripped from young branches of the cinnamon tree, is available either in the ground form or in rather large pieces and is used extensively in cookies, cakes and with fruits.

Cloves are the unopened flower buds of the clove tree, available either whole or ground, and are used for flavouring soups, stocks, meats and desserts.

Powdered *coriander* seed is used mostly in pickling and is a constituent of curry powder.

Cumin seed is ground and used in soups and meat dishes and is a constituent of curry paste.

Ginger is an example of a spice obtained from the rhizome of a plant and is available both in pieces as stem or crystallized ginger and in the ground form; it is used in baked products such as cakes and cookies, in certain meat dishes and in oriental cookery, being a common ingredient of curry powder and pastes.

Mace is the covering of the nutmeg, with a similar delicate flavour, and is used for flavouring the same kind of products as is the nutmeg, as well as in preserving.

Mustard seeds are of two varieties, black and white (yellow); the ground form is used mainly for making a condiment or relish, although it is also used in flavouring meat and cheese dishes.

Nutmeg is available either ground or as whole seeds and is used widely in the preparation of desserts, soups, beverages and baked products.

Both black and white pepper are obtained from the same plant, black pepper from the dried immature fruit and white pepper from the dried mature fruit with the hull removed; pepper is used as a condiment and as a seasoning in all savoury dishes.

Saffron, the dried stigma of a plant related to the crocus, is used occasionally for flavouring and colouring of special type cakes.

Sesame seeds are small, light-coloured seeds with a nutty flavour, and are used in breads and confections.

Turmeric (curcuma) is another example of a dried rhizome or root and is from a plant of the ginger family; the yellow powder is used extensively in curry powder and in prepared mustard.

Vanilla, obtained from the dried pod of a plant, is a very delicate flavouring that can be used for all kinds of sweet dishes.

Others.—Curry powders and pastes are made up of various combinations of many spices and herbs, each combination varying considerably in flavour. Curry, as a dish, is of immemorial use in

India.

TRO important sources of flavour which cannot be classified as either herbs or spices are garlic and horse-radish. Garlic is the bulb of a plant, the small sections of which are known as "cloves" of garlic, and is used extensively in flavouring meat and vegetable dishes and salads, but needs to be used with care and discrimination. Horse-radish is a root with a somewhat peppery taste used grated and usually served as a cream sauce, particularly with roast beef.

FOOD PRESERVATION. As foods in their natural state remain sound and edible for only a comparatively short time, food preservation has engaged the attention of mankind from the earliest times. Prehistoric man preserved his cereals by parching, vegetables and fruits by drying, milk in the form of fermented products or as cheeses, and fruit juices as cider or wines; and the hunter learned to dry or salt his game or fish. The ever-increasing spread of man over different parts of the world, into widely different climates, and still more the increase in urban populations, have rendered the development of efficient methods of preservation a matter of vital necessity. For many centuries the art of preservation was at a standstill or developed only slowly and was purely empirical, fermentation, drying, smoking or curing with salt being the principal methods. As the biological causes of food spoilage became better understood, rapid advances followed and appropriate methods were soon developed for dealing with the causative agents.

Since most foods either carry or eventually acquire bacteria, molds or yeasts, microorganisms are the major cause of food spoilage. Other factors leading to deterioration or spoilage are the enzymes (ferments) naturally present in some foods, and various chemical reactions, particularly oxidation. Some factors which lead to spoilage in one food might be regarded as desirable in another instance and may be, indeed, essential for the protection of certain foods. For example; yeasts are applied in making wine, bacteria in the manufacture of sour milk and pickled products and molds in cheese making. Enzymes are used in both cheese making and in brewing, and the browning of roasts and bread crust is a type of chemical reaction that in many other foods leads to deterioration and spoilage.

There are several major processes for food preservation. The growth of microorganisms (and enzyme activity) in foods may be retarded by cooling or almost entirely prevented by freezing. Since water is necessary for the growth of microorganisms, dried (dehydrated) foods will keep for long periods. Or the enzymes and microorganisms present in foods may be completely or almost completely destroyed by the application of heat as in thermal processing (canning). In canned foods reinfestation by microorganisms must be prevented, hence the need for hermetically sealed containers. Finally, both enzyme action and microbial growth can be prevented by the addition of certain chemicals or through chemicals produced in fermentations. Smoking, salting and candying are the age-old examples of this type of food preservation, but the use of chemical preservatives and inhibitors, including antibiotics, is more important today. The preservation of food with ionizing radiations ("cold sterilization") will doubtless be added to this list when the principles involved and the operational details are sufficiently developed to allow large-scale commercial application. Often several of the principles are applied in combination. For instance, cabbage is preserved as sauerkraut in the presence of salt and by the chemicals produced by the microorganisms during fermentation: and much of this product is later marketed in cans after heat sterilization. Some frozen food products are heated before freezing in order to inactivate the enzymes or to reduce the number of viable organisms present. A combination of dehydration and freezing is used in the processing of dehydro-frozen foods.

The modern objective of food preservation includes more than the mere prevention of spoilage. Quality. economy and convenience are in most instances important in the production and marketing of processed foods. Colour or appearance, flavour, texture or consistency and freedom from defects are the major quality factors. Nutritive value has also come to be recognized as a quality factor. Most countries have detailed and exacting requirements governing food processing from the standpoint of sanitation and quality, but the extent to which such regulations are enforced varies greatly. However, quality requirements for any food are also firmly ingrained in the consumer's mind and thus will govern his purchases. Therefore, quality must be retained by the processed food during preservation and in the period between its manufacture and consumption. Naturally, the emphasis given to quality factors will depend on the cultural and economic state of development and is more important where there is high purchasing power and an abundance of food allowing a choice. Yet quality requirements (or "conforming to common usage") exist even in the most primitive cultures. In hardly any other field of'human activity does tradition play as important a part as in our choice of food.

Convenience is a factor in food processing which has gained much importance. Whereas, not many years ago; most canned and otherwise preserved foods represented starting materials for the preparation of meals, today it is common for some or most of the preparation and compounding into the final complete dish to be done by the food processor. It is clear that the modern food processor, with his scientific control, large-scale operation and use of raw materials in their prime, has many advantages over the cook or housewife. Such preserved, partially prepared or complete dishes, or even complete meals, offer in the home easy preparation in a short time. Although price is still a major consideration in determining the marketability of a processed food, the gradual increase in the world-wide standard of living and the employment of a large proportion of the population (including women) in many countries tend to increase the consumer's willingness to pay the processor for some of the preparation and cooking. In spite of some of the early objections to processed foods it is now generally conceded that the increasing availability and use of processed foods has had a profoundly beneficial effect on the diet pattern in many countries; and that in most instances it has led to substantial improvements in the national nutrition. This is particularly true where fresh fruits and vegetables are available only during part of the year or where foods transported from long distances make up a significant part of the diet. (See FOOD SUPPLY OF THE WORLD.)

Drying and Dehydration. — Desiccation or drying is nature's major method of preservation. Prehistoric man must have observed that dry cereals, berries and nuts kept well, and that meat and fish, when dried, could be kept for extended periods without spoilage. Many traditional sun-dried products are still used today, and the storage of dry cereals was a major factor in stimulating urbanization and the development of civilizations. "Drying" usually ,indicates a sun-dried product, whereas "dehydration" is used mostly for foods from which the water has been removed by artificial means. However, there are exceptions to the use of this terminology, particularly where artificial drying is used to supplement sun drying.

Food preservation by drying and dehydration depends on the fact that microorganisms cannot grow on dry materials and that enzyme action and various other deleterious chemical reactions are similarly retarded or prevented when the water content of a food is low. Previously it was thought that a moisture content of about 10% was sufficiently low to prevent both spoilage and deterioration of foods. But of late the upper limit of moisture content has been gradually reduced for most dried foods. This change was due, to a large extent, to the increased emphasis on quality retention, and was made possible by the development of more efficient means of artificial drying. The amount of permissible residual water is different for various products. The temperatures to which the product will be exposed during storage and the length of time between manufacture and consumption are major factors in determining the maximum permissible moisture content of a dehydrated food.

With the exception of eggs and milk, dehydrated foods were never as important in the United States as in Europe. During World Wars I and II, great efforts were made to increase production and to improve the quality of dehydrated foods, since they offer great economy both in tin requirements and in storage bulk and shipping weight. Considerable activity in research and development after World War II continued in the United States and elsewhere and resulted in many new and improved dehydrated products.

Sun drying is used with many fruits such as apples, pears, plums, peaches, apricots, figs, currants and various raisin grapes. In order to prevent excessive darkening, most of these fruits are treated with sulfur dioxide before drying, most of the chemical being lost from the fruit during the subsequent processing. Some fruits, such as figs, must be fumigated with chloropicrin, ethylene oxide, methyl bromide or other agents in order to prevent infestation by insects. The water content of most dried fruits is in the range of 5% to 15%, with different requirements for various fruits. Meat is not now sun-dried in western Europe and the United States but this ancient method of preservation is still used in many other parts of the world. The sun drying of fish is common all over the world, and usually is done in conjunction with salting, brining and smoking, in various combinations.

Artificial drying (dehydration) depends on the efficient transfer of water vapour into a stream of air or other gases that are not saturated with water vapour. Thus the volume, temperature and relative humidity of the drying gas and the surface of moist material exposed to it will govern the drying efficiency. The design of food drying equipment is a highly specialized branch of engineering. Since every food particle has a different and typical attraction to moisture, most types of dehydrating equipment will be suitable for a limited number of products only. Cabinet dryers are drying chambers usually divided into several compartments, each holding several stacks of trays mounted on carriages. The cabinets are commonly heated by steam coils. In the old-fashioned kiln dryer or "evaporator" (still used with apple pomace, hops, etc.) the product to be dried is placed in an upper room which has a slatted floor and a current of hot air is supplied from below. Tunnel dryers are extensively used—the drying takes place in tunnels 30–50 ft. long and about 6 ft. square. The material to be dried is loaded on slatted wooden or metal trays stacked on carriages which fit the tunnel snugly so that the air passes between the trays. The carriage loaded with the fresh material is introduced at one end of the tunnel and the dry material is removed at the other end.

Belts of stainless steel are sometimes used instead of trays and carriages. Drum dryers are commonly used for drying milk, pulped fruit, potato flour, mixtures for prepared foods and other products. In the most common type of double horizontal drum dryers the material to be dried is placed in the top "well" between two identical, closely placed, heated drums 3 to 6 ft. in diameter. The drums are slowly rotated so that the material to be dried is picked up by the drums and carried toward the outside. The drying is completed by the time the material on the drum reaches the scraper or "doctor blade" which shaves off the product. The material to be dried may also be fed from a pan under a single drum or sprayed on the drum.

Spray dryers are extensively used in the large-scale drying of milk and other dairy products, whole eggs, egg yolks, fruit and vegetable juices, purees, soluble coffee and tea and many other foods. This method of drying often allows economical large-scale production with the least damage to flavour. The material to be dried is finely atomized, usually into the top of a large cone-shaped chamber in which heated air or gas is circulated. The water in the droplets evaporates in the heated air and the solid particles are trapped by a collector which usually consists of a smaller cone-shaped structure. Spray drying is the quickest means of drying but the method is applicable only to a limited number of foods and the installation costs are high. Vacuum dryers provide rapid drying at lower temperatures and may be of the tray or continuous belt type. A specific form of vacuum drying is freeze-drying (lyophilization), which was developed for purposes other than food production during World War II but is now used for foods to a limited extent. Here the product is dried by sublimation of the water without raising the product temperature, a point of much importance in the food processors' effort to preserve flavour. Both vacuum drying and freeze-drying are expensive in comparison with other methods of dehydration and therefore are applied mostly to food products of special requirements or of high price.

Often it is most expedient to use a combination of various drying procedures. For instance, some vegetables are most economically dehydrated in tunnel dryers which remove the bulk of water. This is followed by drying in cabinet dryers, and lastly by removing additional moisture in bins through which air, dried in silica gel, is circulated. For storage and distribution, many dehydrated products are packed in cans in an inert atmosphere or under vacuum. The use of in-container dehydration by small packets of moisture-absorbing agents placed in the container with the dehydrated product allows attainment of new and hitherto impractically low levels of moisture content.

Salting and Pickling.— Salt is one of the oldest preservatives used for enhancing the keeping quality of fish, meat and vegetable foods. However, the preservative function of salt is not the same for all food products and some of the principles involved are not yet entirely understood. (See FISH CURING; PICKLING.)

Meat and fish are treated directly with dry salt crystals or are soaked in a strong brine. Salt is almost universally used for enhancing the keeping quality of butter, the proportion applied (in the U.S. and Canada) being in the range of 2.0% to 2.5%. Salt is used extensively in the manufacture of various types of cheese. In the preservation of vegetables the main function of salt is to govern the type of microorganisms which will grow in the product and the extent of the changes which the growing microorganisms will be able to produce. The effectiveness of salt in the control of microorganisms has been explained by a number of somewhat contradictory theories. Whatever may be its action, the fact remains that salt, particularly in combination with acids, has a selective action on microorganisms. This effect is extensively used in the manufacture of pickles, sauerkraut, cured olives and many other products. Pickles and sauerkraut are typical of foods stabilized by directed fermentation. Other examples in this classification are meat, buttermilk, yogurt, cheese and the many foods which in their original forms were susceptible to spoilage before the advent of food processing and therefore were allowed to be fermented by the ever-present yeasts. Honey beer (mead), the common malt-hop beer and the innumerable types of fermented fruit juices and wines are in this category.

Smoking.— Preservation by smoking is applied almost exclusively to meat (particularly ham) and fish and is often used in conjunction with other methods of preservation. The preserving action of smoking arises from the drying action of heat as well as from chemicals (*e.g.,* wood creosote) deposited on the food during smoking. However, increased palatability is undoubtedly the major reason for the smoking of fish and meat in countries where other methods of food preservation are easily available. Smoke usually is produced by the slow burning of sawdust from such hardwoods as hickory, maple and birch.

Chemical Preservatives.— The use of chemicals is an old and well-recognized practice in both household and commercial preservation of foods. A large number of chemicals having real or supposed preservative properties have at different times been added to foods. This subject is inseparable from the problems presented by food adulteration and from the occurrence in foods of the toxic residues from chemical agents used to protect plants or animals against pests and diseases. Whereas in most countries willful adulteration has come to present less of a problem, the complications introduced by the multitude of protective chemicals necessary in agricultural production are serious.

Chemical food preservatives are substances which. under defined conditions, delay the growth of microorganisms without necessarily destroying them. Since the concept of food preservation now includes retention of quality as well as prevention or delay of spoilage, a distinction has to be made between the use of chemicals which will prevent deterioration of quality during manufacture and distribution on the one hand and those added for preventing microbial spoilage on the other. The first group includes some natural food constituents such as ascorbic acid (vitamin C), which is added to frozen peaches to prevent brouning, and a long list of chemical cumpounds foreign to foods and classified as antioxidants. bleaching agents, acidulants, neutralizers, stabilizers, firming agents, humectants, etc. The second group again includes some natural food constituents which, when added to foods, will retard or prevent the growth of microorganisms. Sugar is used partly for this purpose in making jams, jellies and marmalades and in candying fruit. The use of vinegar in pickling and of alcohol in brandying is in this category as is the use of salt. Finally there is the group of chemicals foreign to foods and added strictly to prevent the growth of microorganisms, the chemical preservatives.

Sodium benzoate and other benzoates are among the principal chemical preservatives. The use of benzoates in certain products and in prescribed quantity (usually not exceeding 0.1%) is permitted in most countries, some of which, as the United States, require a declaration of its use on the label. Since free benzoic acid actually is the active agent, benzoates must be used in an acid medium in order to be effective. The ability of cranberries to resist rapid deterioration is attributed to their high benzoic acid content. Benzoic acid is more effective against yeasts than against molds and bacteria. The effectiveness of benzoic acid can be increased by the introduction of a side chain or by other modifications of the molecule. Other organic compounds used as preservatives include vanillic acid esters, monochloroacetic acid, propionates, dehydroacetic acid and glycols.

Sulfur dioxide and sulfites are perhaps the most important inorganic chemical preservatives. Although special laws forbidding the use of sulfur compounds were passed as early as 1400, a more tolerant view is now taken. Sulfites are more effective against molds than against yeasts and are widely used in the preservation of fruits and vegetables. Sulfur compounds are extensively used in wine making and. as in most other instances when this preservative is used, much care has to be exercised to keep the concentrations low in order to avoid undesirable effects on flavour. Sodium sulfite has been used as a preservative for meat although there is some doubt about its effectiveness. However, when incorporated with chopped meat which is in an incipient state of decomposition, it serves to bring out a red color thus tending to make the meat appear fresh. Oxidizing agents such as nitrates and nitrites are commonly used in the curing of meats.

Most governments attempt to control the addition of foreign substances to foods and the occurrence of toxic residues in foods. In the United States, the federal, state and city governments have regulations concerning this matter, but it is the Federal Food. Drug and Cosmetic act of 1938, amended and extended from time to time, which regulates the application of chemical preservatives in foods. Regulations concerning the use of food additives, including chemical preservatives, change frequently as new compounds become available or as the desirable or undesirable properties of agents in use become better understood.

The period after World War II saw an increasing use of antibiotics in food preservation; some European food preserving agents presumably containing antibiotics appeared on the market in the late 1940s. The use of antibiotics was given legal approval in the United States for the temporary preservation of poultry. and ice containing antibiotics was successfully applied in the cooling of fish. When the mode of action and absence of deleterious effects of residues and decomposition products are better understood, antibiotics may be more extensively used in food preservation.

Thermal Processing. — In thermal processing (called canning in the United States) the food is packed in hermetically sealed containers and heated sufficiently to destroy all living organisms or, at least, to assure that the conditions inside the container are such that no growth of residual organisms will occur. Many hundreds of different products are preserved by thermal processing in cans or tins and in hermetically sealed glass containers. In nonacid products the temperature must reach 240° F. inside the container and be maintained for several minutes. Even more extensive heating is required in some instances. Cured meats with salt and nitrate can be processed at somewhat lower temperatures, while for canned fruits the temperature of boiling water suffices. The flavour of some products, particularly liquid foods, is often detrimentally changed by heat sterilization and in such instances pasteurization is used since it involves only sufficient heat to destroy pathogenic bacteria without altering the flavour; pasteurization also will reduce the number of other organisms present sufficiently to enhance the keeping quality of the product. A common heat treatment is 145° F. for 30 min. or 160° F. for 15 sec. Milk is one of the most important foods pasteurized in large quantities. In the pasteurization of fruit juices, wine, beer, etc., treatment at different temperatures and for other periods of time is effective on account of the presence of alcohol and acids, which in combination with the heating prevent the growth of microorganisms.

(See CANNING, COMMERCIAL.) (Z. I. K.)

Cold Storage. — The only method by which fresh foods may be preserved for a considerable period in the raw state is by subjecting them to as low a temperature as possible without causing damage by freezing. Storage at temperatures above freezing, in the neighbourhood of 35° F., is known as cold storage. Storage at such temperatures makes possible the holding in good condition of many fresh foods for considerable periods, and their shipment to distant markets and consumers. This has helped immeasurably to improve the variety and quality of foods in the markets of many parts of the world, notably in Europe and the Americas. Some cold storage is accomplished by means of ice which, in most cases. is produced artificially in ice-making plants. The great majority of cold storage is accomplished by the direct use of refrigerants in one or another of the mechanical or chemical refrigerating cycles, as in household refrigerators. Cold storage equipment ranges from the smallest of home refrigerators to marine, rail or motor truck refrigerated transportation and commercial warehouses.

Freezing. — It has been found that many varieties of foodstuffs can be preserved for considerable periods with excellent results when frozen and kept in low-temperature cold storage. Under proper conditions the original flavour, appearance, nutritive value and texture of many foodstuffs are preserved more truly than by any other method of preservation. The remarkable similarity of the preserved product to the fresh or unpreserved food makes this method one that is most desirable. Coupled with this is the advantage that there is somewhat less labour involved in the preservation of foods by this method than by any other, especially in the case of home preservation in relatively small quantities.

History. — Freezing, as a method of preservation of foodstuffs, is not new. It has been used probably for as long as man has inhabited arctic regions where fish, game and other meats obtained in cold weather could be frozen and kept in that state for weeks and even months by natural means.

As early as 1842 a patent was granted to H. Benjamin in England for freezing foods by immersion in an ice and salt brine. Other patents followed at intervals during the century, both in the United States and in Great Britain, covering the freezing of meats and fish by special applications of ice and salt mixtures, either by direct or indirect contact. Indirect contact was obtained by placing the ice and salt in pans over the product to be frozen or by placing the products in tightly closed metal containers which were immersed in the ice and salt mixture.

It was not, however, until the development of mechanical refrigeration that it became possible to apply this method of preservation extensively. Mechanical refrigeration first made possible the freezing and transportation of meats over long distances, chiefly by sea. The first shipment of meat from Australia to Great

Britain, about 1880, by refrigerated ship was not frozen before loading, nor was it intended that it be frozen. However, it did freeze and the results led to freezing as a standard practice.

Early in the 20th century attempts were made to preserve foods other than meats and fish by freezing. H. S. Baker, Sr., is credited with freezing fruits in Colorado about 1908. Large crops that could not be immediately marketed or processed by the commercial canners presented a potential waste unless they could be held and processed gradually over an extended period. Freezing part of the crop for use later appeared to be a solution, and experiments showed that this could be done. Only certain fruits were frozen at first by what was known as the cold-pack method. These were chiefly strawberries and cherries. The method consisted of placing alternate layers of berries and sugar in large barrels or smaller metal containers which were then placed in cold storage rooms where the temperature was maintained at $-10°$ or $-15°$ F. Held at this temperature (or slightly higher) fruits kept well and later, after thawing, could be used for making preserves or directly in desserts such as ice creams, pies, etc.

Some experimental work was done by scientists in Europe on the freezing preservation of foods. In 1916, R. Plank, E. Ehrenbaum and K. Reuter are credited with showing in Germany the advantage of quick freezing; *i.e.*, freezing in a few hours as contrasted with several days. After that developments were rapid both in Europe and the United States. Most of the early investigations and development of procedures for freezing were carried on by the United States department of agriculture, the state colleges of Washington and Oregon and the growers and packers of the American northwest. Much credit can be given to Clarence Birdseye for the development of methods of freezing foods in small containers suitable for the retail trade. He began his work about 1917, but it was not until 1929, after much experimental work had been done by General Foods corporation, that the first Birds Eye commercial pack was placed on the market. This experimentation included work on vegetables as well as fruits: and it was found that many vegetables were admirably adapted to preservation by this method. Many obstacles were in the way of the acceptance of frozen foods by the public at large, chiefly the lack of adequate facilities in the retail market for handling frozen foods, coupled with a lack of knowledge on the part of the prospective consumers of the desirability of such foods and of how to use them.

Types of Frozen Foods. — Meats, including game and fish, were the first foods to be frozen for preservation. Dairy products, such as butter and cream, probably followed, except for possible isolated experiments. Early work on the freezing of fruits and vegetables indicated that, almost without exception, fruits and vegetables could be frozen and kept in storage in the frozen condition for considerable periods. On thawing it was found, in fruits and vegetables more than in meats, that the cell structure was broken down, causing a reduction in greater or lesser degree of the firmness or crispness of the fresh foodstuff. This structural change makes for rapid spoilage after thawing. making it necessary to hold such foods in the frozen state until nearly the time for using. However, when properly prepared and frozen, fruits and vegetables are much like the fresh product, even after months of storage, while there are some claims that meat is improved by being frozen; this, if true, is a result of the tenderizing effect.

Following World War II there appeared a new kind of frozen food product in the form of prepared dishes in considerable variety. Such dishes, requiring only to be thawed and heated before serving, gained ready acceptance. By the mid-1950s more than 500,000,000 lb. of such dishes were being frozen annually in the United States. and consumption increased thereafter. With the increasing production of frozen fruits and vegetables there was an intensified effort to develop new varieties which would be more desirable for freezing from the standpoints of growing, processing and acceptability as foods.

Processing of Foods for Freezing. — Meats in general require no special treatment prior to freezing. In the case of beef and venison a period of several days of aging in a room chilled to about 35° F. prior to freezing may improve the favour and tenderness. With most other meats and poultry it is desirable that they be frozen as quickly as possible after slaughtering. Chilling to about 40° F. before cutting the meat for freezing is desirable, as it facilitates the cutting and helps to preserve the meat in the best possible condition. The reason for haste in freezing such meats is that the process causing rancidity of the fatty tissues sets in shortly after slaughtering. If rancidity starts even imperceptibly prior to freezing, it will rapidly become evident in the taste of the fat. as freezing and storing at 0° F. retards its development but does not completely inhibit the process. The table shows the periods during which different meats and dairy products, as well as other foodstuffs, may be stored with reasonable expectation of good results. Many cases are on record of foods stored satisfactorily over much longer periods than those indicated in the table.

Safe Storage Periods for Various Food Products

Foodstuff	Approximate storage period (months)		
	At 0° F.	At 5° F.	At 10° F
Beef, fruit juices	—	10 to 12	6 to 8
Fruits, vegetables, veal, venison		8 to 10	3 to 6
Lamb, poultry, rabbits, game birds, eggs	8 to 10	t o	3 to 4
Fresh pork, ham, creamery butter, cheese	6 to 8	4 to 6	2 to 3
Ground meat (unsalted), lean fish, cottage cheese	4 to 6	3 to 4	1 to 2
Beef liver, fatty fish, slab bacon, cooked foods	2 to 4	2 to 3	1 to 2

In the case of fruits it is important that the maturity of the product when harvested for freezing be that which is best for eating the fruit fresh and that only fruit uniformly ripe and free from blemishes be frozen. It is also important that a minimum of time elapse between harvesting and freezing, as deterioration sets in and develops rapidly at room temperatures. Harvesting in the cool of the morning is advantageous as the fruit is then naturally cool and does not deteriorate rapidly after being picked.

Fruits may be frozen in a sirup or a dry sugar pack. Sirups for this purpose are most easily made from sugar and water in concentrations of from 20% to 65% sugar, depending on the acidity of the fruit to be preserved and the taste of the individual. When the fruit has been prepared as for serving, it is placed in containers and cold sirup added in sufficient quantity to cover the fruit. This is to exclude air and prevent both oxidation and desiccation. Dry sugar may be used in place of a sirup when the fruit is sliced or cut so that the sugar will draw out enough juice to form a sirup and coat the fruit thoroughly. The handling of the fruit should be as rapid and as careful as possible, especially in the case of fruits that oxidize rapidly. Oxidation is evidenced by discoloration and is also accompanied by a somewhat unpleasant flavour. Browning of fruits, such as peaches and apples. before, during and after freezing may be prevented by treatment with a small amount of ascorbic acid.

The same precautions should be taken with vegetables as with fruits in the choice of quality. maturity, variety, harvesting, speed in handling and prevention of oxidation and desiccation. After preparing the vegetables as for cooking for the table they must be blanched or scalded in boiling water for from 1 min. (for peas) to as much as 10 min. (for corn on the cob).

The purpose of blanching is to inactivate the enzymes by heat, so preventing the deterioration which would take place even at very low temperatures were the enzymes to remain active. It is possible to freeze and store most vegetables for a short period without blanching; but for normal periods of storage at 0° F. blanching is essential. Without it all vegetables soon acquire a haylike flavour and deteriorate in colour. With proper blanching. however, frozen vegetables retain their colour, flavour and general appearance remarkably well.

Methods of Freezing. — There are several methods by which foodstuffs can be frozen. Essentially the problem is that of removing heat in a relatively short time. and lowering the temperature of the product below its freezing point, commonly to 0° F. or somewhat lower, which is the recommended storage temperature for frozen foods.

One of the earliest methods of freezing foods was by immersion of the product either directly or within a container in a mixture of ice and salt or a brine chilled by mechanical refrigeration. A method known as the "Z process" was developed in Europe for freezing fish by M. T. Zarotschenzeff. This consisted in passing the foodstuffs either packaged or unpackaged through a chamber in which they come in contact with an atomized, secondary liquid refrigerant, such as a brine. In the United States, R. B. Taylor and L. H. Bartlett developed a method for freezing foodstuffs naturally small in size or cut in small pieces, such as berries, peas, sliced peaches, cut beans, etc. Their method consisted in immersing'the foods directly in a solution of glucose, sucrose or sodium chloride or combinations of the three. The disadvantage of direct immersion in brine is that brine tends to penetrate into the foodstuff. The Taylor and Bartlett method tends to eliminate this effect or to produce a pleasing result in spite of some penetration.

With development of mechanically refrigerated cold storage, foodstuffs were at first simply placed in rooms at low enough temperatures to freeze them in due course in the still air. Still-air freezing is the slowest of all methods for any given temperature, because of the poor heat transfer that exists where the only circulation of air is that caused by natural convection currents. Fans placed in such rooms will help the air currents and improve the freezing rate somewhat. A systematic use of air in motion is obtained in numerous freezers developed chiefly between 1930 and 1940. Blowers are used to circulate air over refrigerated coils which chill the air, then over the foodstuffs and back to the blower to repeat the cycle. With velocities of 500 ft. per minute or more the rate of heat transfer is increased and freezing can be accomplished in a much shorter time than in still air. This is known as blast freezing.

Contact freezing is obtained by placing the foodstuffs either in packages or loose in metal trays on refrigerated surfaces: which may be either pipe coils made in the form of shelves, or refrigerated plates. Here the heat transfer by conduction through the metal surfaces is much better than that through air; the method is effective in proportion to the area of the foodstuff in contact with the refrigerated surface.

Storage *of Frozen* Foods. — Generally speaking it has been found that the lower the storage temperature the better and longer mill foodstuffs keep in the frozen state. Deterioration takes place in the forms of oxidation, desiccation and enzymic action even at very low temperatures. However, it has been found that for most foodstuffs a temperature of 0° F. (−17.8° C.) is satisfactory for normal periods of storage. Many foods will keep for several years very well at this temperature if properly processed and packaged before freezing. Therefore, 0° F. has become accepted commonly as a satisfactory storage temperature, though much storage of commercially frozen foods is at lower temperatures. However, the lower the temperature the more costly the storage, both from the point of view of the insulation of the space and the power to maintain that temperature.

An important factor in the proper storage of foodstuffs is the packaging, which must be such as to resist injury during the period of storage and which must also be of a vapourproof nature to prevent as far as possible desiccation and oxidation of the foodstuff within.

Locker Plants. — Plants or concerns devoted to the storing of frozen foods for individuals for private use and in relatively small amounts came to be known in the L.S. and Canada as locker plants. This enterprise began when farmers and hunters started early in the 20th century in the American northwest to store game or meat slaughtered on the farm in low-temperature cold-storage plants where it froze and kept quite well over extended periods As this practice gren it became necessary for the cold-storage operators, nho rented space for this type of storage, to make provision for separating the produce of one patron from that of another. For this purpose boxes were first used, and later locked closets or simply lockers, which gave the industry its name. Before long fruits and vegetables were being stored along with meats and the trade grew to the point where it was recognized as a business distinct from cold storage in the usual sense. In the late 1920s, it is believed, though there are no accurate records, the first locker plants were established to cater to this trade exclusively. The earliest growth of the locker plant industry in the L.S. was in the northwest, and from there it spread to the mountain states and on into the midwest where it grew rapidly in the heavy meat-consuming communities. During World War II public interest in frozen foods increased and the demand for locker plant facilities grew far beyond the supply, and in the years following the war expansion of the locker plant industry was rapid. However, in this same period a vigorous competitor for locker plants appeared in the form of the home freezer, similar in principle to the refrigerator for fresh foods, but maintaining the necessary 0° F. temperature. As the number of home freezers grew, the demand for locker space fell off so that after the mid-1950s the number of locker plants diminished increasingly.

Transportation.—Along with the growth of the frozen food industry and the wide-spread distribution of frozen products came the problem of transportation. This was solved satisfactorily by refrigerated railway freight cars and refrigerated motor trucks. In the former, ice with salt has been widely used, although some cars are equipped with self-contained, completely automatic, diesel-powered refrigerating systems. Most motor trucks for frozen food transportation have self-contained refrigerating systems, powered mostly by gasoline engines, but many carry tanks containing some salt solution whose freezing point is around −5° F. The solution in these tanks is frozen by electrically driven refrigerating systems on the trucks that are connected to power sources when the trucks are at their bases, or by refrigerant supplied from a stationary system through demountable hose connections. Low-temperature refrigeration is thus provided until the solution is once more thawed.

FOOD PRESERVATION (IN THE HOME). Food preservation, or the prevention of food spoilage, is of importance in providing adequate supplies throughout the year and making possible the transport of foods from areas of production to centres of need. Home food preservation makes it possible to save locally produced foods and provide more and a greater variety of foods.

The causes of food spoilage fall into two major classes: changes brought about by reactions normal to the food and changes due to outside sources. The first group includes such factors as the sprouting of grain or potatoes, development of a woody or starchy texture in vegetables, liquefaction of fresh meats or eggs and softening of fruits. These are caused by the continuance of certain chemical reactions promoted by enzymes normal to the particular product. The second class is comprised largely of microorganisms which are present everywhere and which are divided into three classes: yeasts, molds and bacteria. In a favourable situation they are in the actively growing or vegetative stage. When the environment becomes unfavourable, many types change to the spore or resting form and are much harder to destroy. The procedures used in home food preserving are based on inactivation of enzymes and destruction of microorganisms.

Yeasts are one-celled plants which live chiefly on solutions of sugars and other carbohydrates. Their growth is favoured by moisture and warmth and is usually shown by production of gas bubbles. Though this fermentation is desirable when making wines, in preserves it can cause development of undesirable flavours and odours. Yeast growth slows or stops entirely at temperatures below 37" F. (3° C.) or when the moisture content of the food is reduced sufficiently, and the cells are destroyed at high temperatures, 150°–180° F. (65°–82° C.), although some spores are more resistant to heat.

Molds reproduce by spores which are carried in the air. The different species can grow on a wide variety of organic materials. The spores develop into actively growing colonies, forming fuzzy, coloured patches or clumps which are easily seen and can be removed from the surface of the food. However, if growth has continued for some time unpleasant flavours will have permeated the food. Like the yeasts, molds are inhibited by low temperatures and most of them are destroyed by heating to 150°–180° F. (65°–82° C.), though one species found in Great Britain can withstand temperatures up to 212° F. (100° C.).

Bacteria are the most difficult to control and the most dangerous. Yeasts and molds cause souring and off-flavours, but some bacteria can cause illness and possibly death. Bacterial growth may or may not produce visible signs and many bacteria cause spoilage without any readily apparent change in the food. Bacteria can grow over a much wider temperature range than yeasts and molds. Most of them grow at temperatures of 60°–100° F. (16"–38" C.) but psychrophilic or cold-loving bacteria can grow at considerably lower temperatures, while thermophilic or heat-loving bacteria can grow at temperatures as high as 160° F. (71° C.). The vegetative cells are killed at the boiling point of water (212° F., 100° C.) but some spores require temperatures as high as 240° F. (116° C.) maintained for more than 30 minutes for their destruction.

BOTTLING AND CANNING

Canning refers, in Great Britain, to preserving food in metal containers, while bottling is used for similar preservation in glass jars or bottles; in the United States canning refers to both. Since glass containers are used much more frequently than metal cans for food preservation in the home, the term bottling will be used in this article and will include canning unless otherwise stated. Bottling depends on heating the food to inactivate enzymes and destroy microorganisms and on hermetic (airtight) sealing to prevent recontamination. In bottling the jars are sealed while hot and, provided that no air can enter while the jars are cooling, the pressure inside the cold jar will be less than that of the surrounding atmosphere so that the lids will remain firmly in place. Metal cans, however, are sealed before processing.

Foods for Bottling.—A very wide variety of foods can be preserved successfully by bottling but, since the method itself includes cooking, any food ordinarily eaten or preferred in the raw state cannot be preserved in this way. Also, the amount of heating necessary to sterilize some foods causes serious overcooking and the development of off-flavour and mushy texture. Foods selected for bottling should be fresh, clean and sound and of the proper variety and maturity. Certain varieties of fruits and vegetables, as well as certain kinds of protein foods, yield a more palatable bottled product than others.

Two essentials in the selection of an adequate processing procedure are that the temperature be high enough to destroy any microorganisms present that can grow in the food being preserved, and that this temperature be attained throughout the entire mass of food being bottled. Foods may be divided into two general classes in selecting processing methods: fruits, most of which are acid in reaction, and vegetables and meats, fish and poultry, most of which are neutral or nearly so. Not only are microorganisms more easily destroyed in an acid medium than in a neutral one but the acid prevents any dangerous bacteria from developing, so that acid foods require less heat and lower temperatures for safe processing than do neutral or nonacid foods. Another important factor is the consistency of the food. Products which are bottled as distinct pieces surrounded by liquid will heat through to the centre of the container more rapidly than foods which pack down and fill the container solidly. In the same way, larger containers will take longer to heat through to the centre than smaller ones.

Processing Methods and Equipment.—The temperatures used in bottling depend chiefly on the acidity and the consistency of the food. Acid liquid foods, such as fruit juices, need only be processed at 140° F. (60° C.) for 30–40 minutes or for a correspondingly shorter time at a higher temperature. Low temperatures are particularly useful for fruit juices in which the flavour may be changed by high temperatures. With the exception of fruit juices and similar products, all foods should be heated at least to the boiling point. In acid products, this is sufficient to destroy any microorganisms present. Nonacid foods require long holding at the boiling point (more than five hours) or, preferably, temperatures above boiling to be sure that the products are sterile. It is particularly important to destroy any spores of *Clostridium botulinum,* which can produce a deadly poison. These spores are very resistant to boiling in a nonacid medium but are killed by heating for approximately 10 minutes at 240° F. (116° C.). In an acid food they are destroyed more readily by boiling and any survivors will fail to develop. It should be borne in mind that altitude has a considerable effect on the temperature attained in processing; water boils at sea level at 212° F. (100° C.). At higher altitudes the boiling point of water is lower; the decrease amounts to approximately 2° F. or 1° C. for each 1,000 ft. of elevation. This may be compensated for by increasing the processing time or by raising the boiling point of water; *e.g.,* by using a pressure cooker. A pressure cooker, or pressure pan, is a heavy pan which can be sealed so as to retain steam under pressure. The lid has a pressure indicator or control, a pet cock or vent which can be opened and a safety plug to prevent the pressure from rising above safe limits.

The temperature obtained is calculated on the basis of steam pressure, not air pressure, and the air in the cooker must therefore be replaced by steam to obtain the correct temperature. The pressure should be kept constant during processing, thus reducing loss of liquid from the bottles.

Various methods of processing fruit can be used. The prepared fruit may be heated sufficiently to kill the microorganisms, then put into sterile containers and sealed. This method is adequate for acid foods and may be more convenient with solid fruits, softening the structure so that the pieces fit into the containers more readily. The containers and lids must be very carefully sterilized, filled with boiling hot fruit and sealed immediately so that the contents will not be contaminated. More frequently the food is placed in the container before processing, fruit being covered with sugar sirup or water and vegetables with dilute brine. Foods may be raw or partially cooked before being placed in the container.

In most cases the processing time required for a given hot-packed food is essentially the same as when raw-packed. In fact, in foods which soften during preheating to the stage where a more solid pack is obtained in hot-pack than in raw-pack, the processing time for the hot-pack will be longer than for the raw-pack. However, when dealing with large, solid pieces or highly starchy foods, preheating does reduce the time required for the material in the container to attain the correct processing temperature.

When the food is placed in metal cans, which are sealed before processing, a small free space should be left at the top to allow room for the expansion of the food during heating. Any empty spaces between the pieces of food should be filled with liquid. If the cans are to be processed above 212° F. (100° C.), provision must be made for exhausting, *i.e.,* driving out most of the air, before they are sealed.

Bottled fruit may be processed in a water bath or a pressure cooker. A water bath is recommended for fruit processed in metal cans. Nonacid foods should be processed under pressure in order to increase the temperature above 212° F. (100° C.).

Storage and Use of Bottled and Canned Foods.—Bottled or canned foods should be stored in a cool place as high storage temperatures lead to more rapid loss of vitamin content and deterioration of flavour.

Glass containers should be stored in the dark to avoid fading of the food colours.

Acid foods may be used cold straight from the can if desired. Nonacid foods should be heated thoroughly before consumption, as the botulism toxin is destroyed by boiling for 20 minutes.

Some loss of nutritional value occurs during canning, mostly of vitamins which are destroyed by heat and/or oxidation. However, if the containers are properly vented to remove air, oxidation will be kept to a minimum. Many vitamins and minerals are water soluble and a large part of the original amount in the food will be in the liquor surrounding the solid food. If this liquid is used, total nutrient losses from properly processed foods will not usually be greater than those caused by normal cooking procedures, with the exception of greater loss of thiamine (vitamin B_1).

FREEZING

Freezing as a method of food preservation depends on the marked reduction in rate of most chemical reactions at low temperatures. When food is frozen the low temperature and solid state of the water entirely inhibit the natural ripening processes or markedly reduce their rate. Growth of microorganisms ceases for the same reason. Some of the microorganisms will be killed by freezing but the products cannot be regarded as sterile since others survive and are capable of multiplying when the food is thawed. Foods can be preserved by freezing in a state close to that of the natural raw product. With the exception of vegetables, foods do not need any heat treatment before freezing, thus shortening the time required for preparation.

Since frozen foods must be held at a much lower temperature than canned foods, however, frozen storage is more expensive. The cost of suitable freezing cabinets seriously limited this as a method of preserving foods at home in Great Britain. There is little danger of food poisoning or food-borne illness from frozen foods, provided they have been properly handled. However. the growth of microorganisms when the food is thawed may be even more rapid than it would have been in the original fresh material as the formation of ice crystals during freezing tends to break up the structure of the food, softening the texture and making possible a more rapid penetration of microorganisms. For this reason foods should be kept solidly frozen until desired for use, then thawed and used immediately.

Guides for Success.—Only foods of high quality should be frozen. Unless the starting material is fresh, sound and adapted to freezing, the final product will not justify the time. effort and money. Some softening of the texture or firmness of the food will occur due to the nature of the freezing process and this should be kept in mind in any further preparation or cooking before the food is eaten.

Foods for freezing should be handled quickly and in small amounts so that they can be frozen as soon as prepared. The freezing capacity of the unit must also be kept in mind. The number of packages frozen at one time should be small enough to allow each package space for air circulation and contact with a primary freezing sarface (in contact with the coils carrying the refrigerant). If the unit is filled with unfrozen food the rate of heat transfer from the centre of the load is so slow that foods in the centre may spoil before they freeze. All foods should be wrapped in moisture-vapour-proof materials and sealed tightly. The low temperature in the freezer produces a very dry atmosphere and unprotected foods mill dry out rapidly, leading to a condition known as freezer burn. However, moisture-vapour-proof must not be confused with waterproof; many waterproof materials will hold nater in the liquid stage, but are not impervious to the passage of water in the vapour or gaseous phase. Packages should be made as solid as possible as oxygen in the air leads to undesirable changes in flavour and colour and loss of some nutrients. However, nhen foods are packed in rigid containers some head space must be allowed since water increases in volume as it freezes.

Products should be frozen and stored at 0° F. (−18° C.) or lower; higher temperatures materially shorten the storage life of the food. Variations in temperature should be kept to a minimum. Every time the temperature rises slightly the food loses a little moisture which, as the temperature falls again, does not re-enter the food but freezes inside the package. This leads to in-package drying, with eventual loss of desirable colour, flavour and texture.

Frozen foods should be used while still in excellent condition. Each type of food has a definite period of storage life during which it will remain of high quality; if stored beyond this time the food may become inedible due to development of off-flavours and odours, destruction of colour and deterioration of texture.

Foods for Freezing.—Most foods can be frozen successfully with the exception of those high in starch, those usually eaten raw for their crisp texture and those containing emulsified fat. Starchy foods tend to become sticky or gummy. Crisp raw foods and those high in water content become limp and soggy due to rupture of the cell walls by ice crystals and collapse of the tissue with excessive loss of fluids on thawing. Freezing usually breaks emulsions so foods containing emulsified fat may curdle and separate.

Fruits may be frozen either with or without added sugar or sirup. In many cases, however, the addition of sugar or sirup improves the retention of the fresh flavour and natural colour of the fruit. Light-coloured fruits which tend to turn brown when cut require treatment to prevent discoloration. Effective measures include a light blanching or scalding of the cut fruit, dipping the pieces in a solution containing sulfur dioxide, or addition of vitamin C (ascorbic acid) to the liquid in which the fruit is packed.

Vegetables should be blanched or scalded, then cooled thoroughly, before packaging. The activity of the enzymes in vegetables is decreased but not stopped by freezing. Scalding is necessary to inactivate the enzymes, or the vegetable colours deteriorate and undesirable flavours develop.

Whole egg meats and egg yolks require treatment to avoid gelling of the yolk material. Egg yolks contain lecithoproteins which coagulate at low temperatures and should therefore be mixed thoroughly with a small amount of sugar or salt before freezing to prevent this.

Many prepared and precooked foods may be frozen. Good foods for freezing are those that require long preparation, little more work when prepared in quantity than when prepared in small amounts and little attention between the freezer and the table. Mixtures should be seasoned cautiously, as some seasonings intensify or increase in flavour in frozen storage while others tend to disappear.

Frozen foods which have been carefully prepared and properly wrapped, frozen and stored will retain a large part of the nutritive value of the original food. However, some vitamins and minerals may be lost during washing and scalding of vegetables and excessive length of storage will lead to loss of nutrients as well as decreased eating quality.

JAMS AND JELLIES

Jams, jellies and other conserves depend on heat and high sugar concentration for preservation. Since they are made from fruit and are therefore acid foods, the boiling required to prepare them is sufficient to produce a sterile product. The high sugar concentration usually found in this type of food will prevent the growth of most microorganisms, although some can thrive in such an environment.

All the various kinds of jams and jellies are made of fruit and are characterized by a thick or gelled consistency which makes them relatively solid although still soft enough to spread easily. Jams contain crushed or pieces of fruit while jelly is made from the strained fruit juice; marmalades consist of slices of fruit and peel, usually citrus, suspended in jelly; preserves or conserves are whole or large pieces of fruit; while butters and cheeses are made from mashed or sieved fruit pulp.

Ingredients.—The traditional methods of making jam and jelly depend on the presence of three ingredients—pectin, sugar and acid—in addition to water, and on the balance among these four. Pectin. the primary gelling material, is present in varying amounts in all fruits and must usually be extracted by heat. Slightly underripe fruits contain a larger amount of pectin than do ripe fruits, while in overripe fruits most of the pectin has been converted to pectic acid, which has no gelling power. The pectin deteriorates if the fresh fruit is cut up or crushed and left in a warm place. Commercial pectins are also available and their use reduces the amount of cooking necessary to reach the gel stage and increases the amount of sugar that can be added to a given amount of fruit.

Sugar is added in relation to the amount of pectin in the fruit. The mixture of fruit and sugar is usually cooked to a sugar concentration of 60%–65%, indicated by a temperature of 219°–223° F. (104°–106° C.), to ensure good keeping quality. A gel may be obtained from a fruit very rich in pectin with a lower sugar concentration, but this may not have good keeping qualities unless hermetically sealed while hot. The sugar usually used is sucrose from sugar cane or beet. When purified, the sugar from these two plants is identical and can be used interchangeably. When sucrose is boiled with acid it is gradually converted into a mixture of equal parts of two different sugars, glucose and fructose, together often called invert sugar. This is an advantage, as there is less tendency for the sugar to crystallize out during storage when there is a mixture of sugars present than when any one predominates. Prolonged boiling of jam or jelly made from a very acid fruit may produce too much invert sugar; this usually separates out without any definite crystalline form. Separation of sucrose, which forms crystals like granulated sugar, is likely to occur when a fruit low in acid is added to a high proportion of sugar and boiled only for a very short time.

Acid is the third major ingredient. Both sugar and acid are necessary to change the pectin from a liquid to a semisolid. The majority of fruits used for jam making contains sufficient acid but if more is required it is often added in the form of lemon juice or citric or tartaric acid.

Preparation and Storage.—Jams are usually made in two stages. In the first, the prepared fruit is cooked slowly, with sufficient water to prevent burning, while the skins are softened and the pectin extracted from cells; in the second, sugar is added and the mixture boiled to evaporate excess water until the gelling point is reached. This occurs most readily when the sugar content is about 65%; roughly 5% of this will come from the fruit, the remainder from the added sucrose. This means that for maximum setting quality, the yield will usually be about 10 lb. for each 6 lb. sugar used. Even if a high proportion of fruit to sugar is used, a satisfactory gel can be obtained with a lower sugar concentration. A rough test for the gel stage may be made by pouring some of the boiling jam from a spoon. If the drops run together on the edge of the spoon and break off as a "sheet," rather than running off as a thick sirup, the product should set when cold.

Jellies are usually made from fruits that have good setting qualities and form a clear bright product. The fruit is cooked slowly with water and strained. A test that can be used in the home to estimate the amount of pectin in the extracted fruit juice is to mix a small amount of juice with an equal volume of alcohol. The formation of a solid clot indicates abundant pectin. Sugar is added in relation to the amount of pectin that the juice contains. A juice containing ample pectin can be mixed with an equal volume of sugar; one lower in pectin should have less sugar added. Boiling the jelly mixture results in evaporation of water and increased concentration of pectin and acid as well as sugar. This is the reason for adding less sugar to a juice containing less pectin; longer boiling will be required to reach the proper amount of sugar and the pectin will be concentrated sufficiently to gel the product. The gel stage can be tested as for jams. Jams and jellies can be made without cooking but the resulting product is not sterile so must be kept in a refrigerator to prevent spoilage.

Marmalades are made in the same way as jams, but as most citrus fruits are rich in pectin a smaller proportion of fruit to sugar is normally used and extra acid is required except for lemon, lime or bitter orange marmalade. Citrus fruits need thorough cooking to soften the peel before the sugar is added and so more water is required than in jams. Cooling the mixture to 176° F. (80° C.) before pouring it into glasses or jars helps to prevent the pieces of fruit from rising to the top of the containers.

Fruit butters are made by cooking the sieved or puréed fruit with sugar until thick and clear; spices are sometimes added. Fruit cheeses are made in the same way and boiled to give a cheese-like consistency when cold.

After these preserves have been cooked to gel stage, they should be poured into clean jars. Those with a high sugar concentration may be covered by pressing a prepared tissue on the hot surface, or by sealing with melted paraffin, and covering the containers to keep out dirt, insects and microorganisms. Those with lower sugar concentration need covering while very hot with an airtight seal, otherwise they may ferment in storage. Fruit cheeses and sometimes jellies are put into containers suitable for turning them out before serving.

A wide variety of fruits and other plant materials may be used in making products of a gelled consistency. They are usually used to add variety and interest to more staple foods rather than by themselves. Success can be achieved by careful following of directions and by experience, since many of the factors governing the gelling of these products are not easily measured.

PICKLING

Food preservation by pickling depends on the presence of acid or salt, or both, in the mixture. The growth of harmful microorganisms is usually inhibited by a sufficient concentration of acid or salt. Either vegetables or fruits may be made into pickles but the methods and type of finished product are quite different.

Vegetables used for pickling are usually high in water content, some of which must be removed. This is achieved by the addition of salt, since the salt solution will be more concentrated than the vegetable cell sap and some of the water will be drawn out of the vegetable to equalize the concentration. When natural fermentation is desired, as in making sauerkraut, salt is added in amounts of 2%–4% of the weight of vegetable. This amount of salt will check the growth of undesirable bacteria but allow the multiplication of acid-producing bacteria. When the acidity becomes high enough the product will keep in a cool place if protected from molds and yeasts. A fermentation process continued for several months is used commercially in the curing of vegetables prior to packing them in vinegar. In the home a quick brining process is generally preferred. The prepared vegetables are usually held for 12 to 48 hours in a 10% brine or sprinkled with salt and subsequently rinsed to remove any excess of salt. To produce a clear pickle, the drained vegetables are packed in jars and covered with spiced vinegar. In a mustard pickle or piccalilli the vegetables are mixed in a sauce containing vinegar, mustard and turmeric. In fruit pickles, preliminary brining is not necessary and the prepared fruit is heated with sweetened spiced vinegar.

Whereas in pickles the fruits or vegetables are kept in recognizable pieces, in chutneys they are cooked to a pulp. The main ingredient is usually a fruit, with onions, garlic or similar vegetables for flavouring. Vinegar forms the chief preservative with sugar, salt and spices. Chutneys are cooked slo ly to a smooth, jamlike consistency.

Sauces are made from essentially the same ingredients as chutneys but are sieved and should be of a pouring consistency.

Pickles, chutneys and sauces should be stored in jars or bottles and sealed to prevent evaporation. The covers used must also resist attack by acetic acid. Some of the sweeter pickles and sauces contain insufficient acetic acid to prevent spoilage and should be processed in a water bath and hermetically sealed while hot. Pickles, chutneys and sauces, like jams and jellies, are usually used to give variety and flavour to a meal. In general, their nutritive value tends to be rather low, especially in the water-soluble vitamins and minerals.

SIRUPS

Fruit sirups can be made from soft fruit that is too ripe to be used for most methods of preservation. The juice is extracted, with the minimum addition of water, sugar is added and the resulting sirup is preserved by means of heat or with chemical preservatives. Black currant, rose hip and citrus-fruit sirups may be useful sources of vitamin C.

CANDIED FRUITS

Candied fruits are made by cooking whole fruits or fairly large pieces of fruit in sirup until the fruit is clear and plump. To avoid shrinking the fruit the sugar concentration must be increased gradually. If the fruit is put directly into a heavy sirup, the water in the fruit will be drawn out because of the difference in concentration of the solutions inside and outside the fruit and the fruit cells will collapse, shriveling and toughening the pieces. Finally, the pieces are drained from the thick sirup and dried slowly until no longer sticky.

FOODS, NATIONAL. There are many similarities in indigenous foods and therefore in prepared dishes among different countries and cultural groups. All countries use frying, baking, grilling and steaming; combinations of meat and vegetables for main dishes are popular all over the world; custards are universal; and every country has sweet cakes and flaky pastry; yet each individual dish is distinctly different from the others. The idea of a foreign food may be said to be attributed mainly to the particular combination of ingredients and the use of unfamiliar flavouring, but also to the variety of fruits and vegetables and the treatment of food materials.

The eating patterns of countries may vary considerably and are influenced by economy, geographical location and religious beliefs. Thus lack of refrigeration enforces greater emphasis on salted or dried foods where production is seasonal; a preponderance of cereal grains is inevitable in the diet of overpopulated and underdeveloped areas; and access to the sea encourages the use of sea foods. So-called typical dishes may alter with new knowledge and facilities, changing economy and the advent of other culture groups. On the other hand, some dishes continue throughout changing times because of high palatability.

UNITED STATES

In the mainly urban population highly developed, competitive food industries market every conceivable item with few seasonal restrictions. Food may be bought partly or totally prepared, packaged flour mixes abound and canned and frozen precooked foods need only heating.

Among meats. beef is the most popular, although large amounts of fresh and cured pork are used; other meats are of minor importance. Cooking of meat is generally plain; grilling. broiling and roasting being the usual methods, but less tender cuts are often braised or stewed with vegetables. Juicy grilled or broiled steaks and medium-rare rib roast of beef are well liked but are relatively expensive; ground beef is used in a great variety of ways and grilled hamburgers compete with "hot dogs" (wieners or frankfurters) for the most popular lunch. Roast turkey with cranberry sauce is the traditional Thanksgiving main course, with pumpkin pie for dessert; chicken and turkey — particularly chicken —are served around the year. Fried chicken is thought of as a typically southern dish but is common throughout the country; with the widespread use of charcoal and other broilers, broiled chicken became popular. Barbecued beef — often but not necessarily cooked over an open fire—is a typical western food. Fish is used in only limited quantity but certain dishes are associated with certain parts of the country — for example, clam chowder and lobster with New England and various shrimp dishes, including shrimp creole, with the south Atlantic and Gulf states.

The commonest bread is commercially baked of white flour, the loaf being very white and soft with moist cakelike qualities, but other types are available in almost all grocery stores. Among hot breads, corn bread, made of ground corn (maize), is thought of as southern but is served throughout the nation. Milk and eggs are used a great deal. Among breakfast combinations, ham and eggs are frequently thought of as the one typically American dish but bacon and eggs are commoner. Prepared cereals are frequently served for breakfast; griddle cakes and waffles are popular but are more likely to be served for special occasions. Unripened curds and aged cheddars head the list of cheeses; cheddars are often softened by processing. Fruits of all types abound and fresh citrus is popular for breakfast. Vegetables are mainly cooked in water and seasoned only with butter. Boston baked beans are well known. Salads of fruits and vegetables are endless in variety and range from a simple accompaniment to a meal to the main course itself, especially for the midday meal. Ice creams in a great variety of flavours and apple pies are popular desserts. Black coffee of medium roast is the main beverage. The U.S. also has a rich heritage of national foods from other countries, and restaurants specializing in Italian and Chinese foods, for example, are common in all larger cities.

GREAT BRITAIN

Cooking is generally simple with the emphasis on roasting and baking and few seasonings or sauces detract from the natural flavour of foods.

Breakfast is traditionally of fried bacon and eggs, followed by toast with butter and marmalade, but smoked haddock and herring (as kippers) are popular alternatives.

The midday meal is frequently of roast meat with boiled vegetables and a dessert of fruit pie and custard. Roast beef with Yorkshire pudding is famous, the latter being made from a thin batter baked in a little hot fat often around the meat. Except in Yorkshire, where it is eaten first, it is served with the meat and roast potatoes. A variation of Yorkshire pudding is called toad-in-the-hole, when sausages are baked with the batter to form a main dish. Roast lamb is served with mint sauce, roast pork (stuffed with sage and onion forcemeat) with applesauce. Grilled lamb chops, rump steak, steak and kidney pie and steamed steak and kidney pudding are other favourites. Many counties are well-known for their special dishes, including Lancashire hot pot—lamb or mutton chops stewed in a casserole with layers of sliced potatoes, onions and mushrooms — Cornish pasties and Melton Mowbray pork pie. Popular are boiled cod with parsley sauce and fried fillets of fish, especially plaice — indeed, "fish and chips" (fried fish and fried potatoes) has become a byword, particularly in northern England.

Both white and whole meal brown breads are eaten and there are many types of richer yeast doughs; *e.g.,* Bath buns, Sally Lunns, Yorkshire teacakes, Chelsea buns, lardy cake and bara brith, the national bun loaf of Wales. Fruit pies and plate tarts, particularly made with apples, are common for dessert, and so are steamed puddings. The plum pudding traditional at Christmas time is a rich steamed pudding with dried fruit, currants, sultanas, raisins, suet and brown sugar. The Christmas cake is a rich fruit cake first covered nith almond paste and then white icing. Buttered scones are popular for afternoon tea and in Scotland they are baked on a griddle or may be dropped scones such as small thick pancakes which are buttered without splitting.

Oatmeal is used frequently in Scotland, where porridge, oatcakes and haggis (*q.v.*) are particularly famous. Herrings are split open and dipped in oatmeal before frying. Scotch shortbread is a rich biscuit of butter, flour and sugar.

Potatoes and cabbage appear often in Irish cooking. Irish stew consists of mutton cooked with potatoes, onions and stock until almost all the liquid has been absorbed. Mashed potatoes replace flour for scones baked on a griddle, which are split open, buttered and eaten hot. A common country dish is boiled bacon or pig's cheek with cabbage. Carrageen moss is an edible seaweed made into a sweetened jelly and eaten with cream.

Throughout Great Britain tea with milk is the most popular beverage. The midmorning habit of "elevenses," consisting of coffee and biscuits, appears to have originated there.

THE BRITISH COMMONWEALTH

Australia and New Zealand. — English cooking combined with indigenous foods characterizes the dishes, together with both

American and Chinese influences.

In Australia cooking is plain with plenty of meat, a variety of vegetables and few sauces. Bacon and eggs for breakfast are popular and so is the roast beef of Great Britain. Fish is plentiful and shellfish, crayfish, lobster, prawns and oysters are favourites. The barramundi, a fish from Queensland, is stuffed with prawns and crayfish and baked in wine and butter for a special occasion. Oysters with steak are not unusual and a carpetbag steak consists of a two inch thick steak cut to form a pocket and stuffed with oysters and mushrooms. A fried egg is also often served with grilled steak and roast pork with cloves and pineapple is another favourite dish.

There are plenty of salads and vegetables all the year round. Salads, which are often combinations of vegetables and fruit, are eaten either as a main course or with the main dish. *Aubergines* ("eggplant") capsicums and pumpkins are well liked, the latter being used as both a vegetable with meat and as a filling for a dessert pie.

World-famous among sweets is Pavlova: a meringue shell, crisp on the outside and like marshmallow inside, filled with whipped cream and fruit, often passion fruit; it is a typical festive dish. Apple blossom pie is also a national dish: a sweet pastry crust is filled with three layers, first a mixture of apples and passion fruit, then a layer of condensed milk, egg yolk and lemon juice, and topped with pale pink jelly whipped with beaten egg white and decorated with whipped cream. Sponge cakes filled with whipped cream and raspberry jam and chocolate cakes with fudge frosting are popular at tea time and lamingtons (sponge squares dipped in chocolate icing and rolled in dessicated coconut) are well-known favourites. In New Zealand the national skill is particularly displayed at tea time in the scones, fruit or nut loaves, biscuits and cakes. Cakes and biscuits are frequently made with whole meal flour, while nuts, dried fruit, brown sugar and treacle are common ingredients. Typical are the crisp round biscuits called anzacs, and a light sponge filled with cream and passion fruit pulp is also very popular.

Canada. — Both French and American as well as British cooking has influenced the national dishes, with original salad mixtures, fish dishes, crisp cookies and maple sirup as a characteristic flavouring. Gammon rubbed with mustard and brown sugar and baked in pineapple juice is a popular meat dish, as is roast turkey with chestnut stuffing. Salads are often sweet and savoury mixtures; *e.g.*, oranges and tomatoes mixed with tomato sauce and orange juice, or celery, pears, peanuts and capers dressed with mayonnaise and lemon juice and served on lettuce leaves. Blueberry, pumpkin and lemon chiffon pies are popular desserts. Popovers are made from a light batter baked in small tins, sometimes with fruit, and are served with butter and maple sirup. Both maple and pumpkin sirups often accompany pancakes and waffles. Maple nut cakes, coconut cookies and brownies are typical.

South Africa. — Many of the national dishes are of Afrikaans origin or developed from those brought from Malaya by early settlers. *Sosaties* consists of cubes of lamb grilled on a skewer, but first soaked in a marinade of browned onions, curry powder, vinegar, chutney, orange or lemon leaves and seasonings, which is afterward strained and served as a sauce with the meat. Boiled rice and chutney are accompaniments. In another dish, *bobotie,* minced cooked meat is flavoured with onions, chopped almonds, raisins and curry powder, covered with an egg and milk mixture, and baked. *Koesisters,* plaits of pastry dough fried in deep fat and soaked in chilled sirup, are eaten as biscuits with coffee. A delicious sweet is *melktert,* a thickened cinnamon flavoured custard baked in a pastry crust.

EUROPE

France. — The French above all have developed cookery into an art. Herbs, spices and wines are delicately blended to give subtle, tantalizing flavours and sauces are often used to enhance the natural flavour of foods.

Specialities of the soup course are broths and bisques. A clear, well-flavoured stock, devoid of fat as in a consommé, is typical of the broths which are served with crisp croutons of fried bread; the famous French onion soup consists of onion rings, cooked in butter, in a well-flavoured stock. Shellfish are widely used for bisques, which are often enriched by folding in whipped cream immediately before serving. The classic Mediterranean fish soup, bouillabaisse, prepared to perfection in Marseilles, is made from eight or more different fish.

A substantial white bread loaf with a crisp crust is often baked in a characteristic long shape. *Croissants* (sweet crescent-shaped flaky rolls) are eaten at breakfast and often with hot chocolate.

A frequently used meat is veal that combines well with ham, mushrooms and other vegetables or elaborate sauces, whereas escalopes of veal can be quickly and simply prepared by coating in egg and crumbs and frying in butter. Veal, chicken or fish may be cooked in their own juices in parchment paper; seasonings and often herbs are added to the individual portions, which are securely wrapped for cooking and then served still in the covering. Typical of the popular grilled fillet of beef are *tournedos,* small fillets of about three ounces served on rounds of fried or toasted bread, which absorb the juices, and accompanied by a particular sauce or garnish which gives the dish its name. Stews are numerous and varied, red and white wine being used as well as stock.

Salads are very popular and generally consist of a single vegetable with a vinaigrette, oil and vinegar, dressing. Plain dressed lettuce is always served with poultry and game. Salads with mixtures of raw and cooked vegetables and also meat, poultry and fish salads are also found. Vegetables are varied and often served as a separate course, young tender vegetables being cooked quickly and flavoured with browned butter. Potatoes are cooked in numerous mays, including mashed with butter and milk to give a typical soft purée, cooked, sliced and fried with onion rings. Potato duchess, made by adding egg, butter and seasoning to mashed potatoes, is used to garnish meat dishes by piping the mixture through a bag with a star pipe and then browning in the oven.

Pastries and cakes are artistic and often require considerable skill. The puff pastry for fruit or cream tarts begins with a thin pastry dough which is rolled out and spread with a layer of softened butter; the process is repeated several times and cases of various shapes are cut before baking. The French dessert course is of a light and airy nature. Soufflés are numerous and so delicate in texture that they must be served directly from the oven. Éclairs and tiny profiteroles are made from a rich *roux* into which eggs are beaten and which is piped through a plain pipe in a bag and then cooked in a hot oven. They are then filled with cream and coated with icing or sweet sauce. **A** rich spongy yeast dough with currants is used to make babas, often round cakes which are soaked in rum sauce for serving. Caramel is a popular flavour and cream caramel custard a favourite dessert. Crepes suzette are rich thin pancakes spread with sweetened orange-flavoured butter, rolled up, covered with liqueur and set alight just before serving. *Petits fours* may be tiny decorated cakes, crystallized fruits or bonbons.

The French excel in using eggs in many ways, frequently as a main dish, but milk is not used extensively except for making cheeses, of which there are several hundred kinds. Roquefort, a salty cheese made originally from ewe's milk and treated with a greenish-blue mold, originated in France; soft-ripened Camembert is another typical cheese.

Coffee and chocolate are the favourite beverages. Strong coffee may be diluted with an equal quantity of hot milk to produce the familiar *cafe' au lait.* The origin of the use of bitter roasted chicory is attributed to the French, although it is not used consistently.

The Netherlands. — A characteristic of Dutch cookery is that typical dishes are based on nourishing ingredients; this is probably because the evening meal is generally the one liot meal of the day. Cheese and boiled eggs are eaten for breakfast with a variety of breads and butter and jam. The midday meal is of a sandwich type; *e.g.,* breads and rusks topped with liver sausage, ham or rare-cooked beef, to which a fried egg or an omelette may be added. Dinner is of three courses: (1) soup, of which those made with eels, beans and peas are all famous; (2) a main dish of meat or fish with potatoes and several vegetables; and (3) a sweet or fruit. Methods of cooking are simple, so that food takes little time to prepare, but the former Dutch possessions overseas have influenced national dishes in the use of rice and spices.

Vegetables are cooked by steaming with butter and are often flavoured with spices, particularly nutmeg and cinnamon. Dried peas and beans—staple articles of diet—are soaked overnight in water, then simmered gently until tender; they may be served with fried bacon, fried onions or gravy. Among other popular vegetables are beetroot served with apples and nutmeg, stuffed cabbage, endive with a nutmeg-flavoured sauce and red cabbage with apples and nutmeg. Much fish is eaten, particularly herrings and plaice. Salted and smoked herrings are famous and uncooked smoked herrings are a national dish. Beef, often cooked rare and sometimes eaten raw, pork and veal are the preferred meats, of which joints may be stuffed or boned and rolled. Small fritters made of yeast dough served hot with melted butter and sugar are frequent features at fairs and carnivals. Pancakes filled with jam or served with treacle or brown sugar are well liked. A popular pudding called John in the sack is made from a yeast dough mixed with milk and egg, with raisins, currants and citrus peel added. It is then put to rise before being wrapped in a cloth and boiled. This is served with butter and brown sugar or treacle. Dutch Edam and Gouda are mild smooth-textured cheeses which may be flavoured with carraway seeds or cloves. Tea without milk and coffee with cream are the main hot beverages.

Belgium.—Although influenced by French and Dutch cuisine Belgium has a number of typical national dishes. One of these is the *waterzoie,* a chicken broth which includes dry white wine. A similar soup is also made with several different kinds of fish. The *carbonnade flammande,* one of the best known Belgian dishes, is essentially a beef stew cooked in a brown sauce made with beer and served with plain boiled potatoes, so that the sauce can be appreciated fully. The popular fricandels are minced meat balls made nith fresh pork which, after frying. are poached with potatoes in white wine. beer or stock. A typical dish from the Ardennes is rabbit with prunes: the meat is steeped in a marinade of red wine vinegar and herbs and simmered in red wine with previously soaked prunes. Chicory, asparagus and hop shoots are favourite vegetables. Chicory is often eaten raw as a salad. or cooked slowly in the oven in a covered dish with butter and seasoning. Cooked heads of chicory are also wrapped individually in a slice of ham and covered with cheese sauce to make a main dish. Among the desserts are rich waffles made from yeast dough enriched nith eggs, butter and cream, and a flaky pastry tart with a sweet filling of cream cheese, sugar, butter and eggs. Brown spicy biscuits (cookies) cut in animal shapes and iced in white and pink are traditional for the feast of St. Nicholas.

Germany.—Characteristics of German cooking are the use of sweet sauces and garnishes for meat and poultry, substantial beer soups. many kinds of sausage and fermented cabbage (sauerkraut), consisting of layers of shredded white cabbage sprinkled with salt and carraway seeds and pressed down in a special kind of tub for three to four weeks. Plenty of bread, particularly pumpernickel, a dark whole meal rye bread. is served at all meals.

Weissbiersuppe consists of a light-coloured beer flavoured with cinnamon and lemon and thickened with potato flour. A favourite fish dish is carp cooked in beer. Both fresh and salt herrings are used a great deal. Rollmops are filleted raw herrings spread with chopped shallots, capers and sliced gherkins, rolled up and skewered. They are put in a jar with a few mustard seeds and peppercorns and covered with wine vinegar, and are ready to eat in a few days. Pork, beef and veal are the favourite meats, pickled pork with sauerkraut being a famous dish; pork chops with plums, stewed in mine, or roast loin of pork stuffed with prunes are also typical. Roast goose is stuffed with apples, chestnuts and raisins, mixed with the liver and giblets. An orange cake with rum icing is popular, and a rich sweet pastry mixed with eggs is used for an open tart with apple purée and chopped almonds. Cinnamon, nutmeg and almonds are used to flavour small cakes and biscuits. Cheeses include the strong-smelling Limburger and also Tilsiter. Light beer, frequently drunk with meals, and medium roast coffee are the usual beverages.

Austria.—Austrian soups are rich and substantial and often a meal in themselves, with the addition of forcemeat balls, dumplings, rice sausages and vermicelli or noodles. Beef broth with liver dumplings is typical. Fresh-water and salt fish are both popular. Dishes, of which paprika is a frequent ingredient, are often highly seasoned. Pork, veal and venison are eaten extensively and veal or beef goulash is popular. A favourite dish is Wiener schnitzel: very thin slices of veal from the fillet or leg are floured, coated in egg and white bread crumbs, fried quickly and served at once with a garnish of lemon slices. Goose is commoner than chicken and a characteristic dish is *kalte Gans,* cold roast goose with cucumber salad flavoured with chopped dill or caraway seeds. These two flavourings are used in many dishes and sauces. Pheasant *Zigeunerart* is stuffed with previously cooked snipe, fat salt pork and truffles.

Austrian pastries are world-renowned, with *Apfel strudel* the particular speciality: a plain pastry dough is pulled to paper thinness on a floured cloth, covered with fried bread crumbs, sliced apples, currants, sugar and cinnamon, then rolled up and baked before cutting into slices. Other fruits are used as well and also sour milk or cream with eggs, sugar, raisins and currants. Yeast doughs are used for sweets and cakes. *Gugelhupf* is made in a special fluted tin and served with coffee or chocolate topped with sweetened whipped cream.

Hungary.—The use of paprika to give the characteristic bright red colour to soups, fish and meat dishes. is typical of Hungarian cookery. So too is the use of fresh green and red peppers, sour cabbage and sour cream. Hungarian goulash is a national dish which may be either a soup or a stew. As a stew equal quantities of beef and onions are cooked slowly with a liberal sprinkling of paprika, very little liquid, tomato purée and a flavouring of caraway seeds. This is served with potatoes, rice or very small dumplings. Chicken paprika is a similar and another characteristic dish. Cherry cake and a poppy-seed cake are typical sneets. Lipto (Liptauer) cheese is made from sour milk and flavoured with capers, anchovies, onion and paprika.

Poland.—Among the Slavonic nations Poland has a distinctive cookery of its oun dating back for many centuries. Basically Slavonic, it is tempered by a sense of balance and proportion common to western cultures. There is a choice of soups of which the cold *chlodnik* (a salt cucumber soup with sour cream) is perhaps the most original. Fresh-water fish are prepared in many ways, the most popular being *karp po polsku* (carp stuffed with veal forcemeat). *Potrawka z rakow* is a tasty dish of crayfish with groats or rice, flavoured with dill. Beef, pork and venison are the commonest meat dishes; *zrazy z kasza* (rolled and stuffed filet steaks with buckwheat groats) and *bigos* (sour cabbage with meat. game, mushrooms, apples and tomato *purée*) are perhaps the most popular. *Flaki popolsku* (tripe prepared with dumplings, grated cheese, paprika and marjoram) is a delicacy. There is a great choice of vegetables, desserts and pastries. Black coffee or China tea (without milk) are the hot beverages.

Italy.—Italian cooking is varied. each region or province often having its onn specialities or variations of a national dish; *e.g.,* in Bologna spaghetti is served with a rich sauce of minced beef, tomatoes and mushrooms.

Among soups is the famous minestrone: made with fresh young vegetables, it is very thick and served either hot or cold, sprinkled with grated Parmesan cheese.

Pastas made from eggs nith either flour, semolina, maize or potato flour appear in many shapes—shells, spirals, tubes and noodles, for instance. The name often varies with the thickness or length of the paste. Pasta is properly cooked *al dente* (literally "to the tooth"), not sticky or mushy. and may be served with cheese alone, or with some kind of tomato or meat sauce. Ravioli are small cushions of broad noodle paste either plain or filled; *e.g.,* with spinach and forcemeat. Rice is used for *risottos,* the best-known perhaps being *alla Milanese,* when the rice is cooked in butter with beef marrow, stock, wine and saffron and served with grated cheese.

Vegetables are important in the menu and include globe artichokes, asparagus, beans, peas, small marrows, sweet peppers or capsicums (yellow, red and green) and also celery and *aubergines*. Fennel1 and oregano are herbs frequently used. Raw salads with oil and wine vinegar are served as an hors d'oeuvre or antipasto. Potatoes are used in soups and gnocchi.

The Neapolitan dish pizza may be either savoury or sweet: bread dough ¼-in. thick is covered with tomatoes, crisscrossed with anchovy fillets and baked, then sprinkled with cheese and browned. As a sweet, short or puff pastry is used and one version is spread with honey, spice and nuts and rolled before baking.

Fish of all kinds are used, including eels, lobster, crayfish, scampi, crabs, scallops, clams, oysters and mussels. The fish dishes of Venice have been famous for centuries.

Beef, veal, lamb, chicken and pork are generally roasted, grilled or fried.

Sweets are not usually served, fresh fruits being more popular, but *zabaglione* is a famous dish made from egg yolks, sugar and Marsala wine beaten together over hot water to form a light and frothy mixture.

There are many varieties of cheeses, notable among them being mozzarella, a soft creamy cheese made from buffalo milk, the well-known Gorgonzola and bel paese.

Coffee is the favourite hot beverage, an unusually dark roast producing a distinctive flavour.

Spain.—Spanish food is characteristically rich, colourful and highly seasoned. Oil is used a great deal for frying and baking and garlic, chili peppers, paprika and cumin are common seasonings. Mixing many foods into one dish is illustrated by the well-known paella which may consist of chicken, lobsters, crabs, mussels, clams, scallops, scampi, globe artichokes, french beans, peas and rice, flavoured with garlic and saffron. Colour is added to dishes by using tomatoes and sweet red and green peppers.

Substantial soups with many ingredients, mainly vegetables, are common and may be thickened with rice and vermicelli. A typical soup has little forcemeat balls added to a good meat stock. Another, la fabada, which is a meal in itself, includes salt beef, ham, black pudding, haricot beans and special local sausages, the meat and sausages being served separately after the soup. Chicken, pork, lamb and mutton are common meats. Salads are very popular, including both raw and cooked vegetables, *e.g.,* pimentos and *aubergines,* tomatoes and runner beans, as well as crisp leaves of lettuce or endive with an olive oil dressing. A great many olives are also eaten. Sweets for dessert often are not served but sweetmeats such as all sorts of crystallized fruits and *turrón* (a kind of very sweet nougat flavoured with vanilla and nutmeg) are universal. Churros, which are eaten for breakfast with chocolate or coffee, are fritters made of chou paste piped into hot fat, where they puff up into long curls; they are sprinkled with sugar for eating.

Portugal.— The food is similar to that of Spain, but simpler and less exotic. Eggs, fried, scrambled and as omelets, are staple food and fresh raw fruit such as oranges, watermelons and many varieties of grapes are eaten as dessert.

Mexico.—Mexican cookery is often considered synonomous with that of Spain, but the food is more highly spiced with hot chili peppers and dishes are frequently made from tortillas. The tortilla, the bread of Mexico, is a thin unleavened cake cooked quickly on a hot ungreased griddle. The flour is made from finely ground lime-treated corn or maize but white flour also may be used. Enchiladas are rolled tortillas filled with minced beef, chopped onion and grated cheese and baked in a spicy tomato sauce. Another popular use of the tortilla is a *tostado,* a crisp envelope made by sautéing the tortilla in a little hot fat and folding once to hold a mixture of lettuce, green peppers, onions and cooked meat. Tamales are also very common; they are made of cornmeal mixed with minced meat and seasoned with chili peppers, small portions of which are wrapped in cornhusks and steamed. Butter beans and rice are mainstays of Mexican cookery. Beans are often just boiled, mashed and sautéed, or may be baked in a casserole with bacon, onions, tomatoes and treacle. *Verdulagas* (vinelike greens) and *nopales* (prickly pear cactus), wild plants indigenous to Mexico, are chopped and cooked in water, which is discarded; bacon fat, garlic and onion are then added and the mixture simmered in a tomato sauce, which may be enriched with eggs. Chili peppers range from very mild to peppery hot; one dish is of stuffed long mild chilis dipped in batter and fried. A popular salad is made of mashed avocados mixed with chopped raw tomato and onion. Mango and papaya are common fruits often eaten at breakfast. Chocolate is a popular beverage, characteristically flavoured with cinnamon. Typical candies are made from cactus and sweet potato.

Scandinavia.— Cooking is influenced by the cold climate and short growing season, particularly in the north, and by accessibility to the sea.

Norway.—Quantities of fish and salted meats are eaten. Fish are frequently bought alive so that they are eaten very fresh. Smoked meats are also common, particularly smoked mutton which is eaten both raw and cooked. Smoked reindeer tongues are a delicacy. Chicken is stuffed with butter and parsley for roasting.

Many varieties of hors d'oeuvre are served with rye bread, including salted herrings, smoked salmon, anchovies and shellfish. This is not unlike the smörgasbord of Sweden which characteristically consists of a variety of both hot and cold dishes eaten with bread and butter and intended as a prelude to the main course.

Sweden.—Herrings are a basic food, eaten salted and raw with a dressing of vinegar. The crayfish season in August is a good reason for kraftor parties, at which these miniature lobsters are eaten and schnapps is drunk. Dill is a frequent flavouring herb, dill sauce being popular with fish and lamb. A typical Swedish jam is made from lingonberries, which resemble cranberries. The characteristic Swedish limpa bread, a yeast dough with a cakelike consistency, contains a high proportion of rye flour and is flavoured with treacle and orange peel.

Denmark.—Soups are substantial enough to form a complete meal; *e.g., gule arter* made with pork and yellow split peas. Flour dumplings and forcemeat balls are often added. A sweet buttermilk soup is made with ground rice, lemon, cinnamon and chopped almonds. Much fish is eaten, particularly cod, which is boiled and served with mustard sauce, and also mackerel, plaice, salmon and shrimps. Beef, veal and lamb are roasted and stewed, and pork, chicken, duck and goose are also common: duck is stuffed with apples and prunes and roast goose, served with stewed red cabbage, is traditional on Christmas Eve. Stewed rhubarb and red currants are common with hot meats and poultry. Among vegetables caramel potatoes are outstanding. Potatoes are boiled in their skins, peeled, rolled in sugar and fried in butter. For salads cucumber and beetroot are well liked. A favourite summer sweet is rodgrod, a fruit jelly made with fresh currants and raspberries and thickened with potato or corn flour. Other sweets are apple cake, pancakes and doughnuts. The world-famous Danish pastries consist of a yeast dough, enriched by rolling in butter as for flaky pastry, formed into different shapes with fillings such as almond paste, vanilla *crème* or prunes, and then baked. They are often eaten for breakfast. Danish blue cheese is well known and other distinctive varieties include Danbo, Fynbo, Elbo and Samsoe. In Denmark cheese is always cut in very thin slices.

The Danish *smørrebrød* are open sandwiches with hundreds of different toppings on thickly buttered bread, usually of rye. Typical is the Andersen sandwich of buttered dark or light rye bread with a topping of crisp fried bacon, liver paste and tomato slices, garnished with horseradish and jellied consommé. Another is tartar med aeg, chopped raw steak spread on buttered bread, in the centre of which a raw egg yolk is circled by a ring of raw onion.

Greece.—Lamb is the favourite meat and grilling the usual method of cooking. At Easter whole animals are roasted. Small pieces of meat (souvlakia) are marinated in oil with onions and herbs, then placed on a skewer alternately with tomato, onion, mushroom and bacon before grilling. This is served with boiled rice. A famous national dish, *moussaka,* is made of alternate layers of minced meat, first fried in oil, and sliced vegetable such as aubergine or potato, covered with a cheese sauce and baked in the oven. A typical soup, *avgolemono,* consists of chicken stock in which rice is cooked, enriched with eggs and flavoured with lemon juice. Olive oil is the popular cooking fat. Baked fish, using bream or mullet with onions, tomatoes and garlic, is another national dish. Grilled eel, fried octopus or mussels and fish soups are also liked.

Rice dishes are popular, the pilafs being very like those of Turkey, whose cookery has obviously influenced that of Greece. Vegetables are stuffed with cooked rice and raw minced meat flavoured with herbs; vine leaves (dolmas), cabbage, lettuce, pimentos and courgettes are also prepared in this way. A salad of shredded white cabbage with olives, capers, beetroot and beans, dressed with a vinegar and oil dressing is frequently served with *souvlakia.* A shortbread, *kourabiedes,* is made from butter, flour and icing sugar worked together and baked very slowly, cut into fingers and coated in icing sugar. This is eaten on festive occasions. An unripened Fedde cheese is eaten with bread for breakfast and enclosed in pastry for snacks. Sweet black tea and Turkish coffee are the favourite hot beverages.

ASIA

Turkey and **the** Arab World. — In Turkey mutton, rice, vegetables and oil are characteristic ingredients. Kebab, a famous dish, consists of small pieces of fat breast of lamb marinated in vinegar with oil, onions, cloves and parsley, then grilled on skewers and served with pilaf (rice cooked so that it absorbs all the liquid and is quite dry with every grain separate). *Aubergines* are a popular vegetable and vine leaves or spinach stuffed with forcemeat of uncooked minced mutton, rice, herbs and spices are also favourites. Sesame seed paste is very popular. Tihini may be seasoned with lemon and served with fish or vegetables or sweetened for a spread on crackers. The well-known sweet halva is made of crushed sesame and sugar sometimes flavoured with chocolate and containing almonds. Two unique breads may be found. *Balady* bread, a mainstay of the Egyptian diet, is baked in small, round, very flat "loaves" which easily open into an envelope for filling. Fool *medames,* well-seasoned beans baked very slowly overnight. are the commonest sandwich filler. A similarly shaped loaf turns out to be a hollow ball of crisp texture. Baklava, a flaky pastry with almonds and honey, is a favourite dessert.

India. — The economy and religious practices of India preclude the use of much meat and therefore grains constitute the mainstay of the diet — particularly rice, dhal (a split pulse resembling lentils) and chapati, the bread of India. It is eaten with everything except rice and is made from wholemeal flour mixed to a stiff dough with water, rolled out thinly like a pancake and baked on a griddle. Other characteristics of Indian cooking are the use of ghee (clarified butter from buffalo milk) instead of oil, and the use of spices, especially the distinctive curry flavour. For best flavour the spices from which curry powder is made need to be freshly ground, the ingredients including turmeric, cummin and coriander seeds, ginger, pepper, cardamon, fennel, chilies, mace, cloves, mustard and poppy seeds in varying proportions. Curries may be made with meat and vegetables or vegetables only. Lamb and chicken are eaten extensively. beef by some groups. The large Dublin Bay prawns or Norwegian lobsters are a favourite fish. *Dopiaza* curries have a small quantity of rich sauce that has been reduced during the cooking; kofta curries are characterized by the forcemeat balls made from minced or pounded chicken, pork, lamb, beef or fish. Many kinds of vegetables are used for curries (chankees) and mashes (bhurthas), the chief ingredients of which are onions, green chilies and lemon juice.

Aubergines, yams, okra, capsicums. potatoes, beans and peas are popular vegetables and are frequently cooked in butter flavoured with cummin. Rice is always served with curry. as are side dishes of various fruit chutneys and Bombay duck, a small phosphorescent fish which is dried, salted and toasted and sprinkled over the curry dish. Milk is used a great deal for cooking, making sneets and yoghurt or soft cheese. Curds (*dahi*) are made from soured milk allowed to stand and may be served as a sweet with sugar or with salt and rice. Curds are mixed with sugar, ground almonds and butter, spread in a dish and decorated with lightly fried sliced blanched almonds. Tea and coffee are both taken as hot beverages.

U.S.S.R.—The distinction of Russian cookery is a combination of western and eastern (mainly Armenian, Georgian and Turkish) influences. There is a great variety of hors d'oeuvres (*zakuski*), the most famous, though expensive, being caviar; a typically Russian way to serve it is on hot *bliny* (buckwheat pancakes) with sour cream. The true *russki* salat comprises not only cold vegetables but also meat, poultry, game or fish; it is served with mayonnaise or *à* la *vinagrette.* Soups are traditionally Slavonic, the most popular being shchi (cabbage soup) and borshch (beetroot soup or meat stock with other vegetables) ; borshchok is a clear beetroot consommé served with piroshki (pancakes stuffed with forcemeat or chopped cabbage with mushrooms). Kulebiak is a roll stuffed with fish (salmon or sturgeon), or with cabbage and mushrooms. There are many game and meat dishes served with sour cream and a choice of vegetables, including pickled cucumber and sour cabbage.

The Russians drink mainly China tea without milk, often without sugar but with cherry or strawberry jam.

China. — Chinese cooking, whose subtle flavour can be compared to those of French art *culinaire,* is characterized by the generous use of rice, of the soybean such as bean sprouts, of bean curd instead of milk and as a sauce, of fresh root ginger, of many dried foods and by the fact that butter, milk, cream and cheese are never used. Spices and herbs are rarely found but garlic and onion are used for strong flavourings. Several dishes, often in multiples of eight, are accompanied by Auffy white rice, a little being taken from each dish in turn, with bites of rice in between.

All food can be eaten with chop sticks or a spoon and fork and a knife never appears at table, since the food is cut up during the preparation.

Chinese birds' nest soup is unique: a hardened gelatinous substance, regurgitated by certain birds in nest making, is softened by soaking and then cooking, and is added to a chicken broth, thickened with rice flour. Other typical soups are light and delicate in flavour, two may be served during a banquet to clear the palate. Fish is a favourite food, particularly fresh-water varieties and lobster and prawns. Pork, chicken and duck are the supreme meats, but beef, lamb and mutton also are sometimes eaten. Both fish and meat may be prepared in a sweet-sour sauce of sugar and vinegar with mixed fruits. The meat is often dipped in batter and shallow fried in peanut or soybean oil before being added to the sauce. Rice and noodles are staple foods and maize and millet are also used. Large quantities of vegetables are eaten. They are cooked quickly in a small amount of liquid and crisp vegetables garnished with slivers of meat form many main dishes. Mushrooms, particularly a large black variety, bamboo shoots, water chestnuts and bean sprouts are typical vegetables. Monosodium glutamate is frequently added to savoury dishes and this and soybean sauce, which replaces salt, are common flavourings. Peaches, pears, persimmon, mango and litchi are enjoyed among fruit.

Almond biscuits and almond paste soup served either hot or cold are typical desserts. as is a tart made of rich, very flaky pastry with a slightly sweet bean paste or other filling.

Shao hsing is Chinese yellow rice wine used in cooking as well as to accompany meals. Tea, either green or semifermented, is served at every meal. Jasmine tea, nhich contains the flowers as well as the leaves. is served in small handleless cups without milk or sugar.

Japan. — Cooking is plain and simple and grilling and baking are common methods. The Japanese excel in the artistic decoration of dishes and the utensils for serving add to the attractiveness of the table.

Many courses of small portions are served. Rice takes the place of bread and noodles made from flour and egg yolks accompany main dishes. Black noodles are made with soybean flour. Stock for soups is frequently made from dried tunny fish. A popular soup is made by adding well-beaten eggs to hot stock so that soft curds are formed. The Japanese are great fish eaters. one hot and one cold dish often being served at a meal. Dried fish is frequently used and some fish is eaten raw with a typical salad of brined sliced cucumber and lettuce.

Sukiyaki is known throughout the world as a Japanese main dish: it consists of beef and vegetables which are cooked at the *table over a spirit lamp.* Vegetables *such as thinly sliced spring onions, bamboo shoots and leeks are browned singly in a little fat, moistened with stock, covered with very thin slices of beef and simmered a few minutes. The dish is seasoned with* shoya*—a sauce made from soybean seeds, wheat and salt—and served with* tufu *(cubes of pressed soybean curd). Pork and chicken can be used instead of beef.*

Sake is the national drink and is made from rice by a fermentation process. Tea is drunk with all meals and the tea ceremony (q.v.), when a bowl of tea is offered to each guest in turn with sweet and salty biscuits, is an important custom.

BIBLIOGRAPHY.—*Countess Morphy (Marcelle* Azra *Forbes), Recipes of All Nations (1935) and Kitchen Encyclopaedia (1934); Henry Smith, The Master Menu and Recipe Book (1952) and Classical Recipes of the World (1954); Good Housekeeping Institute, International Kitchen (1958).* (Co. M.; W. M. CL.)

FOOD SUPPLY OF THE WORLD. *Since time immemorial, food production has been the chief occupation of mankind. It still engages more than half the world's labour force. Processing foodstuffs.their national and international exchange, transportation and retail distribution occupy many additional hundred millions of people. However, the proportion of labour engaged in food production is different in various countries at different levels of economic development, the proportion tending to decline with economic progress. Similarly, the share of expenditure for food in the budget of individual households declines with elevation from lower to higher* income *level.*

Income level is also one of the decisive factors in determining the per capita consumption of food both quantitatively, as measured by the average daily calorie intake, and qualitatively. as *characterized by the variety and proportion of protective* foods*—meat, dairy products, leafy vegetables, vitamin C-rich foods and others. Least elastic is the demand for cereals and root crops, while that for meat, dairy products, fruit and vegetables tends to increase with the rise in standard of living. Income level divides mankind into "cereal eaters" and "meat eaters."*

Nutrition *patterns in different parts of the world have developed around local food production, each people adjusting habits and tastes to domestically produced foodstuffs. In sheep-raising countries, such as Australia and New* Zealand, *the per capita consumption of mutton and lamb is many times greater than in the United States, while the per capita consumption of pork in the* U.S. *is many times greater than in those countries. In sparsely populated cattle-raising countries such as Argentina and Uruguay, meat consumption is among the highest in the world, while milk and dairy products predominate in Switzerland, the Netherlands, Belgium, Luxembourg and the Scandinavian countries—all areas with intensive husbandry. In regions where agriculture is concentrated on production of grains, cereals constitute the bulk of the diet.*

The over-all volume of food production in various parts of the world is determined by the abundance or scarcity of arable land in relation to population, fertility of the soil, climatic conditions and the level of agricultural techniques. Thus, in certain areas there are deficiencies in food production, and in others there are surpluses. (The terms "deficiency" and ,'surplus" are usually applied to staple foods such as cereals, roots and sometimes sugar, rather than to crops that can be raised only under special climatic conditions, such as tea, coffee, cocoa beans, southern fruits or various oil-bearing seeds and nuts.)

Staple crops are largely consumed within the producing areas. In underdeveloped countries with prevailing subsistence economy, a large part of the harvest is consumed directly on the farm without *passing through domestic markets. Only a comparatively small proportion of such crops reaches the international trade: about 15% of wheat, less than 10% of corn. 2%–3% of* rice*—about 5%–6% of all grains combined. Export rates (the ratio of export to output) for the more perishable foodstuffs such as staple vegetables, milk and meat are still lower. They are much higher for sugar (40%), coffee and tea (70%–75%) and cocoa (more than 90%).*

In international trade staple foods move from a few *surplus areas to deficiency regions widely spread over the world.* Wheat *and coarse grains are exported from the U.S., Canada, Australia and Argentina; rice, mainly from Burma. Thailand. Formosa and Indochina, with smaller amounts coming from the U.S. and Italy; meat, from Argentina, Denmark. Ireland. Australia and New* Zealand; *cheese and butter, from Denmark, the Netherlands. Australia and* New Zealand. *The main destination areas are Great Britain, the German Federal Republic and other countries of northwestern Europe, southeast Asia (India. Pakistan. Malaya, Ceylon). Japan and some countries of Latin America. Products of plantation agriculture—tea. coffee, cocoa, spices,* etc.—move *from the tropical zones of Latin America, Africa and southeast Asia to industrially developed areas in temperate zones. International trade in these commodities, as also in wheat, meat and dairy products, is primarily intercontinental and transoceanic. Trade in rice belongs chiefly to the intra-Asian exchange.*

Foodstuffs (including beverages and tobacco) represent approximately 25% of the value of foreign trade, but their importance in international balances of payment is much larger than is suggested by this rate. Even a small deficiency in foodstuffs represents a very serious problem for economically underdeveloped areas. On the other hand, cash crops are the foundation of local economy in certain areas: sugar cane in Cuba. Brazil, Puerto Rico *and Hawaii; tea in Ceylon, India and Indonesia; coffee in Brazil, Colombia. Guatemala, Venezuela and the Sudan, etc.; cocoa in Brazil, the Gold Coast, Nigeria and others; bananas in Central America; pineapples in Hawaii; and coconuts in Ceylon and the* Philippines.

THE WORLD'S LARDER

The food supply of the world *may be represented as a giant larder, from which people draw their everyday food while it is replenished by the never-ending* work *of the tillers of the soil in all parts of the world. Some stocks are replenished once or twice a year after the harvest; others come in continually. 4 part of the supply is carried over for periods longer than a year. Because of fluctuations in weather conditions and other factors, the annual world consumption of single food products is not necessarily equal to the annual output, but in the long run the two items tend to balance one another.*

However, *not all world supplies of foodstuffs are used as human food. Some amounts are needed for seed. and some are* wasted *in the process of storing, transporting and marketing on the long way from the farm to the ultimate consumer. A substantial part of food crops is fed to livestock; another part is diverted to industrial purposes. Of the former, only a fraction reappears for human* consumption *in the form of meat, fat and dairy products: about 10 lb. of grain go into the production of 1* lb. *of meat. For all these reasons, the actual net supply of foodstuffs available at the retail level for human consumption, including foodstuffs consumed directly by producers, forms only a part, though the largest and most important part, of the annual gross output of foodstuffs described here as the* world's *larder.*

This larder may be visualized as divided into three compartments for different types of foods. The largest and most important is that for cereals; next is a huge one for potatoes, other tubers and roots. sugar, pulses (legumes). oilseeds *and fruit; the third one is stocked with meat: poultry, dairy products and fish. For the distribution of the different types of food in the world's larder, see Table I.*

*TABLE I.—The World's Larder, 1954**

(In 000,000 metric tons)

Item	Quantity	Item	Quantity
Cereals	635	Animal foodstuffs	350
Breadgrains	172	Meat	55
Rice, paddy	162	Beef, veal, pork, mutton and lamb	45
Coarse grains	301	Poultry meat, offals	10
Other crops	500	Edible pig fat	3
Tubers and roots	300	Milk	255
Pulses	25	Eggs	10
Oilbearing crops	60	Seafood	27
Sugar	40		
Fruit	75	Total, approximate	1,500

*Excludes the U.S.S.R.

In round numbers, the annual amount of food produced in the world, which approaches and in some years exceeds 1,500,000,000 metric tons or approximately 3,000,000,000,000 lb.. would provide, on the average, a little more than 1,100 lb. annually or 3 lb. daily for each person in the world. These figures do not include tea, coffee, cocoa beans, various vegetables and fruit, and numerous other foodstuffs raised locally in comparatively small quantities for which statistics are not available. Nor do they take account of the loss from extraction for cereals or oilseeds, waste in storage and distribution, or the part of crops used for seed and industrial purposes. Furthermore, some of the crops listed in the first compartment of the larder are used for feed and so reappear, in much reduced amounts, in the tonnage of animal foodstuffs in the third compartment. There is also a great difference between the world per capita amount of available food and the quantity actually consumed by the population in different regions, individual countries and different income groups in each area.

Before discussing the output of different foodstuffs by region, we will briefly survey the shelves of the world's larder.

Cereals. — The most important cereals are rice and wheat, used chiefly for food, but also as feed for animals. In food, cereals are to some extent interchangeable and in feed almost completely so. Grains used for feed in economically advanced countries are consumed as food in underdeveloped parts of the world where cereals supply from 70% to 75% of the daily calories.

Rice is the staple food of the Asian peoples. almost half of mankind. Although Asia accounts for more than nine-tenths of the world's output of rice. it must supplement its production with imports, particularly in years of unfavourable harvest. Rice is an economical crop: it yields more food per acre than any other grain. and only 3% to 5% of the yield need be reserved for seed, as compared with from 8% to 15% for wheat. Indeed. Asia could not support its teeming millions with any other crop. In the history of Asia failure of the rice crop time and again has resulted in famine and starvation.

In contrast to rice, wheat is raised in all parts of the world, occupying a larger part of arable land than any other crop. Wheat enjoys an almost exclusive position among all grains because wheat dough raised with yeast retains large quantities of gases in the bread-making process. Rye. the only other bread grain, possesses this property to a lesser extent. Rye bread has not so fine a texture as wheat bread and is less digestible. Because of the general consumer preference for wheat. even in areas where it cannot be grown in sufficient quantity, the export rate of wheat is higher than that of any other grain. In the past century wheat invaded the areas where rye bread had predominated and made the latter a poor-man's bread. Rye is less exacting to grow, being much more winter-hardy, ripening earlier than wheat, and on low fertility soil yielding more than any other small grain. Because of these advantages and because rye can be raised as a cover crop and is also appreciably cheaper than wheat. it has more or less maintained its position in agriculture of Europe and the U.S.S.R.

Maize is the grain contribution of the western hemisphere to the old world. It ranks first in acreage in the Cnited States and is also important in Latin America. Asia. Africa and southeastern Europe. As direct food. it serves only 50,000,000 to 60,000,000 people but hundreds of millions consume it in the form of pork, beef or dairy products. Most of the corn produced on farms of the U.S. leaves them on the hoof. Processing of corn by animals is, hoaever, expensive: a bushel of corn consumed as whole corn meal meets the daily requirements of 23 persons for food energy and protein, but if consumed in the form of eggs meets the requirements of only 2 persons for energy food, and of 8 for protein.

Sorghum and millet can withstand long periods of dry weather by reverting to a dormant state and then growing again with the monsoons or as soon as the soil obtains enough moisture. Furthermore, these prolific crops have a short growing season and respond to the most primitive cultivation methods. All these characteristics have enhanced their importance in the monsoon area of Asia and the subtropical zones of Africa where they are consumed in the form of flatbread. grits, porridge and confectionery. While the chief use of sorghum and millet in other parts of the world is for feed, a bread variety of millet (proso) is staple food, eaten mostly as thick porridge. throughout the U.S.S.R.

Oats in the form of porridge ranks high among breakfast cereals in many countries of Europe, mostly in the north, and in the U.S. As a well-balanced feed, it has maintained its position in the world, though motorization of highway transport and mechanization of field work have reduced its use as staple feed for horses.

Other Food Crops. — Of other food crops, roots and tubers are the bulkiest. In their raw state they are largely composed of water and carbohydrates and contain only small amounts of protein and still less fat. They are highly perishable and therefore of limited transportability but constitute important energy food in many parts of the world. Also, when hunger arises the farmers often turn to these crops, since they can be raised in abundance rather quickly and at relatively low cost. They are also used extensively as feed for animals.

Potatoes, sweet potatoes and yams, and cassava predominate in this group. Though potatoes originated in the Andes, they are grown today in many areas but mostly in the cool, moist regions of northern and central Europe and the U.S.S.R. In the U.S. potatoes are harvested in some area during any of the four seasons. Sweet potatoes and yams are widely grown in Asia, particularly in China, Korea and Japan. In Japan they are one of the basic foods. Cassava is widely cultivated in Africa, Asia' and Latin America.

Dry beans, broad beans, dry peas, lentils and chick-peas are the main pulses. They contain more protein than the cereals or roots and tubers and can therefore serve as substitutes for animal proteins, particularly in the world's poor regions: less land and labour is required to raise pulses than to provide feed and maintain animals for the same quantities of protein. In the diet of people in North America. western Europe and Oceania they are used merely as vegetables to supplement meat courses. Though pulses have been raised for several thousand years in many parts of the world their nitrogen-producing quality was discovered only late in the 19th century. Because their decaying roots release nitrogen in the soil, pulses are often grown for rotation purposes and also for enriching poor soil.

Oil-bearing crops include oilseeds, nuts and some oil-containing fruit. They supply a wide variety of oils for both human consumption and industrial purposes, and their fat-free residues after extraction of oil provide valuable feed concentrates. The importance of edible oils varies from country to country. Being cheaper than animal fats, they are widely used in butter substitutes by low-income groups even in wealthy countries where preference for butter has become traditional.

Sugar. an essential energy food, is provided by the sugar beet and sugar cane. The former is a root crop grown in temperate climates and the latter is a tropical stalk crop. but in processed form both supply an identical product. Their relative position in the world changed several times during the 19th century, but after the 1920s sugar cane dominated the field. Because these crops contain a large amount of water and are therefore bulky. their processing is usually carried out in the growing area. In the case of the sugar beet, extraction and refining are carried out in a single operation. In contrast, raw sugar extracted from the cane is often shipped for refining to factories closer to consumer markets.

Animal Foodstuffs. — Meat is important in human diet because it contains protein of highest quality, many mineral elements (phosphorus, iron, copper and others), some of the vitamins, and fats. Moreover, it stimulates the flow of digestive juices in the stomach. Another important nutrition element, calcium, is provided mainly by milk. Since milk contains the greatest assortment of nutritive elements of any single food, it is considered a complete food in itself.

The number of domestic animals about equals the number of people in the world (2,400,000,000 and 2,700,000,000, respectively, in 1954). As there is such a large domestic animal population, man has had to assume the responsibility of feeding it. Thus a substantial part of the world's farm land is devoted to pasturage, and where the herds have outgrown the available pastures cropland is taken over for feedstuffs. In the United States, for example, about three-fifths of all land is used for hay and pasture, and two-thirds of all cropland for producing feed and forage crops. In such a densely populated country as the German Federal Republic permanent meadows and pastures occupy nearly 40% of all agricultural land. In New Zealand more than 95% of all agricultural land is in natural and sown pastures. Even in Argentina, with its vast open stretches, pastures compete with crop fields for land. Moreover. a considerable proportion of all crops raised in the world is fed to livestock. In Canada not only about 80% of the barley and 90% of the oats but also about half of the wheat is used for animal feed. In Denmark, only about 10% of all grain goes for direct human consumption. The rest, except for what is withheld for seed and industrial purposes or wasted, is used for feed. In contrast, in poor underdeveloped regions such as India, Pakistan or China, man cannot share with animals even the coarse grains and uses his harvest almost exclusively as food.

Seafood in general and fish in particular is a less expensive source of protein than meat and could therefore be a very important food. especially in areas generally deficient in animal foodstuffs. Yet because of the tenacity of food habits, perishability of fish, inadequacy of handling techniques and, most of all, lack of knowledge of marine resources and insufficient recognition of their food value, fish plays a secondary role in human diet except in a few countries, such as Japan, Thailand, the Philippines and the northwestern countries of Europe. For the world as a whole, fish represents only 2% of all foodstuffs consumed and **3%** of the proteins.

Fish is a unique food source in the sense that it replenishes itself without such efforts as are required to produce all other kinds of food. The distribution of fish on our planet depends, like that of plants, on climatic and physical conditions. The ocean offers a wide range of environmental conditions for vegetal and animal life, the most significant of which are temperature, salinity and currents. In the ever-moving waters, fish. too, are always moving, gravitating toward sources of food. Plankton, the small floating or drifting animal or vegetable matter which is the chief pasturage of the sea. is more abundant in cold waters than in warm, in shallow layers of water exposed to sunlight than in the depths and in coastal waters rather than in the open sea.

Fish find the most abundant and variegated plankton on continental shelves, and it is there that both marine life and fisheries are concentrated. The richest and most productive fishing grounds, supplying nearly 95% of the world's fish catch, are in the northern hemisphere. Since fishing is not limited by national boundaries and fish have no nationality until caught, fishermen of any nation can exploit the world's fishing grounds, no matter how far from their own land. The only limitation to foreign fishing is on coastal waters, usually a 3-to-12-mi.-wide strip. while a few small countries claim a zoo-mi. limit for their coastal waters. On the other hand, a fisherman has no exclusive rights on his customary fishing grounds as has the farmer on his land. He may arrive with all his gear at the fishing banks, only to discover the season's harvest nearly captured by others with faster equipment.

In contrast to the small use of fish as food, the world's demand for fish meal for livestock and poultry feed grew continually. Before the value of its highly concentrated protein was recognized, small fry and little-known species had been simply thrown overboard by the fishermen. This practice was not completely eliminated, but, increasingly, the industry used inedible species and the waste from processing the edible catch. Even a part of the catch previously consumed in fresh or canned form came to be diverted to fish meal production, which was also stimulated by improved reduction techniques. Whenever there is difficulty in marketing the edible catch, fish meal plants present a ready outlet.

OUTPUT BY REGION

Food Crops.—Though rice occupies far less of the world's land than wheat (the ratio is 7 to 10), the world's harvest of rice in normal years is slightly larger than that of wheat: in 1954, 162,000,000 and 152,000,000 tons, respectively. Next in line is maize, with other coarse grains, barley, millet and sorghum, and oats close runners-up. Among roots and tubers, potatoes tanked first, with 167,000,000 tons produced in 1954.

Asia accounts for about 40% of the total output of major food crops in the world (exclusive of the U.S.S.R.). Not only is it the almost exclusive producer of rice but it also raises nearly 70% of millet and sorghum, sweet potatoes and yams, about 60% or more of pulses and half the oilseeds. This huge output is not sufficient, however, to feed its vast population. Were it not for surplus production of rice in a few smaller countries within this region, the largest countries of Asia—China and India—would increasingly depend on food supplies from other continents.

Europe leads in the output of potatoes, with about 80% of the world total (exclusive of the U.S.S.R.. also an important producer), but it is deficient in many other crops and must import them in large quantities for both food and feed purposes. Wheat is the main European crop, the chief producers being France, Italy and Spain, followed by the German Federal Republic and Great Britain.

North America accounts for nearly 60% of the world's maize, more than half the oats and 25%–30% of the wheat. The U.S. ranks first in these crops. Canada is another important producer of wheat.

Some three-fifths of the world's sugar is produced in Europe (beet sugar) and Latin America (cane sugar). Chief European producers are Germany, France. Poland, Czechoslovakia and Great Britain. In Latin America. Cuba leads, followed by Brazil and Puerto Rico. (See Table II.)

*TABLE 11.—Output of Major Food Crops by **Region,** 1954*

*Excludes the U.S.S.R.

†Includes the Sudan, Egypt, Somaliland, Ethiopia and Eritrea, Libya in Africa, and Iran, Iraq, Israel, Jordan, Lebanon, Saudi Arabia, Syria, Turkey, Afghanistan and small adjoining territories in Asia.

‡Cottonseed, rapeseed, peanuts, sesame and sunflower seed.

§Olives, copra, palm kernels.

Animal Foodstuffs.——North America and Europe were the main producers of meat, each accounting for about 30% of the world's total in 1954 (exclusive of poultry meat and edible offals). Asia and Latin America produced about equal amounts (14% to 15% each). The rest came from Oceania, Africa and the near east.

Half the meat produced in the world is beef and veal. which rank first in the meat output of the new world, Africa and Oceania. In Latin America, their share is about 75% of the total meat produced. Pork is next in importance, while mutton and lamb account for less than 10% of the aorld's meat output. Pork predominates in the meat output of Europe and especially in that of the far east.

Poultry meat is a comparatively expensive food for areas short of grain. In such areas—Asia and some European countries—chickens are kept chiefly for egg production. Stimulated by growing demand for lighter protein fare, the world output of poultry meat expanded from 3,100,000 tons before World War II to 5,200,000 tons in 1954–55. About 60% of it was produced in North America (58% in the United States) and about 17% in Europe.

Europe produces half the world's milk, North America three-tenths of it. The world's largest single producer of milk is the U.S. Considering the vast population of the far east, its output of animal foodstuffs and particularly of milk is pitifully low. Half of its milk comes from buffaloes; a little less than half from cows.

In countries with a well-developed dairy industry, the yield per cow has shown a steady increase. It is still very low in areas with poor and unproductive livestock breeds. The annual yield per cow ranges from 6,280 to 7,780 lb. in Switzerland and the Netherlands to 1,220 lb. in Egypt (1954).

While before World War. II half the milk produced in the world was used for butter and cheese production, consumption of milk in liquid form increased in postwar years. Production of powdered milk expanded more rapidly than that of condensed and evaporated milk.

World production of eggs is concentrated in North America (about 40%) and Europe (30%). Better breeding and feeding, a better selection of the laying strains and many improvements in the care of laying hens after World War II brought an increase in egg production of 50% in the world as a whole, 75% in North America and 25% in Europe. (See Table III.)

‡Information not available.

The Food and Agriculture Organization of the United Nations (F.A.O.) estimated the world's seafood catch at more than 27,000,000 tons for 1953. The major world producer of fish was Japan, followed by the U.S., Norway, Great Britain and Canada. In Japan, coastal fishing is carried on in numerous tiny villages, while deep-sea fishing is concentrated in a few ports equipped with the necessary facilities. The U.S., with its two coasts stretching over thousands of miles, has a greater variety of marine life than any other nation. Great Britain and Norway, where fishing is a traditional trade, have excellent fishing grounds off their coasts, efficient fleets and experienced fishermen. In Canada, particularly in Newfoundland, fishing is an important industry, and the entire economy of Iceland is keyed to fishing and export of fish.

Marine fishing supplies nine-tenths of the world's catch; the rest comes from fresh waters, of which about 70% originates in Asia. Cod, herring and related species constitute about 45% of the marine catch, the remainder consists of salmon, trout, tuna, numerous other species and variety of molluscs, crustaceans and other aquatic flora and fauna. Whales and other aquatic mammals are not included in the estimate of F.A.O.

About 45% of the world's live weight of total catch is marketed in the fresh or frozen state; about 25% is cured by salting, drying or smoking; about 7% is canned; and the rest, together with offals from dressing, is used for making fish meal. In international trade, fish products move in greater quantities than meats—2,800,000 and 1,500,000 tons, respectively. However, the value of fish in international trade is less than half that of meat.

POSTWAR CHANGES IN WORLD FOOD PRODUCTION

In 1945 the world found itself with a greatly reduced food production, yet with an increase in population of more than 200,000,000, in comparison with the prewar period. In war-torn countries agriculture was disorganized and beset with many difficulties. The soil needed reconditioning after years of inadequate fertilization, and livestock had been decimated for lack of feed. Obsolescence of equipment, lack of new machinery and parts, a shortage of fertilizer, quality seed, labour and draught animals, and other difficulties were aggravated by unsettled political conditions in many regions. Even in areas where there had been no direct fighting or enemy occupation, agriculture had suffered from such indirect effects of the war as cutting off of normal sources of supplies and outlets, shortage of manpower, lack of goods to offer farmers in exchange for their produce, etc. Food production expanded rapidly during the war only in North America, particularly in the U.S., despite the decline in the agricultural labour force. The uninterruptedly rising output of food crops in North America so far exceeded the growth of population that this continent became the world's chief supplier of grain.

With world agriculture out of balance, the problem of food supply became acute in the early postwar years. In 1946–47, when efforts in many countries were concentrated on the increase of food production, output of food in the world as a whole still lagged 7% behind the prewar level. There was even 15% less food per capita than in prewar years. Only international help through the United Nations relief, large direct shipments of food from the U.S., and rationing and price control in many countries staved off famines.

The problem of an insufficient food supply was attacked in various ways. Some countries continued or intensified the wartime policy of shifting from nonfood crops to those of high-calorie content, forbade the use of cereals for feed, raised the extraction and milling rates of grain, etc. In others, governments assumed control of agricultural production and distribution of foodstuffs. The policy of farm price support and subsidies to farmers for obtaining quality seed, fertilizer and equipment became widespread. Agricultural extension service was established in the majority of countries. The most important factor, however, was a broader application of science in agriculture.

New scientific methods revolutionized world agriculture, and while progress was particularly marked in advanced countries, especially in the U.S., gains were also made in underdeveloped regions. Arable land was expanded by bringing millions of additional hectares under irrigation in Asia, Latin America and the middle east. Commercial fertilizers were used in countries which had never used them before or had applied them only on export crops. Between 1938 and 1954–55, world consumption (exclusive of the U.S.S.R.) of nitrogenous fertilizers increased from 2,400,000 tons to 5,800,000; of phosphoric acid, from 3,500,000 tons to 6,700,000; of potash fertilizer, from 2,500,000 tons to 5,400,000. India, Pakistan and the Philippines built plants for domestic production of nitrogenous fertilizers. Power mechanization was increasingly applied to increase yields by more timely operations, to extend the zone of cultivation or to plow up land with deep-rooted weeds, as in India and some African territories. In the world as a whole, exclusive of the U.S. and the U.S.S.R. where tractorization was a feature of agriculture before the war, the number of tractors increased from about 400,000 in 1938–39 to more than 2,300,000 in 1954–55. In many underdeveloped countries, governments and co-operatives established tractor pools to bring mechanized farming within reach of villages.

Synthetic insecticides and pesticides, introduced during the decade after World War II, came into wide use not only in advanced countries but also in underdeveloped regions. Their general use greatly reduced the losses from pests and plant diseases and in some cases was responsible for sharply increased yields.

Perhaps most significant was the spreading use of high-quality seed. Plant breeding was not a new development, but the hold that it took on farmers in underdeveloped regions and the ever-increasing recognition of its potentialities everywhere were new. Where plant breeding had been concentrated before on export and industrial crops, it became centred on food crops. Rice received primary attention in southeast Asia, maize in Latin America. Hybrid corn, the great achievement of United States agriculture, caught the imagination of farmers in Europe and the U.S.S.R. Some provinces of northern Italy had up to 95% of their maize area under hybrids.

New agricultural methods also invaded livestock production and fisheries. Attack on chief animal diseases and internal parasites was carried out in many countries. For example, application of better and cheaper vaccines on a very wide scale achieved good results in the fight against rinderpest in the far east and Africa. Spraying with insecticides of a large area in southeast Africa nearly eliminated the danger from the tsetse fly. Artificial insemination was used in many underdeveloped regions, and use of antibiotics in animal feeding made great progress, particularly in the U.S. and Europe.

South and southwest Africa, Angola, Peru, Chile and several other countries emerged as considerable fish producers in the postwar decade. Much progress was achieved in better fish preservation, in equipment of fisheries, etc.

The list of technical innovations introduced in world agriculture in the decade could be extended, but even this brief enumeration may provide a picture of the changes in this sector of economy. Simultaneously, many institutional changes were made in land ownership, land tenure and land taxation, in order to raise farmers' income, encourage the improvement of holdings and stimulate intensification of production. Agrarian reforms, varying in extent, were carried out, fully or partly, in Japan, India, Burma, Pakistan, China and Formosa in the far east; in Turkey and Egypt in the middle east; in Bolivia, Guatemala and Puerto Rico in Latin America; in Finland, Italy, Spain and eastern European countries. These reforms involved changes in the tenancy system to provide security to the tenants, establishing the right to compensation for improvements, elimination of personal services to landlords, etc. Attack on excessive fragmentation of land, an old obstacle to the increase of agricultural productivity, was launched in many countries not only in Europe but also in Asia. In Japan, for example, nearly 20% of all cultivated land was consolidated by the end of 1954. India and Pakistan initiated an active policy against land fragmentation. Collection of taxes through intermediaries leading to exploitation and village poverty was abolished in such countries as Japan, India, Pakistan and Mexico, among others.

These and other measures revitalized world agriculture so that ten years after the end of World War II the food output of the world as a whole exceeded the prewar level by 20%; the increase was as large as 29% in the world, exclusive of the U.S.S.R., China and eastern Europe. Because of increased population, however, the output per person was only 1% higher than before the war.

The development was highly uneven. In many regions production did not keep pace with the growth of the population. Thus in

TABLE IV.—Index Numbers of Food Production by Region, 1946–55
(Prewar average= 100)

Region	1946–47	1950–51	1954–55
Total food production			
World	93	111	120
World, exclusive of the U.S.S.R., China and Eastern Europe	103	118	129
North America	138	139	145
Latin America	115	130	139
Western Europe	76	110	124

Asia	91	100	109
Africa	107	128	142
Oceania	92	111	116
Food production per capita			
World	85	97	101
World, exclusive of the U.S.S.R., China and Eastern Europe	91	98	101
North America	124	116	113
Latin America	94	97	94
Western Europe	72	100	109
Middle East	91	99	106
Asia	80	83	86
Africa	93	105	109
Oceania	85	93	87

Latin America food production in 1954–55 was 39% higher than before the war but with the 45% increase in population, the per capita food production was 6% below the prewar level. The worst food situation was in Asia, where food supplies have always been very low and where the rapid growth of the population outstripped the modest advances in agriculture. Moreover, this continent faced much greater difficulties than other parts of the world in expanding its food production because of continuing political disturbances and lack of capital, equipment and technical knowledge. Though the index of per capita food production in 1954–55 was about the same in Oceania as in Asia (87 and 86, respectively, in comparison with prewar years), actual food conditions in the two areas are entirely different. *(See* Table IV.) Oceania's agriculture is highly developed and geared to export of large quantities of agricultural surpluses. The decline in per capita output of foodstuffs does not, therefore, affect the exceptionally high nutritional standards of this area; it only reduces surpluses available for export. On the other hand, food shortage in Asia presents Asian peoples with a dilemma: they must either make further cuts in their meagre diets or seek ways to increase production.

While food deficiency remains a grave problem for a large part of the world population, burdensome surpluses of foodstuffs, especially of grain, have accumulated in the United States and some other countries in postwar years. The traditional exporters of rice in Asia, Burma and Thailand became loaded with surpluses because domestic production of the importing countries began to satisfy the requirements for rice to a greater degree than before the war. For the same reason Latin America was faced with surpluses in sugar. The abnormality of such a situation was somewhat mitigated by the fact that most of the stocks were in the hands of governments trying to avoid dumping of surpluses on the world market in order not to cause a catastrophic drop in farm prices: the experience after World War I had taught the world that unorganized unloading of surpluses disorganizes world agriculture and ruins millions of farmers.

FOOD SUPPLY AND NUTRITIONAL PATTERNS

With due reservation for a considerable margin of error, the food balance sheets prepared by the F.A.O. for individual countries provide a telling picture of the net food supply available in each country at the retail level and can serve as a basis for comparing the nutritional patterns in different countries. These patterns may be measured in pounds and ounces of foodstuffs consumed, or in calorie value of different foods per person in average national daily diets, and characterized by the composition of the daily calorie intake.

According to the F.A.O. estimates, total daily calorie intake per person varies from country to country, ranging from less than 2,000 calories in some underdeveloped areas (the Philippines, India, Peru and others) to more than 3,000 in prosperous countries such as the United States, Canada, Great Britain, Switzerland, Denmark, Australia and New Zealand.

Apart from this general correlation between the level of prosperity, roughly measured by the per capita income and daily intake of calories, the pattern of nutrition in different countries depends on climate, composition of the population and national food habits. The daily number of calories per person in most countries with a per capita income of more than $500 either exceeds 3,000 calories or is very close to it (2,973 in Sweden; 2,928 in Belgium-Luxembourg). The unique position of Ireland in this group with its daily 3,483 calories per person is accounted for partly by the cool moist climate of the island and partly by the large proportion of starchy foods (potatoes) in its diet. Similarly, Uruguay with its very high consumption of livestock products consumes daily nearly 3,000 calories per person although its per capita income ($300) does not permit it to rank among the most prosperous nations. As one moves down the scale of per capita incomes, the daily food supply in terms of calories diminishes and, at the bottom of the scale, falls below the physiological requirements, as in the Philippines and India. *(See* Table V.)

More revealing than total calorie intake is the composition of national diets. The more prosperous a country, the less important are the cereals and starchy roots in its diet. The calorie content of meat and dairy products in the daily intake per person varies from more than 1,000 calories in New Zealand (1,163) and the U.S.

TABLE V.—*National Income and Net Food Supply in Selected Countries, 1954–55*

(Per capita of population)

*Countries are listed in the order of declining per capita income. †Includes calories from unreported sources.

(1,006) to 38 calories in Japan. These are the extremes on the international scale of consumption. But daily rations of meat providing 600 to 1,000 calories are quite usual in prosperous (or livestock-raising) countries. while rations of less than 200 calories are characteristic of primarily agricultural underdeveloped countries. The first group includes countries of northwestern Europe, Australia and the cattle-raising countries of Latin America (Argentina and Uruguay). The second group embraces almost all of Africa, the middle east and the countries of Asia for which statistics are available. A few small areas such as Israel have a slightly higher intake of livestock products than is characteristic of this group, but this does not change the general nutritional pattern of the vast region from the Atlantic coast of Africa to the China sea and the Pacific coast of Asia.

A large part of Latin America from the Rio Grande to the border of Uruguay and Argentina, southern and eastern Europe including Italy, Greece and Yugoslavia, and the southern tip of Africa form a middle group, with 200 to 600 calories from livestock products in their daily diets. In China and the U.S.S.R., for which no statistics are available, the former is among the countries with the lowest consumption of meat. The position of the U.S.S.R. is less certain: there are indications that its consumption of meat and dairy products is very low but it may be close to the borderline between the areas with less than 200 calories and those with 200–600 calories. (*See* map).

Because fish is cheaper than meat, its consumption within a country is usually larger in low-income groups than among the rich. But this correlation disappears when comparison is made among individual countries. The development of fisheries in certain areas has been determined by geographic and historical conditions. Sweden, one of the most prosperous nations in the world, has about the same number of daily calories from fish consumption as poorer Portugal—72 and 74 calories, respectively, New Zealand, with a per capita income of $950 a year, obtains 13 calories daily from fish consumption, as much as Egypt which has a per capita income of $110.

The role played by fruit and vegetables in human diet also depends on geographic conditions. It is greater in subtropical and tropical zones than in areas with temperate climates, but it is also correlated to some extent with the economic level, being much higher in prosperous countries than in the poor ones. In India, for example, less than 2% (30 calories) of daily intake comes from consumption of fruit and vegetables, as compared with more than 11% (141) calories in Canada.

ADEQUACY OF NET FOOD SUPPLY

Individual food requirements vary considerably depending on climate, age, sex, type of work performed and various other factors. The F.A.O. has calculated average physiological requirements for the population of different countries basing its estimates on specific climatic conditions in respective countries and the physical characteristics of their population.

According to these estimates, average daily food requirements in most countries of the temperate zone vary between 2,600 and 2,850 calories: about 2,840–2,850 for Sweden and Norway; 2,710–2,750 for Canada, Switzerland and Denmark; 2,600–2,670 for the United States, Belgium-Luxembourg, the Netherlands, Great Britain, Argentina, Australia and New Zealand. In countries with a warmer climate the requirements are estimated at 2,2jo–a,500 calories for Pakistan and India, and 2,440–2,j50 calories for Italy, France, Portugal, Turkey, Brazil, Mexico and Venezuela.

A comparison of actual daily intake per person with the estimated requirements reveals that average consumption of iood, in terms of calories, in prosperous countries exceeds the physiological requirements. while in other countries the net food supply available to the people at retail level is insufficient to provide them with the number of calories required for health and normal functioning of human bodies. Moreover, food supply is usually very unevenly distributed among different population groups within a country High-income groups may often consume more food than is good for their health, while at the other extreme many low income groups cannot obtain even the required minimum of calories in their daily diet.

After having established minimum food requirements for different countries, the F.A.O. estimated nutritional targets for respective countries for 1960. These targets represent a compromise between the net iood supply available per person at retail level in 1952–53, the physiological requirements and the economic feasibilities. In the case of such underdeveloped areas as many African territories, Japan, India, Paki-

TABLE VI.—*Daily Food Intake, Requirements and Targets in Selected Countries*

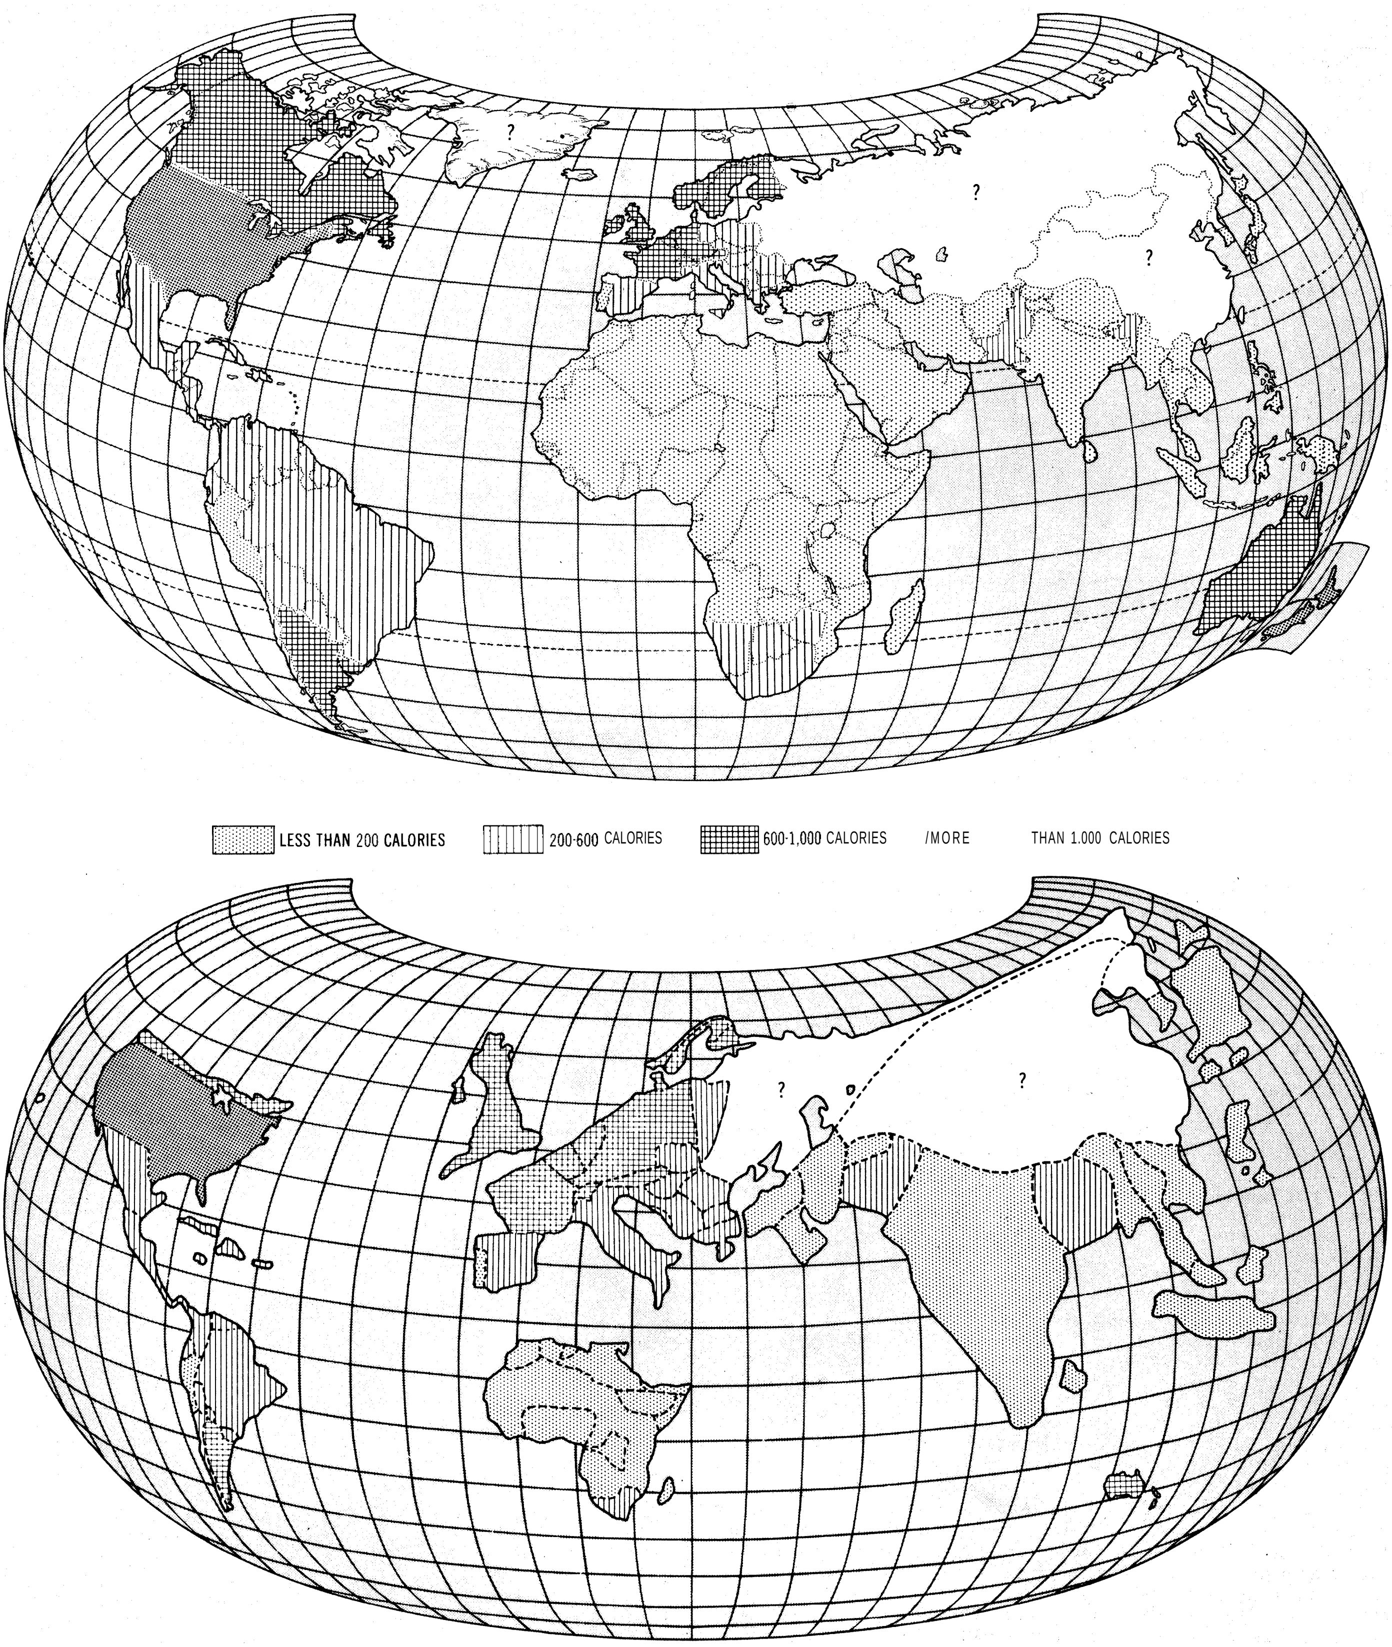
stan, Ceylon, Peru, Mexico and others, these targets fall still short of physiological requirements but come closer to the latter than actual consumption was in 1954–55. On the other hand, the F.A.O. targets were below the actual intake in 1954–55 in some countries such as in Denmark, Great Britain, Australia and others. *(See* Table VI.)

To meet these targets for the world's growing population a tremendous expansion of food production by 1960 was required: 19% more cereals, 47% more pulses, 30% more meat, 33% more milk, 39% more eggs, etc. What made the task even more formidable is that the largest increase in production would have to come in underdeveloped areas



BY COURTESY OF (TOP) ERWIN RAISZ

DAILY PER CAPITA INTAKE OF MEAT AND DAIRY PRODUCTS THROUGHOUT THE WORLD. TOP. CONVENTIONAL MAP SHOWING PER CAPITA INTAKE IN VARIOUS GEOGRAPHIC AREAS. BOTTOM DISTORTED MAP SHOWING THE PROPORTION OF THE WORLD'S POPULATION IN EACH CALORIC CATEGORY. AREAS ARE SHOWN IN SIZE PROPORTIONATE TO THEIR POPULATION where the need was greatest. According to the F.A.O., the increase in cereal supplies in Asia and Africa wouldhave to be twice as large as the expected increase in the population. Expansion in production of other foodstuffs such as pulses, meat, milk, eggs and fish would have to he proportionately still greater. As to the advanced countries, the targets called for an expansion of livestock production that would exceed the estimated population increase in order to raise the proportion of protective foods in their respective diets.

FOOD SUPPLY AND EXPANDING POPULATION

The challenge to world agriculture was twofold, quantitative and qualitative: to produce more food for the growing world population and to intensify production of protective foods—meat, dairy products, etc.

Agricultural experts were confident that, apart irom annual fluctuations depending on weather conditions, the world's iood supply would continue to increase in the years to come, more rapidly than the world population. There were still large areas of unused land capable of cultivation on all continents, and these were to be gradually brought under plough by irrigation, flood control, drainage, fertilization, etc. Yields per unit of land in underdeveloped regions might be expected to rise from their present low levels as a result of broader application of improved agricultural methods developed in advanced countries. Higher yields would cover the world needs for cereals and other starchy foods and release some land, now occupied by crops for human consumption, for pastures and feed crops. Such a development would favour the growth of a modern livestock industry and diversification of agricultural production.

These expectations were supported by the observation that there is a time lag between the improvements in agriculture and their effect: the results of improvements already accomplished or nearing completion in underdeveloped areas in the first postwar decade would become mare and more evident as time passed.

The main and most disturbing ieature of the world food supply at the beginning of the second decade after World War II was the great contrast between the surplus in food production in certain areas and food deficiency in other. There was little possibility of an automatic alleviation of this situation in the near future. Surpluses could hardly be eliminated by restriction on agricultural production in areas with overfilled storehouses, or by the normal growth of world population accompanied by a proportionate increase in demand for foodstuffs.

The equilibrium between production and consumption of food in the u·orld would depend, to some extent, on the outcome of plans for industrialization and economic development in areas where undernourishment of the population is a permanent feature. If and to the extent that these plans were successful, they would lead to a rise in per capita income and a higher standard of living. As income rose in poor countries, the first call of the people would be for more iood to satisfy hunger. Progress in domestic agricultural production might not be sufficient to meet the growing demand. Increased imports of foodstuffs from surplus areas might then become necessary—a logical movement of foodstuffs irom comparatively sparsely populated to overpopulated countries.

Along with measures for further economic development, the F.A.O. recommended measures designed to change food habits by teaching people about the advantages of a nutritionally balanced diet. A campaien of this kind, concerning the nutritional value of liquid milk, had resulted in a substantial increase in milk consumption in western countries. The F.A.O. believed that similar results might be achieved elsewhere.

Among other means for raising consumption of protective foods were measures to reduce production and marketing costs of such foods. This would bring them within the reach of large groups that cannot afford them now, not only in underdeveloped areas but all over the world.

In briei, the problem of food supply in the world is not simply a question of the race between the increasing population and the carrying capacity of the earth. Rather, this is a complex economic problem that appears in different forms in different areas and ultimately merges with the general problem of social and economic progress in the world. *See* also NATURAL RESOURCES.

FOOL (JESTER), a simpleton whose imbecility, real or assumed, is utilized for entertainment. The origin of the professional fool is obscure. In Mohammedan and early Irish sources, madmen are mentioned who, inspired with poetic and prophetic powers, behaved as professional jesters; *e.g.*, Buhlul, who flourished at the court of Harun al-Rashid in the 9th century, and Mac-da-Cherda in 7th-century Ireland. Dwarf fools may have been kept for luck as well as for fun; in the belief that deformity can avert the evil eye and abusive raillery transfer ill luck from the abused to the abuser. The Asian Indian dwarf buffoon Vidusaka, whose name means "an abuser," appears in drama and society during the early centuries A.D. In the 19th century the buffalo sacrifice of south Indian villages was accompanied by the buffoon Raniga, who railed at everyone including the officiating priest and the earth-goddess, and the fool of European folk customs plays a similar part. His raillery and association with a mock king suggest that he was once a scapegoat substituted for a royal victim. E. K. Chambers (see *Bibliography)* finds traces of sacrificial *exuviae* ("garments") in the foxtail, calfskin, etc.. of the festival fool and in the coxcomb. eared hood, bells and bauble which, with the motley coat, formed the official costume of the household jester. At Christmas, particularly in France, medieval clergy celebrated a "Feast of Fools" derived from the pagan Kalendae. A mock bishop or pope was elected. ecclesiastical ritual was parodied, low and high officials changed places and masked clergy rioted inside and outside churches.

In imperial Rome, fools were kept in wealthy houses? and deformity and imbecility fetched high prices in the slave market. References to household fools reappear in the 12th and increase during the 14th and 15th centuries, particularly in French account books. Fools were attached to courts, private households, corporations, taverns and even brothels. During the Renaissance, interest was taken in famous fools such as I1 Matello, the pet of Isabella d'Este. marchioness of Mantua; Triboulet. who amused Louis XII and Francis I; Cardinal Wolsey's enemy Will Sommers; the French female fool Mathurine; the German Claus Narr and Kunz von der Rosen, the intelligent. loyal fool of Maximilian I. The last official French royal fool was the formidable L'Angely who, standing behind Louis XIV at table, terrified courtiers with his sarcasm until finally banished for impertinence. Archibald Armstrong, fool to James I and Charles I, made so much money that. after being "unfrocked" for insolence to Archbishop Laud, he became a landowner in Cumberland. His successor, Muckle John, an insignificant simpleton, was probably the last English royal fool. In the 18th century household jesters declined in western Europe but flourished in Russia, and offending courtiers were sometimes degraded into court jesters.

The fool also appears in drama. In 15th-century French mysteries. he clowns, addresses the audience and even makes satirical comments on God. while the role of the Vice in Tudor interludes is probably derived irom that of the domestic fool. who is thus connected with the English stage clown. When *As You Like It, Twelfth Sight* and *King Lear* were produced, the clown in Shakespeare's company was Robert Armin, who published an account of household fools.

From the late 15th century to the early 17th century, the suppressed Feast of Fools was continued by members of secular fool societies who, adopting the dress and licensed freedom of the domestic fool. satirized contemporaries in burlesque processions and in farces (soties). which culminated in disrobing the characters to display the motley coat beneath the learned gown. The theme of 15th- and 16th-century fool literature was the universality of folly and its satire was Christian satire: Sebastian Brant's *Narrenschiff* is packed with knaves in cap and bells. for the knave is a fool who buys temporal pleasure for eternal pain. On the other hand the fool. having no social standing, can see truth impartially and even symbolize the divine "foolishness" which is "wiser than men." These ideas all contribute to the ironies of Erasmus' *Praise of* Folly and Shakespeare's *King Lear*.

The fool is easily confused with the buffoon. The laughter-making parasites who gained free dinners in Greece and Rome. the itinerant tricksters n·ho contributed to the art of storytelling in medieval and Renaissance Italy and the madcap poets and friars who diverted Pope Leo X, all exploited their eccentricities for purposes of entertainment. Such characters attract stock jokes and may become mythical heroes of jestbooks, and many pranks of Till Eulenspiegel, John Scogan and Bertoldo were derived from the legend of the peasant Marcolf who outwitted Solomon. The buffoon resembles the fool in his irresponsible absurdity, but he is mischievous rather than insane, whereas the fool is essentially a real or pretended lunatic. See also CLOWN.

FOOLS, FEAST OF, the name for certain burlesque, quasi-religious festivals which, during the middle ages, were the ecclesiastical counterpart of the secular revelries of the Lord of Misrule. (Lat. jestum stultorum, *follorum;* Fr. *fête* des fous.) The celebrations are directly traceable to the pagan Saturnalia of ancient Rome which, in spite of the denunciation of bishops and ecclesiastical councils, continued to be celebrated by the people with all their old licence. In the 11th century Bishop Burchard of Worms thought it necessary to fulminate against the excesses connected with it. The clergy set apart certain days as special festivals for different orders: the feast of St. Stephen (Dec. 26) for the deacons, St. John's day (Dec. 2;) for the priests, Holy Innocents' Day for the boys, and for the sub-deacons Circumcision, the Epiphany, or Jan. 11. The Feast of Holy Innocents became a festival of children, in which a boy, elected by his fellows of the choir school, functioned solemnly as bishop or archbishop, surrounded by the elder choir-boys as his clergy. (See BOY-BISHOP.) At first there is no evidence to prove that these celebrations were characterized by any indecorous behaviour; but in the 12th century such behaviour had become the rule. In 1180 Jean Beleth, of the diocese of Amiens, calls the festival of the sub-deacons festum *stultorum.* A young sub-deacon was elected bishop, vested in the episcopal insignia (except the mitre), and conducted by his fellows to the sanctuary. A mock mass was begun, during which the lections were read cum farsia, obscene songs were sung and dances performed, cakes and sausages eaten at the altar, and cards and dice played upon it.

This burlesquing of things sacred, though condemned by serious-minded theologians, conveyed to the child-like popular mind of the middle ages no suggestion of contempt, though when belief in the doctrines and rites of the mediaeval Church was shaken, it became a ready instrument in the hands of those who sought to destroy them. This naïve temper of the middle ages is nowhere more conspicuously displayed than in the Feast of the Ass, which under various forms was celebrated in a large number of churches throughout the West. Often the ass was a mere incident in the Feast of Fools; but sometimes he was the occasion of a special festival, ridiculous enough to modem notions but by no means intended in an irreverent spirit.

Celebration at **Beauvais.**—A singular celebration at Beauvais, which was held on Jan. 14, represented the flight into Egypt. A richly-caparisoned ass, on which was seated the prettiest girl in the town, holding in her arms a baby or a large doll, was escorted with much pomp from the cathedral to the church of St. Btienne. There the procession was received by the priests, who led the ass and its burden to the sanctuary. Mass was then sung; but instead of the ordinary responses to the Introit, Kyrie, Gloria, etc., the congregation chanted "Hinham" (Hee-haw) three times. At the close of the mass the priest, turning to the people, instead of saying, *Ite missa* est, brayed; the people, instead of Deo gratias, thrice responded Hee-haw, Hee-haw, Hee-haw.

Celebration at **Sens.**—At Sens the Feast of the Ass was associated with the Feast of Fools, celebrated at Vespers on the Feast of Circumcision. The clergy went in procession to the west door of the church, where two canons received the ass, amid joyous chants, and led it to the precentor's table. Bizarre vespers followed, sung falsetto and consisting of a medley of extracts from all the vespers of the year. Between the lessons the ass was solemnly fed, and at the conclusion of the service was led by the precentor out into the square before the church (conductus ad ludos); water was poured on the precentor's head, and the ass became the centre of burlesque ceremonies, dancing and buffoonery being carried on far into the night.

Various efforts were made during the middle ages to abolish the Feast of Fools. How little effect these had, however, is shown by the fact that in 1265 Odo, archbishop of Sens, could do no more than prohibit the obscene excesses of the feast, without abolishing the feast itself; the festival was, in fact, too popular to succumb to these efforts, and it survived throughout Europe till the Reformation, and even later in France; for in 1645 Mathurin de Neuré complains in a letter to Pierre Gassendi of the monstrous fooleries which yearly on Innocents' Day took place in the monastery of the Cordeliers at Antibes.

FOOL'S-PARSLEY, in botany, the common name for Aethusa *cynapium,* of the family Umbelliferae (*q.v.*), a common weed sparingly naturalized in the eastern United States and Canada and in cultivated ground in Great Britain. It is an annual herb, with a fusiform root and a smooth hollow branched stem 1 to 3 ft. high, with much divided (ternately pinnate) smooth leaves and small compound umbels of small irregular white flowers. The plant has a nauseous smell, and, like various other members of the family (*e.g.,* water hemlock), is poisonous.

FOOT, that part of the lower extremity on which the body rests when in an upright position, standing or moving. It articulates with the leg at the ankle joint. See ANATOMY, GROSS; SKELETON, VERTEBRATE.

The word is also applied to such parts of invertebrate animals as serve as a foot, either for movement or attachment to a surface. From the resemblance to the foot, in regard to its position, as the base of anything, or as the lowest member of the body, or in regard to its function of movement, the word is applied to the lowest part of a hill or mountain, to the plate of a sewing machine which holds the material in position, to the part of an organ pipe below the mouth, and the like. In printing, the bottom of a type is divided by a groove into two portions known as "feet." Probably referring to the beating of the rhythm with the foot in dancing. the word was applied in prosody to a grouping of syllables, one of which is stressed, forming the division of a verse. "Foot," (*i.e.* foot soldier) was formerly, with an ordinal number prefixed, the name of the infantry regiments of the British army. It is now superseded by territorial designations, but is used in the five regiments of the infantry of the household, the foot guards. As a lineal measure of length the "foot" is of great antiquity, estimated originally by the length of a man's foot (see WEIGHTS AND MEASURES). For the ceremonial washing of feet see MAUNDY THURSDAY.

FOOT, DISEASES AND DISABILITIES OF. The normal human foot is composed of 25 bones related to one another through joints, supported and stabilized by ligaments and controlled by muscles and tendons. (For its anatomy, see SKELETON. VERTEBRATE: *Appendicular* Skeleton: Lower Limb and JOINTS AND LIGAMENTS.) Its purposes are (1) to support the weight of the body and (2) to serve as a lever in propulsion of the body. Function of the feet depends upon anatomical integrity, joint stability, elasticity of the arches and good muscular tone. Anything disrupting any one of these factors will affect function adversely. Measures designed to preserve or improve these factors are basic to all programs of prophylactic or therapeutic foot care. Well-fitted supportive shoes, hygienic care, weight control and muscle-strengthening exercises are the most important.

Congenital Disorders.—Clubfoot and flatfoot, the two commonest congenital anomalies, are discussed in the separate articles CLUBFOOT and FLATFOOT.

A condition often mistaken for clubfoot is one in which the forefoot turns in, unaccompanied by downward flection or extreme rigidity. This is called metatarsus adductus. It is a condition ordinarily self-limited and self-correcting. Prolonged treatment is seldom necessary.

Bunions occur as a result of a congenital foot abnormality. This condition, hallux valgus, consists of an angulation outward of the first metatarsal bone with a compensatory deviation inward of the great toe. This results in a prominence of the medial aspect of the metatarsal head. Irritation by shoes results in an irritation of the soft tissues overlying the bone. The inflamed, tender bursa thus produced constitutes the bunion. Conservative treatment often suffices to control symptoms. Surgical reconstruction of the deformed foot gives the best long-term results in young patients.

Developmental Disorders. — Many of these overlap with congenital disorders. They may be subdivided into those produced by trauma and those produced by disease.

Metatarsalgia is basically an irritation of the soft tissues underlying the forefoot. When it is severe enough, weight bearing may be excruciatingly painful. Proper general foot care plus shoe corrections normally bring gradual relief. Other conditions of similar etiology are "policeman's heel" (calcaneal bursitis), inflammation of tendons (tenosynovitis) and of other bursae.

Disease may attack the feet as anywhere in the body — pyogenic infections. tuberculosis and tumours are not uncommon. Transient interruption of local blood supply to portions of certain bones produces aseptic necrosis, the local death of bone. Treatment is aimed at avoiding trauma until the body can replace this dead bone with living bone, limiting further deformity.

(J. DY.)

FOOT-AND-MOUTH DISEASE (APHTHOUS FEVER, EPIZOOTIC APHTHA, ECZEMA EPIZOOTICA) is a highly contagious disease affecting practically all cloven-footed animals. It is characterized by the formation of vesicles (blisters) on the tongue, lips and other tissues of the mouth, and on parts of the body where the skin is thin, as on the udder and teats, between the claws of the feet and around the coronary band above the hoof.

The disease appears suddenly and spreads very rapidly. The virus has an affinity for epithelium (the covering of the skin and mucous membranes of the gastrointestinal tract); it forms a primary vesicle where it gains entrance in the body. Within 24 to 48 hours it enters the blood stream, causing fever. During this phase, lasting 24 to 36 hours, the virus is excreted in the saliva, the milk, the urine and the faeces. The characteristic smacking of the lips then usually becomes prominent, ushering in the phase of the formation of secondary vesicles. These rupture in about 24 hours, leaving raw, painful surfaces.

Losses caused by foot-and-mouth disease are tremendous. The mortality in ordinary mild epizootics is only about 5%, but malignant forms of the disease have led to losses up to 50%. In those animals that survive, great losses in weight occur because the animals cannot eat. In surviving milk animals the flow is sharply diminished. Abortions and mastitis are common. Secondary infections are frequent, especially about the feet.

The diagnosis of foot-and-mouth disease is complicated by the existence of two other vesicular diseases, vesicular stomatitis and vesicular exanthema. Careful study is necessary to differentiate among the three. As is generally the case in virus diseases, an exact diagnosis can be made on the basis of animal tests. The horse is not susceptible to foot-and-mouth disease. The cow and the guinea pig are not susceptible to vesicular exanthema. When a fever, followed by characteristic vesicles, develops in swine, cattle and guinea pigs, but not in horses. a diagnosis of foot-and-mouth disease is justified. When all four of the animals develop vesicles, a diagnosis of vesicular stomatitis is justified. When lesions are seen in swine, but not in cattle or guinea pigs, and infrequently and to a mild degree in horses, a diagnosis of vesicular exanthema of swine is justified.

The virus of foot-and-mouth disease is the smallest known. Estimates indicate that the virus of smallpox is 10,000 times larger. In common with all viruses, living tissue must be used to cultivate it. It has been cultivated in tissue culture containing epithelium procured from guinea pig embryos.

The virus is resistant to destruction if the conditions are right. When contained in the epithelium of the vesicular coverings, it has been shown to remain active in hay for 30 days. In beef and pork carcasses kept at freezing temperature, the virus from the bone marrow was still active after 76 days. The virus is resistant for hours to such standard antiseptics as 0.1% bichloride of mercury, 5% phenol and 3.5% liquor cresolis compound, but 2% sodium hydroxide destroys the virus in a few minutes.

Immunity to foot-and-mouth disease is complicated by the existence of six known types of the disease virus. An animal recovering from foot-and-mouth disease is immune to the type of virus causing the disease but is susceptible to the other five known types. Further, the immunity is not permanent, many animals being susceptible to reinfection with the same virus type after one year. Immunization by vaccination is possible, but this confers immunity for only about four months. Adding to the complexity of the problem are variants of the disease virus within a type. There are recorded instances in which a virulent variant broke through the protection afforded by a vaccine of the same type.

Diagnosis of the type or types of virus is often important. This had been an expensive procedure until 1952, when the Foot-and-Mouth Disease Research institute at Pirbright, Eng., announced a test which determines the type of virus involved within a few hours.

Foot-and-mouth disease is reputed to be more than 2,000 years old, but not until the 17th and 18th centuries is there found trustworthy evidence of its presence. The disease is present in most countries of the world. In the early 1950s the only countries reporting freedom from it were the United States and its territories, Australia, New Zealand, Greenland, Iceland, Norway, Ireland, Northern Ireland, the Channel Islands, Central America, islands of the Caribbean and the West Indies.

The disease first invaded England in 1839 and quickly spread throughout Great Britain. There were 11 more outbreaks in Britain between 1839 and 1902, then none until after World War I. Each outbreak was stamped out as it occurred, but reinfection from other countries came with disturbing frequency.

Foot-and-mouth disease first invaded the United States in 1870 through cattle imported via Canada from England. Imported livestock were also responsible for outbreaks in 1880 and in 1884. After the latter outbreak, inspection, quarantine and rigid regulations prevented introduction of the disease with livestock. Other outbreaks occurred in 1902, 1914 and 1924 because of the importation of infected materials such as hay and garbage or imported smallpox vaccine. An outbreak occurred in 1929 because regulations were violated.

With the invasion of Venezuela (1950) and Colombia (1951), every country in South America had become victim to the plague. An outbreak which occurred in Mexico during 1946 caused grave concern to the United States. To fight it a Mexican-United States commission was formed that carried on an extensive campaign leading in 1952 to final elimination of the disease in Mexico. At the height of that campaign about 8,200 workers were employed, and more than $1,000,000 a month was spent. (NA. BR.)

FOOTBALL, the name given to a number of games in which each of two teams attempts to kick, carry or otherwise force a ball through a goal or across a goal line defended by the opponent. (For the U.S. game of soccer, *see* SOCCER.) This article, covering the major variations of football, is divided into the following sections:

I. EARLY HISTORY

The highly organized modern games grouped under the generic name of football all developed out of the *mêlées* or mellays of ancient and medieval Britain in which a round or oval object, usually the inflated bladder of an animal, was kicked, punched. carried or driven toward some goal. The immediate origin of the mellays is obscure in most cases. The real origin may well have been the child's apparently instinctive desire to kick any small object in its path, go on kicking it and keep it from other would-be kickers.

The Romans undoubtedly played a game called *harpastum,* the name being derived from the Greek word for "handball." An ancient writer says that the players were divided into two bands. each of which tried to force the ball beyond a line drawn behind its opponents; the game was started by throwing the ball up in the air in mid-field and in the course of the struggle there was much pushing backward and forward. It has not been proven that the Romans played *harpastum* in Britain during their occupation of the country, but it is extremely probable that they did, and in several cities and towns of Roman origin there are traditions of early games which might have been developments of *harpastum.* From early times there was a game of football annually on Shrove Tuesday at Chester, a town founded and named by the Romans. The shoemakers annually delivered a leather ball, to the value of 40d. or more. to the drapers, who played football with it between the hall of Rodehee and the common hall of the city; the tradition that the first ball used was the head of a dead Danish brigand may, however, mean that this game was not a child of *harpastum,* but the result of an indigenous method of celebrating victory over one's enemies. The game became so violent that it was stopped and replaced by a running match at Rodehee. Shrove Tuesday, a day of festival before a fast, became the day on which nearly all these medieval mellays, which seem to bear more or less resemblance to football, took place; among the more notable were those at Derby, Corfe Castle, Alnnick and Bromford, and the Cross of Scone and Midlothian, Scot.; in the last of these the married women of a parish used to play the spinsters and almost invariably beat them severely.

As their popularity increased among the humbler citizens these games were no longer confined to days of festival, and village greens became the scenes of practice matches at all times. Kings of England began to fear that the youth of the country was being distracted from the proper study of archery and that the efficiency of their armies would suffer. A Scottish writer reports that the Anglo-Scottish war which began in 1297 was not taken with a proper seriousness by either party; King Edward I's foot consisted of 2,500 levies from Cheshire and Lancashire, of whom the Lancastrians were old opponents of the Scots raiders and had to be restrained by orders to their commanders from playing football nith instead of fighting their hereditary enemies. Whether this is a true story or not, Edward III decided in 1365 to prohibit football for military reasons and further edicts were made by Richard II, Henry IV, Henry VIII and Elizabeth I; these prohibitions were no more effective in the long run than were those in Scotland against the playing of "gowffe." The festival matches became bigger and bigger, and Richard Carew in his survey of Cornwall, published in 1602, records that goals were set three or four miles apart and two or three parishes united to play two or three others "hurling over country." Most of these games had local names such as "hurling" or "camp ball," but between them they contained in embryo most of the characteristics of modern football with mellays or scrums and judicious passing and running. Joseph Strutt, a great historian of English sport, wrote in 1801 a description of a match at football which is easily recognizable: ". . . an equal number of competitors take the field and stand between two goals placed at a distance of 80 or 100 yards the one from the other. The goal is usually made with two sticks driven into the ground about two or three feet apart. The ball, which is commonly made of a blown bladder and cased with leather, is delivered in the midst of the ground, and the object of each party is to drive it through the goal of their antagonists, which being achieved the game is won. The abilities of the performers are best displayed in attacking and defending the goals; and hence the pastime is more frequently called a goal at football than a game at football. When the exercise becomes exceedingly violent the players kick each others' shins without the least ceremony, and some of them are overthrown at the hazard of their limbs."

So great. indeed, was the violence of the games in the 18th century that other historians report that broken shins, broken heads, torn coats and lost hats were among the minor casualties, and that a Frenchman watching a game at Derby exclaimed that if Englishmen called this playing it would be impossible to say what they would call fighting.

Origin of Rugby.—Football began to become more orderly and a regular pastime, as opposed to a periodic outbreak of legal (or illegal) violence, with the growth of the great English public schools, where the sons of the richer and more aristocratic families were cooped up together and for long periods could not take their sports individually as they had done formerly at home with rod, gun, horse or sword. They adopted in one form or another the rowdy games which had been played so long by workingmen but which still were regarded by the university authorities as boisterous, undignified and totally unsuited to gentlemen, particularly those headed toward scholarly lives.

No two schools seem to have had anything like the same rules; there was still no governing body for the game, and almost the only thing on which there seems to have been common agreement was that the ball must never be carried or passed by hand in the direction of the opponents' goal.

It was a famous violation of this rule on carrying the ball by William Webb Ellis at Rugby school in 1823 which led to the development of the basic feature dividing modern players into two parties, those who want to play with their feet alone and those who want to play with both hands and feet. At first Ellis' behaviour was condemned even at Rugby; but the school soon decided to permit running with the ball by players who received it by fair catch; next it mas permitted if the ball were caught on the bound, and finally all restrictions on running with it were abolished. Ellis was translated from a lawbreaker into a great hero, and a tablet on one of the boundary walls of the Rugby school ground bears the following inscription: "This stone commemorates the exploit of William Webb Ellis who with a fine disregard for the rules of football as played in his time first took the ball in his arms and ran with it, thus originating the distinctive feature of the Rugby game. A.D. 1823." It was at Rugby, too, that the players seem to have been posted in something like the modern Rugby positions in the field; Thomas Hughes records in his description of a Bigside game at Rugby in *Tom Brown's School Days* that the teams were divided into four groups—the forwards nho fought out the mauls or scrummages, the dodgers (rather like halfbacks), the boys in quarters (modern three-quarter backs) and the goalkeepers.

Codification of Rules.—Outside matches were not played by the schools at this time; indeed, it mould have been almost impossible to play them as each school had its own game and there were no independent clubs until the middle of the 19th century. Rugby school played its first outside match only in 1867 and did not meet another school until 1896. However, old boys of the schools began to feel the need for settled rules and organized clubs so that they might go on playing. Two old boys of Westminster founded an ill-fated old boys' club in 1846, and in the same year H. C. Malden and George Sault called a meeting at Cambridge university of representatives of all schools which drew up a code of rules; no copy of this code survived as the game did not achieve popularity at the university at that time; but it is known that the meeting took what it thought the best features of the various games and expressly prohibited running with the ball in the Rugby manner. In the next 15 years a number of independent clubs came into being; among them mere Guy's Hospital Football club (founded in 1843 according to one claim but probably a little later in fact), Sheffield (1855), Blackheath (1857. but reformed in 1862), Hallamshire (1857), Old Harrovians (1859) and Forest F.C. (1859 or 1860), later known as the Wanderers. There were still only a few rules in common; most clubs restricted teams to

20 a side and prohibited offside play; a player was considered off side generally if he was between the ball and his opponents' goal; a match was decided by a majority of goals and a goal was scored by kicking the ball between the sticks or posts defended by the other side and under a tape; the ball was a round inflated rubber "bladder," generally covered with cowhide. Only Blackheath stood firm for the Rugby running with the ball.

In Oct. 1863 football enthusiasts at Cambridge finally agreed upon a set of uniform rules and had them published. In the same month representatives of the various independent clubs met at the Freemasons tavern. Great Queen street, London, to draw up a set of rules. Cambridge had rejected the Rugby principle, but the independent clubs held many long debates on this point. Eventually they decided against carrying the ball and on Dec. 1 published a set of rules entitled *Rules of the London Football Association*, which prohibited carrying. Blackheath, which had once more led the Rugby party, withdrew from the association and went its own way. It was not long alone. for in the same year the Richmond Football club had been formed and supported carrying; the north of England was of the same opinion and had powerful clubs at Manchester and Liverpool; and in 1869 the Oxford University Rugby Football club was formed. Obviously there had to be Rugby rules, and on Jan. 26, 1871, representatives of 17 clubs and 3 schools met at the Pall Mall restaurant, Regent street, London, formed the Rugby Football union, drafted bylaws, appointed officers and instructed a committee of 13 to draw up the laws on the basis of the code in use at Rugby school. The actual drafting of the code was left to three Rugby alumni—A. Rutter, E. C. Holmes and L. J. Maton; they in turn deputed Maton as draftsman, who completed his work in good time, and saw the laws accepted as they stood by a special general meeting on July 24.

Both parties in football now had rules and a governing body; both still consisted almost entirely of old boys of the public schools; probably neither had the least idea that the industrial revolution and consequent collection of huge numbers of persons in the towns was to lead to the spread of their sports until association football (soccer) was the game of all the world and Rugby well known in all the British Commonwealth countries and a popular sport in France and elsewhere. Soccer and "rugger," as they became known popularly, were on the move. (L. M.)

II. U.S. FOOTBALL

A. U.S. College Football History

The Beginnings.—U.S. universities along the Atlantic seaboard had known football as an informal campus pastime from early in the 19th century. alternately frowning on it or tolerating it, as circumstances seemed to dictate. At Princeton in 1820 they played a form of association football called "ballown."

As in the British schools, football in the U.S. colleges varied from campus to campus, but all played fundamentally the kicking game. Intercollegiate contests were undreamed of in the middle of the 19th century.

The Harvard faculty banned football from the campus in 1860, and town authorities at New Haven, Conn., forbade Yale students to play it on the public green in 1858. Football nevertheless continued to grow in the colleges, and finally in 1867 the Princeton rules were drawn up, specifying 25 players to a side, and a Princeton team of that number engaged in a game with Princeton Theological seminary. It was then only a step to the first intercollegiate meeting, played by Princeton and Rutgers at New Brunswick, N.J., on Nov. 6. 1869, by sides of 2j men. Rutgers won by 6 goals to 4. The game, as played at the two colleges, was not timed by a watch, but was decided when one team scored six goals.

The teams used a round, rubber ball, and a goal was scored when the ball was kicked under the crossbar (rather than over it as in the modern game) and between the posts defended by the opponents. No running with the ball was permitted, but it could be batted with the hands as well as kicked. Under Princeton rules a player might make a fair catch and gain a free kick therefrom. The game at New Brunswick mas played under Rutgers' rules. A week later the teams met in Princeton, N.J., under Princeton's rules, with the special provision that eight goals were required for victory. Princeton won that game, 8–0. The faculties of the two colleges then joined forces to prevent the playing of the third game. scheduled for New Brunswick on Nov. 20.

Columbia joined the intercollegiate football family in 1870, suffering a 6–3 defeat by Rutgers at New Brunsmick on Nov. 12. Yale became a competitor in 1872. defeating Columbia at New Haven on Kov. 16 with 20 players on a side. The Harvard faculty lifted its ban on football in 1871 and the game began to reappear on the campus. Harvard, ho ever, played a carrying game. more like Rugby, called the "Boston game." This prevented the university from participating in the first intercollegiate rules convention in the United States because the other colleges—Yale, Princeton, Columbia and Rutgers—adhered to the kicking game.

At that convention, held in New York city on Oct. 19, 1873, uniform rules along association lines were adopted. The first Yale-Princeton game was played under those rules at New Haven on Nov. 15 of that year. Princeton winning 3–0. The same year Yale met a team from England calling themselves the Eton Players. They played with 11 men on a side and persuaded Yale to play with that number instead of 20. So Yale was to become the advocate of 11-man teams.

Harvard continued with its running game, which permitted a player to pick up the ball and, if pursued, to run with it. Lacking games with U.S. colleges because of differences in rules, Harvard scheduled two games with McGill university of Montreal, Que., in the spring of 1874. They were played in Cambridge. A third game was played in Montreal in the fall. The first of the two at Cambridge was played on May 14 under Harvard rules. Largely a kicking game despite the rules allowing running with the ball, it was won by Harvard 3 to 0. The next day the teams played under the rules of the Rugby Football union with an egg-shaped ball, and a scoreless tie resulted. Canadian Rugby rules allowed touchdowns (running with the ball across the goal line) as well as goals to count in the score.

The games with McGill had far-reaching importance in committing Harvard to the running Rugby game, and thus influencing the pattern of the U.S. game that was to evolve. Harvard adopted the Rugby rules and Harvard and Yale met for the first time on Kov. 13, 1875, in New Haven in a game that was largely Rugby. The desire for a contest between the two universities had led to a meeting of representatives at Springfield, Mass., on Oct. 16, 1875, where the "Concessionary Rules" were adopted. Yale conceded to the Rugby principle of running with the ball and tackling. Yale was won over to Rugby in that game. won by Harvard 4 goals to 0, and adopted the Rugby rules in 1876. That year Harvard conceded to Yale's request to play with 11 rather than 15 men on a side.

The 1875 game was witnessed by two Princeton players, W. Earle Dodge and Jotham Potter, who were so taken with Rugby that they called a mass meeting at Princeton in early Nov. 1876. By a narrow margin in a turbulent session it was voted to adopt Rugby and to invite Harvard, Yale and Columbia to a convention. Thus came about the important meeting of Nov. 23, 1876, at Massasoit house, Springfield, at which the Intercollegiate Football association was organized and the Rugby union code adopted with a change in the scoring. Rule 7, which read, "A match shall be decided by a majority of goals alone," was changed to "A match shall be decided by a majority of touchdowns. A goal shall be equal to 4 touchdowns, but in case of a tie, a goal kicked from a touchdown shall take precedence over four touchdowns."

The old round rubber ball was replaced by the egg-shaped leather Rugby ball and players were now initiated into the complexities of "off side" and "on side."

Yale went into the Springfield meeting convinced that Rugby could best be played by 11 men. When the convention voted against reducing the sides, Yale declined to become a full member of the league but readily became a playing member. Yale won the first championship by defeating Princeton and Columbia, each by two goals. The league code was made retroactive to include games played prior to the meeting, giving Yale credit for its victory over Harvard by one goal to nothing the week before the meeting was held.

Experiment With Rules.—Yale continued to attend meetings of the Intercollegiate Football association! being represented by Walter C. Camp of the class of 1880, who had made his football debut on the Yale Blue's 1876 championship team and whose name soon became almost synonymous with football in the United States. Though Camp continued to insist on a reduction of teams to 11 men, the league still refused to effect the change; Yale continued playing in the league while refusing to become a full member. It finally joined the league in 1879, and a year later the league reduced the sides to 11 men. The playing field was reduced from 140 yd. by 70 yd. to 110 yd. by $53\frac{1}{3}$ yd. in 1880, conforming to the British maximum length but dipping almost one-third under the British maximum width.

Next came another distinctive feature of the U.S. game, definite possession of the ball. Also, the quarterback made his appearance, along with a new method of putting the ball in play—by the holder snapping it back with his foot to the quarterback. In Rugby the forwards heeled it back in the scrurn.

This practice was legalized in 1880 when the U.S. scrum officially became a scrimmage and definite possession of the ball became an approved tactic. This was the first great change which sent the U.S. game along a path so divergent from that of Rugby. Thus begun, the tendency to change accelerated, and finally the game of U.S. football evolved.

Definite possession of the ball having been established, teams soon learned that, if they themselves could not score, superior opponents could be prevented from scoring if the team in possession of the ball refused to surrender it. No means had been devised to force surrender of the ball, and Yale and Princeton availed themselves of this oversight to the fullest. The two strongest teams in the association, Yale and Princeton played annually for the championship in the late 1870s and through the 1880s. Having respect for each other, they turned their games of 1880 and 1881 into farces by what became known ,as the "block game." The team receiving the kickoff would retain the ball for the entire half, without making any particular effort to advance it. The result was two dull scoreless ties, and a demand from the college public that something be done about it.

Camp solved this situation in 1882 by introducing the system of downs with a rule requiring a team to gain five yards or lose ten yards in three downs or else surrender the ball to the opponents on the spot of the third domn. In 1883 the distance to be lost was increased to 20 yd. This rule forced the attacking team to kick on third domn unless it seemed certain that sufficient yardage could be gained to retain the ball. The five-yard rule gave the U.S. football field its barred appearance, with white lines at intervals of five yards, and Ied to the term "gridiron" as a synonym for the football field.

The rule was the heart of the modern game. It led to the development of a plan of attack, strategy, and to Yale's abandonment of kicking as the predominant offense and the development of the running attack by short, hard rushes.

U.S. players developed the habit of touching the ball down "for safety" behind their own goal lines so as to be able to gain a free kick from the 25-yd. line. No penalty was attached to the safety touchdown until 1881, and it was the usual procedure for any team having possession of the ball nearer its own goal than 25 yd. to touch it down for safety and kick out. Public disapproval of the Yale-Princeton block game of 1880 led directly to the inclusion of the safety as a scoring play in 1881. It was a provisional scoring play in 1881, decisive only when the game otherwise was tied, but it had half the value of a touchdown in 1882. The touchdown was increased in value in 1881 and 1882. A touchdown and goal after touchdown were ruled to be superior to a field goal, and four touchdowns were made more valuable than a field goal.

The introduction of the safety as a scoring play and the new values assigned to the touchdown further complicated the scoring ratios, but still nobody thought of numerical scoring as the solution. The numerical idea was forced on the football world by the Harvard-Princeton game of 1882, in which Harvard scored a touchdown and a field goal and forced Princeton to make two safeties while the Tigers got a touchdown and goal. Referee R. W. Watson (Yale, 1881) ruled that Harvard had won, but the game aroused so much discussion that Camp decided that the time for numerical scoring had arrived.

Camp accordingly introduced these scoring values for the 1883 season: touchdown, 2; goal after touchdown, 4; goal from field: 5; safety by opponents, 1. In 1884 the touchdown was increased to 4 points and the goal after touchdown reduced to 2. The safety was set at 2 points to maintain its value as half that of a touchdown. Four other alterations were made in scoring values in the ensuing 28 years, each tending to give importance to the touchdown and causing it to overshadow the field goal. Scoring, nevertheless, was let alone more than anything else in the game and was not altered between 1912 and 1958. The touchdown was increased to 5 points in 1897 and the goal after touchdown (conversion) reduced to 1. The field goal was cut to 4 points in 1904 and to 3 in 1909. The touchdown was increased to 6 points in 1912. In 1958 the conversion became worth 2 points if the ball was carried or passed rather than kicked.

Assured of uninterrupted possession of the ball by the revision which established the U.S. scrimmage in 1880, teams soon began to devise signals to indicate to their players the particular play they intended to use. At first, these were spoken words or phrases. Within a decade words had been replaced by numbers. In the early 1920s the huddle was introduced by Robert ("Bob") Zuppke, University of Illinois coach, and soon was universally adopted. In the shouted signals, the quarterback invariably called the play, sometimes at the direction of the captain or the coach. In the huddle, any player may give the signal, or even call the play by name, with no fear that the opposition will be the wiser.

Alignment of the players in the U.S. game, after the establishment of uninterrupted possession of the ball and before the game was closed up, departed sharply from the practice in British Rugby. Instead of being locked in a scrimmage, U.S. forwards were widely spread across the field and the backs played at correspondingly wide posts, from three yards to five yards behind the line. Players in the line (linemen) earned, in the 1880s, the names by which they now are known—ends, tackles, guards and centre—though at the outset the end was known as the end rush and the centre as the centre rush. The centre rush heeled the ball back, or passed it with his hand, to the quarterback, who was not eligible to run with it. The quarterback, in turn, passed it. back to a halfback or the fullback.

Players still were prohibited from taking any part in a play if they were ahead of the ball, but backs soon developed a habit of running at the side of the ball carrier to fend off tacklers. It was only natural to progress from this to running ahead of the carrier and, while thus off side, to blocking intended tacklers out of the play. This infraction first was winked at and then was incorporated into the rules as a legal move. Interference for the runner thus was born and legalized, with Princeton a leader and George W. Woodruff and William W. Heffelfinger of Yale the most famous of the early blockers.

The zeal of interferers was matched by that of tacklers. The rules prohibited tackling below the waist, but inspired defenders began creeping down toward the knee. This practice also was winked at in its early years. Finally, in 1888, it was made legal, completing the final phase of the metamorphosis which had been begun in 1880 with the establishment of definite possession of the ball. At the same time, linemen were required to hold their arms at their sides instead of extending them. As the linemen, formerly spread across the field, mere brought in close, the backs came in close too for protection against the low tackle.

Thus came about the standard close formation, known as the T formation, and the end of the open Rugby game. The wide arc from which the attack might spring in the backfield was constricted. Wide passes and open play disappeared overnight. To plow through tacklers who were permitted to grasp a runner

Bottom right: English (white jerseys) and New Zealand players charging for the ball in a game at Twickenham, Jan. 30, 1954 as low as the knee, backfield men had to charge low and hard and with tremendous interference. Football was no longer graceful and fast; it was lumbering and slow and very rough.

Spread of the Game.—From its cradle in the larger eastern colleges of the United States, football spread quickly through the east and then to other sections of the country. Pennsylvania, Wesleyan, Stevens, Amherst. Williams, Dartmouth, Brown, Cornell, Penn State, Lafayette, Lehigh, Trinity and many others took up the game in the 1870s and 1880s. In Canada, football already was well established at Toronto and McGill.

In the U.S. middle west, the University of Michigan became the pioneer. A team was organized as early as 1873, but Michigan could find no opponent until Racine college, Racine. Wis., was met in the park of the Chicago National league baseball club on May 30, 1879. Michigan won by one touchdown and one field goal to nothing, and went on to establish football on a firm foundation in the next few years. The Wolverines also pioneered in intersectional football in 1881, meeting Harvard, Yale and Princeton within five days on a single eastern trip. Michigan lost all three games but, nothing daunted, tried the same thing again in 1883, this time against Wesleyan, Yale, Harvard and Stevens. Michigan again lost all the games, but football was on its way at Ann Arbor and in the west. Minnesota, Iowa, Purdue. Northwestern and other middle western universities took up the game in the 1880s. Most significant addition of all, although comparatively unnoticed at the time, was that of Notre Dame, which made its debut by losing, 8–4, to Michigan on the Notre Dame campus in South Bend. Ind., on Nov. 23, 1887.

Football was introduced to the south in 1877, when Virginia Military institute played Washington and Lee. On April 9, 1880, Centre college of Danville. Ky., famed 40 years later for its "Praying Colonels," and Kentucky university (later Transylvania) played a scoreless tie in Lexington, Ry., but the game was destined not to catch on in the south until later. Eight years passed before Trinity (later Duke) defeated North Carolina by 16–0 at Raleigh. This game was played on Thanksgiving day of 1888. Football then spread quickly to Virginia, Vanderbilt, Auburn, Georgia and other south Atlantic and southern colleges. It also returned to the Kentucky colleges in the early 1890s, and soon afterward spread to the southwest, the Missouri valley, the Rocky mountains and the Pacific coast. By the turn of the century it had become the national academic game, but the power remained concentrated at the colleges which had pioneered in the game in the east—Yale, Harvard. Princeton and Pennsylvania. In the middle west, Michigan, Chicago, Minnesota and Wisconsin were beginning to challenge the supremacy of the east, but the westerners were about a decade away from gaining real equality.

Concentration on Power.—Speed and deception had been the prime requisites for success at the Rugby-style game played in the United States up to 1888. Legalization of knee-high tackling in 1888 had closed up the game and placed a premium on power. Winning requisites became power, speed and deception, with the first far outweighing the other two.

Inventive genius on the campuses remained the same as it had been in the years when young Americans first began making over the original Rugby game. Other youths began devising ways and means of getting greater power into the plays in order that massed defenders could be either crushed down or split asunder to give the runner free passage toward the enemy goal. The game was rough, but since it also was slow injuries were not so numerous as often supposed. Injuries nere destined to mount only when some semblance of speed had been regained. This speed was acquired when momentum, prior to the snap of the ball. was added to the mass game through the inventiveness of Lorin F. Deland of Harvard and Woodruff of Yale, who coached Pennsylvania to its first real football success in the middle 1890s.

An invention dating back to Rugby days served as the vehicle for the most devastating of these momentum mass plays—the "flying wedge." As early as 1884, strategists at Princeton and Lehigh (no one knons which thought of it first) discovered that nothing in the rules said that the ball had to be kicked to the receiving side on a kickoff. They learned that the rules could be satisfied if the kicker merely touched the ball with his foot. He then was free to tuck himself away within a wedge formed by his ten mates and go trotting along for what usually amounted to a handsome gain against opponents who were restrained by rule to a point ten yards removed from the kickoff. This became known as the "V trick" and was the standard means of putting the ball into play by all teams from 1885 until it was forced on the attention of the rules committee nine years later.

Deland, who never played football at Harvard but who was a master strategist, devised a means of adding momentum to the V trick in 1892. He grouped the ten men of his wedge not around the kicker on the 55-yd. line but near the side lines and back on their own 25-yd. line, five men on each side of the field. At a given signal, the two groups charged forward together, headed for the kicker. At the instant they converged on him, the kicker "babied" the ball with his toe and stepped within the wedge. The play was saved for the Yale game of 1892, and the result was devastating. Harvard failed to win the game, failed even to score with the play, but it did plow 45 yd. through amazed Yale defenders to the Blue's 10-yd. line. Yale later scored a touchdown and goal to win by 6–0, but the flying wedge was the sensation of the game. It spread to all points of the football map in 1893, and injuries from its use aroused widespread criticism.

Woodruff became coach of the University of Pennsylvania in 1892. He introduced the principle of flying interference by grouping two or three linemen in the backfield and having them start for ard, with the spare backs, before the ball was snapped. The carrier took the ball from the quarterback and took his place in this charging set of players, usually second in a group of four interferers or third in a group of five. It was necessary to get power behind the ball as well as in front of it, since interferers and carrier were permitted to run with arms interlocked about bodies, and pushing and pulling was entirely legal. From this mass momentum principle Woodruff, in 1894, invented a famous play known as "guards back," which enabled Pennsylvania to win undisputed championships in 1895 and 1897, its first two titles.

Prior to this Amos Alonzo Stagg, the most inventive of all football coaches and one of Yale's most famous graduates, had launched the fast-moving mass attack with his "ends back" formation of 1890–91 at the International Y.M.C.A. college at Springfield, Mass. (See below.) He followed it with the "turtleback" in 1891 (claimed by Harvard in 1893) and the "tackles back" in 1894 at The University of Chicago.

Meanwhile, the uproar against injuries resulting from mass momentum plays had increased. The universities themselves were at odds over it and over the eligibility of graduate students. Harvard and Pennsylvania, having large graduate departments and schools and an abundance of brawny material, advocated mass play and eligibility of graduate students, regardless of how long they had played football before taking up graduate courses. Yale and Princeton, being in the main undergraduate colleges and having few men other than undergraduate students on their campuses, insisted on a four-year eligibility rule and the minimization or even elimination of momentum from mass play. It never occurred to anyone then that mass play itself could be eliminated. The original Intercollegiate Football association was broken up by these disputed points after the season of 1893 and football was without a governing body. Chaos reigned, and criticism of the game was universal.

In this emergency, the University Athletic club of New York invited Yale, Harvard, Princeton and Pennsylvania to send representatives to a meeting at the club and draw up a code for the use of all colleges. Yale had just broken relations with Pennsylvania; Princeton and Harvard had not been competing for several seasons; Yale was on the verge of its break with Harvard; and Princeton was about ready to say good-by to Pennsylvania. But to save the game, representatives of what had come to be known as the Big Four subordinated their personal differences and agreed on reformations. In the sweeping rules revision the old Rugby kickoff was brought back. The Lehigh V, Princeton wedge and flying wedge were outlawed by a decree forcing the kicking team to kick the ball at least ten yards into enemy territory on the kickoff. Playing time was reduced from 90 minutes to 70 minutes, divided into halves of 35 minutes each, and a compromise mas reached on momentum. The rule makers decreed that no more than three men might group more than five yards behind the line of scrimmage for the purpose of launching a momentum mass play

These reforms accomplished much, but not enough to satisfy Yale and Princeton. These two colleges enlisted the support of Navy and broke with Harvard and Pennsylvania in the spring of 1895 to formulate separate rules of their own. Harvard and Pennsylvania took Cornell into their group and drew up another set of rules. The Yale-Princeton rules struck at momentum mass play by decreeing that seven men must be on the line of scrimmage of the team in possession of the ball and that only one offensive back might start forward before the ball was snapped. Harvard, Pennsylvania and Cornell retained their rules of 1894.

With two sets of rules in effect. the season of 1895 was not chaotic. but it was far from satisfactory to either camp. A compromise was reached early in 1896 and a permanent rules committee was set up. Proponents of momentum mass play yielded by agreeing that no player on the offensive side might take more than one step toward the goal of the defensive team before the ball was snapped without coming to a full stop. The Yale-Princeton group gave ground by permitting the offensive scrimmage line to be reduced to five players, with the other two forwards in the backfield to add power, if not momentum, to the plays. Momentum thus was reduced to a minimum, but the mass remained and football continued to be rough. Nevertheless it proceeded for another decade before being struck by another reform wave.

Chief tactical development of the 1890s, other than Woodruff's guards back, was the play along the same lines known as tackles back, worked out by Stagg, who was coaching at Chicago. It was just as rough and effective as guards back but was more mobile. It depended for its success on the power of interlocked interference, power behind the ball. It embodied the art, expounded for purposes of war by Gen. Nathan Bedford Forrest. of striking a given point with superior force before defenders had time to reinforce it or even realize the necessity of reinforcing it. It had greater deception than guards back. In 1899 Harry Lane Williams of Yale, coaching at Penn Charter school before launching his distinguished career at Minnesota, used the "tackle back," pulling one tackle back to line up behind the other. Camp introduced it at Yale in 1900

Birth of the Modern Game.--In the decade following the reform of the mid-1890s, football went on its course little changed. At the beginning of the 20th century, Fielding Harris Yost of West Virginia and Lafayette coached Michigan to pre-eminence, perennially challenged by Stagg at Chicago and Williams at Minnesota and by various coaches at Wisconsin, including Philip King of Princeton. A Yost pupil, Daniel Earl McGugin, lifted Vanderbilt from the ranks of ordinary elevens and set the pace for development all through the south. Yale let well enough alone in the east and went on winning regularly from Harvard and Princeton.

But football kept on injuring players, and the public outcry against the game became greater and greater. The middle western universities, organized for about a decade into the Western conference. heeded these protests by making drastic revisions following the 1905 season. Freshmen students were barred from varsity teams. and schedules were limited to five games. Transfer students were eligible only after one year's residence, and all players were limited to three years' participation in football. The Western conference was powerless. however, to effect any changes in the game. That authority was vested solely in the rules committee which had grown out of the reform wave of the mid-1890s.

In this emergency Pres. Theodore Roosevelt acted. Realizing the necessity for devising a more open and less brutal game if football was to survive, the president summoned representatives of Yale. Harvard and Princeton to the White House and urged them to take steps to save the game. Representatives of 28 colleges met in New York city and formed a committee that was the forerunner of the National Collegiate Athletic association. Led by Capt. Palmer E. Pierce of the U.S. army, it merged with the established governing body headed by Camp. The two groups formed the American Inter-Collegiate Football Rules committee and at a meeting on Jan. 12, 1906, adopted a reform program to make the game safer and more interesting.

From that conference grew the modern game of football. The prime demand was that the game be opened up. This was accomplished by the revolutionary legalization, contrary to all Rugby fundamentals, of the forward pass. Introduction of the forward pass in 1906 took rank with the legalization of the U.S. scrimmage in 1880 as one of the greatest steps away from parent Rugby toward a distinct U.S. game. Compared with these fundamental changes, other alterations through the years had been minor. Without definite possession of the ball, U.S. football still would have been Rugby. Without the forward pass, it still would have been mass football.

The forward pass, recommended to Camp by John Heisman of Penn as early as 1903, was sponsored strongly at the 1906 meeting by John C. Bell of Pennsylvania and Paul J. Dashiell of the U.S. Naval academy. It was adopted—but with severe restrictions, which were to be eliminated one by one through the ensuing few years. At the outset, the forward pass had to be thrown from five yards behind the scrimmage line and had to cross the scrimmage line at a point at least five yards out from the spot where it had been put into play. Eligible receivers were the players at the ends of the line of scrimmage and those behind it, excepting of course the thrower. Penalty for failure to complete a forward pass was 15 yd. from the point where the ball had been put into play, and loss of a down. With such restrictions, the forward pass was little used, particularly in the conservative universities of the east which had little to gain through the development of the pass and much to lose. Yale nevertheless defeated Harvard in 1906 on a long forward pass.

Other changes adopted included increase of the distance to be gained in three downs from five to ten yards, so that teams would be forced to abandon short-gaining line plays in favour of longer-gaining sweeps and slants. All players on both teams were ruled to be on side the instant any punt struck the ground. Hurdling was prohibited and centres, guards and tackles were forbidden to play in the backfield unless they were five yards back. The neutral zone was established, separating the teams by the length of the ball. Time of the game was cut from 70 minutes to 60, divided into halves of 30 minutes apiece. Like the other and more important changes made in 1906, however, the rule on the time was only the first step in a series of experiments which continued until 1912, when the modern game assumed its ultimate pattern.

In the mass game of 1888–1905 the defensive alignment amounted to a ten-man line. The two halfbacks backed up the tackles and the fullback backed up the centre, virtually on the line. The quarterback was stationed from 20 to 40 yd. back, depending on the down and the ability of the opposing punter. This arrangement was effective and satisfactory as long as the offensive team could not throw the ball forward. It could cope with the interlocked interference hurled at it. In introducing the forward pass in 1906, the rules committee neglected to outlaw interlocked interference. Necessity demanded that the defensive halfbacks withdraw from support of their tackles and play several yards back to be on guard against forward passes. Restrictions on the pass being what they were, this made little difference in 1906, but unsupported tackles took increasingly severe beatings through the next few years as one restriction after another was removed from the pass and as more and more men learned to throw the ball. The defensive halfbacks moved farther and farther away from the tackles and left them more and more open to being overwhelmed by interlocked attackers. Tackles frequently suffered serious injuries from this circumstance.

In 1907 the 15-yd. penalty for failure to complete a forward pass was removed, and in 1910 it no longer was necessary for the ball to cross the scrimmage line at a point 5 yd. out from where it had been put into play. In 1910 the pass could not be thrown more than 20 yd. beyond the scrimmage line and a punt, to put players of the kicking team on side, had to travel 20 yd. or more beyond the line—keeping both the umpire and the field judge busy measuring with their eyes. In 1912 the onside kick was eliminated (unless the kicking team had a man stationed behind the kicker, in ahich case he was on side without regard to the ball's striking the ground) and all restrictions were removed from the forward pass. except that only one such pass could be thrown during a single scrimmage, and it had to be thrown from five yards behind the line of scrimmage. Through these developments of the pass and experimentations with the onside kick. the running game, featuring interlocked interference. came more and more to overtax the capacity of tackles left unsupported by halfbacks who had more demanding chores to perform elsewhere. Matters came to a head in 1909 when at least half a dozen tackles, including Cadet Eugene Alexis Byrne of Army, were killed or fatally injured on the field of play. The solution which had been beckoning after 1906 was accepted; interlocked interference was outlawed, beginning in 1910. The offense was required to have seven men on the line of scrimmage.

Abolition of interlocked interference so weakened the offense in 1910 and 1911 that the balance of pomer passed to the defense and many scoreless ties resulted Teams of anywhere near equal strength were unable to carry out any sustained attack against each other. More often than not games were decided on the breaks or on field goals. This led the rules committee to untrammel the forward pass in 1912 and give the attacking team a fourth down in which to make its ten yards. The value of the touchdown was increased to 6 points in 1912 to enable a team scoring a touchdown and goal to defeat an opponent which had kicked two field goals. The length of the field was reduced to 100 yd. in 1912, but two end zones 10 yd. deep were established. In these end zones the attacking team was permitted to complete forward passes.

Development of the Modern **U.S.** Game.—The metamorphosis of football from the close-order game to the open game was accomplished by the rules changes effected between 1906 and 1912. The rules themselves were changed only by degrees from 1913 to the mid-1950s but tactics and strategy of the open game had hardly begun to take effect before 1913. Up to 1906 the team with the greater power always won. Large eastern elevens, as a consequence, were little disposed to experiment with any innovations in the open game wherein a physically inferior rival with fewer resources might not only score upon but even defeat one of the football mighty. The big teams included the pass in their repertoire of plays but chiefly because all major rivals might be expected to do the same. All used it with caution.

It remained for Coach Jesse Harper and his Notre Dame eleven to open the eyes of the east to the dazzling possibilities of the forward pass in the first Notre Dame-Army game at West Point on Nov. 1, 1913. Led by the forward pass combination of Charles E. ("Gus") Dorais and Knute Rockne, this unheralded Notre Dame team humbled Army by 35–13 that afternoon The result was not only defeat but progress for Army The progress developed when Cadets Vernon E. Prichard and Louis Merillat, Jr , obtained permission from Coach Charles D. Daly to use a forward pass play nhich those tno cadets had been experimenting with all summer, even as Dorais and Rockne had experimented with Notre Dame's pass. The result was a crushing defeat, by 22–9, of a favoured Navy team in Army's climactic game.

Football development continued apace until the entry of the United States into World War I, but it was not until after that war that the game reached its ultimate development by the spread of good material and good coaching to all major colleges and to all sections of the country. It nas not until after the mar that the forward pass reached its highest development and that Rockne led Notre Dame to unchallenged pre-eminence.

Robert C. Folwell of Pennsylvania, coaching at Washington and Jefferson, developed a short forward pass straight over the line and made it more effective by sending his tackles crisscrossing into the enemy backfield to take out the defensive halfbacks. then a legal move. Later. players ineligible to receive a forward pass were prohibited from coming into contact aith defenders.

Williams had developed the Minnesota shift in the years between 1906 and 1909 and had done extremely well with it, the Gophers having won or tied for the Western conference championship in 1909, 1910 and 1911. Heisman, coaching at Georgia Tech, had adapted the shift and improved it in 1910. With its help he won the championship of the south in 1916 and gained national recognition in 1917. Thomas L. Shevlin, called to help bolster a losing Yale eleven with late-season coaching in 1915, introduced the play in time for Yale to win from a highly favoured Princeton eleven, 13–7. Notre Dame used the shift nith conspicuous success under Rockne who credited Stagg with originating it. Stagg first used a line shift at Chicago in 1902 and the backs joined in in 1904. The success of the play resulted from the small momentum the attacking team gained as its linemen leaped into position at the snap of the ball. Some time after World War I the teeth were drawn from the play by requiring shifting linemen to come to a palpable halt before the ball could be put into play.

Erection of Stadiums.—More far-reaching in effect than anything which took place on the playing field in the years immediately preceding World War I was Yale's decision in 1913 to erect a concrete amphitheatre. Harvard had built a concrete stadium seating about 30,000 in 1903 and had added a colonnade on the rim and wooden seats in the open end several years later to increase the capacity to about 50 000. Syracuse had built its Archbold stadium several years later, seating about 35,000, and Princeton already was discussing plans for Palmer stadium, which eventually was sped to completion in 1914 and opened exactly four weeks prior to the dedication of the Yale Bowl. But none of these stadiums had captured the imagination of the public as the Yale Bowl was to capture it. (See also STADIUM.)

U.S. Football Prior to 1917–18.—From 1908 through 1916 Percy Duncan Haughton coached Harvard teams to outstanding victories. Harvard was undefeated and untied in 1912 and 1913, undefeated in 1908, 1910 and 1914 and defeated only once each year in 1909 and 1915. Power remained an essential to victory in the open game. but it was distinctly secondary to speed—and even the power had to be raced hurriedly into position ahead of the ball in the form of interference instead of being placed behind it in the form of "pushers" as had been the case in the old mass game. Haughton won at Harvard where others had failed because he was one of the first major coaches to realize that speed and power were. in themselves, relatively valueless unless properly masked by deception. Harvard played football only informally in 1917 and 1918, but returned to the field in 1919. The master coach had retired, but enough of his teaching and his impetus remained to carry Harvard through to the 1919 championship and a Rose Bowl victory over Oregon by 7–6; yet Harvard was nearing the end of its brief reign as a real football power.

Illinois under the mercurial Zuppke and Ohio State under John W. Wilce had taken prominent places in middle west football. Zuppke's victory over a mighty Minnesota team, 14–9, on Nov. 4. 1916, was still talked about years later as one of the greatest football upsets of all time. Illinois had won the Western conference championship in 1914 and had tied with Minnesota in 1915, but Minnesota was supposed to win as it pleased in 1916—and did everywhere except in the Illinois game. The upset of Minnesota enabled Ohio State to win its first championship in 1916 by what was largely regarded as a fluke. Wilce proved that this charge mas groundless by repeating with another championship in 1917. Michigan, which had withdrawn from the Western conference as a result of the upheaval following the 1905 season, returned to western competition in 1917 and was undefeated and untied in 1918, sharing the championship nith Illinois and Purdue, also undefeated and untied in conference play.

Post-World War I Boom.—Those close to football realized the game was to experience a boom in the years immediately following World War I. but not even the most extravagant estimates encompassed what was in store. The lesson Camp had taught college football managers by inspiring the building of the Yale Bowl was well remembered, and colleges throughout the land began rushing stadiums to completion. on borrowed funds more often than not and nith unfortunate results in some instances. In the main vast stadiums were confined to larger universities, those with larger undergraduate bodies and either large graduate bodies or large concentrations of townsfolk eager to see football games. and in these cases the building programs worked out very satisfactorily. The stadiums were paid for in due course and the earnings of the football teams were diverted to the provision of athletic facilities for the general mass of the students. In the case of Notre Dame, the greatest money-earning team in football, profits from the game also provided new buildings and academic improvements. Because Notre Dame played most of its big games away from home, the university was one of the last of the major institutions to build a modern stadium on its own campus. In colleges of minor football stature, however, the erection of stadiums beyond their needs brought financial disaster, even in boom times. With nobody but the public to dram upon, such colleges soon found that the public would not pay to see a loser. This led to recruiting of players by offering them inducements outside the amateur code, but sometimes not even this proselyting produced winning teams.

Rise of "Small" Teams.—Into this setting of prosperity arrived, in 1919, several so-called "small" teams which achieved sudden success and fame. The two most successful elevens in 1919 were Notre Dame and Centre. Also undefeated was Texas A. & M.. but that feat went largely unrecognized because sectional football developments were not considered, in 1919, to be of national importance. Notre Dame had produced undefeated and untied teams in 1912 and 1913 (without having attracted undue attention in the east, despite its 1913 victory over Army), and Centre college had produced several championship elevens in the south. Rockne mas becoming famous at South Bend, and "Uncle Charley" Moran of Tennessee was putting together another championship team at Centre which became known as the "Praying Colonels" because the players were said to kneel in prayer before each game.

Centre in 1919 attracted even more attention than did Notre Dame. West Virginia, beaten in an early-season game by Pittsburgh, upset Princeton by 25–0 on Nov. 1, but suffered defeat by Centre. 14–6, a week later as Princeton was coming back to tie Harvard. That circumstance forced the Praying Colonels into the consciousness of the football public, with far-reaching results. Harvard. with an undefeated but tied eleven and a Rose Bowl winner, failed to get the recognition which its graduates felt was its due, and agitation was begun to arrange a more difficult schedule for 1920. Urged by influential graduates. Harvard invited first Illinois, Western conference champion of 1919, and next Michigan to play at Cambridge in 1920. Each declined unless Harvard would return the visit in 1921. Harvard authorities then invited Centre to come to Cambridge for the big midseason game of 1920, and Centre accepted.

Camp in 1919 had chosen Alvin N. ("Bo") McMillin and James R Weaver, quarterback and centre respectively of Centre, for his All-America team. contrary to all precedent, and football enthusiasts in Boston were eager to see what manner of men these Praying Colonels, who had upset the accepted order in football, mere. As a result, Soldiers field. Boston, was filled to its capacity of 52,000 on Oct. 23, 1920. Although defeated by 31–14 Centre rewarded the curious by scoring more touchdowns in Harvard stadium in 1j minutes than Yale had scored there in 15 years. Harvard suggested another game in 1921. Centre accepted filled the date and the stadium and won by 6–0 when McMillin ran 32 yd. around right end for a touchdown. aided by the interference of All-American James M. ("Red") Roberts. Harvard naturally wanted revenge, so Centre was invited back for 1922. The Colonels again filled the stadium to its full capacity, but Harvard won by 24–10, and thus ended the series.

Soon after Centre had disappeared from football fame. Notre Dame came back on the scene with even greater achievements. Notre Dame had gone undefeated in 1919 and 1920, but had failed to repeat that success in 1921, 1922 and 1923. Rockne then produced his great 1924 team, which won all its games and went on to defeat Stanford by 27–10 in the Rose Bowl. This team had Elmer Layden at fullback, Harry Stuhldreher at quarterback and Don Miller and Jim Crowley at the halfbacks. When Notre Dame defeated Army by 13–7 at the Polo Grounds in New York on Oct. 18, 1924, Grantland Rice. writing in the *New* York Herald *Tribune,* described the backfield men as "the Four Horsemen," a sobriquet which endured and helped establish the team as one of the most famous in history.

Rise of Pacific Coast Teams.—Football came into its own in the far west simultaneously nith its rise at smaller colleges in other sections of the United States. The University of California had played football as early as the 1880s, and Stanford had adopted the game in 1891. Stanford and California met annually from 1892 (when both spring and fall contests were played) through 1905 in the "big game" of the Pacific coast. Washington, Oregon, Nevada, Idaho. Whitman, Washington Agricultural (later State) and Oregon Agricultural (later State) took up the game in the mid- or late 1890s, and were playing representative schedules, including games with Stanford and California, when the reformation of 1906 struck college football. Stanford, California and other California colleges dropped U.S football and adopted Rugby in that year, and from 1906 through 1915 the "big game" was a Rugby match. This opened the way for the colleges farther north to establish themselves in football, which they proceeded to do by organizing the Pacific Northwest conference in 1908. Coached by Gilmour Dobie, Washington dominated this group from 1908 through 1916, a nine-year stretch without defeat during which Dobie's teams won 58 games and tied 3. From 1909 through 1913 Washington went through five straight seasons without defeat or tie, and set a record for the longest string of that sort in major U.S. football. Washington won or tied for the Pacific Northwest championship in each of the seven seasons from 1908 through 1914, and then tied Oregon for the first Pacific Coast conference title in 1916. Washington and Oregon played a scoreless tie in their own game. but Oregon got the call to the Rose Bowl and defeated Pennsylvania by 14–0 on Jan. 1, 1917, in the third game in this bowl series.

Andrew L. Smith by that time was established at California, laying the foundations for his "wonder teams" of the 1920s. The lesser-known Melbourne C. ("Fighting Bob") Evans coached at Stanford in 1919, and sent an inspired eleven against California in the big game. California finally won by 14–10, but Oregon had a better record and captured the Rose Bowl assignment. No team went through the conference season undefeated, and Harvard added to western woe by winning in the bowl game by 7–6.

From that point onward Smith nas on his way. He won four straight championships from 1920 through 1923, and was undefeated but tied twice in 1924, when Stanford took the title and the assignment to the Rose Bowl (nhere Notre Dame's Four Horsemen won by 27–10). California crushed Ohio State. Western conference champion, by 28–0 in the Rose Bowl on Jan 1, 1921, and played a scoreless tie with Washington and Jefferson on Jan. 2, 1922. The Pacific Coast conference refused to send its champion team to the bowl following the seasons of 1922 and 1923.

Evans a San Francisco businessman, had no desire to remain in the coaching profession, and Stanford authorities began seeking the services of a well-known coach. After trying two temporary coaches. they decided. in 1922, on Glenn ("Pop") Warner. who after 191j had been building strong Pittsburgh teams. From 191j through 1918 Warner's Pittsburgh teams were undefeated by college opposition, ninning 23 major games and losing only to the Cleveland Naval Reserve eleven, 10–9, in the final 1918 game. He rated his 1916 team as the best of all the elevens he developed. Earlier, Warner had coached at Georgia and Cornell, his alma mater, and had won national fame as mentor of the famous Carlisle Indians. who included among their number Jim Thorpe, often considered the greatest player in football's history. The Stanford situation suited Warner exactly, but his commitment at Pittsburgh prevented his taking the post until 1924. In this emergency. Warner dispatched one of his assistants, Andrew Kerr of Dickinson, to Palo Alto to coach in 1922 and 1923.

Southern California meanwhile had joined the conference. and had high football ambitions. Trojan authorities engaged Howard Harding Jones, who had coached Yale in 1909 and Iowa in 1921 and 1922 to championship seasons before moving to Trinity of

North Carolina. Smith died in Jan. 1926 before this new triple rivalry of master coaches could more than get under way, and was succeeded by Clarence M. ("Nibs") Price. Washington. coached by Enoch Bagshaw, had won the 1925 championship, but Price, Jones and Warner fought for the next several titles. The style of play taught by Warner was due to vie with the game advocated by Rockne at Notre Dame for the favour of almost all the other U.S. coaches.

The Game in the South. — In all the years prior to U.S. entry into World War I, the supremacy of Virginia in the south Atlantic states and of Vanderbilt in the central south had never been seriously challenged. North Carolina or Georgetown or 1'irginia Polytechnic in some years would crowd Virginia closely, or even win, but in the main the Cavaliers were victorious. The supremacy of Vanderbilt in the deep south was even more marked. Sewanee, Centre or Auburn would win a championship here or there, or tie for one: Kentucky State (later Kentucky) and Central university of Richmond. Ky., had undefeated, untied elevens in 1898, but failed to meet each other and found Sewanee and Auburn, also undefeated and untied, owning shares in a championship split four ways as Vanderbilt experienced one of its rare losing seasons. Clemson, coached by Heisman, won in 1902 and shared the 1903 title with Vanderbilt and Sewanee, after Cumberland was narrowly eliminated. But for the most part Vanderbilt was on top. From the start of football at Vanderbilt in 1890 through the season of 1912, the Commodores dropped only 12 games to rivals in the central south, exactly half of them to their then archrival. Sewanee. In the nine seasons following the arrival of able Dan McGugin on the Vanderbilt campus in 1904, Vanderbilt lost only one game to a southern team. This was a 16-j defeat by the champion Sewanee eleven of 1909. Sewanee had held the Commodores to a 6-6 tie in 1908. Vanderbilt also proved the worth of southern football, or more properly its own football, in other sections in the 1904–12 era, playing several close games with Michigan, tying Yale, 0–0, at New Haven in 1910 and losing to the champion Harvard eleven of 1912 by only 9-3. Vanderbilt won or tied for the championship of the central south in 1904–07 and 1010–12.

Sewanee had its greatest success just before the turn of the century. The Purple Tigers cut into the four-way tie for the 1898 championship and had fine prospects for 1899. They engaged a capable coach in Herman M. Suter of Princeton. A trip into Texas to play Texas and Texas A. & M. grew into a junket in which five games were played in six days. Sewanee defeated Texas. Texas A. & M., Tulane, Louisiana and Mississippi in succession and held all opposition scoreless. The Tigers finished a perfect season with 12 victories. and saw their goal line crossed only by Auburn, which was defeated by 11–10 in Montgomery. Ala., on Thanksgiving day. Two days later, Sewanee defeated North Carolina by 5–0 in Atlanta, Ga. North Carolina was south Atlantic champion, and the Tigers thus won the championship of the entire south.

Heisman moved to Georgia Tech in 1904, but experienced many lean years before he began to challenge the supremacy of Vanderbilt. Through these years Heisman endeavoured to win by guile and craft, but he failed to make an impression with his Georgia Tech eleven until 1916, when he won the title. George Tech won all its games in 1917, defeating Pennsylvania by 41–0, Carlisle by 98–0, Vanderbilt by 83–0 (the Commodores' greatest setback), Auburn by 68-7, Tulane by 48–0 and Washington and Lee by 63–0.

Such was the status of southern football up to the end of World War I. The postwar years saw the rise of Centre and of Alabama, coached by William Wallace Wade. In Wade's second season he lost only to the champion Centre eleven of 1924, and in his third he completed a perfect campaign with a 20–19 victory over Washington in the Rose Bowl on Jan. 1, 1926, the first visit of a southern eleven to Pasadena. Alabama also won the championship in 1926 and climaxed its season with a 7–7 tie against Stanford in the Rose Bowl. Georgia Tech returned to power in 1927 and 1928, and sent its 1928 eleven to Pasadena to defeat California by 8–7 in the game made famous by the dash of California's Roy Riegels toward his own goal. Bernard ("Bernie") Bierman of Minnesota built Tulane into a feared and respected team before he went to Minneapolis to establish his own alma mater as the greatest eleven in football during the period 1934–41. Capt. (later Gen.) Robert Neyland was turning out great elevens at Tennessee, but the Volunteers seemed always to miss the championship by suffering one tie while some rival turned in an all-victorious campaign. Capt. Lawrence ("Biff") Jones of Army was engaged to build up the Louisiana State eleven, with which Bernard H. Moore of Carson-Newman won championships in 1935 and 1936 after Jones had moved to Nebraska.

Wade had another great year at Alabama in 1930, winning the championship, crushing Washington State in the Rose Bowl by 24–0 and winding up second only to the great undefeated and untied Notre Dame eleven, the last Rockne coached before he was killed in an airplane crash in Kansas on March 31, 1931. Wade then moved on to Duke where he continued to develop championship teams. Frank W. Thomas of h'otre Dame moved from Georgia to Alabama in 1931, and gave the Crimson Tide championship elevens in 1933, 1934, 1937, 1944 and 1945.

In the south Atlantic area, Virginia abdicated from the ruling seat in the early 1920s, but no new power rose to take its place. Virginia Military institute won the championship in 1920, sparked by a great back, James Leach; North Carolina produced great teams coached by the Fetzer brothers, Bob and Bill, winning the championship in 1922. North Carolina repeated in 1929 under Chuck Collins of Notre Dame. Wake Forest. meanwhile, defeated North Carolina in four straight games from 1924 through 1927, and won the south Atlantic title in 1924. But no team in the south Atlantic seemed to aspire to national football honours except Duke, which had not yet become a threat.

Other Sections. — Great teams were developed in the Southwest conference by such men as Dana Xenophon Bible. Ray Morrison, Madison Bell, Leo R. ("Dutch") Meyer, Homer Norton and others. Although southwestern teams failed to get a full share of national attention following World War I, they gave a good account of themselves everywhere in intersectional games. Favouring indiscriminate use of the forward pass, the Southwest conference became known as the "passer's league." From the conference came Sammy Baugh, later of the professional Washington Redskins, whose passing prowess made gridiron history. The southwest's chance for fame came after the 1935 season. when Stanford. hard pressed to choose a Rose Bowl opponent, decided that Texas was far enough "east" to qualify Southern Methodist as the "eastern" team in the classic. Stanford won by 7-0.

In the Missouri Valley conference, Nebraska long had been a power. The Cornhuskers mere strong enough to win their share of games from the great elevens of the Western conference, even before World War I, and they continued the pace in the years following the war. Nebraska continued to dominate its field even after the six leading teams in the Missouri Valley conference withdrew from the old organization in 1928 to form the Missouri Valley Intercollegiate Athletic association, popularly known as the Big Six (Nebraska, Missouri, Kansas. Oklahoma, Kansas State and Iona State). The league became the Big Seven in 1948 with the admittance of Colorado university, and the Big Eight in 1957 with the admittance of Oklahoma State.

The Rocky mountain teams play few intersectional games, and so receive little or no nation-side publicity. Utah, coached by Ike J. Armstrong, became a perennial power in that section. Colorado developed a championship team in 1937 under the coaching of Bernard F. ("Bunny") Oakes—a team made famous by Byron ("Whizzer") White, the greatest ball carrier developed in the Rocky mountains after Colorado college produced Earl ("Dutch") Clark. In 1938 Colorado, Denver, Colorado State. Wyoming, Utah, Brigham Young and Utah State withdrew from the Rocky Mountain conference and organized the Mountain States conference, leaving the older organization to the five "smaller" teams, one of which — Colorado college — soundly trounced one and all in the Rocky mountains in 1943.

New Strategy and Tactics. — The established major teams remained generally conservative in the first few years after World War I, but they changed after a few startling incidents such as the one "Bo" McMillin engineered on an astonished Harvard eleven in the first Centre-Harvard game in 1920. With the score tied at 7–7 in the second quarter, Centre had a fourth down on its own go-yd. line with 6 yd. to go. McMillin stood back for what even Centre supporters supposed would be a punt, but he did not punt. Instead he took the ball, faded back a few more yards, and defied every "don't" in the football book by sailing a high forward pass over the heads of Harvard defenders into the hands of Eddie "Cutie" Whitnell, 50 yd. away on Harvard's 30-yd. line. Whitnell raced over the Harvard goal line for the touchdown which put Centre ahead. Nobody gave McMillin credit for realizing how far and how accurately he could throw a football or for having the courage to throw one in the clutch. Four years later Princeton received Harvard's opening kickoff on the same field and immediately threw a forward pass from deep in its own territory. That one failed, but the Tigers promptly tossed another which succeeded—and then went on to crush Harvard by 34–0.

In the years preceding 1917 large eastern teams used the forward pass mainly as a threat to open up the defense in order that the running plays might work better. Its disuse could be traced to the absence of any passers of outstanding ability. Dartmouth used the air attack in 1924 and 1925 when Andrew J. ("Swede") Oberlander convinced Coach Jess B. Hanley that he could throw a football both accurately and far. With Oberlander passing to Myles J. Lane and George C. Tully, Dartmouth humbled all opposition in 1925 and claimed at least a share of the national championship.

The two most successful coaches in the years immediately following World War I were Rockne of Notre Dame and "Pop" Warner of Pittsburgh and Stanford. It was only natural that other coaches, even conservative easterners, should borrow their methods, that colleges everywhere should demand Rockne-trained or Warner-trained men as coaches. The methods of the tno men were at wide variance, but the results they obtained were similar. Both attacks were predicated on speed, but in the Warner scheme power was on a parity with speed. The Warner game could not be played without power and, if necessary. speed was sacrificed to power. The Notre Dame attack did assign two men to take out the defensive tackle, but otherwise it consisted of precision, speed and timing with man-to-man blocking.

In the first few years after World War I Notre Dame relied a good deal on the backfield shift, but the rule makers removed all advantage from the shift by requiring a full halt between the final jump and the snap of the ball, robbing the play of its momentum. This nullifying of the advantage of the shift led to Rockne's developing the "weak side" attack, thus discouraging opponents from overshifting on defense to the strong side, as had been their practice. Rockne always had his backs work behind a balanced line, with both guards racing out to lead interference. For this reason he required guards who could do more than hold their ground and withstand line drives of the opposition. Rockne needed and obtained (hatch-charm" guards, Notre Dame backs lined up in a T and shifted into an oblique box an instant before the ball was snapped. This arrangement was not unlike Warner's single wing formation, except that in the Notre Dame system the outer back's position nas about two yards inside his own end instead of one yard outside.

The entire Notre Dame attack was designed to produce long gains, to break a man into the open for a touchdown run from any part of the field. It has been said that every play in football would mean a touchdown if each offensive player carried out his assignment perfectly. Notre Dame men then, more often than players on other teams, did carry out their assignments to perfection. Rockne by no means scorned the pass, but he never had a superior passer. The pass therefore never overshadowed his running attack, but remained always a threat. Rockne much preferred to have his players catch passes thrown by other teams and run them back for touchdowns.

When the two defensive halfbacks first were forced away from their tackles by the introduction of the forward pass in 1906, the defensive setup of the backs was changed from an inverted T to a roughly shaped diamond. As passing developed, the points of the diamond were made equidistant. since many coaches believed this to be the best defense against both rushing and passing. As more and more teams began to remove the centre from the line and play him "loose" in support of the fullback (really an eight-man line nith six primary and two secondary defenders), the diamond defense was converted into what is known as the 2–2–1 defense. Rockne to the last preferred the diamond defense, although he did not invariably employ it.

The Warner game, in which defensive power is theoretically crushed by a greater concentration of offensive power, dissipates some of its power in the feints it calls for on sweeps and reverses, but both guards usually are in position to deal telling blows for the carrier on the ultimate development of the play. There is also the danger that the fullback will spin and, without having delivered the ball to some mate as seemingly was his intent, go plunging through the middle of the line, deserted by defenders.

The Warner system operates from an unbalanced line, shifted in either direction and nith both tackles lined up on the same side of the centre. This has the dual benefit of getting interfering power closer to the point of probable attack and of inducing the defense to overshift and leave the weak side vulnerable to a surprise thrust. The Warner single wing attack usually strikes the strong side, sometimes after a back has dashed nith the ball toward the weak side and then handed it to the weak side end moving in the opposite direction (a reverse), but it feints at the strong and then strikes around the usually unguarded weak side just often enough to keep the defenders uneasy. This weak side thrust folloning a feint at the strong side is the "naked reverse"

After Warner had gleaned many victories from the single ning back formation and had seen it copied the length and breadth of the land, he developed the double wing back, which he unveiled for the east in Yankee stadium in New York city on Dec. 1, 1928, to the acute discomfort of Army. Stanford won by 26–0 In the double wing, the fullback stands about four yards back of his centre in an unbalanced line, the quarterback is two yards in front of the fullback and slightly less than two yards to his right, and each of the two halfbacks is about one yard outside one of the ends and one yard to the rear of him. Reverses (nhich are deeper) are even more important in the double ning formation than they are in the single ning, but slants and plunges also are effective. Great physical superiority is required to make the double ning attack effective, and it is little used.

Other coaches modified Warner's single wing attack by pulling the tail or carrying back sufficiently to the rear of the offensive formation to enable him to throw a quick forward pass without being forced to fade backward in order to comply with the five-yards-back-of-the-line rule. As there nas always the possibility, in the minds of the defenders, that he might actually kick, this tended to spread the defense, thus opening the way for running plays. This style of play is called the single wing and short punt formation game.

In the decade preceding the outbreak of World War II, an increasing number of teams began to experiment with five-man lines on defense. These lines retained the eight-man principle of the line in the 6–2–2–1 defense, and further aided the defensive team by confusing the offensive team's blockers on their assignments Most young football players are decidedly upset if they have been taught to block a given defender on a given play and then suddenly discover that the foe is not there to be blocked. Coaches met this situation by drilling their players in two sets of blocking assignments, one for the five-man line and one for the six-man defense. A third set was required when any possibility existed that an opponent might go into the fast-disappearing diamond defense nith a seven-man line, but the variation in blocking between seven- and six-man lines was negligible. The centre could be out of the line without upsetting the offense. It was the disappearing guard or tackle who caused all the confusion. As soon as offenses mastered the five-man line defense its use began to disappear, except for nuisance purposes, although many teams peel down to a four- or even a three-man line to guard against passes in the closing minutes of a game when a beaten foe can do nothing but throw the ball in desperation, hoping for a completion and a score.

In the late 1930s George Halas. owner and coach of the Chicago Bears of the National Football league, departed from the accepted practice of employing either Rockne or Warner football. He revived an offensive formation which had come into being almost simultaneously with the closing up of the old Rugby-style game in 1888 but which had been generally abandoned before the start of World War I. The revived formation became known to the football world as the T formation because in it the backs line up in the form of a capital T. the halfbacks on either side of the fullback and all in a straight line from four to five yards back of the scrimmage line, with the quarterback "up under the centre." In the T formation, the ball is never passed directly to the carrier, but is always handled through the quarterback, who also is invariably the forward passer. Deception is increased by employing one of the halfbacks as a flanker or man in motion. Moving obliquely toward his own goal line in advance of the snap of the ball, this man in motion is a multiple threat to the defense. The T usually operates behind a balanced line. Its leading advantages are its deception and full utilization of speed. The attack breaks sharply and quickly through openings quickly made in the defensive line. With its brush blocking, it calls for less power than either the Rockne or the Warner system, and frequently enables teams of inferior physical ability to defeat, on sheer speed, foes using Warner or Notre Dame football.

Halas' Bears won tremendous victories with the T formation at Chicago. Clark Shaughnessy, while coaching at The University of Chicago, helped Halas develop the formation and install it as the system of the Bears. After The University of Chicago abandoned football folloning the 1939 season, Shaughnessy was engaged to coach Stanford, which had failed to win a single game on the Pacific coast in 1939. Shaughnessy installed the T formation at Stanford in 1940, and the Indians played through an undefeated season.

Coaches who had been hesitant about adopting the T then rushed to install it. Its spread was limited only by the ability of coaches to assimilate it and teach it to players who had spent their football careers working under either Warner or Rockne systems. At Notre Dame itself, Coach Elmer Layden had, quite naturally. been teaching Rockne football to his players after he became head coach in 1934. In March 1941 Layden resigned to become commissioner of professional football. Frank W. Leahy, then coach at Boston college, was engaged to take his place. Leahy adopted the T and developed one of his greatest teams in 1943. Earl Blaik at West Point also went over to the T and Army was invincible from 1944 through 1946 with Felix ("Doc") Blanchard and Glenn Davis in the backfield.

By the end of World War II, more than 60% of the major colleges had adopted the T, but new defense alignments were solving it and these .were countered, in the following years, by combinations of the basic T and single uing formations. resulting in the wing T; widespread linemen. flankers and a deceptive man in motion. The split T, originated by Don Faurot at Missouri in 1941, with wider spacing of the line and making a runner of the quarterback on the famous option play, achieved a great vogue. Oklahoma and Maryland, coached by Charles ("Bud") Wilkinson and James Tatum, who both had been Faurot's assistants during World War II at Iowa Pre-Flight, won national championships with the split T in the 1950s.

Wilkinson achieved great success from 1948, when he became head coach at Oklahoma, through 1958. Prior to this Blaik and Leahy had been the big "name" coaches, along with Fritz Crisler and Bennie Oosterbaan of Michigan. Leahy, after developing his great Notre Dame team of 1943, went into the navy, and Blaik was supreme with his all-conquering Army elevens of 1944 and 1945. Leahy returned from the war in 1946 to challenge Blaik, and their unbeaten teams played a scoreless tie. Michigan challenged Notre Dame for supremacy in 1947 and 1948, but in the latter year Wilkinson started Oklahoma on its climb from mediocrity.

After losing its opening game under Wilkinson in 1948, Oklahoma won 31 games in succession. It then lost to Kentucky in the 1951 Sugar Bowl and to Notre Dame in 1952. In 1953 Oklahoma lost its opening game to Notre Dame and was tied by Pittsburgh in the second game. Then began one of the longest winning streaks in the history of intercollegiate football. For 47 successive games Wilkinson's teams were invincible. The team that ended their winning streak in 1957 was Notre Dame, the same team that had last beaten them, in 1953.

The split T formation that Wilkinson used with such success began to lose some of its vogue in the late 1950s. The slot T, splitting an end wide and putting a back in the gap, off the line, mas introduced by the professional teams and taken up by the colleges as an effective forward-passing arrangement. The wing T, with variations, took on an increasing vogue. The double wing T appeared. and Army's "lonely end" formation, in which the flanker remained out of the huddle, originated by Earl Blaik in 1958 to stop the defense from packing in tight against the running attack, led to the general practice of splitting an end wide, as well as stationing a back far out on the opposite side as another flanker.

All-Star Teams. — Caspar Whitney, probably with the assistance of Camp, in 1889 established the custom of selecting all-star elevens at the close of each football season. His selections were called the All-America team. and they appeared in a magazine called *The Week's* Sport, as did those of 1890. The choices included only 11 first-string players, 4 line substitutes and 4 backfield substitutes. From 1891 through 1896 Camp and Whitney apparently collaborated on the selections. Their selections appeared in *Harper's* Weekly in Whitney's column and in the *Spalding* Football *Guide* under Camp's name. Whitney's own magazine had ceased publication. The 1891–96 selections also mere limited to a first team and eight substitutes, but the "honourable mention" list was introduced in 1891. Camp took over Whitney's column in Harper's in 1897. when Whitney was absent from the United States. Camp in that year introduced the practice of choosing first, second and third elevens and retained the honourable mention list. In 1898 Camp moved to Collier's, and his All-America selections appeared in that magazine through 1924. Camp died in March 1925, and Collier's engaged Grantland Rice to carry on the annual selection.

Even before the turn of the century, other football devotees began to make their own All-America selections. The number of such selectors increased as football grew, but Camp's choices always were accepted by the football public as "official." It seemed doubtful that anybody else could command universal acceptance of selections, since there were hundreds of good football players in the 1920s whereas there had been only dozens in the 1890s. More than 100 good teams mere in the field instead of perhaps 20. Obviously, no one man could possibly hope to see all the good teams or all the good players, much less choose the 11 best. Rice and Collier's met this problem by compiling their selections from the findings of a country-wide board of the American Football Coaches association, of which Rice served as chairman until his death in July 1954. He was as pre-eminent among sports writers as was Camp as a football leader. The three major U.S. news-gathering services, Associated Press, United Press and the International News Service (the latter two combined to form United Press International in 1958), also choose All-America teams annually on the findings of representatives scattered throughout the country, and these selections enjoy wide acceptance. A fifth major selection group was the All-America board, established by Christy Walsh of the Christy Walsh syndicate in 1924. Walsh's honour teams were chosen by "name" coaches whom he enlisted to perform this service. Original members of the board included T. A. D. Jones of Yale. Rockne. Warner and William A. Alexander of Georgia Tech. The Football Writers Association of America picks a team for Look *Magazine*.

World War **II** and the Postwar Years. — The effects of World War II on football and other college sports were not so immediate or so far-reaching as those of U.S. participation in World War I had been. Lessons learned in the earlier conflict enabled colleges to avoid mistakes made in 1917 and to maintain athletic competition for the remaining students. Action of the colleges was backed by the war and navy departments, which requested that athletics, particularly football, be continued, not only to train youths physically but also to bolster civilian morale.

The army and the navy soon began using facilities at most of the colleges of the country. This was projected as early as 1942, but was not carried out until after the completion of the 1942 football season, which progressed much as had any peacetime season, despite the fact that teams everywhere were weakened by loss of players who had entered the armed forces. Crowds remained large, although not quite so large as they had been in 1940 and 1941. Transportation shortages already had begun to be felt, but they had by no means become acute.

Before the 1943 season opened, trainees were in virtually full occupancy of all the colleges, and curtailment of travel had become a necessity. Few civilian players were left from 1942 teams, but the navy department made up for this in navy-trainee colleges by granting permission to use trainees on varsity elevens. The war department, however, forbade army trainees from taking part in varsity competition. This caused many army-trainee colleges to drop football temporarily. Others, however, carried on and some fabulous elevens were produced in the war years, notably the so-called "dream team" at West Point. But many colleges had only 17- and 18-year-old players available and the peacetime competitive balance was missing.

The last season of wartime football was 1945, but many of the colleges which had recently dropped the game were again fielding teams in 1944 and, with the return of draftees from the European front, competition was soon restored to prewar levels. The homecoming G.I.'s brought abundant manpower and talent to nearly all teams and the return of unrestricted auto and rail transportation filled the nation's stadiums with capacity crowds. It was boom time for football. A period of spectacular and record-breaking play followed. The Korean war caused few disruptions and schedules were completed throughout that conflict.

The wartime swing to offensive football continued. The attack was centred in the pass. More were thrown and the portion completed climbed above 60% for outstanding performers. On the ground, bewildering variations of wing and T formations with a man in motion became increasingly popular and increasingly effective. This mounting efficiency in attack led inevitably to more scoring by both of the teams in a game.

In 1948, the last season in which prewar players were eligible, both teams in 965 major games scored and only 2 major games in that season were 0–0 scoreless battles.

Platoons and **De-emphasis.**—The two-platoon system—an offensive and a defensive eleven for each team—was a popular postwar innovation. Introduced by Michigan in 1945, it developed highly skilled specialists and superior play in both offensive and defensive departments. But it also called for greatly increased squads and coaching staffs and, largely because of soaring costs, was eliminated in 1953 by a return to prewar substitution rules.

In the 1948–52 period a move to de-emphasize football gained momentum. The N.C.A.A. stopped mushrooming bowl games by sanctioning only those which allotted 80% of the gate receipts to the participating teams. The Ivy group (Brown, Coluinbia, Cornell, Dartmouth, Harvard, Pennsylvania, Princeton, Yale) and the Missouri Valley conference banned postseason games entirely and also banned spring practice. Steps were taken by the N.C.A.A. to curb excesses in the recruiting and subsidizing of athletes. Football coaches adopted an ethics code to eliminate unsportsmanlike practices.

The N.C.A.A. and some of the conferences, probably influenced by the example of the Ivy group in setting up strict faculty regulations of their athletics under the presidents' agreement of 1954, took punitive action against member colleges for recruiting and giving financial aid to athletes in violation of restrictions. Colleges in the Pacific Coast, Western (Big Ten), Southwestern, Southeastern, Southern, Missouri Valley (Big Eight) and Atlantic Coast conferences were disciplined. The penalties included probation for from one to four years, barring the school from N.C.A.A. championships and postseason (bowl) games, depriving players of a year of eligibility and, in one instance, the suspension of the coach for a year. The punishment meted out to four colleges in the Pacific Coast conference brought a strong protest from alumni groups and in 1959 the conference broke up and a new Big Five was formed.

Postseason Games.—The postseason or "bowl game" idea was launched at Pasadena, Calif., on Jan. 1, 1902, when the Tournament of Roses committee of that city arranged the first tournament game between the national co-champion, Michigan, and a Stanford eleven which had not even been able to win the title on the Pacific coast. Michigan won by 49–0. No more games were played until New Year's day, 1916, when Brown was defeated by Washington State, 14–0. Except for a two-year hiatus in World War I (when service elevens were substituted), the Tournament of Roses (later Rose Bowl) game was an annual feature.

The East-West Shrine games for charity were started at San Francisco, Calif., in 1925. The Orange Bowl game was launched at Miami, Fla., in 1933; the Sugar Bowl at New Orleans, La., in 1935; the Cotton Bowl at Dallas, Tex., in 1937; and the 'Gator Bowl at Jacksonville, Fla., in 1946. All the major bowl engagements are played ordinarily on Jan. 1.

B. Rules and Fundamentals of U.S. College Football

Although U.S. football was born from Rugby, the game in the United States resembles its British parent only in the shape of the ball, which is an oval leather case covering an inflated rubber bladder. Its long axis measures 11 to $11\frac{1}{4}$ in., its short axis measures 6.73 to 6.85 in. and its weight is from 14 to 15 oz.

Number of Players.—Teams consist of 11 players: 4 backs (quarterback, left halfback, right halfback, fullback) and 7 linemen (left end, left tackle, left guard, centre, right guard, right tackle, right end). Players line up in various formations for offense and defense but, when a scrimmage begins, each team must be "on side"; any offensive lineman in the backfield must be at least five yards back, unless the change is permanent; and the offensive team must have at least seven players on its forward line.

FIG I.—DRAWING OF U.S. COLLEGE FOOTBALL FIELD. SHOWING MARKINGS. ZONES AND MEASUREMENTS

Objective of Game.—Each team's objective is to score more points than its opponents. Points are scored for the attacking team only and the team having the most points at the end of the game is the winner. A touchdown (6 points) is scored when a player carries the ball across his opponents' goal line, completes a forward pass or recovers a free ball in his opponents' end zone. With each touchdown goes the privilege of trying for extra points. The ball is given to the scoring team on the defenders' 3-yd. line for one play. One point may be scored by a place or drop kick, two by a run or a pass. A field goal (3 points) is scored by drop-kicking or place-kicking the ball from scrimmage over the crossbar or directly over an upright of the opponent's goal. A safety (2 points) is scored when a play ends with the defenders in possession of the ball behind their own goal line, the defenders themselves having given the impetus which caused the ball to cross their goal line.

Playing time is 60 minutes divided into IS-minute quarters and go-minute halves. Time is taken out for various delays and the elapsed time for a game is uell over two hours. Between the first two and between the last two quarters, there is a one-minute interval when the teams exchange goals and the ball is relocated so that its position, as related to goal lines and side lines, is the same at the start of the ensuing quarter as it was at the end of the previous quarter. There is a 1j-minute intermission between the two halves during which both teams leave the field

Before each game, the referee tosses a coin in the presence of the two captains, asking one to call The winner of the toss gets his choice of goals or of kicking or receiving the first kickoff. The loser gets the same choice at the start of the second half.

Each half of the game starts with a kickoff—a place or drop kick from the kicking team's 40-yd. line and with the receiving team behind a line 10 yd. distant (*i.e.*, a "free kick"). Someone on the receiving team tries to catch the ball and run it back toaard the kicking team's goal as far as he can before someone on that team tackles and stops him. A tackle is made by grasping the runner's body with the arms and throwing him to the ground.

Following the kickoff and runback, the team in possession of the ball gets a series of four scrimmage downs during which it must either advance the ball a minimum of ten yards or forfeit possession of the ball to the defenders. Each down starts with the ball resting on the ground and with the teams separated by a neutral zone whose width is equal to the ball's length. The centre snaps the ball back between his legs to a back who may run with it himself or pass it to a teammate who runs with it. Opponents try to stop any advance toward their goal by tackling the runner or by batting down or intercepting passes in flight. Each down ends when the ball becomes dead. At the end of any down, if the attacking team has the ball beyond its line to gain (ten yards from where the series started) it gets a new series of four downs with a new line to gain. At the end of the fourth down. if the attacking team has the ball behind its line to gain, the ball is given to the defenders and they become and proceed as the attacking team. Scrimmage downs, in successive series for one team or the other, continue until a series ends in a score. Then comes another free kick and the same pattern (free kick—runback—scrimmage—score) is repeated until playing time for the current half expires. After a touchdown (and the try for extra points) or after a field goal, the defenders choose between kicking or receiving the ensuing kickoff. After a safety, the defenders get a free kick from their own 20-yd. line.

During any scrimmage down, the attacking team may, and often does, surrender the ball to the defenders by kicking it. When that is done the kicking team may not interfere with a defender's opportunity to catch the ball. A defender may gain added protection by signaling (arm aloft) for a fair catch. If he does so he must stand fast after a catch and the kicking team is prohibited from tackling him. The traditional privilege of making a free kick after a fair catch was abolished in 1950.

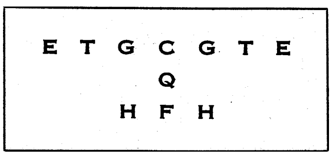

FIG. 2.—BALANCED LINE AND BALANCED BACKFIELD FORMATION
E, end; T, tackle; G, guard; C, centre; Q, quarterback; H, halfback; F, fullback

Three methods of kicking the ball are permitted: a drop kick, made by dropping the ball from the hands and kicking it as it touches, or is rising from, the ground; a place kick, made by kicking the ball while it is resting on the ground or a tee—the ball may be, and usually is, steadied by another member of the team; and a punt, made by dropping the ball from the hands and kicking it before it strikes the ground.

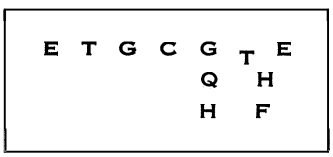

FIG. 3.—NOTRE DAME FORMATION

Systems of Play.—In the T formation. three of the backs (the left halfback, the fullback and the right halfback) line up from four to five yards behind the centre, just as they did in the early days of the game. The quarterback, now as then, plays close to and directly behind the centre. In the older game, the quarterback was required by rule to handle the ball before it could be touched by any other back except on a punt. In the modern T, he always handles it so as to prevent defenders from knowing just which back has received it. a deception less likely to succeed on a direct pass

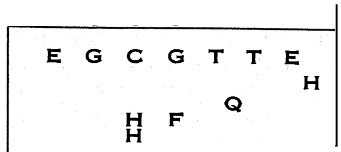

FIG 4.—WARNER SINGLE WING FORMATION

Rockne Notre Dame football, which enjoyed a big vogue in the 1920s and 1930s but was employed by few teams after World War II, also operates behind a balanced line (see fig. 3), but the backs are deployed differently, and the ball is aluays passed to them by direct pass from centre. The backs in the Notre Dame system first line up in a T and then, at a given signal, jump into the formation shown in fig. 3. They may also jump into the same formation toward the left The two forward backs are slightly more than 1 yd. behind the line; the two rear backs are about 4½ yd. behind it.

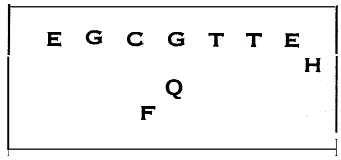

FIG 5—WARNER DOUBLE WING FORMATION

Warner or single or double wing football calls for an unbalanced line (see fig. 4 and 5) and a widely deployed backfield. The line usually is unbalanced by shifting a tackle. but some coaches choose to shift a guard instead. In the single wing (fig. 4), the forward halfback (wing back) stands one yard behind the line and up to one yard outside the end. The quarterback (blocking back) is placed about one-half yard to the rear of the wing back and about two yards inside the wing back position. The fullback (plunging back) is 1½ yd. behind and 1 yd. inside the quarterback. The left halfback (carrying back or tail back) is 1½ yd. to the rear and 1 yd. inside the fullback. In single wing, teams may shift to the left as well as to the right, depending upon the needs of the moment or the position on the field. In the double wing, rarely used

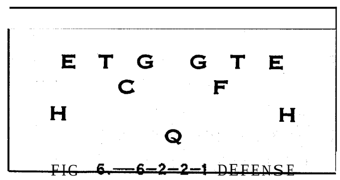

FIG 6.—6–2–2–1 DEFENSE

(fig. 5), each of the halfbacks (wing backs) stands one yard behind the line and one yard outside his end. The quarterback (blocking back) stands about two yards behind the strong side guard. The fullback (plunging back) is from 3½ to 43 yd. behind the centre, depending on what play has been called. The fullback is far more than a plunger in the double wing. He handles the ball first on most of the plays and is a key man in starting the delicately measured reverses.

Defense.—Defensive formations vary with the coaching systems and with the position of the ball on the field. A defense naturally must be much tighter when the attacking team has the ball near the defensive team's goal line than it would be near mid-field. This tightening has given rise to the term, "zone of intense resistance."

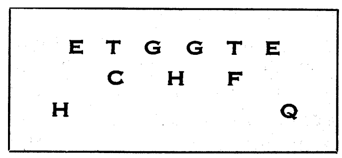

FIG. 7.—6–3–2 DEFENSE

The objective of the defense is (1) to recover the ball if an opponent fumbles it; (2) to throw the runner for a loss or limit him to as short a gain as possible; (3) to bat down or intercept any forward pass; (4) to block and try to recover any punt; or (j) to catch a punt and run it back toward the opposing goal line.

To accomplish these ends coaches employ various defenses. The commonest all-purpose defense is the 6–2–2–1 or 6–3–2 alignment (fig. 6 and 7). The offense must have, as noted, seven men on the line of scrimmage. The defense is free to get along with as few as it dares to leave there. In all defenses where only six men are left on the defensive scrimmage line, the centre, invariably a sturdy player, is the man withdrawn. Defenses calling for fewer than six men on the scrimmage line are used less often.

When the centre is withdrawn from the line of scrimmage to aid in defense back of the line. he shares with the fullback the duty of protecting the zone immediately back of the line. He and the fullback are called the "backers up" or "linebackers." Both stand about one yard back of the line. usually behind the defensive tackles. The line on defense is spread more widely than it is on attack and is shiited to meet offensive shifts.

E T G C G T E

FIG. e.— BOXDEFENSE

From iour to ten yards behind the backers up (in a 6–2–2–1 defense) are the defensive halfbacks. Their lateral spacing varies with different coaches. If they are too widely spaced: a forward pass may easily be completed between them in the "middle alley." If they are too close together, offensive backs may more easily run outside them or passes may be completed in the "flat zones." On an average, the defensive halfbacks stand no more than one yard outside their own ends.

E T G C G T E

FIG. 9.— DIAMONDDEFENSE

Back of the four forward defenders in this secondary defense stands the safety man. He is 20 yd. behind the scrimmage line on ordinary plays, but, if the attacking team is likely to kick, he is from 30 to 40 yd. back.

The 6–3–2 defense is used only when the offensive team is certain not to kick or when the offensive team is so close to the defending team's goal that no kick will be made except a drop or place kick in an attempt to score 3 points by goal from the field. In the 6–3–2 alignment there is no safety man. but there are three backers up.

The box defense (fig. 8) calls for a seven-man line, two backers up and two men in the secondary defense. The diamond defense (fig. 9), favoured by Rockne but now used only rarely, also calls for a seven-man line with one backer up, two defensive halfbacks and a safety man.

Defenses calling for the five-man line are used in part to confuse the offensive players on their blocking assignments. An offensive blocker cannot block a man who is not there to be blocked. The five-man defense invariably calls for three backers up—each a potential line defender if he is agile enough to plunge one yard forward to the threatened area of the forward wall.

The vogue of the T and especially the split T formations changed the defensive thinking. To stop these attacks coaches deployed their forces in ever-changing patterns. The rules favoured the defense in that it was not required to have any set number of men on the line of scrimmage. nor did the players on defense have to come to a pause in their forward movement before the ball was put in play.

The old standard defenses had difficulty in adjusting to the split T line spacing, creating gaps. It became necessary to put more men close to the line of scrimmage. Five-man lines became commonplace and the four-man lines ceased to be a novelty. The 4–5. 4–4, tight j, angling 5 and the Oklahoma 5 or corner defense (which does away with the old type of end play by bringing the ends in so close that they are no longer a force for containment) are among the arrangements used. They amount to eight- or nine-man lines. leaving two or three players in the secondary. The design is to create chaos by getting more men into the offensive backfield.

Along with these new deployments. coaches adopted the practice of keeping their deiense in a constant state of flux. Line backers pop in and out of the line. changing positions and switching assignments. This prevents the offense from taking a second look at the defensive setup before the ball is snapped and has a disconcerting effect upon the offense in carrying out blocking assignments.

Officials.—The playing of a game is supervised by a referee. an umpire, a linesman, a field judge and sometimes a back judge. Primarily the referee positions the ball, orders play started and stopped according to rule, inflicts all penalties, declares all scores and is in over-all charge. The umpire inspects and rules on equipment and conduct of players. The linesman locates the line to gain and keeps count of the downs for each series, notes whether players are on side when each play starts and marks the distance gained or lost by each play. The field judge keeps time. using a stop watch or a scoreboard clock operated by an assistant. and supervises downfield play which has passed his fellow officials.

Fouls and Penalties.— In addition to their primary duties, all officials have a joint responsibility for calling fouls; *i.e.,* infractions of the rules (fig. 10). Each one carries a marker which he tosses or drops when he calls a foul. At the end of the play he reports his ruling to the referee, who inflicts the prescribed penalty. Loss of yardage, loss of a down and forfeiture of the ball to the offended team are the penalties frequently inflicted. S o team, however, may be penalized more than half the distance between the enforcement spot and the goal line. Common fouls, with the penalty for each. are: off side (prematurely charging across a restraining line), j yd.; illegal use of hand or arm (holding an opponent), 15 yd.; ineligible pass receiver (in legal formation, any offensive lineman between the ends when a scrimmage starts) first touching a forward pass beyond the neutral zone, 1 j yd. plus loss of a down; unsportsmanlike conduct (side-line coaching, invalid fair-catch signal, illegal return of disqualified player to the game, rule violation during intermission), 1 j yd.; illegal position or procedure (less than seven men on the offensive scrimmage line at the snap, wing back less than one yard behind the scrimmage line at the snap, false start, illegal substitution), j yd.; illegal motion (by back or lineman at the snap), j yd.: illegal shift (failure to come to a full. one-second stop after shifting). 15 yd.; illegal return (re-entry of a player into the game before eligible under the substitution rule), 1 j yd.; delay of the game (taking more than 2 j sec. to put the ball into play. excessive time-out), j yd. (1 j yd. for delaying the start of a half); personal foul (piling on, hurdling. tripping, kicking an opponent, late tackling, etc.), 1 j yd., possible ejection of the offender from the game; clipping (blocking from behind), 1 j yd.: roughing the kicker or place-kick holder, 1 j yd.; intentional grounding of a forward pass (throwing a pass into the ground to avoid a loss). j yd.. loss of a down; illegal pass (two forward passes during one down. throwing from beyond the scrimmage line, handing ball forward illegally'), j yd.. loss of a down: interference with pass receiver, pass declared completed and offended team given first down on the spot of the foul; interference with pass defender, 15 yd.. loss of a down; interference with opportunity to catch a kick. 1 j yd.; batting or kicking a free ball or illegally touching a free kick, offended team's ball at the spot of the foul; crawling (attempt by a runner to advance the ball after any part of his person, other than a hand or foot, has touched the ground), j yd.; helping the runner or interlocked interference. 1 j yd. Although an incompleted forward pass does not call for a penalty as such. it does result in the loss of a down.

Any penalty may be declined by the offended team but a player who is declared ineligible because oi a personal foul must leave the game. A team will decline a penalty if the play, as completed, has given the team a greater advantage than would accrue to it by accepting the penalty. An example would be a team's declining a penalty on a play which ended in its scoring a touchdown.

On the same play. fouls by both teams offset each other and the resultant penalties cancel each other.

If, on a single play. a team commits two fouls: the offended team may accept either penalty or decline both.

(A. S. Bl.; W. J. Ch.; Xr. R. H.; A. Da.)

C. U.S. Secondary School Football

History.——Since football requires rather expensive equipment, its expansion in high schools was slow prior to 1920. By that time. ton-nship and community high school districts with larger taxing units were being iormed. Since more money was available for the purchase oi athletic equipment and ior the construction

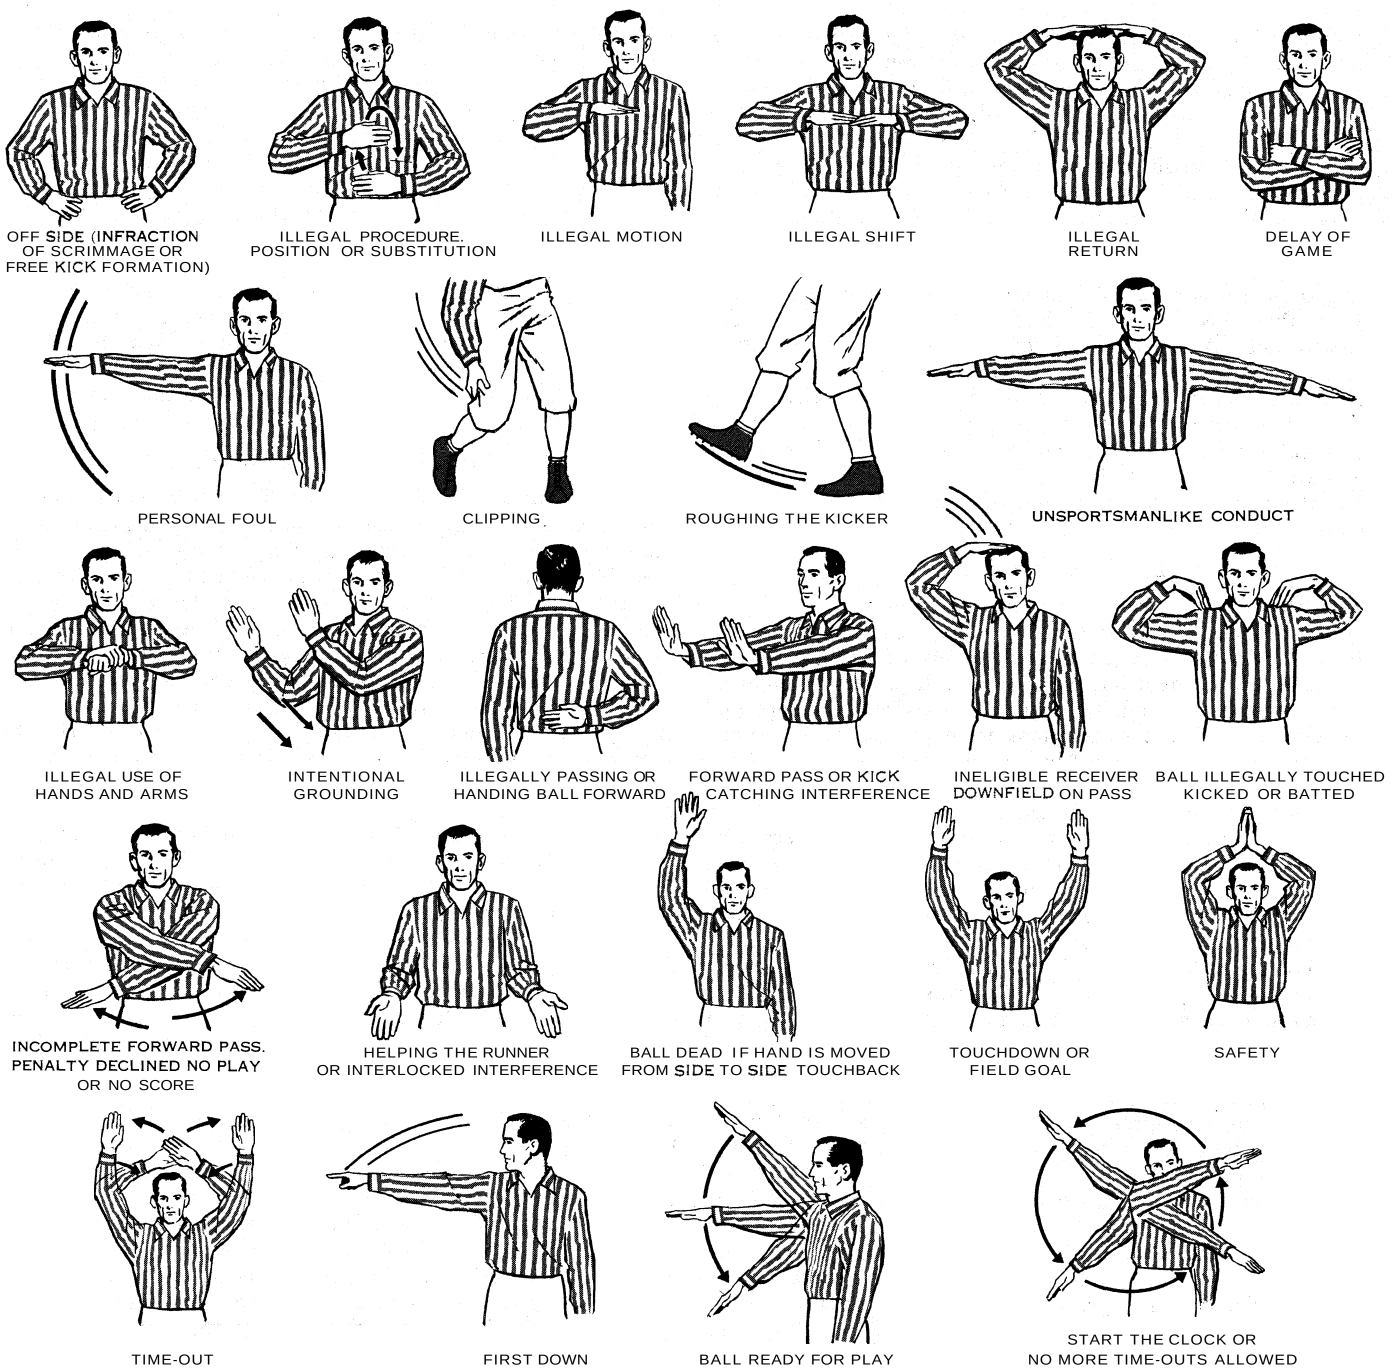

FIG. 10.—SIGNALS USED BY OFFICIALS ON FOOTBALL FIELD TO DESIGNATE PENALTIES AND OTHER DECISIONS

of adequate playing fields. high school football began to expand. About 1928 a high school in eastern Illinois (Westville) provided a lighting system for the playing of night football. This greatly increased the attendance. since it permitted working people to attend and permitted games to be played on Friday night as well as on Saturday afternoon. Approximately 50% of the high school games are now played at night.

Rules.—High school football is played under a code which permits a slightly more open type of game than that played by the larger colleges and universities. Significant features of the code include the following. When a scrimmage kick or a free kick touches anything in the receivers' end zone. the ball becomes dead and no runback is possible The high school game has 12-minute quarters (8-minute for junior high schools) and a 3-minute warm-up period is prescribed before the first and third quarters. More than one forward pass may be thrown provided each is thronn from behind the line of scrimmage; and a forward pass screen may be formed beyond the line of scrimmage if the pass is caught behind the line. Also a kick receiver may make a fair catch after which he may put the ball in play either by a snap or a free kick. The rules are the same for each of the three types of free kick; i e., the kickoff, the free kick after safety and a free kick after a fair catch. Any number of substitutes may enter when the ball is dead and there is no limit on the number of times any player may re-enter. During a time-out charged to either team, a player from each team may confer with his coach at a side line.

A carefully devised penalty system permits fixing the spot of enforcement without the necessity of making exceptions for special cases. This is commonly referred to as the "three-and-one" system of enforcement. This system provides that the penalty for any dead-ball foul is enforced from the succeeding spot (see Glossary, below), regardless of nhere, on or off the field. the foul occurs. If a foul occurs during a loose ball such as during a kick, pass or fumble, the basic spot for measurement is the previous spot. All measurements are from this spot unless the foul is committed by the offensive team and at a place behind the previous spot. In that case, measurement is from the spot of the foul. The same principle applies to a foul which occurs during a running play. In this case, the basic enforcement spot is the spot where the run ends.

High school football rules are made by a committee composed of one representative chosen by each state high school athletic association. This committee acts jointly nith the National Junior College Athletic association and the National Association of Intercollegiate Athletics. Safety and research committees operate during the entire season. All committee efforts are co-ordinated through the office of the National Federation of State High School Athletic Associations. Eligibility rules. regulations about scheduling games, the number of games which may be played during one season, the number of weeks of practice which must precede the playing of the first game and the opening and closing dates which mark the football season are administered in each state by its state high school association. No national or sectional championships are permitted and bowl-type games are not approved,

D. Six-Man Football

History. — Six-man football was originated in 1934 by Stephen E. Epler, athletic coach at Chester high school, Chester. Neb., who felt the need of a game that could be played by small secondary schools which could not produce enough players to build an 11-man squad plus an additional 11 for practice scrimmage and substitutions. Other considerations were the danger to young players in the 11-man game, the cost of equipment beyond the means of many small schools and the great distances between schools in states such as Nebraska.

The rules drawn up by Epler were such as to retain the essential factors of blocking, tackling, running and passing while opening the way to new possibilities for skill and strategy. This produced a sport with many characteristics of a new game rather than merely regulation football played by teams of six players each.

The first six-man game was played in the fall of 1934 at Hebron, Neb. The two teams, made up of players from four different Nebraska high schools, battled to a 19–19 tie. The game had an appeal for small secondary schools which had never attempted to compete in regulation football and to other schools whose athletic budgets had been reduced during the depression years of the early 1930s, and spread throughout the U.S. and to Canada. It was played by primary and secondary schools, boys' clubs and college intramural teams.

Rules. — The game is played by two teams of six men each. A team consists of a centre, two ends, a quarterback, a halfback and a fullback. The field of play is 100 yd. long and 40 yd. wide with two end zones 10 yd. deep. Three officials, a referee, an umpire and a linesman, supervise the play. The essential differences between the 6-man and the 11-man game are as follons. After the ball is snapped, a clear (backward) pass or a forward pass must be thrown before the ball can cross the scrimmage line. Violation of this rule is a foul and calls for a five-yard penalty; a hand-off is not considered a pass. Every player is eligible to receive a forward pass; during a series of downs, the team in possession must advance the ball 15 yd. or give it up to the opposing team. A field goal counts 4 points. The try after touchdown starts at the 3-yd. line with a successful kick scoring 2 points; a run or a pass scores only 1. Fair catches and return kicks are not used. Also, if at the end of the first half or during the second half a team acquires not less than 45 points more than its opponent, the game ends.

In nearly all other essentials the rules for 6-man football are the same as those for 11-man football.

Variations. — In the 1950s many schools changed from 6-man to 8-man teams, which played on the smaller field but under the 11-man rules. The team is made up the same as the six-man team with the addition of two linemen who, with the centre, are ineligible to receive forward passes. In a few areas, games are played by teams made up of five or nine players.

Touch and Tail Football. — Touch football may be played with little or no equipment by varying numbers of players. Either 6-man or 11-man rules may be followed. Body contact is kept to a minimum since the ball carrier need only be touched, usually with both hands, rather than tackled. Sometimes each player carries a handkerchief protruding from a hip pocket. In such cases the possession of the handkerchief is substituted for touching. This form of the game is known as tail football.

Other rules peculiar to touch football are: The ball becomes dead whenever it strikes the ground. A team which intends to punt must announce its intention before the down begins and must actually punt the ball, neither team being allowed to cross the line of scrimmage until after the kick. There is no try after touchdown. If a game ends in a tie the ball is taken to mid-field and each team is allowed one series of four downs. One point is scored by the team making the longest total advance during this overtime series. (H. V. P.)

E. U.S. Professional Football

Early History, 1895–1920. — The first professional football game to be officially recognized as such was played in the township of Latrobe, Pa., on Aug. 31, 1895. Latrobe beat a team from Jeannette, 10 mi. away, by the score of 12–0 and major league football had been inaugurated. For the next ten years, Latrobe fielded a powerful team which played whenever and wherever it could for uhatever returns it could earn.

John Brallier, who became a dentist in Latrobe, was recorded as the first "confessed" professional after he left the University of Rest Virginia team to play for Latrobe. Other college athletes, however, were earning expenses in scattered games of the time. Fielding Yost, later to become an outspoken opponent of professional football, played with the Greensburg, Pa., team. Walter Okeson of Lehigh, Walter Howard of Cornell and Thomas Trenchard of Princeton were heroes of many off-record contests. In 1897 the entire backfield of Lafayette college in Easton, Pa., played also for Greensburg.

During the next few years other professional teams appeared. In Pittsburgh, Pa., the Duquesne County and Athletic club mas created and its rosters listed some of the most famous college players of the day. Heffelfinger of Yale, Arthur Poe of Princeton, G. H. Brooke and P. D. Overfield of Pennsylvania, Fred Crolius of Dartmouth, Bemus and Hawey Pierce, the two magnificent American Indian athletes from Carlisle, all as prominent then as the All-Americans of a half century later, played for Duquesne.

Upper New York state folloned Pennsylvania into professional football soon after the start at Latrobe. There were teams in Buffalo, Syracuse, Watertown, Auburn, Corinth, Clayton, Oswego, Alexandria Bay and Ogdensburg. On Dec. 28, 1902, Syracuse, with "Pop" Warner and his brother Bill in the line-up along with Phil Draper, Williams college immortal, and the Pierce brothers, defeated the Philadelphia Nationals, 6–0, in the first indoor football game at Madison Square Garden, New York city. Thirty years later the Chicago Bears beat the Portsmouth Spartans, 9–0, in the Chicago Stadium. These two contests were the only major league games held indoors.

In 1902 Cornelius ("Connie Mack") McGillicuddy (1862–1956) organized a football team which he named the Philadelphia Athletics. In the line-up was George ("Rube") Waddell, the famous pitcher of Mack's baseball team. Mack claimed the "championship of the world" after his club vanquished a squad representing Pittsburgh which had Christy Mathewson, another great baseball pitcher, as its fullback. Mathewson had been a star during his college days at Bucknell. Again the Pierce brothers were on hand, playing for Philadelphia.

Like New York state, Ohio began to sponsor town teams. For 20 years leading to 1920, uhen the American Professional Football association (later the National Football league) was formed, there were teams in Canton, Massillon, Akron. Shelby. Columbus and Dayton. At Canton Jim Thorpe, the American Indian athlete, first played as an admitted professional after leaving Carlisle in 1912, the year of his triumph at the Olympic games in Stockholm. Thorpe ended his career in 1926, again with Canton after playing with Cleveland, Rock Island, the New York Giants and, in 1923, with a team of his own called the Oorang Indians made up entirely of Indians.

College stars of the time did not enter the professional game as eagerly as they did in the more prosperous years after World War II, but the early squads included such players as Willie Heston of Michigan, D. O. ("Tuss") McLaughry of Dartmouth, Charles Brinkley of Harvard, Herbert ("Fido") Kempton of Yale, Fritz Pollard of Brown. John ("Jock") Sutherland. Earle ("Greasy") Neale. Lou Little of Pennsylvania, the Horween brothers, Arnold and Ralph, of Harvard and many others.

One of the most unusual teams of history represented Columbus, O., in 1906 and for several years thereafter. Sponsored by the Pennsylvania railway and calling itself the Panhandles. this team had six brothers, the Nessers. who were railroad workers, in its line-up. These rugged men practised in their leisure hours after full days of railroad work. All of them—John, Ted, Frank, Phil, Fred and Al Nesser—were besieged with contracts from colleges and other professional teams but they preferred to stay on the job at home and play the bruising game "just for fun." Only Al accepted outside offers. playing with teams in Akron and Cleveland and with the New York Giants championship team of 1927. He completed 25 years of professional football in 1931.

The combination of World War I, a chance remark by Robert Zuppke, veteran coach of the University of Illinois, and the enthusiasm for football of George Halas of Chicago combined in 1918 to spark the beginning of the modern major league game.

Zuppke, at the postseason banquet of his 1917 Illinois team (on which Halas had been an outstanding end), said that it mas unfortunate that football players at the time when they were just beginning to learn something about the game were graduated from college and played it no more. A few weeks later, reporting for training at Great Lakes Naval Training station in Illinois, Halas found several recent college stars eager to continue playing. By New Year's day of 1919, a Rose Bowl championship match was held. in which Great Lakes upset a powerful Mare Island team.

On the Great Lakes squad were players who were to be the first stars of the future National Football league. John ("Paddy") Driscoll of Northwestern university (who succeeded Halas as head coach of the professional Chicago Bears 37 years later for the 1956 season) was one of the Great Lakes halfbacks; James Conzelman (later head coach of the professional Chicago Cardinals' 1947 championship team), Emmett Keefe, Harold Erickson, John ("Dutch") Lauer and Hugh Blacklock were other Great Lakes players.

Through this same period the pattern of football was developing and changing rapidly, with the professionals in large part leading the way. In 1906 the forward pass was legalized in an effort to refine and open up the game but it was not until 1913 that the passing game began to assert itself (see U.S. *College Football History,* above). For the next 25 years the pass play fermented, being used mostly as a desperation maneuver and often not successfully. Then came the explosion of the T formation as played by the Chicago Bears, with Sid Luckman at quarterback. In the championship game of 1940, the Bears defeated the Washington Redskins, 73–0. With this game, and the parallel performance of Sammy Baugh in the same era, the pass took its present place as almost half of each team's attack. (See below.)

Rockne, who was to become one of the immortals of football as a coach at Notre Dame, was one of the busiest and hardest-to-trace professional players of the 1914–20 period. He played as often as he could for whatever team was offering the best salary. One team claimed he played against them in six successive games in six different uniforms. He was one of the trickiest and hardest ends to stop.

The **Growing Years,** 1920–45.—As the early days ended with the organizing of the American Professional Football association in 1920, hundreds of unrecorded narriors of the gridiron faded from the scene. Scant records had been kept and the bruising battles of pickup games were lost forever. Even the glory of the individual stars dimmed, leaving only Jim Thorpe to live a few more years in sports pages. Unpadded, often unpaid, the pioneers played a vicious and smashing game of foothall, often for the full 60 minutes of each encounter unless crippled beyond the possibility of completing the game. A "big" squad of those days might have contained 1j players; the modern teams of more than 30 players, specialists and platoons were unknown.

Jim Thorpe was a superlative back. but his approach to the game was lighthearted and erratic. Despite contempt for the ordinary training rules, however. Thorpe could run in the open, crash the line and shatter the attack of his opponents. He ran like the later star, Harold ("Red") Grange, with swiveling hips, change of pace and extreme confidence. Defensively he broke up opponents with a lethal and "slightly illegal" special shoulder pad with an outer covering of sheet metal, nhich he was ordered not to wear when the league was formed. It mas said by those who had played with and against Jim Thorpe that he was one of the greatest football players of all time. Thorpe, who died in 1953, also excelled in other sports and was recognized by many as a great athlete. In his honour, the towns of Mauch Chunk and East Mauch Chunk. Pa., were joined and renamed Jim Thorpe.

Eleven league franchises at $100 each were sold when the American Professional Football association was officially formed on Sept. 17, 1920. Jim Thorpe was elected president and George Halas purchased a franchise for the Staley Starch company of Decatur, Ill., which had recently made him athletic director. The first 11 teams in the league were the Canton Bulldogs (Thorpe's team), Cleveland Indians, Dayton Triangles, Akron Professionals, Massillon Tigers, Rochester, N.Y., Giants, Rock Island, Ill., Muncie, Ind., Hammond, Ind., the Chicago Cardinals and the Staleys, who became the Chicago Bears in 1922.

The league had a perilous beginning that fall. Few games were played and there seemed little chance that the league would survive. However, in April 1921 the league elected Joe Carr, an experienced promoter, as its new president. Carr, who guided the National Football league until his death in 1939, created an immediate realignment of teams. Massillon, Muncie and Hammond dropped out; Green Bay, Wis., Buffalo, Detroit, Columbus and Cincinnati came in and a full schedule was completed with the Chicago Bears winning more games than any other team. Kot until 1933 did the N.F.L. play in two divisions with an annual championship game.

The appearance of the Green Bay Packers in 1921 was the beginning of a football saga. With a population of only 30,000 (growing to 50,000, 35 years later), Green Bay always gave the team more support than New York city gave its Giants. For more than a decade the National Football league survived with little support from the fans and even less from newspapers. Some franchises moved to other cities; new teams joined; some dropped out. By the 1960s only the Chicago Bears, Chicago Cardinals and Green Bay Packers had survived in the same place they had started. From 1921, 45 cities were the homes of N.F.L. teams.

The first trend toward prosperity began in 192j when "Red" Grange left the University of Illinois to play mith the Chicago Bears. Grange was the biggest name in the sports world at that time, and he was the spark that professional football needed. His debut against the Chicago Cardinals drew a capacity crowd of 36,000. Seven days later 68,000 jammed New York's Polo Grounds to see him play against the Giants. Grange and the Bears then went on a coast-to-coast tour that sowed the seeds of interest in the sport. Later, television helped complete the job of publicizing major league football. Grange established himself as one of the all-time stars of the N.F.L. before he retired in 193j.

Other factors were boosting the public interest. One was the T formation which was to startle the entire sports world in 1940; the other was a long list of brilliant players developed in the K.F.L. Most spectacular of all were two quarterbacks. Baugh and Luckman, beginning careers that stretched over many seasons. Baugh amazed experts through 16 years of competition.

Football's offense at this period was specializing in the single and double wing, with some plays being run from punt and short punt formation. The defense, as it always does, was catching up with these maneuvers, however, and the Chicago Bears' Halas, retired since 1930 as a player and spending his full time as head coach, was working on the T formation. Aiding and abetting these schemes to crush opponents of the future was Clark Shaughnessy, one of the top strategists of the game. In 1939 Luckman, a Columbia university star, joined the Bears and the T was ready.

In the championship game of 1940 against the Washington Redskins it was exploited, and a fine Washington team was the victim of a 73–0 massacre. The single wing and other formations, beginning in 1941, were eclipsed by the T formation in U.S. football.

Luckman's individual brilliance through his 12-year career with the Bears was helped by the outstanding ability of his teammates. Squads were built for years around the centre, Clyde ("Bulldog") Turner, one of the players who will be ranked with the best so long as U.S. football is played.

Baugh. joining the league with the Washington team in 1937, soon demonstrated his unprecedented ability as a passer. When Baugh finally retired in 19j3, he was acclaimed as a great offensive player as well as a sound defensive competitor and the league's leading punter through three seasons. He also led the league in interceptions one season besides being the top passer statistically through six. In 1945 Baugh threw 182 passes, completing 128 for a record .703 completion record. Only four were intercepted, also a record. Twice he tossed six touchdown passes in one game and by the end of his career he had attempted 2,983 and completed 1,689 for 18j touchdowns, all league records. His six-in-one-game record was beaten by Luckman, who fired seven in 1943 against the New York Giants.

During World War II, when 638 N.F.L. players served in the armed forces, 22 of whom died in action. the league continued. Some franchises were merged to provide better competition, and the sport continued to draw growing support of the fans. A strong factor in its fast gronth prior to World War II was the annual All-Star game in Soldier field. Chicago, promoted by the Chicago Tribune Charities fund and fielding the professional champions of each previous season against a picked squad of recently graduated college stars. Started in 1934, the series began to lose public interest in the early 1950s folloning several devastating defeats of the College All-Stars, but interest revived nhen the sponsors appointed professional coaches for the All-Star team in the 1954 game and thereafter.

The Modern Era.—In 1945 a rival league, the All America Football conference, n-as formed with eight clubs representing Brooklyn, Buffalo, Chicago, Cleveland, Los Angeles, Miami. Fla., New York city and San Francisco. Dan Topping, owner of the former Brooklyn N.F.L. team, transferred his entire squad to the A.A.F.C. There was considerable opposition among the N.F.L. owners against the new league, and four years of competition for support followed. When it ended before the 1950 season, professional football in general had come of age and the fans from coast to coast were aware of its existence. Under an agreement between the leagues, Baltimore, San Francisco and Cleveland moved their teams into the N F.L. and the balance of the A.A F.C. players were pooled and drafted by the 13 clubs in the N.F.L. After one season the league was reorganized into 12 clubs: the Baltimore Colts, Chicago Bears, Chicago Cardinals, Cleveland Browns, Detroit Lions, Green Bay Packers, Los Angeles Rams, New York Giants. Philadelphia Eagles, Pittsburgh Steelers, San Francisco Forty-Niners and Washington Redskins. Attendance records started to climb rapidly as the new era opened. Bert Bell, veteran player, coach and owner, was commissioner of the league from 1946 until his death in 1959. Pete Rozelle, general manager of the Los Angeles Rams, was named as Bell's successor in 1960. Annual attendance passed the 2,000,000 mark by the mid-1950s and television made the stars of the league well known nationally. In 1960 the Cardinals moved to St. Louis.

In 1959 a new American Football league was organized with Joe Foss, World War II air hero and former governor of South Dakota, serving as its first commissioner.

Rules.—The rules of professional football permit a more wide-open, high-scoring game than that played by the colleges, despite the fact that only one point can be scored after touchdown whether the ball is run, passed or kicked. Because the professional goal posts are on the goal line rather than at the back of the ten-yard end zone as in the college game, the professionals attempt and make more field goals than college teams.

In professional ball a member of the defensive team can run with a recovered fumble; the colleges call the ball dead at recovery. A professional ball carrier can rise and run if he falls to the ground unless he had gone down as the result of contact with an opponent; the collegian is down even though he slips and falls. The professionals have added a fifth official, the back judge, to the four who are standard in the college game. Substitutions are unrestricted in professional rules while the colleges moved toward the same system after the drastic antiplatoon ruling in 1953.

In professional football, divisional play-offs or championship games cannot end in a tie. If the score is tied after the regulation 60 minutes, additional periods of 15 minutes each are played. The first team to score a touchdown, field goal or safety is declared the winner and the game ends immediately. This "sudden death" system allowed Baltimore to defeat New York, 23 to 17, for the championship in 19j8 by scoring a touchdown after 8 min. 1j sec. of the first overtime period.

Court Ruling.—In 1957 a lawsuit instigated by a former N.F.L. player, William Radovich, resulted in a decision by the L.S. supreme court that professional football is a business subject to antitrust laws (Sherman act) in spite of a previous court ruling that professional baseball is exempt from this law.

(R. L. Tt.)

F. Glossary: L.S. Football

Approved ruling.—An official decision on a given statement of facts. It serves to illustrate the spirit and application of the rules.

Blocking.—Obstructing an opponent by contacting him with any part of the blocker's body; also stopping or deflecting an opponent's kick before it passes the scrimmage line.

Catch.—Act of establishing player possession of a live ball in flight.

Chain gang.—4 group of men under the direction of the linesman who handle the yardage chain and the down indicator.

Completion.—A catch of a teammate's pass.

Conversion.—A successful try.

Dead ball.—A ball not in play.

Dead-ball spot.—The spot on the playing field at which the ball became dead at the completion of the-last previous down.

Disqualified player.—A player who becomes ineligible for further participation in the game.

Down.—A unit of the game which starts with a snap or free kick and ends when the ball next becomes dead.

Down indicator.—A device mounted on a rod and showing the number of the down in the current series, the rod being positioned at one of the side lines on the defending team's scrimmage line.

Enforcement spot.—The spot from which the penalty for a foul is enforced.

Fade.—The movement of a passer toward his own end line prior to throwing a forward pass.

Fair catch.—A catch of a kick beyond the neutral zone by a player of the receiving team who has obviously signaled his intention by raising one hand clearly above his head. When a fair catch is made the ball becomes dead on the spot.

Field goal.—A place kick or a drop kick which passes over the crossbar or directly over an upright of the receiving team's goal before it touches the ground or a player of the kicking team. It may be a scrimmage kick or a return kick, but not a free kick. A field goal scores 3 points for the kicking team (4 points in six-man football).

Flag or handkerchief.—An official's penalty marker.

Forward pass.—A live ball thrown toward the opponents' end line. The ball becomes dead if it touches the ground before being caught.

Free ball.—A live ball, other than a forward pass, not in player possession.

Free kick.—A kick made under restrictions which prohibit either team from advancing beyond established restraining lines until the ball is kicked.

Fumble.—Loss of the ball by a player other than by handling, passing or kicking.

Gain.—Advancement of the ball beyond the line of scrimmage during a down.

Goal to go.—An expression used when the line to gain is the goal line.

Handing or hand-off.—Transferring the ball from one teammate to another without throwing or kicking it.

In-bounds spot.—The intersection of the nearer in-bounds line and the yard line passing through the dead-ball spot or through the spot where the ball is left by a penalty.

Interception.—A catch of an opponent's fumble or pass.

Kickof.—A free kick which starts each half of the game and follows each try or field goal. It must be a place kick or a drop kick.

Lateral or backward pass.—A live ball thrown toward or parallel to the passer's end line. The ball remains live even though it may touch the ground before being caught.

Linr to gain.—For a series of downs, a line 10 yd. (1 j yd. for six-man football) in advance of the ball's most forward point at the commencement of the series, but ii this line is in the opponents' end zone the goal line becomes the line to gain.

Live ball.—A ball in play. A ball passed, kicked or fumbled which has not yet touched the ground is a live ball in flight.

Loose ball.—A free ball.

Loss.—Failure to advance the ball to the line of scrimmage during a down.

Loss *of* a down.—Denial of the right to repeat a down because of a penalty or an incompleted forward pass.

Measurement.—The bringing in of the yardage chain from the side line to determine whether a team has advanced the ball to or beyond its line to gain.

Mug.—An unsuccessful attempt to catch or recover a ball, the ball being touched in the attempt.

Neutral zone.—The space, equal to the length of the football, between the two lines of scrimmage.

Out of *bounds.*—Any area other than that bounded by the two side lines and the two end lines.

Out-of-bounds spot.—The point at which, according to rule, the ball is declared out of bounds.

Pass.—Throw. A pass ends when the hall is caught, recovered or declared dead.

Play.—The tactic used during a down to advance the ball.

Player.—Any one of the participants actually in the game at any particular time.

Play ruling.—Statement of a play situation and the correct ruling.

Possession.—A player is in possession when he has a live ball in his hands and is exercising control over that ball. A team is in possession when one of its players is in possession, while a kick is being attempted or while a forward pass thrown by one of its players is in flight.

Previous spot.—The point from which the ball was last put into play.

Receiver.—A potential pass catcher on the offensive team or a potential kick catcher on the defensive team.

Recovery.—Securing player possession of a live ball after it strikes the ground.

Return *kick.*—A kick after change of team possession during a down, or kicking the ball while it is held ior an opponent's kick.

Runback.—Advancement of the ball by a catcher of an opponent's kick, pass or fumble.

Runner.—A player in possession of a live ball.

Safety.—See Touchback.

Scrimmage.—The interplay of the two teams during a down in which play begins with a snap.

Scrimmage kick.—A kick by the team designated to put the ball into play during a scrimmage before team possession changes.

Scrimmage *line.*—For each team, the yard line and its vertical plane which passes through the point of the ball nearest that team's entl line.

Series of *downs.*—A group of four consecutive scrimmage downs during which the team in possession must advance the ball to or beyond the line to gain. If they succeed a new series of downs is begun. If they fail they must surrender the ball to their opponents.

Snap.—Handing or passing a ball back from its position on the ground with a quick and continuous motion of the hand or hands, the ball actually leaving the hand or hands in this motion.

Spot of the foul.—The point at which a foul occurs; if out of bounds between the goal lines, the intersection of the nearer in-bounds line and the yard line extended through the spot of the foul; if the foul is committed by a nonplayer, the spot of the foul is the previous spot.

Spot *where* a *run* ends.—The point where the runner loses player possession of the ball or where the ball becomes dead in his possession.

Substitute.—.\ replacement ior a player or a player vacancy.

Succeeding spot.—Relating to a foul, the point at which the ball would have been put in play if that foul had not occurrcd. If the foul is committed after a touchdown but before the try, the succeeding spot is the 40-yd. line (30-yd. line in six-man iootball) of the team which next kicks off.

Touchback.—When the ball is out of bounds behind a goal line (except from an incompleted forward pass), when the ball becomes dead in possession of a player behind his own goal line or when a penalty leaves the ball on or behind that line, it is a touchback if the attacking team is responsible for the ball being on or behind that goal line Ii the defending team is responsible, it is a safety and scores 2 points for the attacking team.

Touchdown —A score of 6 points for the team whose player is legally in possession of the ball while any part of it is on, above or behind his opponents' goal line.

Try.—.\n attempt by the team making a touchdown to further increase its score during one scrimmage down from the defending team's 2-yd. line (professional and secondary school football) or 3-yd. line (college and six-man football) while time is out. During this down, a drop kick or a place kick in the manner of a field goal scores 2 points in 6-man, 1 point in 11-man iootball. A forward pass or run ending beyond the goal line scores 2 points in college and A.F.L. football, 1 point in N.F.L., six-man and most secondary school football.

Yardage *chain.*—A chain. joining two 5-it. rods, the rods being exactly 10 yd. apart (1 j yd. in six-man football) when the chain is fully extended. Used on one of the side lines to mark the line to gain.

Yard line.—Any line, marked or unmarked, on the field of play parallel to the end lines. A team's own yard lines are numbered consecutively from its own goal line to the jo-yd. line (40-yd. line in six-man football).

Yards to go.—On any down, the distance between the line of scrimmage and the line to gain. (A. Da.)

III. CANADIAN FOOTBALL

Although Canadian football stems from English Rugby, modern rules changes brought it closer and closer to U.S. football. Only the practised eye can discern the differences. The playing field is larger, being 110 yd. long and 65 yd. wide. The end zones are 25 yd. deep. The wide field encourages lateral passing and the deep end zones. forward passing for touchdowns. There are 12 men on a team. and the extra man is called a flying wing. He is invariably used in the backfield on offense and as a linebacker on defense. The other positions are the same as those in U.S. football and have the same names. Formerly they were different. but many players were imported from the U.S. after World War II and U.S. nomenclature was introduced.

There are only three downs in the Canadian game. Teams must try for the big gain, which makes the play more open than in U.S. football. Blocking. unlimited in U.S. football. was restricted in Canadian football to a point ten yards beyond the line of scrimmage. A single point may be scored in Canadian football if the team in possession kicks the ball over the defending team's dead line, which is 2; yd. beyond the goal line. and it may also he scored if the defending team's safety back is tackled or run out of bounds in his own end zone after receiving a kick. Otherwise the scoring in the Canadian game is exactly the same as that of the U.S. game, except that the try after touchdown (from the 5-yd. line) is worth only 1 point regardless of how it is made. Offensive and defensive formations are similar to those in U.S. football. (D. C.)

IV. ASSOCIATION FOOTBALL (SOCCER)

A. British Association Football

Rules of Play.—Association football (commonly abbreviated as "soccer") is played by two sides of 11 men each, with a round, leather-covered. inflated rubber bladder not more than 28 in. or less than 27 in. in circumference and weighing not more than 1 Ib. or less than 14 oz. at the beginning of the game. The ball may be kicked, butted or played with any part of the body except the hands; only the goalkeeper is allowed to handle the ball and he may handle it only in his own penalty area (and when so doing may not take more than four steps without bouncing the ball on the ground). The game is played on a field (pitch) not less than 100 yd. and not more than 130 yd. long, and not less than 50 yd. or more than 100 yd. wide. As a general rule full-size pitches are 115 yd. long and 75 yd. wide. Goals eight yards wide and eight feet high are placed in the centre of each end line. The markings on the field and the normal positions of the players at the start of the game are shown in fig. 11. The team scoring the greater number of goals wins the match. To score a goal a side must force the ball into its opponents' goal without throwing, carrying or propelling it by hand or arm; a player diverting the ball into his own goal by any method scores for his opponents. A free kick at the spot of the offense is awarded to the nonoffending side after a breach of the rules, the most common offenses being offside play, handling the ball, tripping, pushing or illegally charging or obstructing an opponent. An unintentional breach of the rules in most cases does not earn punishment. Many fouls by a defending player within his own penalty area (see fig. 11) are punished by a penalty kick, taken by any one of the attacking side from the penalty spot 12 yd. in front of the centre of the goal with only the kicker and the goalkeeper within the penalty area. The game lasts for 90 minutes or such less time as may be agreed upon, and is divided into two equal periods, the sides changing over and attacking different ends after half time. The teams toss before the start and the winners of the toss may decide either which end they will attack first or whether they will kick off first. The game is started or restarted after a goal or the change of ends by a place kick from the centre spot. If the ball is driven over a side line or touch line, play is restarted by a member of the side which did not last touch the ball throwing the ball into the field of play with both hands from above the head from a stationary position. This is known as a throw-in. If the attackers force the ball over their opponents' end or goal line, the defenders re-

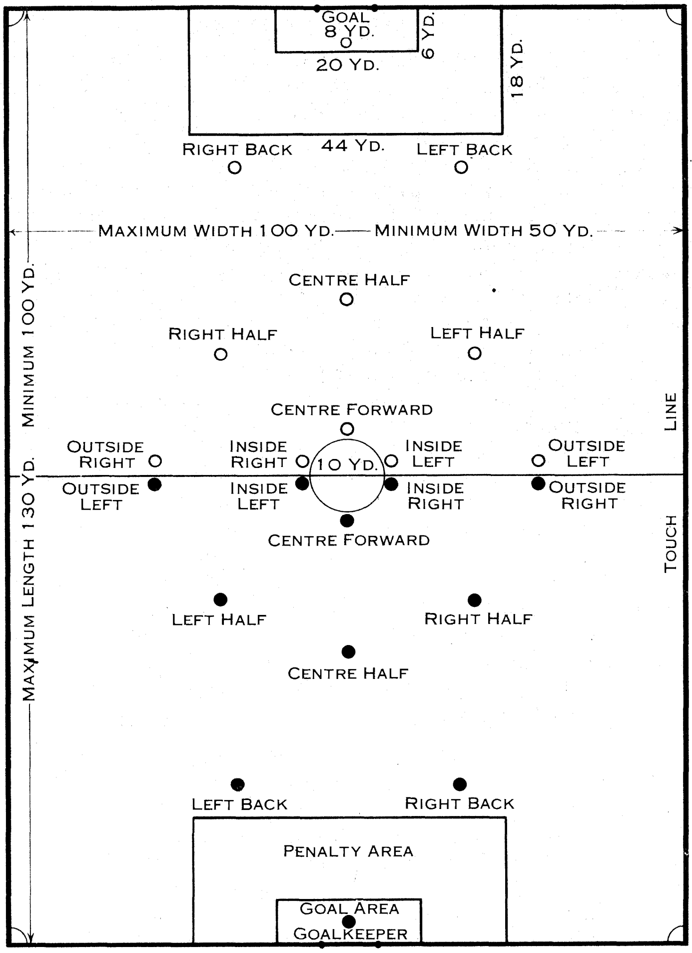

FIG. 11.—SOCCER FIELD AND POSITION OF PLAYERS AT THE KICKOFF

start play with a free place kick from within the goal area (see fig. 11); if the defenders divert the ball over their own end line the attackers restart play uith a free place kick from uithin one yard of the nearest corner of the playing area (a corner kick).

Changing Conditions.—Enthusiasts of the game would have had some difficulty in recognizing the sport until about 30 years after the founding of the Football association in *1863*. For a long time a side consisted of a goalkeeper, one back, one half-back and eight forwards who roamed the field more like a pack of hounds than a forward line. These forwards relied almost entirely on mass dribbling and on charging, especially charging of the goalkeeper out of the way of an expected shot or centre. Preston North End mas, perhaps, the greatest exponent of this method of overcoming the most important member of the defense. The next formation was a goalkeeper, two backs, two halfbacks and six forwards; but from *1883* on, most teams translated another forward into a halfback and so adopted the normal modern formation. The throw-in from touch at first was done with one hand, but so expert did some players become at hurling the ball into the goalmouth from a 40- or even jo-yd. range that it was thought necessary first to make the thrower use two hands and then to make him throw with tno hands from above his head from a standing position. Crossbars did not replace tapes and so avert innumerable arguments until *1883*. Until *1891* there were no linesmen; each side had its own umpire and the referee mas used only as a final court of appeal; after *1891* the umpires were abolished and the referee became an active participant; one result of this was the founding in *1893* of the Referees' association, which improved the standard of refereeing immeasurably and was the forerunner of similar invaluable organizations all over the world. It was only in *1891*, too, that the goalkeeper was protected from charging except when he was in the act of playing the ball or was 'obstructing another player. At about this time, again, the penalty kick uas introduced. It was not only the rules. however, which were far different in those days; so was the appearance of the players. For a long time it was customary to wear knickerbockers fastened tightly below the knee. with long, overlapping stockings; boots were of the ordinary type, with the addition of two or three crossbars on the sole and one crossbar on the heel; the wearing of moustaches and caps was normal, that of beards and top hats not rare.

The Offside Rule.—The rule which caused most trouble through the years was the one defining off side. From *1886* to *1928* it read: "When a player plays the ball or throws it in from touch any player of the same side, who, at such moment of playing or throwing in. is nearer to his opponents' goal line. is out of play and may not himself touch the ball or in any way interfere nith an opponent until the ball has been played. unless there are, at such moment of playing or throwing in, at least three of his opponents nearer their own goal line. A player is not out of play in case of a corner kick or when the ball is kicked out from goal or when it has last been played by an opponent."

Difficulty in applying the law arose from the words "at such moment of playing or throwing in." Presume that a centre forward *(A)* has the ball at his feet at the halfway line, that the outside left (B) is behind the halfway line and that seven or eight of the opposing side are in their own half. ***A*** now kicks the ball forward and high to the left-hand touch line; the attention of the players, and probably the referee, is directed toward the spot where the ball mill fall. But just as it is about to fall B suddenly arrives, having rushed up the field under the kick, and takes the ball on with him, although only two of the opposing side now are between him and the goal line. B obviously is not off side, because when the ball was kicked by ***A*** he was behind *A*. But from the crowd there is likely to be a vociferous shout of "off side." The difficulty of seeing and remembering the exact position of each player at the moment of kicking caused endless disputes. The adoption of the diagonal system of refereeing did much to ensure accuracy of official judgment. Under this system the referee moves along a prearranged diagonal of the field and each linesman is responsible for one set of forwards and alnays will be up with that set when it is attacking. The referee is in the best position to see incidents in the goalmouth and mill always have one linesman co-operating with him there while the other linesman is ready for a breakaway. The offside rule was revised in *1928* to provide that a player cannot be off side in his own half of the field and in his opponents' half needs to have only two opponents instead of three at the moment when one of his onn side behind him sends the ball forward. The change had become necessary because fullback strategists, notably W. McCracken of Newcastle United, had developed great skill in putting whole forward lines off side by clever anticipation of attacks and moving upfield at the crucial moment.

Changes of Style.—There were many big changes in the style of play after association football became an organized sport, and it became a far cry from the pack of eight forwards who dribbled, hacked and barged their combined path hither and thither. In the period 1880–96 the best sides began to add passing to their armoury while retaining all their old skill at dribbling. William Gunn (Notts County) and George Brann (Snifts), two great international cricketers, N. C. Bailey (Old Westminsters), W. I. Bassett (West Bromwich Albion), W. N. Cobbold (Old Carthusians), J. H Forrest (Blackburn Rovers) W. J. Townley (Blackburn Rovers) and J. Goodall (Preston North End and Derby) were among the brightest individual stars of this time. Soon after *1896* passing was developed to an extreme degree, and dribbling, outside Scotland, began to be neglected; individual brilliance began to play a smaller part in comparison with good teamwork, but the great figures of the years between 1896 and the start of

World War I in 1914 became as much household names as any of their predecessors or successors. G. O. Smith (Old Carthusians), who was anarded 21 caps (*i.e.*, played in 21 full international games for England). S. Bloomer (Derby County, 24 caps), R. Crompton (Blackburn Rovers, 42), J. W. Crabtree (Burnley. 14), E. Needham (Sheffield United. 16), W. J. Oakley (Oxford university, 6), J. Pennington (West Bromwich Albion. 2j) and V. J. Woodward (Tottenham Hotspur, 23) mere among England's best; in Scotland R. Walker (Heart of Midlothian) played 33 times for his country, but the most remarkable record of all was that of W. Meredith (Manchester City and Manchester United), who played in 50 full international matches for Wales between 1895 and 1920. Crompton's English record was not broken until W. Wright (Wolverhampton) won his 43rd cap in 1952. Wright played for England 85 times, 70 times as captain, by the end of the 1956–57 season.

After World War I dribbling never recovered its position, and passing at times seemed to become an obsession when quick shooting clearly was demanded. Heading the ball became a great art and W. R. Dean, centre forward for Everton and England, probably was the greatest marksman nith his head ever seen. The speed of the game increased, at times beyond all reason, so that play seemed to become a matter of kick and rush. but the most successful sides always had fine constructive halfbacks.

The most important change, however, was the result of the change in the offside lam (see above). Under the old rule the outside formards had taken the ball down to the corner flag before centring in order to ensure that their companions were on side. There was no longer so much need for this and outsides began to cut in and shoot or make short passes.

Herbert Chapman, manager of Huddersfield Town during its three successive championships in the 1920s, became manager of Arsenal and he fitted a fine team superbly to the new conditions and set a new style. The centre half, who previously had supported his own forwards closely in attack, was now made a defensive player lying well back to block the centre approach to goal; he had to be tall in order to ensure that he could deal with any high balls and he was not to be tempted to wander. The two backs hitherto had marked the opposing inside forwards and had kept fairly close together in front of goal while the wing halfbacks marked the outside forwards; now the backs stayed wider apart and took the outside forwards and the wing halfbacks took the inside forwards. In attack the cutting in by the outside forwards tended to crowd the penalty area and, partly because of this and partly in order to provide a necessary link with the defensive centre half, the inside forwards were stationed behind the other formards so that the line resembled a letter W; this disposition of forwards is. indeed, known as the W formation. Chapman not only worked out the implications of the new offside law but also had the men to put his ideas into practice; J. Hulme and C. S. Bastin were two fast outside forwards who could shoot hard with either foot; E. J. Drake was a fearless and dashing centre forward, and D. B. N. Jack and A. James were two remarkably constructive insides; at centre half he had tall "policeman" H. Roberts and at wing half two great international players in W. Copping and W. J. Crayston. In the last ten seasons before World War II Arsenal won the Football league championship five times and was runner-up once and third once, and won the Football Association cup twice and was runner-up once. It became the most famous team in the world, and its style was copied everywhere; unfortunately where the players modeling themselves on Arsenal were not expert the result was iron defense and kick and rush attack—which was dull.

The great problem in modern football inevitably became how to lure the centre half away from his post in front of goal or circumvent him. In no case has a side been consistently successful in this without having good constructive wing halfbacks. Teams such as Manchester United (Football Association cup winners and perennial top contenders in the Football league after World War II) achieved a good deal of success by having a wandering centre forward who popped up anywhere in the line and performed a scissors movement with his outside forwards, either breaching the defense on the flanks or eventually getting the centre half on the wrong foot. Others used inside forwards who could make cross dribbles toward a far corner flag and then shoot across a through pass back to their own normal position, having again put the defense on the wrong foot. The Italian side that was unlucky to lose to England at Tottenham in Nov. 1949 sorely upset the English centre half by adopting a deep V formation with the centre forward at the point of the V. There he received the ball in unmolested comfort from his own halfbacks and became, as many years before, a distributor of the ball. leaving the centre half, as it were, hanging in the air and confounding him with delicate ground passes for other forwards to run on to behind the centre half's back.

The Austrians developed in the middle years of the 20th century what was called the bolt system of defense. The centre half had a roving commission in mid-field and was helped there by the centre forward. who left the other four forwards to do the brunt of the raiding. The two backs played one behind the other in the centre to cover any breakthrough and the wing halves marked the opposing outside formards. This system was most confusing to sides meeting it for the first time. since they could not mark the men that they were used to marking. At the same time both continental European and South American teams concentrated far more than the British on accurate and patterned passing. nhich often seemed to the uninitiated to go on endlessly and pointlessly but was in fact done in the hope of exasperating their opponents or of causing them to make some desperate attempt to recover the ball which would result in the defense's losing position.

In mid-century Hungary under the autocratic control of G. Sebes developed an almost unbeatable team. It won the Olympic tournament in 1952 and in 1953 became the first team from outside the British Isles to win a full international match on English soil, succeeding by 6–3 at Wembley stadium, and won the return game 7–1 in Budapest. Germany's victory over Hungary by 3–2 in the World cup final in 1954 was the surprise of the year.

The Football Association. — The Football association (F.A.) in 1905 turned itself into a nonprofit limited liability company. It supported the formation of the Scottish. Welsh and Irish associations to supervise the game in those countries instead of trying to keep under its own control the clubs in those countries which had joined it in the early days. When those associations wished to introduce certain rules of their own it settled the differences by proposing an international board with two representatives from each of the four countries and later it joined the Fédération Internationale de Football Association (F.I.F.A.) in forming a new board to look after the rules. When it became obvious that veiled professionalism was taking place, the Football association did not attempt to evade the inevitable, but kept control of the situation by recognizing professionalism in 1885 and fixing rules for it. Its policy has been to avoid interference in the domestic affairs of the professional clubs except where they offend against the bylaws of their association. When this occurs, it comes down on them heavily with the full support of the professional leagues' own management.

The F.A. organized in the 1871–72 season the first of a series of knockout'competitions for the F.X. cup which were soon to become world famous. At first the competition attracted only a handful of entries, fewer than did the Scottish F.A.'s cup, first competed for in 1873. Amateur clubs, including Queen's Park (Glasgow), dominated the competition for the first 14 years and it was not until 1883 that the cup went to the north of England for the first time, to Blackburn Olympic; thereafter it left the north and midlands only rarely. The Scottish clubs soon dropped out but a small number of Welsh teams were admitted annually and one of them. Cardiff City, won the trophy in 1927. By the second half of the 20th century most victories in the final had been won by Aston Villa, Blackburn Rovers, Newcastle United. Wanderers (all before 1880), Sheffield United, West Bromwich Albion. Bolton Wanderers, Arsenal, Sheffield Wednesday and Wolverhampton Wanderers. After 1891 only Newcastle United in 1952 had retained the trophy in the following year. The Wanderers and

Blackburn Rovers each had won it three times in succession and twice in succession. Except in 1893 (Manchester), 1894 (Everton) and 1915 (Manchester), the final had always been played in London, first at the Oval or Lillie Bridge, then at the Crystal palace, then at Stamford Bridge and finally at Wembley; replays usually were outside London but there had been no replay necessary in the final since 1912. Immediately after the coming of professionalism the attendances at the "cup ties" began to increase rapidly. More than 100,000 spectators watched three of the finals at the Crystal palace and the record there was 120,028 in 1913. After the final was taken to Wembley in 1923 the attendance was limited to between 91,000 and 100,000 ticket holders, but when Bolton Wanderers met West Ham United there in 1923 the decision to make the final an all-ticket match had not been taken and the gates were rushed by persons trying to pay at the turnstiles. It was estimated that there were about 150,000 people inside the ground and many more outside. A new record of receipts at a final, £49,881, was set in 1955. The original F.A. cup was stolen from a Birmingham shop where it was on show after Aston Villa's victory in 1895; it was not recovered and a new cup was presented by Lord Kinnaird, himself holder of the record number of five cup winner's medals.

After the professional clubs had begun to swamp the amateurs in the F.A. cup competition the association put up another trophy for competition among amateur clubs. The final for this was taken to Wembley in 1949, and in 1951 a record crowd of 98,327 saw Pegasus beat Bishop Auckland. In 1954 Bishop Auckland and Crook Town had to replay twice; 100,000 watched them at Wembley, 60,000 at Newcastle and 36,727 at Middlesborough.

The association's other activities became almost boundless; by mid-20th century it represented about 50,000 clubs and more than 1,000,000 players. It controls and organizes international and representative matches, plans courses for players, coaches and referees, makes instructional films and publishes instructional books, approves the rules and regulations of all leagues, is the supreme court of appeal for those charged with breaking the rules in England and is continually giving advice and help to football organizations all over the world. Its address at 22 Lancaster gate, London, became one of the best-known in the football world. Two of its secretaries, Sir Frederick Wall and Sir Stanley F. Rous, were given knighthoods for their services to the game.

League Football. — William McGregor, known afterward as the "father of the league," wrote in 1888 to the strongest professional clubs suggesting that they should combine and form a league, arranging a championship on the basis of home-and-away matches with each other. The suggestion was accepted and 12 clubs formed the original Football league for the 1888–89 season. For a time they were almost a closed corporation but in 1892 a second division of the league was formed and the first division was increased to 16 clubs. Soon after the principle was adopted of promoting the first two clubs in the second division at the end of each season into the places of the last two clubs in the first. division. A southern league founded shortly before World War I was incorporated as a third division of the Football league in 1920 and in 1921 a northern section of the third division was formed, the first club in each section of the third division to be promoted annually into the second division into the places of the two bottom clubs in the second and the two bottom clubs in each section of the third to apply to their fellow members for re-election. Twenty-two clubs now were in each of the first two divisions and 24 in each third division, so that after the mid-1950s there were 46 Football league matches each Saturday in the season. Of the original 12 members of division I not one had retained its place in division I continuously; the last of them to fall was Aston Villa in 1936 and it returned to the top flight two years later. Three division I teams had never been relegated, Sunderland, Arsenal and Portsmouth. Sunderland was co-opted in 1890; first division status was won by Arsenal in 1904 and by Portsmouth in 1927. Liverpool had not been out of division I since 1905. Nineteen different clubs had won the championship by 1956— Arsenal (7), Aston Villa and Sunderland (6 each), Everton and Liverpool (5 each), Newcastle United and Sheffield Wednesday (4 each), Huddersfield Town (3 in succession), Manchester United (3), Blackburn Rovers, Portsmouth and Preston North End (2 each) and Burnley, Manchester City, Tottenham Hotspur, Sheffield United. West Bromwich Albion, Wolverhampton Wanderers and Chelsea.

Normally, more than 1,000,000 spectators watch the Football league games each Saturday; more than 80,000 have seen single games on the Chelsea and Manchester City grounds and even in division III 49,000 watched a league game between the two Nottingham clubs in April 1950. Nowhere had there been an association football league of such power and such a hold on the public's interest. Football pools were organized in many countries depending on the Football league results.

One of the most important rules in the Football league is that once a professional player has joined a member club he may not normally leave it for another without his old club's approval and the payment by the new club of such sum for his transfer as may be mutually agreed. These transfer fees grew enormously, even absurdly, and in 1951 J. Sewell, a young inside forward, was transferred from Notts County to Sheffield Wednesday for the record sum of £34,000, the player himself receiving nothing except a legal £10 signing-on fee, percentage of benefit accrued (£750 for each five years of continuous service uith a club) and the top weekly wage then permitted, £12. Such fees had become a burden to players transferred and though these fees might have been an advantage to clubs in financial distress, they were also a complete bar to many clubs' efforts to strengthen their sides. Transfer fees also caused dissatisfaction among the players who claimed that if the clubs could afford to pay out such huge sums for comparatively unknown players they could afford to pay much better wages. The fees had risen because the clubs had refused to impose self-discipline on themselves as a body. J. Seed, manager of Charlton Athletic, a first-division club, wrote in Fenmore's *Football Year Book, 1949–50,* that only their own jealousy and selfishness prevented their calling a halt in a drift toward undisguised commercialism. It was a source of satisfaction to many, however, that huge expenditure on new players in midseason had failed many times to save a club from relegation and that most successful teams. such as Portsmouth, Wolverhampton Wanderers, Burnley and Manchester United, had relied on finding their own talent and spent almost negligible sums on transfers. The transfer fee. or, in the case of a new professional, the big signing-on fee, had become the accepted thing among professional clubs the uorld over, and the F.I.F.A. had to take some steps to control international transfers. Outside Great Britain probably the strongest and best professional league in the mid-1950s was the Italian National league. There the clubs, with the aid of wealthy patrons, offered huge signing-on fees and wages to players in other countries, and their activities seriously weakened the national team of Sweden, where there was hardly any full professionalism.

The Position of Amateurs. — The standard of play in the early British professional clubs rapidly put the amateurs in the shade. In order to enable the best amateurs to meet the professionals on more or less even terms and facilitate the welding of the best of both in international teams, N. L. Jackson, assistant honorary secretary of the F.A., suggested the formation of a club made up of the best amateurs only. In this way was born the Corinthian F.C., and as long as Jackson remained active the club was remarkably successful. After his retirement in 1898, however, the club began to lose ground rapidly. In the 1920s an effort was made to improve matters by entering for the F.A. cup and the team was excused the qualifying rounds, but little success was achieved and later the club had to join forces with the Casual F.C. The Corinthians did not. perhaps, cast their net wide enough, particularly among the smaller universities, and at a time when almost every other club competed in some league there was a natural reluctance on the part of players to desert their old clubs to join a noncompetitive club. There remained, however, many good amateur club sides all over Great Britain and there was a noticeable revival of the game at Oxford and Cambridge, culminating in the formation of a joint past and present club called Pegasus which won the F.A. Amateur cup in 1951 and 1953, its third and fifth seasons. The game at these universities had for long been handicapped by the fact that the majority of the old public schools had adopted Rugby; association remained the chief game, however, at Aldenham. Bradfield, Charterhouse, Highgate, Lancing. Malvern, Repton, Shrewsbury, Westminster and Winchester, among others.

The British associations' insistence on the prohibition of payments to amateurs for loss of time at work doubtless helped to drive many players into becoming professionals, and it became comparatively rare to see an amateur in a club's Football league eleven and rarer still to see one in England's full international team. In Scotland, however, Queen's Park: one of the oldest clubs in the game, maintained its position remarkably. In 1946 it supplied two of Scotland's full team, and in 1948 it was in the A division of the Scottish league; it suffered relegation the next season (not for the first time) but in 1956 recovered its senior status. Its ground at Hampden park had for long been the biggest in the game and it held 149,547 spectators for the Scotland *v.* England match in 1937. Among the most famous players the club produced was A. Morton. an outside forward who later became a professional with the Glasgow Rangers, easily the most powerful Scottish club through the years; while mith the two clubs he won 32 Scottish full international caps between 1919 and 1932.

Outside Great Britain payments to amateurs for broken time were permitted as a normal thing and in consequence full professionalism either did not obtain or rarely became as dominant as in Britain. For instance. Sweden's team, which beat England in, 1949 in Stockholm, was composed entirely of players classified as amateurs under Swedish rules. In any case. however much publicity the professional leagues and players might receive. the amateurs remained the true backbone of the game in all countries; of 1.000.000 players attached to clubs under the F.A. at mid-20th century only about 6,000 were registered professionals.

B. World Association Football

Once association football had become a popular sport in Great Britain, its spread throughout the world was only a matter of time. Everywhere that Britons went they played association or "soccer"; and the simplicity of its basic principles and rules and the fact that it could be played satisfactorily under almost any conditions except in fog added to its appeal. Other countries soon started their own clubs, in many cases with the help of local British residents or visitors; such British clubs as the Corinthian F.C. made innumerable missionary and holiday tours in foreign countries. National associations followed naturally, in almost every case modeled on the Football association, and in 1904 these national associations combined to form the F.I.F.A. This vast federation, earliest and biggest of its kind, directs the game in almost every country in the world from its headquarters in Ziirich, Switz. The British associations withdrew from the international body in 1928 because of differences of opinion on points they regarded as fundamental — the payment of allowances to amateurs for time lost from work and the use of substitutes in a match — but the F.I.F.A. and the British associations remained good friends and continued to work together on the International Football Association board, whose chief duty was to discuss and accept or reject proposed alterations in the rules of the game. The British associations later rejoined the international body and by the second half of the 20th century few countries were not members.

Some form of world tournament became inevitable and in 1930 the F.I.F.A. organized its first competition for the Jules Rimet cup, commonly called the World cup. Uruguay won the title of world champions that year and Italy was successful in 1934 and 1938. The British associations did not compete in these first tournaments, but having rejoined the F.I.F.A. England entered the 1950 competition, in the final of which Uruguay beat Brazil. This tournament is divided into three parts. First. small regional qualifying competitions are decided. The winners of these and a few who have been given byes go forward to the second stage in the host country.

One of the greatest difficulties in international football had been the widely different interpretations put on the rules in different countries. In 1949, therefore. the F.I.F.A. invited Sir Stanley F. Rous. secretary of the Football association and a former referee of the F.A. cup final. to draw up instructions for the referees for the World cup tournament. The referees for the finals are chosen from a list submitted by all national associations, the final choice depending on their experience in international matches, knowledge of languages and age. Arrangements are made to call the chosen officials together in advance for a short course in order to obtain a uniform interpretation and a high general standard; this is one of the most valuable services of the F.I.F.A. to the game.

United States. — In the United States the first professional association football nas played in 1918 nhen a team was organized at the Bethlehem (Pa.) Steel company. Several professional leagues came into existence before World War II, but even the most important of these (the American league) mas limited almost entirely to the factory districts of New York and Philadelphia. The game was played and supported chiefly by foreign-born factory workers. though the business management was predominantly British. Whatever chance it had to become a leading sport in the U.S. was lost when professional U.S. football became established on a solid financial basis in the middle 1920s. Professional U.S. football draws crowds of up to 50,000; at association games it was rare before World War II to find as many as 5,000 spectators. Efforts were made to popularize the game by arranging visits from British clubs and national sides.

The game is played in many U.S. preparatory schools (corresponding roughly to British public schools) and city high schools, but only occasionally in other schools and colleges. Great surprise was caused when the Cnited States team beat England 1–0 in the World cup series in 1950 in Rio de Janeiro. When a return match was played in Yankee stadium. New York city, in June 19j3. however, England won 6–3. The popularity attained by the game in the U S. at that time may be gauged from the fact that only 7,271 spectators were present. (For further history and the rules of the U.S. game, see Soccer.)

The World cup tournament is an open one in which amateurs and professionals compete on level terms. but amateur players also have their private world tournament every four years at the Olympic games (*q.v.*).

C. Glossary: Association Football

Corner area.—At each corner of the playing field, a quarter circle mith a radius of one yard, drawn inside the field of play.

Corner kick.—A direct free kick from one of the corner areas by a member of the attacking team; used to restart play when the ball has been propelled across the goal line, but not between the goal posts, by a member of the defending team.

Direct *free* kick.—A iree kick irom which a goal can be scored directly against the opposing side.

Dribbling. — Movement of the ball along the ground by a player by a series of very short kicks, usually mith the instep or side oi the foot, to gain ground or take the ball past an opponent.

Foul.—A breach of the laws of the game, punishable by a free kick, direct or indirect.

Free kick.—A kick during which no member of the opposing team, unless he is standing on his own goal line between the goal posts, may approach within ten yards of the kicker until the ball has traveled the distance of its own circumference.

Goal. — Two upright posts, eight yards apart, joined by a horizontal crossbar and placed in the centre of each goal line. A net is fastened to the posts below the bar. Also the name given to a score made by propelling a ball betw-een these posts and under the crossbar.

Goal area.—A rectangular area immediately in front of each goal, 20 yd. wide and extending 6 yd. into the field.

Goal kick.—An indirect free kick by a player of the defending team; used to restart play when the ball has been propelled by a member of the attacking team over the goal line, but not between the goal posts. The kick is taken from within the goal area and the ball must be kicked beyond the penalty area.

Handling. — Any other player than the goalkeeper intentionally carrying, striking or propelling the ball with hand or arm.

Heading. — Striking, propelling or deflecting the ball with the head.

Indirect free *kick*.—A free kick irom which a goal cannot be scored unless the hall has been played or touched by a player, other than the kicker, before passing through the goal.

Kickof. — A place kick from the centre of the field by a player who kicks it into the opposing team's half of the field; used to start each half and to restart play after each goal is scored.

Passing.—Propelling the ball by head or foot from one teammate to another.

Penalty area.—A rectangular area in front of each goal, 44 yd. wide and extending 18 yd. into the field.

Penalty kick.—A direct free kick from a spot 12 yd. in front of the centre of the goal with all other players except the defending goalkeeper and the kicker outside the penalty area; may be awarded for any one of nine offenses by defenders within the penalty area.

Pitch.--The field of play, bounded by the goal lines and the touch (side) lines.

Throw-in.—A method for restarting play when the ball has been driven over a touch (side) line; it consists of a player of the team not responsible for the ball being out of bounds throwing it back into the field of play.

Touch line.—Side line.

V. RUGBY FOOTBALL

A. Rugby Union

Laws of *the* Game.—Rugby union football is played with an oval leather-covered ball by teams of 15 players each on a field not more than 110 yd. long and not more than 75 yd. wide, with an extra area, called in-goal. not more than 25 yd. in depth and the same width as the main field behind each end or goal line (see fig. 12). The extreme end lines are called the dead-ball lines. In the centre of each goal line there is a goal, comprising two uprights of not less than 11 ft. in height and 18 ft. 6 in. apart with a cross-bar 10 ft. from the ground. Lines are drawn across the field at halfway and 25 yd. from each goal line. Intermittent lines are marked ten yards each side of the halfaay line and five yards infield from each side (or touch) line. A match consists of two halves of not more than 40 minutes each, the teams attacking different ends in the two halves, and a match is won by the side scoring the greatest number of points.

A player touching the ball down on the ground in his opponents' in-goal area, before any of them can do so, scores 3 points for a try; any member of his own side may then take the ball out any distance into the field of play at right angles to the goal line from the spot at which the ball was touched down and endeavour to kick a goal with a place kick. some other member of the side having placed the ball on the ground; a goal is scored by kicking the ball over the crossbar and between the posts or the imaginary extensions of the posts, the ball not being touched by one of the defending side between the moment nhen it is kicked and the moment when it passes over the bar; the defending side is restrained behind its goal line until the kicker's friend has placed the ball on the ground; thereafter they may charge and endeavour to stop or touch the ball; if the kick is successful, the try is "converted" into a goal and becomes worth j points. A player kicking a goal with a drop kick during the run of play scores 3 points, provided no defender touches the ball in flight; a drop kick is made by a player in possession of the ball letting it fall from his hand or hands to the ground and kicking it at the first rebound as it rises. A player making a fair catch during the run of play off an opponent's kick or knock-on or throw-forward, digging his heel into the ground and simultaneously calling "mark" is allowed a free kick from behind that mark (his opponents being allowed to charge as soon as he moves to make his kick or the ball is placed on the ground for a place kick), and if with the free kick he place-kicks or drop-kicks a goal he scores 3 points for a goal from a mark. After certain offenses by his opponents a player is allowed a penalty kick at the spot of the offense and his opponents are forbidden to charge; if he place-kicks or drop-kicks a goal with the penalty kick he scores 3 points for a penalty goal.

A team normally is divided into eight forwards, one scrum half, one standoff half, four three-quarters and one fullback. The game is started, and restarted after a goal or at the beginning of the second half, by a place kick from the centre of the field; after an unconverted try it is restarted by a drop kick from the centre of the field The ball may be propelled in any direction with any part of the body except the hands and arms; if it is propelled forward by hand or arm it is a throw-forward; if it rebounds forward from arm or hand it is a knock-on except where a player is in the act of charging down a kick. A player catching the ball or picking it up fairly may run with it in any direction and may pass sideways or back to one of his own side. If the ball is driven

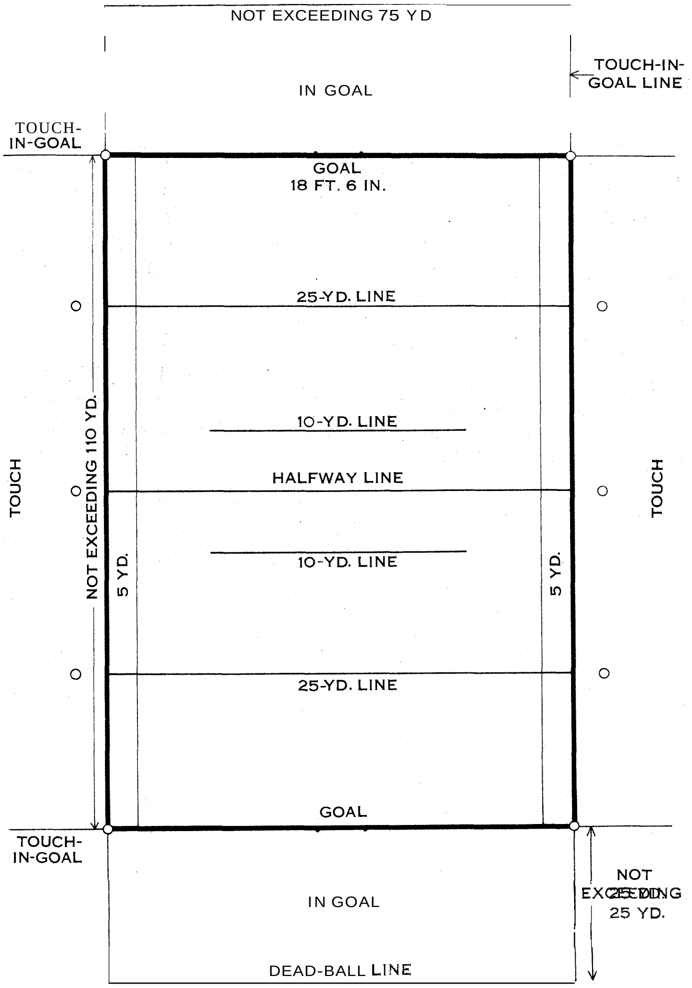

FIG. 12.— FIELD OF PLAY IN RUGBY FOOTBALL SHOWING DIVISIONS AND GOALS

over a touch line it is brought back into play by a member of the side which did not force it into touch; this player must throw the ball in straight across field from the spot where it entered touch, the forwards on each side forming a line straight across field and jumping for the ball when it is thrown to them; this is called a line-out and players in it may not barge opponents before or as they jump. If the ball is forced over a goal line by attackers and then is touched down first by a defender or forced over the dead-ball line the game is restarted by a member of the defending side with a drop kick from the 25-yd. line. But if the defending side carries or diverts the ball over its own goal line and the ball then is touched down by a defender or forced over the dead-ball line, play is restarted with a scrum five yards upfield from the goal line. A tight or set scrurn also takes place after minor offenses.

A tight scrum is formed by the forwards on both sides forming down in two or more rows (three in the front row) and preparing to shove against each other as soon as the ball is put on the ground between the two front rows by the scrurn half or some other player of the side which did not offend. The scrum half, or player acting as scrum half, must insert the ball at a moderate speed fairly between the front rows, with no spin on the ball, and none of the first three feet on each side may be used to "hook" the ball. The centre man of each front row is called the hooker, since he is the first man who may fairly attempt to hook the ball and is therefore carefully trained in this art. A loose scrum is formed when one or more players from each side close round the ball when it is on the ground After a player is tackled. that is to say, being in possession of the ball is so held that he cannot pass it, he must let the ball go free as soon as possible, and no player on either side may play it with the hand until it has been played by foot. While a ball is in either a loose or a tight scrurn no player may handle it.

A player is off side if: he enters any scrurn from his opponents' side; he remains with either foot in front of the ball while the ball is in the scrum, he not being in the scrurn; he stands or moves in front of a line-out before the ball is played; or the ball has been kicked or touched or is being carried by one of his own team behind him. In the last case a player may become on side without penalty (provided he does not interfere with play while off side) when an opponent carrying the ball has run five yards or has kicked the ball or handled the ball intentionally without catching or gathering it; or when one of his own side has run in front of him either carrying the ball or having kicked it nhen behind him Any player falling on the ball must get up immediately and play it with a foot or else roll away.

No player may charge or obstruct an opponent not holding the ball unless he himself is running for the ball. and he may only charge an opponent also running for the ball shoulder to shoulder. A penalty kick is awarded for such serious breaches of law as off side, obstruction, refusing to play the ball or playing it mith a hand after a tackle, handling the ball in a scrurn, putting the ball in crooked at a tight scrurn, illegal hooking for the ball in a tight scrurn, deliberately striking an opponent with fist or foot, tripping and barging in the line-out. A penalty try under the crossbar is awarded if a proper try would have scored had it not been for some exceptionally flagrant breach of the Iaws by the opposition. The game is controlled by a referee, who is sole arbiter. He signals his decisions with the aid of a whistle. He is assisted by two touch judges, armed with flags. whose chief duty is to signal when, uhere and by whom the ball is forced into touch.

The ball is 11 to $11\frac{1}{4}$ in. long, has a 30 to 31 in. end-on circumference, 24 to $25\frac{1}{2}$ in. sideways circuinference and weighs $13\frac{1}{2}$ to 1j oz. Slight variations are allowed in some countries to suit local conditions.

Changes in the Laws. — The original laws of the Rugby union in 1871 provided for a pitch 140 yd. long and 70 yd. nide. a match of 45 minutes each way and sides of 20 players each, with the result depending on which scored the greater number of goals; one goal outweighed any number of tries. Goals, obtained as in today's game, could also be scored mith a fly kick in the run of play (a field goal). The attempt to convert a try could be made from a point directly in front of the spot where the ball was touched down for a try, or one of the attackers could make a free punt out from the goal line in front of the spot where the try was scored to a friend standing in front of goal, and if a fair catch was made the kick at goal was from the spot where the catch was made; failure to make a fair catch forfeited the kick at goal. When a player in possession of the ball crossed his opponents' line they could try by any means to prevent him from touching the ball down, and this produced what was known as a maul-in-goal which theoretically could go on for the rest of the game and often did go on for several minutes in a most ferocious manner. It was only in 1871 that intentional hacking, or kicking of an opponent. were prohibited. The game was presided over by a neutral referee and tno touch judges, one representing each side; it is easy to see how on many occasions these three officials formed as it were a law court, the referee acting as judge and the two judges acting as attorneys at the bar. At the same time. curiously, the captains of the two sides still were sole arbiters of all disputes.

The number of players was reduced to 15 a side in the 1876–77 season for all matches, Oxford and Cambridge having played a similar number a year earlier. In 1875 it was decided that when no goals were scored or each side scored the same number of goals a majority of tries should win a match. It was not until 1886 that a point system of scoring was adopted. This was adopted as a result of a county match in which Yorkshire lost to Middlesex because it could not convert any of a large number of tries while Middlesex scored one dropped goal through A. E. Stoddart in a breakaway. The value of the various scores was altered several times until the 1905–06 season when the field goal was abolished and new values were accepted for all except the dropped goal; this was worth 4 points until after World War II. During the summer of 188j the rather ridiculous position of the referee and the judges was discussed and as a result the referee's authority was greatly strengthened. He was given a whistle while the judges were reduced to touch judges with flags and mere put under the referee for disciplinary action in just the same way as any player. It was not until 1888 that a penalty goal could be scored from a penalty for offside play and many other offenses were made punishable by a kick. At the same time the referee was given power to order a player off the field for rough play and to report to the union cases in which his decision was disputed. Later he could order a player off the field for the latter offense as well as for the former and also for persistent infringement of the laws.

Traveling expenses were first allowed in international games in 1880; hotel expenses were permitted soon afterward. Later a limited number of players playing for recognized club teams could receive traveling and hotel expenses for club matches away from home. The Rugby unions, however, remained constant in their opposition to any form of payment of allowances for loss of earnings suffered while playing or traveling to or from a match. Even presentations to players were strictly controlled, and there was a famous case in 1897 when A. J. Gould, a great three-quarter then at his best for Newport and Wales, was the beneficiary of the product of a large testimonial fund; this almost led to a breach of relations between the Welsh union and the other unions, but in the end bore better fruit in a new set of agreed laws defining acts of professionalism.

Development **of** Different Styles **of** Play. — In the 1860s the 15 or more forwards on each side were true descendants of the players at Derby. They concentrated on carrying the scrummage, as it was called, by superior weight and drive and considered it cowardly to scrummage head down in the modern manner. They hacked with a will and were hacked, tripped as often as they tackled, and usually went on enjoying their maul long after the ball had departed. Individually they could dribble well, but they rarely had a chance to make a combined dribbling rush because it was impossible for more than one or two at a time to disentangle themselves from a maul. Indeed, there was no attempt at combination in the modern sense between any parts of a side. The two halfbacks were complete individualists and it was considered unmanly to pass the ball rather than run with it until overwhelmed. The two backs guarded their goal and the solitary three-quarter roamed over the whole of the middle of the field seeking whom he might devour.

The first reform was achieved when a faster, more open game was found by certain clubs to be more profitable, even if it horrified some of their battle-scarred older members. The reduction in sides from 20 to 15, and consequently of forwards on each side from 15 to 10, was of great assistance to those reformers, who began to concentrate on combined dribbling. quick breaking from the mauls and scrums and intelligent looking for the ball before entering a maul mith a view to controlling its destination rather than overpowering the opposition by brute force. The Blackheath club in 1878 set up a new fashion on these lines which rapidly became popular among players. Their fast and agile forwards developed brilliant short passing movements and were largely responsible for 15 wins in 16 games and the scoring of 54 goals and 30 tries. To the disgust of many old gentlemen they also learned how to wheel a scrurn. Among Blackheath's earliest and best imitators was Oxford university, and in 1881 Oxford had one of the greatest footballers of all time in H. Vassall, who probably was the first to recognize the full value of speed and insisted on his forwards using their hands and their brains as well as their brawn. In 1882 Vassall found a great assistant in A. Rotherham, a halfback who applied his methods to back play. During 1881–85 Oxford lost only two matches, both to Edinburgh university, and it was unbeaten in 1882, 1883 and 1884. The formation of the side was changed gradually during these years to one fullback, three three-quarters, two halfbacks and nine forwards. Rotherham conceived and proved the value of halfbacks who would act as a link to get the three-quarters into action, and he appreciated and taught halfbacks how to get their three-quarters moving fast before passing to them; finally as opponents began to adopt correct defensive tactics to answer his passing out, he developed the use of the dummy or feint to pass when in fact he was going to retain possession.

Almost immediately after Rotherham had come to the front R. Robertshaw, a young Bradford centre three-quarter, applied his principles to centre three-quarter play and was the first to show the way in which a centre should act as link with the wings and make openings for them. Robertshaw wanted to have four three-quarters, taking a man out of the forwards for the purpose, but he found little support for the idea in his own country. Welshmen, however, were quick to profit from his lessons, and in 1885 both the Cardiff club and the Welsh national team included four three-quarters, F. E. Hancock and A. J. Gould being brilliant exponents of how to use the new formation. Wales did not always reap the profit it might have done from being the first to accept the new idea but its merits were obvious and soon the other countries had to follow suit in self-protection. This formation — one fullback, right wing three-quarter, right centre three-quarter, left centre three-quarter, left wing three-quarter, standoff half, scrum half and eight forwards — remained the most popular, New Zealand provided notable exceptions. There, until the laws were altered in the late 1920s and it was laid down that the front row in a tight scrurn must consist of three men, the New Zealanders had seven forwards and eight outsides. The forwards packed 2–3–2, and the outsides were fullback, left wing three-quarter, centre three-quarter, right wing three-quarter, second five-eighth, first five-eighth, scrum half and a rover, who was part forward, part scrum half. The essential differences in the back division are that in normal situations it is always the same man (first five-eighth) who receives the pass from the scrum half, that his pass is always taken by the same man (second five-eighth) and that it is always the same man (the centre) who draws the last man before sending the wing on his nay.

British teams, notably the Oxford university side which was unbeaten up to and including the match with Cambridge in 1949, occasionally used what they called first and second or inside and outside centres in order to achieve the same effect; but no British side really made the same use of the formation, for in New Zealand the two five-eighths are peculiarly a unit, working and planning the attack, whereas in Great Britain in most cases the halfbacks look on themselves as one unit and the three-quarters on themselves as a second unit. New Zealanders do not argue about the merits of their system; they regard its superiority as a self-evident fact and among other things point out that the duties of the third and fourth men behind the scrum (second five-eighth and centre) obviously are different and that certain players are better fitted for the one job than the other.

The only important modern development in back play after the general adoption of four three-quarters was the use of prearranged tactical maneuvers, involving return passes, reverse passes. scissors movements, various types of kick, etc., to force gaps in the middle of the defense, turn its flanks or defeat it by speed before it can turn round to get back to a cunningly placed ball. Between 1905 and 1914 the Harlequins became famous for their back play, but they did not in fact revolutionize back play; rather they assimilated and perfected much of the best shown by Wales and New Zealand in preceding seasons, put their faith in swift passing, running and backing up at all times, even when penned in their own quarter of the field, and had such fine players to carry out the plan as A. D. Stoop. H. Brougham, F. M. Stoop. J. G. G. Birkett, D. Lambert and H. J. Sibree. The basic tactics of back play hardly changed after the early years of the 20th century; they did not include the making of the fullback into a dangerous weapon of attack (see Rugby League, below) and they were affected only to a minor degree by the modern wing forward.

The modern wing forward is the degenerate descendant of D. Gallaher, captain and rover in the first New Zealand All-Blacks team to visit Great Britain and Ireland in 1905. He did not join the scrums and did not claim to be a forward; he put the ball into the scrum as often as did his scrum half and thereafter concentrated in the first place on strangling his opponents' attack at birth by helping his scrurn half smother the opposing scrum half or intercepting his pass to the standoff half. The New Zealanders reckoned and proved that by packing 2–3–2 they could hold any other formation of seven or eight forwards in the scrums and so had a man over to be rover; Gallaher's side lost only to Wales by a disputed try and the second All-Blacks team in Great Britain won every match and soon after returning home routed South Africa. New Zealanders resented the change in the laws toward the end of the 1920s which made it obligatory to have three men in the front row of a scrurn; they found that with three men in the front row they had to have eight forwards against eight and so lost their rover.

The modern wing forward, on the other hand, is neither flesh nor fowl. He is a forward and he packs down at scrums because his weight is needed. But often his shoving is little more than a pretense nhile he is saving himself in order to do the job of the rover; he tends to spend his time driving the opposing standoff half across field and in so doing reduced many a game to an untidy scramble; had he shoved harder like a genuine forward he might have crippled the enemy just as much either by enabling his own pack to get the ball or making the enemy's heel so slow that his own outsides had no difficulty in holding the consequent passing move. His concentration on the standoff half was due at least partly to a change of law, also in the late 1920s, which made it necessary to have both feet behind the ball instead of one while the ball is in a scrum; his chances of spoiling a good scrurn half were greatly reduced and his attention diverted to the next link in the human chain. Also as a result of this change in law it would appear that the standoff's (and consequently the three-quarters') job was made more difficult because the relief afforded to scrum halves tended to make them much slower in passing and thereby give the wing forward and defending outsides time to close on their men. When a really good quick passer-out like H. Tanner (Swansea, Cardiff and Wales) was in action his outsides had just as much chance as ever to be brilliant in attack and the modern wing forward became a liability to his own side as his skirmishing no longer compensated for his failure to do his full share of scrummaging and mauling.

Various theories arose as to how best to arrange eight men in a scrum. By a simple piece of mechanical calculation it can be shonn that, all things else being equal, a pack of forwards arranged 3–2–3 should be able to outshove a pack using the 3–4–1 or 3–3–2 orders, but 3–4–1 became popular early in South Africa and New Zealand and later everywhere except Scotland. The main reasons for this were: (1) in order to get the full benefit of 3–2–3 one must have two men of exceptional strength and ability in the second row capable of shoving themselves and transmitting on to the front row with a minimum of loss the shove applied to their own bodies by the back row; (2) in 3–4–1 heeling tends to be quicker; and (3) in 3–4–1 the wing forwards are a yard nearer their victims and the whole pack can disentangle itself somewhat more quickly.

The only marked tendency after World War II was for players in face of quick-breaking wing forwards to attempt to be clever without having the necessary basic equipment of technique, and for sides to concentrate on perfecting defense, always an easier art than attack for, strictly, if each defender is competent he will always tackle his man in an orthodox move and any move from a set scrum is likely to peter out tamely. A breach in the best defenses can be made, however, after a quick heel from a loose scrum when one or more defenders are on the ground or by introducing some element of surprise. Surprise was the constant tactic of J. Heaton (Waterloo). the finest centre three-quarter since the 1920s, who led Lancashire to a remarkable series of triumphs in the county championship which culminated in three successive championships in the first three years after World War II. Under Heaton. Lancashire's outsides would look quite ordinary for much of a game while he was assessing the strength and weakness of the opposition; then suddenly they would split the defense fatally by feinting to attack in one place and instead hurling their full weight on the weakest link. His greatest success, probably, was in 1947 when he led a combined Lancashire and Cheshire fifteen to the only victory gained by ordinary counties against the Australian touring team.

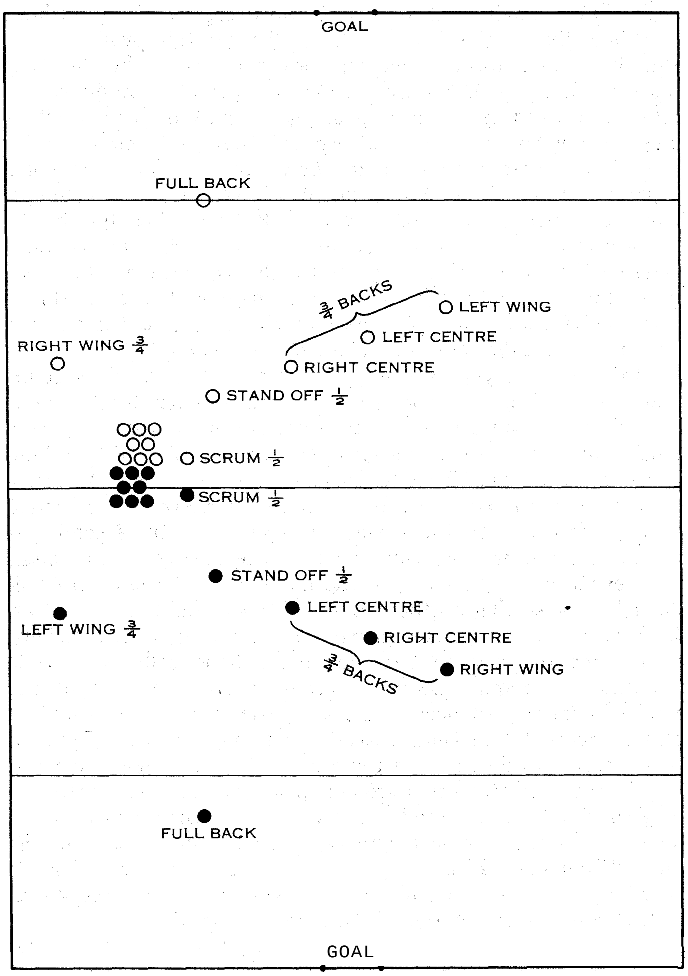

FIG. 13.— DIAGRAM SHOWING PLAYERS IN THE RUGBY FIELD IN POSITION FOR A SCRUMMAGE

There was a considerable revival of back play in the British Isles in mid-20th century. which won approval during the British tours of New Zealand and Australia in 1950 and South Africa in 1955 In all these countries there had been a tendency to concentrate on producing big, strong and fast forwards to dominate the game. The British showed that fast and accurate combined back play still could be effective as well as pleasant to watch, and in South Africa they won two of the four international games and attracted enormous crowds, especially at Johannesburg.

Government of **the** Game.—The formation of the Rugby union in 1871 was followed quickly by the founding of the Scottish Rugby union in 1873. the Irish Football union for southern Irish clubs in 1874, the North of Ireland Rugby union for northern clubs in 1875, the Welsh Rugby union in 1880 and the Combined Irish Rugby union in 1881. England first met Scotland in 1871, Ireland in 187j and Wales in 1881. Scotland first played Ireland in 1877 and Wales in 1883. Ireland and Wales first met in 1882. The unions supported such matches wholeheartedly and the English Rugby union officially sanctioned a county championship in 1890, although Lancashire and Yorkshire had been meeting for 20 years. They strongly discouraged big cup competitions, however, and opposed leagues; the most famous cup competitions permitted are for the Torkshire cup, the London Hospitals cup and the intercollege cups at Oxford and Cambridge; the winners of the England *v.* Scotland match hold the Calcutta cup.

The unions worked in harmony almost throughout. Early changes in the laws mere agreed upon easily. the other three regarding the English Rugby union as the parent and supreme body and changes of law never altering the game from Rugby, whereas in the U.S. modern football has little relation with the original game. The first serious dispute arose over the scoring of a try by England against Scotland in 1884, as a result of which Scotland refused to recognize England's union as sole arbiter of the laws; when the English Rugby union introduced point scoring in 1886 all three other countries refused to play England in the follon-ing season and the matter came to a head As a result of arbitration by Maj. F. A. Marindin (most famous of all F.A. cup final referees) and Lord Kingsburgh it was agreed in 1890 to form an international board to control laws as well as settle disputes of fact in connection with international matches; England was given six representatives on the board, and Scotland. Ireland and Wales were given two each. England's quota was later reduced to two and representation was given to New Zealand, South Africa and Australia. The election of all officials from the smallest to the highest in all the clubs and unions is based on democratic voting.

World-Wide **Rugby** Union.—Immediately after the formation of the Rugby union the game spread rapidly abroad as well as in Great Britain and in the 1870s it was being played in Australia. Canada, France. South Africa and the U.S., but it was only in New Zealand that it at once became the national game. As early as 1888 a New Zealand team composed chiefly of Maoris visited England and defeated many of the leading English clubs. The All-Blacks team of 1905 was the first fully representative New Zealand team to visit Great Britain and was beaten only by Wales by a solitary try. The second All-Blacks team in 1924 was even more successful, winning all its games. Both these teams were superior in basic technique, backing up and fitness, and by playing together regularly developed remarkable combination. The side of 1924 included two superb five-eighths in M. Nicholls and A. E. Cooke. an exceptionally strong and fearless fullback in G. Nepia, a Maori who played in every match, and great forwards in M Brownlie and J. Richardson. Another Maori team visited England in 1926 and the third All-Blacks arrived in 1935; the latter was a fine side, but it was dogged by injuries. especially to key men like J. Oliver. a splendid five-eighth, and W. A. Hadlee. its best hooker, and lost to both England and Wales. The fourth All-Blacks to visit Britain, in 1953–54, lost to Wales and France, but beat England, Ireland and Scotland. It included one of the greatest of fullbacks in R. W. Scott; in addition to being a superb defender and kicker he was. perhaps through playing Rugby league in his youth, a most dangerous attacker.

In Australia Rugby union acquired a great hold in New South Wales and a big following also in Queensland. but it had an unusual rival in Australian rules football and Rugby league was a strong competitor. Representative Australian teams visited Great Britain, in 1908, 1927, 1947 and 1957. There was a steady improvement in their standards. though they never equaled the brilliance of the New Zealanders in back play. Notable members of these sides were A. C. Wallace, a former Oxford and Scottish international three-quarter, and A. T. Lawton, former Oxford standoff half. in 1927 and T. Allan, centre, and D. F. Rraefft. D. H. Keller and C. J. Windon. forwards, in 1947; in the latter tour they also brought C. C. Eastes. a wing three-quarter of most formidable bulk and speed but unfortunately badly hurt early in the visit. The 1957 side included **A.** J. Summons at standoff and J. A. Phipps, inside centre.

In South Africa Rugby union had a long struggle before it took first place over both association football and a local hybrid game which embodied points from both Rugby and association. British sides nhich visited South Africa in 1891, 1896 and 1903 found the opposition stronger each time. These visits were returned by South Africa in 1906 and 1912; in the first of these tours they were good in the backs but were beaten forward; South Africa never forgot the lesson and its later sides were noted for their hard scrummaging. The great Rugby heroes of South Africa were nearly all forwards like P. J. Nel and M. M. "Boy" Louw. Its back play had never made the same progress. though in a tour of Great Britain in 1931 it had a remarkable general at standoff half in B. L. Osler nho, by nursing his forwards and sacrificing all thoughts of constructive back play. was largely responsible for the team's ninning 23 games. drawing 2 and losing only to a combined Leicestershire and East Midlands team (nhen they were a forward short almost throughout the game). British sides under R. Cove-Smith and S. Walker visited South Africa in 1924, 1938 and 1955 and found the opposition extremely powerful, and a New Zealand side (without Maoris) lost a series of international matches in South Africa in 1949. A South African team visited the British Isles and France in 1951–52 and won 30 of its 31 matches, including the 5 international matches against Scotland, Ireland, Wales, England and France. The side had an extremely powerful and skillful pack, which observed all the basic principles, and two brilliant halfbacks, P. A. du Toit and H. Brewis.

Rugby union reached France in the middle of the 19th century, but its development there was slow and it was not until 1906 that France met England in an international match; it began to play Wales in 1908, Ireland in 1909 and Scotland in 1910. For a long time it had little success in international matches but the spirited attempts of its players to play an open attacking game made its visits popular everywhere, and after World War II it was a serious contender for the unofficial international championship. In 1931 the British unions severed playing relations with France because they were dissatisfied with the control and conduct of the game in that country. Just before World War II, however, France was restored to its position in international football.

The game is played by Italy, Spain, Belgium, Rumania and Germany, who combine with France in a European championship, Malaya, Thailand, Japan, Fiji (which has beaten the full Australian side) and Argentina, which has a considerable population of British birth or descent. Teams from Ireland, the Rugby Football union and Oxford and Cambridge have visited Argentina and many clubs have played matches with teams from Europe outside France, but international matches with these countries were not approved by the British Rugby unions.

Largely because Canada and the United States have their own football games, both developed from Rugby, the parent sport has never been widely popular in those countries. There is some enthusiasm among the larger eastern universities in the U.S., in California and in British Columbia. Combined teams from Oxford and Cambridge made visits in 1934 and 1955.

B. Rugby League

Rugby league, played mainly in the north of England, Australia, New Zealand and France, is a direct descendant of Rugby union. There was at first no difference in the playing laws, for the original 22 members of the Rugby Football league, or Northern union as it was called until the 1920s, seceded from the Rugby Football union after and because a Yorkshire proposal to permit the payment of compensation for bona fide loss of working time by players had been defeated at the annual general meeting of the Rugby union in 1893. The majority of Rugby union clubs were then, as later, opposed to any proposal which appeared to prepare the way for the introduction of professionalism into the game. The Northern union clubs recognized professionalism in 1898, subject for a time to a condition that a professional must have another genuine job during the week; eventually this condition was dropped, but in practice almost every Rugby league professional continued to follow another trade or profession during the week, unlike the majority of professional association footballers in Great Britain. The Rugby league's rules governing the status of amateurs are as strict in their way as any put forward by the Rugby unions, and the backbone of the game in the second half of the 20th century was formed not only by the 30 professional teams of the Northern Rugby league but by more than 300 registered amateur teams in the three counties of Cumberland, Lancashire and Yorkshire. There were many cases of players playing as amateurs with the first teams of Northern league clubs.

The seceding clubs quickly established Northern and county league and cup competitions and gradually amended the old Rugby union laws in order to make play more attractive to spectators and, some stoutly maintained, more enjoyable for the players also. The main differences in the playing laws by the 1950s were: (1) there were only 13 men in a Rugby league side, two forwards having been cut out; (2) in Rugby league there was a scrummage instead of a line-out opposite the point where the ball entered touch; (3) from a kick the ball must touch an opponent or bounce on the ground inside the field of play before entering touch, except from a penalty kick or a kick traveling toward the kicker's own line, the penalty for failure to observe this proviso being that the scrum is formed back where the kicker was when he made his kick; and (4) that after a tackle the player with the ball is allowed to stand up and drop it so that it may be played with a foot. A try was still valued at 3 points, but any successful kick at goal after a try, with a penalty, or with a drop kick was worth 2 points. Most of the basic principles of strategy and technique remained much the same as those of Rugby union, but in the Northern Rugby league the standards of fitness and technical efficiency had been raised in the best clubs to a degree rarely seen in Rugby union and many tactical maneuvers had been developed to achieve the strategic end, especially moves making the fullback one of the most dangerous attackers on the field.

Professional players are recruited from the ranks of amateurs and overseas Rugby league teams as well as from Rugby union footballers all over the world but especially in the north of England, south and west Wales, Australia, South Africa and New Zealand. The sums given to players to induce them to change their status and those demanded by clubs for the transfer of registered professionals had increased enormously by the second half of the 20th century, reaching £6,000. The paying of such sums was beyond most clubs for, in the main, Rugby league was still played in the smaller northern England towns and the average attendance at Northern league games was only about 12,000, ranging from 2,000 to 3,000 at Featherstone, a little colliery town in Yorkshire, to about 25,000 at Wigan, where a quarter of the total population had become regular attenders. The export of players from New Zealand, Australia and South Wales had proved such a threat to the game in these countries that they asked for, and in the first two cases won, a part ban on recruitment by English clubs for a period. Naturally the wiser clubs turned more and more to the development of local resources and, of the great Wigan side which in 1949 won the Lancashire cup for the fourth time in succession, all except three were found in the Wigan district and trained to their high standard by the club.

The game was soon adopted in New South Wales and, to a lesser degree, Queensland, and test matches were played between Great Britain and Australia beginning in 1908; by the beginning of the 1955 season the British sides had won 33 and drawn 4 of the 54 games, and had retained the "ashes" from 1921 to 1950, when Australia won the rubber at home. Australia was handicapped by losing many of its best players to English clubs and not having them available for tours or international matches. New Zealand also took to the game early and had played 34 tests with Great Britain between 1908 and the beginning of the 1955 season, winning 10 and losing 24. In New Zealand, however, professionalism in the normal sense had never been obtained; players received free equipment, facilities and expenses but no regular wages. The game took root in France early in the 1930s, one of the main causes being the breach between the British Rugby unions and the French authorities in Feb. 1931. Rugby league acquired a big hold in the south and southwest of France, Toulouse, Bordeaux and Marseilles being the chief centres. Attempts were made to spread the game in Scotland, Northumberland, Durham, London and south and west Wales, but no great or permanent foothold was gained, chiefly because there had been no great popular demand and it had proved too expensive trying to create such a demand. The Rugby League Challenge cup final, however, has been played regularly for a number of years at Wembley stadium, London, and so many northerners make the occasion a holiday festival that by the second half of the 20th century the attendance had risen as high as 95,000 and the receipts to £31,000. In 1954 the final was drawn and the replay at Odsal stadium, Bradford, a natural but largely undeveloped amphitheatre, drew 102,575 spectators.

The first Rugby League World cup competition was played in France in 1954 and was won by Great Britain, the other entrants being Australia, France and New Zealand.

Of the 22 clubs which originally seceded from the Rugby union 15 were still among the 30 members of the Northern Rugby league in the second half of the 20th century: Batley, Bradford (reformed as Bradford Northern), Halifax, Huddersfield, Hull, Hunslet, Leeds, Leigh, Oldham, Rochdale Hornets, St. Helens, Wakefield Trinity, Warrington, Widnes and Wigan. Those which perished or were amalgamated were Brighouse Rangers, Broughton Rangers, Liversedge, Manningham, Runcorn, Stockport and Tyldesley. The leading clubs were those which concentrated on open attacking play, and the records of Huddersfield and Wigan were outstanding over many years. Between them, by 1952, they had been winners of the Northern Rugby league championship 14 times and runners-up 11 times and winners of the Rugby League cup 10 times and runners-up 5 times.

J. Sullivan, Wigan's fullback for 20 years and Great Britain's for 10, achieved the remarkable feat of kicking more than 100 goals in each of 18 successive seasons up to World War II and scoring almost 100 tries as well; he was one of the great defenders whose positional play mas so good that he seemed to run only in attack, when his habit of intercepting one of his own side's passes on the burst baffled innumerable opponents. H. Wagstaff (Huddersfield) was a peerless centre according not only to almost every Rugby league enthusiast but also to many Rugby union players who played with or against him during World War I. A. J. Risman (Salford) was not perhaps so great a centre but as an all-round back he was in a class of his own, being equally expert at fullback, centre and standoff, and after 20 seasons of first-class football he was still greatly to be respected as player-manager of Workington Town at mid-20th century. Among the wings A. Ellaby (St. Helens), a huge long-striding player, B. Bevan, who scored over 500 tries for Wallington, and S. Rosenfeld, Wagstaff's contemporary at Huddersfield, remain in the memory, and of standoff halves three Welshmen, Billo Rees (Sminton), Emlyn Jenkins (Salford) and W. T. H Davies (Bradford Northern) and one New Zealander, C. Mountford (Wigan) were among the great. Jonathan Parkin (Wakefield Trinity) probably would be almost unopposed as scrum half for a world team. but after World War II a wonderful new combination in both attack and defense was worked out for Wigan by M. Ryan, fullback, and T. Bradshaw, scrum half, under the coaching of J. Sullivan which was something new to Rugby of any kind and which penalized the unwary kicker-ahead as never before. The fullback was never left alone to face a follower-up; instead, by brilliant interpassing and changing of direction, the pair turned defense into attacks of blinding speed.

Great forwards were numerous: M. Hodgson, Swinton's towering imperturbable giant; L. Prigg, a tireless, intelligent attacker and deadly tackler from New South Wales; N. Silcock, a burly Widnes front-row man; K. Gee and J. Egan. another remarkable Wigan pair; D. Clarke (Huddersfield), famous also as a wrestler; T. Foster (Bradford Northern); and W. Burgess (Barrow) were only a few of them. Two others played as great a part as any individual player in the successes of their clubs. L B. Todd, a former New Zealand and Wigan player, took over the management of Salford when it was in sore distress in 1928 and by his shrewdness, wise selection, instruction and leadership enabled it to win the Northern league championship three times and the Rugby League cup once in the next 11 years before he was injured fatally in a road accident. Dai Rees, the Bradford Northern trainer and coach. showed such unrivaled knowledge of tactics and ability to nurse injured and aging players that he took his club into five of six Rugby League cup finals between 1944 and 1949.

C. Glossary: Rugby Football

Dead.—The ball is temporarily out of play.

Defending team.—The team in whose half of the ground the stoppage of play occurs.

Drop-out.—A drop kick taken by the defending team after a touch down or after the ball has been in touch-in-god or has touched or crossed the dead-ball line.

Dropped goal.—A goal scored by a drop kick during the run of play.

Fair *catch*.—A catch by a player of the opposing team direct from a kick, knock-on or throw-forward who at the same time makes a mark on the ground with his heel and exclaims "mark."

Field *of* play.—The area bounded by the inner sides of the goal lines and the touch (side) lines.

Free kick.—A kick allowed for a fair catch.

Goal.--Kicking the ball over the opponents' goal-post crossbar from the field of play by means of a place or drop kick (similar to U.S. field goal).

Grounding the ball.—The act of a player placing his hand or hands on the ball, while it is on the ground, so that he is able to exert on it a downward pressure.

Heeling.—Scraping the ball back mith the heel from a loose or set scrummage in the direction of one's own backs.

In-goal.—The area at each end of the field bounded by the goal line, the dead-ball line and the two touch-in-goal lines.

Kickoff.—A place kick from the centre of the halfway line taken at the beginning of each half and after a goal has been kicked; also a drop kick taken at or from behind the centre of the halfway line after an unconverted try.

Knock-on.—Occurs when the ball, after striking the hand or arm of a player, travels in the direction of his opponents' dead-ball line.

Mark.—The place at which a free kick or a penalty kick is awarded.

No-side.—The end of a match.

Penalty goal.—A goal scored from a penalty kick.

Penalty kick—A kick awarded to the nonoffending team by reason of an infringement of the laws of the game by their opponents.

Pitch.—The field of play.

Rebound.—Occurs when the ball, after striking any part of a player except his hand, arm or leg (from the knee to the toe, inclusive), travels in the direction of his opponents' dead-ball line.

Scrum.—Short for scrummage.

Scrummage.—The closing around the ball by one or more players on each team when it is on the ground (called a loose scrummage); a closed-up formation of players of each team in readiness to allow the ball to be put on the ground between them (called a set or tight scrummage), used to restart play after certain minor. infractions.

Tackle.—Occurs when the holder of the ball in the field of play is held by one or more players of the opposing team so that while he is so held the ball comes in contact with the ground or there is a moment when he cannot pass or play the ball in any other manner. When tackled a player must release the ball immediately.

Throw-forward.—Occurs when the ball is propelled by the hand or arm of a player in the direction of his opponents' dead-ball line.

Touch.—Out of bounds between the two goal lines.

Touch down.—The act of a defending player first grounding the ball in his own in-goal (similar to US. touchback).

Touch-in-goal.—Out of bounds between a goal line and a dead-ball line.

Try.—Obtained by the act of an attacking player first grounding the ball in his opponents' in-goal (similar to U.S. touchdown).

VI. AUSTRALIAN RULES FOOTBALL

The game of football under Australian rules seems to be indigenous to Victoria and is said to have been played in Melbourne before Rugby ever was introduced to the continent. It became the favourite game in Victoria, South Australia and Western Australia. It is played on an oval field with a greatest width of 120 yd. and a greatest length of 180 yd. Sides are made up of 18 players, 15 of whom remain in more or less fixed positions and mark fixed opponents. The ball is much bigger than a Rugby ball, the circumference being 29½ in. over the long axis and 22½ in. over the short axis. A player may kick or punch the ball forward but may not run with it unless he bounces it every ten yards. There is no off side. Four posts of any desired height and with no crossbar are set up seven yards apart at each end of the field. Any punt, place kick or drop kick which goes between the two inner posts without being touched by a defender scores 6 points; any kick which goes between the two outer posts or which goes between the inner posts after being touched scores 1 point.

(L. M.)

VII. GAELIC FOOTBALL

Gaelic football is distinctly Irish and is reputed to be the roughest of all football games, It has no connection directly with Rugby or association, being of direct descent from the medieval mellays in which entire parishes would embroil for daylong battles over many square miles of country. (See Early History, above.) The game mas without rules or restraint until 1884. Then two citizens of Carrick-on-Suir, Tipperary. Daniel and Mauric Davin, after watching a particularly bloodthirsty affray between 34 men of Tipperary and 34 of Waterford, decided that something must be done to restrain the ferocity of the players. With the aid of Michael Cusack of Clare and some of the leading players, they drew up a code of rules which slightly restricted brutality, and at a big meeting in Thurles, Tipperary, the same year these rules were accepted and the Gaelic Athletic association was formed and became the ruling body for the game throughout the world. The game is not played much outside Ireland except in the U.S.; the winners of the All-Ireland championship usually visit the C.S. each year to meet Gaelic representative teams in New York and other cities on the eastern seaboard. Sides are made up of 1 j men each, who may not throw the ball but may dribble with hand or foot, punt or punch the ball toward their opponents' goal, which resembles a Rugby goal in that the posts are extended above the crossbar and an association goal in that there is a net fastened to the posts below the bar and to the bar. One point is scored for punching or kicking the ball over the bar and between the posts and 3 points for punching or kicking it between the posts and under the bar into the net. The game consists of two halves of 30 minutes each. (A. S. BL.; W. J. CH.)

VIII. SPECIAL (BRITISH) SCHOOL GAMES

The Eton Wall Game.—Though both Rugby union and association are played at Eton at certain times, the college has retained two entirely distinct games called the wall game and the field game. The wall game owed its origin to the presence of a high wall enclosing part of the college grounds along the road from Windsor to Slough. The area of play comprises a strip of ground running along the wall. At each end there is an area known as "calx" equivalent to the in-goal area in Rugby. One end is called "good calx" and the other "bad calx." and goals are marked at the back of each calx. The teams are of 11 a side, 5 players on each side forming down against the wall in "bully" or scrummage and the others taking up positions outside the bully. The ball is put into the bully at the start of the game and whenever it goes out of the area of play. and the object is to work the ball along the wall with the feet into the calx. When the ball has been forced into calx the attacking side tries to gain a "shy," which is accomplished by a player lifting the ball with a foot against the wall and touching it there. This achieved, the ball may then be "shied" at goal. A goal outneighs any number of shies.

The Eton Field Game.—In the field game the usual number of players is 11 a side but more may be included. The game is played on a large field nith goals of a type similar to but smaller than association goals. The chief features of the play are the bully, resembling an attenuated Rugby scrum, dribbling by the forwards who form the greater part of the team and long and accurate kicking by the "behinds" or backs. A goal may be scored either by an ordinary shot or by forcing a "rouge." A rouge resembles a try in Rugby, being scored by an attacker touching the ball down behind his opponents' goal line. The ball is then brought out and a bully formed in front of goal and the attackers endeavour to force the ball through the goal. A goal scores 3 points and a rouge from which no goal is scored 1 point.

The Harrow Game.—The Harrow game is comparatively simple in principle and play. It consists mainly of dribbling by the forwards and long kicking by the backs. Two sets of posts are set up at each end of the field but there are no crossbars and a goal or "base" as it is called is scored when the ball passes between them at any height. The ball may not be handled but it may be caught from a kick, after which the catcher must either kick it or drop it and begin dribbling it. Players must keep behind the ball; otherwise they are off side except in certain circumstances similar to those recognized in Rugby. The most skillful player is the one who can keep the ball under closest control when dribbling. Teams usually are 11 a side but may be increased or decreased according to circumstances.

The Winchester Game.—The pitch for the Winchester game is much smaller than those used for Rugby or association, being only about 80 yd. long and 25 yd. wide. There are no goal posts, a goal being scored when the ball is forced beyond the end lines. This is not as easy to accomplish as it sounds, for the ball may not be kicked more than five feet in the air except when it comes rolling or bouncing toward a player direct from an opponent, a player is off side if he is in front of the ball and passing is illegal. The main feature of the play is the "hot." which is rather like an old-time Rugby scrum and takes place at the start of play or whenever the ball goes out of play. Dribbling forms no part of the game and almost the sole business of the backs is to kick hard and straight. In spite of the small area of play the game is most exacting and calls for endurance, speed and quickness. (F. I. W.)

FOOTE, ANDREW HULL (1806–1863), U.S. admiral and Union commander during the American Civil War, was born at New Haven. Conn.. Sept. 12, 1806. His father was Samuel Augustus Foote (1780–1846), a prominent lawyer and Whig politician nho as US. senator moved in 1829 "Foote's resolutions" on public lands in the discussion of which Daniel Webster made his "reply to Hayne." Andrew Foote entered the C.S. navy in 1822 and mas commissioned lieutenant in 1830. After cruising round the world (1837–40) in the "John Adams." he was assigned to the Philadelphia naval asylum, and later (1846–48) to the Boston navy yard. In 1849 he was made commander of the "Perry," and engaged for two years in suppressing the slave trade on the African coast. In 1856, as commander of the "Portsmouth," he served on the East India station, under Commander James Armstrong, and he captured the Barrier Forts near Canton. From Oct 1858 to the outbreak of the Civil War, he was in charge of the Brooklyn navy yard, becoming a full captain in 1861. In Aug. 1861 he was assigned to the command "of the naval operations upon the Western waters." His exploit in capturing Ft. Henry (on the right bank of the Tennessee river) from the Confederates, on Feb. 6, 1862. without the co-operation of General Grant's land forces, nho had not arrived in time, was a brilliant success, but their combined attack on Ft. Donelson (12 mi. off, on the left bank of the Cumberland river). to which most of the Ft. Henry garrison had escaped, resulted, before its surrender (Feb. 16), in heavy losses to Foote's gunboats, Foote himself being severely mounded. In March–April he co-operated in the capture of New Madrid (*q* v.) and Island No. 10. In June he retired from his command and in July was promoted rear admiral, and became chief of the bureau of equipment and recruiting. On June 26, 1863, he died in New York city.

See the *Life* (1874) by James Mason Hoppin (1820–1906).

FOOTE, SAMUEL (1720–1777), English actor, wit and playwright, nho had an astonishing gift for mimicry, was born at Truro, the son of a prosperous Cornish magistrate. He attended Worcester college, Oxford, but left without taking a degree. Then. "designed for the law," he established residence in the Temple, but in 1744, having dissipated his inheritance. turned to the theatre. His first efforts as an actor were not successful, but while playing Bayes in the *Rehearsal* he demonstrated his ability as a mimic. In 1747, therefore, he opened the Haymarket theatre nith a series of farcical entertainments called *Diversions of the Morning*, in mhich he ridiculed other actors and celebrities. Later, to avoid the restraints of the Licensing act, he called his entertainments "teas." After 1753 he returned occasionally to the regular stage, playing in Dublin and Edinburgh as well as in London;

but again he was unsuccessful except in his own plays, which, like his "teas," depended on topical allusions and upon his gift for mimicry. Foote was adept in exploiting any event for his purposes, even his own misfortune. In 1766 he fell from a horse and broke his leg, which had to be amputated. Characteristically, he turned this to account by writing *The Devil on Two Sticks* and *The Lame Lover*. Another consequence of this misfortune was that the duke of York, who was responsible for the accident, secured for Foote a life-patent for the Haymarket, which permitted him to continue his performances there without resorting to subterfuge.

Foote was doubtlessly a man of many talents, but his mind was of such a cast that he was incapable of employing them except for purposes of savage attacks upon others. David Garrick, who frequently befriended him, avoided public ridicule only through flattery. Samuel Johnson, who considered Foote's wit "irresistible," was obliged to threaten physical chastisement. In 1777, however. he met his match. Agents of the notorious Elizabeth Chudleigh, duchess of Kingston. whom Foote had satirized in *The Trip to Calais* and *The Capuchin,* retaliated with such persistence that he was compelled to quit the stage. He died at Dover on Oct. 21, 1777, and was buried in Westminster abbey.

In addition to the plays mentioned, Foote's best-known productions are *The Author*, *The Minor*, *The Maid of Bath* and a piece for puppets entitled *Piety in Pattens*.

FOPPA, VINCENZO (*c.*1430–1515/16), Italian painter. leading figure in 15th-century Lombard art, was born at or near Brescia between 1427 and 1430. His earliest dated work is a dramatic painting of the "Three Crosses" in the Accademia Carrara at Bergamo (1456). Among the sources of Foppa's early style were the paintings of Jacopo Bellini and the Cremonese Gothic painter Bonifazio Bembio, and northern manuscript illuminations; after about 1460 he seems to have come in contact with the work of Andrea Mantegna at Padua. Patronized by Francesco and Galeazzo Maria Sforza. he was employed in 1463–67 at the Certosa at Pavia, and he completed, probably by 1468, the first and greatest Lombard fresco cycle in the Portinari chapel in S. Eustorgio in Milan.

A celebrated fresco of "The Martyrdom of St. Sebastian" (1485) from Sta. Maria di Brera, Milan (Brera gallery, Milan), inspired by Bramante. affords a measure of Foppa's success in forging a Lombard Renaissance style. As a panel painter on a monumental scale Foppa's development can be traced from a polyptych of about 1476 painted for Sta. Maria delle Grazie at Bergamo (Brera gallery), through altarpieces at Pavia (c.1486) and Savona (1489/90), to the splendid "Adoration of the Magi" (about 1500; National gallery, London). Foppa died between May 3, 151j, and Oct. 16. 1516.

An artist of exceptional integrity and power, Foppa exercised a formative influence on the work of Butinone, B. Zenale, A. Borgognone and most of his younger Milanese contemporaries. In Milan his style was superseded by that of Leonardo da Vinci, but at Brescia, where he resided after 1490, its effect was more enduring, and it is reflected in the 16th century in the paintings of G. Savoldo.

See C. J. Ffoulkes and R. Maiocchi, *Vincenzo Foppa* (1909); F. Wittgens, *Vincenao Foppa* (1945). (J. W. P.-H.)

FORAIN, JEAN LOUIS (1852–1931), French painter and graphic artist who succeeded Honor6 Daumier as the outstanding illustrator of his day, was born at Rheims on Oct. 23, 1852. As an artist he was largely self-taught. A protégé of E. Degas. he exhibited with the Impressionists, but was from the first more attracted by graphic media.

He made his first etchings in 1876, and although from about 1890 it was lithography that principally occupied him, he returned to etching in 1908. His work was popular and well-suited to reproduction in large numbers. He contributed satirical and humorous drawings to *Le Rire, L'Echo de Paris, Le Figaro, Le Monde Parisien* and other journals. Whatever the medium, Forain took his subjects from the world of the prosperous Parisian bourgeoisie —the exchange, the law courts, the cafés, the artists' studios, the theatres, the demimonde—with a particular emphasis on the disreputable. His attitude was critical, pessimistic and a little cynical, but human behaviour was endlessly fascinating to him. In style and subject matter alike, Forain remained deeply indebted to Degas, and to a lesser extent to Daumier. Toward the end of his life he etched and painted religious subjects. He died in Paris on July 11, 1931. (A. Bs.)

FORAKER, JOSEPH BENSON (1846–1917), American political leader, was born near Rainsboro, Highland county, Ohio, on July 5, 1846. He enlisted as a private in July 1862, served throughout the Civil War and in 186j received a captain's brevet. After the war he spent two years at the Ohio Wesleyan university and two years at Cornell. In 1869 he was admitted to the Ohio bar. He was a judge of the Cincinnati superior court. 1879–82, and from 1885 to 1889 was governor of Ohio. In 1896 he was elected United States senator. was re-elected in 1902 and served until 1909. In the senate he strongly supported President McKinley in the debates preceding, during and immediately following the Spanish-American War. During the administration of President Roosevelt he vigorously opposed various measures advocated by the president, and led the opposition to the president's summary discharge of certain Negro troops after the Brownsville raid of Aug. 13, 1906. In 1916 he published *Notes of a Busy Life*. He died in Cincinnati on May 10, 1917.

FORAMINIFERA. Foraminifera, the so-called "oil bugs" of the petroleum industry, are amoeba-like animals provided with a shell or test. The pseudopodia are filose and anastomosing, never lobose, and the protoplasmic mass within the test contains either one or many nuclei. In most species the test is composed of calcium carbonate and consists of a series of chambers that communicate through passages which were the apertures of the test before each succeeding chamber was added. The name of the group was derived from these passages, the so-called foramina.

Position in the animal kingdom: phylum, Protozoa; class, Sarcodina; subclass, Rhizopoda; order, Foraminifera. *(See* PROTOZOA; AMOEBA.)

Occurrence.—Foraminifera occur in all oceans and most seas, and at all depths. Grayish riffle marks on sandy beaches often contain vast numbers of the empty tests, and the sand bordering some oceanic islands consists for the most part of the tests of pelagic species. These pelagic Foraminifera, the *Globigerinidae,* constitute 50% or more of the sediments covering about 49,000,000 sq.mi. of ocean floor, and the area would be greatly extended if it were not for the fact that the calcareous tests dissolve at depths in excess of from 2,000 to 3,000 metres. At Sanoer on the island of Bali the tests of larger species are used to gravel walks and roads. Most samples of off-shore sediment contain enormous numbers of tests of many species, as do the washings from seaweed taken from protected tide pools.

Geological Importance.—Much chalk, limestone and marble is composed for the most part of entire tests or residual calcium carbonate derived from the tests of Foraminifera. Evidence of this may be seen with the unaided eye in the polished surfaces of ornamental marble used in many bank and office buildings, and a fragment of stone from one of the pyramids of Egypt will show that they too were built from foraminiferal limestone.

Foraminifera occur in the sediments of pre-Cambrian seas but were seldom an important constituent prior to the coal age or the Pennsylvanian. In the Eocene this group reached its zenith in size, complexity of structure and the extent and thickness of deposits. At the 22,000-ft. level on Mount Everest in the Himalayas there is a 200-ft. stratum of foraminiferal limestone belonging to the period, while in other regions these formations are many thousands of feet in thickness. Recent faunas have existed with only minor modification since the hfiocene.

Marine sediments underlie more than two-thirds of all land areas and often contain fossilized Foraminifera. With the passage of time new species have come into existence; while others have become extinct. For these reasons the Foraminifera are useful in determining the probable age of formations and in making geological correlations between widely separated regions. Since petroleum is always associated with marine sediments, they provide a useful guide to structures which might contain oil and, in proved fields, the strata through which the drill must pass before reaching producing zones.

FIGS. 1-4.— FORAMINIFERA IN RECENT AND GEOLOGIC MARINE DEPOSITS

1. Washed sample of gray chalk containing Foraminifera. 2. Marble from Italy containing Orbitoids. 3. Nummulitic limestone similar to that used in building the pyramids. 4. Washed sample of Globigerina ooze

Test Morphology.— Tests of Foraminifera range in size from that of a mere speck to several inches in diameter. **A** restricted group includes species that are little more than marine amoebae protected by a chitinous membrane or primitive test. From this simple beginning, species developed in which this primitive test assumes a globular shape, covered with sand, mica, sponge spicules, or other sedimentary material, or by a dense deposit of calcium carbonate. These globular tests are similar to the initial chamber or proloculus of the more common multichambered tests. To this simple test a meandering or spiral chamber may be imposed, or a number of chambers so arranged as to form a coiled, monoserial, biserial, or triserial test; and to a spiral or coiled beginning, a number of annular chambers may be added. These constitute the basic types from which the tests of most species were derived. The total number of chambers in a test may be one, a few, or many hundreds.

Usually there are either one or many apertures in the terminal chamber; and, when a new chamber is added, these become foramina or communicating passages between the chambers. In one major group the walls of most chambers are perforated by minute pseudopodial pores, and there are lesser groups in which the walls of the tests are provided with an elaborate system of canals.

The tests of many species are ornamented with ridges, spines, or bosses; and, because of the beauty and complexity of these, the Foraminifera were the object of intense study long before their economic significance was recognized.

Tests composed of either calcium carbonate or bits of inorganic debris on a chitinous foundation persist in geological marine sediments with little or no apparent change, except where the sediments were subjected to shearing and excessive pressure or the solvent action of acid-charged water. In consolidated sediments perfect moulds that are characteristic of the species may persist after the tests have been completely dissolved.

The four major groups based on the structure and composition of the tests are:

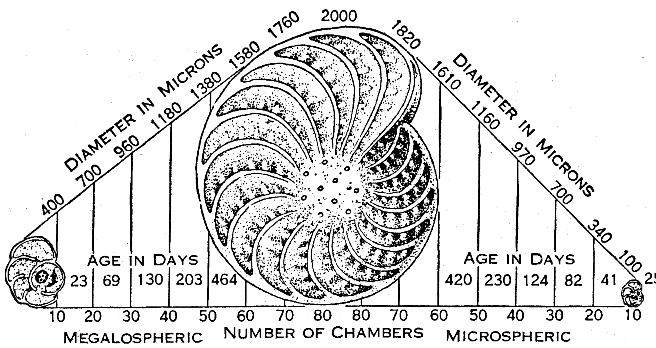
Chitinous, animal cement only;
Aranaceous, inorganic debris and cement;
Perforata, calcium carbonate with pores;
Aperforata, calcium carbonate without pores.

The Living Organism.—Most Foraminifera live on mud, or sandy mud bottoms, or on weed, while a restricted group is pelagic, inhabiting the open sea at moderate depths. The rate of movement in bottom forms is such that most individuals live and die within a matter of inches from the place of origin.

In species having a large aperture, the protoplasm within the test often contains bacteria, flagellated protozoa, spores of algae, diatoms and organic detritus, and it is presumed that these constitute the food of the Foraminifera. When the aperture is too small to admit larger food particles, these are digested by ferments contained in the pseudopodia

The pseudopodia arise from a mass of protoplasm near the aperture of the test or from pseudopodial pores and become attenuated almost to the vanishing point. Where several pseudopodia meet, they fuse or anastornose. These constantly streaming filaments of protoplasm provide locomotion, capture and in part digest food organisms, eliminate solid and liquid waste and, together with the film of protoplasm covering the test, carry on respiratory activities. Circulation within the test is provided by the streaming of the protoplasm, and extends through all of the chambers.

The colour of a living foraminifer is determined by the colour, density and, to some extent, structure of the test; and, when the walls are translucent, the green, brown, or red of the protoplasm and its inclusions may be a dominant factor. Chitin is brown. and often gives a brownish cast to tests that otherwise would be white. The more brilliantly coloured species are found in the vicinity of coral reefs. These range through shades of china-white, orange, bright red, brown and bright green, to lavender and blue, the latter colours being caused in part by refraction. In deeper water, species provided with a translucent test are green. aranaceous tests assume the colour of the shell substance or are made red or brown by iron salts contained in the cement that



FROM EARL H. MYERS IN "JOURNAL OF PALEONTOLOGY"

FIG. 5.— GRAPHICAL PRESENTATION OF THE RATE OF GROWTH BOTH IN NUMBERS OF CHAMBERS AND SIZE OF TEST IN ELPHIDIUM CRISPUM

binds the particles together, while calcareous tests of many species resemble white porcelain.

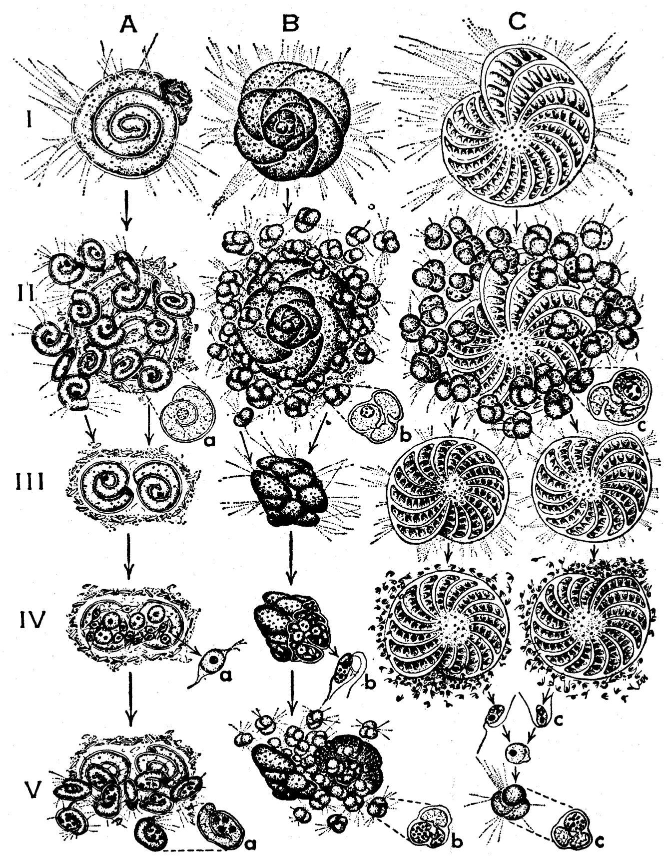
Zooxanthellae are symbiotic algae which live as a protoplasmic inclusion in certain species of Foraminifera inhabiting the shallow waters of warm seas, but their golden colour has little effect upon the colour of the Foraminifera.

Life Cycle.—In the life cycle of most Foraminifera there is a cyclical succession of sexual and asexual generations in which two distinct types of individuals are produced.

Sexual Phase.—In the sexual phase, flagellated gametes associate in pairs in fertilization, and the resulting zygote or fertilization amoeba becomes invested in a spherical test. To this, succeeding chambers are usually added one at a time to form a graduated series of chambers.

Immediately following fertilization, the fertilization nucleus divides, and succeeding divisions result in a number of nuclei that are proportional to the number of chambers in the test. These nuclei are moved from chamber to chamber by the streaming protoplasm and are not restricted to particular chambers. The tests of these sexually produced individuals have minute initial chambers and are therefore referred to as microspheric tests.

Asexual Phase.—Asexual reproduction by microspheric individuals is initiated by a series of nuclear divisions that approximately quadruple the number of nuclei originally present. The protoplasm surrounding each nucleus then separates from the common mass to form mononucleate amoebae which have a diameter several times that of a zygotic amoeba, and these become invested in globular tests that are proportionately larger than the initial test in the microspheric generation. To this relatively large initial test, succeeding chambers are added to produce a test that may be identical in appearance with that of the microspheric generation. These tests are referred to as megalospheric because of the larger initial chamber, and contain but a single nucleus which does not divide prior to reproduction.



FROM EARL H. MYERS IN NATIONAL ACADEMY OF SCIENCES PUBLICATION

FIG. 6.—LIFE CYCLES OF FORAMINIFERA

A. *Spirillina vivipara*, B. Discorbis *globularis*, C. *Elphidium crispum*. I Microspheric generation showing nature of pseudopodia. II Microspheric individuals asexually producing mononucleated megalospheric juveniles. III Beginning of sexual reproduction. in A. Megalospheric individuals merely associate, in B. they actually fuse, and in C. they remain independent. IV In A. gametes form and become fertilized within a brood cyst, in B. within a brood chamber, and in C. gametes are free and pelagic. V Growth of multinucleate microspherio juveniles

Each microspheric individual produces from tens to hundreds of juveniles depending upon the species.

Gametogenesis.—The sexual phase of the life cycle begins with the division of the megalospheric nucleus, and succeeding nuclear divisions produce enormous numbers of minute nuclei. Each nucleus, and the surrounding protoplasm, then gives rise to a small spherical body in which the nucleus—and finally the protoplasm—divides to form two minute amoebae. This final nuclear division is a reduction division. Later each amoeba develops whip-like structures or flagella by means of which it is propelled through the water. These gametes swarm from the test and, when two gametes derived from different megalospheric individuals come into contact, fertilization takes place and the life cycle is repeated.

This description is based on the limited number of life cycles that have been studied and the recognized dimorphic nature of the tests of most species. Briefly, the life cycle includes an alternation of generations in which two types of individuals are produced. In the sexual phase mononucleate megalospheric individuals produce flagellated gametes. Gametes from different megalospheric individuals unite in fertilization and give rise to multinucleate microspheric individuals, which in turn asexually produce the megalospheric generation.

Reproductive activities in most species require from two to three days, both in the sexual and the asexual phase of the life cycle. The addition of a new chamber requires one day, and several days usually elapse before the next chamber is added. The life span of these protozoa is from a few weeks to a year or more, depending upon the species and the season; and the life cycle, including a sexual and an asexual generation, requires from several weeks to two years or more.

Variations in Life Cycles.—In asexual reproduction, two- and three-chambered megalospheric juveniles develop either within the test of a microspheric individual or in its immediate vicinity after the protoplasm has escaped from the test. In sexual reproduction, two or more megalospheric individuals may either fuse or become enveloped in a common cyst or brood chamber before the gametes are produced, or the gametes may be released directly into the water. In still other species only one type of individual is known and, although these have but a single nucleus and would therefore seem to be megalospheric, they reproduce asexually over many succeeding generations. In a few species both microspheric and megalospheric individuals have been observed to reproduce asexually, but there is little evidence to suggest that this occurs in an appreciable number of species.

Ecological Relationships.—Many species of Foraminifera now occurring between certain depth limits are universally distributed. Similar conditions prevailed during other periods in the earth's history, and for this reason it is possible to correlate geological sediments of widely separated regions. Species restricted to shallow water are often limited in their distribution by the temperature of the water, and in ancient sediments these provide an index to the climatic conditions that prevailed on adjacent land areas. Other species are limited by factors other than temperature. These include the salinity of the water, the nature of the substratum and the food available. which in turn is influenced by factors associated with the depth of the water. Growth and reproduction in this group depends upon the availability of suitable food organisms more than any other factor or combination of factors.

The intertidal zone and adjacent water to a depth of a few metres is subjected to a wider range of changes, and more abrupt changes, in ecological conditions than the waters immediately adjacent to this area; and, as a result, the two areas are inhabited by related but different species. Many species of Foraminifera are restricted to areas covered with weed and grass, and the depth to which these plants thrive depends upon the nature of the bottom and the amount of solar radiation. which varies with the turbidity of the water and latitude. The empty tests of these several populations form a common assemblage in off-shore sediments, and in geologic marine sediments these shallow water species provide a guide to the boundaries of ancient seas.

Below the 20-metre line, or to somewhat greater depths where weeds abound out to the edge of the continental shelf at a depth of about 200 metres, there is a gradual change in populations with the increasing depth of the water, although many species inhabit the entire region. Petroleum originates in geological sediments that were deposited at these moderate depths.

From the edge of the continental shelf to a depth of 2,000 to 3,000 metres there is a more or less abrupt descent, and with this further increase in depth there is a corresponding change in populations. At still greater depths, including the abyssal deeps, aranaceous species predominate, since calcium carbonate dissolves under the pressure and slightly acid condition that prevails at the bottom. Pelagic species are typically oceanic and are not numerous in shallow water unless carried there by currents from the open sea. Therefore the relative abundance of the tests of pelagic species in geological sediments is an index to the depth of the water bordering ancient land areas.

The amazing abundance of Foraminifera in geologic sediments suggests sorting caused by current action, but this is not necessarily the case. At Sanoer on the island of Bali nearly pure deposits of a large species *(Tinoporous)* cover the bottom in some places to a depth of many feet, and the turf-like weed on adjacent submerged reefs support many thousands of individuals per square foot of surfsce. On mud bottoms in some portions of the Java sea an even larger species (*Operculina*) is so abundant that the empty tests in the mud constitute nearly one-half of the total mass of the sediments. In deep water the number of living Foraminifera per unit area is no doubt small, but in shallow water they vary from tens or hundreds to even thousands of individuals per square foot.

Role in Historical Geology.—The role of the Foraminifera in palaeoecology and historical geology is exemplified by a comparison of populations and the conditions under which they now exist with the assemblages of species recovered from stratified sediments in the hills back of Ventura, California.

Samples of sand, silt and conglomerate were obtained from oil wells and out-crops in Hall canyon. From the combined thickness of the strata it was determined that marine sediments some two and one-half miles in depth are exposed in the canyon wall, and, from the dip of the strata, that the more recent sediments are exposed at the lower end of the canyon while the older sediments occur near the summit of the ridge. The several hundred species of Foraminifera recovered from the samples could be divided into five more or less distinct assemblages and, on the basis of this, the geologic column is divisible into as many zones. At first it was thought that these several assemblages suggested a gradual change in climatic conditions during that portion of the Pleistocene when the sediments were being deposited.

It was known that many of the species in the Hall canyon fauna still survive in the sea, and a series of samples were obtained from the mud bottom of the San Pedro channel between San Pedro on the mainland and Avalon on Catalina Island. From these samples it was determined that species similar to those in the upper four zones of Hall canyon occur between about the same depth limits on the two sides of the channel while species characteristic of the fifth zone were present in samples obtained from the deeper water of the open sea west of the island.

Fresh water enters the San Pedro channel from the Los Angeles river and small streams on the island, and reduces the salinity of the water near the shore during the winter and early spring. The maximum depth of the channel is 900 metres, and the temperature at this depth remains at about 5° C. throughout the year. From this low the temperature ranges upward to a maxi mum of 25° C. near the shore on the San Pedro side and 17° C. at the surface in the vicinity of Avalon.

From these observations it was evident that the geological history of the Hall canyon formation includes a slow emergence from the sea from a depth of not less than 1,800 metres to its present elevation of 750 ft., and that the water temperatures during this period were about the same as those now prevailing in the sea adjacent to this area. It was further evident that the sediments in the upper portion of the canyon were deposited in deep water; zone 4, between 900 and 300 metres; zone 3. 300 to 50 metres; zone 2, 50 metres or less; and zone 1, at the lower end of the canyon in shallow water of low salinity. It was also apparent that the climatic conditions of the region during early Pliocene times were similar to those now prevailing, although a somewhat heavier rainfall is suggested, and that the cooling of the sea prior to the advance of the Pleistocene ice sheet had not yet set in.

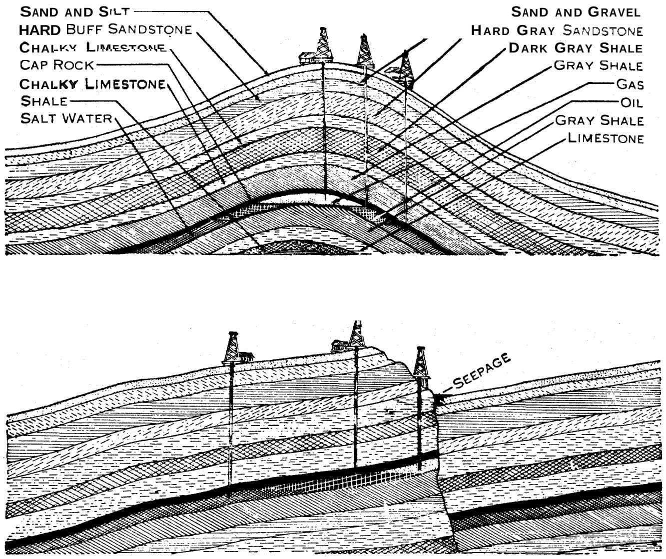
Role in Petroleum Geology. — The mother source of petroleum is the carbonaceous remains of plants and animals, including Foraminifera, that accumulated in the sediments of ancient seas. Conditions of life in these seas, and the chemical changes that occurred both during and after the deposition of the sediments, limited the areas in which petroleum was produced. Further, it was necessary that porous strata, covered with a cap rock of impervious shale, be present to conduct the petroleum to geological traps. These traps are either anticlines — referred to as domes — or sealed faults. Later changes in the earth crust, such as the opening of faults or erosidn, often permitted the oil to escape as seepage or gas. Producing zones are referred to as oil pools, but these pools are nothing more than porous rock, usually sandstone, saturated with oil under enormous pressure.

In the search for petroleum, seepage or escaping gas are valuable clews, but they do not suggest that oil in commercial quantities remain in the structure. Something of the geological history of a region may be determined from samples removed from



BY COURTESY OF EARL H. MYERS

exposures such as cliffs, excavations or wells. The location of probable oil traps, such as anticlinal folds and fault lines, is established through the study of topographical charts, air reconnaissance or, where these fail, subsurface structures which may be recognized through the recording and interpretation of local seismic disturbances set up by the discharge of explosives. Chemical tests of the subsoil may reveal the presence of petroleum but not the existence of recoverable petroleum.

When a favourable site is located and drilling operations are under way, samples of the strata through which the drill passes are removed at frequent intervals and these are sent to a palaeontological laboratory for study. At the laboratory the sample is given a number and a careful description of its characteristics made. A portion of the sample is then reduced by crushing and washing away the finer sediments. It is then dried and the Foraminifera removed under a microscope with the aid of a small brush. The Foraminifera are then mounted on slides, and the individual species as well as the total assemblage of species are studied and compared with the species observed in previously obtained samples. Certain species are then selected as guide fossils for that particular zone, and the assemblage is represented on a chart by means of a special type of marking. From subsequent samples the total thickness of the zone, as well as that of succeeding zones, is also charted. When a producing zone has been located beneath a recognized series of other zones, and a similar sequence is encountered in a new well, the driller knows that the drill is penetrating favourable formations; but, should these zones fail to appear before deeper structures are encountered, he knows that these producing zones do not extend to the new location.

When the sequence of zones has been determined in several wells, these zones are charted by means of an electric logging device; and, when these logs are compared with that of a newly drilled well, correlations may be attempted and these substantiated through the microscopic examination of a minimum number of samples.

Although there are many guides to the possible existence of petroleum in subsurface structures, oil is where one finds it; and the only way to find oil is to sink test wells wherever conditions seem favourable. This is termed wildcatting.

In the ever-widening search for petroleum, geophysical and chemical methods are an aid to success but can never take the place of a sound knowledge of geology, stratigraphy and sedimentation. Recent work on the environment of sedimentation, ecological relationships and possible source rocks should provide a better understanding of the use of guide fossils, especially the Foraminifera, in locating and tracing new oil-bearing formations. (E. H. MY.)

FORBES, DUNCAN, OF CULLODEN (1685–1747), Scottish statesman, son of Duncan Forbes (1644?–1704), genealogist and M.P. for Nairn, was born at Bunchrew or at Culloden near Inverness on Nov. 10, 1685. He studied at Edinburgh and Leiden, and was advocate and sheriff of Midlothian in 1709. The influence of the Argyll family and his loyalty to the Hanoverian cause in 171j secured his rapid advancement. He became M.P. for Inverness (1722), lord advocate (1725), and lord president of the court of session (1737).

Some years before the rising of Forty-five Forbes had urged upon the government the expediency of embodying Highland regiments, putting them under the command of colonels whose loyalty could be relied upon, but officering them with the native chieftains and cadets of old families in the north. In 1739, with Sir Robert Walpole's approval, the original (1730) six companies (locally enlisted) of the Black Watch were formed into the famous "Forty-second" regiment of the line.

On the first rumour of the Jacobite rising in 1745 Forbes hastened to Inverness, and through his personal influence with the chiefs of hlacdonald and Macleod, these clans were prevented from taking the field for Charles Edward; the town itself also he kept loyal. In September 1745, after Cope's departure to the south. Forbes was the sole representative of government in the north. He worked hard to maintain order. But advances of arms and money arrived too late, and though Forbes employed all his own means and what money he could borrow on his personal security, his resources were quite inadequate to the emergency. It is doubtful whether these advances were ever fully repaid. Part was doled out to him, after repeated solicitations that his credit might be maintained in the country; but it is evident his humane exertions to mitigate the savage revenge on the rebels after their defeat at Culloden had brought him into disfavour in London. Forbes died on Dec. 10, 1747.

Forbes was a patriot without ostentation or pretense, a true Scotsman uith no narrow prejudice, an accomplished and even erudite scholar without pedantry, a man of genuine piety without asceticism or intolerance. His statue by Roubiliac stands in the Parliament house, Edinburgh.

FORBES, EDWARD (1815–1854), British naturalist who made an important analysis of the distribution of the natural inhabitants, plant and animal, of the British Isles as related to certain geologic changes. He was born at Douglas. Isle of Man, on Feb. 12. 181j. He studied medicine at Edinburgh. and in 1833 made a tour in Norway, the botanical results of which were published in J. C. Loudon's *Magazine of Natural History* for 1835–36. In 1836 he forsook medicine for natural science, and after a winter of lectures in Paris, he went to Algiers to study land and freshwater Mollusca. In 1838 appeared his *Malacologia Monensis,* a synopsis of the species of Manx Mollusca, and in 1841 his *History* of *British Star-fishes.* From 1841 to 1842 he investigated the botany, zoology and geology of the Mediterranean region, the results being made known in his "Report on the Mollusca and Radiata of the Aegean Sea, presented to the British Association in 1843," and in *Travels in Lycia* (1847). In 1842 Forbes became curator of the museum of the Geological Society of London, in 1843 professor of botany at King's college and in 1844 paleontologist to the Geological Survey of Great Britain. Two years later he published in the *Memoirs* of the Geological Survey, i. 336, his important essay "On the Connexion Between the Distribution of the Existing Fauna and Flora of the British Isles, and the Geological Changes which have Affected their Area," in which he maintains that the plants of Great Britain may be divided into five well-marked groups and that the majority of them, like the terrestrial animals, migrated to those islands over continuous land at three distinct periods, before, during and after the glacial epoch. In 1851 Forbes became professor of natural history to the Royal School of Mines, and in the following year published the fourth volume of Forbes and S. Hanley's *History of British Mollusca* and his *Monograph of the Echinodermata of the British Tertiaries* (Palaeontographical society). In 1854 he became professor of natural history at Edinburgh, but he died on Nov. 18 of that year at Wardic, near Edinburgh.

See G. Wilson and A. Geikie, *Memoir of Edward Forbes* (1861) ; *Literary papers,* ed. *by* Lovell Reeve (1855) ; *Forbes' Centenary Commemoration by* the London Manx Society (1915).

FORBES, JAMES DAVID (1809–1868), Scottish physicist, is best known for his researches on heat and on glaciers. He was born at Edinburgh on April 20. 1809. He studied at Edinburgh: became F.R.S.E. (1828) and F.R.S. (1832), professor at Edinburgh (1833–59), and principal of the United college at St. Andrews (1859–68). He died on Dec. 31, 1868.

Between 1836 and 1844 he published in the *Transactions of the Royal Society of Edinburgh* four series of "Researches on Heat," in the course of which he described the polarization of heat by tourmaline, by transmission through a bundle of thin mica plates, and by reflection from the surfaces of a pile of mica plates. and also its circular polarization by two internal reflections in rhombs of rock salt. In 1846 he began experiments on the temperature of the earth at different depths and in different soils near Edinburgh. Later he investigated the laws of the conduction of heat in bars, and his last piece of work was to show that the thermal conductivity of iron diminishes with increase of temperature. The Royal society awarded him the Rumford medal in 1838 and the Gold medal in 1843 for his work on heat.

He made several visits to Switzerland and also to Norway to study the flow of glaciers and developed a theory which involved him in some controversy with Tyndall and others.

FORBES-ROBERTSON, SIR JOHNSTON (1853–1937), Engiish actor, of great beauty and imagination, who was considered the finest Hamlet of modern times. was born in London on Jan. 16, 1853, the son of John Forbes-Robertson of Aberdeen. an art critic. Educated at Charterhouse school, he studied art before turning to the theatre in 1874, when he first appeared on the London stage as Chastelard in *Mary, Queen of Scots.* He acted with Samuel Phelps, the Bancrofts and John Hare, played opposite Mary Anderson in England and the United States and for some time was a leading member of Sir Henry Irving's company at the Lyceum. His first outstanding success was in Sir. Arthur Pinero's *Tlze Profligate* at the Garrick theatre in 1889, under the management of Hare. In 1895 he took over the management of the Lyceum, with Mrs. Patrick Campbell as leading lady, giving memorable performances of *Romeo and Juliet, Hamlet, Macbeth,* etc., and also producing John Davidson's *For the Crown* and Maurice Maeterlinck's *Pelle'as and Mélisande,* in both of which his romantic style of acting was highly successful. In 1900 he married Gertrude Elliott, who became his leading lady, appearing with him in many plays, such as *The Light That Failed,* Madeleine Lucette Riley's *Mice and Men,* George Bernard Shaw's *Caesar and Cleopatra* and, one of his biggest successeg, Jerome K. Jerome's *The Passing of the Third Floor Back.* Forbes-Robertson was knighted in 1913, and after occasional appearances and a farewell tour in Canada and the Cnited States finally retired in 1915. He died on Kov. 6, 1937. His daughter JEAN FORBES-ROBERTSOX (1905–) became a distinguished actress. (W. J. M.-P.)

FORBIN, CLAUDE DE (16j6–1733), French naval commander, was born at Gardanne, Provence, Aug. 6, 1656. He went to Siam in 1685 with the chevalier de Chaumont, sent by Louis XIV at the invitation of the king of Siam. He remained as admiral and general in chief to the king until 1687. He was the colleague of Jean Bart in his irregular operations in the channel, and distinguished himself at the battle of Lagos. He served in the French navy as *chef d'escndre* 1702–10, and played a brilliant part in the War of the Spanish Succession. In 1710 he retired to St. Marcel, near Marseilles. He died March 4, 1733. The latter part of his life was spent in writing his *Mémoires*'(1730).

FORCE. In general. strength or intensity of effort as applied to physical action. It is also used to denote a military or naval unit; for its legal application *see* CRIMINAL LAW. In physics force is measured by the product of the mass of a body (under acceleration) by the acceleration, or, more generally, by the rate of change, with time, of the body's momentum; *i.e.,* $\frac{d(mv)}{dt}$. *See* also ENERGY ; MECHANICS.

FORCED LABOUR: *see* CORVÉE; FEUDALISM; SLAVERY.

FORCELLINI, EGIDIO (1688–1768), Italian philologist, was born on Aug. 26, 1688, at Fener. Treviso, and studied at Padua under Facciolati (*q.v.*). From 1724 to 1731 he held the office of rector of the seminary at Ceneda. and from 1731 to 1765 that of father confessor in the seminary of Padua. He died at Padua on April 4, 1768, before the completion of the vast *Latin Lexicon,* on which he had for 3j years collaborated with Facciolati.

FORCHHAMMER, PETER WILHELM (1801–1894), German classical archaeologist, was born at Husum, Schleswig, on Oct. 23. 1801, and was educated at Lübeck and the University of Kiel, with which he was connected for nearly 65 years. In 1830–34 and 1838–40 he traveled in Italy, Greece, Asia Minor and Egypt. In 1843 he was appointed professor of philology at Kiel and director of the archaeological museum founded by himself in co-operation with Otto Jahn. He died on Jan. 8, 1894. Forchhammer represented the progressive party of Schleswig-Holstein in the German *reichstag,* 1871–73. His published works deal chiefly with topography and ancient mythology. *Hellenika. Griechenland. Im Neuen das Alte* (1837) contain his theory of the origin and explanation of the Greek myths which, according to him, arose from definite local (especially atmospheric and aquatic) phenomena, and represented the annually recurring processes of nature as the acts of gods and heroes.

FORD, EDWARD ONSLOW (1852–1901), distinguished English portrait sculptor. was born at Islington. London, on July 27, 1852. He was educated at Blackheath, near London, and studied art at Antwerp and Munich. He returned to England in 1874 and attracted attention with a bust of his wife which he sent to the Royal academy in 1875. Ford's best-known statues are Sir Rowland Hill (1882) outside the general post office in London; General Charles Gordon (1890) at Chatham and at Khartoum, and the Shelley memorial (1892) at University college. Oxford. Ford's busts include W. E. Gladstone (1883), Sir Henry Irving (1885), A. J. Balfour (1892), Sir Laurence Alma-Tadema (1896), Herbert Spencer (1897), Queen Victoria (1899) and Lewis Waller (1900).

His bronze statuette of "Folly" is in the Tate gallery, London, and in 1897 he made the Jowett memorial for Balliol college chapel. Ford was elected associate of the Royal Academy in 1888 and academician in 1895. He died in London on Dec. 23. 1901. (R. Gs.)

FORD, HENRY (1863–1947), C.S. industrialist who became within his lifetime the one person most universally identified as the creator of modern mass production, was born July 30. 1863, on a farm near Dearborn. Mich. The principal manufacturing innovation credited directly to Ford is the assembly-line method of automobile production, which he first employed in 1913. However, other technical advances and new ways of planning, organizing and controlling production that were developed during the more than 40 years that he ran the Ford Motor company also came to bear the "Ford label," as much attributed to the man as to the firm. Willingness to depart from previous practice—as by standardizing processes and products, integrating supplying industries, building assembly plants at dispersed locations and organizing manufacturing around continuous line-to-line flow of product components—was a significant factor in the company's success.

Ford's industrial philosophy was simple. Reduce the price of the product, increase the volume of sales, improve production efficiency, increase output to sell at still lower prices, and so repeat the cycle indefinitely. Contemporaries. viewing the automobile as a luxury item or rich man's plaything to be custom-produced for a restricted market, regarded Ford's policies as heretical. While in the company's formative years his ideas were pushed into practice against the resistance of his associates and stockholders, the workability of those ideas was demonstrated vividly by the growth of the Ford Motor company from a firm nominally capitalized at $100,000 in 1903 to an industrial giant with a surplus balance alone of nearly $700,000,000 in 1927, when the last of more than 15,000,000 of the famous Model T's built between 1908 and 1927 rolled off the assembly line.

There was a curious mixture of 19th and 20th century in Henry Ford, and his was a strong and contradictory personality. Though he rejected many of the doctrines of business and economics of his day, on some subjects he clung to anachronistic ideas. In 1914, when workers in U.S. manufacturing industries were making about $11 a meek on the average, he announced that every Ford worker would start receiving at least $5 a day through minimum wages about 15% higher than those paid elsewhere for the same types of work. as well as through participation in a profit-sharing plan. The impact of the move, both damned and praised in the press, naturally was great. It brought for Ford a reputation as a trail blazer. Yet at the same time Ford tightened his paternalistic labour policy, establishing sobriety and thrift on the part of the workers as conditions for sharing in the distribution of profits.

Ford always displayed concern for the welfare of workers and believed firmly in the dignity of work. But he resisted unionization for his employees, seemingly thinking unionism would pass away or that agitators were misleading his men. The company police in his plants for years waged a repressive campaign against union membership. Ford remained nonunion for several years after his competitors had concluded agreements with unions. Yet after he had lost a union-recognition election conducted by the National Labor Relations board in 1941, he signed the first union-shop and check-off contract in the automotive industry with the United Auto Workers.

Ford was a prophet of the new industrial order, yet he was reluctant to use new devices to achieve it. He had a profound distrust of bankers and of Wall Street, preferred financing expansion from earnings rather than by selling stock. and borrowed only when it was unavoidable. In 1917 he fought a suit brought by stockholders to force a distribution of most of the company's accumulated surplus, to compel future distribution of earnings and to enjoin the company from expanding its plant. The outcome was that a special dividend had to be paid, but the right of the company to use its capital for expansion was unimpaired. As he was able, Ford bought out the other stockholders and eventually attained complete control. He thereafter operated to suit himself, and his company ultimately became the only one of comparable size individually owned—a personal empire whose worth was estimated in billions of dollars.

Though Henry Ford showed great vision and "put America on wheels" nith the Model T, the first car designed for a mass market, he later failed to appreciate the dynamic character of that market. Against the advice of his management he held out for the planetary transmission against the conventional gearshift, the mechanical against the hydraulic brake, the four-cylinder against the six- or eight-cylinder engine and a single colour. black, against the colour variety offered by other manufacturers. However, when finally convinced in 1927 that the Model T had seen its day, he retooled completely and produced in the Model A an entirely new car. In 1932 he repeated the process in bringing the V-8 on the market. Nonetheless his adjustment to consumer demand for comfort, style and convenience was too tardy to prevent losing first position in the industry to General Motors.

Ford attended school only to the age of 1j. From an early age he showed a keen interest in things mechanical, an interest that never waned. Even after he had reached the apex of an industrial empire, he delighted in disassembling the watches of his friends or joining the mechanics in his plant in a greasy repair job. He was an empiricist, impatient of theory.

Diet faddist, foot racer, folk-dance enthusiast, collector of early Americana. philanthropist, practical joker, not always consistent—Ford was all these. He endowed a modern hospital and subsidized a newspaper that specialized in anti-Jewish articles. During World War I he chartered a ship and sailed with an oddly assorted list of pacifist passengers to appeal to heads of state to "get the boys out of the trenches by Christmas," and during both World Wars I and II his company was a major producer of war materials. He ran for the senate and lost and thought about running for president. He played his executives off against each other and banned smoking in his plants. Most important, he was the kind of man who could make an auto in his barn with his own hands and could also make the principles of mass production work on a scale unparalleled before his time.

He died April 7, 1947, at Dearborn.

Bibliography.—No definitive biography exists. Much information can be found in *My Life and Work* (1922) and *Today and Tomorrow* (1926), written by Henry Ford in collaboration with Samuel Crowther. *See* also Samuel S. Marquis, *Henry Ford: an Interpretation* (1923); William A. Simonds, *Henry Ford: His Life, His Work, His Genius* (1943); William C. Richards, *The Last Billionaire, Henry Ford* (1948); Keith Sward, *The Legend of Henry Ford (1948)*; and Harry H. Bennett, *We Never Called Him Henry* (1951). (J. D. Rs.)

FORD, JOHN (1586–*c.* 1640), English dramatist, was baptized on April 17, 1586, at Ilsington in north Devon. His father was in the commission of the peace and his mother was a sister of Sir John Popham, successively attorney general and lord chief justice. John Ford matriculated at Exeter college in 1601 and was admitted to the Middle Temple in 1602. In 1606 he wrote the elegy *Fame's Memorial, or the Earl of Devonshire Deceased,* and dedicated it to the widow of the earl, the famous Penelope, formerly Lady Rich. The elegy shows some sympathy for the fate of Essex. Ford's tract of *Honor Triumplzant, or the Peeres Challenge* (printed 1606 and reprinted by the Shakespeare society with the *Line of Life*, in 1843), and the simultaneously published verses *The Monarches Meeting, or the King of Denmarkes Welcome Into England,* show him in the capacity of a court poet. *The Time Poets (Choice Drollery*, 1656) suggests that Ford withdrew from literary life in London to his native place; but nothing is known as to the date of his death.

His career as a dramatist probably began by collaboration with Thomas Dekker with whom he wrote *The Fairy Knight* and *The Bristowe Merchant* (licensed in 1624, but both unpublished); and with John Webster *A Late Murther of the Sonne Upon the Mother* (licensed in 1624). A play entitled *An Ill Beginning Has a Good End,* brought on the stage in 1613 and attributed to Ford, was (if his) his earliest acted play; whether *Sir Thomas Overbury's Life and Untimely Death* (1615) was a play is extremely doubtful; some lines of indignant regret by Ford on the same subject are still preserved.

He is also said to have written, at dates unknown. *The London Merchant* (which! however, was an earlier name for Beaumont and Fletcher's *Knight of tlze Burning Pestle)* and *The Royal Combat;* a tragedy by him, *Beauty in a Trance,* was entered in 1653, but never printed. These three (or four) plays mere among those destroyed by Warburton's cook. *The Queen, or tlze Excellency of tlze Sea,* a play of inverted passion, printed in 1653 by Alexander Singhe for private performance, was edited by W. Bang (*Materialien zur Kunde d. älteren engl. Dramas,* 13, Louvain, 1906), and is by him on internal evidence confidently claimed as Ford's. Of the plays by Ford preserved to us the dates span little more than a decade—the earliest, *The Lover's Melancholy,* having been acted in 1628 and printed in 1629, the latest, *The Lady's Trial,* acted in 1638 and printed in 1639.

Two works, undoubtedly those most characteristically expressive of his peculiar strength, *'Tis Pity She's a Whore* and *The Broken Heart* (both acted 1628–32), were both printed in 1633 with the anagram of his name *Fide Honor.* The first is concerned with incest; the tragedy is well worked out, and the characterization vivid. The problem in which Ford was always most deeply interested is here stated at its most acute: the conflict between overwhelming passion and the whole range of restraints which can be opposed to it. *The Broken Heart* has another vivid and sensational plot, and the pathos, if forced, is effective. The influence of Burton's analysis of the emotions, strong in *The Lover's Melancholy*, is still traceable, but few were so capable of treating them sympathetically, and yet without reckless grossness or extravagance of expression.

For in Ford's genius there was real refinement, except when the "supra-sensually sensual" impulse or the self-delusion that he possessed comic humour came into play. *Love's Sacrifice* (acted *c.* 1630, printed in 1633) is a tragedy of a similar type. *Perkin Warbeck* (printed 1634; probably acted 1635) is a chronicle play; the versification is regular, and the element of buffoonery reduced to a minimum. *The Fancies Chaste and Noble* (acted before 1636, printed 1638) and *The Lady's Trial* (acted 1638, printed 1639) are negligible. There remain two other works. of very different kinds, in which Ford co-operated with other writers, the mask of *The Sun's Darling* (acted 1624. printed 1657), hardly to be placed in the first rank of early compositions, and *The Witch of Edmonton* (printed 1658, but probably acted about 1621), in which we see Ford as a joint writer with Dekker and Rowley of one of the most powerful domestic dramas of the English or any other stage.

Ford owes his position among English dramatists to the intensity of his passion. in particular scenes and passages where the character, the author and the reader are alike lost in the situation and in the sentiment evoked by it; and this gift is a supreme dramatic gift. But his plays — with the exception of *The Witch of Edmonton,* in which he doubtless had a prominent share — too often disturb the mind like a bad dream which ends as an unsolved dissonance; and this defect is a supreme dramatic defect which has caused the neglect of this author's works in modern days.

FORD, PAUL LEICESTER (1865–1902), U.S. author, was born in Brooklyn. N.Y., on March 23, 1865, the son of Gordon Lester and Emily (Fowler) Ford. His delicate health led to his being privately educated, his tastes being formed largely by long hours spent in his father's library, then one of the finest collections of Americana in the world. The environment of a select social circle and extensive travel on both American continents and in Europe fostered and intensified his cultural interests.

At the time of his death, when but 37 years of age, he had gained distinction as an editor, bibliographer, historian and novelist. his edited works and writings totaling more than 70.

In American literature he is most famous for his historical novels *The Honorable Peter Stirling* (1894) and *Janice Meredith* (1899). He was shot on May 8, 1902, by his brother Malcolm Ford, who in turn committed suicide.

FORDHAM, formerly a village of Westchester county, New York, U S., and now a part of New York city. It lies on the mainland, along the eastern bank of the Harlem river, east of the northern end of Manhattan Island. It is the seat of Fordham university (Roman Catholic), founded in 1841 as St. John's college. and since 1846 conducted by the Society of Jesus In 1907 the institution was rechartered as Fordham university. Fordham college, the graduate school, the college of pharmacy, and Fordham preparatory school of the university are all in Fordham. The other schools are housed in two locations in Manhattan.

In Poe park. Fordham, still stands the house in which Edgar Allan Poe lived from 1844 to 1849 and in which he wrote "Annabel Lee," "Ulalume" and other poems.

The hamlet of Fordham was established in 1669 by Jan Arcer (a Dutchman, who called himself "John Archer" after coming to America), who in that year received permission from Francis Lovelace, colonial governor of New York, to settle 16 families on the mainland close by a fording place of the Spuyten Duyvil creek, near where that stream enters the Harlem river.

Between 1655 and 1671 Archer bought from the Indians the tract of land lying between Spuyten Duyvil creek and the Harlem river on the east and the Bronx river on the west and extending from the hamlet of Fordham to what is now High Bridge. In 1671 Governor Lovelace erected this tract into the manor of Fordham.

In 1846 it was included with Morrisania in the township of West Farms; and in 1872, with part of the township of Yonkers, it was erected into the township of Kingsbridge, which, in 1874, was annexed to the city of New York, and in 1898 became a part of the borough of the Bronx, New York city.

FORD MOTOR COMPANY. The manufacturer of Ford and other automobiles, trucks, tractors, Dearborn and Ford farm equipment, industrial engines, parts and accessories, and aircraft engines, the Ford Motor company has its home office at The American Road, Dearborn, Mich. It was incorporated in Michigan June 16, 1903, with a capital of $100,000. Of the original 12 stockholders Henry Ford held $25\frac{1}{2}\%$ of the stock. Later he acquired $58\frac{1}{2}\%$. In 1919 Henry Ford and his only son, Edsel B. Ford (1893–1943), acquired the remaining $41\frac{1}{2}\%$. On July 9, 1919, the company was reorganized under the laws of Delaware, with a capitalization of $100,000,000.

From July 1919 until 1956, the company was privately owned, with all stock being held by the Ford family and the Ford Foundation. On Jan. 17, 19j6, the company again became publicly owned when the Ford Foundation put 10,200,000 of its Ford Motor company shares on the market. On Sept. 21, 1945, Henry Ford II, son of Edsel B. Ford, was elected president, and the company launched on a decentralization, modernization and expansion program.

As part of its international operations, the company established manufacturing subsidiaries in England, Canada and Germany. Other subsidiaries and branches of the company had assembly operations after mid-20th century in Argentina, Belgium, Brazil, Chile, Denmark, Egypt, Finland, the Netherlands, Mexico and Uruguay. Sales subsidiaries were operating in France, Italy, Portugal and Sweden.

The River Rouge plant in Dearborn was the largest industrial unit in the U.S owned by one company, covering 1,200 ac. Within the plant are blast furnaces, open hearth furnaces, blooming mills, hot and cold strip mills, coke ovens, engine plant, assembly plant, iron foundry, stamping plant, tool and die plant, frame plant, glass plant, rolling mills and power house. The plant has its own fire department and hospital and its own telephone and telegraph exchanges. The company owns its own ore boats which bring raw materials from the upper Great Lakes region directly to the Rouge plant storage bins.

On July 23, 1903, the company sold its first car, a two-cylinder — the original Model "A." The first Model T was made on Oct. 1, 1908, and on May 26, 1927, the 15,000,000th Model T left the assembly line. The new Model A was introduced to the public on Dec. 2, 1927, and on March 9, 1932, the first V-8 Ford was built. In 1959 the company introduced the Falcon, a six-cylinder car smaller than the standard Ford.

FORDUN, JOHN OF (d. *c.* 1384), Scottish chronicler. The statement generally made that the chronicler was born at Fordoun has not been supported by direct evidence. It is certain that he was a secular priest, and that he composed his history in the latter part of the 14th century; and it is probable that he was a chaplain in the cathedral of Aberdeen. The work of Fordun is the earliest attempt to write a continuous history of Scotland. We are informed that Fordun's patriotism was roused by the removal or destruction of many national records by Edward III and that he traveled in England and Ireland, collecting material for his history. This work is divided into five books. The first three are almost entirely fabulous. The fourth and fifth books, though still mixed with fable, contain much valuable information. The fifth book concludes with the death of King David I in 1153.

Besides these five books, Fordun wrote part of another book, and collected materials for bringing down the history to a later period. These materials were used by a writer in the middle of the 15th century, who is identified with Walter Bower (*q.v.*), abbot of the monastery of Inchcolm. The additions of Bower form 11 books and bring down the narrative to the death of King James I in 1437. In addition he did not hesitate to interpolate

Fordun's portion of the work with additions of his own, and the whole history thus compiled is known as the *Scotichronicon.*

Fordun's work was first printed in Thomas Gale's *Scriptores quindecim* (vol. iii. 1691). This was followed by Thomas Hearne's (5 vols.) edition in 1722. The whole work, including Bower's continuation, was published by Walter Goodall at Edinburgh in 1759. In 1871 and 1872 Fordun's chronicle. in the original Latin and in an English translation. was edited by Wm. F. Skene in *The Historians of Scotland,* the preface of which contains full bibliographical details.

FORECLOSURE is the extinguishment by order of the court of a mortgagor's equity of redemption. In the law of equity the object of every mortgage transaction is eventually the repayment of a debt. the mortgaged property being incidental by way of security. Therefore. although the day named for repayment of the loan has passed and the mortgagor's estate is consequently forfeited, equity steps in to mitigate the harshness of the common law and will decree a reconveyance of the mortgaged property on payment of the principal, interest and costs. This right of the mortgagor to relief is termed his equity of redemption This estate is no longer merely equitable but legal. However. this has not changed its attributes. which are that it can only be defeated by the mortgagee taking possession of the mortgaged property and retaining it for 12 years without acknowledging the mortgagor's title, or by the decree of the court ordering the foreclosure of it or the sale of the mortgaged property, or by a sale by the mortgagee under his statutory powers.

A foreclosure action is brought by the mortgagee against the mortgagor in the chancery division of the high court claiming that an account may be taken of the principal and interest due to the mortgagee. and that the mortgagor may be directed to pay the same, with costs, by a day to be appointed by the court and that in default thereof he may be foreclosed his equity of redemption. In such an action the court may always order a sale instead of foreclosure. English county courts have jurisdiction in foreclosure actions where the mortgage or charge does not exceed £500, or where the mortgage is for more than £500, but less than that sum has been actually advanced. Where there is a mere charge without an agreement for a legal mortgage there is no right to foreclose; this also applies to a Welsh mortgage.

(J. A. St.; X.)

United States.—Foreclosures in the United States are typically, but not always, by an action in court based upon the pattern of an English suit of foreclosure. But, though the action was copied from England. it differs radically from the English procedure and is highly diversified among the states. Thus strict foreclosure, by which the mortgagor's interest is forfeited to the mortgagee unless the debt is paid within a time fixed by the court, is the usual form of foreclosure only in Connecticut and Vermont. In most states the routine foreclosure action includes a judicial sale by which the property is sold to the highest bidder who may be and often is the mortgagee. The net proceeds of the sale are applied on the debt and the surplus: if any, is paid to the mortgagor. If the sale does not bring enough to pay the debt, the mortgagee is awarded a judgment against the debtor for the deficiency. The foreclosure sale thus serves not only to protect the mortgagor's equity, but also to fix the amount of the deficiency judgment when the sale price is less than the debt.

Experience showed that a forced sale, even though supervised by the court, rarely produced a surplus and indeed that sometimes the mortgagee's bid of a nominal amount was the best that could be obtained. In such instances the mortgagor not only lost his security but was saddled with an excessively large deficiency judgment. To provide additional protection to mortgagors numerous statutes regulating foreclosures were enacted. especially in the western states where debtor influence was strong. Some required that the sale price equal a stated percentage of the value of the property as fixed by appraisers. Others directed that if the "fair" value of the property was more than the sale price, the fair value rather than the sale price should control the deficiency judgment. In many states the equity of redemption was supplemented by statutory rights of redemption which entitled the mortgagor and others designated by statute to wipe out the lien of the mortgage and the foreclosure sale by paying within a specified time, which varied from six months to two years, the price which had been obtained at the sale. Usually the mortgagor would be entitled to retain possession of the property until the statutory period had expired. Thus the redemption statutes gave mortgagors a chance to live undisturbed and raise another crop as well as an opportunity to canvass still further, perhaps under improved conditions, the chances of private sale or refinancing. In addition, the statutes encouraged mortgagees to bid the full value of the property at foreclosure sales.

The long time which was required to complete a foreclosure action made it possible for a mortgagor whose situation was hopeless to milk the security by letting current expenses such as taxes, insurance and repairs accumulate and squeezing from it as much cash as possible before the ax fell. To prevent this, courts would appoint a receiver to manage the property while the foreclosure was pending in court. The purpose of the receivership was to sequester the rents as they accrued so that they might be applied on the mortgage debt and to preserve the property until the foreclosure could be completed. The grounds for a receivership varied from state to state. Usually, if the mortgage contained a clause pledging rents, a showing that the security without the rents was inadequate and that the mortgagor was insolvent would justify a receivership.

A special type of receivership, called a friendly or consent receivership because the proceeding was instigated by the debtor rather than the creditors came to be the usual method by which large corporations were reorganized and new securities substituted for the bonds which prevented the business from being continued on a sound financial basis. After the 1934 and 1938 amendments to the Bankruptcy act, reorganization proceedings in bankruptcy, in which the Securities and Exchange commission had an important role. were substituted for receiverships as the usual procedure for the enforcement of large corporate bond issues.

In the 1930s moratory statutes mere enacted by many states to shield mortgagors from the hardships caused by the general collapse of the economy. Some stayed foreclosures; others extended the time for redemption; others curbed deficiency judgments. Under a 1935 amendment to the Bankruptcy act, a farmer might retain possession of his farm pending an arrangement in bankruptcy and wipe out the mortgage by paying, not the amount due on the debt or the price which might be obtained at a judicial sale, but rather the value of the farm as fixed by appraisers in bankruptcy. The serious constitutional doubts raised by these acts were largely resolved by the supreme court in *Home Building and Loan Association* v. *Blaisdell,* 1934.

Because foreclosures in court are slow and costly, mortgagees have sought informal mays to foreclose. Sometimes a deed conveying the property to the mortgagee is used in lieu of a court decree. This is simple, but the transfer requires the consent of the mortgagor and others who have an interest in the security and it must be a bona fide sale rather than an extension of time for payment of the debt. Sometimes the mortgage authorizes the mortgagee or a trustee to bar the right of redemption by selling the property if default should occur. If such sales are allowed full effect, foreclosures are easy and inexpensive. But the power to sell may be abused and in some states such foreclosures are prohibited. In others, powers of sale are valid but are regulated by statutes to prevent abuses. Some prescribe the notice required for a sale under a power; others permit redemption from the sale, others provide a summary procedure in court to confirm the sale. In a number of states, a sale out of court under a power of sale is the usual method of foreclosure. In others, though the power is recognized, it is seldom used because of the fear that titles based upon such sales are not marketable. Thus in most of the states a practical substitute for foreclosure by action in court is not available even though in the long run the high costs of such actions may really be paid by mortgagors as a class in the form oi high interest rates and other stringent credit terms.

(S. Tt.)

FOREIGN AID PROGRAMS. Economic aid from one government to another and from international organizations to governments has grown from a temporary device adopted by the western Allies in World War II to a permanent feature of international economic relations. It is sometimes called international aid rather than foreign aid. In its evolution, the experience of the United States has been dominant, although other countries have also extended such aid. The dominions, for example, aided the United Kingdom during and after the war. Commonwealth and other countries extended aid to Asian countries under the Colombo plan after 1950. Soviet aid to underdeveloped countries since 1955 has led to competition in assistance. Many states have co-operated in giving aid through the United Nations and other international organizations.

The United States has used foreign aid for a variety of purposes: to transfer military equipment and civilian supplies to Allies during World War II; to assist relief and reconstruction after the war; to buttress resistance to communist aggression, both actual and potential; to meet emergencies of many kinds, such as natural disasters; to help refugees from behind the "iron curtain"; to clear the Suez canal; and to provide technical assistance and economic aid for countries engaged in programs of economic development. The total amount of U.S. aid in the 18 years from 1940 to 1958 amounted to more than $105,000,000,000, as shown in Table I.

Lend-Lease. — Mindful of the problem created after World War I by war debts owed to the United States by European Allies, and not paid, President Roosevelt in early 1941 devised the principle of lend-lease under which the United States agreed to provide supplies to countries engaged in fighting Germany (and later Japan) on a basis to be determined after the war. The equipment might be returned, paid for or regarded as a contribution. In return, these Allies aided U.S. troops when the United States entered the war; this so-called reverse lend-lease amounted over the period of the war to 16% of the value of lend-lease from the United States. The bulk of the lend-lease transfers were settled as grants. A few ships, airplanes and similar items of equipment were returned in kind at the end of the hostilities. (See INTER-ALLIED DEBTS; WAR FINANCE: COST OF WORLD WARS I AND II.)

Relief. — Lend-lease was restricted to Allies engaged in the war against Germany and Japan. But other aid was necessary for liberated countries, both for humanitarian reasons and to prevent

disturbances in the areas through which military supply lines ran. Later, when Italy came over to the Allied side and Austria was liberated, civilian supplies were required for them. Finally, in occupied Germany and Japan, it was necessary for several years to provide minimum diets to prevent "disease and unrest in occupied areas such as might endanger United States forces."

Another quasi-military form of assistance rendered after the war by the United States was the disposal of surplus military stocks, including goods suitable for civilian use, at reduced prices and on long-term credit. Ships represented a special program of surplus disposal.

In 1943, while the war was still in progress, the United Nations (UN) created a relief organization, the United Nations Relief and Rehabilitation administration (*q.v.*) (UNRRA). The United States was the most important contributor, bearing originally 72%, later 78%, of the cost. The agency was established with money and with surplus military stocks, and operated originally in eastern Europe and China. Later, in 1946, it took over from military responsibility the relief of Austria and Italy.

After the abrupt termination of lend-lease in 1945, following the defeat of Japan, aid to United States Allies was initially expected to be given by the International Bank for Reconstruction and Development established at an international conference at Bretton Woods, N.H., in 1944. (See BANK FOR RECONSTRUCTION AND DEVELOPMENT, INTERNATIONAL.) Pending the functioning of this organization, and its sister agency, the International Monetary fund, designed at Bretton Woods to smooth out international payments difficulties, several expedients were used. The capital of the Export-Import Bank of Washington was raised by $3,000,000,000 in 1945. In 1946 a loan of $3,750,000,000 was made to Britain to assist in its reconstruction, but also to enable the pound sterling currency to become convertible into dollars.

These devices, however, proved insufficient. The extent of Europe's need had been seriously underestimated. With the removal of wartime economic controls in the United States in July 1946, prices rose so that the dollar amounts provided bought substantially fewer goods. A hard winter in 1947 compounded European difficulties. In the spring of 1947 western Europe appeared to be headed for economic collapse from which the Communist parties alone would benefit. In this circumstance, Secretary of State George C. Marshall on June 5, 1947, in a commencement address at Harvard university, indicated that if the countries of Europe were prepared to co-operate in a renewed effort toward recovery, the United States would be willing to assist. This was the origin of the European Recovery program (ERP), popularly known as the Marshall plan.

Marshall Plan. — The European Recovery program consisted of an effort by 17 countries of western Europe — broadly defined — to harmonize their recovery efforts and to indicate, on an agreed basis, what assistance would be necessary from the United States. The countries were Austria, Belgium, Denmark, Eire, France, Greece, Iceland, Italy, Luxembourg, the Netherlands, Norway, Portugal, Sweden, Switzerland, Turkey, the United Kingdom and Western Germany. An organization for European economic co-operation was created with its seat at Paris. While plans were being formulated, a program of interim aid was voted by congress. Finally, on April 3, 1948, the Economic Cooperation act of 1948 was signed, setting in operation United States aid for economic reconstruction in Europe. A total of $5,600,000,000 mas appropriated for the first 1j months (to the end of the fiscal year on June 30, 1949.) It was expected that United States aid, amounting in all to some $17,000,000,000, would be eliminated at the end of four years.

Greek-Turkish Aid. — In Feb. 1947, before Secretary Marshall's speech, the British government had informed the United States that it was unable to continue financial support to the Greek government, which was engaged in resisting communist aggression based in Yugoslavia. President Truman responded with the Truman doctrine under which military and economic assistance was made available to Greece and also to Turkey, which was similarly threatened. This was the beginning of peacetime military assistance, apart from post-hostilities aid given to forces of the Chinese Nationalists on Formosa.

Korean War. — In 1950, however, with the outbreak of aggression in Korea and the intensification of the cold war, economic aid became overshadowed by military aid, which took many forms. Loans of military equipment, patterned after lend-lease, took place on a limited scale. Military aid consisted of grants of matériel to countries struggling against aggression, particularly South Korea, French Indochina, and the Republic of China (Nationalists). The United States also assisted its western European Allies, organized with Canada and the United States into a North Atlantic Treaty organization (NATO). The NATO defense plan called for the construction of some common military installations, to which the

United States contributed. With the stationing of United States troops in the far east and Europe, a form of indirect assistance, but one not recorded as such, was the local purchase of supplies, equipment and buildings for defense or personal use by troops.

Point IV and Economic Development. — In his inaugural address of Jan. 1949, President Truman listed as Point IV of his program a plan to make assistance available from the United States to underdeveloped countries. The United Kingdom had long been helping its colonies in this manner, and the world-wide agreement to create the International Bank for Reconstruction and Development had been reached with this end in mind Export-Import bank loans which promoted U S. sales of capital equipment to underdeveloped countries were frequently related to development projects Rut with the enunciation of Point IV, a new chapter in foreign aid began.

While it was unclear at the outset what form aid to underdeveloped countries would take, emphasis quickly was placed on technical assistance, largely in the fields of agriculture, public health and education. To private capital. on a remunerative basis. was left the task of providing public structures and resources needed in industry. Some technical assistance was furnished through specialized UN agencies. including the World Health organization (WHO), Food and Agriculture organization (FAO), and United Nations Educational. Scientific and Cultural organization (UNESCO). Most, however. was provided directly by the United States on a bilateral basis, frequently through the device of contracts nith United States business and educational organizations.

Several new national and international organizations nere created or planned to contribute to various aspects of the development problem. In 1956, for example, the International Finance corporation was formed as an offshoot of the International bank. Its task nas to invest equity capital in private enterprises in underdeveloped countries. The next year the United States regularized its lending operations for development by the creation of a Development Loan fund for long-term credits. In 1958, the capital of the Export-Import bank was raised by $2,000,000,000; the UN established a Special fund of $100,000,000 annually to make grants or loans on special conditions to countries needing capital for basic projects; the Cnited States proposed an increase in the capital of the International bank, enlargement of quotas of the International Monetary fund. and the establishment of an International Development association. This last proposal was for an organization which could relend to developing countries some of the local currencies received by the United States as repayments of previous loans not received in dollars.

In 1958 the congress also increased by $2.500,000,000 the authority of the United States under Public Law 480 (1954) to make loans to underdeveloped countries in surplus agricultural commodities repayable on easy terms.

It can be seen that the character, scope and direction of the foreign-aid program of the United States have been continuously evolving — from military support during the war to reconstruction aid for Europe. then military support for Asian countries subject to aggression. and finally to economic aid for underdeveloped countries. Some idea of the redirection of postwar aid is provided in Table II

Forms. — Aid to foreign countries by the United States has consisted primarily of U.S goods and services — military equipment, civilian supplies, the services of technicians, the education of foreigners in the United States. surplus commodities, etc. But not all such aid has been of this kind. The British Ioan was made in money that could be spent anywhere. The purpose of the loan was to assist world trade through Britain by enabling the British to pay for imports from other countries in dollars. This helped the other countries with their payments difficulties. In the early stages of the Marshall plan some aid consisted in offshore purchases of goods. as, for example. in Canada or Latin America. These purchases provided goods that Europe needed and dollars sought by the seller.

Most assistance to Europe was given directly to individual countries. Some aid, honever, was made conditionally to one country provided it would agree to make certain surplus goods available to a third country. In this way both countries were assisted. This method. designed to stimulate intra-European trade, was abandoned in 1950 in favour of a loan of $526 000 000 to a nenly created European Payments union which cleared intra-European payments It provided, moreover, that if payments did not exactly balance. debtors would receive some credit. and pay some dollars, nhile creditors would receive some cash and extend some credit Since the creditors received more dollars at times than the debtors paid in, the U.S. loan was temporarily needed to balance the position

The United States has searched for opportunities to promote intra-regional trade in other parts of the world by reshaping its economic aid. It offered $200,000,000 to the Simla conference in India in May, 1955, contingent upon the Asian participants preparing an adequate plan for its multilateral use. But no agreement on such a plan could be obtained.

Conditions of Aid. — Under lend-lease, aid was given on the condition that the receiving country use it and its own resources efficiently to defeat the enemy. In addition, the countries were asked, under article VII of the lend-lease agreement, to subscribe to certain broad objectives of U.S. policy in the economic field, including the establishment of a freely trading world with equal access to materials and most-favoured-nation treatment of customers. The first condition gave rise to some difficulties of interpretation. particularly in connection with how rapidly Britain should run donn its holdings of securities, and how much it should maintain in wartime its export connections with an eye to its postnar position.

During the relief phase an objective determination of need was presumably possible. In actuality. however. the United States was reluctant to extend post-UNRRA relief to Yugoslavia, which was firing at U.S airplanes. or to Poland or Hungary after the Soviet coup in Czechoslovakia nhich intensified the cold war.

In the ERP. United States stipulated that each recipient country should co-operate with other European countries and exert a maximum effort toward its own recovery. These criteria mere again difficult to interpret. Moreover, they posed a dilemma which runs through all foreign aid: the more realistic and effective a country is in meeting its requirements, the less aid it needs, but the more it may be said to deserve. Conversely the less able a country is to meet its domestic problems, and the more ambitious its plans of expansion, the less aid it deserves, and the more it needs.

Soviet Aid. — A particular form of this dilemma was furnished by the entry of the Soviet Union into the aid field This aid was not. as a rule, in the form of grants, but consisted of low interest-bearing loans or credits in barter deals. Soviet aid to the Communist bloc mas estimated in 1958 at $7,000,000,000 (see MUTUAL

ECONOMIC ASSISTANCE, COUNCIL OF); and almost $2,000,000,000 in aid was pledged to other countries, largely to Egypt, Yugoslavia, Syria, India, Afghanistan and Indonesia. The $465,000,000 pledged to Yugoslavia, however, was held in abeyance. Soviet loans presented a dilemma for the western powers. If a country's economic needs were being met by the Soviet Union, its assistance from the west could be reduced. But this was considered politically undesirable. The receipt of Soviet aid, therefore, usually enabled a country to get more, not less, aid from the west.

Voices in the United States were raised calling for the imposition of certain conditions of aid, such as the abandonment of socialist forms of enterprise; alignment of the receiving country with the United States in NATO or the Southeast Asia Treaty organization (SEATO); membership in the Baghdad pact; or the repression of anti-American sentiments. These political conditions of aid were not enacted or enforced.

Bilateral versus Multilateral Aid.—Another recurring issue was whether aid should be given bilaterally or through international agencies. This problem goes back at least to UNRRA where the United States with one voice in 17 on the council, and bearing 72% of the cost of the program, sometimes found itself forced to make aid available against its wishes.

An entirely bilateral program is politically difficult in that it focusses all dissatisfaction with amounts of aid on the donor. For this reason the United States encouraged the preparation of multilateral programs in the ERP, and under NATO, and the British and the United States supported the creation of the Colombo plan (*q.v.*) in southern Asia. In the Colombo plan all aid is in fact conducted on a bilateral basis, between the several donors and recipients. Under the Marshall plan, there was at the same time an agreement between the United States and the Organization for European Economic Cooperation (OEEC) and separate agreements with each recipient. In the division of aid, however, the United States followed the recommendations of the OEEC.

The remaining problem, however, is between UN and bilateral arrangements for technical assistance and development loans. In the International bank and Monetary fund, the United States has put up the majority of the resources and retains a controlling voice in the operation of the fund and in the choice of the people running the bank. In the UN, it has far less share of decision-making power in the Economic and Social council (ECOSOC) or the general assembly. Meanwhile, however, the retention of bilateral arrangements for technical assistance and development loans assures the United States that foreign aid cannot be distributed entirely by a logrolling or politically dominated process in the UN contrary to its political interest or its view of the objective requirements. *See* also FOOD AND AGRICULTURE ORGANIZATION; WORLD HEALTH ORGANIZATION.

FOREIGN LANGUAGES, TEACHING OF. The technique of teaching modern languages became a scholastic battleground during the first quarter of the 20th century. Even after Wilhelm Viëtor made his famous plea in *Der Sprachunterricht muss umkehren (1886)* for methods more rational than those used in the study of Latin and Greek, the dead hand of the classics rested heavily upon modern-language teaching. The contributions of Viëtor's disciples, Paul Passy and Daniel Jones, in the field of phonetics. made teachers realize the importance of pronunciation and of an oral approach in the classroom. The idea of giving all instruction in and through the foreign language soon gained ground, and what is termed the direct method came into being. Despite its great vogue it achieved only a partial success. But its fundamental idea. that a modern language should be taught as a living tongue. has become generally accepted. The early direct methodists, in their zeal to remain true to the idea of never using a single English word in their lessons, even by way of explanation, created serious difficulties for themselves and their pupils. Brilliant specialists with selected pupils on a generous allowance of teaching time ensured a measure of success. With vastly increasing numbers of merely average pupils as a result of the great expansion of secondary education from 1918 onward, the direct method showed its failure to secure for large classes firm foundations of language structure and a sufficient amount of reading in the foreign language. Fruitless dramatization and parrotlike repetition wasted much time, with the result that the content of firm, consolidated linguistic knowledge was often much too thin. Shaky grammar deprived oral and written exercise of accuracy. Lack of reading restricted the pupils' vocabulary. Despite these criticisms. the direct method established heightened standards of pronunciation and a consciousness of the need for some knowledge of life as lived in the foreign country.

The demands of the universities, imposed through their external examinations, which pupils take while still at school, required some modification of the direct method. Teachers agreed that there could be no return to formal grammar grind and were inclined to a compromise. The compromise that eventually emerged is called the oral method. This presentation aims at teaching the subject in a realistic atmosphere. the teacher using as much of the foreign tongue as is safely possible, avoiding blurred impressions in the pupils' minds and the blankness of noncomprehension. It is held to be no crime to explain a difficulty in English, but the need for the foreign language to be the main vehicle of instruction is strenuously upheld. A good teacher, without recourse to English. can ensure comprehension by gesture, dramatization, blackboard sketches, paraphrase and the use of contrary expressions already known to the pupils. With or without the aid of phonetic script—there teachers are divided—pronunciation and intonation receive due stress, oral work is fostered from the very start and remains an integral part of every lesson, and the basic foundations of language structure, often by means of memorized colloquial patterns, are firmly laid. Thanks to American research on word frequency, teachers give much thought to the selection of vocabulary and now distinguish between their pupils' "active" and "passive" knowledge of words and phrases which come from their carefully graded course of reading material, prose and verse, designed for intensive or for rapid treatment. Written exercise aims at creating an accurate linguistic sequence through dictation. free composition, formal prose composition and translation, rather than through the wasteful *non sequitur* of unrelated sentence work. Nor is the foreign country forgotten, its songs, its customs, its geography, its people. Older pupils naturally study its literature against social and historical background.

As supplementary visual and aural aids considerable use is made of films, film-strips, libraries, modern language rooms (with posters, periodicals. *Realien),* radio lessons and gramophone records. In Great Britain and Northern Ireland a fine contribution comes from a scheme by which young "assistants" give part-time service for one year in British schools before teaching English in their own country. Exchanges of experienced teachers on a full-time basis are also effected. Many schools organize collective holiday visits. particularly to France and Germany. Of even greater value are individual exchanges of pupils, the linking of foreign schools with their British counterparts, and correspondence.

U.S. Practice.—Between 1870 and 1925, methodologists and teachers of French, German, Spanish and later Italian, advocated six different methods. By 1917 only three survived: the grammar-translation, the direct method and the compromise or eclectic, a combination of the best features of the preceding methods. In 1901, the *Report* of the Committee of Twelve standardized the teaching of foreign languages in the high schools. The first two years of five periods a week were called elementary; the third intermediate; and the fourth advanced. It proposed a fourfold aim: speaking, understanding, writing and reading. the last of which was considered the most attainable. Only the direct-method proponents insisted on the oral-aural approach. Their contentions were borne out temporarily with the advent of World War I when the U.S. government had to encourage the establishment of courses in which large numbers of soldiers and employees were trained to really speak and understand the languages studied.

Later, because of the general dissatisfaction with the results in the teaching of foreign languages, the American Council of Education and the various language associations sponsored a national investigation (1924–27). More than 30 volumes (*The Modern Language Study*) were published from 1927 to 1937 under the chairmanship of Algernon Coleman. Finding that 87% of the students only pursued language study for two years, he reasserted the reading aim with a new reading method. The majority of the teachers opposed him and maintained the superiority of the oral-aural approach even for the reading aim.

J. Milton Cowan of the American Council of Learned Societies directed the setting up of intensive language programs which were developed and improved by the army and navy schools in World War II. Their main characteristics were: (1) insistence upon small drill sections with a native speaker or an informant, for 15 to 20 hours a week instead of the usual five; (2) grammar reduced to a minimum; (3) less emphasis on reading and writing. The army added area studies, to acquaint students with the geography, history and customs of the country of the language studied. Slavic and oriental languages were now included.

In spite of their enthusiasm over the success of these concentrated courses of six to eight months equal to four to eight years of the traditional classes: the schools and colleges were unable to adapt them to existing programs. Some institutions like Yale university. Adelphi College (Garden City. N.Y.) and Georgetown university (Washington. D.C.) continued to keep them as parallel courses to the regular language work.

Nevertheless, language teaching had become enriched with more oral-aural training and various kinds of audio-visual materials: phonograph records, radio. projectors, motion pictures, magnetic tape recorders. By the mid-1950s foreign language teaching was begun in more than zoo elementary schools.

FOREIGN LEGION: see LEGION.

FOREIGN SERVICE. Foreign affairs are of such vital importance to nations that they are a primary concern of the highest levels of government. Professional foreign services. therefore, have been established to represent the home government's interest abroad and to provide the necessary information on which foreign policy is based.

There is a marked similarity in the foreign service organizations of most countries. Diplomatic and consular functions are generally performed by a single service which is expected to serve at home or abroad, enabling interchangeability of consular and diplomatic officers (see CONSUL and DIPLOMACY). The merger of the two functions came about when many European countries. beginning with France in 1880. recognized that the consular service, although less dependent on ceremony and prestige, could not be entirely separated from diplomatic affairs. With the passage of the Rogers act in 1924 the United States followed suit as did the United Kingdom with the promulgation of the so-called Eden reforms of 1943, which combined the diplomatic, consular and commercial diplomatic services into a single foreign service. The United Kingdom had already in 1919 established the interchangeability of personnel in the foreign office and in the diplomatic corps serving overseas following the report of a royal commission on the civil service, 1912–14. The United States was slower to integrate officers in its foreign service, serving primarily abroad, with civil servants in the department of state; and a vigorous "integration" program was not forthcoming until the adoption during 1954–56 of the proposals of the secretary of state's public committee on personnel. headed by Henry M. Wriston.

Recruitment. — Beginning in the middle of the 19th century steps were taken in most countries to establish a professional corps with entrance open to young men and women by competitive examination, advancement by merit and retirement by law at specified ages through a rigorous "selection up or selection out" procedure. Personnel are generally commissioned as foreign service officersand classified into established grades according to salary. Promotion is by commission to a higher class rather than by appointment to a post of higher salary grade.

Although diplomatic officials were once members of royal or noble families and served as the personal representatives of sovereigns who wielded supreme power in kingdoms or empires. private wealth and political connections are no longer essential for a professional foreign service career. When governmental authority came to reside in institutions other than monarchs, diplomats (or diplomatists in British usage) became the representatives of the government in power. As such. they were for a long time drawn primarily from wealthy governing and aristocratic classes. Prior to World War I candidates for the British diplomatic service, for example, had to show that they had an independent income. In the United States, despite the absence of an aristocracy or governing class, wealth and political connections were once important prerequisites owing to low salaries and meagre representation allowances; and in France of the third republic the diplomatic service remained largely in the hands of prosperous upper middle-class citizens and those members of the aristocracy whose wealth remained relatively intact. In imperial Germany and Russia the diplomatic services were almost exclusively in the hands of the aristocracy and high reserve officers of the army and navy. Conditions did not markedly change until after World War I although competitive examinations, notably in Great Britain as early as 1871, made professional competence also a criterion of selection.

More and more, however. recruitment was placed on a broad and democratic basis with the important qualification that a high degree of education and intellectual ability came to be regarded essential, The modern foreign service officer is almost inevitably a university graduate of superior talents who draws sufficient salary and allowances to maintain a relatively high standard of living. Required intellectual and personal standards no longer imply a class bias because the implications of a university degree have been modified sharply by governmental and private scholarship programs. Whereas traditional diplomacy was once the prerogative of the privileged few, it became the responsibility of an elite that is professionally trained and drawn from many segments of society. The means of selection necessarily differ from country to country, however. and generalizations are particularly risky with respect to communist totalitarian states.

Status. — Foreign service officers adhere lo rules and customs that are of long standing and have proved indispensable to governments in conducting their international relations. Modern practice dates principally from the congress of Vienna in 1815 and immediately subsequent congresses, and includes the category of diplomats (ambassador, minister and chargé d'affaires, etc.) and rules of precedence. which depend for all occasions on the priority of the ambassador's appointment to his post in the country to which he is accredited. Several newly established nations, in an effort to disassociate themselves as much as possible from a distasteful past. once sought to dispense with much of the custom and some of the rules of established practice, only to fall in step as experience suggested the utility of generally accepted standards. In varying degrees, for example, this development took place in the newly established United States, in republican France and Soviet Russia.

Under international law and usage personnel in missions abroad (usually embassies, legations and consulates), including members of their households, are immune from the jurisdiction of the government to which they are accredited, and the mission itself has the status of extraterritoriality and as such is considered legally a part of the home country. Personnel may not be sued in civil action or compelled to testify as witnesses, or compelled to pay taxes to the host country. Their official position does not sanction the evasion of private debts, however, and their private property is subject to local municipal law. An officer or staff member who does not conform to local regulations or who is otherwise unacceptable to the government to which he is accredited may be declared unacceptable (persona non grata) and his recall requested, a demand that is invariably obeyed. Accreditation of ambassadors or other chiefs of mission is handled in accordance with internationally accepted procedures, but appointment of both ambassadors and other officers follows the constitutional practice of individual states. In the United States the president, usually with the advice of his secretary of state, nominates a candidate who must then be confirmed by a simple majority of the senate. In the United Kingdom the foreign secretary, with the assent of the prime minister, submits the name of the candidate to the crown, and approval constitutes ratification of the appointment.

A guild spirit tends to characterize all foreign services as a legacy of the past and as a consequence of circumstance. The various services are small in comparison with home civil services, and entrance requirements are both differentand generally more rigorous. Service for the most part is abroad and involves both hardships and rewards not characteristic of other careers. Above all, foreign affairs involve the interplay of national interests including matters of state not infrequently of the highest importance. Since French is no longer the sole language of diplomacy, foreign service officers usually learn several tongues during the course of their careers. Traditionally foreign affairs were relatively distinct from domestic concerns, and diplomats inevitably stood rather apart from the main stream of national life. When the obligations of service and the skills required are taken into account, including knowledge of languages, economics, politics, science and sociology to name but a few, it is no wonder that foreign service personnel regard themselves as a dedicated elite. Like members of the armed services they are subject to assignments that may on occasion be difficult or even distasteful, and they must bring to their task not only highly trained knowledge but unfailing loyalty and devotion. They can never escape the responsibility of maintaining their country's dignity and prestige in both official and private life, and they are inevitably conscious that foreign policy is the first line of defense.

Nonetheless, although a corporate spirit continued, a foreign service career changed somewhat from what it was prior to World War II. Service abroad is scarcely as remote as it was prior to air transportation. Foreign and domestic affairs are no longer considered to be unrelated, and minimum periods of service in the home country are generally required so that diplomats may effectively represent their country's interests abroad. Foreign policy must run the same course as domestic policy in its formulation, and, in the United States, foreign service officers maintain close relations not only with the state department but with other governmental agencies and with members of the congress itself. A modern diplomat, in short, executes national policy that often involves both foreign and domestic considerations and which is formulated with regard to its economic, military and political ramifications.

It is sometimes asserted that professional diplomats do not make foreign policy. This is true only in the sense that they carry out foreign policy without hesitation once it is established by the national government. But it is equally true that reports from the field and judgment placed on reported facts by individual officers are highly influential in shaping policy, particularly since the views of a foreign minister in any government are heavily dependent on the information presented to him by his "desk" officers. To conceive of foreign service officers as messenger boys walled off from important decisions is to misconstrue the case. How they influence policy, however, varies considerably from country to country.

U.S. Foreign Service.—The foreign service of the United States was established on a professional career basis by the act of congress of May 24, 1924, and was reorganized with the passage of the Foreign Service act of 1946 and subsequent amendments and executive orders providing for the classification of officers including career ministers; the establishment of certain branches including a foreign service reserve which is composed of specialists serving for limited periods of time, and a foreign service staff which provides technical and clerical services; and the creation of the Foreign Service institute to train personnel progressively throughout their careers. The service is administered by a director general and the board of the foreign service including, in addition to state department officers. representatives from the agriculture, commerce and labor departments which are also served by the service.

Admission is open to United States citizens, both men and women, who take competitive examinations, usually for the lowest grade depending upon age levels. They serve in the state department as permanent career officials under the direction of the secretary of state, who is the senior member of the president's cabinet, and his undersecretaries and assistant secretaries who, like their chief, are political appointees of each presidential administration. (See GOVERNMENT DEPARTMENTS: Department of State.)

British Foreign Service. — The modern British foreign service was established by the Eden reforms of 1943 as noted above. In addition to unifying all main branches of foreign affairs work, the reforms provided for changes in recruitment, training and pay so that the service was opened to wider competition among men and women of outstanding ability. Four branches of the service were established, each containing several grades: branch A is the senior and political branch, providing the ambassadors, ministers, counselors. secretaries, senior consular personnel and the higher officials of the foreign office; branch B includes personnel of junior grade who enter by less rigorous examinations. who may compete for promotion to branch A and who perform both technical assignments and consular work; branches C and D include typists, messengers and comparable personnel who receive appointment by appropriate civil service examinations. With the exception of branch D which serves abroad, personnel in all branches are liable to service at home or overseas. In-service training is provided, and pensions and allowances permit suitable standards of living. Nowhere is the foreign service more highly professional or more respected than in Great Britain. Although deliberately differentiated from political appointees, such as the foreign minister (secretary of state for foreign affairs) and two assisting parliamentary ministers, called minister of state and parliamentary undersecretary of state respectively. members of the career service hold crucially important administrative positions, including the post of permanent undersecretary for foreign affairs. who is chief adviser on foreign policy and administrative head of the foreign service. Important diplomatic assignments likewise go normally to the most highly qualified members of the permanent service who, under the foreign minister's instructions, carry out foreign policy for which the cabinet is collectively responsible to parliament. The permanent officials, however, do not assume public responsibility for governmental policy, and questions or attacks in parliament are directed at the ministers and not at members of the foreign service. For a historical discussion of the British foreign office, see GOVERNMENT DEPARTMENTS.

FOREKNOWLEDGE: see FREE-WILL.

FOREL, FRANÇOIS ALPHONSE (1841–1912), Swiss geographer and doctor chiefly remembered for his studies of the natural phenomena of the Lake of Geneva, or Lake Léman, was born at Morges on that lake on Feb. 2, 1841. While teaching physiology and anatomy at Lausanne university, he prepared *Le Léman* (3 vol., 1892–1904).

On the science of limnology his standard work is *Handbzrch der Seenkunde* (1901); in this connection his investigations of the previously mysterious movements of lake waters known as seiches are important (see GENEVA, LAKE OF; LAKE). Forel's other researches include work on seismology and on Swiss Alpine glaciers. Forel died at Morges on Aug. 7, 1912.

FORENSIC PSYCHOLOGY: *see* PSYCHOLOGY, **APPLIED.**

FORESHORE is defined as "the shore and bed of the sea, and of any tidal water, below the line of the medium high tide between the spring tides and the neap tides" (Limitation act, 1939, s. 31). In Great Britain, the property in it normally and prima facie vests in the crown, except where it may vest in a subject by ancient grant or charter from the crown, or by prescription from which a grant may be presumed. It forms part of the adjoining county, whose justices have jurisdiction over offenses committed there, whether it is covered with water at the time or not. (*Embleton* v. *Brown,* 1860, 3 E. & E. 234). It also forms part of the adjoining parish. (R. v. *Gee,* 1 E. & E. 1068). The Public Health act, 1936, ss. 231–234, deals with the powers of local authorities to make by-laws for public bathing and allied purposes.

The chief acts showing title to foreshore are taking wreck or royal fish, right of fishing, mining, digging and taking sand, seaweed, etc., embanking and enclosing. There is a public right of user in that part of the foreshore which belongs to the crown for the purpose of navigation or fishery, but there is no right of passage over lands adjacent to the shore, except by a particular custom. So that, in order to make the right available, there must be a highway or other public land giving access to the foreshore. Thus it has been held that the public have no legal right to trespass on land above high-water mark for the purpose of bathing in the sea, though if they can get to it they may bathe there (*Blundell* v. *Catteral,* 1821, j *B.* & Ad. 268).

There is no right in the public to take sand, shells or seaweed from the shore, nor, except in certain places by local custom, have fishermen the right to use the foreshore or the soil above it for drawing up their boats, or for drying their nets or similar purposes. Improvements made by a tenant under the Landlord and Tenant act, 1927, must not infringe the rights of the public. As to registration of land comprising foreshore. *see* c. 21 of 1925, s. 97. (For foreshore protection *see* BREAKWATER.) (X.; W. T. Ws.)

In the United States, until 1947, the foreshore was considered to belong to the coastal state rather than to the federal government. The United States supreme court had stated in 1845 the rule which was to prevail for more than a century: "The shores of navigable waters, and the soils under them, were not granted by the Constitution to the United States, but were reserved to the States respectively."

However. in 1947 the supreme court decided against California in the federal-state controversy over rights to tidelands oil, holding that the federal government had paramount rights and power over the resources of the soil under the water area three miles from shore. Similar suits were decided against Louisiana and Texas in 1950.

Congress overrode these supreme court decisions in 1953 by passing the Submerged Lands act, which restored to the coastal states full rights of ownership to the foreshore and lands under territorial waters, subject only to the federal powers of regulation and control of the said lands for purposes of commerce, navigation, national defense and international affairs, all of which are considered paramount to, but not to include, proprietary rights of ownership. (C. M. FN.)

BIBLIOGRAPHY.—S. A. Moore, *History of the Foreshore end the Law Relating Thereto* (1888); H. J. W. Coulson and U. A. Forbes, *Law of Waters* (1902); *The Dictionary of English Law,* vol. 1.

FOREST LAWS, in medieval England, were laws applicable to land converted by exercise of the royal prerogative into a "forest," in which game mas preserved. Whereas an offender against the ordinary game laws was punishable by the courts of common law, an offender against forest laws was punishable in special courts. Trials took place in the swanimote, held three times a year, where freeholders within the forest did suit and of which the verderers mere the judges, on charges presented by the foresters in the woodmote, held every 40 days. Judgment, however, only took place in the justice seat, held by one of the two chief justices for the forest every three years.

The land within a forest might be owned by anyone, but rights of ownership were so restricted by the forest laws that constant complaint of hardship was made by landowners in and near the forests. The forest laws were among the grievances which united the barons and people against John. They were dealt with by Magna Carta but the first forest charter was Henry III's, in 1217, by which land afforested under Richard and John became purlieu, subject to forest law as it affected nonoviners of the land, but (subject to certain protection for the king's wild beasts) disforested for the landowners. Charles I revived the forest laws to extort revenue, but in 1640 parliament confined forests to their limits as in 1623. After the Revolution (1688) the forest laws fell into complete disuse.

FORESTS AND FORESTRY. The word "forest" has not always had its modern meaning. Toward the end of the 8th century A.D.. it denoted the royal woods in which the right to hunt was reserved by the king. although the right to cut wood and to clear for agricultural use or for pasture remained free to all. A century later it referred to a large tract including woods, pastures and even whole villages in which the rights of chase were reserved to the king. while other rights of use were limited. The famous forests of old England were tracts of this kind set aside by the Norman kings.

Eventually the royal hunt prerogative waned, the old legalistic meaning disappeared, and forest came to refer to wild land covered mainly by tree growth rather than meadows and fields. Forests are defined by the Food and Agriculture Organization of the United Nations (FAO) as "all lands bearing vegetative associations dominated by trees of any size, exploited or not. capable of producing wood or of exerting an influence on the local climate or on the water regime." Lands from which forests recently have been clear cut or burned out but which will be reforested in the near future are included, but not brushlands, groups of trees outside the forest or trees along roads, on agricultural lands (such as orchards) and in parks.

This article is divided into sections and subsections covering the principal aspects of forests and the science of forestry. In addition to the cross references to related articles given throughout this article *see* ARBORICULTURE; LUMBERING; TIMBER; and TREE. Additional information about diseases and pests will be found in the articles ENTOMOLOGY: *Applied Entomology* and PLANT AND PLANT SCIENCE. The various species of trees are treated under their individual titles. The economic role of forests is indicated in articles on individual states and countries.

Following are the main divisions of this article:

I. FORESTS

1. Forest Values.—Several aspects of the modern concept of the forest deserve emphasis. It is essentially a community, in which trees are the dominant form of vegetation but in which other plants, animals and the soil all play an important role. Trees, shrubs. herbs, fungi, insects, birds, mammals, worms. the humus in the forest floor and the organic matter in the soil all are an integral part of the forest and all react on each other. Like any other community—a city, for instance—a forest is an organism which is much more than the sum of its individual constituents. Also, like most communities, it produces a wide variety of goods and services. Of these the most conspicuous is wood nith its many derivatives and manufactured products; but such minor forest products such as turpentine, tar, pitch, naval stores, rubber, cork, tanbark, dyestuffs, maple sirup, lac and oils are also important. They are estimated by FAO to have an annual value of between $3,000,000,000 and $4,000,000,000, or more than a tenth of the estimated value of primary wood products of approximately $30,000,000,000. Of the latter value, 51% was contributed by lumber. 31% by pulpwood and 7% by fuel.

Among the important services rendered by the forest are control of soil erosion, protection of watersheds, amelioration of local climate and the provision of opportunities for physical and mental recreation and spiritual inspiration. The forest canopy breaks the force of violent rainfall on the soil. The decaying leaves and twigs make the soil more porous and, therefore, a more effective reservoir for the storage of water. The layer of humus which the leaves form delays and reduces surface runoff by preventing the formation of drainage rills and by absorbing large quantities of water, which seeps slowly into the underlying soil. Furthermore, the roots of forest trees help to hold the soil in place.

Much difference of opinion exists as to the influence of forests on the broader aspects of climate. which is controlled chiefly by latitude, elevation and meteorological forces that operate over wide areas. There is, however, general agreement that they reduce wind movement, moderate the temperature of the air, particularly in summer, increase the relative humidity of the air and reduce evaporation from the soil both under their immediate cover and to some distance in their lee. The net effect of these influences is to temper the local climate so as to add to man's comfort and to increase crop production in the lee of shelter belts.

Forests provide attractive opportunities for hunting, fishing, picnicking, camping and other forms of relaxation. They are a recreational asset that increases in value as increasing urbanization, industrialization and the mounting tensions of modern life create a need to "get away from it all."

2. Forest Resources.—Forests constitute one of the most prominent geographic features in the world. They are broadly restricted to parts of the earth where the winter season is not so long and cold as to make tree growth impossible. In general, these areas have an average temperature of at least 50° F. for the summer months. Within the zone of favourable temperatures, the occurrence of forests is sharply limited by precipitation, but the limiting amount is difficult to define since it varies with temperature and length of the growing season. Thus, the tropical forests require more water than those of the far north. In the temperate zone, where the subject has been most completely studied, about 16 to 20 in. of annual rainfall seem to be necessary for forests to exist on the well-drained uplands.

By the second half of the 20th century, forests occupied 29% of the land area of the world; another 23%, much of which was once forested, was devoted to agriculture; and 48% consisted of brushlands, deserts, mountain tops, towns and cities, roads, etc. The percentage of the world's forest area which occurred in each of the seven broad regions recognized by FAO is shown in Table I, as is also the percentage of the total land area in each region occupied by forests.

Latin America and Africa together accounted for 44% of the total forest area, the U S S.R. and North America (Canada and the United States) for 3674. and Europe for only 4%. Within regions. Latin America. the U.S.S.R. and North America were well above the average for the world as a whole, while Europe, Africa

and Asia were slightly below, and the Pacific area far below, that average. The reduction in the original forest area as a result of settlement and cultivation has been greater in Europe than in any other region.

By the second half of the 20th century less than one-half of the forest area of the world (47%) was accessible, and of the accessible area less than two-thirds (63%) was in actual use. In other words, the world's entire production of wood for fuel and industrial use was coming from 30% of its forest area. Figures for the different regions are given in Table II. The U.S.S.R. had both the largest area of accessible forest and the largest area in use. Latin America had the largest total forest area, but only 37% of this area was accessible and only 9% in use. In Europe 98% of the total forest area was accessible and 96% in actual use.

From the point of view of composition, the forests of the world are divided into two main classes—conifers, often called softwoods, and broadleaf trees, often called hardwoods, although many of the species are softer than some of the conifers. The broadleaf trees in turn are divided into temperate hardwoods and tropical hardwoods, which commonly differ markedly in the character of their woods. There are extensive areas in which conifers and temperate hardwoods occur in mixture.

The percentage of the total forest area in the various regions occupied by coniferous forests and broadleaf forests is shown in Table III. The preponderance of broadleaf forests in the world as a whole, and of coniferous forests in the northern hemisphere, is striking. Particularly noteworthy is the scarcity of coniferous forests in Latin America and their virtual absence in Africa. In spite of the fact that conifers comprise only a third of the forests of the world, 53% of the forests in actual use consist of coniferous trees. This situation results from the fact that conifers are in

general preferred to broadleaf trees for such purposes as construction, transport, timber fabrication and pulp, and that they occur chiefly in regions of relatively high industrial development. Economic and cultural progress in the less-developed regions, and technological progress in the use of broadleaf trees for a wider variety of industrial products, are bound to bring about a steadily increasing utilization of the tremendous area of broadleaf forests, still largely inaccessible and unexploited.

3. Growing Stock, Growth **and** Drain.—Statistics concerning the amount of standing timber—growing stock—in the forests of the world are even less satisfactory than those for forest area. In large areas, particularly in the tropics, no systematic sampling has been done, and methods of estimation vary widely. On the basis of the best obtainable information, FAO has estimated that the total growing stock in forests in use is 121,000,000,000 cu.m. (1 cu.m. = 35.3 cu.ft.) with bark. Only fragmentary figures are available for forests not in use.

Large but unknown volumes, chiefly of hardwoods, occur in regions where the percentage of forest in use is low. Latin America, for example, has 23% of the total forest area of the world but only 8% of the growing stock in forests in actual use, with large reserves in unexploited forests. Conifers comprise 55% of the total growing stock in forests in use and nonconifers 45%. Stands per hectare (2.471 ac.) average respectively 90 and 85 cu.ft., with an average for all species of 88 cu.ft. The stand per hectare is considerably higher in the U.S.S.R. than in Europe and North America, in all of. which coniferous forests predominate, because of the higher proportion in the U.S.S.R. of trees that are mature or nearing maturity.

The growing stock of marketable species of trees of merchantable size controls the amount of material available for current exploitation. The growth which takes place on the smaller timber, and on the young trees which follow the cutting of mature stands, controls the amount of material that will be available for future exploitation. Accurate information on both growing stock and growth is therefore essential for intelligent forest management. Gross growth in the forests of the world in use is estimated by FAO at 2,400,000,000 cu.m. (with bark) on the basis of the incomplete and often noncomparable information at its disposal. This figure represents 2.4% of the total growing stock in forests in use, with 45% in the form of conifers and 55% in nonconifers.

Net growth, which represents the amount of wood actually available for utilization, is determined by subtracting losses from fire, insects, diseases, windstorms and other causes from the gross growth. In Europe, where climatic conditions are favourable and the standard of forest management is high, natural losses are estimated at about 5% of gross increment. In the United States, including coastal Alaska, the forest service estimated at the beginning of the second half of the 20th century that losses due to mortality over a period of years averaged about 20% of the annual gross increment, plus a large additional loss due to the deterioration of standing timber. Similar figures are not available for other regions.

FAO estimates placed the annual removal of wood (without bark) from the forests of the world in use at about 1,400,000,000 cu.m. This figure was lower than actual removals since it did not include unrecorded and illicit fellings in countries for which no official estimates had been made. Industrial wood comprised 54% of all removals and fuelwood 46%. Conifers contributed 78% of the industrial wood but only 27% of the fuelwood.

Source: Adapted from UN Food and Agricultural Organization, *Yearbook of Forest Products Statistics* (1957).

More detailed estimates are given in Table IV. Two-thirds of the total removals came from North America, the U.S.S.R. and Europe. Industrial wood comprised 84% of the total, with the same three regions leading in the same order of importance. Fuelwood comprised 90% of total removals in Africa, 84% in Latin America and 62% in Asia. Per capita consumption of roundwood, sawnwood, plywood and paper was considerably greater in North America than in any other region.

Sawnwood (chiefly lumber) has long been the most important forest product in terms of both volume and value. During the decade from 1947 to 1956, however, its production was relatively stationary as compared with that of plywood, which increased 237%, and that of wood pulp, which increased 84%, in a group of major-producing countries. Although the use of fuelwood tends to decline as greater use is made of mineral fuels and hydroelectric power, it continues to be an important forest product in all regions. Moreover, the reported production is undoubtedly an underestimate since many removals are not reported and much fuelwood is derived from other sources such as residues from logging and manufacturing and salvage from buildings and fences.

The steadily increasing use of wood resulting from an expanding population and a rising standard of living tends to put a severe strain on the forest resources of the world. Although fully reliable information on the subject is lacking, FAO, in a report on the world's forest resources, concluded that growth and drain were about in balance in the 600,000,000 ha. of coniferous forests in use, and that growth somewhat exceeded drain in the 540,000,000 ha. of broadleaf forests in use. On the other hand: the management of a large part of the forests of the world leaves much to be desired from the standpoint of their ability to meet permanently a continually mounting demand for timber products.

Such information as FAO has been able to obtain indicates that by the second half of the 20th century only 27% of the total area of forests in use was being managed under working plans. The estimates ran from lows of 6% in Latin America and 13% in Africa to highs of 42% in Europe and 54% in Canada and the Pacific area. Cutting practices for the world as a whole were described as good for 25% of the forests in use, fair for 35% and poor or destructive for 40%. Wide differences, of course, exist between countries and individual properties. In Sweden and Switzerland cutting practices were said to be good in 90% of the forests in use, as compared with 15% in Spain and 13% in Argentina. If properly handled, the forests already in use and those still to be exploited, in spite of the relatively poor quality of many of the latter, could support a much heavier drain than that to which they have so far been exposed.

4. World Trade.—International trade in timber products is active. In 1956, for example, estimated exports of industrial wood, as a percentage of removals, ran from 3% in the U.S.S.R. (1955) and the Pacific area to 39% in Europe and 40% in Africa. Much of the trade for Europe was intraregional, while practically all of that for Africa was interregional. European exports were valued at $2,461,000,000 and African exports at $119,000,000. North America was not far behind Europe, with total exports of $1,970,000,000. Both Europe and Africa were also heavy importers of timber. Only North America and the U.S.S.R. were net exporters.

Coniferous species comprised the bulk of the world trade in sawnwood, with Canada the largest exporter. World trade in broadleaf species was, however, increasing and constituted 10% of world exports in 1956. The leading exporters of plywood were Japan, Finland and Canada. In the same year Sweden accounted for 33% of world exports of wood pulp, Canada for 28% and Finland for 17%. The United Kingdom and the United States were the heaviest importers: with well over half of the total. The main lines of trade in wood pulp are from Canada to the United States and from northern European countries to western Europe.

5. Ownership.—Information as to forest ownership is fairly complete for Europe, the U.S.S.R. and North America, but far less so elsewhere. In the less-developed regions, and particularly in the remoter areas, considerable tracts of forest are unmapped, unsurveyed and without established titles. This situation reflects

both lack of knowledge as to the location and extent of the forest resources and failure to appreciate their future, if not present, value. The division of ownership among different classes of owners as reported to FAO for the accessible forests of the world is presented in Table V.

For the world as a whole, 78% of the accessible area was in state and communal ownership and 22% in private ownership. The U.S.S.R. was the only region in which the entire area was in public ownership, although Africa and Asia were not far behind. Private ownership was most conspicuous in Europe (54%) and North America (49%). The division of ownership between different classes of owners varied widely by countries within any given region. In Europe, for example, private owners held none of the accessible forest in Bulgaria, 12% in Poland, 64% in France and 96% in Portugal. In Latin America, private ownership amounted to 17% in Colombia. 49% in Mexico and 93% in Paraguay. In many countries, including the U.S., private holdings are often in tracts of such small size as to make intensive management difficult.

II. FORESTRY

1. Beginnings **of** Forestry.— Planned management of forests with the aim of perpetuating and improving them is a relatively new development. From earliest times, man's activities have tended to reduce the area occupied by forests and to impair their productivity. Large areas were burned, often repeatedly. to improve hunting; fire, girdling and cutting were used to clear the way for farms and pasture; and heavy inroads were made for fuelwood and construction material.

The process of destruction and deterioration was encouraged by the almost universal belief that the forests were inexhaustible. if not in the immediate vicinity of settlements, at least regionally and for the world as a whole. Forests were often a nuisance, and where they were clearly an asset lavish use was the order of the day. Always beyond the horizon were untouched resources. Even at mid-20th century the 70% of the world's forest area that is not in use because of inaccessibility, or for other reasons, helps to maintain the myth of inexhaustibility.

Nevertheless, local shortages of wood long ago led to occasional, usually ineffective, action to assure future supplies. About 450 B.C. Artaxerxes I attempted to restrict the cutting of the cedars of Lebanon. Efforts to prevent the use for other purposes of trees suitable for ship timbers were made in the time of the Roman empire and much later in England. During the 12th and 13th centuries, in Germany, more drastic restrictions were imposed, such as limiting the amount that could be cut by each family and prohibiting the use of live trees for fuel. As time went on, the practice of leaving seed trees, making cuttings so as to avoid wind throw of the remaining trees, and other applications of good sense to the management of the forest began to make their appearance.

Then in the middle of the 18th century a sudden change in attitude and practice occurred in central Europe. Among the factors responsible for the change were local timber famines resulting from the destruction accompanying the wars of the 17th century, the gradual shift of interest from game to wood as the chief product of the forest, and the growth of a group of writers and state officials known as cameralists who were essentially political economists interested in the money-making capacities or public revenue of the principalities with which they were connected. Books dealing with many phases of forest production began to appear, and both public and private landowners became active in developing the capabilities of their lands. During the next century the movement toward modern forestry steadily gained momentum in Europe and spread to other parts of the world, particularly those most affected by the Industrial Revolution.

2. Modern Forestry.— Forestry has been defined in many ways. In essence. it is the management of forests and forest lands for the continuous production of goods and services. It is an art based on scientific information applied with due regard to economic and social considerations. The biological. physical and social sciences, mathematics. engineering and even philosophy all make substantial contributions to its successful practice. It has. in short, developed into a profession for which a broad and intensive training is required.

Several features of forestry deserve emphasis. It deals with production as well as exploitation, with the future as well as the present. with services as well as goods and with intangible and social as well as tangible and economic values. It must compare the value of products and services for which there is no common measuring stick, such as the lumber and pulp produced from wood and the pleasure and inspiration afforded by recreation; and it must convert anticipated returns into present worth. This responsibility requires foresight and sound judgment in the development of plans and technical skill in their execution.

Two important aspects of modern forestry are multiple use and sustained yield. Multiple use means the management of any given area (usually an administrative unit of considerable size) for several different purposes, such as timber production. watershed protection and recreation. Since some uses are incompatible under certain conditions. and since maximum yields from all uses are a physical and biological impossibility, a decision must be reached as to which uses shall be given priority. In effect, this means determining the use or combination of uses to which the different parts of a forest are best adapted in the light of the natural environment and of economic and social considerations.

Sustained yield implies the continuous production and use at a given level of some product such as wood or wildlife, or the maintenance without impairment of some service such as watershed protection or the values afforded by wilderness and other recreational areas. Of major importance is the level at which the yield is to be sustained, with constant pressure for higher and higher levels as population increases and standards of living rise. The technical difficulties of attaining such higher levels for products and services of various kinds mount rapidly and complicate the problem of multiple use.

The first steps in placing a forest under management are to establish its boundaries, to map its topography and other physical features. to determine the kind and amount of its various resources and to provide for its protection from fire, insects and disease. These are basic activities that must be undertaken whatever the specific objectives of the owner.

3. Forest Protection.— The danger from fire varies widely depending upon the climate and the nature of the forest. Coniferous forests. for example, burn more readily than broadleaf forests. Fires are virtually unknown in the tropical rain forests but are common even in broadleaf forests wherever there is a long, dry season. as for example, in parts of Latin America and Africa. The danger is slight where the forest is broken into small, more or less isolated holdings, as is the case in much of central Europe. On the other hand, it is great in the broad coniferous forests of North America and Asia, where conflagrations are not uncommon, particularly in portions subject to thunderstorms accompanied by little rainfall.

In much of the world. fire is still regarded as the most serious enemy of the forest. Although there are circumstances under which it may prove a useful tool in forest management, when out of control it kills and weakens trees of all sizes, destroys wildlife, paves the way for attack by insects and diseases, results in deterioration of the soil and increased surface runoff of water and reduces recreational values. Protection from fire is. therefore, an essential part of forestry and a prerequisite to the actual management of the forest resource. Much progress is being made in determining the conditions under which fires occur most commonly and under which they spread most rapidly, and in the more effective use of mechanical machinery, chemicals and airplanes in their suppression. Less progress is being made in the prevention of fires, the great bulk of which are caused by human carelessness.

Insects and diseases are other enemies that must be controlled, particularly as the resources at stake increase in value. Even normal, endemic populations may cause serious losses,. and the danger becomes acute when these populations swell, often rapidly, to epidemic proportions. In North America forests have been virtually wiped out over vast areas by bark beetles and by the spruce budworm, while the imported chestnut blight has completely eliminated the native chestnut as a commercial species. The forest service estimates that by the second half of the 20th century the mortality on commercial forest lands in the United States caused by insects and diseases was, respectively. more than four times and more than three times that caused by fire: with still larger additional losses of wood from heart rot in living trees.

Methods of protection vary widely depending on the characteristics of the particular organism involved. Leaf-eating insects such as the spruce budworm and the hemlock looper can be controlled by spraying with poisons from airplanes, but bark-boring beetles can be controlled only by logging operations. Biological control by the introduction of parasites and predators that live on the destructive insects is feasible in some cases. White pine blister rust can be controlled by the eradication of all currant and gooseberry bushes, on which the fungus spends part of its life, in the neighbourhood of pines. There is no known method of control for some diseases, such as the chestnut blight. In general, the most effective and permanent control for most forest pests lies in the production of stands composed of thrifty trees of more than one species and harvested at maturity; in other words, in management of the forest: not of the pest.

4. Timber **Management.**—Although forests are commonly used for more than one purpose (multiple use), it is convenient to consider separately their management for their major products and services. Of these, timber is by and large the most important, and the technique for its production is the most highly developed.

One of the first things a forest manager must determine is how much timber of different sizes the forest contains, how fast it is growing and what yields can be expected at various future dates under whatever methods of cutting and utilization he may adopt. He must then develop a working plan which will enable him annually or periodically to harvest the same amount of timber (sustained yield), with sufficient provision for flexibility to enable him to adjust cutting operations to changing market conditions and to unexpected occurrences such as fires or insect attacks. For convenience of administration the tract is divided into a number of smaller units, often on the basis of small drainages or other topographic features. Cutting operations are allocated to these units in accordance with their productive capacity and consequent ability to yield the harvests called for in the working plan.

Silviculture, literally "care of the forest," includes practices designed (1) to maintain a vigorous, productive forest of the desired species and sizes; and (2) to provide for the replacement of stands as they are harvested, either by natural means or by tree planting or seed sowing. The first objective is attained chiefly by the removal of trees that are undesirable because of species, shape, injury or other defect (weed trees), and by thinning out stands that are too dense so that growth will be concentrated on a smaller number of high-class trees whose growth will be stimulated by the reduction of competition. Weedings are usually conducted at a current net cost, but thinnings may yield a substantial net income where there is a market for small material.

Silvicultural systems for obtaining reproduction after cutting by natural means are divided into several conventional classes. Clear cutting of all merchantable trees may be done in narrow strips or in small patches, with the expectation that the area will be reforested by seeds from the adjacent uncut stands, or enough scattered seed trees may be left on the cutover area to provide for its reforestation. The shelterwood method involves a series of cuttings several years apart in which the stand is first opened sufficiently to permit reproduction to come in under the shade of the overwood and is later removed after the reproduction has become established. These two systems are best suited to even-aged stands, in which the trees do not vary in age by more than about 20 years.

The selection system involves the harvesting of individual trees and is much better adapted to uneven-aged forests. The entire forest is gone over at regular intervals and the trees that have matured or reached a specified size since the previous cutting are removed. This procedure always leaves uncut a part of the stand from which reproduction is expected to take place. but the process is somewhat uncertain, and undesirable species may tend to dominate. Another system depends on reproduction by sprouts from the stumps of the cut trees. With a few exceptions. such as redwood, it is applicable only to broadleaf trees. It usually results in gradual deterioration of the stand and should be supplemented by provision for the establishment of seedlings.

Modifications and combinations of these various methods are common. When they fail to obtain adequate reproduction. or when the forest is destroyed by fire or other catastrophe. recourse must be had to artificial reforestation. Planting of young, nursery-grown trees is the method generally used, but direct seeding is possible and has the advantage of cheapness where climatic conditions are favourable and protection of the seeds from destruction by birds and rodents is feasible. Planting machines drawn by tractors are increasingly used where the ground is not too steep or too stony. The rate of planting has risen markedly and there is a growing tendency to use artificial reforestation immediately after cutting as a means of obtaining prompt restocking with desirable species, even where the prospects for natural reproduction are reasonably good.

Efficient harvesting of the timber by logging requires a carefully planned network of permanent forest highways, together with many temporary woods roads or trails over which the logs are hauled out. Logging methods vary widely in different countries and in different forest types. Throughout the world there is a tendency toward increased use of heavy bulldozers and graders for road construction, of power saws for tree felling, of tractors for moving logs from the stump to the log yard and of trucks for transporting the logs to the mill. Where close utilization of the tops and branches is impracticable, it may be necessary to treat the debris. or slash, by burning, piling or scattering so as to reduce the danger from fire or insects or to prevent the smothering of established reproduction.

Manufacture of timber into lumber, veneer, furniture, containers, pulp. paper and innumerable other products is not a part of forestry, but it is an activity in which the forest manager has a keen interest. These products not only furnish a market for the forest crop, but they determine the kind and amount of material for which there will be a demand. Making wood go twice as far has the same effect as doubling its production. For many reasons wood technology exercises a profound influence on forestry and is a field with which the forest manager must be well acquainted.

5. Range Management. — In many parts of the world grassy meadows and other range lands are so intermingled with forest lands that the two classes of land must be managed together. Furthermore, there are some forest types, as in the coniferous forests of the western United States. in which much forage suitable for use by domestic livestock occurs within the forest itself. In such situations the forest manager must have sufficient knowledge of range management to assure full use of the range resources. both in the open and in the forest, without overgrazing and consequent damage to the forest, to the water supply, to recreational values or to the range itself.

A different situation exists in forests of broadleaf trees. where grazing by domestic livestock is nearly always injurious. Trampling packs the soil and exposes tree roots, while browsing kills off the young growth and prevents reproduction. Here the problem is primarily one of exclusion rather than control of grazing.

See also RANGE (IN AGRICULTURE).

6. Watershed Management. — In hilly and mountainous country, a primary responsibility of the forest manager is to reduce the surface runoff of water so as to minimize erosion and to regularize the flow of springs and streams. Where clear cutting of any considerable area is avoided. the occurrence of organic matter in the soil. the accumulation of litter on the forest floor and the presence of herbs, shrubs and trees are ordinarily adequate to attain this result.

In arid and semiarid regions, the total amount of water available for domestic, municipal and industrial use, 'for irrigation and for power is another item of major concern. Here the influence of the forest may be adverse because of the large amounts of precipitation which it intercepts and the large amount of water which it transpires. There is some experimental evidence that the opening up of a forest by small clearings or in other ways may substantially increase the total runoff of water. but far more research is needed to determine how and to what extent such openings can be made without unduly increasing the danger of soil erosion. And there is always the further question as to whether the water or the timber is the more valuable.

7. Wildlife and Recreation **Management.**—Wildlife is an ever-present component of the forest in which hunters, fishermen and nature lovers have a special interest. Since many animals. such as deer, prefer edge conditions where forest and open land meet. the forest manager must face the problem of creating such conditions without undue interference with timber production.

Other forms of recreational use of the forest. such as picnicking and camping. are steadily increasing in importance and occasionally come in conflict with uses such as timber management and range management, Here again. much needs to be learned about ways and means of reconciling the different uses and about the relative values involved. Of particular urgency is decision as to the extent to which forests should be set aside as wilderness areas. and how they should be managed to best serve the purposes for which they are established.

8. Education and Research. — Formal schools for the training of foresters were first started in Russia. Germany. France and Sweden in the early 1800s. Other schools followed gradually. first in Europe and later in other parts of the world. Professional instruction in forestry was not undertaken in the Cnited States until 1898 but thereafter developed rapidly. In most countries the trend has been toward the broader training of general practitioners and the more intensive training of specialists.

Experiment stations for the conduct of forest research were established in Germany in the 1860s and 1870s. Other countries gradually followed suit, and research has received steadily increasing attention as forest problems have grown in importance and in complexity. That developments are not keeping up with needs. however. is indicated by a study made by a committee of the Society of American Foresters which recommended that expenditures of $45,400,000 in 1953 for research in timber management and related fields (including wood technology) be increased to $200,000,000 by 1978. Governments are generally the leaders in the research field. but substantial contributions are made by educational institutions and private organizations.

III. WORLD SURVEY

1. Government and Forestry. — Forests are of such vital significance in the economy and general well-being of a nation that governments have long recognized a responsibility to see that they are so managed as to promote. or at least not to jeopardize, the public interest. Governmental participation in forestry affairs may take the form of ownership of forest lands. of control of the activities of private onners or of assistance to private owners. All three approaches are commonly used in the same country, with uide differences in the reliance placed on each.

With 78% of the accessible forests of the world in public ownership, governments are clearly in a position to exercise direct control over the bulk of the world's forest resources. Such control does not, however, necessarily result in efficient forest management. particularly in countries with relatively small industrial development. Outside of the U.S.S.R.. where all of the forests are in public ownership, forestry has made the most progress in Europe and North America, where 54% and 49% of the accessible forests are in private ownership.

2. Protection Forests. — Public regulation of the management of their forests by private owners is of long standing in Europe, particularly in the case of protection forests. which include those so located that mismanagement is likely to result in serious damage to the community from such causes as soil erosion. floods. avalanches and the encroachment of sand dunes. Any general regulation of the management of other private forests is a later development. which perhaps has gone farthest and been most successful in Sweden. Norway and Finland. In the Cnited States, a few states have enacted regulatory legislation of this character.

Public assistance to private owners is extended in a wide variety of ways. It may take the form of partial or complete assumption of the responsibility for protection from fire, insects and disease, of payments for the adoption of improved forest practices. of tax concessions. of credit under favourable terms. of the provision of nursery stock at or below the cost of production, of education and of free or low-cost service in the management of forests and in the harvesting and marketing of forest products. Research by public agencies: much of which deals directly with private lands, also may be regarded as falling in this category.

3. Forestry in Europe. — The development of forestry throughout the world can be illustrated by a brief presentation of the policies and practices of a few selected countries in the various regions. Forestry as an art with a sound scientific foundation was first developed in Germany. and German-trained men played an important part in early developments in Scandinavia. Russia, the British Commonwealth and the United States. Special emphasis was placed on the technology of forest management, on financial considerations and on the organization of forest properties for sustained yield. Theories and formulas commanded much attention and were rather rigidly applied in practice. Policies with respect to private forests have swung between the two extremes of strict controls and virtually free enterprise. From World War II private forests in west Germany have been largely under state supervision. while those in east Germany are all managed by the central administration.

France became interested in forestry at an early date. In 1669 Jean Baptiste Colbert. Louis XIV's great minister, promulgated a comprehensive forest code which set up a complete administration for all the forests of the country and prescribed many detailed silvicultural practices. This code was abrogated by the French Revolution, but in 1827 a new Code Forestier prescribed in detail for the management of public forests and provided severe penalties for trespass and for starting fires on any forest land. Except that the clearing of forest land without permission was prohibited, private owners were otherwise left practically free of public control, as is still the situation. Among France's outstanding achievements are the control of mountain torrents, the stabilization of extensive sand dunes and the reforestation of large areas of waste lands.

The forests of the Alps are important to Switzerland both as source of timber and as a scenic and protective asset. A law of 1902 authorized the federal government to designate protection forests, a fourth of which proved to be in private ownership, and provided for such public control over their management as necessary to prevent impairment of their protective function. Subsidies are granted the private owner to aid in reforestation, the construction of dams and other measures to control torrents. In general, the technical management of Swiss forests is of a high order. The city forest of Zurich (*Sihlwald*) has been under management with a definite working plan since about 1680, making it the oldest continuously managed forest in the world.

Sweden's extensive forests, largely located on rivers which provide cheap power and log transportation, long have enabled it to be a heavy exporter of lumber and of wood pulp and paper. The public forests were placed under the supervision of trained personnel toward the middle of the 19th century, and about 50 years later intensive management practices began to be adopted by the larger private owners. particularly in the pulp and paper industry.

Public control over private forests was established by the law of 1903, which was revised and strengthened in 1923 and 1948.

The 1948 law provides that "Forest land together with the forest growing thereon shall, through suitable use of the productive capacity of the soil. be so managed that a satisfactory economic return is obtained and, so far as possible, substantially sustained yield." Responsibility for supervising the management of forests in accordance with the law is lodged in county boards of forestry. These boards usually consist of three members of whom the chairman is appointed by the king and the others by the county council and the county agricultural society. They must be well acquainted with forestry and forest conditions in the county and are typically forest oaners. The county forestry boards are in turn supervised by a private forestry board in the department of agriculture which exercises general federal leadership with respect to private forestry. Educational and service. as well as regulatory, activities are conducted by the county boards through their technical staffs; and under certain conditions owners may receive grants to aid in undertaking measures that are desirable but too costly to promise satisfactory economic returns.

The Swedish system of controlling the management of forest lands in private ownership places the determination of policy at the national level and administration of the policy at the county and district levels. It meets with almost universal approval in theory and in general works well in practice. Although it has greatly improved the handling of the small farm wood lots, which comprise more than three-fifths of the total area in private and community ownership, it has fallen considerably short of getting them all under really satisfactory management. Management of the forests in the hands of the larger companies, on the other hand, compares favourably with that of the national forests. In Sweden, as in many other parts of Europe, forest owners, co-operative associations and forest management associations exert a constructive influence in the management of the smaller forest properties.

Great Britain, once densely wooded, was gradually deforested until by the outbreak of World War I it was almost wholly dependent on imports for its wood supply. The virtual stoppage of these imports by German submarines awakened the nation to the importance both of wood and of building up a domestic supply on which it could rely in time of crisis. Little progress had been made in this direction when World War II created a second and even more drastic emergency. As a result, parliament in 1945 adopted a plan for the creation of 5,000,000 ac. of forest in the next 50 years. partly by national purchase and planting and partly by regeneration of badly depleted private woodlands. A unique arrangement for encouraging action by private owners was embodied in subsequent legislation (1947) and in agreements entered into between the government and associations of forest owners. Under these agreements private owners, in return for heavy public subsidies, voluntarily covenant to dedicate their lands permanently to forest production..

4. Forestry in the **U.S.S.R.**—Interest in the perpetuation of the forests of European Russia developed in the 17th century. and from then on sporadic attempts were made to check devastation, particularly in protection forests. In 1888 a comprehensive law provided for the conservation of forests. public and private alike.

Following the fall of the czar, the U.S.S.R. in 1918 ended all private ownership in land. water and forests. Since then the forests have been managed, and production from them tremendously increased, under the various five-year plans. The volume of timber cut has not been limited to the annual growth but has been determined by the economic and industrial needs of the country.

Much stress is laid not only on the economic value of the forests but on their influence on climate, erosion, streamflow and health. Large areas have been set aside around health resorts and industrial areas; protection forests, in nhich cutting is forbidden or restricted, have been established on critical natersheds and along the banks of the larger rivers; and the forest area has been extended by large-scale planting operations. ;\ particularly ambitious project is the erection of a forest barrier about 3,300 mi in length in the path of hot southeast winds. and the planting of nearly 6,000,000 ha. of shelter belts around cultivated fields.

The U.S.S.R. has 12 institutes of university grade for the training of students in all branches of forest management and forest utilization. These schools graduate between 2,500 and 3,000 students each year. Many vocational schools also are training forest personnel. Research is conducted at the professional schools of forestry, at 1j special forest research institutions and at scores of experimental stations and laboratories.

5. Forestry in North America.— With some minor exceptions. practically uncontrolled exploitation of the forests of the United States continued until the end of the 19th century, when acts passed in 1891 and 1897 authorized the president to reserve portions of the public domain from alienation.

Then in 1911 and 1924 congress authorized the purchase of forest lands by the federal government for watershed protection and, under certain conditions, for timber production. By the second half of the 20th-century national forests reserved from the public domain and acquired by purchase totaled about 180.000 000 ac. in the U.S.. including 21,000,000 ac. in Alaska, all of which were handled under the multiple-use principle. There was an additional 225,000,000 ac. of public land in Alaska. much of it in forest, uhich received inadequate protection from fire and was otherwise unmanaged. Most of the other states (notably Michigan. Minnesota. Pennsylvania and Washington) had state forests which aggregated 19,000,000 ac.. or 4% of the commercial forest area of the country. An additional 8,000,000 ac. was in county and municipal ownership. Each state has its own system of forest fire protection and co-operates with private owners in educational and service activities. Grants-in-aid for these purposes are received from the federal government.

Private forestry started on a small scale in the early years of the 20th century, but it was not until after 1940 that the movement gained real momentum. The change in attitude and practice nas due to a variety of factors, among which increased timber values, improved technological processes and the need for adequate permanent supplies of raw material to safeguard heavy investments in plant and equipment were of prime importance. A helpful influence was the tree farm program initiated by industry in 1941. In less than 20 years more than 11,000 forest owners in 45 states with a total of 45,000,000 ac. were participating in the program. Its purpose is to encourage better forest practices by formal recognition of onners who meet certain specified standards of practice. As elsewhere throughout the world. the management of farm wood lots and other small tracts is much less satisfactory than that of large properties. A few states exercise some control over the management practices of private owners, but there is no federal legislation on the subject.

Because of adverse climatic or soil conditions only three-fifths of Canada's forest area is classified as capable of producing crops of merchantable timber and of this area 30% nas considered inaccessible for commercial purposes. In spite of these handicaps forests play a major part in the economic life of the country. Exploitation ran about the same course as in the United States, with planned management on any considerable scale not taking place until well into the 20th century.

Of the total forest area. 73% is owned by the provinces and 21% by the federal government. Private ownership constitutes 50% or more only in Prince Edward Island. Nova Scotia and New Brunswick. Forests in the provinces are administered by the provincial governments, with financial assistance from the federal government. Cutting is done by private operators under timber licences, which may contain detailed requirements as to the amount to be cut and the methods of cutting. Increasing emphasis is being placed on silviculture. sustained yield and integrated utilization of all merchantable wood. Steady progress toward well-planned, long-range management is being made under the combination of public ownership and private operation.

6. Forestry in Latin America.— Throughout Latin America, utilization and management of the forests have been complicated and delayed by their inaccessibility and by the enormous number of species of which they are composed. For the majority of these species. little is known as to the characteristics of the trees and the properties of their woods, and still less as to their growth. yield and management. The more accessible forests have deteriorated greatly as a result of temporary clearing for agriculture, culling of the more valuable species and overutilization. In general, drain considerably exceeds growth.

The division of the forest area between public and private ownership varies tremendously in the different countries. With both classes of ownership, only a small start has been made toward satisfactory forest management. Forestry is officially recognized in the central governments of all the Latin-.American republics, but the forest services lack in stability, in financial support and in professional training of their personnel. Legislation dealing with the control of cutting by private owners and operators is not uncommon, but is more honoured in the breach than in the observance.

In spite of these difficulties, forestry, in the second half of the 20th century, was making considerable progress. Mexico and the European territorial possessions were the first to inaugurate substantial forestry programs, but promising developments were occurring in other countries throughout the region. Far greater emphasis on education and research, greater stability and financial support of governmental agencies and the introduction of sound practices in the utilization of the forests are essential to enable them to play the part which they should in the economy not only of the region but of the world. FAO's Latin American forestry commission exerts a helpful influence in these directions.

7. Forestry in Africa. — The rain forests of Africa constitute a vast reserve. full utilization of which probably will come slowly because of their relative inaccessibility, the high cost of harvesting and transportation to world markets and the preponderance of hard and very hard woods. Exploitation in general, as late as the 1950s, was promoting deforestation, with which the local governments were unable to cope in spite of good intentions and the establishment of limited areas of forest reserves. The dry forests were cut almost entirely to meet local needs, chiefly for fuel. Because of the unfavourable climate and the prevalence of fires, their continued deterioration seemed probable.

In South Africa, the true forest of evergreen hardwoods, never extensive, has been pushed back until by the second half of the 20th century it occupied only about 0.5% of the land area. In 1876 the government undertook to control unconsidered exploitation, but without much success. Since 1913 cutting has been much restricted with a view to keeping the drain within the annual growth. Planting, chiefly of pines from other parts of the world, has been extensive and is being continued on an increasing scale.

8. Forestry in Asia.——Forestry in India had its beginnings in the middle of the 19th century, when the British organized an Imperial forest department. Forests were classified as "reserved," because of the vital role they play in the national economy, in which only well-defined and limited private rights were recognized, and as "protected," in which only such restrictions were imposed as were in the interest of the right-holders themselves. Neither these provisions nor those of the Indian Forest act of 1927 were adequate to prevent continuing destruction of the private forests. A "New Policy" adopted by the Indian government in 1952 designated those private forests over which governmental control was to be exercised and provided for their management in accordance with approved working plans. Special attention is paid to the preservation of protection forests. Professional education and research have occupied a prominent place in forestry affairs in India since the establishment of a forest rangers' school at Dehra Dun in 1878.

In the Philippines forestry started with the establishment of the bureau of forestry by the United States in 1900. With 96% of the accessible forest area in public ownership, the government has been able to exercise virtually complete control over their utilization and has made steady progress in the development of working plans and the application of sustained yield. Lumbering, which is one of the main industries of the islands, is not permitted in areas classified as protection forests.

Japan is a mountainous country in which forests occupy 62% of the land area. As elsewhere throughout the world, they were long exposed to destructive utilization in spite of sporadic governmental efforts at control. Although there is evidence that the relationship between forest devastation and destructive floods was recognized early in the Christian era, well-defined national efforts to correct the situation did not appear until 1878. when a bureau of forestry was organized. Since that time progress toward improved forest management has been steady and in places intensive forest practices are in force. However, the heavy post-World War II need for wood resulted in enormous demands on the forests which led to overcutting. The greatest drain has been on the coniferous forests, estimated early in the second half of the 20th century at more than two and one-half times the annual growth. The problem of soil stabilization and flood prevention in the mountains is receiving intensive study but has not yet been solved. A promising development was the formulation by the U.S. occupation force of forestry programs which are being effectively carried out by the Japanese government.

Except during the Chou dynasty (1122?–256 B.C.), forest destruction in China continued unabated until by the middle of the 20th century its once "boundless stretches" of forest had been reduced to 9% of the land area. Even this diminished area, all of which is theoretically in government ownership, provides considerable wood for lumber, pulp and fuel. Forestry, first given official recognition in the government in 1911, was elevated to the status of a ministry in 1951. A comprehensive national forest law provides for the recognition and maintenance of protection forests and requires the reforestation of all cutover areas, but its enforcement is another matter. Planting has been done rather extensively, but no long-range plans for forest management have been developed.

9. Forestry in the Pacific Area. — The forests of Australia, which are confined to a relatively narrow belt along the coast, comprise nearly one-half of the total forest area of the Pacific area and more than three-fourths of the accessible forest area. They consist predominantly of evergreen hardwoods, among which eucalyptus is the characteristic genus. To help remedy the deficiency in coniferous timber extensive plantations, largely of Monterey pine, have been made. Approximately 65% of the productive forest area is under some form of reservation. The individual states are autonomous in forestry matters, but there is a central forestry and timber bureau which is concerned chiefly with education, research and advising the administrations of the commonwealth territories on forest management. The application of intensive silviculture and the practice of sustained-yield management is likely to be slow until fire control becomes much more effective.

New Zealand's forests, once regarded as inexhaustible, have been greatly reduced in area by the use of fire for land clearing. Fire and exploitation have resulted in deterioration of a considerable part of the remaining forest and the beautiful and famous kauri pine (*q.v.*) is no longer of major economic importance. Forestry activities have been largely concentrated on the planting of exotic conifers.

10. Outlook. — Accurate information is not available as to the area: volume. growth and use of the forest resources of the world. Indications are, however, that these resources, if properly managed, are adequate to meet the world's needs for wood and other forest products for an indefinite period. Although progress is being made in many countries, there is as yet no assurance that effective management will be attained. Much remains to be done in securing the adoption and execution of policies and practices that will assure the contribution of which forests are potentially capable to the economic and social well-being of people everywhere, a process in which education, research and constructive legislation must play a prominent part.

FOREY, ELIE FREDERIC (1804–1872), marshal of France, was born in Paris on Jan. 5, 1804, and entered the army from St. Cyr in 1824. In 1844, after ten Algerian campaigns, he was a colonel. Services in Paris in 1848 and in the coup d'état of Dec. 2, 1851, made him general of division and gave him the 1st corps in the Crimea; but A. J. J. Pélissier replaced him in Jan. 1855. A good general of division in Italy in 1859, he won an independent success (May 20) at Montebello and fought hard at Solferino. But the command of the expedition in Mexico from Sept. 1862 was too much for him; made a marshal on July 2, 1863, after the capture of Mexico City in June, he was superseded in August by A. F. Bazaine and recalled to France. His health gave way in 186; and he died at Paris on June 20, 1872. (I. D. E.)

FORFAR, a royal and small burgh and the county town of Angus (Forfarshire), Scot. Pop. (1951) 9,981. It lies at the east end of Forfar loch in the valley of Strathmore, 13 mi. N. by E. of Dundee by road. The town and county hall is one of the principal buildings and contains portraits by Sir Henry Raeburn, George Romney, John Opie and others. Peter Reid, a merchant, gave the Reid hall and a public park to the town. The staple industries are linen and jute manufactures and minor industries include the manufacture of agricultural machinery, fruit and vegetable canning, an iron foundry and ladder making.

Forfar is at least as old as the time of Malcolm Canmore, for the first parliament after the defeat of Macbeth (1057) met in the castle. which stood on a mound north of the town. The parliaments of William the Lion, Alexander II and Robert II also assembled within its walls. The town was created a royal burgh by David I and was burned about the middle of the 13th century. Edward I captured the castle, Robert the Bruce seized and destroyed it, its site now being marked by a 17th-century octagonal tower. which was presented by Charles II as a mark of regard for the loyalty shown by the town to his father, Charles I, during the Civil War. A witches' bridle, a gag to prevent witches from speaking while being led to execution, is still preserved in the town and county hall. One mile to the east lie the ruins of Restenneth priory, of 13th-century origin but believed to have been founded six centuries earlier by St. Boniface. (I. A. M.)

FORFARSHIRE: see **ANGUS.**

FORFEITURE, in law, the termination of a right; the loss or liability to the loss of property in consequence of an offense or breach of contract; it is also applied to the property of which the party is deprived. Under common law, conviction and attainder on indictment for treason or felony was followed by forfeiture of the life of the offender as well as his lands and goods. In the case of treason all the traitor's lands of whomsoever holden were forfeited to the king; in the case of felony (*q.v.*), including *felo*-de-se, or suicide (*q.v.*), the felon's lands escheated to his immediate lord, subject to the king's right to waste them for a year and a day. This rule did not apply to lands held in gavelkind in the county of Kent. The goods of traitors and felons were forfeited to the king. The desire of the king and his officers to realize the profits of these forfeitures was one of the chief motives for instituting the circuits of the king's justices throughout England, and from time to time conflicts arose from attempts by these justices to extend the law of treason — under which the king levied all the forfeitures — at the expense of felony, in which the lord of the felon benefited by the escheats. As regards theft, the king's rights overrode those of the owner of the stolen property, until, in the reign of Henry VIII, provision was made for restitution of the goods to the owner if he prosecuted the thief to conviction. It was common practice for persons anticipating conviction for treason or felony to assign all their property to others to avoid the forfeiture; and in some instances the accused refused to plead to the indictment and endured the *peine forte* et dure, until death supervened, to avoid these consequences of conviction. The royal rights to forfeitures arising within particular areas were frequently granted by charter to corporations or individuals. In 1897 the courts had to interpret such charters granted to the town of Nottingham in 1399 and 1448. All forfeitures and escheats with respect to conviction and attainder for treason and felony were abolished as from July 4, 1870, except forfeitures consequent upon the now disused process of outlawry, and the forfeitures included in the penalties of praemunire.

The term "forfeit" is also applied to penalties imposed by statute for acts or omissions which are neither treasonable nor felonious. In such statutes the forfeiture enures in favour of the crown unless the statute indicates another destination; and unless a particular method of enforcing the forfeiture is indicated it is enforceable as a debt to the crown and has priority as such. The words "forfeit and pay" are often used in imposing a pecuniary penalty for a petty misdemeanour, and where they are used the court dealing with the case must not only convict the offender but adjudicate as to the forfeiture.

Statutory forfeitures in some cases extend to specific chattels; *e.g.*, of a British merchant ship when her character as such is fraudulently dissimulated (Merchant Shipping act 1894, ss. 70, 76), or of goods smuggled in contravention of the Customs acts or books introduced in violation of the copyright acts. Recognizances are said to be forfeited when the conditions are broken and an order of court is made for their enforcement as a crown debt against the persons bound by them.

The term "forfeiture" is now most commonly used with reference to real property; *i.e.*, with reference to the rights of lessors to determine the estate or interest of a lessee for breach of the contractual terms of tenure. By legislation of 1881 and 1892 there is jurisdiction to grant relief upon terms against the forfeiture of a lease for breach of certain classes of covenant; *e.g.*, to pay rent or to insure. This previous legislation was re-enacted by the Law of Property act, 1925.

FORGERY, a common-law crime (*i.e.*, one originally created by England's courts rather than by its parliament), has been defined in various ways; one definition is "a false making (which includes every alteration of or addition to a true instrument), a making *malo* animo, of any written instrument for the purpose of fraud and deceit" (2 East, Pleas of the Crown, 852 [1803 ed.]). At common law, forgery and its companion crime of uttering a forged instrument (see below) were misdemeanours; under modern statutes in the U.S. and England these crimes generally are felonies. Forgery and uttering are made criminal acts principally to safeguard confidence in the various papers relied upon in commercial activity.

Definition. — Unless the definition is varied by statute, forgery consists of three elements: the making of a false writing (including the material alteration of a genuine writing), of a type that either has legal significance or is commonly relied upon in business or commercial transactions, with intent to defraud.

Writing. — The writing which will do for forgery is not limited to handwriting; it includes printing, engraving and typewriting as well. Thus a railroad ticket, though entirely printed, can be forged. "Writing" excludes pictures, sculptures and antiques; signing the name "Rembrandt" at the foot of a painting done by someone else is not forgery. (In some cases, however, the scope of forgery has been expanded by statute to apply to these and other articles which are not considered "writings" in common law.) Generally speaking, the writing must have legal significance — that is, it must be of a kind that, if it were genuine, would impose or alter or extinguish a legal obligation. Thus checks, promissory notes, stock certificates, bonds and other negotiable instruments, deeds, mortgages, leases, wills, receipts, contracts and the like may be forged. But forgery also encompasses some documents which, even if genuine, have no legal efficacy, such as a false letter of recommendation for employment, as it is a document commonly relied upon in the business world. On the other hand, a false letter of introduction will not suffice for forgery, even though it may request that courtesies be extended to the bearer of the letter.

Making a False Writing. — The forger may begin with an entirely blank piece of paper, with an incomplete genuine instrument with blanks to be filled or with a completed genuine instrument that may be altered. The usual manner of forging is to prepare a false writing and sign another's name to it, or to make a material alteration to a valid writing already signed by another. Forgery may be committed not only by the forger's signing of another's name. but by signing the name of a fictitious person whose purported signature is entitled to more credit than the forger's own signature; or by signing one's own name intending it to be accepted as the signature of another person of the same name; or by fraudulently securing the signature of another (as by showing the other an innocent writing and then fraudulently substituting a legal document for him to sign). It may be committed by an unauthorized filling-in of blanks in a genuine writing, as where the drawer of a blank check, after signing it, hands it to the forger with instructions to use it to pay the drawer's debt to his creditor, and the forger, in violation of his instructions, makes it payable to himself. It may be committed by a material alteration of a genuine writing, as by "raising" the figure "nine" to "ninety" on a valid check payable or endorsed to the forger. The alteration may be accomplished by means of the addition or substitution or erasure of words or letters or figures on a writing. The alteration must be material; it is not forgery to raise the figure 9 to 90 on a check if the written word "nine" is not raised to "ninety," since it is the written words, not the figures, which control in case of a variance.

A writing which contains false statements is not necessarily the "false writing" which forgery requires. Thus an employee who writes and signs a time sheet showing that he has worked 40 hours, when in fact he has worked but 30, is not guilty of forgery though he intends to defraud his employer. A check drawn on a bank wherein the drawer has no funds is not forgery, though the drawer implies that he has funds therein. These are examples of genuine writings containing lies. Thus it is sometimes said, "A forgery tells not merely a lie but a lie about itself."

Intent to Defraud.—A successful forgery may cause financial loss either to the person whose signature is upon the forged instrument or to the person to whom the instrument is negotiated and who relies on its genuine character. The forger need not intend to defraud any particular person; an intent to defraud in general will suffice. He need not intend to benefit himself; thus he may forge a check payable to his son. He is guilty of forgery though he intends to restore later what the injured party loses, or though he forges to collect a debt which he honestly believes the injured party owes him. Although in these situations he is not morally as much at fault as the forger who intends to obtain permanent financial rewards for himself, the goal of protecting commercial activity from spurious documents is furthered by the stricter rule. On the other hand, it is not forgery for one to sign another's name or fill in blanks or alter a genuine writing honestly, though mistakenly, believing that such conduct is authorized For forgery it is not necessary that anyone be actually defrauded by the false document. Unlike crimes such as criminal homicide, battery and arson. which require a specified bad result (a human death or injury; the burning of a house), forgery is committed when the forger makes the false writing nith fraudulent intent, without regard to any bad result of his conduct.

Uttering.— One who does not himself forge an instrument may be guilty of the related crime of uttering a forged instrument This crime is committed by offering as genuine a writing which the offerer knons to be false, done with intent to defraud. It is not necessary that the person to nhom it is offered be deceived, for "utter" means "offer" rather than "pass." Though the common-law crime of uttering a forged instrument is a crime separate from forgery proper, modern statutes sometimes consolidate the two, providing in effect that nhoever either forges a writing or utters a forged writing is guilty of "forgery."

Related Crimes.— Forgery is different from, but related to the crime of obtaining property by false pretenses. Making false statements in a genuine document— as in the case above of the employee who "padded" the figures in the time sheet in order to obtain more pay than he was entitled to—is not forgery; but if money or property is obtained as a result of the false statements. the crime of false pretenses is committed. "Bad check" statutes commonly make it a crime to draw a check on a bank in which the drawer has no funds, or insufficient funds, with intent to defraud, although such conduct does not amount to forgery.

A thorough study of bad checks in the state of Nebraska *(see* F. K. Beutel, *Some Potentialities of Experimental Jurisprudence as a New Branch of Social Science,* pp. 405–407, 1957) disclosed that one-half of 1% of all checks written in Nebraska were bad checks in the broad sense of forgeries, no-fund checks or insufficient-fund checks. Of these bad checks, 90% were insufficient-fund checks, 9% were no-fund checks and only 1% were forgeries. What is true in Nebraska is doubtless indicative of the situation elsewhere. So far as fraudulent checks are concerned. forgery does less harm to commercial activity than other forms of criminal conduct relating to checks.

See also CRIMINAL LAW. (4. W. ST.)

FORGES, COMITÉ DES. The *comite' des forges,* a French body, under state control, founded in 1864 to centralize and divide up the supplies of rough casting and to deal in British steels. was instituted as a "professional syndicate" in accordance with the law of 1884.

The *comite' des forges* dealt on behalf of its adherents with matters referring to their corporative interests: development of the industry on the home market and on the market abroad, commercial agreements, specifications, company matters and labour questions, etc.. etc. the study of these latter questions taking place in agreement with the other syndical chambers making part of the Union of the Metallurgic and Mining Industries; *e.g.,* the drafts of law on the workmen's superannuation, weekly rest: working of children in works with continuous fire, duration of work, company insurances, etc.

In 1891, seven years before the legislative work, the *comite' des forges* created and organized, under the form of a mutual insurance pay office. the pecuniary compensation of working accidents. This institution inspired the general principles of the law of 1898. Later the Insurance Pay office against working accidents was completed by a department for prevention of working accidents.

In 1894, the *comite' des forges* created the Superannuation Pay office of the forges of the metallic construction, the electric industries and industries combined with same, to ensure retiring pensions for metallurgical workers.

Seven years later the law on workmen's pensions was voted; a legislative regulation allowed joint-stock companies having the object of supplying pensions to workmen, to continue their operations; only the Pensions Pay office of the *forges* was able to benefit by this exception. (P. PE.; X.)

FORGET-ME-NOT, called also scorpion grass, the name popularly applied to the small annual or perennial herbs forming the genus *Myosotis*, of the family Boraginaceae (*q.v.*), from the Greek *mys* ("mouse") and *otos* ("ear")— the shape of the leaves. The genus is represented in Europe, north Asia, North America and Australia by over 40 species, and is characterized by oblong or linear stem leaves; the small flowers in terminal one-sided clusters are blue, pink or white with a five-cleft persistent calyx. The common Eurasian forget-me-not, *M. scorpioides,* found in Great Britain and naturalized in North America is perennial; it grows to a height of 6 to 18 in., with a creeping rootstock, softly hairy stem and light-green leaves. The flower buds are pink, becoming blue as they expand; the saucer-shaped corolla is bright blue with a yellow centre. The forget-me-not has several horticultural forms; some dwarf forms make fine ground covers.

ROCHE

ANNUAL FORGET-ME-NOT, A HORTICULTURAL FORM

About a dozen species are native in the United States, and

M. virginica is found throughout the country.

The forget-me-not, a favourite with poets, and the symbol of constancy, is a frequent ornament of brooks, rivers and ditches and, according to an old German tradition. received its name from the last words of a knight who was drowned in the attempt to procure the flower for his lady. It attains its greatest perfection under cultivation and; as it flowers throughout the summer, is used with good effect for garden borders. Various species are widely cultivated, especially *M. scorpioides* and *M. sylvatica. M. azorica,* which has no yellow "eye," is best grown as an annual, and is not easy to cultivate.

In *M. versicolor* the flowers are yellow when first open and change generally to a dull blue. Many reputed species are widely cultivated for their generally prostrate habit and profuse bloom. Most of the popular sorts are horticultural forms of M. *sylvatica,* which is an annual, but best treated as a biennial, and often persists from self-sown seeds. Some species make a beautiful ground cover when planted under tulips. (S. TR.)

FORGING. In the principal forging processes, articles of metal are shaped by hammering or pressing metal blanks between a pair of forging dies. In most processes an upper die is attached to the ram of a forging hammer, or press, so that it may be raised and dropped or forced under pressure against the rigidly supported, stationary lower die.

There are few theoretical limitations on the shape or size of a forging. other than the obvious need for a shape which can be removed from the die cavity. It has been estimated that more than 600,000 different closed die forgings are in regular production, including parts ranging from one-half ounce automobile carburetor links up to aircraft landing gear weighing as much as four tons.

DROP FORGING

Drop forging employs a drop hammer. so designed that the falling weight of the ram and upper die forces the heated metal into cavities cut into the face of each die. Similar closed dies are used for forging in presses. upsetters, etc.. described below.

Drop-forged articles are irequently confused with castings. but the manufacturing process is entirely different. Drop forging is essentially a shaping operation. the metal being worked in a forging hammer or press, commonly at a sufficient heat to bring it to a plastic state but never in the molten condition necessary for the production of castings.

Steel forgings ordinarily are produced from forging-quality steel. In producing forging-quality steel, improvement of the metal properties begins in the melting stage. The chemistry of the steel is carefully controlled. As the steel is processed from the ingot stage to bars, blooms, billets and slabs for forging, special care is exercised to eliminate foreign material and porosities which might be detrimental to metal quality. The forging operation constitutes a final step in improvement of metal quality to its maximum degree.

To understand the effect of the forging process on metal quality, it is necessary to consider the normal state of solid metal. Metals solidify from the molten state in minute crystal form. The process of rolling bars, billets, etc., from the ingot tends to elongate these crystals of metal and lock them together. This produces a "grain" in the metal (so called from the analogy to grain in wood) and the mechanical properties of the metal are usually found to be somewhat better in the direction of the grain. (This is not to be confused with "grain size," which refers to crystal size.)

In closed-die forging, the fibrelike flow lines of grain structure developed by rolling are worked into such positions as to impart maximum strength relative to the stresses expected in the forged article. For maximum strength the grain should not run transversely to the axis of the greatest bending stress. This is one of the great advantages of drop forgings over castings. In a casting, where the metal is melted and poured into a mold, there is no grain in this sense; but in closed-die forgings, always made from bars or billets which have the grain running longitudinally, very careful attention can be paid to the grain disposition so that maximum strength is achieved.

Forgings are made in many metals. In addition to the various alloys of steel and iron, other metals and alloys that may be forged include copper, brass, bronze, nickel, aluminum, magnesium, titanium and the various high temperature alloys. Considerable progress has been made in forging the newer light alloys.

Conventional iorging is divided into four classes, dependent on the type of machine used: hammer forging, upsetting, open frame or smith forging, and helve hammer forging.

Hammer Forging.—In hammer forging, four types of hammers are employed: the board drop gravity hammer; the air lift gravity drop hammer; the steam drop hammer; and the steam-driven hammer. All have these features in common: a base; a hammer or ram which strikes the base and which travels vertically between side guides, and the overhead mechanism for lifting the hammer and releasing it. In the board drop gravity hammer a board, or set of boards, generally of maple, raises the ram. The lower end of the board is fastened to the upper portion of the ram and the upper end of the board travels between two driven rolls revolving in opposite directions. An automatic mechanism moves rolls toward one another, into contact with the board, and as they revolve they lift the board and attached ram. The rolls then spread apart, allowing the ram to fall. The steam drop hammer utilizes a steam cylinder for the lifting mechanism, a piston rod taking the place of the board and the ram being fastened to the lower end of the piston rod. The air lift gravity drop hammer is fundamentally the same as the steam drop hammer, but uses compressed air instead of steam. The steam-driven hammer operates in similar fashion except that the downward stroke of the ram is accelerated by both gravity and steam pressure.

Whether for closed die or flat die (smith) forging, metal to be drop forged is first heated in an adjacent furnace. In closed die forging, the heated metal is placed between the drop hammer dies and several blows are struck in quick succession, forcing the metal evenly into the die impressions. The number of blows must be gauged with close accuracy by the forging hammer operator. Too few blows will not obtain uniform strength in the forging, while too many will shorten the life of the dies. A small quantity of metal is forced outward, beyond the limits of the actual forging impressions when the two dies meet, and this surplus, called "flash!" is removed after forging by means of trimming tools fixed in a press. One tool duplicates, in solid form, the outline shape of the forging; the other is made hollow to the outline of the part at the point of the flash. The forging is forced through the hollow tool by the solid one, cutting off the flash. The forging may subsequently be returned to the hammer for one more blow to correct any small distortion occurring during the trimming operation.

Drop forging hammers are rated according to the weight of the falling ram. Ratings range from 400 to 7,500 lb. capacity for board drop hammers; 500 to 5,000 lb. for air or steam lift gravity drop hammers; 1,000 to 50,000 lb. for steam-driven closed die drop hammers; and 200 to 100,000 lb. for steam-driven smith hammers.

Upsetting.—In the upsetter or forging machine, a bar or "multiple" is heated and placed in the opening between a pair of gripping dies; one of these may be fixed or both may be movable. A ram is then forced against the end of the held bar, upsetting it and forcing the metal to fill whatever impression the gripping dies contain. The ram is then withdrawn and the gripping dies open for removal of the piece. The size of forgings produced by the upset method ranges from less than a pound to as much as 500 lb. Gpsetters are rated according to the size of the initial stock processed. Commonly, the size range of equipment is from one-half inch to about eight inches.

Open Frame or **Smith** Forging.—Open frame forgings are made by hammer forging the metal between a pair of flat dies, and some of the shape may be given to the piece by use of stock hand tooling. Thus, the shaping of the forging depends to a great extent upon the skill of the hammersmith. Smith forgings are made to approximate sizes and usually must be machined on surfaces requiring close dimensions. For this reason, the smith-forging method is usually employed when quantities are small and the finished shape can be completed by machine work, or when sizes are too large or irregular to be contained in closed dies. The size range of smith forgings is from less than a pound to more than 200 tons.

Helve Hammer Forging. — Helve hammers are used principally for high-speed work for which the heavy impact of drop hammers is not required. The striking force is delivered to the dies by a wooden helve (handle), operating with the motion of a hand sledge. The upper die may be fastened to a guided ram operated by the helve, or to the helve itself. Preparatory and finishing operations and light production work are usual applications of helve hammers.

Forging Presses. — The machines used for forging can be classified in two major categories, hydraulic and mechanical. Hydraulic forging presses are used both for smithing operations and for closed-die forging. The hydraulic medium may be either water or oil, but steam- and air-operated presses are also used. The hydraulic pressure may be applied through one or more rams to give single pressing action from above or below, or in combination with side-cylinder movements. For double-action purposes, one set of rams may furnish a holding action while another ram or rams complete the forming action. The source of fluid pressure may be a storage accumulator of the water, air or nitrogen type. Alternatively, a direct pumping system commonly is used for efficiency and rapid response on self-contained presses.

Mechanical forging presses are the second structural type. A crank or eccentric drive furnishes power stored in a flywheel through a clutch to the slide and dies of the press. Mechanical forging presses are used particularly for mass-production closed-die work. More care must be taken with billet-size control and with thorough heating of billets to avoid damage to the positive actuating structure of the press. Single-crank machines are the most common, although wider double-crank types are desirable where a number of operations are required to complete the forging. Also in use are double-action mechanical presses in which one action closes the dies and the second action forces the metal to fill the dies.

The sizes of commonly used forging presses range from 50- to 300-ton capacities (this rating describes the pressure which can be exerted), while larger mechanical presses range up to 6,000 tons. The need for larger, stronger parts for jet and turbojet aircraft made necessary the development of giant hydraulic forging presses ranging from 25,000 to 50,000 tons capacity and larger. On these presses, complete wing and air-frame components formerly requiring hundreds of assembled parts can be forged in one piece, resulting in important savings in time and tooling costs as well as improvements in strength-to-weight ratio and performance.

In conjunction with the larger presses, heavy mobile manipulators or overhead cranes and lift trucks are essential for handling large forgings and for changing dies. Control systems for forging presses vary widely in design, depending upon the type of press and the work to be performed. Thus. for flat-die presses the ram is made to respond directly to manual hand or foot control so that the stroke may be long or short and pressure may be applied in a series of rapid strokes or intermittently, as required. For production types with closed dies, it is more usual to employ push-button or foot-pedal remote control, and the operator, aided by simple gauges, plus sight, sound and touch, can easily judge the proper action.

Control of the larger 25,000- to 50,000-ton forging presses requires the operator to depend on indicating instruments, servo-mechanisms and electronic aids for instantaneous, exact information on press reactions. Operators must also undergo special training. Severai crewmen and observers are required, working under the chief operator who is stationed at a console-type control board.

OTHER FORGING PROCESSES

Roll Forging. — Another method of forging is by the use of matched rotating rolls or segments of rolls which have impressions sunk in their surfaces. The metal blank is rolled into these impressions a's the rolls turn. Forging rolls are used chiefly for elongating and tapering stock for parts such as gear shift levers. Processing in forging rolls is frequently used in conjunction with other forging operations in hammers or upsetters.

Impact Forging. — The impacter is essentially a forging hammer in which both dies are moved from opposite directions, meeting at the point where the forging blow takes place. The movement of the dies is in the horizontal plane. The process has several advantages. Since the dies are of approximately the same weight, each tends to absorb inertial energy of the other at the point of impact. in contrast with the conventional hammer which transmits energy through the anvil and hammer base to its foundation. For this reason the impact type of equipment does not require the heavy foundations necessary for conventional hammer-type equipment. For the same reason, more energy is absorbed by the metal blank being forged, which is of advantage in processing material which is tough and resistant to forging, such as stainless steel, or which has a low modulus of elasticity and consequently absorbs much energy, such as aluminum. Other advantages include the facts that stock is worked equally from two opposing sides; that contact between stock and die occurs only during actual impact, resulting in lower die temperature and longer die life; and that stock is moved more rapidly and less forging energy is required. The capacity of impacters is rated according to the force of the blow delivered, measured in foot-pounds, and sizes range from 400 ft.-lb. to 15,000 ft.-lb.

Counterblow Forging. — Similar to the impacter, counterblow forging hammers were introduced in the United States after World War II. The counterblow hammer, as may be inferred from the name, uses two vertically operating, counteracting rams. The lower ram and die replace the anvil of the conventional forging hammer. The rams move together with nearly equal kinetic energy, imparting this energy to the metal being forged. Thus, kinetic energy is concentrated upon the forged piece from two opposite sides. This symmetrical blow of two rams on the forged piece, with accompanying energy concentration, makes possible the forging from resistant alloys of intricate shapes to close tolerances. It also provides for shock absorption within the forging itself. eliminating the need for deep hammer foundations and avoiding energy losses into the foundation. The impact velocity of the rams for counterblow hammers is reported to be about half that required for conventional drop hammers. The counterblow hammer fills a gap between the drop hammer and the hydraulic press, because it makes possible the economical forging of larger parts and complex shapes.

Cold Forging. — Much progress has been made in forging metals "cold." or at temperatures below the point at which grains begin to coarsen (a point above 1,700° F. for steels, varying according to alloy content). Advantages of dimensional accuracy, improvement of mechanical properties and other benefits are gained. Cold heading has of course been used for many years in the manufacture of bolts and similar products.

DIE BLOCKS AND DIE MAKING

For production of a closed-die forged article, impressions are cut in two die blocks to the exact shape and size of the part wanted, with compensation for normal die wear and shrinkage. Since metal is forged while hot and shrinks in cooling. contraction must be allowed for when making dies. All forging dies are made larger than the size of the cold piece by an amount equal to normal shrinkage. Careful attention is given to the cutting of die impressions, which are frequently very intricate. Expensive steel is employed for dies, and highly skilled craftsmen prepare the die impressions. In the design of dies for production of forgings. no hole or depression may be larger at the bottom than at the top, although it may be smaller. In actual practice. it is ordinarily slightly smaller by an amount equal to the "draft." as the angle at the side of every depression is called. No surface of a drop forging may be parallel to the path of travel of the dies, but must depart from parallelism by an amount not less than the draft angle and in the direction which will make all parts of the forging smaller at the bottom of the impression than at the top in each die. The usual draft angle is 7°.

Die design is influenced by the quantity of parts to be made at one setting of the dies as well as by the quantity eventually wanted. Dies may be designed to make two or more forgings at once, the forgings later to be cut apart by trimming.

The cutting of die blocks involves several steps. and various impressions may be cut into the die faces to permit successive stages in forging the part to final shape. Basic preshaping forging impressions in sequence are fullering and edging, to alter the cross section of the material and blocking, to rough-shape the metal prior to placing it in the finishing impression. After the finishing impression has been cut in the die blocks, accuracy of the nork is tested by placing the pair of die blocks face to face and pouring melted lead into the impression and allowing it to harden. The resultant lead model of the finished forging is checked against specifications for the desired part

The quantity of forgings which one pair of dies will produce varies from as few as 100 pieces under poor conditions to a maximum of 500,000 under the best conditions. Normal life lies between 10.000 and 40 000.

Much attention has been given to improvement of die-sinking methods. One of the newer methods employs semiautomatic machinery which sinks die impressions by pantographic copying from a master or mock-up. Another method employs electrical disintegration. The "tools" used in this latter method are electrodes cast in the shape of the part to be forged. The cast electrode is placed in contact uith the face of the new die block and high voltage electric current is passed through it. The die metal erodes at points of contact with the electrode. passing into a solution in which the die is immersed. As metal is eroded the electrode sinks into the die face, forming the exact impression required It is reported that this method eliminates bench work and produces new dies at approximately 50% saving. The same method can be used to resink worn dies. *See* also METALLURGY. (R. E. KR.)

FORK, an implement formed of two or more prongs at the end of a shaft or handle the most familiar type of which is the table fork for use in eating. In agriculture and horticulture the fork is used for pitching hay and other green crops, manure, etc.; this has two to five prongs, or tines; for digging, breaking up surface soil. preparing for hand weeding and for planting the three-pronged fork is used. The word is also applied to many objects which are characterized by branching ends, as the tuning fork. with two branching metal prongs. which on being struck vibrates and gives a musical note, used to give a standard pitch; to the branching into two streams of a river. or the junction where a tributary runs into the main river; and in the human body, to that part where the legs branch off from the trunk. The *furca,* two pieces of wood fastened together in the form of the letter A, was used by the Romans as an instrument of punishment. It was placed over the shoulders of the criminal, and his hands were fastened to it. Condemned slaves were compelled to carry it about with them, and those sentenced to be flogged would be tied to it; crucifixions mere sometimes carried out on a similarly shaped instrument. See also CUTLERY.

FORKEL, JOHANN NIKOLAUS (1749–1818), German musician, was born on Feb. 22, 1749, at Meeder. Saxe-Coburg. The son of a cobbler, he was a good musician; but his fame rests on his historical work. His library, which was accumulated with care and discrimination at a time when rare books were cheap, forms a valuable portion of the State library in Berlin.

Forkel became organist to the university church of Gottingen, where he had been a student. in 1770, was made musical director of the university in 1778 and obtained the Ph.D. degree in 1780. He died there on March 20. 1818. His most important work is the *Allgemeine Literatur* der *Musik* (1792). His Uber *J. S Bachs* Leben, Kunst *und* Kunstwerke (1802), the first biography of that master, remains valuable and was translated into English in 1820 (new trans. by C. S. Terry, 1920).

FORLÌ, a town and episcopal see of Emilia Romagna (anc. *Forum Livii*), Italy, capital of the province of Forli. 40 mi. S.E. of Bologna on the railway to Rimini, 108 ft. above sea level. The population (1931) 45,927. The church of S. Mercuriale in the square contains paintings, and good carved and inlaid choir stalls. The fine square, brick campanile (1178–80) is 252 ft. in height. The municipal picture gallery contains works by Marco Palmezzano (1456–1537) and other interesting pictures, including a fresco representing an apprentice with pestle and mortar (Pestapepe), the only authentic work in Forli of Melozzo da Forli (1438–94), pupil of Piero della Francesca, and master of Palmezzano, of whose works there are several there. The Palazzo del Podesta is a brick building of the 13th century. The citadel (Rocca Ravaldina) uas constructed about 1360–70 and rebuilt later. The felt industry has considerable importance and the surrounding territory is very fertile.

Of the ancient Forum Livii, which lay on the Via Aemilia, hardly anything is known. In the 12th century we find Forli in league with Ravenna. and in the 13th the imperial count of the province of Romagna resided there. In 1275 Forli defeated Bologna with great loss. Martin IV sent an army to besiege it in 1282, which was driven out after severe fighting in the streets; but the town soon afterward surrendered. In the 14th and 15th centuries it was under the government of the Ordelaffi; and in 1joo was taken by Caesar Borgia, despite a determined resistance by Caterina Sforza, widow of Girolamo Riario. Forli finally became a part of the papal state in 1504.

FORM, in ordinary language, is the shape or structure of a thing, as contrasted with the materials of which it is made, or with its contents. Two objects might then be said to differ from each other in respect of their contents while being similar in form (*e.g.,* two of Shakespeare's sonnets); or in respect of their form, while being similar in materials (*e.g.,* two different models built from the same constructional apparatus) or similar in content (*e.g.,* Shakespeare's play *Othello* and Verdi's opera based on the story); or in respect both of form and of materials or content. Differences and similarities of form are a matter of degree. Two musical compositions may both be in sonata form, while differing greatly in their formal detail.

One play may resemble a second in being operatic, while differing from it and resembling a third nonoperatic play in being a tragedy. The greater the emphasis placed by an author, composer or artist on the structure of a composition, and the leis on its content. the more formal the work is said to be, so that in the extreme case "formal" is applied as a term of critical disapproval to a work which is highly strict and rigid in its structure, while bloodless in its content.

philosophy **and Logic.**—The notion of form has been constantly used in a variety of different ways throughout the history of philosophy. While Plato's word *eidos,* which is normally translated "form," perhaps should not be so translated (see IDEALISM; UNIVERSAL), Aristotle certainly made the distinction between matter (hypokeimenon or hyle) and form (eidos or *morphe*). The matter of a thing will consist of those elements of it which, when the thing has come into being, may be said to have become it; and the form is the arrangement or organization of those elements, as the result of which they have become the thing which they have. Thus bricks and mortar are the matter which, given one form, become a house, or, given another, become a wall. As matter they are potentially anything that they can become; it is the form which determines what they actually become. Here "matter" is a relative term, for a brick on the pile, while potentially part of a house, is already actually a brick; *i.e.,* it is itself a composite of form and matter, clay being matter to the brick as the brick is to the house or to the wall. Matter is that which is potentially a given object but which actually becomes that object only when it is given the right form.

Aristotle's notion of form combines with his teleological viewpoint to give the conclusion that formal development has a direction and may have a goal and that some things are more informed than others. Bricks are more informed than clay, and a house more than bricks. The four elements of which man is, as it was held. composed are the matter of man, but he, although at death he decomposes into them, is not the matter of them, for in his creation they are given a form whereas in his dissolution he is not given a form.

In logic (*q.v.*) it has always been recognized that form is the central notion of the subject; that logic is the study of the rules of argument, independent of the particular subject matter involved in the argument: and that the validity of the argument depends upon the formal properties and relations of the statements. Because logic is in this sense formal, logicians have since the time of Xristotle tended to employ symbolic notations designed to exhibit the forms of statements and of arguments independent of their subject matter. in this way assimilating logic to mathematics; some have even gone so far as to claim that mathematics is reducible to logic. While the use of a special notation is helpful for displaying logical form. it has encouraged certain erroneous tendencies such as to suppose that a given statement has only one form. so that the question can sensibly be asked what is the form of that statement (whereas in fact it may have different forms in difierent respects) ; that the parts which a statement may play in arguments depend on its form (whereas in fact those parts are its form); or that the logical form of a statement is quite separate from its linguistic form (a mistake made possible only by a very superficial view of the nature of language). The logical forms of statements are wrongly conceived of as the skeletal structure of each: they should rather be thought of as the logical powers which they possess in varying kinds of arguments and inferences. (A. D. W.)

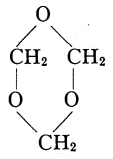
Other Senses. — Some notion of form is indispensable to the practice and criticism of several disciplines other than philosophy and logic. In literature, form is the schema or structure that a writer chooses for the presentation of his matter; *e.g.*, novel, short story. maxim: epic. sonnet: pantoum, etc. (see the individual articles on the various prose and verse forms). In criticism of the graphic and plastic arts. form means either the effect achieved by draftsmanship or mass as opposed to that achieved by colour or the total effect of the technical organization of the work as opposed to its representational significance (if any). In the study of the Gospels, form criticism is the attempt to analyze the narrative according to supposed sources and to classify each episode according to the form in which it is recorded, this form being regarded as distinctive of the special interests and motives of a particular body of preaching from which the evangelists derived the story of the episode. In sport, form is the standard of an athlete's or an animal's attainment as tentatively calculated from past performances.

FORMALDEHYDE, is the first member of the aldehyde group of chemical compounds. Pure monomeric formaldehyde is a rather unstable compound. but it has been obtained and is a gas (boiling point. −21° C.; melting point, −92° C.). It has the formula H.CHO. On keeping, the monomer is transformed into the polymer, trioxytrimethylene, $(CH_2O)_3$, which has the cyclic structure (I) below.

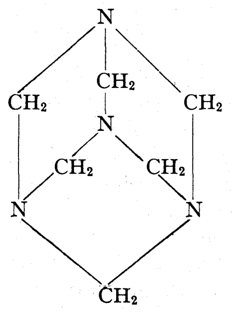
Practically all the formaldehyde now produced is made by a catalyzed vapour phase oxidation of methanol, $2CH_3OH + O_2 \rightarrow 2CH_2O + 2H_2O$. Of the many different catalysts which are effective, those which are used most frequently are silver either as a deposit on asbestos or as a fine wire mesh. Formaldehyde is available commercially as its aqueous solution, which is normally called formalin and which contains 36%–38% by weight of formaldehyde. On keeping formalin solutions. paraformaldehyde is precipitated as a white Solid; it has the indefinite structure $(CH_2O)_n$. H_2O. Paraformaldehyde is of considerable technical importance because it is transformed into formaldehyde just by heating. Thus the solid paraformaldehyde is a convenient source of gaseous formaldehyde.

Chemical Properties. — Although formaldehyde contains the aldehydic $-CH=O$ function, it does in fact show many reactions which are not typical of the other aldehydes. Formaldehyde is oxidized to formic acid and is reduced to methanol. It reacts with practically all types of organic compounds including unsaturated hydrocarbons. aldehydes. ketones, esters, alcohols. carbohydrates. proteins, amines. amides and phenols, and it is this versatile chemical behaviour which makes formaldehyde such an important intermediate in technical processes.

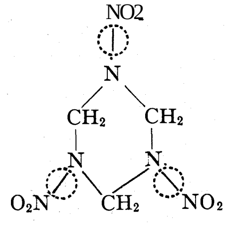
Industrial Uses. — Formaldehyde and ammonia yield hexamethylenetetramine (II), which is used medicinally as a urinary antiseptic. Nitration of hexamethylenetetramine gives the explosive, RDX (III). Formaldehyde, acetaldehyde and calcium hydroxide give pentaerythritol, $C(CH_2OH)_4$, the intermediate in the manufacture of the explosive penterythritol tetranitrate, PETS.



I



II



III

Large quantities of formaldehyde are used in the manufacture of urea-formaldehyde and phenol-formaldehyde plastics (*see* RESINS: Synthetic Resins). The reaction of proteins with formaldehyde forms the rationale for its use in the tanning industry and in the treatment of various vegetable proteins so that they become fibrous and can then be used in textile manufacture. The reactivity of proteins toward formaldehyde is also the reason for its use as a disinfectant, as an embalming agent and as a sterilizing agent for soil.

See J. F. Walker, Formaldehyde (1944). (W. D. Os.)

FORMALIN: see FORMALDEHYDE.

FORMALISM, in philosophy generally, means undue attention to forms (of thought. or reasoning, etc.), at the expense of content and concrete circumstances. In ethics and religion it refers to the attachment of undue significance to the externals of convention, or to ritual, at the expense of the spirit and substance of morality and religion respectively.

FORMAN, ANDREW (c. 1465–1521), Scottish ecclesiastic, was educated at the University of St. Andrews and entered the service of King James IV, who employed him on various foreign missions. In 1501 he became bishop of Moray, and in July 1513 Louis XII of France secured his appointment as archbishop of Bourges, while Pope Julius II promised to make him a cardinal. In 1514 Forman was nominated by Pope Leo X to the vacant archbishopric of St. Andrews and was made papal legate in Scotland, but his possession of the see was delayed until 1 j16 because of the rivalry of Gavin Douglas, the poet, and John Hepburn, prior of St. Andrews. He died on March 11, 1521. As archbishop he issued a series of constitutions which are printed in J. Robertson's *Concilia* Scotiae (1866).

A. Lang (History of Scotland, vol. i) describes Forman as "the Wolsey of Scotland, and a fomenter of the war which ended at Flodden."

See J. Herkless and R. K. Hannay, The Archbishops of St. Andrews, vol. ii (1909).

FORMAN, SIMON (1552–1611), English quack physician and astrologer, was born on Dec. 30, 1552, in Quidhampton, a small village near Wilton, Wiltshire. At the age of 14 he became apprentice to a druggist at Salisbury, but at the end of five years he exchanged that profession for one of a schoolmaster. Shortly afterward he entered Magdalen college: Oxford: where he studied chiefly medicine and astrology. After continuing the same studies in the Netherlands he commenced practice as a physician in London, but he possessed no diploma and was imprisoned a number of times.

Ultimately, however, Forman obtained a diploma from Cambridge university after he had established himself as a physician and astrologer at Lambeth, where he was consulted by many persons of high society, especially women.

A professed practitioner of necromancy, he was condemned on various occasions by the College of Physicians: He died suddenly while crossing the Thames on Sept. 12, 1611.

FORMIA, a town of Lazio. Italy (anc. *Formiae*), province of Latina, on the new direct line between Rome and Naples, 50 mi.

N.W. of the latter. Pop. (1951) 12,077. It is situated at the northwest extremity of the Bay of Gaeta and commands beautiful views. It lay on the ancient Via Appia, and was much frequented by wealthy Romans; and it is still a seaside resort in the summer. There was considerable imperial property there and along the coast as far as Sperlonga, and there are numerous remains of ancient villas along the coast and on the slopes above it in some of which important sculptures have been found. The so-called villa of Cicero contains two well-preserved *nymphaea* with Doric architecture, now visible in the villa Caposele, once a summer residence of the kings of Naples. There are many other modern villas, and the sheltered hillsides (for the mountains rise abruptly behind the town) are covered with lemon, orange and pomegranate gardens. The now deserted promontory of the Monte Scauri to the east is also covered with remains of ancient villas; the hill is crowned by a large tomb, known as Torre Giano. To the east at Scauri is a large villa with substructions in "Cyclopean" work.

The ancient Formiae was a Volscian town. Cicero possessed a favourite villa there, and was murdered in its vicinity in 43 B.C., but neither the villa nor the tomb can be identified with any certainty.

FORMIC ACID was first prepared from red ants (Lat. *formica*). It occurs naturally in animal secretions and in muscle. It is the first member of the series of aliphatic monobasic acids (*q.v.*), distinguished from the other members of the series by certain characteristic properties. For example, it shows an aldehydic characte'r in reducing silver salts to metallic silver, it does not form an acid chloride or an acid anhydride, and, by the abstraction of the elements of water from the acid, carbon monoxide is produced, a reaction which finds no parallel in most higher members of the series. Finally, formic acid is, as is shown by the determination of its ionization constant, a much stronger acid than the other acids of the series. Its formula is H.COOH. It may be prepared synthetically by the oxidation of methyl alcohol and of formaldehyde; by the rapid heating of oxalic acid (J. Gay-Lussac, 1831); but best by heating oxalic acid with glycerine at a temperature of 100°–110° C. (M. Berthelot, 1856). In this reaction a glycerol ester is formed as an intermediate product, and undergoes decomposition by the water which is also produced at the same time.

On the industrial scale, formic acid is made from sodium formate (*see* below). It is employed in the dyeing and tanning industries and in organic synthesis.

Formates are produced by the action of moist carbon monoxide on soda lime at 190°–220° C. (V. Merz and J. Tibiriçá, A. Geuther, 1880). An interesting process for sodium formate, due to Bredig and Carter (1915), consists in reducing a solution of sodium bicarbonate with hydrogen at 70° C. under 60 atm. pressure in presence of a palladium catalyst. Sodium formate is manufactured by absorbing carbon monoxide by sodium hydroxide at 120°–130° C. under a pressure of 8 atm.

Concentrated formic acid is prepared by dissolving sodium formate in an equal weight of 90% formic acid, and then distilling the mixture with concentrated sulfuric acid in copper vacuum pans (M. Goldschmidt, 1894). Anhydrous formic acid results when the lead or copper salt is decomposed by dry hydrogen sulfide at 130° C. Solid formic acid melts at 8.6° C. At ordinary temperatures, formic acid is a colourless, sharp-smelling liquid that boils at 100.8° C. Its specific gravity is 1.2206 (20°/4°). It is miscible in all proportions with water, alcohol and ether. The sodium and potassium salts, when heated to 400° C., give oxalates and carbonates of the alkali metals, but the magnesium, calcium and barium salts yield carbonates only. The free acid, when slightly warmed with concentrated sulfuric acid, is decomposed into water and pure carbon monoxide; when heated with nitric acid, it is oxidized first to oxalic acid and finally to carbon dioxide. The salts of formic acid, the formates. are mostly soluble in water. The calcium salt, when heated with the calcium salts of higher homologues, gives aldehydes. The esters of the acid may be obtained by distilling a mixture of the sodium or potassium salts and the corresponding alcohol with hydrochloric or sulfuric acids.

Formamide, $H.CO.NH_2$, is obtained by heating ethyl formate with ammonia, by heating ammonium formate with urea to 140° C., or by heating ammonium formate in a sealed tube for some hours at 230° C. It is a liquid ahich boils at 122° C. under a pressure of 32 mm., but at 200° C. under ordinary atmospheric pressure. with partial decomposition into carbon monoxide, water, ammonia and hydrogen cyanide. (*G.* W. WD.)

FORMICARIIDAE: *see* PITTA.

FORMIGNY, BATTLE OF (1450). The battle of Formigny, fought on April 15, 1450, was the last but one waged by the English during the Hundred Years' War. Its special interest lies in the use of field artillery, and its influence on bow and lance tactics. The duke of Somerset was at Caen threatened by an overwhelming French army under King Charles. To open a way to this city. Sir Thomas Kyriel and 4,500 men were dispatched from England. At Formigny this force was confronted by the count of Clermont at the head of about 3,000 lances, a body of local infantry and two small cannons. Kyriel should have attacked the French at once, since his object was to relieve the duke who was hard pressed, but so wedded were the English to defensive tactics that he fell back behind Formigny to a brook lined by orchards, and there drew up his men in a convex line, the archers covering their front by a trench and the usual palisade of stakes. The French, having by now learned the folly of assaults on unshaken bowmen, skirmished for a while. Then Clermont ordered Giraud. "master of the royal ordnance" to bring up his two guns to enfilade the English line. This proved so effective that the archers left their defenses and charged forward capturing the pieces. Kyriel, in place of advancing the whole line and so taking advantage of the mêlée, persisted in the defensive, with the result that the archers who had captured the two guns were attacked in flank, and not being able to make use of their bows were thrown back in disorder onto the men at arms. A clinch then took place, and the battle was decided by a fresh body of French knights (under the counts of Richemont and Laval) appearing on the field. This force charged the English in flank, surrounded them and annihilated Kyriel and his main battle. The English losses amounted to no less than 3,750, those of the French were probably about 1,200. This battle marks one of the great turning points in tactics, for before the 15th century ended cannon played an increasingly important part at every siege, and on every field.

See Blondel, *Reductio Normanniae;* C. Oman, *The Art* of *War in the Middle Ages* (1924). (J. F. C. F.)

FORMOSA, a northern province of Argentina bordering the republic of Paraguay, has an area of 27,825 sq.mi. Pop. (1956 est.) 184,719, a large percentage of whom are Indian. The province lies within the Chaco (*q.v.*), a vast alluvial plain covered with forests interspersed with grasslands and marshes. It has a subtropical climate, with a long rainy season (October to June) and an average temperature during those summer months of 80° F. The winter months are dry, with an average temperature of 63°. Agriculture (particularly tobacco and sugar) and cattle-grazing are the chief sources of wealth, but both activities are seriously handicapped by recurrent droughts and floods. Quebracho trees (from which tannin is extracted) grow wild in the more distant forests. The capital is Formosa (pop. 1956 est., 26,645) on the bank of the Paraguay river. (GE. P.)

FORMOSA (TAIWAN), is an island separated from the southeast coast of China by the 100-mi. wide Taiwan strait (T'ai-wan hai-hsia) and one of a great island system rimming the western Pacific ocean. Generally oval-shaped and with a north-northeast-south-southwest axis, it is 235 mi. long and 90 mi, wide at maximum; it lies between parallels 21° 54' N. and 25° 20' N. and meridians. 120° 4' E. and 121° 57' E. Its area, exclusive of the neighbouring Pescadores but including several other small offshore islands, is 13,837 sq.mi. To the northeast are the Ryukyus; to the south the Bashi channel and the Philippines. The origin of the Chinese name T'ai-wan (conventionally Taiwan) is unclear; Formosa, commonly used by many is from the Portuguese word meaning beautiful.

Physical Geography. — Formosa is a great fault block, tectonically unstable, trending north-northeast — south-southwest and tilted toward the west. Its eastern margin marks the edge of the continental shelf. The highest areas are in the Chung-yang Shan-mo (Central range). the crest of nhich lies east of the island axis. Numerous peaks rise above 10.000 ft.. the highest being Yu Shan (12,959 ft.; called Niitaka Yama by the Japanese and Mt. Morrison by westerners). Old. resistant sedimentary and metamorphosed rocks are exposed by erosion in the east. and younger softer sedimentary formations in the west. East of the mountains is a long (100 mi.), narrow (5–9 mi.) valley of fault origin, covered with alluvium and open at its northern and southern ends to the sea. Farthest east are the eastern coastal ranges of volcanic origin, rising to 7,000 ft.

TIERS FQOM MCNKMEYER

COOKING ON A HABACHI ("STOVE") IN T'AI-CHUNG, FORMOSA

West of the central highlands is a coastal alluvial plain, still being extended into the shallow Taiwan strait, 25 mi. at its greatest width. and the heartland of the island. This plain is broken by hills north of 24° N. into a southwestern component and a lesser, fragmented northern portion, including the fertile T'ai-pei basin, to the north of which are volcanic highlands rising to 3,700 ft. Along the northeastern coast is an isolated alluvial lowland. the triangular I-Ian plain.

Rivers in general are short and subject to extreme variations in flow especially on the southwestern plain. Soils of alluvial origin cover about a fourth of the island and are its chief wealth. Upland soils are leached, acid and of low fertility.

About 55% of the island is forested; another 12% is wasteland. Forests are graded altitudinally, from coniferous stands above 9,000 ft. through mixed stands to about 6,500 ft. of cedars, cypress. junipers, rhododendrons. maples and cryptomeria to broad-leaved evergreen forests which include camphor trees. In the lowlands are mixed bamboo, evergreen and palm stands. Steppelike vegetation occurs in the drier southwest.

Climate.—Lowland Formosa is frost-free. The climate is ameliorated by the waters of the warm Japan or Black current. The mean temperature of the coldest month, January, in the north is about 58° F.; summers are hot and humid. and in the south winters are warm to hot as well. Temperatures fall with altitude. however, and the central mountains are snow-covered in winter. All areas receive 40 or more inches of rainfall. and the mountains receive up to five times that figure. The southwest. which lies in the winter lee of the central mountains, receives its rainfall almost entirely in the summer months. The northeast also receives orographic winter precipitation.

Population. — Population is predominantly Chinese. Most are the descendants of immigrants from Fukien (Fu-chien) province, chiefly from the Lung-ch'i (Chang-chou) and Ch'üan-chou areas; secondly from Kwangtung (Kuang-tung) province, chiefly Hakkas (*q.v.*) from the hinterland of Swatow (Shan-t'ou). Seven major Chinese dialects are spoken by these people. In addition, a sizable immigration of Chinese, many Mandarin-speaking, from other parts of China occurred after 1946. The aborigines, numbering some 200.000. are of Indonesian origin and reside in the foothills and highlands where many practice shifting cultivation. The Ami. Atayal, Paiwan, and Apayao (Izneg) are the major groups, all experiencing partial assimilation.

In 1905 the Japanese took the first census! and seven population censuses were taken thereafter at five-year intervals: followed by censuses in 1946 and 1956. The population of Taiwanese (exclusive of Japanese and other foreigners) increased from 2,970,000 in 1905 to 5,510.000 in 1940. By the mid-1930s the rate of natural increase had accelerated to 24 per 1,000. This rate increased in the late 1950s to about 36 per 1,000 because of falling death rates (8 per 1,000 in the late 1950s) and continued high birth rates (about 46 per 1,000). This meant a young population, and over 40% was under 16 years of age. The official population for 1956 was 9,390,381, not including military personnel from the mainland. their families or others not classified as permanent residents. Estimates of total population, however, reached 12,000,000 or 867 per square mile.

Most Taiwanese live in villages, as in the south, or in dispersed rural settlements, as in the north. Few are urban, although a pre-World War II drift to the cities mas accelerated after 1949. The mainland Chinese are urban, and the rapid urban growth since 1946 partially reflects their arrival. In 1956 T'ai-pei with 748,510 population and Kao-hsiung, the southern regional focus with 371,-22j, were the major cities. Three others had populations of over 200,000, including Chi-lung (Keelung), the port of T'ai-pei. However, population figures were inflated by many rural people living within the official municipalities. Other large towns are Hsin-chu (Sin-chu) and P'ing-tung (*qq.v.*).

History.—Taiwan was known to the Chinese as early as the beginning of the 7th century A.D., but settlement did not take place until the first quarter of the 17th century after recurrent famines in Fukien province encouraged the emigration of Fukienese from the Chinese mainland. Before then, the island was a base of operations for Chinese and Japanese pirates. The Portuguese who discovered the island in 1590 and named it Formosa. made several unsuccessful attempts at settlement. The Dutch and Spaniards established more lasting settlements, the Dutch at An-p'ing in southwestern Taiwan (1624), the Spaniards in 1626 at Chi-lung. Until 1646 when the Dutch seized the Spanish settlements, northern Taiwan was under Spanish domination. the south under Dutch control. The Dutch were defeated in 1661 by Koxinga (Cheng Ch'eng-kung), a man of mixed Chinese-Japanese parentage and supporter of the defeated Ming emperors. who used the island as a centre of opposition to the Ch'ing (Manchu) regime. In 1683, 20 years after Koxinga's death, the island fell to the Ch'ing and became part of Fukien province. Meanwhile. sizable migrations of refugees. Ming supporters, had increased the population to about 200.000. Settlement proceeded from south to north and from the western coast to the foothills of the central highlands, held by the aboriginal tribes.

Population increased rapidly as immigrants streamed in from the southeast China coast: and large areas in the north came under the plow. T'ai-nan (then known as T'ai-n-an) acted as the capital. Settlement of the eastern coastal areas began in 1796. By 1842 the population had risen to an estimated 2,500,000, and both rice and sugar had become important exports to China proper. In 1858 the treaty of T'ien-ching (Tientsin) designated two Taiwan ports as treaty ports. T'ai-nan and Tan-shui, the latter a river port, long used as a port of call under the Spanish and Dutch, and downstream from the growing city of T'ai-pei. Tea became an important export crop, and the island's trade centre shifted to the north. particularly to Tan-shui where British and other trading companies established their headquarters. In 1875 T'ai-pei became the capital of northern Taiwan.

Japan's continued interest in the island was reflected in a Japanese punitive expedition of 1874 ostensibly to protect the lives of Ryukyu fishermen along the island's coasts. The French

PHOTOGRAPHS. (TOP LEFT, CENTRE RIGHT) BARRY SCHUTTLER FROM BLACK STAR, (TOP RIGHT, BOTTOM LEFT) PAUL BERG— POST DISPATCH PICTURES FROM BLACK STAR. (BOTTOM CENTRE AND RIGHT) HEDDA MORRISON— CAMERA PRESS PIX FROM PUBLIX blockaded the island during the undeclared Chino-French war of 1884–5 and occupied Chi-lung for a short period. In 1886 Taiwan became a separate province of China with a legal capital at T'ai-chung and a temporary capital at T'ai-pei which became the legal capital in 1894. Considerable economic development took place in the next eight years under the initial leadership of Liu (Ming-chuan).

In 1895, as a result of the treaty of Shimonoseki after the Chinese-Japanese War (*q.v.*), China ceded Taiwan and the Pescadores Islands (*q.v.*) to Japan, and the Japanese occupied T'ai-pei in June of that year over the violent opposition of the Chinese population. For several months a Republic of Taiwan was in existence. but it was overcome by Japanese army and naval forces. The Japanese also faced the hostility of the aborigines, some of whom remained uncontrolled until the outbreak of the Pacific war. Under the Japanese. Taiwan was developed as a major supplier of rice and sugar for Japan. Irrigation projects, agricultural extension services, and improvements in transportation and power supplies led to rapid increases in Taiwan's gross product. Japanese policy was oriented toward the Japonicization of the Taiwanese; Japanese was the language of instruction in a widespread basic educational system, and even after the end of World War II Japanese remained a *lingua franca* among the various Chinese dialect groups. In the 1930s Japanese economic policy shifted toward the development of industries based on relatively cheap hydroelectric power. such as aluminum refining and ferroalloy manufacturing. Nevertheless, rice and sugar remained the basis of Taiwan's prewar export trade, almost all of which was directed toward Japan. Imports consisted largely of diverse manufactures from Japan. During World War II, Taiwan was a major staging area for Japan's invasion of southeast Asia, and it was described as the largest "aircraft carrier" outside Japan. By 1940 its total population, including Japanese, had risen to 5,870,000.

As a result of the Cairo agreement of 1943, Taiwan was turned over to the Chinese Nationalist government on Oct. 25. 1945, after the defeat of Japan. Antagonism against the new regime was reflected in an uprising in 1947. In 1949–50, following the victories of the Chinese Communists on the mainland, a stream of Nationalist troops, government officials and other refugees estimated at 2,000,000 persons. poured onto the island, and Taiwan became the effective territory, apart from a number of islands off the China coast. of the Republic of China (Nationalist China).

Following the outbreak of the Korean war in 1950, the United States interposed its 7th fleet between the island and the mainland to protect it from further Communist attack. In 1955, Nationalist China and the Gnited States entered into a mutual security agreement to defend the island and the Pescadores. American assistance was given in two forms, economic and defense. Economic support amounted to about $650,000,000 between 1951 and 1958. Direct military assistance was estimated to be at least that figure. An American military advisory group was established in 1951 to assist in training military forces and to advise on other military matters. Throughout the 1950s the government of the People's Republic of China declared its intention of eventually conquering the island; the Nationalists, also describing it as an integral part of China, held to their objective of using Taiwan as a stepping-off point for an eventual return to the mainland. (*See* also CHINA: *History;* CHIANG KAI-SHEK.)

Administration and Social Conditions.—Taiwan is regarded by both Communist and Nationalist Chinese as a province of China (T'ai-wan sheng). Controlled by the Nationalists, it is divided into 16 counties (hsien) one of them the Pescadores, and 5 municipalities (*shih*)—T'ai-pei, Chi-lung, T'ai-chung, T'ai-nan and Kao-hsiung (Takao) ; the provincial government is headed by an appointed governor; a provisional provincial assembly is elected. Governments at the *hsien* and *shih* level also are elected, as are officials of townships and villages. T'ai-pei is the temporary capital of the Republic of China. The provincial capital is located at Chung Hsing Hsin Ts'un, near T'ai-chung. Thus. two governments are operative on the island, one national. one provincial.

In the late 1950s a national military establishment numbering about 600,000 persons, chiefly mainland Chinese, was based on the island. equipped with weapons provided under the military aid program of the United States; American personnel acted as advisors.

Living standards in Taiwan were among the highest in Asia in the 1950s, but rapid population increases, underemployment and overcronding, particularly in the cities, have created major problems. Although a third of the people were illiterate. education at the elementary level was available for about 94% of the younger population; instruction was in Mandarin, the Chinese national language. Only one-fifth of the lower school graduates attended secondary school. and less than 4% attended institutions of higher learning The latter included the National Taiwan university (T'ai-pei), with over 6 000 students and a library of 500,000 volumes, the Taiwan Provincial Normal university (T'ai-pei), the National Political university (near T'ai-pei), the Cheng-kung university (engineering) at T'ai-nan, and after 1957 a new National Ch'ing-hua university at Hsin-chu. Several American universities were co-operating with these and other institutions.

Public health facilities uere widely distributed in the form of over 400 government-supported health stations and clinics, although environmental sanitation remained poorly developed, and only the major cities had pure nater supplies.

Social change in Tainan was accelerated during the 1950s as an urban way of life began to permeate the island through improved communications. About 30 newspapers had a combined direct circulation of 350,000 and an effective circulation several times that number. There were some 475 periodicals and magazines and over 200 000 radio sets, each serving several people. The many traditional and government-sponsored local associations, organized for varied socioeconomic purposes, reflected both Chinese and Japanese influences. but the family was becoming less important as the key to social organization. Religion tended to be a polytheistic amalgam of Buddhist, Confucian, Taoist and animist ingredients,

TIERS FROM MCNKMEYER

WASHING CLOTHES AT THE EDGE OF A CANAL IN T'AI-CHUNG, FORMOSA

with Christianity a minor element.

Economy. — Formosa's industrial resources are limited and agriculture is the leading element in the framework of the economy. In the late 19jos. 60% of the gainfully employed were engaged in agriculture and fishing

Agriculture.—The single most important crop was rice, which supplied one-half of the total agricultural product and occupied 61% (most of the irrigated portion) of the total cultivated area (2 200,000 ac.. one-fourth of the island's area). Most paddy fields nere double-cropped. Half the rice produced was high-grade *pon-lai* rice, introduced originally by the Japanese. Both rice acreages and output were higher than in the pre-World War II period, output reaching 1,900,000 metric tons of brown rice, or one-third more than in 1938, although yields per acre remained about the same. Sugar cane, the next most valuable crop in the southwest, competes with rice for land and is raised on smallholdings. Acreages vary, but averaged about 200,000. Annual sugar output was about 800,000 metric tons, considerably lower than the 1,400,000 tons produced in 1938–9. Sweet potatoes occupied the second largest acreage, 625,000, chiefly on slope lands unsuited to rice or cane. Production approximated 2,500,000 metric tons. Other important crops included tea, peanuts, bananas, pineapples, soybeans, wheat, citrus fruit and citronella grass. Increased consumption of wheat, both local and imported, reflected both dietary shifts and the presence of urban northern Chinese.

Production of rice and sugar cane depended on commercial fertilizers (500,000 tons consumed annually; 350,000 imported). Farm-originated fertilizers also were intensively applied, nightsoils and hog manures contributing to the formation of compost. The hog population exceeded 3,000,000; the water buffalo and cattle population 400,000. Agricultural improvement was encouraged by the Sino-American Joint Commission for Rural Reconstruction established in 1948. Farmers' associations and co-operatives helped provide credit, marketing facilities and technical assistance. The Land-to-the-Tillers act of 1953 resulted in a diminution of tenancy to 15% of the cultivated land from a previous 40%.

Fisheries.—Fisheries production rose to 200,000 metric tons annually, of which one-fourth mas produced by pisciculture.

Forestry.—Forestry production amounted to less than 500,000 cu.m. annually, chiefly from government-owned lands. Inaccessibility, low quality of many stands, and high costs of production made substantial lumber imports necessary. Over-cutting and delayed reforestation were associated with excessive erosion and destructive floods.

Mining.—Mineral resources are modest. Coal deposits, the most important, measured 115,000,000 metric tons of low-grade sub-bituminous reserves, and production varied around 2,500,000 tons annually. Some petroleum and natural gas were produced. Sulfur and sulfur pyrites mere important mineral resources; copper and gold less so. Salt (300,000–400,000 tons annually) was produced by the evaporation of seawater, though at relatively high costs.

Industries.—Industrialization, begun by the Japanese, centred about the generation of electric energy. Total capacity in the late 1950s was 520,000 kw. of which 75% was hydroelectric. The island is covered by an integrated distribution grid centring about the great installation at Sun Moon lake (Jih-yueh T'an). Nearly 80% of the electricity produced (1,800,000,000 kw.hr. was consumed by industry. Government participation characterizes almost every major industry. Government-owned enterprises include fertilizer, aluminum, sugar (26 large mills), coal, cement, paper, mining and machinery manufacturing, power, fertilizer. A largely privately owned textile industry with nearly 300,000 spindles makes the island virtually self-sufficient in cotton goods, and woolen, rayon, and silk mills also contribute to textile production. Glass, cement, leather goods, rubber goods and electrical equipment are important products, but the processing of agricultural products (rice-milling, sugar refining) remains the chief industrial activity.

Communications.—The government-operated railway system, also developed originally by the Japanese, extends for 590 mi., chiefly on the western plain; most trackage is Cape-gauge, but the 109 mi. east-coast line between T'ai-tung and Hua-lien is two feet six inches gauge. Additional two feet six inch gauge tracks (nearly 1,860 mi.) primarily carry cane, sugar and timber. Highways are less well developed. Of the total of 9,750 mi of roads and highnays, about 10% is surfaced, all-weather roads. A main north-south highway connects Chi-lung and Kao-hsiung; and there is a cross-island road. Port facilities are best developed at Kao-hsiung and Chi-lung, each of which can accommodate ships up to 20.000 tons gross.

Trade.—Merchandise trade balances in the 1950s unlike those of pre-World War II years, are adverse. In 1958, total trade was U.S. $397,000,000, of which U.S. $164,400,000 were exports. The deficit was balanced by United States economic assistance. As before 1941, the chief export items were sugar, rice and other agricultural products, but sugar exports were restricted by international agreement to 750,000 tons annually as compared with a pre-World War II average of nearly 1,000,000 metric tons. Rice exports amounted to only 15% of the prewar annual total of over 700,000 tons. Japan was the chief postwar customer, taking from 35% to 60% of Taiwan's exports; it also supplied up to 60% of the imports. Nevertheless, trade orientations were diversified as compared with the prewar period when Japan was virtually the sole trading partner. Imports were highly diversified, consisting chiefly of a variety of consumer goods plus raw materials (*e.g.,* bauxite, lumber, rubber, cotton and wool) for Taiwan's infant industries.

FORMOSAN LANGUAGE: see MALAY LANGUAGE; POLYNESIAN LANGUAGE.

FORMOSUS (*c.* 816–896), pope from 891 to 896, was made cardinal bishop of Porto by Nicholas I, who sent him to Bulgaria to promote the conversion of that country. In 867 Formosus returned to Rome. where he enjoyed the favour of Adrian II. Pope John VIII, however. treated him as a personal enemy, and Formosus fled from Rome and was excommunicated and reduced to the lay state. Absolved under Marinus I and restored to his see of Porto by St. Adrian III, Formosus was elected pope on Oct. 6, 891. He died on April 4, 896. Under Stephen VII his political enemies had his body disinterred and subjected him to a posthumous trial. His election was declared invalid and his acts quashed. A mob cast his body into the Tiber. Later popes reversed the decisions of Stephen's synod.

Formosus' letters are printed in J. P. Migne (ed.), Patrologia *Latina,* vol cxxix, 837–848. (J. V. HN.)

FORMULA, in general, a stereotyped form of words to be used on stated occasions, for specific purposes, ceremonies, etc. In the sciences, the word usually denotes a symbolical statement of certain facts; for example, a chemical formula exhibits the composition of a substance (see CHEMISTRY); a botanical formula gives the differentia of a plant; a dentition formula indicates the arrangement and number of the teeth of an animal.

FORNER, JUAN PABLO (1756–1797), Spanish scholar and satirist, one of the most violent agitators in the literary polemics of his time, was born in Mérida. Spain, on Feb. 23, 1756, and died at Madrid on March 17, 1797. His brilliant wit was often admirably used against fads, affectations and muddleheadedness, but often cruelly and spitefully against personalities. Typical of his libelous satire is El *asno erudito* ("The Erudite Ass"; 1782) ridiculing the character and works of the erudite but irritatingly self-righteous Tomás de Iriarte. His scholarly *Exequias* de la *lengua* castellana ("Exequies of the Castilian language"; 1795) is a constructive defense of Spanish letters addressed to writers who ignorantly despised them. (I. L. McC.)

FORRES, a royal and small burgh of Moray, Scot., 12 mi. W.S.W. of Elgin by road. Pop. (1951) 4,463. Forres (Gaelic, far *uis,* "near water") in the centre of the Laich of Moray, one of the most fertile areas of Scotland, is among that country's most ancient towns. It is mentioned by Andrew of Wyntoun and Fourdun, according to whom King Donald (d. goo), son of Constantine, and King Duff (d. 967) died there. It had a castle, the site of which is still known, associated with Duncan, Macbeth and many later kings of Scotland. Within the burgh boundary is Sweno's stone, a sculptured sandstone monolith with figures of men—soldiers or captives—on one side and an elaborately carved cross with Runic ornamentation on the other. This is now under the care of the Ancient Monuments commission. Nearby is the Witches' stone, which marks the site of early witch burnings The town house, or tolbooth, stands on the site of earlier tolbooths, the distinctive ieatures of which have been retained in the present structure; the town cross, in the square in front of the tolbooth, is Decorated Gothic.

The Falconer museum was erected in memory of Hugh Falconer, the scientist responsible for the introduction of the tea plant into India, who was born in Forres in 1808. Forres also possesses a fine park, the Grant park, at the eastern entrance to the town, and behind it the Cluny hills, a property given to the town by royal charter. On the northern hill is the Nelson monument. To the south is the beautiful valley of the Findhorn. The climate is dry and sunny. The chief industries are those connected with farming and forestry; there are woolen and oat mills. distilleries and engineering works. Forres is largely residential in character.

FORREST, EDWIN (1806–1872), U.S. actor, centre of two major scandals of the mid-19th century. was born in Philadelphia on March 9, 1806. In 1820 he made his stage debut as Young Norval in Home's *Douglas* at the Walnut Street theatre in Philadelphia. After four years spent on the frontier, he arrived in New Orleans (1824), where the wild, colourful life made a lasting impression on him. In 182j he played in support of Edmund Kean, and his maturity as an actor dates from this experience. During 1826 he played Othello in New York to great critical acclaim. On ofiering cash prizes for plays by U.S. authors. Forrest received several plays suited to his talents. including John Augustus Stone's *Metamora* and Robert Montgomery Bird's The *Gladiator*. In Metamora and Spartacus, Forrest found characters that served him to the end of his career.

Forrest was initially successful in his first engagement in England in 1836, but a misunderstanding led him to hiss publicly a performance of William Macready's, arousing great indignation in England. His disagreement with the English actor culminated in the infamous Xstor Place riot of May 1849. While Macready was playing at the Xstor Place Opera House, a mob of Forrest supporters stormed the theatre. The militia was called out. the rioters fought the militia, and the militia men fired on the mob. Twenty-two persons were killed and 36 wounded. Forrest's reputation never quite recovered from this catastrophe. and only two years later he caused another national sensation when he instituted a divorce suit against his n-ife. the former Catherine Sinclair. Although he lost the verdict. he appealed the decision for 18 years. Aiter 1852 Forrest acted only sporadically: spending much time alone in his gloomy Philadelphia mansion. where he died on Dec. 12, 1872. He left most of his money for the establishment of a home for aged actors.

Opinions on Forrest as an actor varied. Although many critics considered him first-rate. he was described by William Winter as "a vast animal, bewildered by a grain of genius."

See M. J. Moses, *The Fabulous Forrest* (1929); B. Matthews and L. Hutton, *Actors and Actresses of Great Britain and the U.S.*, vol. iv (1886). (S. W. H.)

FORREST, JOHN, FORREST, 1ST BARON (1847–1918), Australian statesman and explorer who increased the knowledge of the interior oi Western Australia, was born at Bunbury, Western Australia, on Aug. 22, 1847. He joined the government survey department in Perth, and in 1869 led an expedition into the desert to search for traces of Friedrich Wilhelm Ludwig Leichhardt. In 1870 he traveled overland from Perth to Adelaide, and in 1874 explored the arid country from Champion bay eastward to the telegraph line between Darwin and .Adelaide. Forrest was appointed surveyor general of Western Australia in 1883. He took part in Western Australia's struggle for self-government and, after it was granred in 1890. became the state's first premier. He attended the discussions which led to the federation of the .Australian colonies in 1900. contested the first federal election, and until his death was a member of the commonwealth parliament and a minister in liberal governments.

He was raised to the peerage in 1918, the first native-born Australian to be so honoured, and died at sea en route for England on Sept. 3. 1918. (T. M. PY.)

FORREST, NATHAN BEDFORD (1821–1877); Confederate cavalry general in the American Civil War who achieved fame for his brilliant cavalry raiding, chiefly against enemy communications or against posts deep within the enemy lines, mas born near Chapel Hill, Tenn., on July 13, 1821. He never received any formal education, but he taught himself with very fair success and is said to have been an able mathematician. He was in turn a horse and cattle trader in Mississippi and a slave dealer and horse trader in Memphis, Tenn., until 1859, when he took to cotton planting in northwestern Mississippi and acquired considerable wealth. At the outbreak of the Civil War in 1861 he volunteered as a private, raised a cavalry unit of which he was lieutenant colonel, and in Feb. 1862 took part in the defense of Ft. Donelson. Refusing, like Generals J. B. Floyd and Gideon Pillow, to capitulate with the rest of the Confederate forces, he made his way out, before the surrender, with all the mounted troops there. He was made a colonel and regimental commander, and fought at Shiloh with distinction. He was promoted brigadier general in July 1862. At the head of a mounted brigade he took a brilliant part in Gen. Braxton Bragg's autumn campaign, and in the winter of 1862–63 was continually active in raiding hostile lines of communication. One of his most remarkable actions was the capture, near Rome, Ga., after five days of marching and fighting, of an entire cavalry brigade under Col. A. D. Streight (April 1863).

He was present at Chickamauga in September, after which he was transferred to the Mississippi. He was made a major general in Dec. 1863.

On April 12, 1864, he assaulted and captured Ft. Pillow, in Tennessee on the Mississippi; U.S. Negro troops formed a large part of the garrison and according to survivors many were massacred after the fort had surrendered. The "massacre of Ft. Pillow" has been the subject of much controversy and there is conflicting testimony regarding it, but it seems probable that Forrest himself had no part in it.

On June 10 he decisively defeated a superior Federal force at Brice's Cross Roads, Miss.. and throughout the year, in spite of the efforts to crush him, he raided successfully in Mississippi, Tennessee and Alabama. He was once more with the main Confederate army of the west in the last disastrous campaign of Nashville, and fought stubborn rear-guard actions to cover the retreat of the broken Confederates. In Feb. 1865 he was made a lieutenant general, but the struggle was almost at an end and Gen. James H. Wilson rapidly forced back the few Confederates. now under Forrest's command, and stormed Selma, Ala., on April 2. The surrender of General Forrest and his whole command followed on May 9.

After the war he lived in Memphis, and for several years was president of the Selma, Marion and Memphis railroad. He died at Memphis on Oct. 29, 1877.

Of great height and commanding appearance, exemplary in personal habits, Forrest came near to being a military genius. As he never commanded a considerable force of men, it remains a matter of speculation what he might have done in charge of an army, but as a leader of cavalry he has had few equals.

See the biographies by J. A. Wyeth (1899) and J. H. Mathes (1902).

FORRESTAL, JAMES VINCENT (1892–1949), U.S. cabinet member and first secretary of the defense department, mas born on Feb. 15, 1892, at Beacon, N.Y. He studied at Dartmouth college, Hanover, N.H., and at Princeton university, graduating in 1915. He served in naval aviation during World War I, and in 1919 resumed his connection with a New York city investment banking firm, of which he was made president in 1938. In June 1940 he became an administrative assistant to Pres. F. D. Roosevelt, and in Aug, was named undersecretary of the navy to direct the huge expansion and procurement programs. He was appointed secretary of the navy in May 1944, following the death of Sec. Frank Knox.

Upon enactment of the National Security act of 1947, Forrestal was appointed to the nen cabinet position of secretary of defense and initiated a reorganization and co-ordination of the armed services.

He resigned, effective March 28, 1949. Suffering from what navy doctors called "a severe depression of the type seen in operational fatigue during the war," Forrestal entered the U.S. naval hospital at Bethesda. Md., and on May 22, 1949, plunged through a window to his death.

See *Forrestal Diaries,* ed. by Walter Millis (1951).

FORSSELL, HANS LUDVIG (1843–1901), Swedish historian and political writer, was born at Gefle on Jan. 14, 1843 He studied at Uppsala, and had a distinguished career in the civil service, becoming in 1880 president of the department of inland revenue. He died at San Bernardino, Switz., on Aug. 2, 1901. Of his historical writings the most important were: *The Administrative and Economical History of Sweden After Gustavus I* (1869–75) and *Sweden in 1571* (1872).

FORSSMANN, WERNER (1904–), German surgeon, who shared with A. Cournand and D. W. Richards (*qq.v.*) the 1956 Nobel prize for medicine, was born in Berlin on Aug. 29, 1904. Having qualified in medicine at Berlin university, he started practising at a private hospital at Eberswalde. His contribution to the development of cardiac catheterization (*q.v.*) started in 1929 when he opened a vein in his arm and inserted a catheter until it reached the right atrium of the heart. He then had an X-ray photograph made of his chest. By this daring experiment Forssmann showed the practicability of passing a radio-opaque catheter into the heart for investigating its structure and function. This method made slow progress, however, because of difficulties of research. During World War II Forssmann served first at the front and later as chief surgeon of a military hospital for the seriously mounded. In 1950 he was appointed chief surgeon of the urological department of a hospital at Bad Kreuznach. In 1951 he was honoured as a pioneer in heart research by the *Deutsche Gesellschaft für Kreislaufforschung,* and three years later he was awarded the Leibniz medal of the German Academic Societies. Finally, on Dec. 10, 1956, his services were internationally recognized. From 1957 Forssmann served as chief surgeon of the evangelical hospital at Dusseldorf. (R. B. J.)

FORST (originally FORSTA or FORSTE), town of Germany, in the district of Cottbus, on the Neisse, 44 mi. S. of Frankfurt an der Oder. Pop. (1950) 30,475. Founded in the 13th century, Forst became part of electoral Saxony in 1740. It was ceded to Prussia in 1815. The chief industry of Forst is the manufacture of cloth. but spinning and dyeing are carried on.

FORSTER, EDWARD MORGAN (1879–), British novelist, was educated at Tonbridge school and King's college, Cambridge. His first novel, *Where Angels Fear to Tread* (1905) was followed by *The Longest Journey* (1907) and *A Room With a View* (1908). Wider attention was won by *Howards End* (1910), but thereafter, except for some short stories. *The Celestial Omnibus* (1911), he published little till 1924. when *A Passage to India* appeared. This was a fruit of first-hand observation of Indian life, and with it Forster entered into a fuller recognition of his powers as a writer. In 1927 appeared *Aspects of the Novel,* his first volume of criticism; in 1936, *Abinger Harvest.*

Forster deals with the interaction of two types of character, the intersection of two planes of living. In all his novels he brings into conflict those who live by convention and those who live by instinct; those for whom property and propriety, and those for whom personal relationships, are the most important things in life. The world of convention he describes with keen observation and satire; and his descriptions of it abound in unforgettable touches of wisdom and humour; in the world of instinct and emotion he is really at home, and perhaps never so much as when (as in several of his short stories) he is frankly telling a fairy tale. (J. SP.)

See L. Trilling, *E. M. Forster* (1943).

FORSTER, FRANÇOIS (1790–1872), French engraver. was born at Locle in Neufchâtel on Aug. 22. 1790. In 1805 he was apprenticed to an engraver in Paris, and at the same time he studied painting and engraving in the École des Beaux-Arts. He obtained in 1814 the first *grand prix de gravure.* The king of Prussia. then with the Allies in Paris, bestowed on him a gold medal and a pension of 1,500 fr. for two years. He then pursued his studies in Rome. nhere his attention was devoted chiefly to the norks of Raphael. In 1843 he succeeded Tardieu in the Academy. He died at Paris on June 27, 1872. Among his works may be mentioned "The Three Graces" and "La Vierge de la Légende," after Raphael; "La Vierge au bas-relief," after Leonardo da Vinci; Francis I and Charles V, after Gros; St. Cecilia, after Paul Delaroche; Durer and Henry IV, after Probus; Wellington, after Gérard; and Queen Victoria. after F. X. Winterhalter.

FÖRSTER, FRIEDRICH CHRISTOPH (1791–1868), German historian and poet, was the second son of Karl Christoph Forster (1751–1811) and a brother of the painter Ernest Joachim Forster (1800–85). Born at Münchengosserstadt on the Saale on Sept. 24, 1791, he studied theology at Jena, afterward devoting some time to archaeology and the history of art. At the outbreak of the War of Liberation in 1813 he joined the army, and by his war songs added to the national enthusiasm. He then became professor at the school of engineering and artillery in Berlin, but was dismissed in 1817 because of his democratic leaning. About 1829 he received an appointment at the royal museum in Berlin. He was the founder and secretary of the *Wissenschaftlicher Kunstverein* in Berlin, and died there on Nov. 8, 1868.

FORSTER, (JOHANN) GEORG (ADAM) (1754–1794), German explorer, writer, scientist and politician, was born at Nassenhuben, a small village near Danzig, on Kov. 26, 1754. With his father, Johann Reinhold Forster, a clergyman and brilliant amateur scientist, he emigrated to England in 1766. In 1772 the father and son were invited to accompany Capt. James Cook on his second voyage around the world. Georg Forster's account of the journey, entitled *A Voyage Round the World,* appeared in London in 1777, and the German version, *Reise um die Welt,* in Berlin in 1778–80. This book is a work of travel, science and literature all in one! and it established Forster's name as one of the most advanced German thinkers and accomplished stylists of the time. It had a wide influence on German scientific and literary writing, including that of Goethe, Johann Gottfried von Herder, Friedrich Schlegel, Samuel T. Sommerring and Alexander von Humboldt. Since its publication the literary travel book has become a favoured genre in German literature, and Goethe's *Italienische Reise* and Heinrich Heine's *Harzreise* are its direct successors. Forster made also, in his articles and letters! major contributions to the scientific, especially botanical, knowledge of the South seas. From 1778 to 1784 he held a professorship at Kassel, and from 1784 to 1787 at the University of Vilna. He subsequently became university librarian in Mainz. A keen sympathizer with the French Revolution, he became the leading spirit in the republican government of Mainz. In 1793 he went to Paris to carry out negotiations on behalf of that government. Meanwhile the Germans seized Mainz. Unable to return, publicly reviled in Germany as a traitor, especially by Friedrich Schiller, and disillusioned by what he had seen of the Revolution in France, Forster died in Paris on Jan. 12, 1794.

His collected works are *Sämmtliche Schriften* (1843) and *Werke* (1958–).

FORSTER, JOHN (1812–1876), English writer and journalist, friend and biographer of Charles Dickens and a notable figure in mid-19th-century literary London. Born at Newcastle on Tyne. April 2, 1812, he read law and history at University college, London. and began to write, undertaking biographies of statesmen of the Commonwealth period for a 10-vol. *Cyclopedia* and contributing to periodicals. In 1832 he became a critic on the *True Sun* and there met Leigh Hunt, through him entering on the third aspect of his career—as adviser, agent and proofreader to most of the writers of the day. He joined the staff of the *Examiner* in 1834 and was editor from 1847 to 1856. He met Dickens in 1836 and, until Forster's marriage in 1856, was his closest personal and professional friend, following him as editor of the *Daily News* and receiving from him the innumerable letters "of unexampled candour and truthfulness" which formed the basis of his biography. After 1850, ill-health caused his withdrawal into the research which had formed the background to his busy life. He became secretary to the commissioners in lunacy in 1855 and a commissioner in 1861, and died in London, Feb. 2, 1876.

Forster was a discriminating editor, an indefatigable friend and a careful scholar. Pugnacious and possessive, yet inexhaustibly kind, he roused strong feelings. He was nicknamed "Fuz" by Carlyle, and "the Beadle of the Universe" by Thornton Hunt. caricatured as "Fuzbuz" in Rosina Bulwer's novel, *Cheveley,* loved and admired by "L. E. L." (Letitia Landon) to whom he was briefly engaged, Lady Blessington, Landor, Tennyson and Browning. His *Life of Dickens,* 3 vol. (1872–74) is an essential source book and a literary masterpiece, despite its personal bias and occasional suppressions and inaccuracies, especially for the period after 1856. His *Life of Oliver Goldsmith* (1848; expanded into *Life and Times,* 1854), his *Life of Landor* (1868), and the unfinished *Life of Swift* (1875) remain authoritative and readable, revealing, as do his now superseded historical works on the 17th century, his shrewdness, trenchancy of style and keen, yet selective, interest in detail.

See R. Renton, *John Forster and His Friendships* (1912); *M.* Elwin in *Victorian Wallflowers* (1934).

FÖRSTER, JOSEF BOHUSLAV (1859–1951), Czech composer belonging to the school of Dvořák and Smetana. Born at Prague, Dec. 30, 1859, he was the son of the composer of organ music, Josef Forster (1833–1907). After studying at the Prague conservatory, he was organist at several Prague churches and music critic of *Narodny Listy.* In 1888 he married the Wagnerian soprano, Berta Lauterer, and from 1893 to 1903 lived in Hamburg where he became a friend of Gustav Mahler and taught at the conservatory. From 1903 to 1918 he was music critic of *Die Zeit* in Vienna. In 1919 he taught composition at the Prague conservatory and was later appointed director. He died at Nový Vestec, near Mladá Boleslava, May 29, 1951.

Forster's music was largely inspired by personal memories and associations. His second and fifth symphonies, his cantata, *Mortuis fratribus* and his Trio in A minor were tributes to his near relatives. He was a devout man and his fourth symphony ("Easter Eve"), and his operas, *Nepromozeni* (1918), *Srdce* (1923) and *Bloud* (1936), were inspired by religious subjects. He also wrote four masses, two violin concertos, a cello concerto and chamber and vocal works. Though his romantic and religious outlook suggests Mahler, his simpler, lyrical works, notably the song-cycle, *Liebe,* show his allegiance to the heritage of Dvořák and Smetana.

See J. B. Forster, *Der Pilger. Erinnerungen eines Musikers,* trans. by *P.* Eisner (1955); *J.* B. *Foerster,* a symposium ed., with a bibliography, by J. Bartóš *et al.* (1949).

FORSTER, WILLIAM EDWARD (1818–1886), British statesman, was born of Quaker parents at Bradpole in Dorsetshire on July 11, 1818, and educated at the Friends' school at Tottenham. Becoming a woollen manufacturer at Bradford. Yorkshire (whence after his marriage he moved to Burley-in-Wharfedale), he became known as a practical philanthropist. In 1846–47 he accompanied his father to Ireland as distributor of the Friends' relief fund for the famine in Connemara, Ire., when the state of the country made a deep impression on him. He married in 1850 Jane Martha, eldest daughter of Thomas Arnold of Rugby. Being childless they adopted the four orphans of Mrs. Forster's brother, William Arnold. when he died in 1859. One of these children. H. O. Arnold-Forster (18jj–1909), the well-known Liberal-Unionist member of parliament, became a member of Lord Balfour's cabinet; he was secretary to the admiralty (1900–03); secretary of state for war (1903–05); and was the author of numerous educational books.

In 1859 W. E. Forster stood as Liberal candidate for Leeds, and was beaten. In 1861 he was returned unopposed for Bradford and again in 1865 and 1868. In 1865 he was made undersecretary for the colonies in Earl Russell's ministry, and became a prominent advocate of imperial federation. In 1866 his attitude on parliamentary reform attracted a good deal of attention. He demanded universal education as the essential complement of an extension of the suffrage. Forster and Cardwell. as private members in opposition. brought in Education bills in 1867 and 1868; and in 1868, when the Liberal party returned to office, Forster was appointed vice-president of the council, with the duty of preparing a government measure for national education. The Elementary Education bill (*see* EDUCATION, HISTORY OF) was introduced on Feb. 17, 1870. The Dissenters were by no means satisfied with Forster's "conscience clause" as contained in the bill, and they regarded him, the former Quaker, as a deserter from their own side; while they resented the "25th clause," permitting school boards to pay the fees of needy children at denominational schools out of the rates, as an insidious attack upon themselves. The controversy assumed threatening proportions, and Dixon. the Liberal member for Birmingham and chairman of the Education league, moved an amendment, the effect of which was to prohibit all religious education in board schools. The government made its rejection a question of confidence, and it was withdrawn; but the result was the insertion of the Cowper-Temple clause as a compromise. Extremists on both sides abused Forster, but it is to his enduring credit that the bill of 1870, imperfect as it was, established some approach to a system of national education in England.

Forster's next important work was in passing the Ballot act of 1872. In 1874 he was again returned for Bradford, in spite of Nonconformist attacks, and took his full share of the work of the opposition front bench. In 187j, when William Gladstone "retired." he was strongly supported for the leadership of the Liberal party, but declined to be nominated against Lord Hartington. On Gladstone's return to office in 1880 he was made chief secretary for Ireland, with Lord Cowper as lord-lieutenant. He carried the Compensation for Disturbance bill through the commons, only to see it thrown out in the lords, and his task was made more difficult by the consequent agitation. On Jan. 24, 1881, he introduced, with reluctance, a new Coercion bill in the house of commons, to deal with the growth of the Land league. The Irish party used every opportunity in and out of parliament for resenting this act, and Forster was kept constantly on the move between Dublin and London, conducting his campaign against crime and anarchy and defending it in the house of commons. He was nicknamed "Buckshot" by the nationalist press, on the supposition that he had ordered its use by the police when firing on a crowd. After the arrest of C. S. Parnell (Oct. 13) Forster's life was in constant danger, and he had to be escorted by mounted police when he drove in Dublin. On May 2, 1882, Gladstone announced that the government intended to release Parnell and his fellow prisoners in Kilmainham, and that both Lord Cowper and Forster had in consequence resigned; and the following Saturday Forster's successor. Lord Frederick Cavendish, and Burke were murdered in Phoenix park.

It was characteristic of the man that Forster at once offered to go back to Dublin temporarily as chief secretary, but the offer was declined. He delivered his fiercest attack on Parnell in the debate on the address (1883), charging him, not with directly planning or perpetrating outrages or murder, but with conniving at them. Forster died on April 6. 1886, on the eve of the introduction of the Home Rule bill, to which he was stoutly opposed. He had found himself in an increasing degree at variance with Gladstonian Liberalism on other questions, for instance, as regards the Sudan and the Transvaal, nor was he inclined to tolerate the claims of the Caucus or the Birmingham programme. When the Redistribution act divided Bradford into three constituencies, Forster uas returned for the central division, but he never took his seat in the new parliament.

See T. Wemyss Reid, *Life of the Right Hon. H. E. Forster.*

FORSYTH, ANDREW RUSSELL (1858–1942), Scottish mathematician, was born at Glasgow, on June 18, 1858. He studied at Liverpool and Trinity college. Cambridge, and held the following posts: professor of mathematics, University college, Liverpool (1882–83); lecturer in mathematics. Trinity college, Cambridge (1884–9j); Sadlerian professor at Cambridge (1895–1910) and professor of mathematics, Imperial College of Science and Technology, London (1913–23). After 1923 Forsyth held the post of emeritus professor at the Imperial college. London. His work covered a wide field in pure mathematics and his treatises contained much that was original, showed creative ability and at the same time established his reputation as a teacher. Forsyth was the author of a number of papers on different. equations, on the theory of functions and on the differential invariants of space. His *Treatise on the Theory of Functions* (1893, etc.) dealt with the theories of Friedrich Riemann. Augustin Cauchy and Karl Weierstrass and by means of this work and his other writings on the theory of functions, Forsyth stimulated interest in the works of Felix Klein, Jules Poincaré, Weierstrass and other mathematicians.

Forsyth also wrote exhaustively on the subject of differential equations and most of his work on this subject is contained in *A Treatise on Differential Equations* (188j. etc.) and *Theory of Differential Equations*, 4 vol. (1890–1906). Forsyth edited volumes viii to xiii and the supplementary volume of *Cayley's Collected Mathematical Papers* and was the editor of the *Quarterly Journal of Mathematics* from 1884 to 1895. He was a member of many learned societies and was awarded the Royal medal of the Royal society in 1897.

The works of Forsyth included *Lectures Introductory to the Theory of Functions of Two Complex Variables* (1914); *Lectures on Differential Geometry* (1912, etc.); *Calculus of Variations* (1926); *Intrinsic Geometry of Ideal Space* (1935). He died June 2, 1942.

FORSYTH, PETER TAYLOR (1848–1921), an outstanding Scottish Congregationalist theologian, was born at Aberdeen on May 12, 1848. The son of a postman, he was educated at Aberdeen grammar school and university, and spent a term at Göttingen, where he was deeply influenced by Albrecht Ritschl. After a brief period studying theology at New college, London, he was minister of several Congregational churches in England, including Emmanuel church, Cambridge. In 1901 he became principal of Hackney theological college, London, where he remained until his death in London on Nov. 11, 1921. He was a distinguished preacher, but exercised his influence chiefly through his numerous books and published lectures, which were written in a vigorous and highly characteristic, though over-epigrammatic, style.

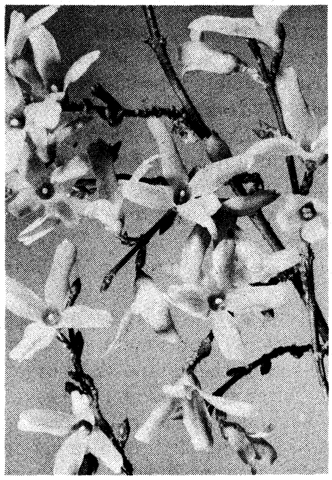
Beginning as a theological liberal, Forsyth gradually moved to a position of great originality and power to which there was no precise equivalent in his own time, although it had some affinity with the "positive theology" of Germany. He had little in common with old-fashioned evangelical orthodoxy but was the shrewdest critic of the modernistic liberalism which was then at the height of its popularity in the free churches. He reasserted the classic faith of the Reformation in terms appropriate to his own time, bringing the word "grace" back into Protestant theology and showing afresh what was meant by the sovereignty of God revealed in holy love in Christ. He thus anticipated many of the characteristic insights of Karl Barth, and there are also similarities of spirit between the two men.

Forsyth's most famous book, *The Person and Place of Jesus Christ* (1909), was an attempt, in his own phrase, "to moralise dogma," to express in terms of modern personal experience the meaning of the doctrine of Christ's divinity. His *Positive Preaching and the Modern Mind* (1907) and *Lectures on The Church and the Sacraments* (1917) recalled Protestants to the richness of their own teaching about the church at a time when liberalism and evangelicalism together were in danger of making them forget it. He also wrote on the relation between Christian faith and the questions of his day. *The Justification of God* (1916) is one of the best essays of the 20th century in this subject. *Christ on Parnassus* (1911) was notable as one of the first efforts in the same century to relate theology and the arts, although it has worn less successfully than most of his writings.

In the range of his interest and the breadth of his sympathy Forsyth was the successor in the theological life of England of John F. D. Maurice (*q.v.*), whom he greatly admired. Like Maurice, he was widely misunderstood in his own time, although never without powerful support and devoted disciples. Since the theological revival led by Barth, however, his work has been much more readily understood and appreciated.

See G. O. Griffith, *The Theology of P. T. Forsyth* (1948); R. M. Brown, *P. T. Forsyth: Prophet for Today* (1952). (D. T. J.)

FORSYTHIA, an old world genus of the olive family with several very showy, hardy, spring-blooming species that are widely planted for their profuse, usually yellow flowers that bloom before or with the unfolding of the foliage. and are commonly called golden bell. They usually have arching or spreading branches bearing opposite leaves. $2\frac{1}{2}$ to 6 in. long, that are carried late in the fall and often become olive or purplish in colour. The plants are not particular as to soil and do well in partial shade, although they prefer the open, especially in masses against a background of evergreens.



ROCHE

WEEPING GOLDEN BELL (FORSYTHIA SUSPENSA)

Weeping golden bell (F. *suspensa*), an upright shrub to 10 ft., with the tips of the long, arching, hollow branches often pendulous and, in age, rooting at the tip, has golden-yellow flowers about an inch long. Some of its horticultural varieties show variations in plant form. Greenstem golden bell (F. *viridissima*), has erect, bright green branches, reaching 10 ft., and greenish-yellow flowers about an inch long. Border golden-bell (F. *intermedia*), a hybrid between F. *suspensa* and F. *viridissima*, is deemed by many as the best of the forsythias, particularly the variety *spectabilis* with its bright yellow flowers about $1\frac{1}{2}$ in. long.

Other varieties show flower colours from pale to deep yellow. Early golden bell (F. *ovata*), sometimes called Korean forsythia, a shrub up to j ft.. has solitary, amber-yellow flowers about $2\frac{1}{2}$ in. long. It is the earliest to bloom. (J. M. BL.)

FORTALEZA, a city and port of Brazil and the capital of the state of Ceara (*q.v.*), on a crescent-shaped indentation of the coast line. $7\frac{1}{2}$ mi. from the mouth of the Ceara river. Pop. (1950) 205,052, (1958 est.) 375,264. The city stands on an open sandy plain overlooking the Atlantic. and is regularly laid out. with broad streets and numerous parklike squares.

Because of the arid climate the vegetation is less luxuriant than in most Brazilian cities. The usually high temperature is modified by the strong sea winds and the climate is considered healthful. A small branch of the Ceará river: called the Pajeu, traverses the city and divides it into two parts, that on its right bank being locally known as Outeiro. Fortaleza is the see of a bishopric, created in 1854.

Its public buildings include the government house, legislative chambers. bishop's palace, an episcopal seminary, a lyceum (high school) and hospital. The port is the principal outlet for the products of the state. Long an open roadstead harbour, it has been much improved by construction of a breakwater and port facilities at Mucuripe point 4 mi. E. The Baturité railway, built by the national government partly to. give employment to starving refugees in times of long droughts. connects the city and its port with fertile regions to the southwest and extends southeast to Patos in Paraiba.

The exports include sugar. coffee, rubber, cotton, carnauba wax, oiticica oil, rum, rice, beans. fruits. hides and skins.

Fortaleza had its origin in a small village adjoining a fort established by the Portuguese at this point in early colonial times. In 1654 it took the name of Villa do Forte da Assumpção, but it was generally spoken of as Fortaleza.

In 1810 it became the capital of Ceará captaincy and in 1823 it was raised to the dignity of a city under the title of Fortaleza da Nova Bragança. It is sometimes referred to as Ceará.

(Js. J. P.)

FORT ANCIENT, prehistoric Indian defensive work on the Miami river in Warren county. Ohio, stands on a headland (260–280 ft.) projecting from a plateau. and is now included in a state park. The total area is estimated at 100 ac., and its solid content at 3,000,000 cu.ft. The wall, chiefly of earth cast up from an inner ditch. follows the zigzag course of the bluff. except where it crosses the level neck in the rear of the fort. and is 18.712 ft., or a little more than 33 mi. in length, while the height is 6 to 10 ft., except at the only level point of approach, the neck referred to above. where it is 18 to 19 ft. At the north the points more easily approached are generally narron, sloping ridges, crossed at the upper terminus by a wall, outside of which the ridge was cut down several feet to present a steep slope corresponding to the outer slope of the wall; but where similar ridges form approaches from the south and at some other points, the defenses are formed by raising the wall considerably above the usual height. The most vulnerable point was at the isthmus separating the two portions of the fort, known as the Old Fort and the New Fort. where a short space was undefended, though the ascent is not difficult. Several small mounds and a number of stone graves containing human remains mere within the fort.

FORT DODGE, a city of Iowa, U.S., situated on the Des Moines river at its junction with the Lizard, 85 mi. N.W. of Des Moines; the seat of Webster county. It was established as an army post, Ft. Clarke, Aug. 23, 1850, and in 1851 was renamed in honour of Israel and Henry Dodge, father and son, senators from Wisconsin and Iowa. When the troops left in 1853 Maj. William Williams remained and bought the land and buildings. He laid out the town the following year and became its first mayor and postmaster. The town was chartered as a city in 1869. Many of the earlv settlers of the fertile lands around Fort Dodge who held title under federal patents were dispossessed in the 1860s by the Des Moines Navigation and Railroad company which had its grant from the state of Iowa ior work done in a futile effort to make the river navigable.

Extensive gypsum deposits make Fort Dodge one of the centres of this industry. Clay is abundant and several plants make tile, brick and sewer pipe. Other industries include meat packing, farm implement plants and pharmaceutical production. (For comparative population figures see table in IOWA: *Population.*)

The "Cardiff giant," famous hoax of the 19th century was carved from the Fort Dodge gypsum deposits. In 1868 George Hall of Binghamton, N.Y., procured a block of gypsum from the deposits in Fort Dodge, hauled it overland to Chicago, had it carved in the shape of a human figure, and buried it near Cardiff, Onondaga county, N.Y., where it was discovered by men digging a well in 1869. The "Cardiff giant" was exhibited in various parts of the country as a petrified man or a statue dating from prehistoric times, and was the subject of much discussion among scientists and scholars, until the hoax was exposed by Othniel C. Marsh of Yale, and the perpetrator confessed his part in it. (E. J. BR.)

FORTESCUE, SIR JOHN (*c.* 1385–*c.* 1479), English judge, is famous for his legal treatise written for the instruction of Prince Edward, son of Henry VI. The second son of Sir John Fortescue, he was born at Norris, near South Brent, Somersetshire. He was admitted to Lincoln's Inn before 1420, and in 1421 was elected to parliament. In 1430 he became a serjeant and in 1441 king's serjeant. In 1442 he became chief justice of the king's bench, and was knighted the following year. He fled to Scotland with Henry VI in 1461, when he seems to have been appointed lord chancellor. In 1463 he went into exile with Queen Margaret, and returned to England with her in 1471. On the final defeat of the Lancastrians, he submitted to Edward IV. He retired to Gloucestershire and died some years later. He was most learned and upright, and from his decision in *Thorpe's* Case in 1452 stems the modern doctrine of parliamentary privilege. His treatise, De Laudibus *Legum Angliae,* was written while in exile, and eulogizes the constitution and much of English law and legal education, with many comparisons with Roman and continental law, and proposals for law reform. Its outlook was ahead of its time, and it was not published until 1546.

His other works included *The Difference between an Absolute and a Limited Monarchy (see* C. Plummer, ed., *Sir John Fortescue: The Governance of England* [1885]). *See* S. B. Chrimes, ed. and trans., *Sir John Fortescue: De Laudibus Legum Angliae* (1942); Lord Campbell, *Lives of the Lord Chancellors (1868).* (R. E. MY.)

FORTESCUE, SIR JOHN (*c.* 1531–1607), English statesman, was the eldest son of Sir Adrian Fortescue (executed in 1539), and of his second wife, Anne Reade or Rede. Through his father's mother, Alice, daughter of Sir Geoffrey Boleyn, he was connected with Queen Elizabeth I. He directed the princess Elizabeth's classical studies in Mary's reign, and, on his pupil's accession, was appointed keeper of the great wardrobe. He entered parliament in 1572. In 1589 he was appointed chancellor of the exchequer and a member of the privy council. In 1592 he was knighted, and in Nov. 1601, in addition to his two great offices, he received the chancellorship of the duchy of Lancaster. He was a member of the court of the star chamber and an ecclesiastical commissioner, sat on various important commissions, and as chancellor of the exchequer explained the queen's financial needs and proposed subsidies in parliament. He was deprived by James of the chancellorship of the exchequer, but retained his two other offices. In 1604 Sir John: who stood for Buckinghamshire, was defeated by Sir Francis Goodwin, whose election, however, was declared void by the lord chancellor on the ground of a sentence of outlawry under which he lay, and Fortescue was by a second election returned in his place. This incident gave rise to a violent controversy, regarding the chancellor's jurisdiction in deciding disputed elections to parliament, which was repudiated by the commons but maintained by the king. The matter after much debate was ended by a compromise, which, while leaving the principle unsettled, set aside the elections of both candidates and issued a new writ. Fortescue died on Dec. 23, 1607.

FORT GEORGE RIVER (BIG RIVER), Quebec province, Can.. rises in Lake Nichicun at 1,737 ft. above sea level and flows northward for 60 mi. before turning west for the final 420 mi. to discharge into James bay. Except for its lower course it has no well-defined valley and consists of a series of irregular lakes connected by rapids. Hudson's Bay company posts are situated at its mouth (Fort George) and on Lake Nichicun, the latter being established prior to 1800. (J. D. I.)

FORTH, a river and firth of east Scotland, the *Bodotria* estuary of Ptolemy. It is formed by the junction, 1 mi. W. of Aberfoyle, of two headstreams, Duchray water and Avondhu, the latter carrying the overflow from Loch Xrd. The Kelty. the main right-bank tributary, joins the Forth on Flanders Moss, S mi. below Aberfoyle. The largest tributary is the Teith which enters the main river on the left bank, 2 mi. N.W. of Stirling, and carries the discharge of Loch Katrine and Loch Vennachar. All these streams have their sources in the high ridge east of Loch Lomond. Other left bank tributaries are the Allan water and the Devon. After receiving the Kelty the Forth follows a most tortuous course over the flat, alluvial, moss and carse country to Stirling and Alloa. Thus its course to Kincardine is 65 mi.. whereas the direct distance is only 38 mi. The fall from Aberfoyle to the sea is about 80 ft., a fact which largely explains the meanders. The lowest road bridge at Kincardine is generally taken as the beginning of the firth. The tidal flow reaches beyond Stirling but very little shipping moves above Grangemouth.

The firth extends 48 mi. from Kincardine to the Isle of May. Its width increases rapidly below Queensferry to 19 mi. between Musselburgh and Largo but narrows again to 8½ mi. between Elie and the east Lothian shore. Depths are greater in the inner firth (over 200 ft. near the Forth bridge) and decrease seaward for a distance.

The chief ports are, on the north side, Methil and Burntisland, serving the Fife coalfield, and the naval base of Rosyth; on the south side. Leith and Granton serving Edinburgh, and Bo'ness and Grangemouth dealing with the trade of the industrial areas to the west. Inchkeith and Inchcolm are small islands of volcanic rock. Both have monastic ruins. (T. HER.)

FORTIFICATION, the military art or science of strengthening positions against attacks. Permanent fortifications include lasting and elaborate forts and troop shelters; they are usually constructed of masonry, concrete or stone and are most often erected in times of peace. Field fortifications are those constructed when in contact with an enemy, or when contact is imminent. They consist of entrenched positions for personnel, weapon emplacements, cleared fields of fire for weapons, manufactured obstacles like mines and barbed-wire entanglements. and the strengthening of available natural obstacles by utilizing felled trees, rocks and other materials. Modern field fortifications require concealment and camouflage, and covering fire to hold the enemy at bay.

There are two chief reasons for fortifications: to obtain the greatest advantage from one's own strength and weapons; and to prevent the enemy from using his resources to advantage. The defender is shielded by the protecting fortification, and the attacker is delayed or his impetus minimized by obstacles.

The defense of cities and trade centres, usually by high walls, has been important for centuries as a protection for their wealth. Permanent fortifications have also been established at strategic points along routes of invasion. Seacoast fortifications have normally been for protection against naval attack, though from a military standpoint they sometimes included protection from the land side. Field fortifications have been used in varying degrees since the time of the Greeks and the Romans.

The citadel was the municipal fortress of the ancient world. It appeared in cities of Egypt, Greece and the Roman empire. Roman citadels were less important than those of Greece because they were less necessary as most Roman cities were less exposed to potential attackers.

Obstacles have been utilized throughout history to prevent an enemy from coming to close quarters. The Romans depended upon protective walls and dry ditches' in the republican era but later utilized ditches filled with water and spiked tree trunks set in the ground. Obstacles were of little value unless they were tied into the defense system. For instance, the concrete dragon's teeth of the German west wall of World War II were an inconsequential obstacle when no troops or defense guns were nearby. Bulldozers merely pushed dirt over them to create an elevated road, or engineers dynamited a path through them.

In ancient days, fortifications held up the best attacking troops for months and even years. The medieval castle was almost impregnable until gunpowder gave artillery increased battering power. Even against artillery, the "land battleships" of World War I, which were tremendous fortifications, were able for a time to bear up successfully. In World War II new methods of combined attack made even the strongest permanent fortifications vulnerable. Field fortifications gave some help to the defense by channelizing enemy offensive and local attack. though at no time were they impregnable for any considerable period.

Historically, both permanent and field fortifications were strong against hand weapons and engines of war (*q.v.*), but required extensive modification after the arrival of gunpowder. In the age of the tank and airplane, permanent fortifications became inadequate, but field fortifications were able to compel some delay in enemy advances.

EARLY HISTORY OF FIELD FORTIFICATIONS

The Ancient World.—Field fortifications played an important role in warfare of the ancient world. The main purpose, particularly among the Greeks, was to secure an advantage by being above the enemy, so that the defenders could stand on a hillside while engaging in personal combat. A Roman legion was trained to dig a ditch and erect a palisade each night that it made camp. In preparation for the defense of the camp, each man had a set job to do, and each legionary carried a piece of the palisade that was erected inside the ditch. When Roman columns met with resistance while on the march, half of the force would engage the enemy while the remainder prepared a fort on a height or slope. The palisades were low because the men behind them fought with shields and needed space to use their lances. When campaigns extended over long periods, the main camp of the Romans was further protected by outlying redoubts, or small forts, which were occupied by a cohort of the legion.

Julius Caesar mentions the building of walls as much as 14 mi. long during his campaign in Gaul. On one occasion, Caesar reversed the usual procedure. He surrounded a town with a line of fortifications 11 mi. long, thus permitting his 60,000 Romans to bottle up 80,000 Gauls in Alesia. Then he turned in the other direction to fight 100,000 Gauls who were in turn besieging him. It appears that had it not been for Caesar's fortifications, all Gaul would have been lost. Caesar was a master at field fortification and the construction of obstacles; he employed nearly all the basic types known in modern times.

In later centuries, when the Roman empire had been extended through much of Europe, a system of permanent forts was built along the Rhine and Danube rivers to form the defense of the empire. The technique of entrenching for the protection of the legion was passed on to the Byzantine armies, which insisted that troops entrench their camps in the manner of the Roman legion. The Byzantines also erected a chain of fortresses to defend the line of the Danube river. These frontier posts were worked into a system of defense together with the walled towns and castles of the Balkan area. After the fall of Rome, field entrenchments were almost unknown for many centuries because the code of feudal warfare looked upon such devices as unchivalrous.

Middle Ages.—In the 13th century the Mongols revived the long-forgotten field entrenchment in Europe. Timur consistently followed a tactic of defending his centre in battle by entrenchment, employing the troops thus released for strengthening his flank operations on the wings of the defended position. The next notice of field fortification is in the late 16th century during the Huguenot uprisings against Henry IV. The duke of Parma, in support of the Catholic monarch of Spain, fought Henry several times from behind field fortifications which his veterans had erected overnight. In this same period the Spaniards, under Parma and his successors, encountered a master at maneuver and fortification in Maurice, comte de Saxe. Spanish generals tried again and again to bring Maurice to a pitched battle. When challenged he threw up field fortifications too strong to be taken.

17th, 18th and 19th **Centuries.**—Gustavus Adolphus, the father of modern tactics and organization of armies, also made a considerable contribution to field fortification. The Swedes were thoroughly impressed with the necessity of digging as well as shooting. Gustavus had adopted the Dutch engineering system of Maurice, comte de Saxe, but he was more than an imitator. Outlying posts were defended by redoubts, while his forts were protected by palisades and entanglements; in the field, his armies always built a ditch and a wall around their camp. Instead of the single line common to his day, he prepared two lines of mutually supporting fortifications, possibly the forerunner of the 20th-century system of detached fortresses. Gustavus' field fortifications staved off his defeat by Johann Tzerclaes, count of Tilly, on the banks of the Elbe. Tilly twice attacked the earthworks of the Swedes, but was repulsed by case shot fired at point-blank range from the Swedes' new regimental cannon.

The American Revolution dramatically demonstrated the value of field fortifications. At Bunker Hill, the Americans utilized entrenchments in a manner that seemed entirely natural to the frontier spirit. A low trench, a parapet chest-high or a tree gave the frontiersman protection while he reloaded and aimed his musket. In all the battles of the Revolutionary War, the Americans utilized field fortifications, particularly earthworks. At the last battle of the war, Yorktown, the Americans and French conducted a successful siege against the excellent British defenses, utilizing Marshal Sébastien de Vauban's system of digging parallel trenches and moving forward gradually against the main system of entrenchments and redoubts. Within a generation, American troops under Andrew Jackson at the battle of New Orleans made effective use of cotton bales to defend their position against the advancing British troops.

In the Napoleonic period the one great historical example of field fortification was that known as the Tôrres Vedras line. The duke of Wellington, with 60,000 men, faced French armies of more than double his strength in the campaign in the Spanish peninsula. During the winter of 1810 he built a series of 87 connected redoubts about 25 mi. N. of Lisbon. There, from two low ranges of hills and with almost 300 guns in his redoubts, he defended the

Lisbon peninsula from the Tagus river to the sea. Again and again the Frenchmen assaulted the slopes but were unable to take Wellington's position. Later, the lines were blockaded by the French, but in the spring both armies had to withdraw because they were near starvation.

From the start of the American Civil War, troops fought behind stone walls and trees, or dug entrenchments. In two notable sieges. that of Vicksburg. Miss., in the west and a later one at Petersburg, Va., in the east, trench warfare was the accepted method of siege. The Vicksburg siege lasted almost a year. The Union forces supplemented their artillery and rifle fire by mining, much in the nature of siege warfare against permanent forts. The men tunneled under the fort and placed there a charge of powder to explode after they had withdrawn to safety. In the Cold Harbor, Va., campaign, when Gen. Ulysses S. Grant sent his troops against earthwork defenses of the Confederates he lost 14,000 men in 13 days. Early in the war Gen. Robert E. Lee adopted the frontier riflemen's breastwork comprising two logs on the parapet of the entrenchment. The logs afforded protection to the upper part of the soldier's body but enabled him to fire from the slit between the logs.

At no time during the Civil War were great efforts made to furnish material and supplies for such fortifications. The soldiers usually brought their own spades and axes, and with them built field fortifications far beyond anything known to that date. Changes in tactics wrought by the new rifles and by field entrenchments on defense did not reach European battlefields in time for the Franco-German War in 1870. Both armies were so steeped in the idea of attack that it was unthinkable to take advantage of the folds in the ground and of trenches for defense.

World War I.—The offensive tactics in which the German and French armies were educated bogged donn within a few months after the outbreak of World War I. The fire power of the machine gun brought the war to a stalemate. War on the western front took on the nature of a gigantic siege operation.

For 600 mi. from the border of Switzerland to the channel, two systems of trenches faced each other. During the period from December 1914 to March 1918 this zigzag gash of trenches shifted no more than ten miles at any one place with the single exception of one salient which the Germans voluntarily gave up in order to straighten their lines. For 29 months the expression "western front" became synonomous with a new way of life which was lived by several million uniformed men. "No man's land" was known around the world. At night it was often lighted up by coloured flares and brilliant star shells. At the glimpse of a patrol nervous fingers touched off hundreds of rifles, machine guns and artillery cannon. As the danger disappeared, the battlefield returned to its former quiescence, while a few men did sentry duty in the trenches and their fellow soldiers slept as best they could in the dugouts deep under the earth. In daytime the opposing lines were marked by balloons and occasionally by the dogfights of a few biplanes, which strangely enough enlivened by their combat the daily grind of the human moles in the trenches.

Throughout this entrenched line, the typical trench system was not unlike the parallel trenches which Vauban (*see* belon, *Permanent Fortifications: Vauban's Siegecraft*) had prepared two and one-half centuries before as a means of attacking fortresses. Early in the war. the trenches were normally in four parallels about a mile in depth. Each trench was angled so that no enemy, standing at one end, could fire for more than a few feet down its length. In the zigzagging of the trenches lay protection for the defenders when a breakthrough occurred at one point. Each of the four lines of trenches was connected by a series of communication trenches. perpendicular to the front. These were the supply avenues for the bringing of food, ammunition and mail and through which relief and replacement of troops were affected. In general, the first line of trenches was known as the outpost line and was thinly held. The next tno lines were commonly called the main line of resistance and the supporting line, while the fourth was the reserve line. Still farther to the rear of this rigid defense system, the artillery was posted. The main purpose of this defense in depth was to prevent an enemy from getting through the third iine.

After many months of stalemate. both sides adopted new ideas in both attack and defense. The Hindenburg line in the rear of the regular trench system was the German contribution to defense in depth, far beyond the one-mile-deep, rigid defenses previously used. The Hindenburg trench system was an extremely elaborate field fortification with a unique feature known as the pillbox. These concrete shelters for machine guns were spaced along the front where the protected machine guns were most effective against infantry attack. Behind the pillboxes were trenches and dugouts reinforced with concrete designed to withstand artillery bombardment. These defenses were scattered over a depth of three or four miles. The second position, spaced approximately two miles from the first, was out of range of artillery. The artillery, being about two miles behind its own front lines, was therefore four miles from the second. or main positions, of the Hindenburg line. This distance was further than the artillery could fire effectively. Another reason for this spacing was that, in the attack formations, the co-ordination between infantry and artillery had become so close that the troops followed a creeping barrage which moved forward on a regular time schedule without regard to the actual position of the troops.

FIELD FORTIFICATIONS OF WORLD WAR II AND THE KOREAN WAR

Defensive Systems.—Entrenchments in World War II followed somewhat the general pattern of those of World War I, with one great exception. They had to be prepared for all-around defense against tank attacks The development of the land mine made it possible to work out field fortifications which restricted the movement of tanks but actually did no more than delay the enemy for a time. When the German army attacked France in 1940, the tank columns were organized into two groups; the first was primed to rupture the French defense. and the second, in the rear, to penetrate and then fan out in exploitation of the attack.

The French field fortifications were in many places well built. There were ditches sufficiently deep to stop tanks. and antitank guns sited to fire down the front of these ditches. First of all, the Germans bombarded the French positions with artillery and low-flying aircraft. The tanks then advanced under the cover of smoke against the zigzag antitank ditches. Knowing about where the antitank guns would be placed in the defensive system. one vehicle moved against the antitank gun position and, when it was knocked out, blocked the view of the gunner. In this way, some protection was given to other machines nhich moved upon the ditch. bridged it with special equipment and then moved forward. Against each of the successive defense lines, German tanks advanced under cover of smoke against the concrete emplacements and pillboxes, utilizing flame throwers to compel the defenders to close their loopholes. The German tanks then pulverized them with their heavy guns.

During World War II, field fortifications were thrown up in practically every kind of terrain. In north Africa, men dug individual protection trenches, called foxholes, in the desert. or used sandbags for the same purpose. The coral rock of some Pacific islands made it impossible to dig field fortifications. In such cases the only salvation was to stack sandbags. cut down vegetation and make use of other devices to create a form of field fortification. In the Pacific nar there were many atolls where Allied forces had to mop up Japanese troops hidden in caves, log bunkers or trenches that had been covered and cleverly concealed. Japanese field fortifications had been built methodically during the long period of preparation for the expected U.S. offensive; they were probably the most difficult ones attacked by the Allies during the war. Jungle foliage quickly covered the earth which had been dug out, making entrances to emplacements and shelters almost impossible to discover except by close inspection, an extremely dangerous practice.

Attack of Field Fortifications.—The U.S. method of operating against the cave systems of field entrenchments was to employ machines, instead of manpower, in every possible way. The sequence sometimes included aerial bombing. followed by naval bombardment of the area for days, or even weeks, and then close-up attack by artillery and tanks. The final effort was an infantry mopping up after infiltrating through the jungle areas.

On the eastern European front, the Germans found little difficulty in moving through the field fortifications of the Stalin line, employing tactics of penetration and exploitation by teams of tanks and dive bombers which had been so successful in France. However, the Germans made the mistake of believing that once through the Stalin line they could move unopposed, as they had in France. Russians of all ages and sexes helped dig parallel trench systems outside such cities as Moscow and Leningrad. They were hasty, improvised trenches and antitank ditches, but they proved sufficient to stop the German attack, which had been blunted by continuous fighting.

Hasty Fortification in Towns.—A striking development in the realm of fortifications was the house-to-house fighting in western Europe. As combat troops moved into a new village they invariably selected certain homes, preferably those of stone on the outskirts of the village, as their field fortifications. The next problem was how to develop a co-ordinated field fortification system utilizing the inherent strength of the buildings augmented by fieldworks on commanding ground near the town.

Field Methods.—The location of field fortifications required knowledge of terrain and of the fire power of weapons and evaluation not only of the protection offered by the ground but also the terrain advantages to the attacker. The usual sequence after determining the general location of combat emplacements was the clearing of fields of fire, the provision of observation and signal communication, the laying of mine fields and barbed mire entanglements, the preparation of individual shelters, the emplacement of weapons, the preparation of obstacles other than mine fields and the improvement of supply routes and paths for the movement of reserves. As a part of camouflage and concealment, most armies took advantage of ruses such as dummy positions and the use of deceptive devices, both of which might be interpreted as part of field fortification methods.

The tools the men used for field fortifications were necessarily what they were normally carrying with them and in the use of which they were skilled. The most important was the entrenching tool; an axe was helpful in hard turf and power tools were especially good for heavier construction. Bulldozers, tractors, pneumatic drills and other construction tools, as well as explosives, were helpful in preparing field fortifications. Individual shelters and hasty emplacements were usually built with the materials naturally available. Manufactured items were also necessary for barbed wire, concrete construction and mine fields.

Occasionally there were natural breastworks and parapets, such as in the hedges of the *bocage* country in Normandy. Stone walls in Germany and France on practically every farm and in every village also assured certain defensive assistance. In the hedge country, ports for firing machine guns and other weapons were cut through the dirt ridges, thus providing a well-camouflaged strong point. In the villages, stone and brick walls as well as rubble from demolished buildings made natural breastworks and parapets. German forces in Italy showed great skill and ingenuity in taking advantage of terrain features to develop a network of field fortifications that forced the Allies to pay dearly for every foot of ground, particularly at Cassino. (*See* WORLD WAR II: The *Italian Campaign, Sept. 1943–May 1945*.)

Foxholes.—Foxholes provided the best defensive position for the individual rifleman. They afforded good protection against enemy fire, both small arms and artillery, except for direct hits by shells. Furthermore, they gave protection against the crushing action of tanks. The first reaction of foot soldiers in their foxholes when confronted by a tank attack was one of flight. However, once it mas realized that the tank guns were unable to fire at a depressed angle, the men's best protection was to crouch down in their foxholes when the tanks passed over them. The best foxhole was found to be about three and one-half feet long, two feet wide, or the nidth of a man's shoulders, and at least four feet deep to the firing step. Below the firing step. it was desirable to dig a drainage pit which, in dry weather, gave some measure of comfort as a place for the feet when in a sitting position. Soldiers found that the earth taken out of foxholes needed to be removed since it gave away the location of the hole. Camouflage was achieved by covering the hole with sticks and vegetation. If the unit was in the line or in a defensive position for a day or more, foxholes were connected into V- or Y-shaped figures for better defense.

Emplacement of Weapons.—Dugouts for weapons were more involved, since not only the weapon but the men had to be concealed, and yet there had to be sufficient elbow space for efficient use of the weapon. The pit with parapet was the normal type of emplacement for weapons.

The digging in of heavy artillery and supply depots created great difficulty. Not only were large areas needed, but mechanical equipment was required to dig these emplacements and shelters. In many cases, time and effort mere saved by digging into the sides of hills or by merely constructing a camouflaged area in heavy woods. Another method was to push earth around the supplies and then cover the area with camouflage nets or natural materials.

Mines.—In field, as well as permanent, fortifications, the obstacles of World War II were much more complex than and varied greatly from those of World War I. The greater use of vehicles, amphibious operations and air-borne drops all evoked the development of obstacles. On the defensive, antipersonnel and antitank mines mere located so as to offer additional security to the defending unit. For example, antipersonnel mines were used to break up or hinder enemy patrol action and to slow down infantry assaults. The antipersonnel mine was a charge of explosive, encased in steel, wood or plastic and equipped with a detonator activated when a fuse was stepped on, pulled or kicked. German box mines popped into the air when fired, often blowing off the foot of the individual who had fired it. This mine was also used for "booby traps," a method of killing or injuring souvenir-hunting soldiers particularly. Traps were placed on doors of evacuated buildings, on equipment which might be picked up, in abandoned vehicles and wherever else human ingenuity dictated. The trap was usually so hidden that an unsuspecting person set it off merely by lifting or moving an apparently harmless object.

Antitank mines were similar to antipersonnel mines in their action. but were heavier and had greater explosive charges in order to blow the tracks off tanks and to blow up vehicles. Obviously, mine fields were of permanent defensive use only when covered by weapon fire.

It was absolutely essential to leave paths through friendly mine fields, and it was required that all friendly mine fields be shown on maps. During the mar, retreating troops often laid what were known as nuisance mine fields. scattering them along normal avenues of approach to slow the advance of their opponents. In laying mine fields the geometric patterns were varied so as not to be obvious. Yet mine fields had to be laid quickly and recorded so there would be no difficulty with them later. Mine clearance never quite caught up with mine laying, partly because it was slow work locating mines and then deactivating them to make them harmless. Toward the end of the war, mines were made with plastic and were impossible to locate with the normal radar-type mine clearance device which "pipped" when its rays struck metal. (*See* MINE, LAND.)

Other Obstacles.——Many obstacles other than mine fields were used against troop movements. The Germans, for example, set up tree trunks in fields before the Normandy invasion as obstacles to parachute troops or gliders. They also felled trees or left vehicles abandoned in open pastures where landings might occur.

There were a number of types of barbed-\$ire entanglements, but the most effective were balls three feet in diameter with two on the ground and one placed on top. The wire was rolled in continuous piece in what is known as a concertina. In Europe, antitank ditches were common and in some places were dug on beaches. Other types of obstacles were roadblocks made of logs (the abatis), which included trees placed across an enemy path of approach so as to point at a 45° angle. Another obstacle was a forest of steel beams and the cement dragon's teeth of the Siegfried line, which traversed the whole frontier of Germany. At a distance, eight or ten rows of them looked like the tread of an automobile tire.

Typical Field Fortifications.—The sequence of field fortification in World War II included the location of a defensive position preparation of emplacements and shelters and the creation of obstacles such as mine fields and barbed-wire entanglements. It was regularly put together in a defensive situation in land warfare. A schematic picture of a typical battlefield showed an antitank ditch running down the centre. The defenders behind it would have in sequence concealed entrenched riflemen and gunners spaced backward about 600 yd.. so that their machine guns, mortars and bazookas were able to fire most effectively on an enemy held up momentarily by the obstacles in front of the antitank ditch. The defenders looked out beyond the antitank ditch to barbed mire and the main mine fields, then more barbed wire and, farther in the distance, antipersonnel mines and again barbed wire uith mine fields among it The total depth of this obstacle area in front of the defensive position was usually from 400 to 600 yd.

An example of the development of complete field fortifications in World War II was the Papuan campaign in New Guinea in early 1943, when U S. troops attacked Japanese positions in the jungles. The defenses often consisted of groups of bunkers arranged about five yards apart in circular or oval patterns. Automatic neapons mere sited to fire six or eight inches above the ground and long fire lanes so skillfully cleared that the jungle appeared undisturbed. A typical Japanese perimeter defense in the Sananand area was about 120 yd. long and 70 yd. wide. The network of trenches gave protection to the riflemen and automatic weaponeers. The positions were linked by connecting trenches, and in the centre were bomb shelters to which all the men could repair. The outer perimeter included concrete pillboxes artfully worked into the jungle vegetation so that they were concealed completely. About ten yards from the perimeter and encircling it were trip wires, to which antipersonnel mines were attached.

From 1941 until the Allied invasion of Normandy in 1944, the Germans publicized the Atlantic wall as their response to any attempts at invasion. Huge guns, pillboxes, entrenched troops, antitank ditches and barbed-wire entanglements were pictured. The Allies meanwhile were photographing the beaches from the air and gathering data about them. Underwater obstacles, though not publicized, were an essential part of this field fortification. As many of them were festooned with mines, they caused great concern to the Allies.

From the bluffs, attacking troops were under constant fire, both plunging and grazing, from all types of infantry weapons. In addition, lateral fire was received along the beaches from emplaced artillery in concrete pillboxes. Behind the close-up infantry entrenchments, antitank ditches were laid about roo yd. from the beach and along the limited number of roads and paths running inland from the beach.

When the combination of defensive fire, obstacles and well-trained troops nas considered, it looked at first as if any invasion would be thrown back into the channel. However, bombardment from the air, sea and land was effective in knocking out some of the field fortifications. Once a breakthrough was made. and the Allied invaders got inland in any area, they compelled the Germans who were nearby to withdraw from their long-held Atlantic wall. *(See* WORLD WAR II: *Allied Reconqzrest of Western Europe*)

Korean War.—After the first year of the Korean war, elaborate field fortifications assumed a prominent role in the fighting. The North Korean and Chinese troops nere indefatigable in burrowing into the earth, particularly on the reverse slopes of hills. and concealing their positions. They were known at times to dig all the way through a hilltop to reach the crest facing the enemy. Extensive log-faced bunkers of the type built by the Japanese in World War II provided safe refuges and were remarkably resistant to artillery fire. Both sides followed the standard practice of establishing a thinly held line of outposts to sound the alarm if the enemy attacked. The lines of field fortifications were often five or ten miles deep and extended across the entire Korean peninsula.

PERMANENT FORTIFICATIONS

Permanent fortifications have been important in the history of warfare since earliest times. These fortifications followed a pattern which essentially included: the use of walls during the period of the Greeks and Romans; the feudal castle with its moat and drawbridge; the bastioned fortresses of the early modern period; and the ring fortresses or "concrete battleships" of the early 20th century.

Permanent fortifications were. of course, either emphasized or relatively forgotten as the cycle of war changed from the defense to the offense. When the defensive was predominant, fortifications were inevitably important; when the offensive was supreme, permanent fortifications were bypassed or blasted and their place taken by field fortifications.

Ancient Fortifications.—The civilized tribes of Africa utilized a bank of earth from which they were able to gain an advantage over an attacking force by defending from behind a parapet filled with alternate layers of stone, earth and logs. Some time later came the wall made of mud, sun-dried brick or masonry. The construction of towers at intervals along the wall was the next development. The towers served as sentry posts, barracks and rallying points for the defenders; they were spaced close enough to permit archers to cover the intervening distance with arrows.

In Egypt, labour was available to build walls as much as 120 ft. high and 30 ft. thick. Frequently a ditch was dug on the outside to keep attackers and their siegeworks at a distance. The attacking group usually tried to scale the wall or heap up materials, such as branches, to give them a footing and to permit them to hurdle the wall. As the walls became higher and too difficult to scale, men turned to attacking devices such as the battering ram and to mining. The use of devices for throwing heavy missiles came later, though they were mentioned at the defense of Jerusalem against the Philistines in the 8th century B C. At the siege of Jerusalem two centuries later, there is the first mention of the ram and of movable towers designed to overlook the walls. *(See* ENGINES OF WAR.)

In Greece and Rome the feats of building fortresses and towers and constructing the mechanical devices for attack are the wonder of modern engineers accustomed to machinery and the use of steam, hydraulic and diesel engines. The Romans brought fortifications to a stage of development unequaled until Vauban. They perfected the siege towers, one of which Caesar mentions as being 150 ft high. The lower stories housed the battering ram, which had a pointed head for breaching walls and a ram's head for battering walls. The upper stories were occupied by archers whose object was to drive the defenders from their platforms. Mention is made also of hinged bridges at the top of the tower which were dropped to assist the assaulting parties to get into the fortress.

The long history of the wall as a dominant feature of permanent fortifications must include mention of the famous Chinese wall, built about the 3rd century B.C. The great wall was 1,400 mi. long with 25,000 towers; it was as much as 17 ft. thick with an average height of more than 20 ft., but even so did not prevent invasion by large armies. It did serve as an obstacle to small raiding parties who nere unable to get their horses over it and lacked the tools for opening a gap in the wall.

Roman Empire Defense.—Great walls were built by the Roman emperor Hadrian in Britain and between the Rhine and Danube. The barbarians, though able to make raids against Roman outposts. were not capable of strong attacks against walled fortresses Accordingly. the Roman plan for frontier defenses included masonry malls and fortified camps, and in places merely a line of detached forts. The number of defenders was normally small, though reserves had to be concentrated to meet the invaders when they broke through. As the barbarians grew in strength, the forts developed into fortified cities nhich served as refuges for the neighbouring people.

The defense of the empire was on the Rhine, or in Britain, but always a great distance from the city of Rome. As a result, the city was relatively unfortified and stood as testimony to the fact that fortification was not needed when a nation's strength was great enough to meet the enemy far from its borders. On the other hand, Constantinople, which stood for 1.000 years as the bulnark of the eastern Roman empire, fought off one besieger after another. During this period the genius of its military leaders managed at first to extend the empire's frontiers, but there were a number of times later when the empire was overrun except for its greatest city.

Medieval Castles. — The decline of the Roman empire and the barbarian invasions brought new problems to the defense of western Europe. The more powerful groups fortified their states against the marauding bands, and the weaker turned to the stronger for protection. Central governments dwindled away, to be replaced by local lords whose strongholds were their castles, located on difficult ground since they were used mainly for passive defense.

The forts constructed by William the Conqueror to consolidate his conquest of England were of wood. On the other hand, the Norman castles in western Europe were built of stone, to get maximum strength and utility with a minimum perimeter to defend. The Normans constructed a single large tower, named a keep or donjon, and surrounded it with a low wall a short distance from the tower. As time went on, this outer wall became the first line of defense and was gradually moved farther from the keep. Most of these castles were practically impregnable against the siege weapons then available. Blockade was the only way to reduce them, but long blockades were very difficult to maintain because the lords were unable to keep their serfs for more than 40 days' service each year (see CASTLE).

Influence of Gunpowder. — The introduction of cannon in the 14th century brought about new developments in fortifications. Protection thereafter lay only in the erection of much larger and better-built fortifications. In 1450 Charles VII of France had so powerful a siege train that he captured all the castles in Normandy from the English in one year. Charles VIII moved against Italy at the end of the same century and conquered so many castles and fortified towns that it became obvious a new defense system was needed. The leaders of the opposition came from Italy, and many of them were the greatest figures of the Renaissance. Leonardo da Vinci, Michelangelo and Niccolò Machiavelli all interested themselves in the problems of defense. About this time the famous painter Albrecht Dürer became the first to write of modern fortifications.

Bastioned Forts. — After 1500, when the private castle had lost its defensive capacity, interest centred again on the defense of cities and towns, as had been common in ancient ages. The citadel once again achieved a position of importance as the centre of municipal defense. Strategically significant were border towns like Metz and Verdun between France and Germany, and cities like Liége, Namur and Charleroi on the Franco-Belgian border. Nations sought to control the key approaches to their territory while giving themselves a base or springboard for invasion against enemy countries. From that day to the 20th century, military engineers laboured to make these fortress cities strong.

The terms used by military engineers which are of importance in studying forts and sieges include: the complete wall, known as the *enceinte;* the parapet or top of the wall; the escarp or face leading into the ditch; the counterscarp or opposing wall of the ditch; the covered way on top of it; and finally a mound or glacis leading away from the fort (see fig. 1). The glacis was sloped upward so that a projection of its incline was higher than the parapet wall. Artillery fire directed at the fort could not be raised, and thus projectiles were often lost in the soft earth of the glacis instead of reaching their target.

The general outline of the fortress was also changed, the old straight walls being altered by adding a bastion. These were projections shaped like an ace of spades, which assured that the defenders' weapons and artillery would ward off the assault forces when they approached the walls. Bastions were built into the forts at intervals and so arranged that their guns covered each other. The usual forts had five or six bastions, and were called star fortresses.

Military engineers developed many elaborate geometric patterns to increase the power of defense, their competition in design emphasizing that once again the defense had become dominant over attack.

After the development of the bastion, military engineers still sought the objective of obtaining the greatest amount of protection, combined with the strongest defensive fire power. The simple star trace (*i.e.,* outline) with four or five bastions was replaced by the tenaille trace (fig. 2), in which the flanks were placed back-to-back between the faces. This had the disadvantage that there was still a certain amount of dead ground in the ditch which could not be reached by the guns on the parapets. Eventually military engineers found the solution in what became known as the bastioned trace, its flanks directly opposite each other and linked by curtains (fig. 3). In succeeding decades, fortifications became geometrical patterns with all sorts of details such as gates, sally ports and hornwork coverings. Each part of the fortification became a separate fort that could be divided off from the remainder and be self-sustaining with its own garrison, while still offering mutual support to the remainder of the units in the system.

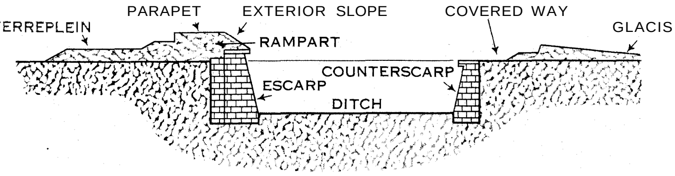


FIG. 1.— DIAGRAM OF A TYPICAL CROSS SECTION OF A FORT

FIG. 2.—TENAILLE TRACE

Vauban's Siegecraft. — Even the bastioned fortress had a short-lived day of predominance, for in the latter part of the 17th century Louis XIV's engineer officer, Marshal Sébastien de Vauban, developed a systematic method of attacking bastioned forts. His objective was to make a breach in the walls through which the attacking column could pass, but to do this he had to establish his artillery on the glacis directly opposite the wall. To make his own artillery safe, he had to knock out that of the enemy. Since the range of guns was from 600 to 700 yd., the first move after the investing forces had established themselves was to set up batteries at that distance to engage in a duel with the artillery in the fort. When the artillery defenses had been reduced, though not necessarily silenced, trenches had to be pushed to the front, so that the guns could be taken to the glacis and the assaulting troops prepared in safety for the launching of their attack. The Vauban system. which long served as a model for armies, was known as the approach by parallel lines (see fig. 4). Its first use was at the siege of Maastricht in 1673, where Vauban completed the capture in 13 days after commencing the digging of trenches.

FIG. 3.—BASTIONED TRACE

Vauban placed his engineers just behind his heavy siege artillery, where they dug a trench parallel to the fort's walls. This served as a shelter for the infantry, from which they could protect the batteries when the defenders sallied forth to try to capture them. While the counterbattery duel was in progress, approach

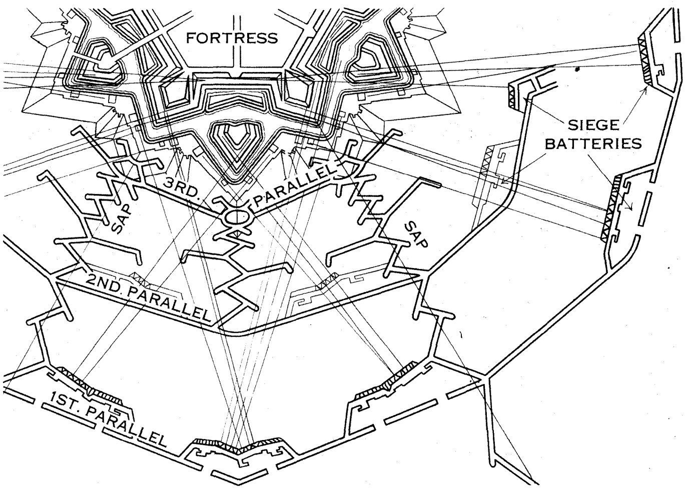

FIG. 4.— REGULAR ATTACK ON A FORTRESS (VAUBAN'S SYSTEM)

trenches perpendicular to the walls were dug from the parallel, but in zigzag form so that the batteries of the fort could not sweep down their length.

From the approaches, a second parallel trench was dug closer to the fort. These trenches were about 12 to 15 ft. wide and 3 ft. deep. with the earth from the excavation thrown forward to make a parapet. The second parallel, about halfway to the wall, was again used as a base for the infantry, and was protected in part by its own batteries which were brought up in closer support. Again the approaches were pushed out, and now they came within musket range of the fort's defenders. Specially trained men called

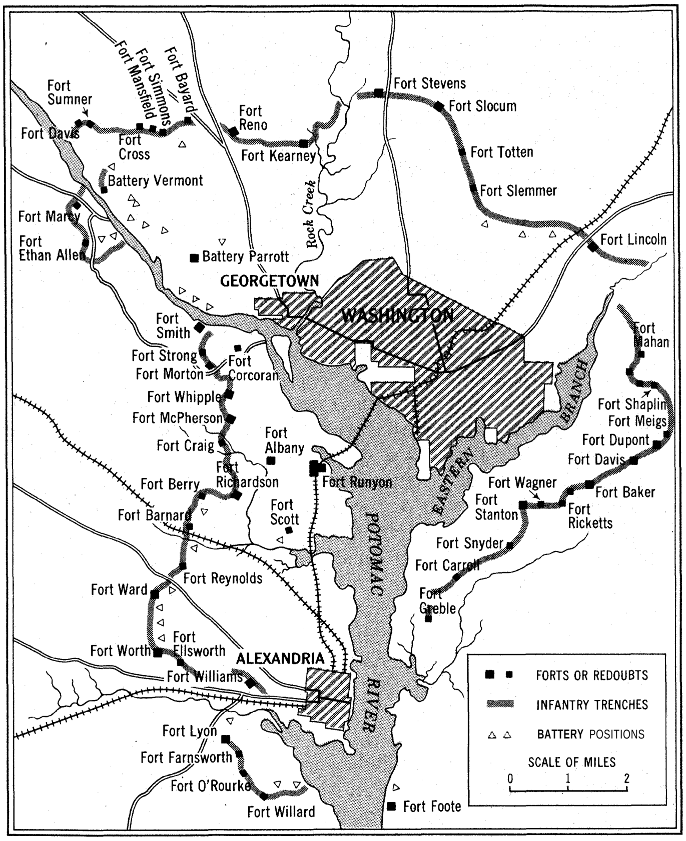

FIG. 5.— DEFENSES OF WASHINGTON, D.C., IN AMERICAN CIVIL WAR

sappers dug slowly ahead under a shelter called a gabion. This was a shield on wheels pushed ahead by the first sapper. The leading man was followed by others who increased the width of the trench and its depth under cover of additional shields. Because of the danger of the work at the head of the sap, Vauban paid them on the spot piecework rates which rose rapidly in proportion to the risk. He counted on a rate of progress of about 50 yd. a day for the usual sap.

Finally, the third parallel was dug near the glacis, irom where the sappers dug their way up the slope to its top. The breaching batteries were then established in iull view oi the escarp, and when it was breached the fortress usually surrendered. Most of the sieges during the century and a half aiter Vauban's successes followed his method with some variation.

19th Century. — As a result of the open tactics of the Revolutionary army in America, the idea of linear battle formations and infiltration was taken up by Napoleon. Also, in the manner of Frederick the Great, he depended upon superior strategy and expert battlefield tactics to win victories. He did not believe in shutting up his armies in fortifications, and whenever possible he avoided attacks against permanent forts. When in exile he stated that in his campaigns against Austria, Prussia and Spain those nations might well have been saved irom defeat had their capital cities been iortified. Under the mode of warfare of that day, as long as the government was preserved and had fighting forces ior protection, the country was not defeated. Napoleon added, "Had Paris been fortified in 1814, my own Empire would have been saved from overthrow."

At the outbreak of the American Civil War, the U.S. had no permanent iortifications except on the seacoast. Several fortresses were built later, however. such as those in Washington, D.C. The system included 68 separate forts, a number of blockhouses and 20 mi. of connecting rifle trenches. The works were so devised that they could support each other by fire. Though never put to test, these fortifications had an indirect influence on the campaigns in Virginia (see fig. 5).

Greater attention was paid to permanent fortifications in the Franco-German War. Developments in rifles and artillery made attacks against fortresses successful. The Germans were victorious in rapid order since they attacked with rifled guns against French fortifications armed with smooth-bore artillery, and in many cases insufficiently protected by detached forts. The German siege howitzer was able to breach the walls of the fort at Strasbourg from more than a mile away, while the largest German gun hurled shells into Paris from a distance of four miles.

The great increase in artillery range compelled the spreading out of detached forts around the fortresses, from a minimum of a few hundred yards to a minimum of six miles by 1910. These detached works were moved out so far from fortress towns that they became almost independent of them. Consequently, fortifying of towns became too expensive, and declined rapidly. The towns began to seek some other means of defense, and unless a town dominated a strategic point its fortifications fell into disuse.

Artillery made its greatest advance in the race against the defensive capabilities of fortifications in the latter half of the 19th century. Once again the attack became ascendant, requiring land fortifications to be rebuilt. The idea of detached forts had, of course, increased the capability of defense, but now the construction of the forts themselves bad to be changed. It was useless to have correct dispersion and mutually supporting fire unless the forts could stand up under artillery pounding. Revetments had to be strengthened immensely and concrete roofs from six to ten feet thick were built over them.

The leading fortification engineer in this period in Europe was Gen Henri Brialmont, who was considered a Belgian Vauban. He placed his iorts at an average distance of four miles from a city such as LiCge, and at intervals of approximately two and one-half miles. At Antwerp, his defense system was even more dense. His idea was that forts could be joined by a ring of infantry trenches, but this was never effected by the Belgians. One of his greatest contributions was the use of armour to protect the guns. He devised disappearing cupolas, and turrets of steel, so that the guns popped out only when they were being fired. The remainder of his fortress (known as the ring fortress) was built of concrete.

Some of the iorts were five-sided, while others were triangular. They appeared far smaller than they actually were, because most of their bulk was concealed underground. Brialmont's ideas were used by the French in developing their fortress systems along the German frontier. Antwerp, Liége and Namur were Brialmont's masterpieces.

Wbrld War I.—Though the Allies subscribed to the axiom of war that victory is the result of offensive action. they looked to their fortresses to give them time for mobilization. The fortresses in France and Belgium were designed not only to delay the enemy on important lines of advance but also to channel his attack. From an offensive standpoint, the fortresses were useful for maneuvering since they formed a pivot for the attacking formations.

By marching through Belgium in 1914, however, the Germans avoided the strong fortresses on the eastern border of France. The fortresses of Liége and Namur in Belgium, and their counterparts in northern France, which were in the path of the German right wing, were weak in comparison with those iurther south on the eastern frontier of France. The Germans had assessed this problem and developed what mas known as the Schlieffen plan. This called for a strong right wheeling movement in an area where there were good railway connections. As long as the Belgians held Liége, the German plan would be blocked. However, it was not a modern, strong fortress and its ring of 12 forts fell within 11 days. The town itself, with its vital bridges over the Meuse, was captured on the third day, after which the howitzers pounded the fortifications for a week more. Namur stood up for only four days under German bombardment, and four of the Xntwerp forts were reduced in three days.

Further south, the forts on the eastern front of France gave a better account of themselves. There were no serious attacks against the Verdun and Belfort fortifications. though the Germans did reduce some of the lesser forts in from 2 to 11 days. Consequently the French high command, seeing how weak fortifications were against the new artillery, decided to abandon permanent forts like Verdun and put their faith in field fortifications. However, when it was later discovered that the steel turrets and concrete of the modern forts had sufferedlittle damage, they were reoccupied and became the focal points for some of the greatest battles of the war.

Permanent fortifications were nor only costly but they gave an illusion of security. Field fortifications had proved as effective as permanent ones since they were able to take advantage of concealment and had been built rapidly in many areas. During the war there had been few instances of the use of mines, or sapping, against permanent fortifications. On one occasion 20 mines, containing 1,000,000 lb. of explosives, were detonated under the German lines on the Messines ridge. Before that time, mining operations had been resorted to in the battle of the Somme, where great quantities of explosives were used against the Ludendorff line. One mine, for instance, took months to'complete and when exploded its concussion nas felt ten miles away. Gen. Erich Ludendorff reported that "the moral effect of these explosions was simply staggering." Just as the appearance of the tank made fortifications of a permanent type less useful, so, too, did tanks eliminate the need of these tremendous mining operations.

The experience of World War I appeared to have dictated the passing of the great fortified areas, but the French continued to rely upon an elaborate chain of defenses which they built in the interim between World Wars I and II.

Developments Between 1918 and 1939.—The fact that certain modern fortresses had held out against German artillery during World War I, as well as the admitted saving in military manpower, induced France to build the celebrated Maginot line as a permanent defense against German attack. This ultramodern defensive fortification showed traces of the old circular system of fortifications but its dominant feature was linear. The Maginot line was, from the standpoint of the troops, a tremendous advance over previous fortifications. Its concrete was thicker than anything heretofore known and its guns heavier. In addition, there were air-conditioned areas for the troops, and the line was usually referred to as being more comfortable than a modern city. There were recreation areas, living quarters, supply storehouses and underground rail lines connecting various portions of the line. Strong points had been established in depth, capable of being supported by troops moved underground by rail.

Germany, too, fortified the Rhineland in 1936 with a series of obstacles and pillboxes known as the Siegfried line. It had steel and concrete defensive positions, behind great masses of concrete and steel obstacles running along the entire frontier of Germany. The frontier fortifications of the Soviet Union against Poland, known as the Stalin line, were built on the model of the Maginot line.

World War 11.—The Germans marched through Belgium in May 1940 on a modified Schlieffen plan. As in 1914, they struck at the crossings of the Rleuse and at the Albert canal near LiCge. Once more the Allies expected the LiCge fortifications to hold the enemy for a time along the Meuse. However, the system's key fort of Eben-Emael fell within 24 hours. The whole world mas startled by this rapid fall of a modern fortification. The Belgians had manned the fort with good troops and incorporated the newest ideas in its erection.

The alarm of the western world was expressed in the phrase "secret weapon." The Germans never disabused the world of this thought. For a long time there was a belief that the Germans actually had some new weapon which could bring about the downfall of a modern fort in a day's time. In reality, the Germans had merely planned the operation completely and rehearsed their attack with models. The assault was perfection in co-ordination. Early in the morning German gliders landed troops directly on top of the fortification. Trained engineers acted swiftly in placing charges to blow up the cupolas, used explosives against the ammunition hoists, and even dropped grenades into the muzzles of the guns. By the time the air raid sirens had given their warning, dive-bombing planes were bombarding the other forts. The airborne troops were strengthened by infantry which crossed the river in rubber boats, and together they mopped up the entire LiCge fortification system in an unbelievably short period. Besides attributing the fall of the forts to new weapons, the "fifth column" was also blamed. The real reason was skill, plus the action of the air-borne troops, and the co-ordination of all German arms, both ground and air, in the attack.

The Germans continued their march through Belgium and crossed the Somme, where they struck at Sedan at the northern end of the Maginot line. Having made a breakthrough with their tanks and planes, they continued around to the rear of the line, making it useless. Later, on the eastern front, the Germans used similar tactics in cutting through the Stalin line. Again and again they broke through at one point, employing a combination of tanks, planes, infantry and engineer troops to exploit their success as they had done in France. In some places the Russian zone of permanent fortiiications was roo mi. deep but it was insufficient to halt the German blitzkrieg.

The Soviet Union, however, had never placed the same dependence upon the Stalin line that the French had on the Maginot, but considered it rather as a method to compel the Germans to attack through certain areas. One writer maintained that upon the German breakthrough of the Stalin line they were the victims of a Maginot-line complex in reverse, for they believed the offensive had been successful once the fortified line was pierced. The delay which the Germans encountered in getting through the line gave the Russians two months to determine the direction of the German attack and to bring up their reserves. Also, the line had blunted the cutting edge of the German offensive.

A short time later, the great coast defense of Singapore fell to the Japanese, an event which the western nations hardly believed possible. For Singapore was "the mighty bastion of the far east" and a symbol of Allied resistance. The Japanese landed far to the north of Singapore and after fighting their way southnard, attacked it from the land side. The fort was under constant attack from the air and was heavily bombed by artillery. It had neither fighter planes nor anti-aircraft guns for defense, and its huge 16-in. guns could fire only seaward.

During the middle period of the war, little was heard about permanent fortifications playing a part in any of the battles. 'There mere none in north Africa except the crumbling Mareth line in southern Tunisia, and none at all in the Pacific war after the fall of Corregidor in the Philippines. The great battles of 1942 and 1943 were fought behind and against field fortifications, though during this period there mere the great defense and siege operations at Leningrad. This city, despite the support of a number of naval forts on the Baltic and a lake to its rear, was not completely fortified. However, the combination of permanent forts, water barriers, field fortifications and ruined buildings made of the city a fortress which held out for 515 days until relieved by Soviet forces.

By 1944 there was more and more emphasis on concrete and steel fortifications in the defense of Germany's "fortress of Europe." Newsreels from Germany filtered out through neutral nations to show the world the strength of the channel defenses. Tremendous areas of concrete served by rail and road and mounting railway guns in disappearing turrets brought fear to the onlooker. The forts were built into the sides of cliffs and gave an appearance of impregnability, beyond anything known in previous fortifications. However, when the Allied troops went ashore in the invasion of Normandy they caught certain of the garrison troops napping and also utilized both air and naval bombardment to drive the garrisons underground. It was found upon entering the continent that the permanent fortifications at the seacoast had insufficient support of infantry troops and that there was not a continuous fort along the entire seacoast as had been intimated by German propaganda.

At the close of World War II it was generally concluded that permanent fortifications were not worth the economic cost and the material effort, because, in most cases, delay of an enemy could be accomplished by other means. That is not to say that permanent fortifications were forever outmoded, since in an atomic attack troops might well return to earth or concrete dugouts. Also, permanent fortifications when fitted into a defense pattern continued to have a definite use along river lines and near mountain passes. Third-dimensional warfare, however, had very nearly ended their usefulness as harbour defenses or beach defenses. *See* COAST DEFENSE; TACTICS.

FORTIS, ALESSANDRO (1842–1909), Italian statesman, a prominent republican of the Risorgimento who eventually became prime minister under the monarchy, was born at Forlì. He was brought up as a republican under the influence of Giuseppe Mazzini in the most revolutionary of Italian regions, the Romagna. He fought with Garibaldi in 1866 against the Austrians in Trento and again in 1867 against the papal troops when Garibaldi tried to capture Rome. Most of the Italian republicans had defected since the success of the monarchy in 1860. But Fortis still remained faithful for some time longer. In 1874 the government arrested him with other republicans as they were working out their party program at Villa Ruffi, but a jury acquitted them. In 1876 the party congress at last agreed to drop their former intransigence and to accept the permission held out to them by the new government of the left to take part in parliamentary politics. Fortis himself became a deputy in 1880, attaching himself to Francesco Crispi's group, which sat well over on the left of the chamber. In parliament he proved to be an assiduous but not brilliant politician. He was minister of agriculture in Luigi Pelloux's government in 1898–99. Giolitti chose him as a safe man to take over the premiership for a few months in 1905–06. Fortis' most important achievement in this post was to carry through the nationalization of the railway system. He died in Rome on Dec. 4, 1909. (See also ITALY: History.) (D. M. SH.)

FORT KNOX, a U.S. army reservation, is approximately 35 mi. S. of Louisville in Kentucky. Comprising 110,000 ac., the reservation contains the United States Army Armored centre and the principal U.S. bullion depository.

The fort was established in 1918 as Camp Knox and used as the army's Field Artillery Officer Training school. In 1932 the name was changed, and the following year the 1st cavalry regiment mas moved from Marfa, Tex., to Ft. Knox where it was mechanized. The fort was made headquarters of the armoured force in 1940 and became the armoured centre in 1944.

Located at the centre are several units, including the U.S. Army Armor school, 6th armoured cavalry, Army Armored Training centre, Army Medical Research laboratory, army armour board and the army maintenance board. The primary function of the post is the training of soldiers for armoured warfare.

For maximum security, the bullion depository was built at Ft. Knox in 1936. By the second half of the 20th century the gold stocks there were valued at more than $10,000,000,000. The fabulous treasure is housed in a solid square bombproof building, constructed of granite, steel and concrete, enclosing a two-level torch-proof steel and concrete vault. Added security is provided by guards, sentries and an encircling steel fence, as well as by mechanical protective devices, such as the photoelectric eye. The nearby army post gives further protection.

During World War II the gold vault was used as a repository for the original copy of the U.S. constitutian and the Declaration of Independence, the Magna Carta, a copy of the Gutenberg Bible and the original draft of Lincoln's Gettysburg address.

(G. H. T.)

FORTLAGE, KARL (1806–1881), German philosopher, was born at Osnabrück. Originally a follower of Hegel, he turned to Fichte and Beneke, with whose insistence on psychology as the basis of all philosophy he fully agreed. The fundamental idea of his psychology is impulse, which combines representation (which presupposes consciousness) and feeling (*i.e.*, pleasure). Reason is the highest thing in nature, and God is the absolute Ego, the empirical egos being his instruments.

FORT LAUDERDALE, a residential and resort city of southeastern Florida, U.S., at the mouth of New river on the Atlantic ocean, 26 mi. N. of Miami; the seat of Broward county. The city is noted for its water areas and water fronts; of the incorporated area 10% is water, and there are 260 mi. of ocean, bay, river and canal frontage, 135 mi. of which are navigable. The Intracoastal waterway, a yacht highway in winter, brings 1,000 boats a year to city-owned Bahia Mar yacht basin. Port Everglades on the south limits of the city, built jointly with Dania and Hollywood, is the deepest harbour on the Atlantic coast south of Norfolk, Va., and ranks third in Florida after Jacksonville and Tampa in cargo volume, much of it tanker borne fuel.

A fort named for Maj. William Lauderdale in 1838 was a base for expeditions into and across the nearby Everglades in search of Seminole Indians for removal to the west. Washington Jenkins came to the region in 1876 as keeper of a house of refuge on the uninhabited and lonely coast. Frank Stranahan, the first permanent white settler came from Ohio to operate a ferry and a trading post where he befriended and traded with Seminole Indians. There were 52 inhabitants in 1900, and 175 people incorporated the city in 1911. In 1930 there were less than 9,000 inhabitants but by 1960 the population was 83,648. (For comparative population figures see FLORIDA: Population.) The city adopted a council-manager form of government in 1925. (C. W. TE.)

FORT LEE, a borough of Bergen county, in northeastern New Jersey, U.S., across the Hudson river to the west of New York city and connected to the borough of Manhattan via the George Washington bridge. It is a residential community, lying mainly along the top of the Palisades. It was the site of Ft. Constitution (later renamed Ft. Lee) which along with Ft. Washington defended the southern approach to \Vest Point during the American Revolutionary War. The location has been continuously inhabited since about 1700, but the borough was not incorporated until 1904. From 1907 till 1919 Fort Lee was the motion-picture capital of the world and important players of the early silent films — such as Rudolph Valentino, Charlie Chaplin, Lon Chaney, Theda Bara, Lillian Gish, "Fatty" Arbuckle and Marie Dressler—worked there. The last picture mas made there in 1923, but the borough remains a major film processing centre, turning out large quantities of film daily for the motion-picture industry. For comparative population figures see table in NEW JERSEY: Population.

(D. N. A.; M. P. M.)

FORT MADISON, a city in the southeastern corner of Iowa, U.S., on the Mississippi river; the seat of Lee county.

Fort Madison has large railroad shops and various manufacturing industries. It is the seat of a state penitentiary. A 525-ft. movable swing span railroad bridge across the Mississippi was completed in 1927. A fort was built there in 1808, and was named after James Madison, who was elected president that year. It was constantly harassed by the Sauk and Fox Indians, who considered that its erection was a violation of the treaty made with them by Gen. William Henry Harrison in 1804.

In Sept. 1813, the little garrison of 100 men abandoned the post, burning the fort behind them and escaping to the river through a tunnel. Permanent settlement began in 1833. The town was incorporated in 1838 and chartered as a city in 1839. The courthouse, built in 1841 and constantly in use thereafter, is the oldest in the state. For comparative population figures see table in

IOWA: *Population.*

FORT MYERS, a city of southwestern Florida, U.S., on the Caloosahatchee river. 13 mi. from the Gulf of Mexico. 145 mi. N.W. of Miami; the seat of Lee county. The city is at the western end of the cross-state waterway through the St. Lucie canal and Lake Okeechobee. There is a municipal boat basin with a capacity for 100 yachts and smaller boats. The city is the centre of a trading area including five nearby counties. A state farmers' market and local packing houses process the citrus fruits, truck crops, cut flowers and commercial fishing products of the area'. The city's boulevards are lined with royal palms, and more than 100 varieties of palm are found in the city and along the banks of the river. which is stocked with tarpon. Fort Myers, named for Lt. Col. Abraham C. Myers, was established on Feb. 20. 1850, on the site of the old Ft. Harvie, a temporary post during the Seminole War (1835–42). The city was incorporated in 1905. For comparative population figures *see* table in FLORIDA: *Population.* (J. E. *D.)*

FORTROSE, a royal and small burgh and seaport of Ross and Cromarty. Scot.. on the southeastern coast of the Black Isle peninsula. by Inverness firth, 28 mi. N.N.E. of Inverness by road. Pop. (1951) 882.

The burgh of Fortrose consists of the two towns of Fortrose and Rosernarkie, about 1 mi. apart. which were united into a free burgh by James II of Scotland in 1455. though total union was achieved only by an act of the Scots parliament of 1661.

Rosemarkie had a monastery founded by St. Moluag in the 6th century, and St. Peter's church, built in the 8th century, while David I in 1124 instituted the bishopric of Ross with its seat there. A century later the bishop's seat was transferred to Fortrose, thereafter to be known as the Chanonry of Ross. a name which survived the Reformation and is still used locally. Tradition has it that part of the cathedral was built by a countess of Ross (her canopied tomb still exists'). while it seems to have been completed in about 1500 by Bishop Fraser. The style has been described as of the purest and most elaborate middle-Pointed. The north aisles were never erected, and all that now remains is the south aisle to the nave and chancel. with the chapter house, a two-story structure, standing apart near the northeastern corner. The curfew is sounded nightly on a bell of 1460.

An ancient Celtic carved cross stands in the old churchyard of Rosemarkie. The academy is the successor of an ancient grammar school. Fortrose and Rosemarkie are residential and seaside holiday tonns.

FORT SMITH, a city on the western border of Arkansas. U.S.. the state's second largest city, midway between the Ozark or Boston mountain range to the north and the Ouachita mountains to the south, on the south hank of the Arkansas river at the mouth of the Poteau river; the seat of Sebastian county. The site was known as Belle Pointe to the early French explorers. An army post was established there in 1817 and named for Gen. Thomas A. Smith. The town was laid out in 1821, incorporated in 1842 and chartered as a city in 1845. Troops were finally withdrawn in Sept. 1871. and the military reservation was transferred to the department of the interior.

The U.S. district court for the western district of Xrkansas was located in Fort Smith for many years and had jurisdiction over the Indian territory. now the state of Oklahoma. Isaac C. Parker. judge of the court from 1875 to 1896, had the difficult task of enforcing federal law in Indian territory, refuge for great numbers of outlaws and the home of the "five civilized tribes." He used 200 deputy United States marshals in the task. In 1957 the Fort Smith Historical Restoration corporation restored Judge Parker's courtroom in its original building and built an exact replica of the hanging gallows used by this court in punishing convicted capital offenders.

Local industries include the manufactures of wood. metal: paper, glass. fibre and electronic products. The city is in the heart of a natural gas region and the Arkansas-Oklahoma coal field. Truck and food crops are grown in abundance in the rich Xrkansas river valley. Livestock production, dairying, poultry and meat packing are important sources of income. One of the greatest horse and mule markets in the nation is located in West Fort Smith.

Two city-owned mountain lakes and several man-made lakes within easy driving distance provide excellent Ozark mountain water and recreational facilities in addition to the many parks and playgrounds and the Arkansas-Oklahoma Livestock Exposition grounds n-ithin the city limits.

Van Buren, Ark.. to the north. and West Fort Smith, Okla., are adjacent cities. Ft. Chaffee army base is 8 mi. E.

The population in 1960 was 52.991 by federal census. For comparative population figures *see* table in ARKANSAS: *Population.* (E. P. *Hi.)*

FORTUNA (FORTUNE), an Italian goddess who later became identified with the Greek Tyche, a divinity of chance or lot. The original Italian deity, however, was not an abstraction of chance or luck, but rather the bearer (her name is derived from the root *fer-)* of, it is hoped, prosperity and increase. As such she approaches a fertility deity and hence her association with the bounty of the soil and the fruitfulness of women. Frequently she is an oracular goddess, consulted in various ways regarding the future. She is worshiped under numerous cult-titles (*e.g., muliebris, virilis, equestris,* etc.), a complete account of which is to be found in W. Roscher, *Ausführliches Lexikon der griechishen und römischen Mythologie.*

Fortuna was worshiped extensively in Italy from the earliest times Her introduction at Rome was comparatively late, traditionally under the auspices of Servius Tullius. who built a temple of Fors Fortuna outside the city on the right bank of the Tiber. She had numerous other shrines in Rome, many of nhich traced their founding back to the regal period. The most celebrated shrines of Fortuna outside the city were those at Praeneste and Xntium. At Praeneste. where she was norshiped particularly by women as Primigenia. "first born" (apparently of the daughters of Jupiter), her shrine was an oracular seat of some celebrity. The procedure was for a child to draw at random from an ancient collection of nooden tiles bearing various messages, nhich would then be related to the problems of the consultant. The cult of Fortuna Primigenia on the Capitoline was according to tradition established by Servius Tullius. The shrine at Antium, well known from Horace's *Odes* i. 35, had two Fortunae who gave responses by the mysterious movement of their cult statues.

ALINARI

STATUE OF THE GODDESS FORTUNA HOLDING CORNUCOPIA AND RUDDER, THE SYMBOLS WITH WHICH SHE IS USUALLY ASSOCIATED. FOUND AT OSTIA, THE STATUE IS NOW IN THE VATICAN CITY. ROME

Fortuna is represented in literature and art as bearing a cornucopia as the giver of abundance. a rudder as controller of destinies, or standing on a ball to indicate the uncertainty of fortune.

See also G. Wissowa, *Religion und Kultus,* pp. 256–268 (1912) ; W. W. Fowler. *Roman Essays and Interpretations,* pp. 64–70 (1920). (R. B. LD.)

FORTUNATIANUS, ATILIUS. Latin grammarian of the 4th century A.D. He was the author. of a treatise on metres, dedicated to one of his pupils. a youth of senatorial rank. The manual discusses the fundamental ideas of metre and the rules of prosody. and ends with an analysis of the metres of Horace. The chief authorities used are Caesius Bassus and the Latin adaptation by Iuba the grammarian of the *Techne* of Heliodorus.

Editions of the *Ars* in H. Keil, *Grammatici Latini,* vi, and separately by him (1885).

FORTUNATUS, the hero of a popular European chapbook.

He was a native. says the story, of Famagusta in Cyprus, and meeting the goddess of Fortune received a purse which was replenished as often as he drew from it. He wandered through many lands, and at Cairo was the guest of the sultan. Among the treasures which the sultan showed him was a hat which had the power of transporting its wearer to any place he desired. Of this he feloniously possessed himself, and returned to Cyprus, where he led a luxurious life. On his death he left the purse and the hat to his sons Ampedo and Andelosia; but they, by their recklessness and folly. fell on evil days. The moral of the story is obvious: men should desire reason and wisdom before all the treasures of the world. In its full form the history of Fortunatus occupies more than 158 pages in Karl Simrock's *Dte deutschen Volksbucher,* vol. iii. The style and allusions indicate a comparatively modern date for the authorship; but the nucleus of the legend can be traced back to a much earlier period. The earliest known edition of the German text of Fortunatus appeared at Augsburg in 1509. Innumerable versions occur in French, Italian. Dutch and English,

The story was dramatized by Hans Sachs in 1553, and by Thomas Dekker in 1600. Tieck has used the legend in his *Phantasus,* and Chamisso in *Peter Schlemihl;* and Ludwig Uhland left an unfinished narrative poem entitled "Fortunatus and His Sons."

See W. V. Schmidt, *Fortunatus und seine Sohne, eine Zauber-Tragödie, von Thomas Decker, mit einem Anhang,* etc. (1819); J. J. Görres, *Die deutschen Volksbucher* (1807).

FORTUNATUS, VENANTIUS HONORIUS CLEMENTIANUS (530–609), bishop of Poitiers, and the chief Latin poet of his time, was born near Ceneda in Treviso in 530. He studied at Milan and Ravenna, with the special object of excelling as a rhetorician and poet, and in 565 he journeyed to France, where he was received with much favour at the court of Sigbert, king of Austrasia, whose marriage with Brunhild he celebrated in an epithalamium. After remaining a year or two at the court of Sigbert he traveled in various parts of France, visiting persons of distinction and composing verses. At Poitiers he visited Queen Radegunda, and she induced him to prolong his stay in the city indefinitely. There he enjoyed the friendship of Gregory of Tours and others. He was elected bishop of Poitiers in 599. and died about 609. The later poems of Fortunatus were collected in 11 books, and consist of hymns (including the *Vexilla regis prodeunt,* translated into English by J. M. Neale as "The Royal Banners Forward Go"), epitaphs, poetical epistles and verses in honour of his patroness Radegunda and her sister Agnes, the abbess of a nunnery at Poitiers. He also wrote a large poem in four books in honour of St. Martin, and several lives of the saints in prose.

An edition of the works of Fortunatus was published by C. Brower in 1603 (2nd ed, 1617). The edition of M. A Luschi (1785) was afterward reprinted in Migne's *Patrologiae cursus completus,* vol lxxxviii. *See* the edition by Leo and Krusch (1881–85). There are French lives by Nisard (1880) and Leroux ([illegible]).

FORTUNE, ROBERT (1813–1880), Scottish botanist and traveler, was born at Kelloe Berwickshire, on Sept. 16, 1813. He was employed in the botanical garden at Edinburgh, and afterward in the Royal Horticultural society's garden at Chiswick, and upon the termination of the Chinese war in 1842 was sent out by the society to collect plants in China. His travels resulted in the introduction to Europe of many beautiful flowers; but another journey, undertaken in 1848 on behalf of the East India company, had much more important consequences, occasioning the successful introduction into India of the tea plant. In subsequent journeys he visited Formosa and Japan, described the culture of the silkworm and the manufacture of rice paper, and introduced many trees, shrubs and flowers later generally cultivated in Europe. The incidents of his travels were related in a series of interesting books. He died in London on April 13. 1880.

FORTUNY Y CARBÓ, MARIANO JOSÉ MARÍA BERNARDO (1838–1874), an influential Spanish historical painter. was born at Reus on June 11, 1838. He entered the Academy of Barcelona, where he worked for four years under Claudio Lorenzale, and in March 1858 he gained a scholarship which enabled him to complete his studies in Rome. On the outbreak of the war between Spain and the emperor of Morocco in 1859 Fortuny was sent by the authorities of Barcelona to paint the most striking incidents of the campaign. He returned to Spain in 1860. He visited Paris in 1868 and shortly afterward married the daughter of Federico Madrazo, the director of the royal museum at Madrid. Another visit to Paris in 1870 was followed by a two years' stay at Granada, but then he returned to Rome where he died on Nov. 21, 1874.

The work which Fortuny accomplished during his short life is distinguished by facility of execution and cleverness in the arrangement of brilliant hues.

FORT WAYNE, a city of northeastern Indiana, U.S., and the seat of Allen county. Kekionga (Miami Town or Great Miami village), chief town of the Miami Indians, was located within the limits of the present city, where the St. Marys and St. Joseph rivers join to form the Maumee. Because of the natural advantage of the site for both travel and defense, French traders and soldiers built Fort Miami there. In 1760 the fort was occupied by the English, but in 1763 it was captured by the Indian chief, Pontiac. In 1790 Pres. George Washington sent Gen. Josiah Harmar to establish a post there. He was quickly defeated by Little Turtle, as was Gen. Arthur St. Clair a year later. In 1794 Gen. "Mad Anthony" Wayne defeated the Indians and built a stockade which came to be known as Fort Wayne.

From a crude military and commercial outpost, Fort Wayne turned into a fur-trading centre. It was incorporated as a town in 1829, and became a city in 1840. Although its industrial growth was stimulated by the building of the Wabash and Erie canal, true industrial and commercial development resulted in the 1850s with the coming of the railroads. Easy access to raw materials and to markets permitted diversification in industrial development. Manufactured products include wire, electrical machinery, pumps and tanks, radio and television equipment, motor trucks, pistons, dredges, mining machinery, oil burners, biscuits and beer. Pop. (1960) city 161,776; Fort Wayne standard metropolitan statistical area (Allen county) 232,196. (For comparative population figures for the city *see* table in INDIANA: *Population.*) A part of the growth between 1950 and 1960 is accounted for by annexations which doubled its area.

Among the city's buildings is the tower of the Lincoln National bank, and the home office building of the Lincoln National Life Insurance company, which houses a remarkable collection of Lincolniana. Fort Wayne is the site of Indiana Technical, a private college founded in 1930; St. Francis, a Roman Catholic coeducational college founded in 1940; Concordia Senior College (1957), a theological school of the Lutheran Church–Missouri Synod, the successor of Concordia College, closed in 1957; and centres of Purdue and Indiana universities. The Fort Wayne state school for the mentally retarded is there also. (I. G. G.)

FORT WILLIAM, a city of the Thunder Bay district, in southwestern Ontario, Can., is on Lake Superior at the mouth of the Kaministikwia river alongside its twin city Port Arthur (*q.v.*); the two cities comprise the area called the lakehead.

Fort William is a major transportation centre, on both the Canadian Pacific and Canadian National railways, it is also served regularly by air and by several Great Lakes steamship lines. There are more than 25 mi. of river front, with water-rail docks, coal docks, freight sheds and grain elevators. The grain storage facilities are among the largest in the world. Other industries in the second half of the 20th century included newsprint paper mills, marine and general engineering shops, foundry, sawmills and woodworking factories, bus and aircraft factories, brewery and brick and clay works. Plants on the Nipigon river and at Kakabeka falls provide hydroelectric power. Fort William is the centre of a rich mining area of gold, copper, silver and iron, and of an extensive fur-farming industry.

The site was probably first occupied as a French fur trading post in 1678. The North West Fur company built Fort William there (1801–05), and during the early 1800s company employees and partners met annually at Fort William. Pop. (1961) 44,563. (F. A. CK.)

FORT WILLIAM, a small burgh of Inverness-shire, Scot., at the northeastern end of Loch Linnhe, an arm of the sea, about 62 mi. S.S.W. of Inverness and 115 mi. N.N.W. of Glasgow by road. Pop. (1951) 2,674. The original fort, called Inverlochy, was built by Gen. George Monk in 1654 to keep the peace in the Highlands. It fell into ruins during the Restoration and in 1690 was rebuilt by Gen. Hugh Mackay, who named it Fort William after William III, calling the little village at its foot Maryburgh after his queen. The Jacobites unsuccessfully besieged it in 1715 and 1746. The fort was dismantled in the mid-19th century and demolished to provide room for the railway and freight yard, but the town had by then taken its name. Fort William is a touring centre for the west Highlands, and a starting point for the ascent of Ben Nevis, invisible from the town, although lying 4½ mi. E.S.E. Corpach, about 2 mi. N., stands at the head of the Caledonian canal. To the northeast are the modern Inverlochy castle, with extensive cattle rearing in the vicinity, and the ruins of old Inverlochy castle, near which was fought the battle of Inverlochy, when the marquess of Montrose defeated the earl of Argyll on Feb. 2, 1645. Fort William was the first town in the British Isles to light its streets by electricity entirely generated by water power. Water from Loch Treig, conveyed by a 15-mi. tunnel, provides electricity for the engines of a large aluminum works, which absorbs much local labour. The employees are housed in Inverlochy village. Other industries are cattle farming and distilling. The west Highland museum exhibits local crafts and historical relics, including the "secret portrait" of Prince Charles Edward.

FORT WORTH, the seat of Tarrant county, Tex., U.S., is located at the confluence of the Clear and West forks of the Trinity river, 30 mi. W. of Dallas. Pop. (1960), city, 356,268; standard metropolitan statistical area (ahich includes Tarrant and Johnson counties) 573,215. The average temperature in Fort Worth is 65.8° F.; average annual precipitation is 31.63 in.

History. — Fort Worth was founded May 8, 1849, by Maj. Ripley Arnold and the second dragoons on a site suggested by ranger officer Middleton Tait Johnson of Johnson's Station (present Arlington) as a frontier outpost against Comanche depredations, and was named for Maj. Gen. William J. Worth, commander of federal troops in Texas at that time.

A fort in name only and abandoned as a garrison in 1853, Fort Worth hovered on the ragged edge of disappearance until 1856, when by election it was chosen to succeed Birdville as seat of Tarrant county, named for Gen. Edward H. Tarrant, Indian fighter and legislator. According to some disgruntled citizens of Birdville, the outcome was determined by the generous use of whisky and by voting "every man as far West as the Rio Grande." A second election validated the choice, however, and Fort Worth was on its may from a crude frontier settlement to a cattle and rail centre. In the 20th century it was a sophisticated, cosmopolitan focus of transportation facilities, industry, commerce and the arts.

Early growth was accentuated by the cattle drives of the 1870s. Fort Worth was the last major population centre between the Brazos and the Kaw rivers, and it appealed to cowmen as a place where the cowboy "got a square deal from the merchants, and could have a high old time"; hence its names, "Cowtown," and "Where the West Begins." Boom, short-lived but exciting, came with the Texas and Pacific railroad, July 19, 1876. Anticipating its arrival, the city rejected scornfully a challenge from Dallas to a baseball game, replying that its young men were too busy to engage in such foolishness, an ironic twist since the Fort Worth Panthers subsequently were to establish an all-time record for successive Texas League pennants.

Another milestone was the opening of the great packing plants by Armour and Swift in 1902. A silver spade dug into wet soil, April 18, 1949, marked the beginning of a new chapter in the story of Fort Worth—the genesis of aviation manufacturing. Thereafter, the growth of population—and its concomitants—was phenomenal; for comparative figures *see* table in *TEXAS: Population.*

In the latter half of the 20th century Negroes made up somewhat over 10% of the population, Latins less than 5%; the rest was largely native-born white. Western gear goes unnoticed on the streets, yet 25,000 people build jet bombers and other thousands are white collar workers. Hospitality and friendliness of the old west accompany air-conditioned comfort and interest in the arts.

Government. — Incorporated in 1873, Fort Worth employed several forms of city government until the adoption in 1924 of the council-manager plan. The city has experimented with the recall, ousting six councilmen by the method in 1938.

Commerce, Industry and Transportation. — Within a 30-mi. radius Convair, Bell Helicopter, Chance Vought of "Crusader" fame, and Temco have written aviation history. General Motors is at nearby Arlington. Carswell air force base and the Fort Worth General depot are important. Carter field, international airport near Arlington, and Meacham field aid in making the city a centre of southwest aviation.

Packing houses and stockyards constitute the second major industry. Fort Worth is one of the most active oil areas in the U.S. It is a large grain milling and storage centre and is important in the production of air-conditioning equipment, work garments and quality candy. Other items processed in Fort Worth range from saddles to expensive jewelry and from serums to fertilizers.

Fort Worth is served by trunk line railroads, buses, intercontinental highways, a toll road, and an expanding series of expressways. The Trinity Industrial authority works with river cities to extend future ocean barge transportation to Dallas and Fort Worth.

Educational and Cultural **Activities.**—Fort Worth is the home of Texas Christian university, founded in 1873 and supervised by the Disciples of Christ; and Texas Wesleyan, a Methodist college founded in 1891. Arlington State college is 6 mi E , in Arlington. Cultural assets include the Children's museum; the Noble planetarium; the Fort Worth Art centre; the Woman's club; the Fort Worth Public library; the Opera association; the Civic Music association; and Fort Worth Symphony orchestra. Reactivated Casa Manana presents local and national theatre. Area colleges boast active fine arts groups. Two newspapers, the *Star-Telegram* and the *Press,* and the famous *Cattleman's Magazine* are Fort Worth publications.

Parks and Recreations. — Recreational facilities include over 60 parks; the famed Botanic gardens; an aquarium; a zoo; six inland lakes; North Fort Worth's western restoration, "Cowtown U.S.A."; the Will Rogers Memorial Coliseum and auditorium; and the annual Southwest Exposition and Fat Stock show with its world championship rodeo. Among the many area towns are Weatherford, 27 mi. W., a birthplace of the Populist party and home of Douglas Chandor, the artist, and Mary Martin, the actress; and Thurber, a ghost coal town. (E. C. BE.)

FORTY-SEVEN RŌNIN, the 47 loyal retainers of the lord of Akō, whose vendetta ranks as one of the most dramatic episodes of Japanese history. The incident began in April 1701, when imperial envoys from Kyōto arrived in Edo, the capital of the shogun. Three provincial *daimyō* were appointed to receive them, including Asano Naganori (1667–1701) from Akō. Because these men were ignorant of court etiquette they were directed to consult Kira Yoshinaka (1641–1703), an expert in such matters. The other two *daimyō* gave Kira lavish presents to ensure his cooperation, but Asano offered only a token gift. Kira mas apparently annoyed and expressed his displeasure by constantly taunting the inexperienced Asano. The latter finally gave way to his pent-up wrath, and on April 21, 1701, in the audience hall of the shogun's palace, he flew at Kira with his dirk. Kira escaped with minor wounds, but Asano's gross breach of etiquette enraged the shogun, who ordered Asano to commit suicide the same day.

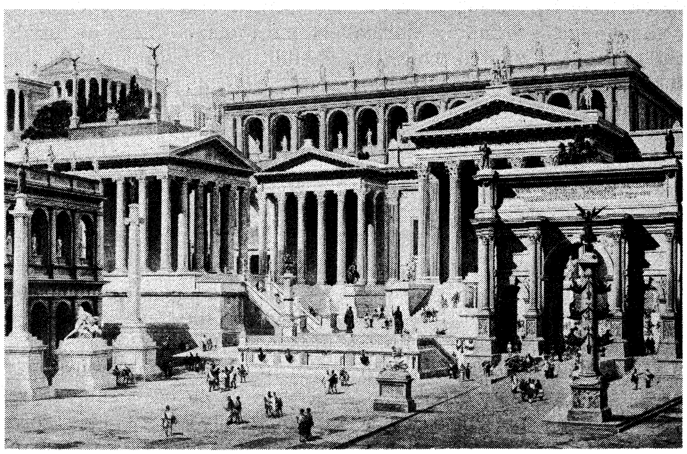
Word of the unhappy event reached Akō five days later. Asano's retainers, headed by Oishi Yoshio (1659–1703), at once met to determine their future actions. Some favoured resisting if the castle had to be yielded; others swore an oath to disembowel themselves before the castle gate; but Oishi counseled caution, and his view prevailed. The castle was surrendered on May 26.

For over a year Oishi and other retainers lived in apparent retirement. Ōishi passed much time in the gay quarters of Kyōto, leading so dissolute a life that Kira's spies were convinced that he entertained no thought of revenge. In the autumn of 1702 Ōishi decided to strike. He and the 46 other *rōnin,* including his son, gathered in Edo. On the night of Jan. 30, 1703, they attacked Kira's mansion, forced their way in and killed their hated adversary. That night they offered up his head at Asano's grave. When the shogun learned of the vendetta he was sympathetically disposed to Ōishi, but finally decided that the 47 *rōnin* could not be allowed to take the law into their own hands. They were accordingly ordered to disembowel themselves on March 20, 1703.

The incident created an immense stir in Japan. The samurai virtues, seemingly forgotten during long years of peace, asserted themselves again. Innumerable poems and essays described the vendetta, and by 1844 no fewer than 47 plays had been written about the *rōnin.* Of these the greatest was *Chūshingura* (1748), in 11 acts, by Takeda Izumo (1691–1756) and others, a work whose popularity has never flagged.

See Sakae Shioya, *Chûshingura: an Exposition* (1940); Jukichi Inouye, *Chushingura,* rev. ed. (1937). (Dᴅ. K.)

FORUM, an open place used, like the Greek agora (*q.v.*), for the transaction of mercantile, judicial or political business. It was level, rectangular in form, surrounded by porticoes, basilicas, courts of law and other public buildings. In the laws of the Twelve Tables the word is used of the vestibule of a tomb; in a Roman camp the forum was an open place immediately beside the *praetorium;* and the term was no doubt originally applied generally to the space in front of any public building or gateway. In



CULVER SERVICE

RESTORATION OF THE FORUM ROMANUM

Rome (*q.v.*) itself forum was almost a proper name, denoting the flat and formerly marshy space between the Palatine and Capitoline hills (also called Forum Romanum), which even during the regal period afforded the accommodation necessary for such public meetings as could not be held within the area Capitolina. In early times the Forum Romanum was used for athletic games, and over the porticoes were galleries for spectators; there were also shops of various kinds. But with the growth of the city, more than one forum became necessary, and under the empire a considerable number of *civilia* (judicial) and *venalia* (mercantile) forums came into existence. In addition to the Forum Romanum, the forums of Caesar and Augustus belonged to the former class; the forum *boarium* (cattle), *holitorium* (vegetable), etc., to the latter. The forum Nerva (also called *transitorium* or *pervium* because a road led through it to the Forum Romanum) and those of Trajan and Vespasian, although intended to facilitate the course of public business, were chiefly erected to embellish the city. In Pompeii, at the northeast end of the forum, there was a *macellum* (market) and shops for provisions, and on the east side a cloth-workers' exchange; at Timgad in north Africa (a military colony founded under Trajan) the whole of the south side of the forum was occupied by shops. The forum was paved, and although on festal occasions chariots were driven through, it was not a thoroughfare and was enclosed by gates at the entrances, of which traces have been found at Pompeii. The word forum frequently appears in the names of Roman market towns; as, for example, in Forum Appii, Forum Iulii (Fréjus), Forum Livii (Forli), Forum Sempronii (Fossombrone). These were distinguished from mere *vici* by the possession of a municipal organization, which, however, was less complete than that of a prefecture. In legal phraseology the word is practically equivalent to "court" or "jurisdiction."

FOSCARI, FRANCESCO (1373–1457), doge of Venice, belonged to a noble Venetian family, and held many of the highest offices of the republic—ambassador, president of the Forty, member of the Council of Ten, inquisitor, procurator of St. Mark, *avvogadore di comun,* etc. His first wife was Maria Priuli and his second Maria Nani; of his many children all save one son (Jacopo) died young. He was elected doge in 1423, and reigned for 34 years. In proclaiming the new doge the customary formula which recognized the people's share in the appointment and asked for their approval—the last vestige of popular government—was finally dropped. Through the doge's influence Venice joined the Florentines in their campaign against Milan, which was carried on with varying success for eight years. In 1444 began the domestic tragedy by which the name of Foscari has become famous. The doge's son Jacopo was accused of taking bribes. He escaped, but was tried in contumacy before the Council of Ten and banished to Treviso (1446). Four years later Ermolao Donato, who had been a member of the Ten at the time of the trial, was assassinated, and Jacopo Foscari was suspected of complicity in the deed. After a long inquiry he was brought to trial for a second time, and was banished to Candia for the rest of his life, with a pension of 200 ducats a year. In 1456 he was accused of treasonable correspondence with the duke of Milan and the sultan of Turkey. He was tried and condemned to a year's imprisonment, to be followed by a return to his place of exile. Jacopo died at Candia, in Jan. 1457. The doge was overwhelmed with grief at this bereavement and, incapable of attending to business, he was finally compelled to abdicate. and died two days later (Nov. 1, 1457).

FOSCOLO, UGO (originally Nɪᴄᴄᴏʟò) (1778–1827), Italian poet and novelist who expressed the aspirations of his compatriots during the French Revolutionary and Napoleonic wars and under the Restoration in some of the most perfect works of the national literature, was born of a Venetian father and a Greek mother on the Ionian island of Zante (Zakynthos) on Feb. 6 (Jan. 26 in the Greek calendar), 1778. He went to Venice about 1793, frequented the literary circles of the countess Isabella Teotochi-Albrizzi, Ippolito Pindemonte and Melchiorre Cesarotti and became famous in 1797 with his tragedy *Tieste.* His early enthusiasm for Napoleon, proclaimed in his ode *A Bonaparte liberatore* on the overthrow of the Venetian oligarchy in 1797, was followed by bitter resentment when the French ceded Venice to Austria under the treaty of Campoformio, and his novel *Le ultime lettere di Jacopo Ortis* (1798) contains a courageous denunciation of the transaction. However, when the Austrians and the Russians invaded Italy in 1799, Foscolo, with other Italian patriots, fought bravely on the French side; and after the battle of Marengo he became a captain in an Italian division of the French army.

After several commissions in Milan, Bologna and Florence and a brilliant. rather dissipated life which involved him in many love affairs (his love for Isabella Roncioni is expressed in a revised edition of *Ortis),* Foscolo in 1804 was sent to France. In the long vigil on the Channel coast with the French army expecting to invade England, he found time to translate Laurence Sterne's *Sentimental Journey.* The news of the battle of Trafalgar moved him to include open praise of Nelson in his poetical masterpiece *I sepolcri,* which was published in 1807. Returning to Italy in 1807, Foscolo became professor of Italian rhetoric at Pavia in 1808, but the chair was abolished before the end of that year and he went to Milan. Satirical references to Napoleon in his tragedy *Ajace* (1811; first printed 1828) brought suspicion on him there, and in 1812 he moved to Florence. There he composed another tragedy, *Ricciarda* (1813; printed 1820), and most of his great unfinished poem. *Le Grazie,* fragments of which he had already published in 1803. He returned to Milan in Nov. 1813.

After the fall of Napoleon, Foscolo refused to serve the Austrians and went into exile! going first to Switzerland and then, in 1816, to England. As an Italian patriot he was greeted with sympathy by the liberal circles in London and was for some time a frequent guest of Lord Holland; but Foscolo's difficult character and extravagant life gradually estranged most of his English friends. He tried to support himself by giving lessons and contributing to periodicals. including the *Edinburgh Review* and the *Quarterly Review,* in which he published some valuable essays on Italian literature; but his last years were spent in great poverty. He died at Turnham Green on Sept. 10, 1827. His remains were transferred to Florence in 1871 and buried in the Santa Croce church, close to the tombs of the great men whom he had sung.

If one does not count the numerous juvenile poems which he later repudiated, Foscolo's poetical output mas not large: 12 sonnets. 2 odes and 2 longer poems. These 16 poems, however, are among the masterpieces of Italian literature. The sonnets are the best in Italy since Tasso's and convey admirably the tumultuous feelings of the young lover, the soldier who despairs of his country, the exile longing for his distant home. The odes, "A Luigia Pallavicini" (1802) and "All' amica risanata" (1803) are colder in style. with a beauty of a neoclassic kind; both develop the idea that beauty is the only comfort granted by the gods to unhappy mortals; and both (the later one more felicitously than the earlier) exalt a woman with the attributions of a pagan goddess.

Foscolo's masterpiece, *I sepolcri,* begins with the supposition that Napoleon had forbidden inscriptions on tombs and so had violated one of the dearest illusions of mankind. 'The tombs of great men are an inspiration to the living; Florence is blessed because it keeps in Santa Croce the remains of Michelangelo, Machiavelli and Galileo; the dead heroes of Marathon revisit the battlefield; and from the tombs of the Trojan kings Homer derived power to sing their glory. With such themes the poet summons contemporary Italians to be worthy of their national heritage, and the poem is clearly patriotic. It helped to inspire the *Risorgimento* and is still very popular in Italy. Its sources include not only the Greek tradition (especially Homer and Pindar) but also the work of the English poets Edward Young, James Hervey and Thomas Gray.

Foscolo's second long poem, *Le Grazie* (fragments 1803 and 1818; 1822), partly mythological, partly biographical, has passages of surpassing beauty and is unparalleled in its formal perfection but has never attained the popularity of *I sepolcri.* His tragedies have little merit.

On the other hand *Le ultime letteve di Jacopo Ortis* has pleased generations of Italian readers. In this youthful novel the Venetian Ortis, who in some respects closely resembles Goethe's Werther, finally kills himself after recounting to a friend, in a series of letters full of patriotic eloquence and tragic pathos, the story of his decline from hope to despair as his country is sold by a tyrant and his beloved married to another man.

BIBLIOGRAPHY.—For the complete works of Foscolo *see* the edition by F. S. Orlandini and E. Mayer, 11 vol. (1850–62), with 1 vol. appendix (1890), and the "national edition" (1933–). The best English translation of *I sepolcri* is *The Sepulchres* by S. C. (?Sinclair Cullen; c. 1820). For biography *see* G. Chiarini, *La vita di Ugo Foscolo* (1927); D. Bulferetti, *Foscolo* (1952); also E. R. P. Vincent, *Ugo Foscolo* (1953). *See* also A. Ottolini, *Bibliografia foscoliana* (1921); G. Citanna, *La poesia di Ugo Foscolo* (1920); M. Fubini, *Ugo Foscolo, saggio critico* (1931). (F. DI.)

FOSSANO, a town and episcopal see of Piemonte. Italy, province of Cuneo, 1j mi. N.E. of the town of Cuneo by rail. 1,180 ft. above sea level. Pop. (1951) 11,017. It has an imposing castle with four toners, begun by Philip, prince of Achaea in 1314. The place appeared as a commune in 1237, but in 1251 it had to yield to Asti. It finally surrendered in 1314 to Philip, who brought it under the house of Savoy. Fossano lies on the main railroad line from Turin to Cuneo and has a branch line to Mondovi.

FOSSANUOVA, an abbey of Italy, province of Rome, near the railway station of Sonnino, 64 mi. S.E of Rome. It is the finest example of a Cistercian abbey. and of the Burgundian Early Gothic style, in Italy. The church (1187–1208) is similar to that of Casamari. The other conventual buildings also are noteworthy. St. Thomas Aquinas died there in 1274.

FOSSE (Foss) **WAY,** the early English name of a Roman road or series of roads in Britain used later by the English running from Lincoln (Roman Lindum) via Leicester (Ratae Coritanorum) and Bath (Aquae Sulis) to Exeter (Isca Damnoniorum). Almost all the Roman line is still in use as modern road. It passes from Lincoln through Newark and Leicester to High Cross (Venonae). where it intersects Watling Street (*q.v.*) at a point often called the "centre of England." Hence it runs to Moreton-in-Marsh, Cirencester, Bath and Ilchester, crosses the hills near Chard, Axminster and Honiton and enters Exeter.

See BRITAIN.

FOSSIL. The term fossil comes from the Latin word *fodere,* literally "to dig." In its early usage the word fossil referred to any curious object that was dug out of the earth, whether organic or not. Since about the middle of the 16th century it has been applied. for the most part, specifically to objects of the past geologic ages that provide evidence of organisms. Actual remains of organisms, remains replaced by minerals, casts, molds. impressions, such as those of leaves, skin and feathers, and tracks and trails, fall under the category of objects classed as fossils. Coal, petroleum, some limestones and some deposits of graphite have organic origin and thus give evidence of ancient life. Technically, they might be called fossils, but generally such deposits are excluded from the definition.

This article deals with the nature of fossils, including a brief history of concepts of fossils; the preservation of the fossil record, including hon remains are preserved; what fossils tell about evolution. hon they serve as a basis of stratigraphy and their economic importance; and major collections and exhibitions of fossils and the role of amateur collectors. Additional information on the subject will be found in the separate articles on the major orders and families of plants and animals, as EQUIDAE; on extinct plants and animals. as DINOSAURIA; and on the geologic systems and eras, as CAMBRIAN SYSTEM. *See* also EVOLUTION, ORGANIC; GEOLOGY; MAN, EVOLUTION OF; PALAEOBOTANY; PALAEONTOLOGY.

THE NATURE OF FOSSILS

Fossils appear to have attracted the attention of man even prior to the beginning of written history. Throughout the known history of man they have been the subject of innumerable speculations and have been given various shades of supernatural interpretation. Even in the pre-Christian era, however. their essential nature was recognized by some of the Greek scholars. In early writings there are hints of the present-day concept that fossils represent a record of an orderly evolution of life through the past ages. The modern version of this concept began to take form prior to the publication of the *Origin of Species* by Darain in 1859, in the work of such men as Lamark, Linnaeus and Cuvier among biologists and William Smith among geologists. With the advent of the theory of organic evolution, fossils came to assume an increasingly important place in the interpretation of earth history and the changes that life has undergone during geologic ages. In the second half of the 19th century, fossils played two dominant roles as man strove to extend his knowledge for both theoretical and practical ends. They served as a historical guide in the interpretation of the course and meaning of life. and as an essential basis for determination of age equivalencies and the nature of deposition of many of the sedimentary rocks accumulated in ages long past.

The Fossil Record. — The record of life on earth extends back over 1,000,000,000 years. The early part of the record is vague and difficult to decipher, but for the last 500,000,000 years it is written with amazing clarity by abundant, varied and well-preserved organic remains. Both plants and animals contribute to the record. Only an extremely small part of the total of all life has been preserved, but it seems remarkable that even this infinitesimal fraction has come donn to the present in view of the vicissitudes of time to which it has been subjected.

Persistence of organic remains occurs only when the organism, some part of it or some impression that it has made. has maintained sufficient equilibrium nith the environment of the encompassing rock to insure that its identity is not totally obliterated. This condition is met most commonly in sedimentary rocks (*q.v.*). The diagenetic changes, or alterations of sediments after they have been deposited, involved in the development of metamorphic rocks and the heat and chemical activities of igneous rocks usually destroy organic remains that may have been incorporated within them.

Buried impressions, such as footprints, skin and leaf impressions, as well as impressions of hard structures, tend to persist unless the sediments in which they are buried are drastically altered. Preservation of the organisms themselves, however, is a somewhat different matter. With notable exceptions, only hard parts, skeletal parts in a very broad sense, tend to be preserved. Hard parts may persist in their original state, but in rocks of appreciable age some degree of mineralization is the rule. Thus fossil remains are often said to be petrified.

Mineralization may merely involve filling of the interstices of skeletal elements by minerals carried by water. There may, however, be partial or total replacement of the original skeletal material by other mineral matter. Sometimes this is a crude process that preserves only the general outline of the structure, but in many cases the introduced minerals reproduce the details of both external and internal structure with remarkable fidelity, even to the extent that cell structure may be determined. One of the best-known examples of this type of preservation is found in the silicified trees in petrified forests, such as the one in Arizona in the United States. A wide variety of mineral compounds act as agents of replacement, but by far the most common are calcium carbonate, calcium phosphate and silica.

Although hard parts generally are essential to preservation, there are notable and highly instructive exceptions in the record. These have given special insight into the structure and age ranges of some groups of organisms which otherwise would have been very poorly known. From the very recent past have come frozen carcasses of mammoths in Siberia and hair and dung of ground sloths from a cave in New Mexico. The fossil ambers of the Baltic region have preserved mid-Tertiary insects, perfect in every detail. Much more ancient are records of such soft-bodied animals as worms in the Cambrian Burgess shales of British Columbia. Such finds are spectacular, but extremely rare.

The degree to which different organisms are subject to preservation is highly varied. This introduces a strong bias into studies designed to probe into the past history of life on our earth. A second important bias is produced by the obvious fact that rocks which provide the medium of preservation must persist to the present time and be accessible for study. This bias is partially time-dependent, since increasing remoteness in time affords increasing chances of removal of rock by erosion and obliteration of fossils by diagenetic activities. In general, deposits formed along sea margins, either on land or in relatively shallow marine waters of continental shelves and broad epicontinental seas, are the most likely to be preserved and later made available for study. Erosive forces tend to be at a minimum in such regions and many have displayed structural stability over the ages so that these deposits have been neither seriously altered nor destroyed. However, even where belts of deposition have been folded into mountain ranges, remnants of the sediments may remain and include excellent records of life.

The great majority of accessible deposits of fossils of the Paleozoic era and the early and middle Mesozoic era were formed on deltas, in vast, shallow coal swamps, in shallow epicontinental seas and in linear, subsiding basins known as geosynclines. The last in particular have been subject to strong structural deformation to provide many of the great mountain ranges of present and past time. The record of marine life now many thousands of feet above sea level is commonplace in the sediments of such ranges.

Because of this localization of the types of deposits likely to persist, records of organisms that lived under other circumstances, in higher continental interiors or in open seas, are rare. Only since the late part of the Mesozoic era have upland continental deposits been well preserved, and the percentage of preservation increases sharply from the late Mesozoic to the present. Through this time, the Cenozoic era, animals and plants that lived in these circumstances provide an increasingly important part of the fossil record. Thus, the nature of organisms, their geographic and ecological distribution, types of rocks, sites of deposition and geological time all play important roles in determination of the completeness and validity of the fossil record of ancient life. While much can be known, some facets of ancient life must always be denied for direct study through fossil remains.

FOSSIL STUDY

The study of fossils is called paleontology, but under this general term are grouped various subdisciplines such as paleozoology, paleoecology, paleobotany and micropaleontology. Fields of interest of the majority of paleontologists fall into two general categories, one in which concern is primarily with geological problems, and the other in which the biological aspects of fossils are uppermost.

Geological Research. — The uses of fossils in the area of geological research include the ordering of strata in time series, temporal correlation of formations in different parts of the world and studies of the conditions of sedimentation during deposition of the rocks that contain fossils. Late in the 18th century William ("Strata") Smith observed, in the course of his work in sedimentary strata in England, that each bed of rock contained a characteristic suite of fossils and that beds in vertical succession showed sequences of characteristic fossils from the base to the top. From these observations stemmed the concepts of temporal correlation of rock formation by use of the fossils that they contained. For the first time authoritative geological maps became a possibility.

Index Fossils. — Extension of the basic idea led to the concept of the index fossil, a particular species or genus which has a wide geographic range and limited temporal range, and thus is diagnostic over a short span of geological time. Over half a century elapsed before the concept of diagnostic faunas could be cast into the framework of the theory of evolution. Even without this integrating theory, by which successions find logical explanation, stratigraphic studies dependent upon fossils and geological maps made great strides.

Commercial Importance. — As industrialization increased, petroleum and other mineral resources that occur in sedimentary rocks, for example, coal, limestone, lead and zinc, became of great economic importance. The study of stratigraphy assumed a major role in the search for these mineral deposits and the use of fossils provided an essential tool for solution of problems in the industrial nations. Remains of marine invertebrates have played the dominant role in these studies. Particularly important are the fossil remains of very small organisms such as foraminifera and ostracoda (*qq.v.*). The subfield of micropaleontology, which deals with these small animals, has taken on a major significance.

Evolution. — Vertebrate animals and plants have been less important in the development of practical stratigraphy, since they are less characteristic of the important marine strata. Both have been used in the solutions of particular problems and in nonmarine stratigraphy. For the most part, however, students of fossil plants and vertebrates have directed their efforts to studies more specifically biological in nature. In their biological role fossils have provided a factual record of the past life of the earth. Irrespective of the interpretation that may be put upon them, they serve to answer many questions about the characteristics of life in times long past. The earliest fossils date back over 1,000,000,000 years. They represent very primitive plants and animals such as algae and sponges. Then, in grand succession, appear the various more complex phyla of invertebrate animals, the vertebrates, fish, amphibians, reptiles, mammals and birds, and the arrays of plants that show the early invasion of land, development of great forests, such as those of the Carboniferous coal measures, and the development of ancestors of the present forests and grasslands.

Beyond a mere recording of facts fossils have stimulated the development of many theories and hypotheses relating to the course of life. Foremost among these is the theory of organic evolution. Fossils provide the critical opportunity to view the changes of life over long periods of time. In effect, they provide the fourth dimension in the study of organic evolution. Neither the organisms that live today nor the record of the past, known from fossils, alone can give an adequate understanding of evolution. Together, however, they provide the basis for one of the most significant concepts yet revealed by the studies of man: the concept of the continuity of life on our earth, and of the patterns and causes of changes that have produced the myriads of divers plants and animals that lived through past geologic ages and are seen alive in our own fleeting glimpse of the passage of time.

Collections.—Fossils occur under such a wide variety of circumstances throughout the world that sites for collection are available to the great majority of its peoples. Major collections have been brought together and displayed to portray historical aspects of the theory of evolution by large and small museums of natural history and by colleges and universities in many parts of the world. The most striking displays are those of large vertebrates, such as dinosaurs, but equally significant are exhibits of small vertebrates, plants and invertebrate animals. Outstanding large exhibits are to be found in New York, Chicago, Washington, D.C., and Pittsburgh in the United States, and in London, Paris and Moscow in Europe. Smaller but excellent exhibits are to be found in the museums of such universities as Harvard, Yale and the University of California, at Berkeley, in municipal and state museums in the United States, as well as equivalent museums throughout much of the world.

The study of fossils is an important profession, but, unlike many areas of scientific endeavour, it provides a rewarding avocation for amateur paleontologists. Opportunities for collection of fossils, for study of semitechnical and popular literature and for use of outstanding collections in museums are available to a vast segment of the populations of North America and Europe and to significant parts of the populations of other continents. Amateurs who have taken advantage of these opportunities have made many truly significant contributions to the total knowledge of life as gleaned from the fossil record. (E. C. O.)

FOSSIL PLANTS: *see* PALAEOBOTANY.

FOSSOMBRONI, VITTORIO, COUNT (1754–1844), Tuscan statesman and mathematician, was born at Arezzo. In 1796 he was made minister for foreign affairs, but on the French occupation of Tuscany in 1799 he fled to Sicily. On the erection of the grand duchy into the ephemeral kingdom of Etruria, under the queen regent, Maria Louisa, he was appointed president of the commission of finance. In 1809 he went to Paris as one of the senators for Tuscany to pay homage to Napoleon. He was president of the legislative commission on the restoration of the grand duke Ferdinand III in 1814, and was prime minister for 30 years until his death in 1844.

He was the real master of Tuscany, and the bases of his rule were equality of all subjects before the law, honest administration of justice and toleration of opinion.

FOSTER, SIR CLEMENT LE NEVE (1841–1904), an eminent English authority on mining and mining legislation, was born at Camberwell, London, on March 23, 1841. After preliminary schooling at Camberwell and Boulogne, France, he studied in turn in France, where he took a science degree, in England at the Royal School of Mines and in Germany at the mining school at Freiberg. He joined the Geological survey in 1860, but resigned in 1865 to become lecturer to the Miners' association of Cornwall and Devon. From 1868 to 1872 he was engaged in mining and exploration work abroad, and was then appointed inspector of mines under the new Metalliferous Mines Regulation act. In 1890 he became professor of mining at the Royal School of Mines. While investigating the cause of an underground fire at Snaefell, Isle of Man, in 1897, the cage jammed at the bottom of the shaft and he was subjected to slow carbon monoxide poisoning. Although rescued, he never fully recovered, and he resigned the inspectorship in 1901. Elected a fellow of the Royal society in 1892 and knighted in 1903, Sir Clement Foster died at Earl's Court, London, on April 19, 1904. (C. W. D.)

FOSTER, SIR GEORGE EULAS (1847–1931), Canadian statesman, was born in New Brunswick Sept. 3, 1847. Educated in New Brunswick, Edinburgh and Heidelberg, he took up teaching in Canada. In 1882 he entered the Canadian parliament as Conservative member for New Brunswick, and in 1885 became minister of marine and fisheries. From 1888–96 he was minister of finance. In the Borden administration of 1911 he was minister of trade and commerce, retaining the portfolio in the union government of 1917, in which year he was summoned to the senate. He was a great advocate of preferential trade within the empire, and in 1903 made a series of speeches in England in support of Chamberlain's policy. Sworn into the imperial privy council in 1916, he was in the same year appointed one of Great Britain's four representatives at the Economic Conference at Paris. In 1918 Foster was created knight commander of St. Michael and St. George, and he represented Canada at the Peace Conference, 1919, at the first assembly of the League of Nations in 1921, when he was elected a vice-president, and at the 7th and 9th assemblies, 1926 and 1929.

FOSTER, SIR MICHAEL (1836–1907), English physiologist, who had a very large share in the organization and development of the Cambridge biological school, was born at Huntingdon on March 8, 1836, the son of a surgeon. After a brilliant career at University college, London, he studied in Paris, and then taught physiology for two years at University college. In 1870 he was appointed by Trinity college, Cambridge, to its praelectorship in physiology, and 13 years later he became the first occupant of the newly created chair of physiology in the university, holding it until 1903. From 1881 to 1903 Foster was biological secretary of the Royal society. In 1899 he was created knight commander of the Bath and in 1900 was returned to parliament as a Unionist for London university. In 1906 he stood as a Liberal, and was defeated. His chief writings were a *Textbook of Physiology* (1876), which became a standard work, and *Lectures on the History of Physiology in the 16th, 17th and 18th Centuries* (1901), lectures delivered at the Cooper Medical college, San Francisco, in 1900. He died in London on Jan. 29, 1907.

FOSTER, STEPHEN COLLINS (1826–1864), American composer, was born July 4, 1826 at Pittsburgh, Pa. In 1852 he "concluded . . . to pursue the Ethiopian business without fear or shame" and "to establish my name as the best Ethiopian song writer." This he said to E. P. Christy, who, with Foster's consent. originally figured as author and composer of "The Old Folks at Home," and whose minstrel troupe helped to popularize Foster's songs in America and Europe, among persons of all classes and qualities alike.

He was born of prosperous middle-class parentage of mainly Scotch-Irish stock. With the exception of two years spent at Athens academy, some restless months at Jefferson college, and the period (1846–50) when he was employed as a bookkeeper in Cincinnati, he spent most of his life in Pittsburgh. In July 1860. he finally took up his residence in New York city, where his death. due to an accident, occurred on Jan. 13, 1864.

His musical inclinations appeared at the age of six. His first recorded attempt at composition ("Tioga Waltz" for an ensemble of flutes!) occurred about 1840. More promising was the sentimental song "Open Thy Lattice, Love" (1842). Significantly enough, he became the star performer of a boyish "Thespian Society" in Negro-minstrel jingles (in trade jargon called Ethiopian), but Pittsburgh with its meagre fare of better music was sterile soil for higher creative attainments, especially since Foster, though enjoying great music never felt stirred to serious study of composition. Nor did his father, who in 1841 commented on Stephen's "strange talent" and "devotion to musick," ever comprehend that nature beckoned for its serious cultivation. Hence, Foster's technical equipment remained very slender, but it sufficed for his purposes and was supported by a keen ear for imperfections in first ideas.

Foster invented no new type of song, but with his occasionally magic gift for felicitous turns of melody or phrase, he outshone numerous competitors in his two chosen fields of simple song, then equally in vogue—the sentimentalized drawing-room "ballad" and the "Ethiopian" song. To the absurdities of the "Ethiopian" song he contributed freely, for example his once enormously popular "De Camptown Races" (1850), but the best of his Negroid songs contain something vitally distinctive. In them, to quote his competent biographer H. V. Milligan, "the Negro ceases to be a caricature and becomes a human being. . . . In this type of song, universal in the appeal of its naïve pathos, he has never had an equal. . . . This is not the Negro of 'Jump Jim Crow' and 'Zip Coon' but of Uncle Tom's Cabin."

By 1850 the popularity of his songs prompted Foster to derive a living from professional song writing. During the next four years his vogue spread with incredible rapidity, but also by then he had practically sung his song, though half of his 175 compositions, generally to his own words, were yet to come. They yielded substantial royalties, but after 1860 Foster apparently preferred to sell his songs outright for a few dollars. This trapped him into song-factory methods; for instance, almost all of his 40 odd compositions of 1863 are potboilers. Most of his songs merely humoured the market and became historically negligible. Among the exceptions, however, the following possess the power and function of imperishable American folk songs: "Uncle Ned" (1848), "Nelly Bly" (1849), "Swanee River" or "The Old Folks at Home" (1851), "Massa's in the Cold, Cold Ground" (1852), "My Old Kentucky Home" (1853), "Old Dog Tray" (1853) and "Old Black Joe" (1860). (O. G. So.)

FOSTER, WILLIAM Z. (1881–1961), U.S. Communist leader and presidential candidate in 1924, 1928 and 1932, was born at Taunton, Mass., on Feb. 25, 1881. He came to national attention as the American Federation of Labor leader in the 1919 steel strike. In 1921 the Russian Communists designated Foster's Trade Union Educational league, which he founded in 1920. as the U.S. branch of their Profintern (Red International of Labour Unions), thereby moving Foster into the U.S. Communist organization as a top leader. In 1932 he suffered a serious heart attack, and party leadership passed to Earl Browder. Foster disapproved of Browder's policies, especially during World War II, but did not assert his more extreme position until international Communist leadership indicated its dissatisfaction with Browder in 1945. Foster then became party chairman. In 1948 he was among the Communist leaders indicted under the Smith act, but because of his precarious health he was not brought to trial.

Foster's extreme position and control of the party were endangered in a conflict among Communists precipitated in 1956 by Soviet repudiation of Stalin and by Russian suppression of the Hungarian revolution. Foster, who steadfastly defended the Russian leadership, was made chairman emeritus, however, at the party's national convention in New York city in Feb. 1957. The Dec. 1959 convention retained him in that position. He died on Sept. 1, 1961, at Moscow.

See T. Draper, *The Roots of American Communism* (1957); D. A. Shannon, *The Decline of American Communism* (1959). (*D. A.* SN.)

FOTHERGILL, JOHN (1712–1780), English physician, was born on March 8, 1712, in Wensleydale, Yorkshire, of a Quaker family. He studied medicine at Edinburgh and later acquired a large practice in London. His "Account of the Sore Throat Attended With Ulcers" (1748), which contains his observations on a severe epidemic, probably of scarlatina, brought him into wide prominence. He was interested in botany and maintained a large botanical collection. He popularized the use of coffee and extended the use of cinchona bark. He died in London on Dec. 26, 1780.

FOTHERINGHAY, a parish in the Peterborough parliamentary division of Northamptonshire, Eng., picturesquely situated on the left bank of the river Nene, 4 mi. N.N.E. of Oundle. Pop. (1951) 199. The castle, of which nothing but the earthworks and foundations remain, is famous as the scene of the imprisonment of Mary, queen of Scots, from Sept. 25, 1586, to her trial and execution on Feb. 8, 1587. The earthworks, commanding a ford of the river, probably bore a castle from Norman times. It became an important stronghold of the Plantagenets from the time of Edward III, and was the birthplace of Richard III in 1452. The church of St. Mary and All Saints, originally collegiate, is Perpendicular; the nave with aisles, and the tower surmounted by an octagon, are in the best style of the period. Of the Plantagenets, Edward, and duke of York, who was killed at the battle of Agincourt in 1415, Richard, the 3rd duke, and his duchess. Cecily (d. 1495), as well as his son the earl of Rutland, who with Richard himself fell at the battle of Wakefield in 1460, are buried in the church. Their monuments were erected by Elizabeth I, who found the choir and tombs in ruins. The oak pulpit was given by Edward IV.

FOUCAULD. CHARLES EUGÈNE, VICOMTE DE (1858–1916), French soldier, explorer and ascetic, was born at Strasbourg on Sept. 15, 1858. After military training he led a dissolute life as an officer in Algeria until in 1882 he left the army and explored Morocco, then forbidden to Christians, disguised as a Jewish rabbi. His *Reconnaissance au Maroc* (1888) describes his discoveries there. In 1886 he was converted, and decided to devote his life to God. After visiting Palestine he became a Trappist monk in 1890 at Notre Dame des Neiges in the Cevennes and then in Syria. He left the order in 1897 to become a hermit, living first in Palestine as a convent servant, then. after ordination in France to the priesthood (1901), returning to Algeria. He spent several years at Beni Abbès before settling at Tamanrasset, in the Hoggar mountains. There he learned the Tuareg language, for which he wrote a grammar and a dictionary, and became endeared to the people. It was largely because of him that the Tuareg remained loyal to the French when the Senussi (*q.v.*) in Tripoli were inciting them to rebel. He was a valuable source of intelligence to the French authorities until he was assassinated by the Senussi on Dec. 1, 1916.

The process for his beatification was initiated in 1927.

See *Les écrits spirituels de C. de Foucauld*, ed. by R. Bazin (1923; Eng. trans. by C. Balfour, *Meditations of a Hermit*, 1930). R. Bazin, *C. de Foucauld* (1921; Eng. trans. by P. Keelan, 1923); A. Fremantle, *Desert Calling* (1949).

FOUCAULT, (JEAN BERNARD) LÉON (1819–1868), French physicist, best known for his experimental work in light and motion. He was the son of a publisher at Paris, where he was born on Sept. 18, 1819. After studying medicine he became interested in experimental physics. With A. H. L. Fizeau (*q.v.*) he carried on a series of investigations in light and heat. By the use of a revolving mirror, he was able in 1850 to establish that the velocity of light in different media varies inversely as the refractive indices of the media, and later to measure the velocity of light in air.

For his demonstration in 1851 of the diurnal motion of the earth by the rotation of the plane of oscillation of a freely suspended, long, heavy pendulum (later called the "Foucault pendulum"), and for his invention of the gyroscope, he received the Copley medal of the Royal society in 1855, and in the same year he was made physical assistant in the imperial observatory at Paris. He discovered the existence of eddy or "Foucault currents" induced in a copper disk moving in a strong magnetic field.

Foucault invented the polarizer which bears his name, and devised a method of giving to the speculum of reflecting telescopes the form of a spheroid or a paraboloid of revolution. He also introduced improvements in the electric arc.

Foucault received many honours during his life; he died of paralysis on Feb. 11, 1868, at Paris. From the year 1845 he edited the scientific portion of the *Journal des Débats.*

FOUCHE, JOSEPH, DUKE OF OTRANTO (1759–1820), French statesman, was born near Nantes on May 21, 1759. He was educated by the Oratorians at Nantes, and in Paris, and afterwards taught in various schools. At Arras he had some dealings with Robespierre in 1789.

In Oct. 1790 he was transferred by the Oratorians to their college at Nantes, where he became a leading member of the local Jacobin club; and on the dissolution of the college in May 1792, Fouché gave up all connection with the church, whose major vows he had not taken. In Aug. 1792 he was elected as deputy for the department of the Lower Loire to the National Convention. His sympathy with the Girondists soon gave way to an enthusiasm for the more violent doctrines of the Jacobins. After some preliminary hesitations, he demanded the immediate execution of Louis XVI. and denounced those who "wavered before the shadow of a king."

The crisis which resulted from the declaration of war by the

Convention against England and Holland (Feb. 1, 1793), and a little later against Spain, brought Fouché into notoriety as one of the fiercest of the Jacobins. The Convention deputed Fouché with a colleague, Villers, to proceed to the west as commissioners for the crushing of the revolt of "the whites" in La Vendée. He soon held the post of commissioner of the republic in the department of the Nikvre. With Chaumette, he helped to initiate the atheistical movement, which in the autumn of 1793 aimed at the extinction of Christianity in France. In the Nièvre he ransacked the churches, sent their spoils to the treasury and established the cult of the goddess of Reason.

Fouche then proceeded to Lyons with Collot d' Herbois (*q.v.*) to execute the vengeance of the Convention on that city, which had revolted against the Jacobins. Toward the end of the Lyons terror Fouché exercised a moderating influence, though outwardly his conduct was marked by the utmost rigpur. By that time Robespierre had struck down the other leaders of the atheistical party; but early in June 1794, at the time of the "Festival of the Supreme Being," Fouché ventured to mock at the theistic revival which Robespierre then inaugurated, and Robespierre procured his ejection from the Jacobin club (July 14, 1794). Fouché, however, was working with his customary skill and energy, and with Tallien and others, effected the overthrow of Robespierre on Thermidor 10 (July 28), 1794. In the intrigues which followed, a vigorous attack on him by Boissy d'Anglas, on Aug. 9, 1795, caused his arrest, but he was released by the amnesty which was passed on the proclamation of the new constitution of 1795.

Under the Directory (1795–1799), Fouché established contact with the communists, once headed by Chaumette and now by François N. ("Gracchus") Babeuf (*q.v.*); whether he betrayed to the director Barras the secret of the Babeuf plot of 1796 is uncertain. In 1797 he gained an appointment for the supply of military *matériel.* After offering his services to the royalists, whose movement was then gathering force, he again decided to support the Jacobins and the director Barras. In the *coup* d'ktat of Fructidor 1797 he made himself useful to Barras, who in 1798 appointed him to be French ambassador to the Cisalpine republic. At Milan he carried matters with so high a hand that he was removed. Early in 1799 he returned to Paris, and after serving as ambassador at The Hague, he became minister of police at Paris (July 20, 1799). The newly elected director, Sieyès (*q.v.*), desired to repress the Jacobins, who had recently reopened their club. Fouché closed the Jacobin club and hunted down the pamphleteers and editors, whether Jacobins or royalists, who were obnoxious to the government, so that at the time of the return of Bonaparte from Egypt (October 1799) the ex-Jacobin was one of the most powerful men in France.

Fouché now lent himself to the schemes of Bonaparte and Sieyès for their overthrow of the directors, and furthered the coup *d'état* of Brumaire 18–19 (Nov. 9–10), 1799. During the Consulate (1799–1804) Fouché was careful to temper as far as possible the arbitrary actions of Bonaparte. In this difficult task he acquitted himself with so much skill as to earn at times the gratitude even of the royalists, and he tried to save the Jacobins from the vengeance of the First. Consul, especially in the "Plot of the Placards" in the spring of 1802. In any case Bonaparte resolved to rid himself of a subordinate who had too much power and skill in intrigue. On the proclamation of Bonaparte as First Consul for life (Aug. 1, 1802) Fouché was deprived of his office; the ministry of police was suppressed, and most of its duties handed over to an extended ministry of justice. Fouché became a senator, and received half of the reserve funds of the police which had accumulated during his tenure of office. The information gained by his spies was so valuable to Napoleon at the time of the Cadoudal-Pichegru conspiracy (February–March 1804), that he now brought back Fouché to the re-constituted ministry of police (July 1804). Fouché later on became minister of the interior. His police agents were ubiquitous, and the terror which Napoleon and Fouché inspired, partly accounts for the absence of conspiracies after 1804. After Austerlitz (Dec. 1805) Fouché uttered the mot of the occasion: "Sire, Austerlitz has shattered the old aristocracy; the boulevard St. Germain no longer conspires."

While engaged in the campaign of Spain, the emperor heard rumours that Fouché and Talleyrand, once bitter enemies, were having interviews at Paris in which Murat, king of Naples, was concerned. Napoleon hurried to Paris, but found nothing to incriminate Fouché, who now became duke of Otranto. During the absence of Napoleon in Austria in the campaign of 1809, the British Walcheren expedition threatened for a time the safety of Antwerp. Fouché thereupon issued an order to the prefects of the northern departments of the empire for the mobilization of 60,000 National Guards, in which he gave offence by the words: "Let us prove to Europe that although the genius of Napoleon can throw lustre on France, his presence is not necessary to enable us to repulse the enemy." The next months brought further causes of friction between emperor and minister. Napoleon found that Fouché had forestalled him in making overtures for peace to the British ministry in 1809. Fouché was dismissed (June 3, 1810), but was made governor of Rome. Hearing of the emperor's anger at his refusal to give up certain documents of his former ministry, he prepared, soon after his arrival at Florence, to sail for the United States. But he found a mediator in Elisa Bonaparte, grand duchess of Tuscany, and was allowed to settle at Aix and finally to return to his domain at Point Carré. In 1812 he sought vainly to dissuade Napoleon from invading Russia; and on the return of the emperor to Paris at the close of that year, Fouché was suspected of complicity in the conspiracy of General Malet. From this suspicion he cleared himself and Napoleon sent him to administer the Illyrian provinces. On the break-up of the Napoleonic system in Oct. 1813 Fouché was ordered to Naples, to watch the movements of Murat. Before he arrived at Naples Murat threw off the mask and invaded Roman territory. Fouché returned to Paris on April 10, 1814, when Napoleon was being constrained by his marshals to abdicate.

At this crisis Fouché tried to gain favour with the new régime without compromising himself too deeply. When he found that there were no hopes of advancement, he entered into relations with Lafayette and Davout. Shortly before the return of Napoleon to Paris (March 19, 1815) Louis XVIII. offered Fouché the ministry of police, which he declined, saying, "It is too late; the only plan to adopt is to retreat." On the arrival of Napoleon he received for the third time the portfolio of police. Nevertheless he entered into secret relations with Metternich at Vienna, his aim being, as always, to prepare for all eventualities. Meanwhile he used all his powers to induce the emperor to popularise his rule, and is said to have caused the insertion of the words "The sovereignty resides in the people; it is the source of power" in the declaration of the council of state. On June 22 Napoleon abdicated for the second time, and Fouché was elected president of the commission which provisionally governed France. Already he was in touch with Louis XVIII., then at Ghent. While ostensibly working for the recognition of the duc de Reichstadt, he facilitated the success of the Bourbon cause. But he could not conciliate royalists who remembered his vote as regicide and his terrorist record. He resigned office, and after acting for a time as ambassador at Dresden, he retired to Prague. Finally he settled at Trieste, where he died on Dec. 25, 1820. He had accumulated great wealth.

In Fouché the enthusiasm of the revolutionary period appeared as a cold, selfish and remorseless fanaticism; in him the bureaucracy of the period 1795–1799 and the autocracy of Napoleon found their ablest instrument. Yet he was never a mere tool He multiplied the means of resistance even to Napoleon, so that though removed from office, he was never wholly disgraced. While appearing to be the servant of the victors, present or prospective, he never gave himself to any one party. In this versatility he resembles Talleyrand, of whom he was a coarse replica. Both professed, under all their shifts and turns, to be desirous of serving France. Talleyrand certainly did so in the sphere of diplomacy; Fouché may occasionally have done so in the sphere of intrigue.

BIBLIOGRAPHY.—Fouché wrote some political pamphlets and reports, the chief of which are *Réflexions sur le jugement de Louis Capet* (1793); *Réflexions sur l'éducation publique* (1793); *Rapport et projet de loi relatif aux collèges* (1793); *Rapport sur la situation de Commune-Affranchie* [Lyons] (1794); *Lettre aux préfets concernant les*

prêtres, etc. (1801); also the letters of 1815 noted above, and a *Lettre au duc de Wellington* (1817). The best life of Fouché is that by L. Madelin, *Fouché,* 2 vol. (1901). The so-called *Fouché Memoirs* are not genuine, but they were apparently compiled, at least in part, from notes written by Fouché, and are often valuable, though their account of the negotiations of 1809–1810 is untrustworthy. For those negotiations *see* Coquelle, *Napoléon et l'Angleterre* (1903; Eng. trans., 1904).

FOUGÈRES, town of northwestern France. capital of an arrondissement in the *département* of Ille-et-Vilaine, 30 mi. N.E. of Rennes by rail. Pop. (1954) 22,111. Fougitres frequently figurts in Breton history from the 11th to the 15th century. It was taken by the English in 1166, and again in 1448. In 1488 it was taken by the troops of Charles VIII. In the middle ages Fougères was a lordship of some importance, which in the 13th century passed into the possession of the family of Lusignan, and in 1307 was confiscated by the crown and afterwards changed hands many times. In 1793, during the wars of the Vendée, it was occupied by the insurgents. It was formerly on the frontier towards Normandy, and, of its mediaeval fortifications, the 15th century Porte St. Sulpice still exists. The castle, situated in the lower part of the town, overlooking the Nançon, is now in ruins, but its ruined towers and outworks give evidence of its strength. The finest of the towers was erected in 1242 by Hugues of Lusignan, and named after Mélusine, the mythical foundress of the family. The churches of St. Léonard and St. Sulpice both date, partly at least, from the 15th century. An hôtel de ville and a belfry, both of the 1jth century, are of architectural interest, and the town possesses many curious old houses. Fougitres is the seat of a subprefect, and has a tribunal of first instance, a chamber of commerce. It manufactures boots and shoes; tanning and leather-dressing and the manufacture of sail-cloth and other fabrics are also important. Trade is in butter and salted goods and in the granite of the neighbouring quarries.

FOULARD. A light silk fabric, having a distinctive soft finish and of the plain or simple twill weave. It is said to come originally from the Far East. In French, the word "foulard" signifies a silk handkerchief. The fabric is figured with a pattern printed in various colours, and used for dress material, handkerchiefs, scarves and neckties. Fine cotton textures of good quality and produced from yarn spun from superior grades of cotton (as Egyptian and Sea Islands), are also sold as "foulard." Cotton foulard, which is usually of the plain calico or simple twill weave, is mercerized, and printed with patterns in styles and colourings similar to those of silk foulard, and employed for similar purposes.

FOULD, ACHILLE (1800–1867), French banker and politician, was born in Paris on Nov. 17, 1800. He belonged to a Jewish family of bankers, and as minister of finance under Louis Napoleon (as president and as Napoleon III.), from 1849 to 1852, and again from 1861 to 1867, carried out important financial and administrative reforms.

During his last tenure of office. he reduced the floating debt, which the Mexican a ar had considerably increased. by the negotiation of a loan of 300,000,000 francs (1863). Fould had a taste for the fine arts. and during his youth he visited Italy and the eastern coasts of the Mediterranean. In 1857 he was made a member of the Academy of Fine Arts. He died at Tarbes, Fr., on Oct. 5, 1867.

FOULIS, ANDREW (1712–1775) and **ROBERT** (1707–1776), Scottish printers and publishers, were the sons of a Glasgow maltman. Robert was apprenticed to a barber; but his ability attracted the attention of Dr. Francis Hutcheson, who strongly recommended him to establish a printing press. He started business in 1741 in Glasgow, and in 1743 was appointed printer to the university. In this same year he brought out Demetrius Phalereus de elocutione, in Greek and Latin, the first Greek book ever printed in Glasgow; and this was followed in 1774 by the famous 12mo edition of Horace which was long believed to be immaculate: though the successive sheets were exposed in the university and a reward offered for the discovery of any inaccuracy, six errors at least, according to T. F. Dibdin, escaped detection. Soon afterwards Robert went into partnership with Andrew, who had been educated far the church, and they continued for about thirty years to issue carefully corrected and beautifully printed editions of classical works in Latin, Greek, English, French and Italian. They printed more than five hundred separate publications, among them the small editions of Cicero, Tacitus, Cornelius Nepos, Virgil, Tibullus and Propertius, Lucretius and Juvenal; a beautiful edition of the Greek Testament, in small 4to; Homer (4 vols. fol., 1756–58); Herodotus, Greek and Latin (g vols. 12mo, 1761); Xenophon, Greek and Latin (12 vols. 12mo, 1762–67); Gray's poems; Pope's works; Milton's poems. The Homer, for which Flaxman's designs were executed, is perhaps the most famous production of the Foulis press. The brothers spared no pains, and Robert went to France to procure manuscripts of the classics, and to engage a skilled engraver and a copper-plate printer. Unfortunately it became their ambition to establish an institution for the encouragement of the fine arts. Their countrymen were not ripe for such an attempt, and the "Academy" involved the projectors in ruin. Andrew died on Sept. 18, 1775, and Robert on June 2, 1776. Robert was the author of a Catalogue of Paintings with *Critical* Remarks. The business was afterwards carried on under the same name by Robert's son Andrew.

See W. J. Duncan, *Notices and Documents illustrative* of *the Literary History of Glasgow,* printed for the Maitland Club (1831), which *inter alia* contains *a* catalogue of the works printed at the Foulis press, and another of the pictures, statues and busts in plaster of Paris produced at the "Academy" in the University of Glasgow. *See* also J. Ferguson, *The Brothers Foulis and early Glasgow Printing* (1889); D. Murray, *Robert and Andrew Foulis and the Glasgow Press* (Glasgow, 1913); *Letters of Robert Foulis* (Glasgow, 1917).

FOUNDATIONS, as referred to building and construction, is appropriately applied to all those portions of the structure below the footings of walls, piers and columns. Foundations are designed to transmit the weight of the superstructure to that portion of the earth's surface on which it rests and which may be called the foundation bed. Foundation beds vary in bearing capacity. All are compressible, hence the erection and loading of any superstructure is accompanied by settlement, though the amount for solid rock is negligible. The object of foundations is to transmit the entire load to the foundation bed at a safe pressure and with small and uniform settlement.

Foundation Beds.—Corresponding geological surface formations may show marked local variations, hence, though foundation beds may be scientifically classified, practical experience of a locality often decides the ultimate treatment.

Rock.—In some districts massive rock formations may occur near the surface, in others they may be exposed by excavation or otherwise reached. Massive rocks provide good foundation beds. Igneous rocks, dense limestones and sandstones can easily bear pressures of 15 tons per square foot, but on softer rocks the limit may be 8 tons. Many foundation beds are products of rock-disintegration; these include gravel, sand, clay, silt, etc.

Gravel.—Gravel consists of water-worn rock fragments varying much in size. Well-compacted gravel overlying a strong substratum, offers a dependable foundation bed which will support at least 4 tons per square foot.

Sand consists of fine rock particles, from $\frac{1}{4}$ in. downwards in diameter. Sand foundations need protection from running water, to prevent lateral escape. Confined sand may support from 2 to 4 tons per square foot.

Clay.—This term embraces cohesive soils, in which the characteristics vary with the composition. Pure clay contributes to plasticity, sand reduces it. Clay becomes plastic with moisture and changes in volume with plasticity; the moisture-content of clay should, therefore, be kept low and uniform; actual contact with water is to be avoided. Drainage of and diversion of water from the site are the usual precautions. Clay foundations need protection from seasonal variations of temperature and humidity; otherwise changes in volume may lead to structural fractures. Such foundations should be 3 to 4 ft. below ground. Bearing pressures on dry yellow clays are usually limited to 2 tons per square foot and on blue clays to 4 tons per square foot.

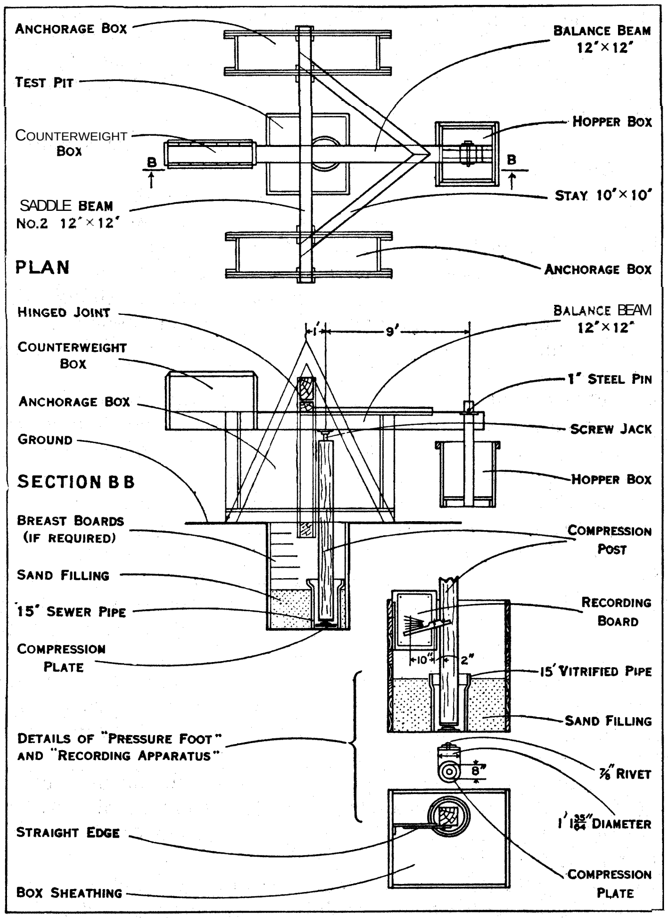
Made or Filled Ground; Silt.—Depressions and excavations are often filled artificially. "Filled" ground continues to consolidate over many years. Building over such ground requires excavation or penetration of the filling to a solid bed, and sites with a soft overlying bed may be similarly treated. On low-lying soft ground, buildings may be "floated" on "rafts," *i.e.*, timber or reinforced concrete slabs continuous over the site. Settlement is thus controlled and rendered uniform.

Other foundation beds may be mixtures of materials and will possess intermediate characteristics.

Protection of Foundation Beds.—Lateral support and protection are often required. Friable earths crumble on upright faces and soft rocks disintegrate. These may be protected by retention walls. Underlying streams of water should be enclosed in a culvert. Where "ground water" is freely rising and falling basements should be constructed as watertight tanks to resist external hydrostatic pressure and prevent the incursion of water.

Bearing Capacity.—Before planning the foundations of an important building an investigation of the site is usually necessary; experience of adjacent sites will assist the investigation If examination of the underlying strata is found necessary a trial pit would be sunk, or "boring" adopted, and samples of the strata raised to the surface and examined.

Allowable bearing capacities for foundation beds in any one locality are often scheduled as in the London Steel Framed Build-



FROM HOOLE AND KINNE, "FOUNDATIONS" (MCGRAW-HILL)

FIG. 1.—LOAD-TESTING APPARATUS FOR FOUNDATION SOILS

ings Act of 1909. Many American building codes include similar schedules. In doubtful cases experiments may have to be employed to determine the bearing capacity.

British regulations do not impose bearing tests, but the Building Code of New York City details a test to be conducted on a minimum area of 4 sq.ft. and after four days 50% more pressure than the proposed bearing capacity must not produce settlement. Fig. 1 shows the apparatus designed for this test by the American Society of Civil Engineers.

Loads Carried.—The constant load is the weight of the structure; its magnitude and distribution are readily determinable.

The movable load fluctuates with occupancy and use, with wind-pressure and snow, and varies from zero to a maximum value. It is difficult to estimate designing loads on foundations but usually when the movable load forms a substantial part of the possible foundation load, the foundations may be designed to carry about 60% of the sum of the loads for which the structural units have been designed This percentage is specified, with qualifications, for certain types of American buildings

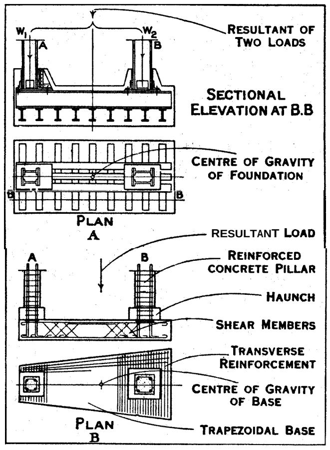


FIG 2—SPECIAL FOUNDATIONS

(A) Compound steel grillage foundation, parallel base; (B) Compound reinforced concrete foundation, trapezoidal base. These methods are applicable where projection beyond the external pillar (A) is strictly limited

Types of Foundations.—There are two general classes. (a) spread foundations, constructed near the surface and having a base area proportional to the load; and (b) deep foundations, excavated or driven to considerable depth, the horizontal area occupied having little relation to the load carried. Cement concrete (see CONCRETE) is used almost universally for foundations. It is strong and conforms to the inaccuracies of the foundation bed

Grillage Foundations.—Projections in foundation concrete may be reinforced with steel, the thickness being then reduced; or steel may be employed as the principal material. In the latter type, steel beams are used to form a "grillage" in two or more tiers. The load is transmitted through a steel or cast iron base to the tiers of the beams, which are bound together transversely by steel sections or by metal packings and bolts.

The foundation steelwork is bedded upon and encased in concrete.

Reinforced Concrete Foundations.—A foundation having the same function as the steel grillage is also shown in fig. 2. Reinforced concrete (*q.v.*) is employed.

Cantilevered Foundations.—When a large pillar occurs at a boundary adjoining an existing building. and an ordinary foundation is impossible, an external pillar is linked with an internal one by a heavy beam, having one end projecting as a cantilever. The outer foundation is well within the boundary. Load from the external pillar is transferred to the cantilever. which bears on the foundation and is balanced by the load on the internal pillar. The foundation is designed to exert uniform pressure on the bed when fully loaded.

In another method two pillars may have a common foundation. The base may be parallel or trapezoidal, and so arranged that the resultant of the two loads lies over the centre of gravity of the base. The trapezoidal base is more suitable for reinforced concrete construction.

Stepped Foundations.—Changes in foundation level should be made in small "steps" to avoid (a) the diagonal shearing of the foundation bed between levels; and (b) fracture at the vertical junction of the higher and lower sections. The concrete bed should be stepped and made continuous by vertical "ramps."

Deep Foundations— Extensive foundation beds, otherwise good, may reveal soft pockets, which can be bridged over by beams or arches. Foundations on soft strata or filled material may be supported on brick or concrete piers erected in deep excavations, on a firm bed. The piers are connected by arches or beams.

Pile Foundations.—A stout pillar of any material driven into the ground is known as a pile. It is generally more economical to use piles than piers, and they may be of round timber, or of square timber shod and banded with iron. Piles may be driven by mechanical devices worked either by man or steam Dower. Steam hammers for rapid driving, give light and quick blows, so reducing damage to the head of the pile. Piles are conveniently grouped to support concentrated loads as at bridge abutments, or under columns in a building. They may be driven until either (a) their points are embedded in a firm substratum (*bearing* piles), or (b) the friction on their sides is sufficient to provide resistance (friction piles). To distribute the load, timber frarnes or masses of concrete are laid on the piles.

Concrete Piles.—Concrete piles are mainly of two kinds, viz. (a) pre-cast and (b) cast in-situ. The former have vertical steel bars, bent in at the point, hooped transversely and diagonally and enveloped in concrete. Reinforcement adds to the compressional strength and provides resistance to end blows and to possible side bending when driving. The points are shod with steel or cast iron. Modern rapid-hardening cement permits of moulding and driving in a few days. The "cast in-situ" piles have marked advantages over those pre-cast; space for moulding 'is not required, work is rapid and piles can be loaded soon after driving. This type may be classified into (a) systems in which a tapered tube is driven, withdrawn, and the space filled with concrete, or in which a mandrel and sheath are driven, the mandrel being withdrawn and the sheath left and filled with concrete; (b) systems in which a parallel tube, shod with solid metal, is driven, the tube being gradually withdrawn and concrete poured to fill the hole and enclosing a frame of reinforcement if desired; (cj systems designed for enlarged bases to increase the load .capacity; and (d) systems in which tubes are sunk into the ground, the earth withdrawn from the inside, and the tubes filled with concrete. In one patent form, the tube employed is vibrated on withdrawal to assist the consolidation of the concrete.

The supporting power of piles is a difficult and controversial subject and cannot be included here.

Special Foundations.— Exceptional forms of foundation occur in large and heavy structures, bridge piers, dock walls and harbour work, in which large excavations may cover an entire building site. The vertical sides of the cutting must usually be maintained by temporary supports provided by shoring (see SHORING).

Deep Foundations for Piers.—Timber is usually employed to strut the sides of deep excavations for piers, the timber being inserted in short stages. In the U.S.A. a circular excavation is often made and the sides supported by short vertical poling boards wedged against cast iron circular frames.

The Open *Caisson.*—Danger to property may occur if adjacent excavations cause withdrawal of running sand, hence for excavations through wet strata, water and fine sand must be kept out of the cutting. In vertical shafts the sides may be supported by steel or concrete linings added in short lengths at the top, as the excavation proceeds. An enlarged base is usually formed to increase the bearing area; and the lining is filled with concrete upon which the surface foundation is laid.

The Pneumatic Caisson.—For preventing the incursion of water to excavations in wet strata and in river beds, the pneumatic caisson is employed, this being a cylinder of steel or reinforced concrete of the same size as the foundation. The caisson is a rigid casing without base and having cutting edges. Units are added above water level as the caisson sinks. A working chamber is formed in the base, isolated by an "air-lock." The men work in compressed air, which must resist the incursion of water. To admit and withdraw men and materials the air-lock chamber has two doors at different levels. The air pressure is maintained by re-sealing one door before opening the other; at the required depth the space of the working chamber is sealed with concrete. Steel caissons are usually filled or lined with concrete, and reinforced concrete shells are bridged over to receive the superstructure.

Sheet Piling.—One function of sheet piling is to support laterally foundation beds which would spread under pressure; sites are occasionally *surrounded* by sheet piling. It also gives continuous support to very soft ground, as in water-bearing strata, where shallow excavations and conditions do not make a closed caisson imperative. For much ordinary work timber sheet piles are used, driven between horizontal walings secured to square guide piles. Sheet piles formed by special sections of rolled steel are in common use, and various forms of reinforced concrete sheet pile are also employed.

A patented type of reinforced square pile has two wings Driven edge to edge these piles may be used as sheeting or for retaining "made" earth, assisted by reinforced ties anchored to the earth behind the wall. The piles are designed to resist the consequent bending moments. Sheet piles have the feet splayed to induce the entering pile to close against the edge of its neighbour.

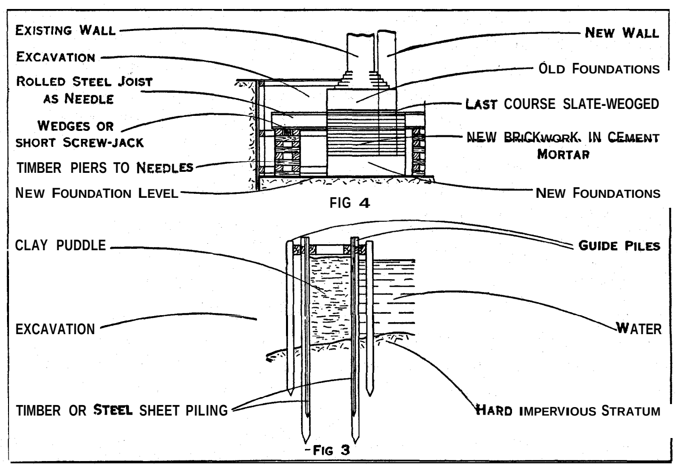
The Coffer Dam is a substantial temporary dam, used where the hydrostatic head is considerable and simple sheet piling is inadequate. A coffer dam may surround an enclosure for the removal of water and soil and the insertion of a foundation or, for quay walls, may be on the water side only. In modern practice two rows of close piling are used, 5 ft. and upwards apart, driven to impervious ground. The space within the piles is cleared and filled with puddled clay. On completion the water is pumped from the enclosure and excavation or construction may proceed. For deep interior excavation after withdrawal of water the coffer dam is supported by transverse strutting or by inclined shoring.

PROTECTION OF ADJOINING STRUCTURES

When inserting foundations for new buildings the foundations of adjoining structures must not be disturbed. Most laws recognize the rights of adjoining owners, and impose penalties for damages to existing property. The upper portions of existing structures must be supported by shoring while adjacent excavations are in progress (see SHORING).

If the new foundations are to be lower, to admit of deeper basements, then the old structure must be re-supported at the lower level. The process of inserting new supports is known as under-pinning.

Under-pinning.— The problem in under-pinning is to place solid supports underneath the old foundations and to avoid settlement of the existing building in the process. Methods of underpinning cannot be standardized; fig. 3 shows one method in which short lengths of foundation are exposed by pits sunk to the new level. In heavy structures, dead shoring is required which consists of "needles" passed beneath the foundations and supported on short uprights or from the adjacent ground. The excavations are then extended and portions of the new foundations

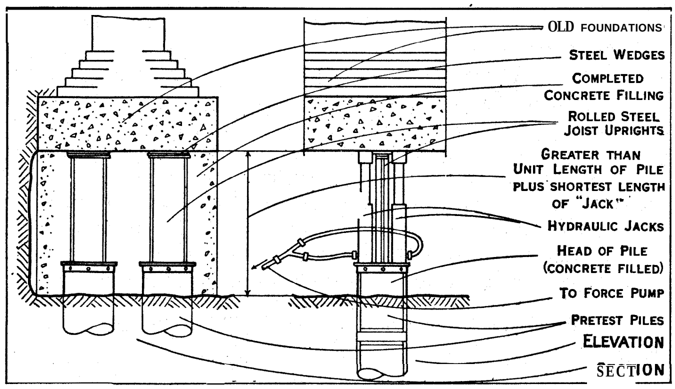


FROM "THE STRUCTURAL ENGINEER"

FIG. 3.— COFFERDAM. SUPPORTING WATER PRESSURE ON ONE SIDE
FIG. 4.— USUAL METHOD OF UNDERPINNING OLD FOUNDATIONS

erected. For brickwork, cement mortar is used and the last joint wedged with slate. If in concrete the top clearance'is grouted solid with cement. When the new work may receive load the intervening portions of foundation are inserted. For small buildings, on firm ground, under-pinning can sometimes be done without temporary 'support.

Pre-test Piles.—A method of pile under-pinning has been patented in America (1917) and in England known as "pre-test" piling Pre-test piles may also be used for new buildings. For the purpose of under-pinning, short lengths of the old foundations are exposed to allow of the insertion of a short length of steel tube, 14 in. to 20 in. diameter and $\frac{3}{8}$ in. thick, which becomes the casing to a complete pile—afterwards concrete filled. The short tube is forced into the ground by a pair of powerful hydraulic jacks operated by a force pump working at high pressure. The tube is cleared of earth by grabbing or otherwise. Another length is added and the process repeated, additions being made by sleeve-



FROM HOOLE AND KINNE, "FOUNDATIONS" (MCGRAW-HILL)

FIG. 5.— THE PRE-TEST METHOD OF UNDERPINNING, DEVELOPED AND PATENTED IN THE UNITED STATES OF AMERICA

jointed sections until the hard substratum is reached. The interior of the steel tube is filled with concrete and the pile completed. In the space between the old foundation and the head of the pile, a steel joist packing is inserted and wedged tight while two jacks keep the full load on the pile (*see* fig. 4).

By wedging tight while the pressure is maintained on the pile, a great advantage in supporting power is gained. When the pressure on such a pile is being increased, a "bulb of pressure" develops in the earth beneath the base of the pile and opposes its further penetration. If the load be released this "bulb" disappears and will only be re-formed if the pile be once more forced forward into the ground. Hence, if the under-pinning be completed while the pile is not under pressure, the full resistance can only be developed by further settlement. The pre-test method eliminates this settlement and may also ensure a known factor of safety, since the jacks can be made to develop a definite and known thrust.. Care is required in packing the bearings of the jacks on the concrete both of the pile and the old foundation and in wedging up the new support to avoid local damage to the concrete. The steel support and the heads of the piles are finally encased in concrete.

Patton, *Practical Treatise on Foundations;* White and Prentis, *Modern Under-pinning* (1929); M. J. McCarthy, "Piling in the Service of Structural Engineering," *Structural Engineer* (1927). (F. E. D.; J. L. M.)

FOUNDATIONS, PHILANTHROPIC. The philanthropic foundation, broadly defined, is a legal and social instrument for applying private wealth to public purposes. Although charitable endowments existed in antiquity, the modern foundation is predominantly a 20th-century American phenomenon. It is a large, autonomous organization formed to support research or public service in such fields as education, science, medicine, public health and social welfare. It may be an operating foundation with a service and research staff but it is usually a grant-making organization. Its legal form may be that of a charitable trust or a nonprofit corporation. It may be either a perpetuity with only its income distributed, a discretionary perpetuity with capital also expendable, or a liquidating fund with mandatory distribution of capital. An individual may endow a foundation by bequest or by a gift made during his lifetime; a business corporation or a family may create and support a foundation through continued giving.

In ancient Greece, Egypt and Rome a foundation was usually a single-purpose perpetuity supporting an academy, library or local charity. The typical medieval foundation was an ecclesiastical perpetuity operating a monastery, almshouse, orphanage or school. Many early hospitals, colleges and universities in western Europe and in the United States were supported by foundations. usually under religious control. During the Elizabethan period and afterward, thriving English merchants created numerous special foundations for educational and local charitable purposes. notably for poor relief. These small perpetuities, both in Great Britain and on the continent, drew increased criticism after 1750 for their mismanagement, narrowness or obsolescence of purpose, and their palliative character. Adam Smith in England and Turgot in France were among their early critics.

Although foundations or charitable trusts with narrow, local purposes have survived, they are overshadowed by large foundations possessing broad purposes and flexibility of action. Among the first of these in the United States was the Smithsonian institution (*q.v.*), created in 1846 "for the increase and diffusion of knowledge among men." In 1867 the Peabody Education fund was founded in the U.S. to promote education in the south. As business fortunes and organized philanthropy developed, other general foundations were created, notably by Andrew Carnegie (*q.v.*) and John D. Rockefeller (*see* ROCKEFELLER) after 1900. As a result of the publicity and success attending these foundations. many others appeared in the United States; a number also appeared in Canada and Great Britain and a few on the continent. After 1914 the United States also witnessed a substantial growth of community foundations and after 1940 a wave of personal, family and company-sponsored foundations.

Modern foundations are usually tax-exempt and have independent, self-perpetuating boards of trustees with considerable freedom of action. They stress studies and experiments to determine the fundamental causes and solutions of the problems of mankind. They often act as pioneers in social betterment by investigating basic problems that lie beyond the reach of local philanthropy or government and by using philanthropic "venture capital" to start programs that are later taken up by other private or public agencies.

UNITED STATES

Foundation directories show that there were at least 27 philanthropic foundations in the United States in 1915, 179 in 1926, 243 in 1939, 505 in 1946, 4,162 in 1955. and approximately 12.000 in 1960. New ones were being created at a rate exceeding 1,000 a year by 1960. Over 90% of them had assets of less than $1,000,000 each in 1960; fewer than 1,000 had assets exceeding $1,000,000.

Types **of** Foundations.— Despite their diversity, four general types of foundations may be identified: general research, family or personal, company-sponsored and community foundations.

Research foundations are the large, well endowed organizations that are noted for their research programs in education, health, social welfare and the sciences. They are usually grant-making organizations but a few are partly or wholly operating foundations. In 1960 there were 178 such foundations. 129 of which had assets of $10,000,000 or more. They possessed more than half of all foundation assets and played a pioneering role in social betterment through research and experimentation.

Family or personal foundations are created by bequest or, more commonly, by living donors to facilitate their charitable giving. A few, such as the Ford foundation, have become huge through continued gifts and bequests. The larger family or personal foundations have broad philanthropic programs resembling major research foundations; the smaller ones have local, specialized programs resembling ordinary family giving. They have multiplied in number because they carry prestige, provide a convenient means for systematic philanthropy and offer income tax exemption for sponsors' gifts,

Corporation foundations, or those sponsored by individual companies, multiplied rapidly after World War II. They were created by many large concerns to systematize corporate giving and several have assets exceeding $10,000.000 each. Company-sponsored foundations are tax-exempt, independent legal entities whose trustees are almost exclusively officers of the sponsoring firm. Since their sponsors' profits and gifts may fluctuate, they use a reserve fund to regularize this "in-and-out" giving. Although small foundations stress local charity, most large corporation foundations support education, especially scholarships and fellowships, and also health, scientific research and social welfare. Several have distinctive programs keyed to the interests of their industry. The Bulova Watch Company foundation, for example, trains disabled veterans to be watch repairmen. The Nutrition foundation, supported mainly by food manufacturers, promotes basic research and education in nutrition. The Statler foundation finances research on hotel construction, operation and personnel training.

Community foundations or community trusts are charitable organizations that operate in individual cities or areas. They receive gifts and bequests from many persons and apply these funds as the donors stipulate or as a distribution committee of representative community leaders decides. They stress local philanthropic activities, especially education and social welfare The community trust movement began in Cleveland in 1914 with the creation of the Cleveland foundation. New ones have appeared regularly, especially in large eastern cities. By mid-century there were about 100 and their aggregate assets approached $150,-000.000. At least eight had assets exceeding $10,000,000 each.

The government foundation is another type worth noting The National Science foundation was established in 1950 to advance fundamental scientific research. Although tax-supported, it has an independent governing board and makes grants for research projects, fellowships and related programs.

Peabody and Slater Funds.—The Peabody Education fund mentioned above is often called the first modern American foundation. George Peabody, an American who became a wealthy banker in England, endowed it in 1867 with $2,000,000 primarily to advance public education in the south. It was an optional perpetuity and was liquidated in 1914. The John F. Slater fund was established in 1882 and promoted southern education until it was terminated in 1937. Influenced by the Peabody and Slater funds, by growing concern over educational, medical and social problems, by the philanthropic possibilities of great family fortunes, and by Carnegie's "gospel of wealth," millionaire philanthropists created foundations at an increasing rate after 1900.

Carnegie Trusts.—With his concept of the stewardship of wealth, Andrew Carnegie deemed it a disgrace to die wealthy. The philanthropic foundation was his favourite means of employing personal riches for long-run social good His gifts and bequests, exceeding $330,000,000, went mainly to endow several perpetuities whose income was applicable to broad purposes as interpreted by the trustees.

The Carnegie Institute of Pittsburgh was created in 1896 with original grants of $11,700,000. It serves the Pittsburgh, Pa., area as a general educational agency, including libraries, museums of fine arts and natural history, a music hall and the Carnegie Institute of Technology.

The Carnegie Institution of Washington was established in 1902 with a $10,000,000 grant "to encourage, in the broadest and most liberal manner, investigation, research, and discovery, and the application of knowledge to the improvement of mankind." It conducts fundamental research in various scientific fields.

The Carnegie Hero Fund commission was endowed in 1904 with $5,000,000 to recognize heroic deeds in civil life through awards and grants to heroes or their survivors.

The Carnegie Foundation for the Advancement of Teaching was created in 1905 with an original gift of $10,000,000, primarily to provide retirement pensions for professors at nonsectarian colleges and universities. It pioneered in the pension field, raised educational standards, and helped free many institutions from strict denominational control. Its noncontributory pension scheme taxed its resources and in 1918 it established the Teachers Insurance and Annuity Association of America to handle these pension commitments and develop contributory retirement plans. These activities influenced the retirement plans developed by insurance companies. private industry and the federal government. Among this foundation's important educational studies was the famous Flexner report of 1910 on *Medical Education in the United States and Canada*, which produced a revolution in medical education.

The Carnegie Endowment for International Peace was founded in 1910 with a $10,000,000 fund to promote world peace. It attempts to increase international understanding by conducting research on international law, history, economics and other aspects of foreign relations.

The Carnegie Corporation of New York, established in 1911 with gifts of $135,000,000, is a grant-making organization promoting "the advancement and diffusion of knowledge and understanding among the people of the United States and of the British dominions and colonies." It has made large gifts to the other Carnegie trusts and to many colleges, universities and research organizations for educational and research programs. It created the Church Peace union and materially supported the National Research council. It has made substantial grants for adult education, the fine arts, modern languages, engineering education, international affairs, and fellowship programs.

Carnegie created several philanthropic trusts in Europe, including ten hero funds, the Carnegie Trust for the Universities of Scotland (1901) with a $10,000,000 endowment, a $3,750,000 trust (1903) for the benefit of Dunfermline, Scot., his birthplace, and the Carnegie United Kingdom trust (1913) with a $10,000,000 grant.

Rockefeller Benefactions.—Three generations of Rockefellers have given well over $1,000,000,000 to philanthropy. The elder John D. Rockefeller gave more than $530,000,000, primarily to four large foundations. He helped build the University of Chicago and gave to several colleges. He believed, in general endowment gifts on a matching basis, to encourage further philanthropy. Prior to 1928 the foundations he created made extensive endowment gifts on this basis. They were independent charitable corporations with broad powers and self-perpetuating trustees. Rockefeller disliked perpetuities and empowered his trustees to expend both capital and income.

The Rockefeller Institute for Medical Research (1901), the only operating foundation created by Rockefeller, received gifts totaling $60,000,000 to advance and disseminate knowledge about the nature, causes, treatment and prevention of diseases. Located in New York city, it has become a well equipped medical research centre. In 1908 its charter was amended to allow educational activities. A further amendment in 1954 permitted it to be incorporated into the University of the State of New York as a degree-granting institution for graduate training and research in the medical and biological sciences.

The General Education board was founded by Rockefeller in 1902 as a discretionary perpetuity of nearly $130,000,000. In 1903 it was chartered by congress for "the promotion of education within the United States of America, without distinction of race, sex or creed." By 1952, it had distributed nearly $316,000,000 to strengthen educational institutions. It promoted agricultural education in the south by instituting a farm demonstration program in collaboration with the U S. department of agriculture. It worked with southern educational officials to establish and improve rural schools and public high schools. It helped establish normal schools for Negro teachers and public schools for Negro children, spending nearly $30,000,000 on Negro education in its first three decades. Prior to 1928 it made matching endowment gifts of $60,000,000 to nearly 300 colleges and universities and $90,000,-000 to various medical schools.

The Rockefeller foundation was created in 1913 "to promote the well-being of mankind throughout the world." Directly and indirectly it received nearly $242,000,000 from the founder. By 1960 it had distributed well over $500,000,000, one-third of it abroad. Until 1928 it emphasized public health and medical education. In 1909 Rockefeller personally financed the Rockefeller Sanitary commission to help health departments curb hookworm in 11 southern states. The foundation assumed this work in 1913 and created the International Health board. The two organizations co-operated in the south to combat hookworm. yellow fever, malaria, pellagra, smallpox, tuberculosis, etc., and to strengthen county and state public health departments. They extended this program to many other countries and the Rockefeller foundation spent $94,000.000 on public health abroad in its first 40 years. It co-operated with the General Education board to improve American medical schools and made grants to several American and foreign universities to create schools of public health. Directly and through the China Medical Board of New York which it created, it provided nearly $45,000,000 to develop the Peking Union Medical college.

When the Rockefeller philanthropies were reorganized in 1928, the Rockefeller foundation mas broadened in scope and thereafter liberally financed pure research. It created divisions of public health, medical sciences, natural sciences: social sciences and humanities, each of which supported fellowship programs, special research projects and independent research agencies. The medical sciences division also supported psychiatry and mental hygiene. The natural sciences division financed costly research tools such as marine biology laboratories, telescopes and cyclotrons. The social sciences division continued the work of the Laura Spelman Rockefeller memorial, on which the two spent about $100,000,000 in a 25-year period. It helped support university and independent research agencies, including the National Bureau of Economic Research. Brookings institution, and Social Science Research council. It also helped finance publication of the *Encyclopaedia of the Social Sciences*. The humanities division made special grants to individual universities, museums; and libraries, to the American Council of Learned Societies, and for publication of the *Dictionary of American Biography*. In its first 35 years the Rockefeller foundation spent $28,000,000 for 10.000 fellowships in 75 countries and $10,000,000 on research grants-in-aid.

Laura Spelman Rockefeller memorial was endowed with nearly $74,000,000 by Rockefeller in 1918. Before being merged into the Rockefeller foundation in 1929, it made grants exceeding $55.000.000, of which $41,000,000 was for social science research.

In addition to its international public health work, the Rockefeller foundation developed technical, educational and research programs to aid agriculture in several Latin-American countries and. since 1957, in India and other eastern countries. The Rockefeller Brothers fund also supports foreign aid programs, especially in Latin America. In 1946 it created the American International Association for Economic and Social Development and the two have since founded the Association for Credit and Rural Assistance (providing supervised credit and technical assistance to farmers), International Basic Economy corporation (investing in developmental enterprises in Latin America), and IBEC Research institute (studying agricultural problems). These agencies have been operating in Brazil, Venezuela and other Latin-American countries; in the late 1950s they entered India and Africa.

John D. Rockefeller, Jr., helped administer these foundations and made additional charitable gifts of $473,000,000. In 1923 he endowed the International Education hoard. with $20,000,000. It supported research in the natural sciences! agriculture and humanities, and spent more than $18,000.000 before merging with the Rockefeller foundation in 1928. He also endowed the Bureau of Social Hygiene, Institute of Social and Religious Research, and Sealantic Fund. Inc. He died in 1960. leaving half of an estate valued at $150,000,000 to the Rockefeller Brothers fund, created in 1940, to which he had previously given $58,000,000.

Ford Foundation.— In 1960 the Ford foundation held about one-fourth of all U.S. foundation assets. It was created with an initial $25.000 gift in 1936 to facilitate the Ford family's charitable giving. Later gifts and bequests from Edsel and Henry Ford II made it very wealthy and by 1960 it had distributed pearly $1,200~000,000. It made grants to existing organizations and to 11 autonomous funds of its own creation. including the Fund for the Advancement of Education (1951), Fund for Adult Education (1951), Fund for the Republic (1952) and National Merit Scholarship Corp. (1955). In 1954 it established the Center for Advanced Study in the Behavioral Sciences at Stanford. Calif. In 1956–57 it distributed $500,000.000 from capital funds among 615 private colleges and universities, 3.500 nonprofit hospitals and 42 privately supported medical schools. In 1959 its annual expenditures reached $110,000,000.

The Ford foundation's chief concern is education and it is the leading foundation contributor to social science research. It makes grants to groups engaged in international affairs and to universities and research institutes for intensive study of foreign areas. Its technical assistance programs are designed to improve farming, local industry, public administration and education in underdeveloped countries. It spent $78,000,000 on overseas development between 1951 and 1958; $28,000,000 was for India and smaller amounts for other countries of south and southeast Asia, the middle east. Africa and Latin America.

Other Foundations.— Charitable foundations created by other wealthy philanthropists help to illustrate their diversity.

The Russell Sage foundation is a perpetuity chartered in 1907 with a $10,000,000 endowment to promote better social and living conditions, in the United States. It is primarily an operating foundation, conducting research, demonstrations, publication and other educational endeavours. Its work has greatly advanced the professions of social work and city planning.

The Julius Rosenwald fund was created in 1917 as a liquidating fund to be ,terminated within 25 years after Rosenwald's death, reflecting his dislike of perpetual endowments. He died in 1932 and it was liquidated in 1948. Its charter purpose was to serve "the well-being of mankind," and it aided southern rural education, race relations and the health and education of Negroes.

The Twentieth Century fund is a discretionary perpetuity chartered by Edward A. Filene in 1919 to improve economic, industrial, civic and educational conditions through research and publication. It pioneered in studying economic and social problems and became strictly an operating foundation.

The John Simon Guggenheim Memorial foundation was created in 1925. It awards fellowships each year to further the development of scholars and authors.

The Duke endowment is a charitable trust created by James B. Duke in 1924 to establish Duke university and serve other educational, health and religious needs in North and South Carolina. Duke required that 20% of the annual income be reinvested to double his original gift of $40,000,000, thus making it an accumulating fund. The trust indenture allocated the available income among Duke university, nonprofit hospitals, orphanages, three other colleges and universities, and support of certain retired ministers and rural churches. Duke bequeathed additional funds to this trust.

The largest foundations in the United States include:

Name	Date founded	Assets (approximate; 1959)
Ford foundation	1936	$3,316,000,000
Rockefeller foundation	1913	648,000,000
Duke endowment	1924	414,000.000
John A. Hartford foundation	1942	414,000,000
Carnegie Corporation of New York	1911	261,000.000
W. K. Kellogg foundation	1930	215,000,000
Alfred P. Sloan foundation	1934	176,000.000
Lilly endowment	1937	157,000,000
Commonwealth fund	1918	120,000,000
Danforth foundation	1927	110,000,000

Other foundations which reportedly had assets approaching the $100,000,000 class in 1960 included the Vincent Astor foundation (1948). Charles F. Kettering foundation (1927), Moody foundation (1942) and Sid W. Richardson foundation (1947).

The 12,000 foundations in existence in the U.S. by 1960 had combined assets of about $11,500,000,000 and total annual expenditures of approximately $625,000,000. This slightly exceeded all direct corporate giving but was less than 10% of total private charitable giving. The foundations' support of new ideas. research and social experimentation in neglected or controversial areas has had great significance despite the fact that their expenditures are dwarfed by federal spending.

Tax and Regulatory Aspects.—The most significant and direct influence of government on foundations is through tax legislation. Foundations are exempt from federal and state income taxes on their investment-type income. They are also usually exempt from local property taxes. Gifts of property to foundations are not subject to gift taxes and bequests are exempt from estate and inheritance taxes. Charitable contributions to them are deductible within limits in determining taxable income for a person or corporation. A person's charitable contributions (including gifts to a foundation) are tax-exempt to an amount equal to 20% (30% under special conditions) of his adjusted gross income. High surtax rates encourage tax-exempt giving; an individual with income subject to the 91% tax rate may give to charity at a net cost in spendable income of nine cents on the dollar. An individual or firm may give appreciated assets such as securities and make a charitable deduction at their market value without incurring capital-gains taxes. Since 1935 a corporation's contributions (including gifts to a foundation) have been tax-exempt up to 5% of its taxable income. During World War II and the Korean war a corporation with income subject to the excess-profits tax then prevailing could supply charitable dollars costing as little as 18 cents (or even less if also subject to state income tax).

As noted above, these tax provisions have encouraged some companies and individuals to create foundations and make tax-exempt gifts to them. However, several large foundations were created before the federal income tax was enacted in 1913 and many more before tax rates became high. Factors other than the income tax exemption have been important in the growth of foundations; these include the pure philanthropic motive, desire to perpetuate a family name or improve a "corporate image," prestige value of foundations, their advantages in making family or corporate giving more regular and effective, and their use to maintain control of a family-o ned corporation upon the death of a principal owner by avoiding forced sale of the firm or its assets or stocks to pay estate and inheritance taxes.

The privilege of tax exemption as an encouragement to charitable giving has been preserved and protected from abuse through a long series of tax laws, court decisions and internal revenue service (IRS) regulations. Federal tax law, particularly the exemption privilege, has actually become the chief instrument of public control over foundations. A foundation must apply for tax exemption, giving prescribed information as to its purposes, intended activities, finances and sponsorship. This application is open to public inspection. The IRS will approve it only if the foundation's purposes are genuinely charitable and if its intended activities conform to its declared purposes. Every foundation must file with the IRS an annual report of its assets, liabilities, net worth, accumulation, gross income, total gifts received and total disbursements for tax-exempt purposes. Most of this annual report is open to public inspection. The IRS annually audits these reports to see that foundations conform to their declared purposes. A foundation may forfeit its tax-exempt status if it engages in propaganda or lobbying, makes an unreasonable accumulation of income, invests capital recklessly. uses a substantial part of its income for nonexempt purposes, or engages in certain "prohibited transactions" benefiting its donors or directors. The IRS also scrutinizes a foundation's sources of income. Its income (in excess of $1,000) from business activities not substantially related to its exempt purposes is taxable, as is a "feeder" corporation's income which is devoted entirely to a sponsored foundation.

Officials of large foundations believe that they have an obligation to make voluntary public reports of their operations. While most large foundations published periodic reports in the late 1950s, less than 5% of those with assets of less than $10,000,000 did so. In 1956 the Foundation Library Center was established in New York city to encourage foundation reporting and to collect and disseminate information about foundations.

GREAT BRITAIN

In Great Britain, unlike the United States, no special meaning attaches to the word "foundation." It is simply a name given to certain charitable trusts, and the words "trust" and "foundation" are used interchangeably. Foundations' vary in size and scope from the Barlboro (Old Infant school) foundation for the educational benefit of children in a particular parish, to the Nuffield foundation which distributes funds to a wide variety of causes in a large number of countries.

In Britain a foundation as a charitable trust was defined originally by the Statute of Charitable Uses (1601). This statute was repealed in 1888 by the Mortmain and Charitable Uses act which, however, retained the preamble to the Elizabethan statute in which were listed the charitable uses which the law recognized. Chief among these were relief of aged, impotent and poor people; the maintenance of sick and maimed soldiers and mariners, schools of learning, free schools, scholars in universities; the repair of bridges, ports, havens, causeways, churches, sea banks and highways The English judge Edward Macnaghten further added to this list of charitable uses the legal definition of a charity: "Charity in its legal sense comprises four principal divisions—trusts for the relief of poverty; trusts for the advancement of education; trusts for the advancement of religion; and trusts for other purposes beneficial to the community. not falling under any one of the preceding heads " Certain statutes also contain special definitions of charity; *e.g.*, the War Damage act of 1943 The fourth heading of the Macnaghten classification is indefinite, leaving ample room for ambiguities in defining a charity and resolvable only by litigation. A large fund of case law therefore exists which is relevant in determining whether or not the object of a foundation is charitable. The *Report* of the committee on charitable trusts, published in 1952, recommended that a definition should be enacted based upon the Macnaghten classification, which should itself be ended, but preserving the case law as it stands. The only law to be passed as a result of the committee's recommendations, however, was the partial adoption of their views on the retrospective validation of certain imperfect trust provisions in the Charitable Trusts (Validation) act, 1954. The legal basis of a foundation thus remained unaltered at the beginning of the 1960s.

Legal Position. — The legal recognition of a foundation as a charity carries several important privileges. In the first place, gifts to charity have always enjoyed a privileged position in the law of testamentary dispositions. A charity is treated as an artificial legatee with the right to hold property in perpetuity and with the additional important advantage that the courts are willing to provide new purposes as near as possible to the original objects of a charity if these become incapable of fulfillment. This latter doctrine, known in law as cy pres has, however, been widely criticized in that it does not allow changes in the purposes of charitable trusts and foundations sufficient to enable them to keep in step with a rapidly changing social environment. Thus, for example, the doctrine would be difficult to apply to a foundation which had originally had as its object the abolition of slavery. After the 1860s, parliament was willing to relax the doctrine of cy pres for some particular kinds of charity, notably in the case of educational endowments under the various Endowed Schools acts passed between 1869 and 1948 and in the case of parochial endowments in the city of London. The economic changes and especially the wide extension of the social services in the 20th century made urgent the need for its more general relaxation and the 1952 *Report* on charitable trusts recommended that the doctrine be relaxed for all trusts and foundations.

As against the special position which charitable trusts and foundations enjoy in law, various attempts were made to check the possible abuses and maladministration which might arise as a result of their perpetual legal existence. The Statute of Charitable Uses (1601) authorized the appointment of ad *hoc* commissioners to inquire into malpractices, but these appointments became infrequent during the 18th century and finally died out in 1803. The Charities Procedure act and the Charitable Donations Registration act; both passed in 1812, were further attempts (largely ineffective) to correct abuses and in 1818 a parliamentary commission was created to record and investigate the charitable trusts of England and Wales. The 1835 select committee on public charities recommended the creation of an independent authority with powers to investigate any trust. It was not until 1853, however, that the Charitable Trusts act was passed "for securing the due administration of charitable trusts and for the more beneficial application of charitable funds in certain cases" and it led to the naming of the Charity commissioners. The act of 1853 was of additional importance in that it created the official trustee of charity lands and the official trustee of charitable funds, thus providing a way in which lands and securities could be held by charitable foundations having perpetual succession, without cost to their trustees and without interfering in their administration of their trust. Trust funds were further relieved of the constant expense of transferring their property on the death or retirement of a trustee and the appointment of a new one. The *Report* of the committee of charitable trusts of 1952 made several recommendations intended to reinforce the powers conferred by the Charitable Trusts acts; *e.g.,* it was recommended that the statutory provisions for recording trusts should be re-established.

Foundations are also subject to restrictions on the assets they hold in the form of land and investments in securities. By the Charitable Trusts Amendment act of 1855, trustees are forbidden to sell, mortgage or charge charitable property, or to grant a lease in reversion after more than three years or for a term of more than 21 years, unless. expressly authorized by the commissioners. Restrictions upon the acquisition of land are imposed by the Mortmain and Charitable Uses act of 1888 and the amending acts of 1891 and 1892. Investments in securities can be made by foundations only if they are permitted by the terms of the trust instrument, by the provisions of the Trustees act of 1925, or by a high court order. The trustees are personally liable for loss from unauthorized investment and the range of securities in which investment is authorized is limited by the Trustees act. The financial position of trust funds thus suffers from a rigidity of income particularly onerous in a world prone to inflation.

Trusts and foundations enjoy a privileged position in the levying of rates and income tax. During the late 18th and early 19th centuries, properties provided and used for charitable purposes were frequently omitted from the poor rate: while the Scientific Societies act of 1843 specifically exempted such bodies from rate paying. In 1865, however, as the result of the decision in the case of *The Mersey Docks and Harbour Board Trustees* v. *Cameron,* public charities were held not to be exempt from the payment of taxes. Although the law quickly placed some charitable foundations in a more favourable position, as in the Sunday and Ragged Schools (Exemption from Rating) act, 1869, and subsequently extended rate relief to others, most charitable foundations between 1865 and 1955 were dependent upon sympathetic treatment by local rating authorities for which there was no statutory sanction. In 1955, however, charities were granted statutory relief from rates by the Rating and Valuation (Miscellaneous Provisions) act, though the relevant provisions were regarded as only temporary.

A foundation which is legally recognized as a charity is also. under the 1952 Income Tax act, able to claim tax exemption upon its income from land, interest, dividends or other annual payments and from the profits of a trade carried on by it. In effect this amounts to approximately doubling the taxed income of all charitable trusts and foundations.

Existing Foundations.— The precise number of foundations and trusts in Great Britain is unknown. It was estimated in 1952 to be at least 110.000: as compared with about 29.000 known to the Brougham commissioners in 1837, and new foundations were being created at the rate of about ten a week. Œ the 110,000, about 30.000 were educational and about 40.000 catered for the needs of the poor. sick and needy. It was further estimated that more than one-third of the total number of trusts had an annual income of F25 or less. Excluding their considerable holdings of land. the assets of the 110,000 trusts existing in 1952 were estimated at £200,000,000, or about 5% of the estimated value of the national productive capital.

As opposed to the great mass of small foundations, there was an increasing tendency in the 20th century to emulate the U.S. practice of creating great charitable foundations with wide objectives, exercising their benevolence within and even beyond the country as a whole. Some of these giant foundations are, indeed, of U.S. origin as, for example, the Carnegie United Kingdom trust or the Pilgrim trust. The latter was founded in 1930 by E. S. Harkness and during the 1930s equally supported schemes to alleviate unemployment and to preserve the national heritage. Others are foundations with headquarters abroad such as the Commonwealth fund, founded in 1918, or the Gulbenkian foundation, founded in 1955 to support artistic, scientific, educational and charitable projects. In addition to these there are the great British foundations such as King George's Jubilee trust, founded in 1935; the King Edward's Hospital fund. London; and the series of Lord Nuffield's foundations, culminating in the creation of the Nuffield foundation in 1943 with an initial capital of £10,000,000.

Foundations make a valuable contribution to contemporary society, not only in their charitable disbursements but in the scope which they provide for voluntary service. Even with the greatly increased scale of provision by the state of education and of help for individuals faced with poverty, sickness, old age and unemployment, foundations supplement state activity. Thanks to the greater flexibility which they enjoy the foundations carry the fruits of philanthropy into areas in which the state does not function. The state tends to support existing activities and there is, therefore, room for the foundations in pioneering new ventures and in supporting new ideas which would otherwise remain untried for lack of funds. *See* also CHARITY; PHILANTHROPY; TRUST.

FOUNDING, the process of melting metal and pouring it into a cavity that has been molded on a pattern of the desired shape. When the metal solidifies the result is a casting—a metal object conforming to the shape of the cavity. This process is practised by foundries all over the world as a basic method for the production of metal shapes, utilizing in one form or another almost all of the metals known to man.

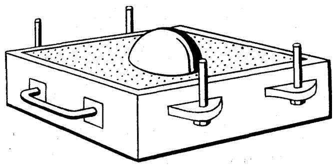

FIG. 1.—MOLD BOX AND PATTERN

This article deals with the materials and processes used in foundries: for a discussion of metallurgical aspects of these processes *see* METALLURGY: *Cast and Wrought Metal.*

The Mold.—A variety of materials is used in making molds, the most common being a mixture of sand and clay moistened with water. This mixture is firmly packed over the face of the pattern forming the cavity in which the casting is to be made. The whole is enclosed by a receptacle called a box or flask. (*See* fig. 1.)

The mold must be strong enough to resist the pressure of the metal and at the same time sufficiently permeable to permit the escape of air and gas from the mold cavity. Otherwise, these would remain as holes in the casting. The mold material must resist fusion by the heat of the metal and the surface next to the pattern be so closely knit as to avoid a rough casting surface.

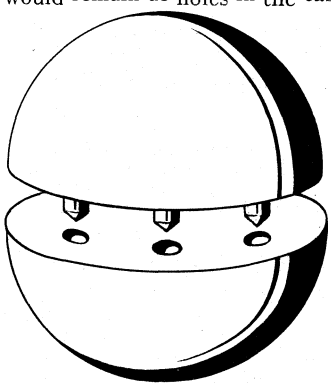

FIG. 2.— DIVISION OF PATTERN

The mold is made in two halves, each formed as described above and each contained in its own box. The upper half is known as the cope, the lower as the drag. The pattern must be so designed that the half mold can be lifted from its surface without breaking or tearing the mold materi'al. (See fig. 2.) This requirement can be modified by the use of loose pattern

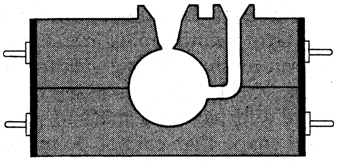

FIG. 3.—SECTION, COMPLETE MOLD

pieces, withdrawn after the mold has been lifted.

After removal from the patterns the cope and drag halves are joined, as shown in fig. 3, to make a complete mold.

The two halves are aligned so that the pattern cavities match exactly. This is accomplished by pins and bushings that are close fitting and located with precision. In forming the mold, provision is made for channels or gates through which the metal flows to the casting. Since the metal shrinks appreciably in volume as it solidifies, it is sometimes necessary to provide an additional reservoir of metal, called a riser, which stays fluid long enough to feed metal to the casting during this critical period.

Patterns of unusual or more complicated contour require the use of multiple boxes (fig. 4). In molding boxes of more than 14 in. square, crossbars serve to carry the sand; fig. 5 shows a drawing of the sections of this type box.

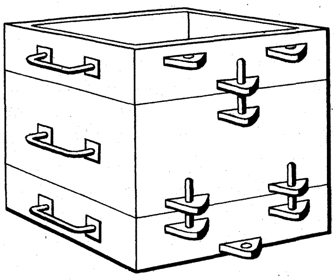

FIG. 4.—MULTIPLE MOLDING BOX

Mold Materials.—Suitable molding sands are found in natural deposits from which they can be mined and used without much alteration. The size and shape of sand grain is important and requirements vary for different metals. Comparatively coarse sands are employed for casting steel and iron; finer sands are needed for copper and aluminum alloys. Molding sand deposits contain sufficient clay to serve as a bond.

As natural deposits of good molding sand have become exhausted or less accessible, there has resulted a practice of using what are called synthetic sands. In this process, sands containing little or no clay are blended with clay or a claylike material such as bentonite (*q.v.*). Sand is prepared for use by mixing with the desired amount of water in a muller which coats each grain of sand with moistened clay by a kneading action. At this point certain other materials may also be added, such as flour to give the molded sand a certain amount of elasticity. Finally the mixture is aerated in a machine that breaks up lumps and gives the sand a fluffy texture. These operations are sometimes performed by hand with a shovel, but even in small foundries the use of machines is more common. For best results the physical character of the sand must be closely controlled; this is accomplished by testing equipment designed to measure strength, moisture content and porosity or permeability. These properties need to be held within narrow limits, whether the sand in use is natural or synthetic.

While clay and water are most often used to bond the sand, other bonds are sometimes employed. Molds can be made from sand mixed with a petroleum product or with man-made materials such as the synthetic resins or plastics. These are used only when their greater cost is offset by special advantages or unusual molding requirements. Several less generally used molding methods, described below, are based on a variety of differing materials.

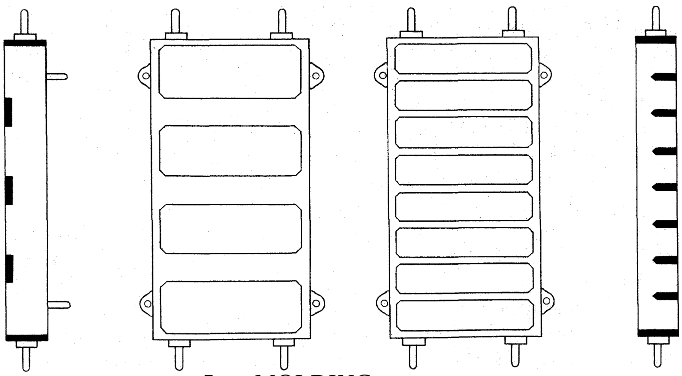

FIG. 5.—MOLDING BOX WITH CROSSBARS

Patterns.—If an accurate casting is to be obtained it is evident that an accurate pattern must be used in forming the mold. The making of such a pattern is a craft requiring great skill. When a considerable number of castings is needed it is usual to make a master pattern of wood from which working patterns can be cast in metal. Otherwise, the original pattern of wood or metal may be used in the foundry.

Since the metal in the casting will shrink as it solidifies, the pattern must be larger than the desired casting. Different metals have different shrinkage characteristics and allowance for this is made in making the pattern. Also the shrinkage is not always uniform in different directions, a variation which is sometimes unpredictable.

Sample castings have to be made before the pattern is actually put in service. When several pattern pieces are mounted on one plate for machine molding, their position on the plate must be perfectly matched so that the cope and drag halves of the mold will have an exact fit at the parting line. All pattern pieces must taper away from the parting line so that the pattern can be withdrawn from the mold without disturbing the mold material. Because of this taper some patterns must be formed of several loose pieces temporarily held in position by pegs, as shown in fig. 6 (left), or without pegs as in fig. 6 (right). Removal of the pattern may be facilitated by sprinkling it with a fine parting sand or compound to prevent adhesions.

When a metal pattern is employed, the need for a parting compound may be avoided by heating the pattern while in use, commonly by means of electrical heating elements.

Cores.—While many castings are solid, it more often happens that a hollow space is desired within the casting. Obviously this cannot be accomplished by the pattern, which must be removed without breaking the mold. To form the hollow, it is necessary to set a core in the drag. The core is so placed that there is an open space for the flow of metal between it and the face of the mold. In the finished casting the core is surrounded by metal except at openings through the casting wall, which form orifices from the hollow centre to the outside. The core material is removed through these openings and consequently must be so constituted that it loses strength when exposed to the heat of the metal and can easily be broken up.

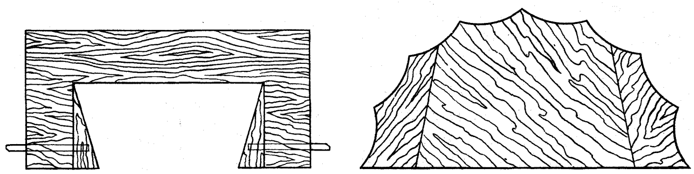

FIG. 6.—PATTERNS

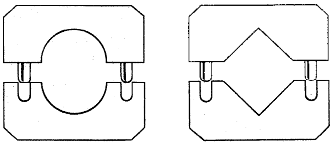
(Left) with loose pieces, (right) for fluted column

Like molds, cores are made from a variety of materials, but most cores consist of clean sand mixed with an organic binder, often linseed oil or a blend of linseed oil with rosin, fish oil, vegetable oils or petroleum oils. Other substances such as cereal flours or bentonite are sometimes used. The core is very fragile when first made but is hardened by baking in an oven at 400° F. or more. Cores of the linseed oil type require slow baking in the presence of air since the hardening process is one of oxidation. A synthetic plastic resin is sometimes used as a binder and, when this is the case, the core can be baked very rapidly by an electrothermic process. In this method the core is heated from the inside out, the oven itself remaining comparatively cool. The hardening of the binder is a chemical change which takes place within the resin itself as a result of heat.

Simple core boxes built in sections to allow removal of the core are illustrated in fig. 7. Sometimes, as in fig. 8, loose pieces are employed that are withdrawn separately. Cores may take various curved forms as shown in fig. 9, a half-core box for an elbow pipe. Freshly made cores are so weak that they may have to be transferred to supporting frames or driers to hold them in shape until after baking.

Cores are made manually by packing the sand mixture into an open core box or, if the shape of the core and the quantity re-



7.—SIMPLE CORE BOXES

quired permit, they are made in machines. In the latter case, the core box is clamped in place underneath a reservoir of the sand mixture which is then blown into the box by compressed air at a pressure of about 100 lb. per square inch. Often the box contains several core cavities that are thus filled at the same time. Since filling is almost instantaneous, provision must be made for rapid escape of air; otherwise the cavity will not fill completely. This is accomplished by means of orifices with screens so fine as to prevent the passage of sand.

Patterns have core prints and the cores are placed in the imprints so that alignment is assured (see fig. 10).

Mold Making.—Molds may be made by hand and, in the case of very large molds, this is a common practice. Molds of medium or large size are often packed by a machine called a slinger. This has a head which can be moved to apply sand, by blowing or throwing, with equal force on all parts of the pattern. When the molds are not baked or dried they are known as green sand molds.

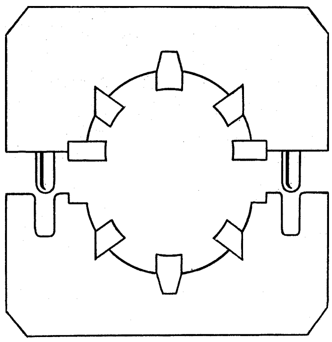


FIG. 8.—CORE BOX PIECES

Unless the number required is small, or unusual molding skill is needed, small molds are made in machines that compact the sand by squeezing with air pressure, by mechanically jolting the sand into place, or by a combination of these methods. When a machine is used the molder is a machine operator rather than a craftsman; a minimum of skill is required and rapid production is possible.

Methods of Molding.—In large-scale production, where a great many identical small castings are to be made, the whole operation of sand conditioning and molding is sometimes almost completely automatic. The sand is carried by conveyers to conditioning units where water, clay, new sand and other additions are mechanically made in predetermined amounts. At the molding machines measured quantities of sand pour into the flasks; the flasks themselves and completed half molds are handled mechanically. Both cope and drag are conveyed to a closing position, where they are accurately joined. The finished green sand molds, on a moving conveyer proceed to the pouring area and then to the shakeout, also mechanized, where the castings are removed from the molds. Broken moldings, reduced to sand, leaves the shakeout on one conveyer, castings on another.

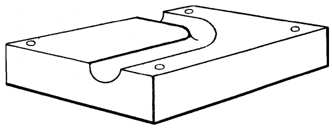

FIG. 9.—ELBOW CORE BOX

Cope flasks automatically go back to the cope machine and drag flasks to the drag machine. An outfit of this kind results in spectacular laboursaving but the investment is so great that it can be justified in only the largest operations. Smaller foundries make such use as they can afford of conveyers and laboursaving machinery.

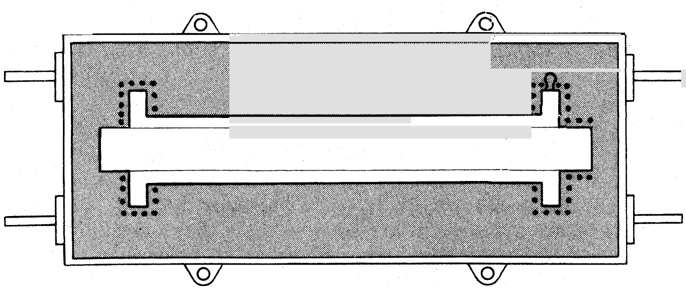

FIG. 10.—HALF-MOLD FLANGED PIPE READY FOR CORE
Core placed on two prints will leave space as shown

Although most molding is done by the green sand method, a number of other methods are in use. Green sand molds are sometimes strengthened by baking in an oven or the working surface is hardened by going over it with a torch. Molds may be assembled with shapes made from a core mixture and baked, a method particularly applicable for castings of odd shape that cannot be made in a conventional mold. Sand may be bonded with a synthetic resin, in place of clay and water, and used in the shell molding process. For this purpose a dry mixture of sand and powdered resin is spread over a heated pattern. The heat of the pattern melts the resin and then hardens it, forming a thin shell in the shape of the pattern.

The shell, after curing at a somewhat higher temperature, has considerable strength and can be stored indefinitely. The finished mold is formed by clamping or cementing together the cope and drag shells. In this manner more accurate dimensions and an improved surface can be obtained in casting some metals, notably the stainless steels. Cores, hollow instead of solid, are also made by the shell process.

For certain special applications, cements are used in place of clay. Iron and steel castings weighing many tons are sometimes made in sand bonded with portland cement. Time must be allowed for the cement to set before metal can be poured into the mold. Small castings of intricate shape, where a smooth finish and a minimum of machining are important, are often made in plaster of paris molds. The properties of the mold are augmented by mixing the plaster of paris with talc, asbestos and sometimes sand. The molds must be baked and should be poured while still warm from the oven.

Castings with very delicate parts, or so shaped that they cannot be made by conventianal methods, can be produced by what was once known as the lost-wax process, more often called precision or investment casting. (See also SCULPTURE TECHNIQUE: *Casting* and *Finishing.)* The desired shape is formed from wax or a synthetic plastic and is coated with a refractory cement. After drying, this is placed in a box and enveloped in a porous cement which makes up the main body of the mold. When the cement has set and is sufficiently dry the mold is heated to a temperature sufficient to melt the wax which drains out, leaving cavities to be filled with metal for the finished casting. Alloys with low melting points or even frozen mercury are sometimes substituted for the wax.

If sand is mixed with sodium silicate (water glass) and formed into a mold which is then treated with carbon-dioxide gas, a reaction takes place between the gas and the silicate forming a colloidal or jellylike silica gel that acts as a firm binder for the sand. While this method is in use for molding, it is especially applicable for the making of cores that are so strong when first made that they do not require baking.

Metal molds which can be used over and over again are widely employed for casting alloys of aluminum and magnesium when a large number of identical castings are to be produced. Some cast iron is also made in this manner and to a limited extent brass and bronze. The molds are coated with a refractory wash to protect them from the action of the molten metal. These molds are poured by gravity just as when expendable molds are used. Such low-melting alloys as those composed principally of zinc or aluminum lend themselves well to what is called pressure die casting. In this process a metal mold is mounted in a machine equipped with automatic controls. The [illegible] metal is forced into the die under high pr[illegible] and solidifies in [illegible] di[illegible]el[illegible]

This [illegible] th[illegible] is particularly applicable when many [illegible]ll intri[illegible] cate castings are t[illegible] be [illegible] rather la[illegible]g[illegible] castings, [illegible] as [illegible] frames and grillwork, where there is an exte[illegible]d area of thin cross section. The dies are costly and at high temperatures are too short lived for use with such metals as iron and steel. To a limited extent the process is used with the copper alloys.

In the manufacture of small castings "stack molding" is sometimes employed. Half molds are stacked one on too of another to form a multiple mold that is poured at one operation from a common feed. Large cast-iron pipe, or cylinders of other metals, are

cast by a centrifugal method, in which a metal or baked sand mold is rotated rapidly enough to overcome the action of gravity. The liquid metal is forced against the face of the mold to form a spun casting of high density. Some progress has been made in the application of this process to smaller castings, not necessarily cylindrical, arranged around a central feed.

Furnaces.—Various steel composition, alloys of nickel and some of the complex alloys required for high-temperature service are melted and superheated to temperatures in the range of 2,500° to 3,000° F. or even higher. While certain types of fuel-fired furnaces, such as the open hearth, can be employed at these temperatures, foundries commonly use electric furnaces.

In the direct arc furnace intense heat is generated by bringing a carbon or graphite electrode directly into contact with the metal to be melted. Passage of electric current forms an arc at the point of contact. In the induction furnace the metal to be melted is separated by a refractory wall from a coil carrying electric current. The arrangement is such that passage of current through the coil induces a flow of current in the metal itself. The temperature attainable is limited only by the electrical resistance of the metal as it melts. For relatively small melts of stainless steel and the like this is a favourite method.

Cast iron is most commonly melted in a cupola, a sort of chimney in which the iron is mixed with burning coke. The mixture of iron and coke is charged at the top of the cupola. The iron melts as it progresses downward and is eventually drained through a tap hole at the bottom.

The copper alloys, such as brass and bronze, melt at lower temperatures and contain volatile constituents that cannot tolerate the high temperature of the direct arc or, in most cases, direct contact with fuel. A variety of furnaces is employed. One is the indirect arc, in which the source of heat is an electric arc between two graphite electrodes above the surface of the metal. Electric induction furnaces are also widely used.

In some fuel-fired furnaces burning gas or vapourized oil strikes directly against the surface of the metal. In others the metal is enclosed in a crucible or melting pot surrounded by burning fuel. For aluminum and magnesium alloys cast-iron melting pots are commonly employed. Many of the metals will not produce satisfactory castings unless the temperature at which they are poured is closely controlled. This is accomplished by temperature measuring instruments known as pyrometers.

For descriptions of various furnaces and their operation see FURNACE, METALLURGICAL.

FOUNDLING HOSPITALS. It is significant that by the mid-19 jos there were few countries left in which hospitals existed solely for the purpose of receiving foundlings; *i.e.,* children who have been abandoned or exposed and left for the public to find and save. Definite institutions for the care of foundlings were established during the 7th and 8th centuries in Trèves, Milan and Montpellier, followed by others in Venice during the 14th and in Paris and Lyons during the 17th centuries. The celebrated Foundling hospital of London was established by Capt. Thomas Coram in 1739, and has since completely changed its original character.

The modem method of dealing with illegitimate children—and nearly all those who were placed in foundling hospitals were born out of wedlock—is based on the proved advantage both to the mother and child of keeping them together, at any rate for the first year, thereby greatly reducing the infant mortality rate, strengthening the natural ties and lessening the chance of the mother's erring a second time. There is also an increasing reluctance to herd very young children together in large institutions, not only because of the risk of infection with small children but also because an institutional environment, except for short periods, is today recognized as being bad for any child unless he is in need of some specialized treatment; so that the boarding-out or foster-mother system of caring for these children is being more and more employed in all countries.

The London Foundling hospital can be said to be a pioneer in boarding out and today all children admitted to that foundation, now known as the Thomas Coram Foundation for Children, are boarded out.

At first the London Foundling hospital admitted any child under two months of age who was free from certain specified diseases, without any questions being asked or any attempt made to identify its parents. Indeed, a basket was hung outside the entrance gate and unwanted infants were deposited there and admitted without question; this resulted in angry scenes outside the gates and in 1742 a system of balloting for admission was introduced. Grants were made by parliament to the hospital from 1756 onward, £10,000 being paid to the governors in that year, on condition that all children offered were received. In 1757 no fewer than 3,727 children were admitted and branch hospitals at Ackworth, Shrewsbury, Westerham, Aylesbury and Barnet were opened to cope with the number of children for whom admission was sought.

This general admission was soon found to be a serious error, for the social evil of illegitimate birth received no discouragement, while of the 14,934 children received during the three years and ten months it was in force, no less than 10,389 died in early infancy. Parents even brought dying children for the purpose of having them buried at the expense of the hospital, and strangers were employed to bring children from all parts of the country to the hospital in London, for payment; many such children, through the brutality or criminal negligence of those to whom they were entrusted, never reached their destination alive. State grants and indiscriminate admission ceased in 1771. From that time onward the hospital has had to depend on private philanthropy for its funds; admission had perforce to be by a process of selection, and gradually the rules and conditions of admission in force at mid-20th century were evolved, as follows: a child can only be received upon the personal application of the mother. The children of married women and widows are not received. The petitions must set forth the true state of the mother's case. No application can be received previous to the birth of the child, nor after it is 12 months old. No child can be admitted unless the committee is satisfied, after due inquiry, of the previous good character and present necessity of the mother. and that both mother and child have been deserted by the father. A liberal interpretation is placed upon the term deserted, which covers cases where no payment, or insufficient contribution, is obtainable from the child's father to provide for the maintenance of the child.

On admission children are taken in to the Coram Residential nursery for about a month and are then boarded out in foster homes, found in the home counties. There the children are visited regularly and supervised by qualified child welfare officers, working from headquarters in London.

The charity's substantial capital fund (nearly £2,000,000 in the mid-1950s) is principally the outcome of the purchase in 1741 of 56 ac. of land in Bloomsbury. London, for the first hospital for a sum of £6,500. The property was let on ground rents, and sale of the property in 1926, when the hospital was removed to the country, realized f 1,650,000. After a temporary home at Redhill, Surrey, the children were moved to new premises at Berkhamsted, Hertfordshire, in 1935; there they remained until July 1954, though the education was taken over by the local authority in 1951. In 1954 the governors were planning to sell the school and thereafter all children would remain in their foster homes, going to local schools, their welfare being supervised by visiting child welfare officers appointed by the foundation governors. There were then more than 600 children under the age of 21 in care of the foundation; and on the average 60 children are admitted to care each year—of this number a large percentage are restored to their mothers before reaching the age of three. (H. H. Ns.)

United States.—Foundling hospital and foundling are terms no longer common in the United States despite the continued existence of a number of institutions for abandoned and deserted children. The foundling hospital in America was instituted about 1850–60 by Catholic nuns. Protestant churches or private individuals such as George E. Shipman in Chicago and John S. Parry in Philadelphia. Pa.. doctors appalled at the high mortality among exposed infants; records covering a period of 20 years in one hospital show that of a yearly average of 52 admittances there were 35 deaths, The first institution designated for foundlings seems to have been St. Vincent's Infant asylum (448 children), established by the Sisters of Charity (St. Vincent de Paul) in Baltimore. Md., in 1856. Between 1860 and 1873 six others were founded; two in Washington, D.C.. and one each in San Francisco. Calif.. New York city. Chicago. and Cleveland. O. Within the last three decades. many of the babies formerly referred to as "foundlings" or "deserted" have been cared for by legal adoption.

In the latter part of the 19th century several persons in New York city were aroused to the tragic situation of the babies harboured in foundling hospitals. Quoting from the book *The Adopted Child,* written by Eleanor Garrigue Gallagher and published by John Day in association with Reynal and Hitchcock in 1936, "One of the first women in this country to recognize the need of organized work for the saving of babies was Miss Clara B. Spence. who in 1895 became interested in the subject of adoption. and worked in close co-operation with her friend Miss Josephine Plows-Day. of London — founder of the National Children's Adoption Society of England. The Spence Alumnae Association was formed to carry on her work."

Henry Dwight Chapin, one-time president of the American Pediatric society. and his wife were also much interested in the subject of the adoption of children and organized the Alice Chapin Adoption nursery in New York city. Most of their babies were cared for in supervised boarding homes — designated as Speedwell units.

In 1923 the Cradle society was organized in Evanston. Ill., by Florence Dahl Walrath. The Cradle is a model adoption nursery for babies deprived by whatever circumstances of proper care. During the first few years of 'its existence, the mortality rate of infants cared for at the Cradle was remarkably low, in comparison with the 10% which had long been accepted as an irreducible minimum for institutions caring for babies. In 1927, however, there was throughout the United States an epidemic of enteritis with a high mortality rate. It baffled the best medical minds. This problem was solved by work done at the Cradle by George and Gladys Dick and J. Lisle Williams. As a result. a new aseptic nursery technique was evolved at the Cradle by Gladys Dick. It was put into effect in 1928 and has been rigidly adhered to ever since, resulting in a mortality rate of less than .05% and no instance of hand-borne cross infection. In 193j Louis W. Sauer gave a detailed report on the Dick diet kitchen and nursery technique. Following this. the New York city and Chicago departments of health passed new regulations requiring all maternity hospitals to use a similar aseptic technique in their newborn nurseries.

In 1938 the Cradle society erected a building designed to further scientific research on the prevention of air-borne cross infections. The Cradle showed that nearly all infants who are given up for adoption are adoptable. More than 7.000 infants were cared for by the Cradle and 6.090 of them placed in adoption between its founding in March 1923 and June 30, 1954. There were 95 deaths and the remainder were claimed by their parent(s) or placed in institutions' for needed care. Adoption nurseries properly equipped. like the Cradie. for the scientific care of infants during the first few months of life. when they are under the close observation of pediatricians. can remove the need for institutions for the care of the majority of babies who formerly were reared in foundling hospitals and orphanages. (F. D. W.; H. R. F.)

FOUNDRY TYPE, in printing, is reusable metal type cast from an alloy of 62% lead, 13% tin and 25% antimony. Sometimes up to 2% of copper is also added *(see* TYPE METAL). With a melting point of 32j° C. and a Brinell hardness number of 34— higher than any hot-metal, machine-set type — foundry type is used for the highest quality of printing work since it will retain its clarity for long periods without causing the impression to become light. The greatest disadvantage of foundry type is the slowness of setting and justifying it by hand *(see* PRINTING TYPE: *Composition).* Because of this it has given way in most instances to the use of hot-metal, machine-set type. It is still used, however, by many job printers as well as for large headlines on many newspapers.

FOUNTAIN, a term applied to simple arrangements for letting water gush into a basin, and to more elaborate ones in which water is forced mechanically in high jets. The term is applied equally to the ornamental receptacle and to the jet of water itself.

An early example is preserved in the carved Babylonian basin (*c.* 3000 B.C.) found at Tello, the ancient Lagash in Mesopotamia. An Assyrian fountain discovered in the gorge of the Gomel river consists of basins cut in solid rock and descending in steps to the stream. Small conduits led the water from one basin to the other, the lowest of which uas ornamented by tuo rampant lions in relief.

Greek. — During the Aegean civilization, as in later Hellenic Greece, springs were frequently considered sacred and shrines were built around them, the water often emerging into artificial basins.

In historic Greece, more highly developed fountains existed; both literary references and excavated remains abound. Sometimes a planted grove or architectural setting provided for nearby shrines. Some were surrounded by columns; as at Lerna. The city of Corinth was noted for its fountains, particularly the spring dedicated to the nymph Pirene. Greek fountains were utilitarian as well, being provided with ample draw basins and reservoir supply and often shaded by a portico.

Roman. — In Roman civilization, water was distributed from each terminal reservoir, or *castellum,* to baths and large houses as well as to many public fountains which supplied the bulk of the population. Examples uncovered at Pompeii illustrate both types, the more decorative courtyard fountain of the aristocratic house and the utilitarian public street fountain. The latter consisted of a simple rectangular stone basin with a small pedestal above it carved with a human or animal head from whose mouth water flowed. The lip of the basin was notched for overflow.

In addition to the above types, the Romans developed the nymphaeum (*q.v.*), a purely decorative type of fountain originating in Hellenistic times. Roman nymphaea became monumental pleasure houses. often in the shape of an exedra covered by a half dome. The details of the fountain proper varied from multiple basin arrangements to the jet of water issuing from a sculptured figure. The architectural decoration was rich, often in mosaic. In addition to actual remains. wall paintings of the period illustrate Roman fountains and testify to their popularity as garden decorations.

In early Christian times. fountains were placed in the atrium court of the Christian basilica as symbols of purification; *e.g.,* old St. Peter's, Rome. Similar courtyard fountains continued to be used in the monasteries of western Europe and the Byzantine empire (*e.g.,* Cluny; Vatopedi on Mt. Athos).

Medieval. — In the earlier middle ages, ornamental and architectural treatment of fountains passed out of use; wells furnished the greater part of the necessary water. From the 12th century, however, public fountains began to reappear and the spring fountains received architectural treatment. The usual form of the latter consisted of a large basin reached by a descending stairway and covered over with a vault, sometimes enclosed and sometimes supported only on piers. At Poitiers, the Fontaine Joubert (14th century, restored 1597) was originally of this type. Other crude examples are common in Brittany. The public fountains of the medieval towns usually had a polygonal or circular basin, occasionally lobed, in the centre of which rose a column or pier carrying a series of spouts. The architectural details are of infinite variety. From the simple hexagonal vase and column of the 12th-century fountain at Provins to the elaborate richness of the 15th-century fountains of southern Germany, every kind of Gothic detail is found. Fountains were a peculiar feature of the communal building activities of the late middle ages, often commissioned by guilds. Few of these survive. A noteworthy example is the Schone

Brunnen at Nürnberg (1398), distinguished by its high, rich Gothic spirelet with many statues and ironwork railing.

The late middle ages developed decorative table fountains as extravagant toys. Also, contemporary Byzantine court versions of table fountains running with spiced wines are recorded. Unfortunately no examples of this type have survived.

Islamic. — The fountains of Moslem countries are of great importance, especially the public drinking fountains, called sebeels. They are an institution in the east. A common type is the simple spout and basin enclosed within a graceful niche. The more ambitious designs take the form of a richly decorated pavilion.

Renaissance and Baroque. — The Renaissance in Italy began a new phase of fountain design in which sculpture became prominent. A common type was a sequence of circular or polygonal basins on a vertical support topped by a fountain figure from which water spouted. Leonardo da Vinci did designs for fountains. During the following period of the Italian baroque, fountains became complex compositions of basins, sculpture and water display. Rome is noted for its many fountains of baroque design, notably the Fountain of the Rivers (1647) in the Piazza di Navona by Giovanni Bernini and the Trevi fountain (completed 1762) by Nicola Salvi. Such fountains dramatized the rebuilding of the city, its piazzas and its churches, done under papal direction.

In addition to these public fountains, the Italian development included an enormous number of original villa garden fountains of spectacular and sometimes amusing designs. Trick effects were made possible by elaborate mechanical devices. For example, the water organ at the Villa d'Este, Tivoli (1549), played only when certain pavement stones were stepped on. The hillside location of most villas was utilized, upper fountains supplying the lower ones in turn as at the Villa d'Este and the cascade at Villa Aldobrandini, Frascati.

Italian precedent set the design for monumental civic fountains and for ornamental garden fountains in northern and western Europe.

An early example of an ornamental fountain in France is the Fountain of the Innocents (1550) in Paris by Jean Goujon, an original work which does not follow Italian models. The Medici fountain in the Luxembourg gardens in Paris by Salomon de Brosse is a fine example of the niche type. The most spectacular and ambitious fountains in France are those at Versailles, part of the vast garden complex designed by André Lenôtre (1661). Large reflecting pools were part of the axial scheme and fireworks often accompanied the fountain display. Hardly secondary to the artistic achievement was the engineering feat of supplying water in volume and pressure to run the numerous fountains at Versailles. Purely ornamental fountains continued to be popular in the 18th century as focal points for civic design in large cities and as decoration for royal palaces and country seats.

Modern.—Chatsworth in England was noted for its fountains designed by Sir Joseph Paxton in the 19th century, especially the single jet of water 260 ft. high issuing from a formal reflecting pool. Elsewhere at Chatsworth, a false willow tree of copper rained water on the unsuspecting beneath its branches.

In the 19th and 20th centuries fountains did not lose their popularity although quality and imagination is less evident. Expositions have provided occasion for ambitious fountain displays. Among the many examples are the Crystal palace at Sydenham, London; the World's Columbian exposition at Chicago, Ill. (1893) and the New York World's fair (1938). At the Festival of Britain, London (1951), a mobile water sculpture composed of pivoted receptacles was set in motion by changing points of gravity. When each receptacle was filled, it would overturn only to right itself and be filled again with water from above. Of permanent fountains, a fine modern example, although derivative in design, is the Buckingham Memorial fountain in Chicago (1927) by Jacques Lambert. (T. F. H.; H. F. K.)

FOUNTAIN **PEN,** a writing instrument in which a quantity of writing fluid is contained in a reservoir in a holder, the fluid communicating with a writing point or nib through a channel in a fluid control called a feed. The nib extends from one end of the holder and is covered by a cap when the fountain pen is not in use, the cap being detachably engaged with the holder.

While the fountain pen had its origin much earlier, the beginning of its popularity was in the 1880s, and it became one of the most essential items of use, with millions being produced and sold each year.

The writing point or nib is the heart of the fountain pen, and its writing expresses the individuality of the user. Nibs are generally made in various point gradations ranging from a needlelike point to one which produces a line about $\frac{1}{16}''$ in width. About 90% of the nibs sold are in the fine and the medium nib gradations although a full line would include the following types: accountants, extra fine, shorthand, fine, medium, coarse, stub, broad stub, left oblique, right oblique and music points. Also, the nibs are produced in various degrees of flexibility ranging from manifold to flexible, the manifold being an almost rigid point and the flexible one bending with the least amount of pressure.

Because of the expected long life of a fountain pen, a metal highly resistant to the corrosive action of writing fluids is preferably used for the nibs, the most popular being stainless steel and 14-carat gold. Because these materials are relatively soft, that portion of the nib which contacts the writing surface in writing is provided with a relatively hard tipping material, preferably an alloy of metals of the platinum group, in order to resist wear and thus to obtain a long life.

The feed for controlling the movement of the writing fluid is made of plastic or of hard rubber and underlies and in most instances supports the nib. Air and writing fluid channels in the feed communicate between the reservoir of the holder and the nib, fluid from the reservoir moving down the fluid channel to supply the nib as air moves up the air channel to take the place of the fluid in the reservoir. These channels are of capillary dimensions, and a delicate balance of pressures outside and inside the reservoir holds the fluid in the reservoir and overcomes the force of gravity. This balance is broken when. in writing, the capillary cells in the paper or other writing surface draw fluid from the slit in the nib, the slit being supplied from the fluid channel of the feed.

Because the reservoir is seldom completely full of fluid, it contains air and frequently in a substantial amount. Temperature and pressure conditions act to expand or contract the air in the reservoir. For example. a rise in temperature caused by body temperature in holding the pen or a decrease in pressure by gaining altitude in air travel causes an expansion of the air in the reservoir. If the pen is held in a writing position, the expanding air is behind the fluid and forces it out of the reservoir. Comb cuts in the feed forming capillary chambers in communication with the air and fluid channels accommodate the fluid in excess of that needed for writing. Continued writing uses the oversupply in the comb cuts before fluid is again withdrawn from the reservoir.

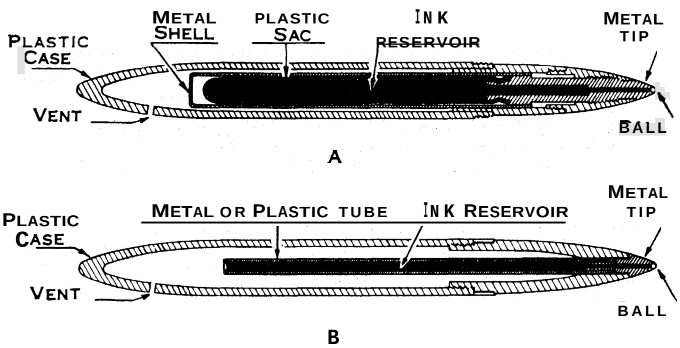
The filling of the reservoir, initially done manually with an eye-dropper, is now done automatically in different ways. One common type of reservoir is a flexible rubber sac which is deflated mechanically or pneumatically. Upon release of the deflating means, the sac inflates by its own resiliency and fills itself by suction as the nib is immersed in writing fluid. The other common type of automatic filling means is that by which the bore of the holder is the reservoir, and the movement of a piston fitted to the bore creates a suction to fill the bore as the nib is immersed in writing fluid.

The holder, originally made of vulcanized rubber, is made of a plastic. There are several different plastics used, each depending on the quality of the product or the facilities of the manufacturer. The early plastic holders were drilled from solid plastic rod. Later the holders were wrapped into cylindrical form from sheet material, and still later most holders were moulded from plastic moulding powders. The plastic materials have the advantage of appearance appeal and are structurally stronger than the vulcanized rubber originally used.

Caps of fountain pens. while protecting the nibs from damage, have the principal function of preventing evaporation of the water from the water-based inks used in them. The caps are frictionally or threadedly engaged with the barrel for detachable engagement therewith. Usually there is a hermetically sealed relation between the cap and the barrel to prevent an accumulation of dried dye from the writing fluid clogging the ink channels and preventing normal writing action.

Ball Point Pen.—In this type of instrument a ball, housed within a socket of a tip, transfers a viscous ink from a reservoir onto a writing surface.

Patents on ball point pens in several countries date back to the late 1800s, and commercial constructions appeared as early as 1895. It was not until 1944, however, that the ball point pen be-



FOUNTAIN PEN AND MECHANICAL PENCIL MFRS. ASSB., INC.

BALL POINT PENS: (A) SAC TYPE: (B) STANDPIPE TYPE

gan its ascendency in the writing instrument field. The impetus was supplied by the office of the quartermaster general of the United States which had requested of industry a writing instrument which would not leak in high altitudes, having an ink which would be unaffected by climatic changes and be quick drying, and which would have a sufficient supply of ink in the reservoir to last a considerable length of time.

The ball point pen usually comprises a holder for containing a replaceable writing unit although in some instances the holder itself is the writing unit and is discarded after the ink is used up. In either event the writing unit consists of a metal tip having at the point a socket which contains a ball. The lip of the socket is constructed so that the ball cannot fall out, yet can rotate freely when in contact with the writing surface. The inner construction of the socket is such that the ball is constantly bathed in ink from a reservoir.

The ink reservoirs of ball point pens are of two types. One comprises a flexible synthetic resin sac housed in a metal shell and the other a metal or plastic rigid tube, one end of which is open and is attached to the writing tip. The ink capacity of ball point pen reservoirs generally ranges from 0.5 to 1.5 ml.

The balls used are steel bearing and in some instances synthetic sapphire balls which are very hard and highly accurate as to sphericity. Most manufacturers use a ball 1 mm. in diameter, although a few special purpose pens have been made using larger as well as smaller balls.

Satisfactory ball point pen inks are highly specialized materials. They are viscous liquids having either oil-soluble dyes or spirit-soluble dyes. The type of ink containing the oil-soluble dyes dries by absorption into the paper or other writing surface while the type of ink containing spirit-soluble dyes dries by evaporation.

(F. L. KG.)

FOUQUÉ, FERDINAND ANDRÉ (1828–1904), French geologist and petrologist, was born at Mortain, La Manche, on June 21, 1828. In 1877 he became professor of natural history at the Collège de France, in Paris. As a stratigraphical geologist he rendered much assistance on the geological survey of France, and he was the first to introduce modern petrographical methods into France.

Fouqué died on March 7,1904.

His chief publications were: *Santorin et ses éruptions* (1879); with A. Michel Lévy *Minkralogie micrographique, Roches éruptives françaises,* 2 vol. (1879); and *Synthèse des minkraux et des roches* (1882).

FOUQUE, FRIEDRICH HEINRICH KARL DE LA MOTTE, BARON (1777–1843), one of the early German romantic writers, was born of French Huguenot stock in Brandenburg, Feb. 12. 1777. A godson of Frederick the Great, and loyal to the Hohenzollern house, he composed most of his works with the patriotic intention of awakening in his contemporaries during the Napoleonic era an awareness of German tradition and national character. He also tried to re-establish confidence in aristocratic government. His ideas were based on the view of linguistic development developed by J. G. Fichte, and he stressed the influence of the mother tongue in shaping the mind. At first his romantic allegories and popular versions of Germanic myth were enthusiastically received, but after 1820 his ideas were increasingly rejected as outmoded, his approach as unrealistic. Of his prolific writings only the fairy tale *Undine* (1811; modern edition by W. W. Chambers, 1956; Eng. trans., with other stories, by E. Gosse, 1932) is still widely known. For the literary historian, *Der Held des Nordens* (1810), the first modern dramatic treatment of the *Nibelungen* story, and *Der Zauberring* (18'13; Eng. trans., 1846), a popular allegorical novel describing the racial complex of Europe, are, however, of interest. The conventional rating of Fouqué dismisses him as an unpractical dreamer, underestimating his thorough scholarship in the matters of Germanic folklore and even more his effective writing between 1810 and 1820. During that decade he was highly esteemed by A. W. Schlegel, among many others, and was chosen as their literary sponsor by Adelbert von Chamisso and Joseph Eichendorff. He died in Berlin (Jan. 23, 1843) in poverty, after belated recognition by Frederick William IV.

FOUQUET, JEAN (*c.* 1415–1485), French painter remembered especially for his miniatures, was born at Tours. He visited Italy before 1447, since he executed the portrait of Pope Eugenius IV, who died in that year at Rome. There he absorbed the progress that such Italian painters as Tommaso Masaccio. Fra Angeliro and Piero della Francesca had made in the handling of central

SOCIÉTÉ GIRAUDON

"CHARLES VII" BY JEAN FOUQUET. IN THE LOUVRE, PARIS perspective and foreshortening and in the rendering of plasticity and volume.

Upon his return to Tours Fouquet created a new, realistic art similar to that of Jan van Eyck in Flanders, with the same exquisite precision of characterization and detail. He was soon favoured in court circles by the king and high nobility. Like other great painters of the 15th century, he worked both as a panel and a miniature painter. He even worked in enamel, as his remarkable medallion with the self-portrait in the Louvre proves. For the royal secretary and lord treasurer, Étienne Chevalier, he executed between 1450 and 1460 his most famous works: a large "Book of Hours" with about 60 full-page miniatures, of which 40. now dismembered, are among the great treasures of the castle of Chantilly; the diptych from Notre Dame at Melun with Chevalier's portrait (Kaiser Friedrich museum); and a Madonna with the features of Agnes Sorel, the king's mistress (Antwerp museum). In these works he revealed his unsurpassed mastery of the new monumental representation which permeated European art in this century. In the same decade he also painted the portrait of King Charles VII (Louvre, Paris) and his queen (now lost), and that of the royal chancellor, Guillaume Jouvenel des Ursins (Louvre). Also to this last decade of the reign of Charles VII belong the two richly illuminated manuscripts, Boccaccio's *Cas des Nobles Hommes et Femmes* (1458, Munich library), and a copy of the *Grandes Chroniques des Rois de France* (Bibliothèque Nationale, Paris); and finally, the large altarpiece of the "Pietà," which was discovered in the church at Nouans. The latter represents his only monumental painting, since his "Ascension of the Virgin," painted for the archbishop of Tours in 1763, was destroyed by the iconoclasts.

In 1469 King Louis XI founded the Order of Saint Michael, and Fouquet was charged to illuminate the statutes of the order (Bibliothèque Nationale, Paris). In 1474 he worked with the sculptor Michel Colombe on the design of the king's tomb, and in the same year received the official title of royal painter. About the same time he completed the illustration of two volumes of Josephus' *Antiquités judaïques* (Bibliothèque Nationale, Paris). *See* also ILLUMINATED MANUSCRIPTS: *15th- and 16th-Century.*

(P. W.)

FOUQUET (or FOUCQUET), **NICOLAS** (1615–1680), viscount of Melun and of Vaux, marquis of Belle-Isle, superintendent of finance in France under Louis XIV, was born in Paris in 1615. He belonged to an influential family of the *noblesse de la robe*, and was admitted as *avocat* at the parliament of Paris at the age of 13. In 1636 he bought the post of *maître des requêtes*. From 1642 to 1650 he held various intendances at first in the provinces and then with the army of Jules Mazarin, and, coming thus in touch with the court, was permitted in 1650 to buy the important position of *procureur général* to the parliament of Paris. During Mazarin's exile Fouquet shrowdly remained loyal to him, protecting his property and keeping him informed of the situation at court.

Upon the cardinal's return, Fouquet demanded and received as reward the office of superintendent of the finances (1653). The appointment was a popular one with the moneyed class, for Fouquet's great wealth had been largely augmented by his marriage in 1651 with Marie de Castille, who also belonged to a wealthy family of the legal nobility. His own credit, and his unfailing confidence in himself, strengthened the credit of the government, while his high position as *procureur général* secured financial transactions from investigation. As minister of finance, he soon had Mazarin almost in the position of a suppliant. The long wars, and the greed of the courtiers, made it necessary at times for Fouquet to borrow upon his own credit, but he soon turned this confusion of the public purse with his own to good account. The disorder in the accounts became hopeless; fraudulent operations were entered into with impunity, and the financiers were kept in the position of clients by official favours and by generous aid whenever they needed it. Mazarin was too deeply implicated in similar operations to interfere, and was obliged to leave the day of reckoning to his agent and successor Jean Baptiste Colbert. Upon Mazarin's death Fouquet expected to be made head of the government; but Louis XIV decided otherwise. In Aug. 1661 Louis XIV, already set upon his destruction, was entertained at Fouquet's great house at Vaux with a *fête* rivalled in magnificence by only one or two in French history. The splendour of the entertainment sealed Fouquet's fate. Three weeks after his visit to Vaux the king took Fouquet with him to Nantes and had him arrested on the charge of embezzlement. His trial lasted almost three years, and violated the forms of justice. Public sympathy was strongly with Fouquet, and Lafontaine, Madame de Sévigné and many others wrote on his behalf; but when Fouquet was sentenced to banishment, the king, disappointed, "commuted" the sentence to life imprisonment. He was sent at the beginning of 1665 to the fortress of Pignerol, where he died on March 23, 1680.

FOUQUIER-TINVILLE, ANTOINE QUENTIN (1746–1795), French revolutionary, was born at Hérouel, Aisne. Originally a *procureur* attached to the Chatelet at Paris, he sold his office in 1783 and became a clerk under the lieutenant-general of police. He was public prosecutor to the Revolutionary Tribunal of Paris (March 10, 1793, to July 28, 1794). His function was not so much to convict the guilty as to see that the proscriptions ordered by the faction for the time being in power were carried out with due regard to a show of legality. He was as ruthless and as incorrupt as Robespierre himself; he could be moved from his purpose neither by pity nor by bribes. His passionless detachment made him an effective instrument of the Terror. He had no forensic eloquence; but the cold obstinacy with which he pressed his charges was more convincing than any rhetoric, and he seldom failed to secure a conviction.

His horrible career ended with the fall of Robespierre and the Terrorists on 9 Thermidor. On Aug. 1, 1794, he was imprisoned by order of the Convention and brought to trial. His defense was that he had only obeyed the orders of the Committee of Public Safety; but, after a trial which lasted 41 days, he was condemned to death, and guillotined on May 7, 1795.

See the documents relating to his trial enumerated by M. Tourneux in *Bibliographie de l'histoire de Paris pendant la Révolution Française*, vol. i, no. 4445–4454 (1890); also F. Dunoyer, *Fouquier-Tinville . . .* (1913).

FOURCHAMBAULT, a town of central France in the *département* of Nièvre, on the right bank of the Loire, 4½ mi. N.W. of Nevers, on the Paris-Lyon railway. Pop. (1954) 4,641. It has large iron-works, established in 1821, which produce engineering material for railway, military and other purposes. Among the more remarkable *chefs-d'oeuvre* of the town are the metal portions of the Pont du Carrousel, the iron beams of the roof of Chartres cathedral, and the vast spans of the bridge over the Dordogne at Cubzac. A small canal joins the works to the Lateral canal of the Loire.

FOUR FREEDOMS, a formulation of social and political objectives for the people of the U.S. and, ultimately, the world, as defined by Pres. Franklin D. Roosevelt in his "state of the union" message to congress Jan. 6, 1941. Roosevelt stated these freedoms to be: the freedom of speech and expression, the freedom of every person to worship God in his own way, the freedom from want and the freedom from fear.

An integral part of freedom from fear was Roosevelt's plea for "a world-wide reduction of armaments to such a point and in such a thorough fashion that no nation will be in a position to commit an act of physical aggression against any neighbor—anywhere in the world."

FOUR-H CLUBS. In the early 1900's the sporadic organization of a few corn, canning and poultry clubs in central and southern U.S. states gave rural school children "learning by doing" experience. These clubs were the beginning of the largest volunteer youth organization in the world—the 4-H clubs. By mid-20th century the organization had a membership of more than 2,000,000 rural boys and girls between the ages of 10 and 21, and nearly 300.000 adult and junior leaders in 85,000 clubs throughout the United States and Puerto Rico. Outstanding farmers and homemakers, together with clergymen, teachers and other professional men and women play an important part as volunteer local leaders in the development of 4-H club work.

The 4-H program is conducted under the supervision of the extension service of the state agricultural colleges, the U.S. department of agriculture and county governments co-operating, under the provisions of the Smith-Lever act of 1914 and other acts of congress and of state legislatures authorizing the establishment of agricultural extension work and making appropriations for it.

Each local club is composed of voluntary members who elect their own officers and receive instruction from a volunteer adult or junior leader. Because of the varying types of agriculture in the United States, more than 50 different phases of homemaking and agricultural projects may be undertaken by 4-H club members. For example, in agricultural club activities a club member may voluntarily, under the direction of his local leader and county extension agent and in accordance with recognized improved practices. grow a crop; raise a garden or a flock of poultry; purchase, breed and care for a sow and for her litter of pigs; care for a dairy calf to maturity and build a dairy herd; or run and maintain tractors and other farm machinery.

Much emphasis is placed on the development of constructive citizenship. leadership and intelligent ability to co-operate. the improvement of the health of the individual and the community. and the services that may be rendered in the home, on the farm and in the local community.

The 4-H club emblem is the four-leaf clover with the letter H on each leaf. The club colours are green and white. The white background of the 4-H flag symbolizes purity; the green of the 4-H emblem represents nature's most common colour and also is emblematic of youth. life and growth.

At regular 4-H meetings. achievement days and other club events, the giving of the 4-H pledge has a prominent place. It is as follows:

I pledge

My Head to clearer thinking,
My Heart to greater loyalty,
My Hands to larger service, and
My Health to better living, for
My Club, my Community, and my Country.

The U.S. department of agriculture sponsors and directs annually a National 4-H camp in Washington, D C.. during which member delegates become acquainted with the functions of the government in general and those of the department of agriculture in particular. Youth leaders of many lands are special guests at the National 4-H Camp. This is in line nith the 4-H effort to share world friendships with rural youth of the cultures.

A major annual event is the National 4-H Club congress. to which members are named delegates as rewards for outstanding records of achievement in 4-H club work. This event is conducted jointly by the co-operative extension service and the National Committee on Boys and Girls Club Work, Inc. The committee, which publishes *National 4-H News,* a monthly magazine. and provides incentives for meritorious 4-H work. is a privately supported voluntary group of citizens, incorporated not for profit.

(G. L. NE.)

FOUR HUNDRED, in the United States, the expression popularly used to denote the inner circle of highest society. The term originally applied to New York city society and is said to have arisen in 1892 when Mrs. William Astor asked Ward McAllister, a celebrated leader of society in New York city, to assist her in cutting down the invitation list of her annual ball to 400 persons as that was as many as her ballroom would accommodate. McAllister, who held a unique though self-appointed position as directing executive of New York society functions at that time, was heard to remark afterward at one of his clubs that there were really only 400 people living in New York city who had any claim to be called "society." The remark nas repeated and spread rapidly until newspapers and magazines were full of discussions on it. From that time on the term became commonly used. It has, however, lost all meaning in recent years. There is no New Tork society in McAllister's sense of the term. There are scores of social groups and levels but no hierarchy.

FOURIER, FRANÇOIS MARIE CHARLES (1772–1837), French socialist writer. was born at Besançon, Franche-Comté, on April 7, 1772. After completing his studies there he travelled for some time in France, Germany and Holland. Fourier entered the army, but after two years' service as a chasseur was discharged because of ill-health. In 1803 he published a remarkable article on European politics which attracted the notice of Napoleon. some of whose ideas were foreshadowed in it. Inquiries were made after the author, but nothing seems to have come of them.

After leaving the army Fourier entered a merchant's office in Lyons. and some years later undertook on his own account a small business as broker, devoting his leisure time to study.

He had become deeply impressed with the conviction that social arrangements resulting from the principles of individualism and competition mere essentially imperfect and immoral. He proposed to substitute for these principles co-operation or united effort, by means of which full and harmonious development might be given to human nature. The scheme, worked out in detail in his first work, *The'orie des quatre mouvements* (2 vol., Lyons, 1808, published anonymously), has for foundation a particular psychological proposition and a special economical doctrine. Psychologically Fourier held what may with some laxity of language be called natural optimism — the view that the full. free development of human nature or the unrestrained indulgence of human passion is the only possible way to happiness and virtue, and that misery and vice spring from the unnatural restraints imposed by society on the gratification of desire. This principle of harmony among the passions he regarded as his grandest discovery. Throughout his works, in uncouth, obscure and often unintelligible language, he demonstrates the fundamental harmony to be found in the four great departments — society! animal life, organic life and the material universe. In order to give effect to this principle and obtain the resulting social harmony, society should be reconstructed; for, in the existing drganization of society innumerable restrictions are imposed upon the free development .of human desire. As practical principle for such a reconstruction Fourier advocated co-operative or united industry. But the full realization of his scheme demanded much more than the mere admission that co-operation is economically more efficacious than individualism. Society as a whole must be organized on the lines requisite to give full scope to co-operation and to the harmonious evolution of human nature.

Society. on his scheme, is to be divided into departments or *phalanges*, each *phalange* numbering about 1.600 persons. Each *phalange* inhabits a *phalanstère* or common building. and has a certain portion of soil allotted to it for cultivation. The *phalanstères* are built after a uniform plan, and the domestic arrangements are laid down very elaborately. The staple industry of the *phalanges* is, of course, agriculture. but the various *séries* and *groupes* into which the members are divided may devote themselves to such occupations as are most to their taste; nor need any occupation become irksome from constant devotion to it. Any member of a group may vary his employment at pleasure. may pass from one task to another. The task regarded as menial or degrading in ordinary society can be rendered attractive if advantage is taken of the proper principles of human nature. It is not, on Fourier's scheme, necessary that private property should be abolished, nor is the privacy of farnily life impossible within the *phalanstère*. Each family may have separate apartments, and there may be richer and poorer members. But the rich and poor are to be locally intermingled, in order that the broad .distinction between them, which is so painful a feature in actual society. may become almost imperceptible. Out of the common gain of the *phalange* a certain portion is deducted to furnish to each member the minimum of subsistence; the remainder is distributed in shares to labour, capital and talent — five-twelfths going to the first; fourtwelfths to the second and three-twelfths to the third. Upon the changes requisite in the private life of the members Fourier was in his first work more explicit than in his later writings. The institution of marriage is of necessity abolished; a new and ingeniously constructed system of licence is substituted.

The scheme thus sketched attracted no attention when the *Théorie* first appeared, and for some years Fourier remained in his obscure position at Lyons. In 1812 the death of his mother put him in possession of a small sum of money, with which he retired to Bellay in order to perfect his second work. The *Traité de l'association agricole domestique* was published in two volumes at Paris in 1822, and a summary appeared in the following year. After its publication the author proceeded to Paris in the hope that some wealthy capitalist might be induced to attempt the realization of the projected scheme. Disappointed in this expectation he returned to Lyons. In 1826 he again visited Paris, and as a considerable portion of his means had been expended in the publication of his book, he accepted a clerkship in an American firm. In 1829 and 1830 appeared what is probably the most finished exposition of his views, *Le Nouveau monde industriel.* In 1831 he attacked the rival socialist doctrines of Saint-Simon and Owen in the small work *Pièges et charlatanisme de deux sectes, St. Simon et Owen.* His writings now began to attract some attention. A small body of adherents gathered around him, and the most ardent of them was Victor Considérant (*q.v.*). In 1832 a newspaper, Le *Phalanstdve ou la rtforme industrielle* was started to propagate the views of the school, but its success was not great. In 1833 it declined from a weekly to a monthly, and in 1834 it died of inanition. It was revived in 1836 as *Le Phalange,* and in 1843 became a daily paper, *La Ddmocratie pacifique.* In 1850 it was suppressed Fourier did not live to see the success of his newspaper, and the only practical attempt during his lifetime to establish a *phalanstdre* was a complete failure In 1832 M Baudet Dulary, Deputy for Seine-et-Oise, who had become a convert, purchased an estate at Condé-sur-Vesgre, near the forest of Rambouillet, and proceeded to establish a socialist community. The capital supplied was, however, inadequate, and the community broke up in disgust. Fourier was in no way discouraged by this failure, and until his death, on Oct 10, 1837, he lived in daily expectation of the realization of his scheme.

Several experiments on the lines laid down by Fourier were made in the United States by American followers of Fourier, whose doctrines were introduced there by Albert Brisbane (1809–1890). Indeed, in the years between 1840 and 1850, during which the movement waxed and waned, no fewer than 41 *phalanges* were founded, of which some definite record can be found. The most interesting of all the experiments, not alone from its own history, but also from the fact that it attracted the support of many of the most intellectual and cultured Americans, was that of Brook Farm (*q.v*).

FOURIER, JEAN BAPTISTE JOSEPH, BARON (1768–1830), French mathematician and physicist famous for his pioneer work on the representation of functions by trigonometric series, was born at Auxerre, France, on March 21, 1768, the son of a tailor. Left an orphan at eight years, he was admitted. through the influence of the bishop, to the military school at Auxerre, where he revealed his mathematical talent. Unable to enter the artillery because of his low birth, he became a teacher in mathematics at the military school in 1784 and later took a prominent part locally in promoting the Revolution, although he objected to the Terror. He taught at the Bcole Normale at Paris from its institution in 1795, where his success soon led to the offer of the chair of analysis at the École Polytechnique. He was one of the savants who accompanied Bonaparte to Egypt in 1798 and was made governor of lower Egypt. Returning to France in 1801 he became prefect of Isère, with headquarters at Grenoble. M'hile there he carried on elaborate investigations into the conduction of heat. In 1815 he rejoined Napoleon during the Hundred Days. Following the second restoration he settled in Paris in 1816. He was made a member of the Academy of Sciences in 1817 and he became joint secretary with G. Cuvier in 1822. Believing that desert heat was ideal for health, he lived swathed like a mummy in overheated rooms.

Fourier died in Paris on May 16, 1830.

Fourier's masterpiece was his mathematical theory of heat conduction stated in *Théorie Analytique de la Chaleur* (1822; trans. by A. Freeman, 1872), one of the most important books published in the 19th century. It marked an epoch both in the history of pure and of applied mathematics, for in it Fourier developed the theory of the series known by his name and applied it to the solution of boundary-value problems in partial differential equations *(see* FOURIER SERIES). This work brought to a close a long controversy, and henceforth it was generally agreed that almost any function of a real variable can be represented by a series involving the sines and cosines of integral multiples of the variable. The first announcement of this discovery was made by Fourier in 1807. By his method the coefficients in any series of this type can be expressed in a form suitable for computation. The process is the same mathematically as the analysis of a musical sound into its fundamental and successive harmonics. Fourier's work was not received without criticism, the weak point in his analysis being his failure to provide a general proof that the Fourier series actually converges to the value of the function concerned.

This difficulty was not satisfactorily resolved until the development of the Lebesgue integral nearly a century later.

(G. J. Ww.)

FOURIER SERIES. Let us consider first an infinite series *(see* SERIES)

$$(1)\quad \tfrac{1}{2}a_0+(a_1\cos x+b_1\sin x)+(a_2\cos 2x+b_2\sin 2x)+\dots,$$

where the quantities a_0, a_1, b_1, a_2, b_2, ... are constants, and x is a variable taking any value between $-\infty$ and $+\infty$. Such series are called *trigonometric.* Suppose now that series (1) converges for all values of x, and let $f(x)$ denote the sum of the series. The function $f(x)$ is periodic, of period 2π, since replacing x by $x+2\pi$ does not change the series. If we multiply both sides of the equation $f(x)=\tfrac{1}{2}a_0+(a_1\cos x+b_1\sin x)+\dots$ by $\cos nx$ or $\sin nx$ and integrate the result over the interval $(0, 2\pi)$, we obtain that

$$(2)\qquad a_n=\frac{1}{\pi}\int_0^{2\pi}f(x)\cos nx\,dx,\quad b_n=\frac{1}{\pi}\int_0^{2\pi}f(x)\sin nx\,dx,$$

for all n. Though this argument is purely formal (it is justified, if series (1) converges uniformly, or even in some more general cases), it suggests the following important problem. Suppose we take any function $f(x)$ of period 2π, compute the numbers a_n, b_n by means of formulas (2), and form the series (1). Does the series so defined represent the function $f(x)$? The numbers (2) are called the *Fourier coefficients* of the function $f(x)$, and the series (1) just obtained is the *Fourier series* of $f(x)$. The fact that, under suitable conditions concerning $f(x)$, the problem just stated admits of an affirmative answer, is one of the main achievements of the theory of Fourier series. The latter take their name from Jean Baptiste Fourier, who based on them his mathematical theory of conduction of heat. Fourier's work *Théorie Analytique de la Chaleur* was published in 1822, but the discovery of Fourier series dates back to the first half of the 18th century, in connection with the problem of vibrating chords (Daniel Bernoulli, Leonhard Euler). Thus Fourier series originated in problems of mathematical physics, and they continue to be a very valuable tool there.

Not less important are Fourier series in mathematical analysis. Very often they appear there in a more general form, as *orthogonal* series *(see* below), and provide a unifying link of various mathematical theories, like differential and integral equations, analytic functions, etc. Especially important are trigonometric (and, in particular, Fourier) series for the theory of analytic functions, since for $z=e^{ix}$ the real part of the power series *(see* SERIES)

$$(3)\qquad \tfrac{1}{2}a_0+(a_1-ib_1)z+(a_2-ib_2)z^2+$$

is the series (1). Thus trigonometric series are real parts of power series, and so form a bridge between real and complex functions. However, while stressing the value of trigonometric series as a method of investigation, we should also be aware of the great role it played in the historic development and clarification of various mathematical concepts, some of them quite abstract. A few examples may suffice.

Already in the days of its inception, in the 18th century, the theory of Fourier series stirred controversies in connection with the notion of mathematical function (see FUNCTION). The general attitude at that time was to call $f(x)$ a function, if $f(x)$ could be represented by a single analytic expression, like a polynomial, a power series, a trigonometric series, etc. If the graph of f(x) were "arbitrary," *e.g.* a polygonal line, f(x) would not have been accepted as a function. So it came as a shock to many when the discovery of Fourier series showed that many such ('arbitrary" graphs could be represented by trigonometric series, and so should be treated as functions. It took a long time before the matter was completely clarified, and it was not merely a coincidence that the now universally adopted definition was first formulated in a memoir of Lejeune-Dirichlet (1837) devoted to the theory of Fourier series. (Incidentally, this memoir contains the first rigorous proofs of the representation of functions by their Fourier series. The work of Fourier himself and of his predecessors was rather formal.) Another instance of application of trigonometric series to the theory of functions is due to Karl Weierstrass, who gave the first example of a continuous function without a derivative at any point. Weierstrass' function was given in the form of a trigonometric series, and it exemplified the general fact that trigonometric series are particularly useful in the construction of functions with various peculiarities. Another much more imvortant example of the influence of Fourier series may be found in the history of the notion of integral. On account of formulas (2), this notion is a prerequisite to that of Fourier series. It is therefore interesting to note that the classical definition of integral, due to Bernhard Riemann (usually given in the textbooks of Calculus) was for the first time expounded in the latter's fundamental paper Ueber die Darstellbarkeit einer *Funktion durch eine* Trigonometrische Reihe (1854). The ideas contained in that paper influenced the work of Georg Cantor concerning the uniqueness of the representation of a function by a trigonometric series. Cantor had to consider various sets of points which would not interfere with the uniqueness of representation. Starting from simplest cases he tried to master the structure of such sets—"sets of uniqueness" (see below). He was not completely successful, and the problem is still open, but his investigations led him to the general theory *of* sets, and in particular of point sets, which was one of the greatest mathematical discoveries of the 19th century. His results have permeated, and changed the aspect of many mathematical theories. The theories of measure and of integral developed later by Emile Borel and Henri Lebesgue, which are so fundamental in mathematical analysis, find their roots in Cantor's work on the theory of sets.

Particularly important is the work of Lebesgue, who through his theory of integral put Fourier series on a new basis. Though more general definitions of integral are possible, and though some of them are of interest for Fourier series, Lebesgue's definition is the most appropriate and almost universally adopted in research. In this connection, mention should be made of work of Arnaud Denjoy who showed that, with a definition of integral more general than that of Lebesgue, an everywhere convergent trigonometric series is always the Fourier series of its sum. Important for Lebesgue's theory is the notion of set of measure zero. A point set S situated, for example, on a straight line is said to be of measure zero if S can be covered by a finite or infinite system of intervals of total length arbitrarily small. In Lebesgue's theory sets of measure zero are considered as negligible, and if a certain property holds for all points except those forming a set of measure zero, that property is said to hold almost everywhere.

Convergence and Divergence of Fourier Series.—Let $s_n(x)$ denote the sum of the first $n+1$ terms of series (1). Using (2), we get

$$(4) \qquad s_n(x)=\frac{1}{\pi}\int_0^{2\pi} f(x+t)\,\frac{\sin\,(n+\frac{1}{2})t}{2\,\sin\,\frac{1}{2}t}\,dt,$$

a formula basic for Fourier series. It may be proved that, as n increases indefinitely, $s_n(x)$ tends to $f(x)$, provided the function f(x) satisfies certain conditions. For example, if the graph of the function $f(x)$ in the interval $0\leq x\leqq 2\pi$ has only a finite number of maxima and minima (Dirichlet's condition), the Fourier series of $f(x)$ converges to $f(x)$ at every point of continuity of the function. At the points x where such a function is discontinuous, the Fourier series also converges, its sum being &$[f(x+0)+f(x-0)]$ (where $f(x+0)$ is the limit of the function at the point x from the right, and $f(x-0)$, a similar limit from the left). Another condition ensuring the convergence of the Fourier series, to sum f(x), is the convergence of the integral

$$\int_0^{\pi}\frac{|f(x+t)+f(x-t)-2f(x)|}{t}\,dt$$

(the Dini condition). It certainly is satisfied at every point where the function f(x) is differentiable. These and all other known conditions for convergence are *sufficient* conditions only. Conditions which would be both necessary and sufficient (and would not be trivial tautologies) are not known. That mere continuity of the function is not sufficient to ensure the convergence of the Fourier series was shown by Paul du Bois-Reymond (1872). He constructed a continuous function whose Fourier series diverges at some points. Whether there is a continuous function whose Fourier series diverges at every point, is the most outstanding and still, in 1945, the unsolved problem of the theory. That there exist integrable (in the Lebesgue sense) functions whose Fourier series diverge everywhere, was shown by Andrei N. Kolmogoroff (1926).

Summability of Fourier Series.—The fact that Fourier series of continuous functions need not converge everywhere, endangered the whole theory of the representation of functions by their Fourier series. The situation was salvaged by Leopold Fejér (1900), who showed that the Fourier series of a continuous function $f(x)$ is summable to $f(x)$ by the method of the arithmetic mean (see SERIES). More precisely, if $s_n(x)$ has the same meaning as above, the expression

$$\sigma_n(x)=\frac{s_0(x)+s_1(x)+\cdots+s_n(x)}{n+1}$$

tends to $f(x)$ at every point of continuity of the function. Following this, Lebesgue proved that for every integrable function $f(x)$ the expression $\sigma_n(x)$ tends to $f(x)$ almost everywhere. This again put the theory on a firm basis, and at the same time showed that summability rather than convergence is important for Fourier series. Using (4), one obtains the formula

$$(5) \qquad \sigma_n(x)=\frac{1}{\pi(n+1)}\int_0^{2\pi} f(x+t)\frac{\sin^2\frac{1}{2}(n+1)t}{2\,\sin^2\frac{1}{2}t}dt$$

It is not unlike (4), but there is one essential difference. The factor $\sin^2$&$(n+1)t/2(n+1)\sin^2\frac{1}{2}t$ in (5) called *Fejér's* kernel, is non-negative, whereas the factor $\sin(n+\frac{1}{2})t/2\sin\frac{1}{2}t$ in (3) *Dirichlet's* kernel) is of variable sign. This positive character of Fejér's kernel is responsible for many interesting properties of the expressions $\sigma_n(x)$, and in particular for the fact that they represent $f(x)$ so much better than the $s_n(x)$ do.

Besides the method of the arithmetic mean, many other methods of summability have been applied to Fourier series. The most important of them is the method of Niels Abel (see SERIES), which defines the sum of series (1) as the limit of the expression

$$\tfrac{1}{2}a_0+(a_1\cos x+b_1\sin x)r+(a_2\cos 2x+b_2\sin 2x)r^2+\ldots,$$

where r tends to 1 through values less than 1. If (1) is the Fourier series of $f(x)$, the last expression may be written

$$\frac{1}{2\pi}\int_0^{2\pi} f(x+t)\,\frac{1-r^2}{1-2r\cos t+r^2}\,dt,$$

and is called the Poisson integral of f(x). As $r\rightarrow 1$, it tends to $f(x)$ at every point of continuity of the function (or almost everywhere, if f(x) is merely integrable).

Conjugate Series and Functions.—For $z=e^{ix}$, the real part of the power series (3) is the trigonometric series (1). The imaginary part of (3) is the trigonometric series

$$(a_1 \sin x - b_1 \cos x) + (a_2 \sin 2x - b_2 \cos 2x) + \ldots$$

which is called the *conjugate* of the series *(1)*. Suppose that *(1)* is the Fourier series of a function $f(x)$; the conjugate series is then almost everywhere summable by the method of the arithmetic mean, or by the method of Abel, the generalized sum being equal to the integral

$$(6)\qquad -\frac{1}{\pi}\int_0^{\pi}\frac{f(x+t)-f(x-t)}{2\tan\frac{1}{2}t}\,dt,\ \text{defined as}\ \lim_{\epsilon\to 0}\left\{-\frac{1}{\pi}\int_{\epsilon}^{\pi}\right\}$$

This integral is called the *function conjugate* to $f(x)$ and will be denoted by $f(x)$. The fact that for every integrable function $f(x)$ the integral *(6)* exists almost everywhere. is a very remarkable property of integrable functions, a property which is far from obvious even in the case when $f(x)$ is continuous. Conjugate series are a link between trigonometric series and power series. They are also of importance for the theory of Fourier series, since there seems to be a close relation between the behaviour of the partial sums of Fourier series and the behaviour of certain conjugate functions. The function conjugate to an integrable function $f(x)$ need not be integrable. Thus the series conjugate to the Fourier series of $f(x)$ need not be a Fourier series.

Parseval's Formula.—Suppose that *(1)* is the Fourier series of $f(x)$. If in the formula $f(x) = \frac{1}{2}a_0 + (a_1\cos x + b_1\sin x) + \ldots$ we square both sides and integrate the result over the interval $0 \leq x \leq 2\pi$, we get the equation

$$\frac{1}{\pi}\int_0^{2\pi} f^2(x)dx = \tfrac{1}{2}\,a_0^2 + (a_1^2+b_1^2) + (a_2^2+b_2^2) + \cdots$$

called *Parseval's formula.* The above argument was formal, but rigorous proofs are available and show that the formula is valid for any function $f(x)$ such that $f^2(x)$ is integrable. Thus the Fourier coefficients $a_0, a_1, b_1, \ldots$ of any such function have the property that the sum $\sum(a^2{}_n + b^2{}_n)$ is finite. That the converse is true, was proved by F. Riesz and E. Fischer (1907). The Riesz-Fischer theorem, one of the great achievements of the Lebesgue theory of integration, asserts that, given any sequence of numbers $a_0, a_1, b_1, a_2, b_2, \ldots$ such that the series $\sum(a_n^2+b_n^2)$ converges, there is always a function $f(x)$ having the numbers $a_0, a_1, b_1, \ldots$ for Fourier coefficients and such that $f^2(x)$ is integrable. This function is unique. Thus the theorems of Parseval and of Riesz-Fischer give a very simple characterization of function with integrable square in terms of their Fourier coefficients. No other class of function has a characterization of comparable simplicity and completeness.

Uniqueness of Representation by Trigonometric Series.—Can a function be represented by two different and everywhere convergent trigonometric series? By taking the difference of two such series we may restate the problem as follows. Can a trigonometric series not identically zero (*i.e.* a series whose coefficients a,, b_n are not all zero) converge everywhere to *o?* That this is impossible was proved by Georg Cantor. His result is the simplest theorem on the uniqueness of the representation of a function by a trigonometric series. Let us call a point set S situated in the interval $0 \leq x \leq 2\pi$ a *set of uniqueness* (set U, for brevity), if every trigonometric series convergent to *o* outside S is identically zero. Otherwise, the set S will be called a *set of multiplicity* (set M), and there will be trigonometric series convergent to o outside S, but not identically zero. Generalizing the result just stated. Cantor proved that every set S consisting of a finite number of points, and even certain infinite sets, are sets U. It may be shown that every set U must be of measure zero, but it is remarkable that among sets of measure o we find sets U as well as sets M. The problem of characterizing sets U and M in structural terms was in 1945 still unsolved. One of its implications is that from the point of view of trigonometric series the notion of set of measure zero is too general, and that special classes of such sets may be of particular importance.

Orthogonal Series.—Fourier series as defined above are a special class of more general series. Suppose that in an interval $a \leq x \leq b$ we have a fixed set of functions $\varphi_1(x)$, $\varphi_2(x), \ldots$ with the following properties

$$(7)\qquad \int_a^b \varphi_m\varphi_n dx = 0,\ \text{if}\ m\neq n;\quad \int_a^b \varphi_n^2 dx = \lambda_n \neq 0,$$

for all m and n. Such sets of functions are called *orthogonal.* If a function $f(x)$ has a representation $f(x) = c_1\varphi_1(x) + c_2\varphi_2(x) + \ldots$, then, multiplying both sides by $\varphi_n(x)$, integrating over x the interval (a, b), and using (7), we are formally led to the equations $c_n = \frac{1}{\lambda_n}\int_a^b f(x)\ \varphi_n(x)\ d\,x$, for all n. Conversely, given any function $f(x)$, we may use the latter formulas to construct the series $c_1\varphi_1(x) + c_2\varphi_2(x) + \ldots$, and ask whether this series actually represents $f(x)$. This last series is called the *Fourier series of $f(x)$ with respect to the orthogonal system $\varphi_1, \varphi_2, \ldots$.* Trigonometric Fourier series are obtained if for φ_1, $\varphi_2, \ldots$ we take the system *1*, cos x, sin x, cos 2 x, sin 2 x, . . . , and for *(a, b)* the interval $(0, 2\pi)$. Many other orthogonal systems are of considerable importance for mathematics.

Fourier Integrals.—Fourier series are used for the representation of periodic functions. For the study of a nonperiodic function $f(x)$ we use the *Fourier integral* of $f(x)$. It has the form

$$(8)\qquad \int_0^{\infty}\{a(u)\ \cos\ ux + b(u)\ \sin\ ux\}du,$$

where $a(u)$ and $b(u)$ are defined by the formulas

$$a(u) = \frac{1}{\pi}\int_{-\infty}^{+\infty} f(t)\cos\,ut\,dt,\ b(u) = \frac{1}{\pi}\int_{-\infty}^{+\infty} f(t)\ \sin\ ut\,dt$$

The integral *(8)* is analogous to the series *(1)*, the only difference being that instead of summation we have integration. The functions $a(u)$ and $b(u)$ are analogues of Fourier coefficients, and are called the *Fourier transforms of $f(x)$.* Under very general conditions, the integral *(8)* actually represents $f(x)$, the proofs being similar to the corresponding proofs in the case of Fourier series.

FOURMIES, a town of northern France, in the *département* of Nord, on an affluent of the Sambre, *39* mi. S.E. of Valenciennes by rail. Pop. *(1946) 12,694.* Wool combing and spinning are important, and a great variety of cloths is produced. The glassworks of Fourmies date from *1*599, and were the first established in the north of France. Iron is worked in the vicinity, and there are important forges and foundries. Enamelware is also manufactured.

FOURNIER, PIERRE SIMON *(1712*–1768), French engraver and typefounder, was born at Paris on Sept. 15, *1712.* He designed many new characters, and his foundry became celebrated not only in France; but in foreign countries. .His *Table des proportions qu'il faut observer entre les caractkres* (1737) was followed by several other technical treatises. His principal work, however, was the *Manuel typographique* (2 vol., 1764), the first volume treating of engraving and type founding, the second of printing, with examples of different alphabets. He died in Paris on Oct. *8, 1*768.

FOURTEEN POINTS, THE. On Jan. *8, 1918,*Pres. Woodrow Wilson, in his address to the joint session of congress, formulated under *14* separate heads his ideas of the essential nature of a post-World War I settlement. Before the delivery of his address he had received from a committee of inquiry, set up by Col. Edward House in Sept. 1917, a report upon the territorial settlement that should follow the conclusion of the war. It has been stated that no fewer than six, and these the territorial points, of Wilson's Fourteen Points were "directly framed" upon the recommendations contained in the report. It has also been stated by Ray S. Baker in his *Woodrow Wilson* that the report was drawn up by S. Mezes, D. H. Miller and Walter Lippmann.

The text of the Fourteen Points was as follows:

1. Open covenants of peace, openly arrived at, after which there shall be no private international understandings of any kind but diplomacy shall proceed always frankly and in the public view.

2. Absolute freedom of navigation upon the seas, outside territorial waters, alike in peace and in war, except as the seas may be closed in whole or in part by international action for the enforcement of international covenants.

3. The removal, so far as possible, of all economic barriers and the establishment of an equality of trade conditions among all the nations consenting to the peace and associating themselves for its maintenance.

4. Adequate guarantees given and taken that national armaments will be reduced to the lowest point consistent with domestic safety.

5. A free, open-minded, and absolutely impartial adjustment of all colonial claims, based upon a strict observance of the principle that in determining all such questions of sovereignty the interests of the populations concerned must have equal weight with the equitable claims of the government whose title is to be determined.

6. The evacuation of all Russian territory and such a settlement of all questions affecting Russia as will secure the best and freest cooperation of the other nations of the world in obtaining for her an unhampered and unembarrassed opportunity for the independent determination of her own political development and national policy and assure her of a sincere welcome into the society of free nations under institutions of her own choosing; and, more than a welcome, assistance also of every kind that she may need and may herself desire. The treatment accorded Russia by her sister nations in the months to come will be the acid test of their good will, of their comprehension of her needs as distinguished from their own interests, and of their intelligent and unselfish sympathy.

7. Belgium, the whole world will agree, must be evacuated and restored, without any attempt to limit the sovereignty which she enjoys in common with all other free nations. No other single act will serve as this will serve to restore confidence among the nations in the laws which they have themselves set and determined for the government of their relations with one another. Without this healing act the whole structure and validity of international law is forever impaired.

8. All French territory should be freed and the invaded portions restored, and the wrong done to France by Prussia in 1871 in the matter of Alsace-Lorraine, which has unsettled the peace of the world for nearly fifty years, should be righted, in order that peace may once more be made secure in the interest of all.

9. A readjustment of the frontiers of Italy should be effected along clearly recognizable lines of nationality.

10. The peoples of Austria-Hungary, whose place among the nations we wish to see safeguarded and assured, should be accorded the freest opportunity of autonomous development.

11. Rumania, Serbia, and Montenegro should be evacuated; occupied territories restored; Serbia accorded free and secure access to the sea; and the relations of the several Balkan states to one another determined by friendly counsel along historically established lines of allegiance and nationality; and international guarantees of the political and economic independence and territorial integrity of the several Balkan states should be entered into.

12. The Turkish portions of the present Ottoman Empire should be assured a secure sovereignty, but the other nationalities which are now under Turkish rule should be assured an undoubted security of life and an absolutely unmolested opportunity of autonomous development, and the Dardanelles should be permanently opened as a free passage to the ships and commerce of all nations under international guarantees.

13. An independent Polish state should be erected which should include the territories inhabited by indisputably Polish populations, which should be assured a free and secure access to the sea, and whose political and economic independence and territorial integrity should be guaranteed by international covenant.

14. A general association of nations must be formed under specific covenants for the purpose of affording mutual guarantees of political independence and territorial integrity to great and small states alike.

President Wilson developed these theories during 1918 in a series of speeches, to which reference was subsequently made during the Armistice negotiations. These are generally known as the "Four Principles." "Four Ends" and "Five Particulars."

The Four Principles.—In the "Four Principles" speech in congress, Feb. 11. 1918, he declared:

1. That each part of the final settlement must be based upon the essential justice of that particular case and upon such adjustments as are most likely to bring a peace that will be permanent;

2. That peoples and provinces are not to be bartered about from sovereignty to sovereignty as if they were mere chattels and pawns in a game, even the great game, now forever discredited, of the Balance of Power; but that

3. Every territorial settlement involved in this war must be made in the interest and for the benefit of the populations concerned, and not as a part of any mere adjustment or compromise of claims amongst rival states; and

4. That all well-defined national aspirations shall be accorded the utmost satisfaction that can be accorded them without introducing new or perpetuating old elements of discord and antagonism that would be likely in time to break the peace of Europe and consequently of the world.

The Four Ends.—In the "Four Ends" speech of July 4, 1918, occurs the following passage:

These are the ends for which the associated peoples of the world are fighting and which must be conceded them before there can be peace:

1. The destruction of every arbitrary power anywhere that can separately, secretly, and of its single choice disturb the peace of the world; or, if it cannot be presently destroyed, at the least its reduction to virtual impotence.

2. The settlement of every question, whether of territory, of sovereignty, of economic arrangement, or of political relationship, upon the basis of the free acceptance of that settlement by the people immediately concerned, and not upon the basis of the material interest or advantage of any other nation or people which may desire a different settlement for the sake of its own exterior influence or mastery.

3. The consent of all nations to be governed in their conduct towards each other by the same principles of honor and of respect for the common law of civilized society that govern the individual citizens of all modern states in their relations with one another; to the end that all promises and covenants may be sacredly observed, no private plots or conspiracies hatched, no selfish injuries wrought with impunity, and a mutual trust established upon the handsome foundation of a mutual respect for right.

4. The establishment of an organization of peace which shall make it certain that the combined power of free nations will check every invasion of right and serve to make peace and justice the more secure by affording a definite tribunal of opinion to which all must submit and by which every international readjustment that cannot be amicably agreed upon by the peoples directly concerned shall be sanctioned.

These great objects can be put into a single sentence. *What we seek is the reign of law, based upon the consent of the governed and sustained by the organized opinion of mankind.*

The Five Particulars.—The "Five Particulars" (speech of Sept. 27, 1918) were as follows:

1. The impartial justice meted out must involve no discrimination between those to whom we wish to be just and those to whom we do not wish to be just. It must be a justice that plays no favorites and knows no standard but the equal rights of the several peoples concerned;

2. No special or separate interest of any single nation or any group of nations can be made the basis of any part of the settlement which is not consistent with the common interest of all;

3. There can be no leagues or alliances or special covenants and understandings within the general and common family of the League of Nations.

4. And more specifically, there can be no special, selfish economic combinations within the League and no employment of any form of economic boycott or exclusion except as the power of economic penalty by exclusion from the markets of the world may be vested in the League of Nations itself as a means of discipline and control.

5. All international agreements and treaties of every kind must be made known in their entirety to the rest of the world.

Special alliances and economic rivalries and hostilities have been the prolific source in the modern world of the plans and passions that produce war. It would be an insincere as well as an insecure peace that did not exclude them in definite and binding terms.

Armistice and Peace Settlement.—On Oct. 4, 1918, Prince Maximilian of Baden, the German imperial chancellor, informed President Wilson:

The German government accepts the program set forth by the President of the United States in his message to Congress of Jan. 8, 1918, and in his later pronouncements, especially his speech of Sept. 27, as a basis for peace negotiations.

The Fourteen Points were thus designated by the German (and separately by the Austrian) government as an acceptable basis for peace. See VERSAILLES. TREATY OF.

BIBLIOGRAPHY.—*The Public Papers of Woodrow Wilson*, v (1927); H. W. V. Temperley, *History of the Peace Conference of Paris*, i (1920); Charles Seymour, *Woodrow Wilson and the World War* (1921). See also Ray S. Baker, *Woodrow Wilson and World Settlement* (1923).

FOURTOU, MARIE FRANÇOIS OSCAR BARDY DE (1836–1897), French politician, born at Ribérac (Dordogne) on Jan. 3, 1836, represented Dordogne in the national assembly after the Franco-German War. He was minister of public works (1872). of religion (1873) and of education (1874). As minister of the interior in Broglie's cabinet in 1877, he resumed the administrative methods of the second empire. In the general elections of that year he used the whole weight of officialdom to secure a majority for the right-wing group, which supported a clerical and reactionary program. In spite of these efforts the cabinet fell, and a commission was appointed to inquire into their unconstitutional abuse of power. Fourtou was unseated in consequence of the revelations made. In the chamber of deputies Gambetta gave the lie direct to Fourtou. A duel was fought in consequence, but neither party was injured. Fourtou died in Paris on Dec. 5, 1897.

FOUSSA (*Cryptoprocta* ferox), the largest carnivorous mammal peculiar to Madagascar, which combines characteristics of the civets and the cat family. It is about twice the size of a cat (five feet from nose to end of tail), with short dense fur of pale brown. Most active at night, the foussa usually dwells in trees during the day. Although it has been known to prey upon poultry, sheep and cattle, it more commonly feeds on birds and lemurs. The specific name refers to its ferocity, which the foussa shows when wounded.

See CARNIVORA: Feloidea. (J. E. HL.; X.)

FOWEY, a seaport and municipal borough in the Bodmin parliamentary division of Cornwall, Eng., 12 mi. S. of Bodmin and 28 mi. W. of Plymouth by road and ferries. Pop. (1951) 2,347. Area 4.7 sq.mi. It lies on the west bank of the river Fowey where it widens into a deep-water estuary which vessels drawing 30 it. can enter. The river banks are high and wooded; the town, with its steep narrow streets. is a residential one. attracting many artists and writers. It is also a holiday and yachting centre, with the latter's headquarters at the Royal Fowey Yacht club. Deep-sea fishing is carried on, and china clay is exported. There is a car ferry to Bodinnick and a passenger ferry to Polruan opposite Fowey. The 14th-century church, dedicated to St. Fimbarrus or Fin Barr of Cork. stands on the hillside. Place house, adjacent, is a Tudor building. and there are 16th- and 17th-century houses in the town, which is portrayed in various writings of Sir Arthur Quiller-Couch. There is a ruined fort of the time of Henry VIII; the grammar school was established in 1692.

Fowey held a leading position among Cornish ports from the time of Edward I to the days of the Tudors. The numerous references to the privateering exploits of its ships in the Patent and Close rolls testify to its importance. Tin was exported in medieval times. Incorporated by James II, Fowey retained its charter until 1882. A new charter came into force in 1913. In 1316 the prior of Tywardreath, as lord of the manor, obtained the right to hold a Monday market and two fairs, which in 1690 were altered to a Saturday market and three fairs that continue to be held.

FOWL. Originally used to mean any bird, this term has now become (except in combination, as seafowl, wild fowl) almost restricted to the wild red jungle fowl, *Gallus gallus,* its domestic races and its wild allies. (For domestic fowls, see POULTRY AND POULTRY FARMING.) *Gallus gallus* inhabits northern India, Burma, southern Vietnam, the Malay archipelago and neighbouring islands. It resembles in plumage the domestic black-breasted game breed. It inhabits forests: thickets and bamboo jungles, dwelling in small parties. The crow of the cock is like that of a bantam. The cream-white eggs, 8 to 12 in number. are laid on the ground.

Three other species occupy much the same habitat. The gray jungle fowl, G. *sonnerati,* is found in western, central and southern India; the cock has the shaft of the neck hackles dilated) and his crow is more like a cackle. The Sinhalese species, G. lajayetti, is peculiar to Ceylon; the cock has a yellow comb with a red edge and is red beneath. G. *varius* inhabits the hlalay islands from Java to Flores; it does not possess hackles, and the cock has a large unserrated comb. All the species will interbreed with domestic poultry and with the wild G. *gallus,* but the hybrids are sterile.

See also GAME BIRDS.

FOWLER, CHARLES (1792–1867), English architect best known for his buildings in Covent Garden and Hungerford markets, was born at Cullompton, Devon, on May 17, 1792, and died at Great Marlow on Sept. 26, 1867. After an apprenticeship of five years at Exeter, he worked in the office of David Laing in London from 1814 until he began to practise alone. His first important work was the court of bankruptcy in Basinghall street (1821). In 1822 he gained first premium for a design for London bridge, which, however, mas not used. Among Fowler's designs for bridges was one erected across the Dart at Totnes. He also designed the markets of Gravesend and Exeter (lower market), several churches. the Devon lunatic asylum (1845), the London fever hospital (1849) and the hall of the Wax Chandlers' company, Gresham street (1853). He was honorary secretary and a vice-president of the Institute of British Architects.

FOWLER, SIR JOHN (1817–1898), English civil engineer, best known as the designer of the London hfetropolitan railway and as joint designer of the Forth bridge in Scotland, was born on July 1j, 1817, at Wadsley Hall, near Sheffield. He engaged in railway construction at an early age and set up his own business in 1844, laying out many small railway systems, which were later amalgamated into the Manchester, Sheffield and Lincolnshire railway. Fowler was engineer of the London Metropolitan railway, the forerunner of the underground railways, which was noteworthy in that it was mostly made not by tunneling but by excavating from the surface and then covering in the permanent way. He designed and constructed a special type of locomotive for this railway, afterward known as "Fowler's Ghost." He lived to be one of the engineers officially connected with the deep-tunneling "tube" system extensively adopted for electric railways in London. Fowler was also engineer for the construction of Victoria station. He was also engaged in the making of railways in Ireland, and in 1867 he served on a commission to consider a state purchase of the Irish railway system. He also carried out considerable works in relation to the Nene valley drainage and the reclamation of land in the Norfolk estuary.

In 186j Fowler was elected president of the Institution of Civil Engineers, the youngest president who had ever sat in the chair. He was strongly opposed to the project of a channel tunnel to France, and in 1872 he endeavoured, in vain, to obtain the consent of parliament to a channel ferry scheme. For eight years from 1871 he acted as general engineering adviser in Egypt to the khedive Ismail. The railway he planned to the Sudan mas not developed for financial reasons, but the maps and surveys were given to the war office and proved most useful to Lord Wolseley in his Nile expedition. For his service Fowler was knighted in 1885. He was created a baronet in 1890 on the completion of the great Forth bridge, of which he was joint engineer with his partner, Sir Benjamin Baker. He died at Bournemouth on Nov. 20, 1898.

See T. Mackay, *The Life* of *Sir John Fowler* (1900). (T. M. S.)

FOWLER, JOHN (1826–1864), English engineer, inventor of the steam-hauled plow, was born at Melksham, Wiltshire, on July 11, 1826. He was at first engaged in the corn trade but later trained as an engineer. In 1850 he joined Albert Fry in Bristol to found a works for the production of steam-hauled implements; and in the same year he laid porous pipe drains 2 ft. 6 in. deep by horsepowered windlass. He applied the steam engine to draining in 18j3 and to cultivation in 18j6. In 1857 he was awarded a £200 prize by the Highland Agricultural society for cultivation by a single stationary engine, using the first steel wire rope. The following year he won the Royal Agricultural society's £500 prize, using a single self-moving engine hauling the implement by a rope around a disk anchor on the headland opposite. He patented his famous clip drum and coiling gear in 1859. In 1861 he founded at Leeds the firm of John Fowler and Co. to make this machinery, and at one time other firms did so under licence. Fowler died at Ackworth, Yorkshire, on Dec. 4, 1864. (R. H. C.)

FOWLER, WILLIAM (*c.* 1560–1614), Scottish poet, attended St. Leonard's college. St. Andrews, between 1574 and 1578, and in 1581 was in Paris studying civil law. In that year he issued a pamphlet against John Hamilton and other Catholics, who had, he said, driven him from his country. He subsequently (about 1590) became private secretary and Master of Requests to Anne of Denmark, wife of James VI., and was renominated to these offices when the queen went to England. In *1609* his services were rewarded by a grant of *2,000* acres in Ulster. His sister Susannah was mother of the poet William Drummond of Hawthornden. A ms. collection of *72* sonnets, entitled *The Tarantula of Love*, and a translation *(1587)* from the Italian of the *Triumphs of Petrarke* are preserved in the library of the University of Edinburgh, in the collection bequeathed by his nephew, William Drummond. Two other volumes of his manuscripts are preserved among the Drummond mss., now in the library of the Society of Antiquaries of Scotland. Specimens of Fowler's verses were published in *1803* by John Leyden in his *Scottish Descriptive Poems*. Fowler contributed a prefatory sonnet to James VI.'s *Furies;* and James, in return, commended, in verse, Fowler's *Triumphs*.

FOX, *CHARLES JAMES (1749–1806)*, British statesman and orator, was born at 9 Conduit Street, Westminster, on Jan. 24, 1749, third son of Henry Fox, 1st Lord Holland, and his wife, Lady Caroline Lennox, eldest daughter of Charles Lennox, 2nd duke of Richmond. The father, who treated his children with extreme indulgence, allowed him to choose his school, and he elected to go to one kept at Wandsworth by a French refugee, named Pampelonne. Then the boy asked to be sent to Eton, where he was entered in the autumn of *1758*. During the six years he spent at Eton he acquired the love and knowledge of the classics in which he found refreshment and solace all through life. Lord Holland treated his children, and in particular Charles, as friends and companions in pleasure from the first. In *1763* he took Charles to Paris and to Spa, and encouraged him in dissipation and in gambling. In spite of this extraordinary interlude in his studies, Fox read hard from natural inclination. After he went up to Hertford College, Oxford, in *1764*, he made repeated visits to France and Italy during the vacations. He became a good French and Italian scholar, with a keen appreciation of Italian literature and art.

If Fox's youth was disorderly, it was never indolent. He was incapable of half doing anything which he did at all. He was as energetic in sport as in learning. At a later period when he had grown fat he accounted for his skill in taking "cut balls" at tennis by saying that he was a very "painstaking man." He was all his life a great and steady walker.

In *1768* Lord Holland bought the pocket borough of Midhurst for him. and he entered on his parliamentary career, and on London society, in 1769. Within the next few years Lord Holland reaped to the full the reward for all that was good, and whatever was evil, in the training he had given his son. The affection of Charles Fox for his father was unbounded, but the passion for gambling which had been instilled in him as a boy proved the ruin of the family fortune. He kept racehorses, and bet on them largely On the racecourse he was successful, and it is another proof of his native thoroughness that he gained a reputation as a handicapper. It is said that he won more than he lost on the course. At the gaming table he was unfortunate, and he was fleeced both in London and in Paris by unscrupulous players. Fox took his losses and their consequences with an attractive gaiety. He called the room in which he did business with the Jew money-lenders his "Jerusalem chamber." When his elder brother had a son, and his prospects were injured, he said that the boy was a second Messiah, who had appeared for the destruction of the Jews. "He had his jest, and they had his estate." In 1774 Lord Holland had to find £140,000 to pay the gambling debts of his sons For years Charles lived in pecuniary embarrassment, and during his later years, when he had given up gambling, he was supported by the contributions of wealthy friends, who in 1793 formed a fund of £70,000 for his benefit.

Early Years in Parliament.— In the House of Commons he began by supporting the court; and in *1770*, when only 21, he was appointed a junior lord of the admiralty with Lord North. During the violent conflict over the Middlesex election *(see* WILKES, JOHN) he took the unpopular side, and vehemeptly asserted the right of the House of Commons to exclude Wilkes. In *1772* during the proceedings against Crosby and Oliver—a part of the "Wilkes and liberty" agitation—he and Lord North were attacked by a mob and rolled in the mud. But Fox's character was incompatible with ministerial service under King George III. The king, himself a man of orderly life, detested him as a gambler and a rake. And Fox was too independent to please a master who expected obedience. In Feb. 1772 he threw up his place to be free to oppose the Royal Marriage Act, on which the king's heart was set. He returned tc office as junior lord of the treasury in December. But he was insubordinate; his sympathy with the American colonies, which were now beginning to resist the claims of the mother country to tax them, made him intolerable to the king and he was dismissed in Feb. 1774. The death of his father on July *1*, of that year removed an influence which tended to keep him subordinate to the court, and his friendship for Burke drew him into close alliance with the Rockingham Whigs. From the first his ability had won him admiration in the House of Commons. He had prepared himself as an orator by the elaborate cultivation of his voice, which was naturally harsh and shrill. His argumentative force was recognized at once, but the full scope of his powers was first shown on Feb. 2, 1775, when he made a remarkable speech (unfortunately lost) on the disputes with the colonies. "Taking the vast compass of the question before us," says Gibbon, "he discovered powers for regular debate which neither his friends hoped nor his enemies dreaded." When parliament met on Oct. *26*, Fox supported the amendment to the Address censuring ministers for increasing the discontent in America. "Ministers," he said, "have reason to triumph. Lord Chatham, the Ring of Prussia, nay, Alexander the Great, never gained more in one campaign than the noble lord [North] has lost—he has lost a whole continent." Next year, speaking again on the amendment to the Address (Oct. *31, 1776)* he maintained that if the choice lay between conquering and abandoning America he was for abandoning it; the advantages of the connection arose from trade and from relationship with a people of the same ideas and sentiments. These would be cut off by war, and the army there would oppress the people and be dangerous to liberty at home.

Fox's great political career is unique among the careers of British statesmen of the first rank, for it was passed almost wholly in opposition. Except for a few months in 1782 and 1783, and again for a few months before his death in *1806*, he was out of office. He declared, indeed, that he had "totally subdued" ambition, and was content with his life; yet it was certainly a cause of bitter disappointment to him that he had to stand by while the country was in his opinion not only misgoverned, but led to ruin. His reputation as an orator and a political critic, which was great from the first and grew as he lived, most assuredly did not console him for his impotence as a statesman.

During the eight years between his expulsion from office in 1774 and the fall of Lord North's ministry in March *1782* he planted the seed of the modern Liberal party as opposed to the pure Whigs. He became a member of the Rockingham party and worked in alliance with the marquis and with Burke. In opposing the attempt to coerce the American colonists, and in assailing the waste and corruption of Lord North's administration. as well as the undue influence of the crown, he was at one with the Rockingham Whigs. During the agitation against corruption, and in favour of honest management of the public money. which was very strong between 1779 and 1782, he and they worked heartily together. It had a considerable effect, and prepared the way for the reforms begun by Burke and continued by Pitt. But if Fox learnt much from Burke he learnt with originality. He declined to accept the revolution settlement as final. or to think with Burke that the constitution of the House of Commons could not be bettered. He believed that, if the House was to be made an efficient instrument for restraining the interference of the king and for securing good government, it must cease to be filled to a very large extent by the nominees of boroughmongers and the treasury. He became a strong advocate for parliamentary reform. He was the ardent advocate of what have in later times been known as "Liberal causes," the removal of all religious disabilities and tests, the suppression of private interests which hampered the public good, the abolition of the slave trade, and the emancipation of all classes and races of men from the strict control of authority.

A detailed account of his activity from 1774 to 1782 would entail the mention of every crisis of the American War of Independence and of every serious debate in parliament. Throughout the struggle Fox was uniformly opposed to the coercion of the colonies and was the untiring critic of Lord North. While the result must be held to prove that he was right, he prepared future difficulties for himself by the fury of his language. He was the last man in the world to act on the worldly-wise maxim that an enemy should always be treated as if he may one day be a friend, and a friend as if he might become an enemy. At the opening of the autumn session in 1779 Fox, who was convinced that the king was responsible for North's continuance of the American War, stated plainly that the doctrine that the king could be his own minister was entirely unconstitutional and drew attention to the fate of Charles I. and James II. He denounced William Adam, a supporter of Lord North's, and in a duel which followed (Nov. 29) Fox was wounded. He assailed Lord North with unmeasured invective, directed not only at his policy but at his personal character, though he knew that the prime minister remained in office against his own wish, in deference to the king who appealed to his loyalty.

When the disasters of the American war had at last made a change of ministry necessary, and the king applied to the Whigs, through the intermediary of Shelburne, Fox made a very serious mistake in persuading Rockingham not to insist on dealing directly aith the sovereign. The result was the formation of a cabinet (March 1782) belonging, in Fox's own words, partly to the king and partly to the country—that is to say, partly of Whigs who wished to restrain the king, and partly of the king's friends, represented by Shelburne, whose real function was to baffle the Whigs. Dissensions were acute between Shelburne and Fox, the two secretaries of state. The old division of duties by which the southern secretary had the correspondence with the colonies and the western powers of Europe, and the northern secretary with the others, had been abolished on the formation of the Rockingham cabinet. All foreign affairs were entrusted to Fox. Lord Shelburne, as secretary for the colonies, claimed a right to interfere in the negotiations for the peace at Paris, and fundamental differences arose. Fox thought the independence of America should be unconditionally acknowledged; Shelburne wished it to be the price of peace. The majority in the cabinet sided with Shelburne. Fox was about to resign, but resignation was deferred by the illness of Rockingham, who died on July 1, 1782. The king offered the premiership to Shelburne, Fox resigned, and was followed by a part of the Rockingham Whigs.

The 1783 *Coalition.*—Fox's next step was ruinous. On Feb. 14, 1783, he formed a coalition with Lord North, based as they declared on "mutual goodwill and confidence." Fox maintained that the original cause of quarrel, the American War, being over, there was no longer any serious ground of difference. But to the country at large this union, formed with a man whom he had denounced for years, had the appearance of an unscrupulous conspiracy. In the House of Commons the coalition was strong enough to drive Shelburne from office on Feb. 24. The king made a prolonged resistance to the pressure put on him to accept Fox and North as his ministers (see PITT, WILLIAM). On April 2, he was constrained to submit. In the new ministry the duke of Portland was prime minister and Fox and North were secretaries of state. The new administration was ill liked by some of the followers of both. Fox increased its unpopularity both in the House and in the country by consenting against the wish of most of his colleagues to ask for the grant of a sum of £100,000 a year to the prince of Wales. The introduction by Fox of the India bill in Nov. 1783 offended the king by the provision which gave the patronage of India to a commission to be named by the ministry and removable only by parliament. The coalition, and Fox in particular, were assailed in a torrent of most telling invective and caricature. George III. gave it to be understood that he would not look upon any member of the House of Lords who voted for the India bill as his friend. The bill was thrown out in the upper House on Dec. 17, and next day the king dismissed his ministers.

Fox now went into opposition again. The remainder of his life may be divided into four portions—his opposition to Pitt during the session of 1784; his parliamentary activity till his secession in 1797; his retirement till 1800; his return to activity and his short tenure of office before his death in 1806. During the first of these periods he deepened his unpopularity by assailing the undoubted prerogatives of the crown, by claiming for the House of Commons the right to override not only the king and the Lords but the opinion of the country, and by resisting a dissolution. This last pretension came very ill from a statesman who in 1780 had advocated yearly elections. He lost ground daily before the steady good judgment and unblemished character of Pitt. When parliament was dissolved at the end of the session of 1784, the country showed its sentiments by unseating 180 of the followers of Fox and Korth. The defeated candidates were known as "Fox's martyrs."

Fox himself was elected for Westminster with fewer votes than Admiral Lord Hood, but with a majority over the ministerial candidate, Sir Cecil Wray. The election was marked by an amazing outflow of caricatures and squibs, by weeks of rioting in which Lord Hood's sailors fought pitched battles in St. James's Street with Fox's hackney coachmen, and by the intrepid canvassing of Whig ladies. The beautiful duchess of Devonshire (Georgiana Spencer) is said to have won at least one vote for Fox by kissing a shoemaker who had a romantic idea of what constituted a desirable bribe. The high bailiff refused to make a return, and the confirmation of Fox's election was delayed by the somewhat mean action of the ministry. He had, however, been chosen for Kirkwall, and could fight his cause in the House. In the end he recovered damages from the high bailiff. In his place in parliament he sometimes supported Pitt and sometimes opposed him with effect. His criticism on the ministers' bill for the government of India was sound in principle, though the evils he foresaw did not arise. His support of Pitt's Reform Bill was qualified by a just dislike of the ministers' proposal to treat the possession of the franchise by a constituency as a property and not as a trust. His unsuccessful opposition to the commercial treaty with France in 1787 was unwise and most injurious to himself. He committed himself to the proposition that France was the natural enemy of Great Britain, a saying often quoted against him in coming years. It has been excused on the ground that when he said France he meant the aggressive house of Bourbon.

In 1788 Fox travelled in Italy, with his faithful companion, Mrs. Armistead (Elizabeth Cane), but returned in haste on hearing of the illness of the king. Fox supported the claim of the prince of Wales to the regency as a right. a doctrine which provoked Pitt into declaring that he would "unwhig the gentleman for the rest of his life." The friendship between him and the prince of Wales (see GEORGE IV.) was always injurious to Fox. In 1787 he was misled by the prince's ambiguous assurances into denying the marriage with Mrs. Fitzherbert. On discovering that he had been deceived he broke off all relations with the prince for a year, but their alliance was renewed. During these years he was always in favour of whatever measures could be described as favourable to emancipation and to humanity. He actively promoted the impeachment of Warren Hastings, which had the support of Pitt. He was always in favour of the abolition of the slave trade (which he actually effected during his short tenure of office in 1806), of the repeal of the Test Acts, and of concessions to the Roman Catholics, both in Great Britain and in Ireland.

The French Revolution affected Fox profoundly. Together with almost all his countrymen he welcomed the meeting of the states-general in 1789 as the downfall of a despotism hostile to Great Britain. On hearing of the fall of the Bastille he wrote to Fitzpatrick: "How much the greatest event it is that ever happened in the world! and how much the best!" He continued to adhere stoutly to his opinion that the Revolution was essentially just and ought not to be condemned for its errors or even for its crimes. As a natural consequence he was the steady opponent of Pitt's foreign policy, which he condemned as a species of crusade against freedom in the interest of despotism. Between 1790 and 1800 his unpopularity reached its height. He was left almost alone in parliament, and was denounced as the enemy of his country. On May 6, 1791, occurred the painful scene in the House of Commons, in which Burke renounced his friendship. In 1792 there was some vague talk of a coalition between him and Pitt, which came to nothing. The scene with Burke took place in the course of the debate on the Quebec Bill, in which Fox displayed real statesmanship by criticizing the division of Upper from Lower Canada, and other provisions of the bill, which in the end proved so injurious as to be unworkable. In this year he carried the Libel Bill. In 1792 his ally, the duke of Portland, and most of his party left him. In 1797 he withdrew from parliament, and only came forward in 1798 to reaffirm the doctrine of the sovereignty of the people at a great Whig dinner. On May 9 he was dismissed from the privy council.

The interval of secession (he and his friends ceased to attend parliament in 1797) was perhaps the happiest in his life. In company with Mrs. Armistead he established himself at St. Anne's Hill near Chertsey in Surrey. In 1795 he married her privately, but did not avow his marriage till 1802. Fox's time at St. Anne's was largely spent in gardening, in the enjoyment of the country, and in correspondence on literary subjects with his nephew, the 3rd Lord Holland, and with Gilbert Wakefield, the editor of Euripides. Greek and Italian were his first favourites, but he was well read in English literature and in French, and acquired some knowledge of Spanish. His favourite authors were Euripides, Virgil and Racine, whom he defends against the stock criticisms of the admirers of Corneille with equal zeal and insight.

Fox reappeared in parliament (Feb. 3, 1800) to take part in the vote of censure on ministers for declining Napoleon's overtures for a peace. The fall of Pitt's first ministry and the formation of the Addington cabinet, the peace of Amiens, and the establishment of Napoleon as first consul with all the powers of a military despot, seemed to offer Fox a chance of resuming power in public life. The struggle with Jacobinism was over, and he could have no hesitation in supporting resistance to a successful general aho ruled by the sword, and who pursued a policy of perpetual aggression. During 1802 he visited Paris.

The death of Pitt (1806) left Fox so manifestly the foremost man in public life that the king could no longer hope to exclude him from office. The formation of a ministry was entrusted by the king to Lord Grenville, but when he named Fox as his proposed secretary of state for foreign affairs George III. accepted him without demur. Indeed his hostility seems to a large extent to have died out. A long period of office might now have appeared to lie before Fox, but his health was undermined. Had he lived it may be considered as certain that the war with Napoleon would have been conducted with a vigour which was much wanting during the next few years. In domestic politics Fox had no time to do more than insist on the abolition of the slave trade. He, like Pitt, was compelled to bow to the king's invincible determination not to allow the emancipation of the Roman Catholics. When a French adventurer calling himself Guillet de la Gevrillière, whom Fox at first "did the honour to take for a spy," came to him with a scheme for the murder of Napoleon, he sent a warning on Feb. 20, to Talleyrand. The incident gave him an opportunity for reopening negotiations for peace. A correspondence ensued, and British envoys were sent to Paris. But Fox was soon convinced that the French ministers were playing a false game. He was resolved not to treat apart from Russia, then the ally of Great Britain, nor to consent to the surrender of Sicily, which Napoleon insisted upon, unless full compensation could be obtained for King Ferdinand. The later stages of the negotiation were not directed by Fox, but by colleagues who took over his work at the foreign office when his health began to fail in the summer of 1806. After carrying his motion for the abolition of the slave trade on June 10, he was fgrced to give up attendance in parliament, and he died (of dropsy) in the house of the duke of Devonshire, at Chiswick, on Sept. 13, 1806. His wife survived him till July 8, 1842. No children were born of the marriage. Fox is buried in Westminster Abbey by the side of Pitt.

The striking personal appearance of Fox has been rendered very familiar by portraits and by innumerable caricatures. The latter were no doubt deliberately exaggerated, and yet a comparison between the head of Fox in Sayer's plate "Carlo Khan's triumphal entry into Leadenhall," and in Abbot's portrait, shows that the caricaturist did not depart from the original. Fox was twice painted by Sir Joshua Reynolds, once when young in a group with Lady Sarah Bunbury and Lady Susan Strangeways, and once at full length. A half-length portrait by the German painter, Karl Anton Hickel, is in the National Portrait Gallery, where there is also a terra-cotta bust by Nollekens.

(D. H.; X.)

FOX, EDWARD (c. 1496–1538), bishop of Hereford, was born at Dursley, Gloucestershire; he is said on very doubtful authority to have been related to Richard Fox (*q.v.*). From Eton he proceeded to King's College, Cambridge, and after graduating was made secretary to Wolsey. In 1528 he was sent with Gardiner to Rome to obtain from Clement VII. a decretal commission for the trial and decision of the case between Henry VIII. and Catherine of Aragon. On his return he was elected provost of King's College, and in Aug. 1529 conveyed to the king Cranmer's historic advice that he should apply to the universities of Europe rather than to the pope. After a brief mission to Paris in Oct. 1529, Fox in Jan. 1530 befriended Latimer at Cambridge, and took an active part in persuading that university and Oxford to decide in the king's favour. He was sent to employ similar methods of persuasion at the French universities in 1530–31, and was also engaged in negotiating a closer league between England and France. In April 1533 he was prolocutor of convocation when it decided against the validity of Henry's marriage with Catherine, and in 1534 published his treatise *De vera differentia regiae potestatis et ecclesiae* (2nd ed. 1538, Eng. tr. 1548). He received the archdeaconry of Leicester (1531) and the bishopric of Hereford (1535). In 1535–36 he was sent to Germany to discuss the basis of a political and theological understanding with the Lutheran princes and divines, and had several interviews with Luther, who could not be persuaded of the justice of Henry VIII.'s divorce. Bucer dedicated to him in 1536 his *Commentaries on the Gospels,* and Fox's Protestantism was also illustrated by his patronage of Alexander Aless, whom he defended before Convocation. Fox died on May 8, 1538. He was the most Lutheran of Henry VIII.'s bishops, and was largely responsible for the Ten Articles of 1536.

FOX, GEORGE (1624–91) was born in 1624 at Drayton in Leicestershire, the son of a weaver. As a child he was unusually serious and sensitive to right and wrong. His relatives thought of educating him as a clergyman, but he was eventually apprenticed to a shoemaker and grazier. After a time he felt that the command of God was for him to leave his family and friends and go forth alone and he went on a series of journeys visiting preachers in search of spiritual guidance.

The influence of his remarkable personality soon made itself felt. The mysticism of Fox was positive and practical; leading him at the outset of his ministry to denounce all kinds of social evils.

In 1647 he began a peripatetic ministry which continued till the closing years of his life, broken by intervals of imprisonment. He was first imprisoned in 1649 at Nottingham, for interrupting a sermon by an impetuous appeal from the Scriptures to the Holy Spirit as the authority and guide. In 1650 he was committed to Derby gaol as a blasphemer, and at Derby, the nickname of Quakers was given to Fox and his friends by Justice Gervase Bennett. But Fox won such esteem that while still in gaol he was offered a captaincy in the Parliamentary army which he declined.

He bore his frequent sufferings and hardships with great courage and found a wide response to his appeal, especially in the north-west of England, among companies of "Seekers." By 1651 other Quaker preachers joined him in his service. The centre of the movement was for some years at Swarthmore Hall, near Ulverstone, the home of Judge Fell, Cromwell's chancellor of the duchy of Lancaster, who was friendly to the Quakers, while his wife, Margaret, joined them.

He spent six years in various prisons, at Nottingham (1649), Derby (1650–51), Carlisle (1653), Launceston (1656), Lancaster and Scarborough (1664–66) and Worcester (1673–75), sometimes amid terrible conditions. Throughout his active ministry he found time to issue numerous books and pamphlets. His style was uncouth, his grammar and spelling often faulty, but amid occasional obscurities and repetitions pregnant phrases occur, while his *Journal* often shows striking power of narrative. Recent research has shown that he was more widely read than has been supposed. But it was his presence and spoken words which made the deep impression vividly portrayed in Penn's preface to his *Journal,* winning universal respect, affection and attention.

By 1666 his strong frame was shattered by severe imprisonment, and henceforth much of his time was given to building up the Quaker community in a church order, which offered freedom of service to men and women and at the same time gave expression to the group spirit. Fox also took care to institute careful provision for the poor and for the accurate registration of births, deaths and marriages.

In 1669 he married Margaret, the widow of Judge Fell, but continued his travelling mission, visiting the West Indies and America in 1671–72, Holland and north Germany in 1677, and Holland again in 1681. After his long imprisonment at Worcester, he stayed to recuperate at Swarthmore Hall (1675–77), and resided there once again in 1678–80, making use of this time to arrange his papers and prepare his *Great Journal.* But feeling still the call to a wider service, he went south again, his later years being passed chiefly in and around London, where his wife came at intervals to stay with him.

Notwithstanding failing health he still kept at work, visiting Quaker meetings and families, promoting the establishment of schools, corresponding with the Quaker communities abroad, advising his fellow Quakers in difficulties great and small and even interviewing members of parliament to help in the framing of the Toleration Act. He died on Jan. 13, 1691.

Fox's *Journal,* the work by which he is principally known, was printed in 1694, being edited from his papers by Ellwood The complete *Journal* was edited verbatim in 1911 by Norman Penney, and the *Short Journal* and itinerary journals in 1925. Folio volumes of Fox's epistles and doctrinal works were issued in 1698 and 1706. In 1852 an edition of his works in eight volumes was published in Philadelphia, but no complete collection has yet been printed.

For Fox's life *see* Thos. Hodgkin's *George Fox* (1896) and *A.* N. Brayshaw's *The Personality of George Fox* (1919). (T. E. H.)

FOX, RICHARD *(c.* 1448–1528), successively bishop of Exeter, Bath and Wells, Durham and Winchester, lord privy seal, and founder of Corpus Christi College, Oxford, was born about 1448 at Ropesley, near Grantham, Lincolnshire. His parents belonged to the yeoman class, and there is some obscurity about Fox's early career. He probably studied at Magdalen college, Oxford. whence he drew so many members of his subsequent foundation, Corpus Christi. He also appears to have studied at Cambridge. In 1484 he was in Paris, where he met the earl of Richmond (the future Henry VII.) and was taken into his service. In January 1485 Richard intervened to prevent Fox's appointment to the vicarage of Stepney on the ground that he was keeping company with the "great rebel, Henry ap Tuddor."

On Henry's accession Fox became the King's principal secretary. and soon afterwards lord privy seal and bishop of Exeter (1487). The ecclesiastical preferment was merely intended to provide a salary not at Henry's expense; for Fox never saw either Exeter or the diocese of Bath and Wells to which he was translated in 1492. His work was political and especially diplomatic. In 1487 he negotiated a treaty with James III. of Scotland, in 1492 he helped to conclude the treaty of Etaples, and in 1497 he was chief commissioner in the negotiations for the famous commercial agreement with the Netherlands, the *Magnus Intercursus.*

Meanwhile in 1494 Fox had been translated to the see of Durham, which was of political importance as a palatine earldom and because of its position with regard to the Borders and relations with Scotland. Fox therefore visited and resided in his new diocese; and he occupied Norham castle, which he fortified and defended against a Scottish raid in Perkin Warbeck's interests (1497). But his energies were principally devoted to pacific purposes. In that same year he negotiated Perkin's retirement from the court of James IV., and in 1498–1499 he completed the negotiations for that treaty of marriage between the Scottish king and Henry's daughter Margaret which led ultimately to the union of the two crowns in 1603 and of the two kingdoms in 1707. The marriage itself did not take place until 1503.

This consummated Fox's work in the north, and in 1501 he was translated to Winchester, then reputed the richest bishopric in England. In that year he concluded the negotiations for the betrothal of Prince Arthur to Catherine of Aragon. He also arranged the betrothal of the king's younger daughter Mary to the future emperor Charles V. In 1500 he was elected chancellor of Cambridge university, and in 1507 master of Pembroke hall in the same university. The Lady Margaret Beaufort made him one of her executors, and with Fisher, he was principally responsible for the foundation of St. John's college and the Lady Margaret professorships and readerships.

His financial work brought him a less enviable notoriety, though a curious freak of history has deprived him of the credit which is his due for "Morton's fork." The invention of that ingenious dilemma for extorting contributions from poor and rich alike is ascribed as a tradition to Morton by Bacon; but the story is told in greater detail of Fox by Erasmus, who says he had it from Sir Thomas More. a well-informed contemporary authority.

Under Henry VIII. the personnel of the ministry at first remained unaltered. The Venetian ambassador calls Fox *alter rex* and the Spanish ambassador Carroz says that Henry VIII. trusted him more than any other adviser, although he also reports Henry's warning that the bishop of Winchester was, as his name implied, "a fox indeed." Wolsey's rapid rise in 1511 put an end to Fox's influence. The pacific policy of the first two years of Henry VIII.'s reign was succeeded by an adventurous foreign policy directed mainly against France; and Fox, who desired peace, complained that no one durst do anything in opposition to Wolsey's wishes. Gradually Warham and Fox retired from the government; the occasion of Fox's resignation of the privy seal was Wolsey's ill-advised attempt to drive Francis I. out of Milan by financing an expedition led by the emperor Maximilian in 1j16. Tunstall protested, Wolsey took Warham's place as chancellor, and Fox was succeeded by Ruthal, who, said the Venetian ambassador, "sang treble to Wolsey's bass." He bore Wolsey no ill-will, and warmly congratulated him two years later when warlike adventures were abandoned at the peace of London. But in 1522 when war was again declared he refused to bear any part of the responsibility, and in 1523 he opposed in convocation the financial demands which met with a more strenuous resistance in the House of Commons.

He now devoted himself assiduously to his long-neglected episcopal duties. His sight failed during the last ten years of his life. The crown of Fox's career was his foundation (1515–16) of Corpus Christi college. Originally he intended it as an Oxford house for the monks of St. Swithin's, Winchester; but he is said to have been dissuaded by Bishop Oldham. who denounced the monks and foretold their fall. The scheme adopted breathed the spirit of the Renaissance; provision was made for the teaching of Greek. Erasmus lauded the institution and Pole was one of its earliest fellows. The humanist Vives was brought from Italy to teach Latin, and the reader in theology was instructed to follow the Greek and Latin Fathers rather than the scholastic commentaries. Fox also built and endowed schools at Taunton and Grantham, and was a benefactor to numerous other institutions. He died at Wolvesey on Oct. 5, 1528; Corpus possesses several portraits and other relics of its founder.

Church in the 16th Cent.* (1899); A. F. Pollard, *Henry VIII.* (1905); Longman, *Political History*, vol. v. (1905); other authorities cited in the article by T. Fowler (formerly president of Corpus) in the *Dict. Nat. Biog.*

FOX, ROBERT WERE *(1789–1877)*, English geologist, was born at Falmouth on April *26, 1789.* He made researches on the internal temperature of the earth, being the first to prove that the heat increased definitely with the depth; his observations being conducted in Cornish mines from 1815 for a period of forty years. In *1829* he commenced a series of experiments on the artificial production of miniature metalliferous veins by means of the long-continued influence of electric currents, and his main results were published in *Observations on Mineral Veins (Rep. Royal Cornwall Polytech. Soc., 1836).* He constructed in *1834* an improved form of deflector dipping needle. In *1848* he was elected F.R.S. He died on July *25, 1877.* (See *A Catalogue of the Works of Robert Were Fox, F.R.S., with a Sketch of his Life,* by J. H. Collins, *1878.)*

His daughter, CAROLINE FOX (1819–1871), born at Falmouth cn May *24, 1819,* wrote a diary recording memories of many distinguished people, including John Stuart Mill, John Sterling and Carlyle. Selections from her diary and correspondence (1835–71) were published under the title of *Memories of Old Friends* (ed. by H. N. Pym, *1881*; 2nd ed., *1882).* She died on Jan. *12, 1871.*

FOX, SIR STEPHEN *(1627*–1716), English statesman, born on March *27, 1627,* was the son of William Fox, of Farley in Wiltshire, a yeoman farmer. At *15* he entered the service of the earl of Northumberland; then he entered the service of Lord Percy, the earl's brother, and was present with the royalist army at the battle of Worcester (Sept. *3, 1651)* as Lord Percy's deputy at the ordnance board. Accompanying Charles II. in his flight to the continent, he was appointed manager of the royal household, on Clarendon's recommendation. He was employed on several important missions, and acted eventually as intermediary between the king and General Monk. After the Restoration he was appointed to the lucrative offices of first clerk of the board of green cloth and paymaster-general of the forces. He entered parliament in *1661,* was knighted (1665), and was a commissioner of the treasury from *1679* to 1702. In *1680* he resigned the paymastership and was made first commissioner of horse. In *1684* he became sole commissioner of horse. In *1685* he was again M.P. for Salisbury and opposed the bill for a standing army supported by the king. During the Revolution he maintained an attitude of decent reserve, but was confirmed in his offices by William III.

Fox died on Oct. *28, 1716.*

FOX, SIR WILLIAM (1812–93), New Zealand statesman, was born in England on June *9,* 1812, and educated at Wadham college, Oxford. He was called to the bar in *1842,* but immediately emigrated to New Zealand, where, in *1843,* he became the New Zealand company's agent for the South Island. In *1848* Fox became attorney-general, but gave up the post to join in the agitation for a free constitution. In 1850 he came to London as political agent to urge the demands of the Wellington settlers, but the Colonial Office refused to recognise him. When government by responsible ministers was initiated in *1856.* Fox ousted the first ministry and formed a cabinet, holding office for 13 days. In *1861* he became premier for nearly *13* months, and in *1863* again took office with Sir Frederick Whitaker as premier. Fox's third premiership was from *1869* to *1872,* and his fourth for five weeks in March–April *1873.* Soon afterwards he left politics, though he led the attack which overthrew Sir George Grey's ministry in *1879.* He lost his seat in the dissolution which followed in that year, and did not again enter parliament. He was an active champion of self-government for the New Zealand colonists, and laboured to secure their just rights for the Maori races, and to establish peace among the tribes. Sir William Fox was made K.C.M.G. in 1880. He died on June *23, 1893.*

FOX, WILLIAM (1879–1952), U.S. motion-picture producer and distributor, was born in Tulchva, Hung., on Jan. *1,* 1879. Brought to the U.S. as an infant, he was reared in New York city and worked there in the garment industry. He entered the motion-picture business in 1904 when he bought a nickelodeon in Brooklyn for *$1,600.* He soon formed an exhibition company, a chain of motion-picture theatres and later a production company in Staten Island, N.Y. In 1915 he founded the Fox Film Corp. to produce, distribute and exhibit films. His holdings were expanded until by 1929 his interests in the Fox corporation, Loew's, Inc., and Gaumont-British were valued at $300,000,000. After the 1929 stock market crash the Fox empire swiftly crumbled, and in *1936,* plagued by lawsuits, he went into bankruptcy.

Fox died in New York, May *8, 1952.* (M. S. BY.)

FOX (female, vixen), primarily the popular name for the European species of the dog family *(Canidae)* which by Linnaeus was named *Canis vulpes;* but by modern zoologists this species and others related to it are assigned to the genus *Vulpes,* because the nasal passages do not open into hollow spaces of the frontal bones as they do in *Canis* and its allies, and the postorbital processes are flat or hollowed instead of convex.

The typical fox *(Vulpes vulpes)* differs from other foxes in having a white "tag" to the tail combined with black on the backs of the ears—as thus defined the species has a wide geographical range, embracing practically the whole of Europe, Africa north of the Sahara, the whole of temperate Asia and North America as far south as Mexico. It has adapted itself to the most varied physical conditions and has become differentiated into a large number of local races or subspecies differing in size, colour, thickness of coat and other respects. There are too many to mention in detail; but the little fox (V. *v. leucopus)* of the plains of northwest India is of interest as illustrating the general principle that the southern races are smaller than the northern, the Himalayan fox (*V. v. montana)* and the Egyptian fox (*V. v. aegyptiaca)* being intermediate in size between it and the European race. In the matter of coat the finest foxes come from the far north. The typical colour of the species is reddish, grizzled with gray or buff, desert forms being paler than others; but the prevalent tint varies from fiery red to black, melanism being of frequent occurrence. In North America and parts of Asia there are three main varieties, the red, the cross and the silver; the cross fox being intermediate between the other two. The silver, a black fox sprinkled with white, provides valuable furs; but the price is likely to decline owing to the success that is being achieved by breeding these animals in fox farms. Most of the red fox skins on the market come from Australia where European foxes were introduced years ago to check the rabbit plague.

Habits of **the** Fox.—So far as is known the habits of the common fox vary in no important respect wherever it is found. It is a predacious, mostly nocturnal animal, feeding principally upon small birds and mammals but taking frogs, shell-fish, insects and even fruit at times. The sexes may live apart except at the mating season, which occurs early in the year. The male may assist in raising. After a gestation of about *63* days, the vixen brings forth her litter of four or a few more young in a burrow or natural crevice, in the spring. Only one litter is produced in the year and the young, which are blind for about ten days, are able to shift for themselves by the autumn and become adult when about a year old. Foxes do not hibernate and are as active in winter as in summer even in the coldest latitudes. Accounts of hybrids between dogs and foxes have often been published, but there is no authenticated case known and specimens never come to hand for expert examination when demanded.

Foxes are noted for the cunning they evince in the avoidance of traps and, in countries where they are hunted by hounds, for the methods they adopt in breaking the line of scent left by their footfall on the soil, even by leaping on to the backs of sheep. Since foxes have no natural enemies other than man to trap and pursue them in that way, it has been suggested that their devices are due to instinct engendered by man's persecution continued generation after generation. But all the indications of the cleverness of foxes cannot be explained in that way.

No other species of fox has a range nearly so extensive as the red fox. A few close relatives occur in the same latitudes. The small corsac (V. *corsac)* of the Siberian plains differs in having a black tail-tip. The hoary fox *(V. cana)* of Baluchistan and the northwestern frontier of India is about *16* in. long, the tail about 11 in.; the colour is gray, the tail-tip black. The Tibetan sand fox *(V. ferrilata)* has short ears and tail; the colour is yellowish, the tail-tip white; the skull with very narrow and elongate nostrum and wide zygomatic arches. Its eyes differ from those of other foxes in having round pupils. The kit fox *(V. velox)* lives on the northern great plains, from southern Canada to Wyoming. It is small (head and body about *18* to 21 in., tail about 11 in.), buffy gray in colour. The long-eared kit fox *(V. macrotis)* of the southwestern United States and Mexico is extremely slender, with large ears; its colour is grizzled gray with ochraceous buff on the sides. It is about the same size as the swift fox, but its legs and ears are longer. The tail is gray to the tip. Other species are more southern in their ranges. The small Indian fox *(V. bengalensis).* grayish in colour, with a black tail-tip, the ears coloured like the back of the neck, is found in most parts of India between the Punjab and Assam. The fennec *(I!'. zerda)* of the Sahara and north Africa is the smallest of the foxes (being only about $15\frac{1}{2}$ in., the tail $6\frac{3}{4}$ in.). while its ears are relatively larger than those of any other, and wide. In colour the fennec is a reddish buff. the tail-tip black, the underparts, the edges of the ears and around the eyes, white. Riippell's fox (I^{r}. *rüppellii)* is found in upper Egypt and the Nubian desert. It is about *19* in. long, the tail about 9 in., and the ears are nearly as large as in the fennec. The African sand fox *(V. pallida)* is pale yellowish, the tail mixed with blackish and with a poorly marked black tip. It is found from Senegal to the Nile region and in Cyrenaica. The South African "silver fox" *(V. chama)* is grayish mixed with some yellowish, the tail-tip black and the sides of the face marked with ochraceous. It is a little smaller than the red fox and has much longer ears. There are no foxes in the Malay region.

The American gray fox *(Urocyon cinereoargenteus)* is found from New England to South America. The grizzled upperparts and reddish sides of this fox, its short ears, erectile dorsal crest on the tail, as well as cranial characters, distinguish it from other foxes. It frequently climbs trees and may choose a hollow- in a tree trunk as a home den. The South American wild dogs are related to *Urocyon.*

Mainly north of the range of the red fox, but partly overlapping it, occurs the circumpolar Arctic fox *(Alopex lagopus).* This fox is somewhat intermediate between *Vulpes* and *Canis.* In summer this fox is grayish brown above but in winter it turns pure white. A colour variety, the blue fox, does not turn white in winter. The African long-eared fox *(Otocyon megalotis)* is gray, with blackish legs and tail-tip. It is about the size of a red fox but its ears are as extreme as those of the much smaller fennec. The sectorial carnassial teeth characteristic of the dog family are not differentiated in this species and there is an extra molar usually in both upper and lower jaws. *(See* CARNIVORA.)

(R. I. P.; J. E. HL.)

FOXE, JOHN (1517–1587), author of *The Book of Martyrs,* was born at Boston, Lincolnshire. in 1517. A devout and scholarly boy, he was sent to Brasenose college, Oxford, whence he migrated to Magdalen college, holding a fellowship for seven years. But in 1545 being suspect for Protestantism he resigned his fellowship, and took a tutorship with the Lucy family at Charlecote, Warwickshire, where he married Agnes Randall of Coventry. In 1547 he moved to London, and became tutor to the grandchildren of the duke of Norfolk. He was ordained deacon in *1550* by Nicholas Ridley, and worked for the Reformation, writing several tracts. He also began a Latin history of the persecution and martyrdoms in England from John Wycliffe onward, but had carried it no farther than the year 1500 when Mary's accession *(1j53)* forced him to flee with his wife overseas, hotly pursued by emissaries of Stephen Gardiner, bishop of Winchester and lord chancellor. Proceeding to Strasburg he printed his unfinished martyrology in octavo *(Commentarii rerum in ecclesia gestarum,* 1554), and then spent a year in Frankfurt, where in the violent controversies over the use of the *Book of Common Prayer* he gave a moderating support to the Calvinistic party of John Knox. When his party was defeated in *1jjj,* he settled at Basel, earning a meagre living by correcting proofs for the printer Oporinus, and writing a burning appeal to the English nobility to restrain the queen from persecuting *(Ad inclytos Angliae proceres,* 1557). But his chief labour was the extension of his martyrology. By aid of manuscripts from England he carried this to Thomas Cranmer's death in 1556, and printed it in folio *(Rerum in Ecclesia gestarum . . . Commentarii,* 1559). He then returned to London with his family, and devoted himself to the completion of his great work. Ransacking registers and using the memories of eyewitnesses, he enlarged and rounded off his story. The book was printed in March *1563* by John Daye under the title *Acts and Monuments of these latter and perilous Days.* It was a big folio, written in English, and adorned with woodcuts. It made a great sensation and immediately acquired the popular name, *The Book of Martyrs.* But Foxe was not satisfied. There were errors to amend. and much fresh material was flowing in. For seven years more he laboured, to the lasting detriment of his health, and in 1570 produced his second edition, not a little improved, in two gigantic volumes. This was the crown of his achievement: for he made few changes in his third *(1576)* and fourth (1583) editions.

Foxe was ordained priest in *1560* by Edmund Grindal, bishop of London, but having Puritan scruples refused all preferments save two prebends—at Salisbury (1563–87) and Durham *(1572–73).* But he often preached. and a sermon delivered at Paul's Cross (Of *Christ Crucified,* 1570) had a wide sale. In the plague of *1563* he ministered to the victims and wrote a beautiful tract of consolation. For Archbishop Parker he edited in *1j71 Reformatio Legum Ecclesiasticarum* (the proposed revision of canon law) and *The Gospels, Anglo-Saxon and English.* He was much in request as spiritual counselor, and never feared to speak his mind even to the greatest. When Anabaptists in 1575 and Jesuits in *1581* were condemned to death Foxe wrote vehement letters to queen and councilors begging a reprieve. His integrity, warm heart and social gifts won him friends of all classes: among them Lord Burleigh and Sir Francis Drake. He died on April *18, 1587,* and was buried in the chancel of St. Giles. Cripplegate, his parish church, amid a great concourse of mourners.

Foxe's monument is his book. It spoke straight to the heart of Elizabethan England. It was installed in churches, read aloud by Drake on the western seas to his shipmates, praised by Knox, archbishop Whitgift and William Camden. But it speaks also to our cooler age. It is indeed prolix, unsystematic, carelessly edited, one-sided, oversharp, sometimes credulous. But it is honest and it is strong in facts. It opens a window upon the English Reformation by preserving much firsthand material unobtainable elsewhere. Foxe's ready pen and deep compassion for suffering can make his death scenes very moving. The charges of deliberate falsification brought against him by Alan Cope (1566), Robert Parsons *(1603)* and some moderns have no substance. Despite faults the book lives and it deserves to live.

See J F Mozley, *John Foxe and his Book* (1940). This book reviews the whole case and clears the controversial air, vindicating Foxe from the gravest charges made by S. R. Maitland (1792–1866) and his followers. It also proves (against Maitland) that the long memoir of Foxe inserted into *Acts and Monuments* (1641), was written by his younger son, Simeon Foxe (1568–1642). (J. F. MY.).

FOXGLOVE, biennial and perennial herbs of the family Scrophulariaceae, comprising the genus *Digitalis.* It contains about 20 species found in Europe, western Asia and the Canary Islands. The common or purple foxglove, *D. purpurea,* is common in dry hilly pastures and rocky places and by roadsides in various parts of Europe; it ranges in Great Britain from Cornwall and Kent to Orkney. and is sparingly naturalized in North America. It flourishes best in siliceous soils, and is not found in the Jura and Swiss Alps. Its characters are: stem erect, roundish, downy, leafy below, and from *18* in. to 5 ft. or more in height; leaves alternate, ovate or elliptic-oblong, and dull green, with the undersurface downy and paler than the upper; root of numerous, slender, whitish fibres; flowers $1\frac{3}{4}$–$2\frac{1}{2}$ in. long, pendulous, on one side of the stem, purplish crimson, hairy and marked with eyelike spots within; corolla bell-shaped with a broadly two-lipped obtuse mouth, the upper lip entire or obscurely divided; stamens four, two longer than the other two (*didynamous*); capsule ovate and pointed; and seeds numerous, small. It normally flowers in June: and ripens its seed in August, but may occasionally be found in blossom as late as September. Many varieties have been raised by cultivation, with flowers varying in colour from white to deep rose and purple. Its commercial cultivation in Michigan and Oregon is extensive, as its leaves are the only source of digitalis, a valuable drug in certain types of heart disease (*see* DIGITALIS). Other. but nonofficial, species of *Digitalis* are also grown in Spain and France, especially *D. lutea.*

J. HORACE MCFARLAND CO.

COMMON OR PURPLE FOXGLOVE (DIGITALIS PURPUREA)

The foxglove, probably from folk's-glove (*i.e.,* fairies' glove), is known by a great variety of popular names in Britain. In the south of Scotland it is called bloody fingers; farther north, dead-men's-bells; and on the eastern borders, ladies' thimbles, wild mercury and Scotch mercury. In Ireland it is generally known as fairy thimble. Among its Welsh synonyms are *menygellyllon* (elves' gloves), *menyg y llwynog* (fox's gloves), *bysedd cochion* (redfingers) and *bysedd y cwn* (dog's fingers).

In France its designations are *gants de notre dame* and *doigts de la Vierge.* The German name *Fingerhut* (thimble) suggested to Fuchs, in 1542, the employment of the Latin adjective *digitalis* as a designation for the plant.

Other species of *Digitalis* are grown in England for ornament, notably *D. ambigua,* with yellow, brown-spotted flowers; *D. lanata* of eastern Europe, with white and purple flowers; and *D. lutea* of Europe with yellow or whitish flowers. Few are grown in the U.S., where summer heat discourages them, except in cooler regions.

(N. TR.)

FOX HUNTING: *see* HUNTING.

FOX INDIANS, the name, from one of their clans, of an Algonkin tribe. whose former range was central Wisconsin. They call themselves Muskwakiuk, "red earth people." Owing to heavy losses in their wars with the Ojibways and the French, they allied themselves with the Sauk tribe about 1780, the two tribes being now one.

FOXTAIL GRASS, the name given to perennial grasses of the genus *Alopecurus,* comprising about 30 species, natives of cool north temperate regions. Of these the meadow foxtail (*A. pratensis*) is extensively cultivated in Europe as a pasture grass, and is also naturalized in North America. Various species of *Setaria* are likewise called foxtail grass, of which the yellow foxtail (*S. lutescens*) and the green foxtail (*S. viridts*), widely naturalized from Europe in North America, are often troublesome weeds. (*See* GRASSES.)

FOX-TROT, a modern dance of smooth, easy movement resembling a walk taken with long, rather springy steps, with knees slightly bent. Many variations are introduced. The music is in $\frac{4}{4}$ time. (*See* also DANCE.)

FOY, MAXIMILIEN SÉBASTIEN (1775–1825), French general and statesman, was born at Ham, Picardy, on Feb. 3, 1775, and educated at the college of Soissons, passing to the artillery school of La Fère. After his first campaign in Flanders (1791–92) he attained captain's rank, and served under Dampierre, Jourdan. Pichegru and Houchard. In 1794 he was imprisoned by the Convention, but released on the fall of Robespierre. He distinguished himself in Moreau's campaigns of 1796–97, and in the Swiss campaign of 1798, winning the rank of *chef de brigade* under Masséna in 1799. In 1800 he served in the Marengo campaign. Foy's opposition, as a republican, to the rise of Napoleon, and his vote against the establishment of the empire led to his joining the army in Holland. In 1807 he took part in the defense of the Dardanelles against the English. and later served throughout the Peninsular War. He won the rank of general under Junot, and served under Soult and Masséna. Napoleon, to whom Masséna sent him on a mission, made him a general of division. He won new laurels at Salamanca (1812) and in the Pyrenees, and received a command at the first restoration of the Bourbons. He joined Napoleon when the king fled the country, and held a divisional command in the Waterloo campaign (*q.v.*). He retired from the army at the second restoration, and in 1819 was elected to the chamber of deputies, where he used his considerable influence on the side of the liberal principles of 1789. At this time he began his history of the Peninsular War. In 1823 he protested against French intervention in Spain. and after the dissolution of 1823 was re-elected for three constituencies. He died in Paris on Nov. 28, 1825, and the great esteem in which he was held for his maintenance of liberal principles was shown by the vast concourse at his funeral.

The *Histoire* de *la guerre de la Péninsule sous Napoléon* mas published from his notes in 1827, and a collection of his speeches (with memoir by Tissot) appeared in 1826. *See* Cuisin, *Vie nzilitaire, politique, etc., du général Foy;* Vidal, *Vie militaire et politique du général Foy.*

FRACASTORO [FRACASTORIUS], **GIROLAMO** [HIERONYMUS] (1478–1553), Italian physician and poet, was born at Verona. He studied at Padua and became professor of philosophy there in 1502, afterward practising as a physician in Verona. It was by his advice that Pope Paul III, on account of the prevalence of a contagious distemper, removed the Council of Trent to Bologna. Fracastoro's theory of infection was that "infection" was due to the passage of minute bodies, capable of self-multiplication, from the infector to the infected, a theory which bears a superficial resemblance to modern doctrine. The term "syphilis" apparently originated with him. In 1517, when the builders of the citadel of San Felice (Verona) found fossil mussels in the rocks, Fracastoro took the view—following Leonardo da Vinci—that they were the remains of animals once capable of living in the locality. He died at Casi, near Verona, on Aug. 8, 1553; and in 1559 the town of Verona erected a statue in his honour.

The principal work of Fracastoro is a kind of medical poem entitled *Syphilis sive Morbi Gallicus,* (Verona, 1530), which has been often reprinted and also translated into French and Italian. His complete works were published at Venice in 1555, and his poems were collected and printed at Padua in 1728.

FRACTION, a part of any unit, as a fraction of a pound, of an acre, of an inch, of an hour, or of a group.

FIRST IDEAS

Elementary Idea of Fraction.— If we take any two positive integers, say 2 and 3, the quotient $\frac{2}{3}$ is a fraction. More generally speaking, if we take any two positive finite integers, a and *b*, such that *b* is not zero, the quotient $\frac{a}{b}$ is integral, if and only if, *a* is exactly divisible by *b*. If *a* is not so divisible and is less than b, speaking in the primitive sense $\frac{a}{b}$ is called a *fraction* or, according to relatively late usage, a *proper fraction.* In this expression *a* and *b* are called the *terms* of the fraction, *a* being the *numerator* (numberer) and b the *denominator* (namer). We may also consider this fraction as representing *a* of the *b* equal parts of some unit. *a* being then the "numberer" of the parts and *b* the "namer" of the parts, as in three-fourths ($\frac{3}{4}$) of a pound. We may also look upon the fraction as representing one bth of *a* units; for example, $\frac{2}{3}$ may be thought of as representing one-third of two units. These various ideas of a fraction are consistent with one another! as also with the idea that, say, $\frac{3}{4}$ means the ratio of 3 to 4, or the number which, multiplied by 4, becomes 3.

Extension of the Idea **of** Fraction.— These elementary ideas of fraction have been extended from time to time so as to permit of terms that are fractional, irrational, or imaginary, or that represent still other types of number, the denominator b never being zero.

The tendency to generalize has led to allowing the numerator to be any multiple of the denominator, the fraction then becoming 1 or some other integer; or to be any number whatsoever, not only less than but equal to or greater than the denominator. Since these two latter generalized cases do not properly represent fractions in the primitive sense ("proper" fractions), they are called *improper fractions.*

The fraction $\frac{a}{b}$ may be expressed as a/b, this being a more convenient form for printing or typewriting. Since the slanting bar resembles ihe old symbol for *solidus* (later used in the British 2/6 for 2s. 6d.), the form a/b is sometimes called the *solidus form*. If a and b are both rational, a/b is called a rational fraction; if both are integers, it is called a *simple fraction;* if either a or b is fractional, a/b is called a *complex fraction.* Questions relating to the least (in algebra, *lowest)* common denominator are sufficiently discussed in any elementary text book, where it is also shown that any rational complex fraction can be reduced to a simple fraction.

For the study of such continued fractions as

$$a+\frac{b}{c+}\,\frac{d}{e+}\ldots \text{ or } 2+\frac{1}{3+}\,\frac{1}{4}$$

see CONTINUED FRACTIONS.

Laws of Operations.— In any of these cases the laws governing the fundamental operations with fractions are as follows:

$$\frac{a}{b}+\frac{c}{d}=\frac{ad+bc}{bd}; \text{ for example, } \frac{3}{4}+\frac{2}{3}=\frac{9+8}{12}=\frac{17}{12}=1\tfrac{5}{12};$$

$$\frac{a}{b}-\frac{c}{d}=\frac{ad-bc}{bd}, \text{ for example, } \frac{3}{4}-\frac{2}{3}=\frac{9-8}{12}=\frac{1}{12}.$$

$$\frac{a}{b}\times\frac{c}{d}=\frac{ac}{bd} \text{ for example, } \frac{2}{3}\times\frac{3}{4}=\frac{2\times 3}{3\times 4}=\frac{1}{2};$$

$$\frac{a}{b}\div\frac{c}{d}=\frac{ad}{bc}; \text{ for example, } \frac{2}{3}\div\frac{3}{4}=\frac{2\times 4}{3\times 3}=\frac{8}{9};$$

$$\left(\frac{a}{b}\right)^2=\frac{a^2}{b^2}; \text{ for example, } \left(\frac{2}{3}\right)^2=\frac{4}{9};$$

$$\sqrt{\frac{a}{b}}=\frac{\sqrt{a}}{\sqrt{b}}; \text{ for example, } \sqrt{\frac{8}{9}}=\frac{\sqrt{8}}{\sqrt{9}}=\frac{1\sqrt{8}}{3} \text{ or } \frac{2\sqrt{2}}{3}.$$

Reduction.— With respect to the reduction of fractions to higher or lower terms, the following laws are valid for any value of m except zero and infinity:

$$\frac{a}{b}=\frac{ma}{mb} \qquad \frac{a}{b}=\frac{a\div m}{b\div m}$$

When all common factors have been removed from both terms of a fraction. the fraction is said to be *reduced to lowest terms,* or to be *irreducible.*

It is often possible to reduce a proper fraction a/b to the sum of two or more simpler fractions. For example, to perform the following reduction to *partial fractions:*

$$\frac{a^3-6a^2+a+2}{a^2-4a-12}=\frac{a^2}{a+2}+\frac{1}{a-6}.$$

The methods of procedure are given in most intermediate or higher algebras, but the importance of the subject is not seen until the student reaches the calculus.

Difficulties Created by Colloquial Expressions.— The colloquial use of a fraction like $\frac{1}{2}$ is so extended as to cause considerable difficulty on the part of a learner. He hears of half of an object, and can easily visualize it; half of a group is a little more difficult; half as large is still more so; and the idea becomes still less distinct when he hears such expressions as "half as long a time," "half as dark," and "half as beautiful." The simplest fraction thus comes, through such colloquial expressions, to be unusually difficult. Certain other fractions—notably $\frac{1}{4}$, $\frac{1}{10}$, and $\frac{1}{100}$—are used in the same loose way.

Vicissitudes of the Name.—Since "fraction" (from Lat. *frangere,* to break) means "broken," it was natural for the English writers of the 16th century to speak of "fractions or broken numbers" and of a "broken of broken" (Baker, 1568), meaning a fraction of a fraction. The word "frsgment" was also occasionally used for "fraction." In the middle ages the word *minuciae* was used as the equivalent of *fractiones,* and not solely with the meaning of "minutes" as in sexagesimal fractions. The fact that a fraction is a broken number led to such exprrssions in the early printed books as *Ein gebrochene zal* (Riese, German, 1522), and *Die ghebroken ghetalen* (Raets, Dutch, 1580). Since the Latin *ruptus* also means "broken," such names as *rotto* (Italian), *rocto* (Spanish), and *roupt* and *nombre rompu* (French) appear in the early printed books.

Fundamentally One **Type.**—We speak of proper fractions, mixed numbers, irrational fractions, and the like; but in view of the gradual extension of meaning, it is legitimate to say that any expression a/b is a fraction. It would even be allowable to admit the case of $b=0$, giving an interpretation accordingly, if this were necessary or advisable. Moreover, while we speak of common or vulgar fractions, of decimals, and of sexagesimals, these are chiefly differences in symbolism and have little bearing upon the nature of such a fraction as $\frac{1}{2}$, 0 5 (or 0 j), 30° (1° being the unit), or 2^{-1}, all of which have the same value.

VULGAR OR COMMON FRACTIONS

Relation to Compound Numbers.— The ancients had such difficulty in representing fractions that they generally resorted to compound numbers in order to avoid their use. Thus the Roman fractions of weight and of value were referred to the *as.* A twelfth part of the *as* was an *uncia,* as was also the twelfth part of a foot, whence our words "ounce" and "inch." Since 16 *asses* (in early times, 10 *asses)* made a *denarius,* the Romans were able to avoid speaking of $\frac{1}{2}$ of a *denarius* by referring to 8 *asses,* just as we may refer to 8 ounces instead of to $\frac{1}{2}$ of a pound, avoirdupois. To represent $\frac{1}{8}$ of a *denarius* the Roman would say *denarii uncia semuncia;* that is, $\frac{1}{12}$ and $\frac{1}{2}$ of $\frac{1}{12}$ of a *denarius.* This use of unit fractions goes back to some of the earliest fraction forms known, appearing in the Rhind (Ahmes) Papyrus of *c.* 1650 B.C., where the ratio of 2 to 43 is expressed (to use modern symbols) as $\frac{1}{42}+\frac{1}{86}-\frac{1}{129}+\frac{1}{301}$. The same plan was used by Heron (Hero) of Alexandria (possibly *c.* 200), in the Akhmim Papyrus (*c.* 8th century), by Rabbi Sa'adia ben Joseph el-Fayyumi (*c.* 930), and even, for certain purposes, up to modern times. Such compound numbers as 3yd. 1ft. 6in., instead of $3\frac{1}{2}$yd., and as £2 10s. instead of £$2\frac{1}{2}$, are late evidences of the desire to avoid fractions whenever possible.

Ancient Symbols.— In the Egyptian hieroglyphics the unit fraction was represented by a symbol resembling the outline of an eye, the denominator being represented underneath. In hieratic a dot replaced this symbol, $\frac{1}{3}$ appearing in somewhat such form as ııı. The Greeks had various forms, one being two short lines above a numeral, as in Γ″ for $\frac{1}{3}$, and Δ for $\frac{1}{4}$. The most common of all their fractions, the half, had a special symbol resembling our initial parenthesis (. Aristarchus *(c.* 260 B.C.) wrote the word or its initial for the numerator and the numeral for the denominator, as we might write "ten 71st,"—in Greek, ΔΟΑ̈. The Greeks also used the plan of writing the numeral for each term, but doubling it for the denominator, as if we should write 2′3″3″ for $\frac{2}{3}$.

On their coins the Romans commonly represented the half by the symbol S (for *semis),* or the Greek Σ or (; $\frac{1}{3}$ (the triens) was . . . . (that is, $\frac{4}{12}$), and $\frac{1}{6}$ (the sextans) was . . They also used bars instead of dots, as in =– (that is, $\frac{3}{12}$) for $\frac{1}{4}$ (the quadrans).

Modern Symbols.— Our present fractions seem to have had their genesis in India. Brahmagupta *(c.* 628) and Bhāskara *(c.* 1150) wrote $\begin{smallmatrix}2\\3\end{smallmatrix}$ for $\frac{2}{3}$. The Arabs introduced the bar, but they did not make use of it in all cases. When Abraham ben Ezra (Rabbi ben Ezra, *c.* 1140) adopted the Moorish forms he generally omitted it; but it is commonly found in manuscripts after his time.

The Name.—The fractions that were commonly used by merchants in the iate middle ages were called *fractiones vulgares,* whence the French use of *fractions vulgaires* (Trenchant, 1566) and the English "vulgare or common Fractions" (Digges, 1572).

The English writers finally adopted the adjective "vulgar," and the early American writers did the same; but about the beginning of the 19th century the latter changed to "common fractions." In English the word numerator (numberer) has given place to such terms as *numerus*, "topterme," "top," *superior*, and *denominato*, the *denominator* having such equivalents as *"base," inferior*, and *denominate*.

SEXAGESIMAL FRACTIONS

Nature and Origin.—Fractions written on the scale of 60 (Latin, *sexaginta*) are called *sexagesirnal fractiorts* (from the Latin *sexagesimus*, 60th). Since the Babylonians wrote their numbers on a combined scale of 10 and 60, in which the character for 1 represented any power of 60, they naturally used 60 as a radix in certain systems of measure, as in the case of 60 *maneh* making a talent. The statement that 60 seconds make a minute was probably looked upon quite as our statement that 12 inches make a foot, the idea of sexagesimal fractions, as we have it, not being present. The Greek astronomers no doubt received the scale of 60 from the Babylonians or their successors, and it seems to have been they who developed sexagesimal fractions on a large scale. When they decided to take 120 units as the length of the diameter of their standard circle (probably because its numerous factors, 2, 3, 4, 5, 6, 10, 12, 15, 20, 30, 40 and 60 made the representation of fractions easy), the circle (using the old value 3 for π) became 360 units. To each of these units they gave the name μοῖρα (*moi'ra*), which became (either through the Latin *de+gradus*, step, or the Arabic *daraja*, step, scale, ladder) our "degree." They then called $\frac{1}{60}$ of a degree a first part (πρῶτα ἑξηκοστά, *pro'ta hexekostá;* Latin, *pars minuta prima*, first small part), whence our "minute"; and $\frac{1}{3600}$ a second part (δεύτερα ἑξηκοστά, *deu'tera hexekostá;* Latin, *pars minuta secunda*), whence our "second," and so on. Since these fractions were used in astronomy, they were called "astronomical fractions" in the middle ages. They were also known as "physical fractions," and so we find Gemma Frisius (*c.* 1540) writing *De Fractionibus Astronomicis, siue de minutiis Physicis*, to distinguish them from the *fractiones vulgares*. He wrote:

	$\tilde{\text{s}}$.	$\tilde{\text{g}}$.	$\tilde{\text{m}}$.	$\tilde{2}$.	$\tilde{3}$.	$\tilde{4}$.
	1.	10.	25.	17.	21.	27.
for	1 sign (30°),	10°,	25′,	17″,	21‴,	27$^{\text{iv}}$.

To the mediaeval astronomers and their successors in the Renaissance such fractions were probably as significant as our decimal fractions are to us, but the operations beyond subtraction were difficult.

DECIMAL FRACTIONS

Forerunners.—The mediaeval computer who wished to find the square root of 7, having no decimal fractions with which to work, first multiplied the number by, say, 10,000, then found the square root of 70,000 to three figures, and then divided the result (246) by 100, obtaining $2\frac{46}{100}$, or $2\frac{23}{50}$. The process was known to the Hindus and the Arabs and is found in Europe as early as the 12th century. Even after the decimal fraction was known, such devices remained; this is seen, for example, in the custom of comparatively recent writers in taking the radius of a circle as 10,000,000 so as to avoid the use of decimals in the trigonometric functions. Early in the 15th century al-Kashî, assistant of the prince astronomer, Ulugh Beg of Samarkand, is said to have given the value of π as $\frac{\text{sah-hah}}{3}$ 1415926535898732, where *sah-hah* (modern Turkish *sahih*) means complete or integral. If the manuscript of his work now in Constantinople goes back to his time, this is the earliest evidence we have of any precise knowledge of the decimal fraction. Pellos (1492) made use of the decimal point in cases like 9537919÷70. He first placed a decimal point, 953791·9, then divided by 7, obtaining 136255 with a remainder, and finally wrote the result as $136255\frac{69}{70}$. In Rudolff's *Exempel-Büchlin* of 1530 an example in compound interest is solved by the aid of decimal fractions written in the form 393175, 413|4375, and so on to 20|6164099697265625oooo, the operations being carried on as they are to-day. The first book devoted solely to these fractions was *De Thiende* (Flemish; there was a French translation, *la Disme*, The Tenth, in the same year), written by Simon Stevin (Stevinus) and published in 1585. In this the decimal 27.847 (English) or 27.847 (American) appears as 27⓪8①4②7③. The first writer to use a decimal point with full understanding of its significance seems to have been Clavius. In the columns of differences of his table of sines printed in his work on the astrolabe in 1585, differences like 46·5 are given, this particular one being explained in the chapter "De parte proportionali sinuum, & arcuum" (p. 229) as equivalent to $46\frac{5}{10}$. The question as to what kind of decimal point to use has never been settled. The use of a separatrix of some kind was generally agreed upon early in the 17th century, but the precise form or position is still uncertain. The decimal (or centesimal) symbol % appears in the 15th century under the form "per c°," the "per" being finally dropped and the c° becoming $\frac{o}{o}$ in the 17th century. It is of Italian origin.

Operations.—The operations with decimal fractions are the same as with integers except for the proper placing of the decimal point, a matter of no difficulty as the subject is now taught. The rules are easily deduced by first writing each fraction as a common fraction. For example, $\frac{3}{10}\times\frac{7}{100}=\frac{21}{1000}$, and hence $0{\cdot}3\times0{\cdot}07=0{\cdot}021$ (British), or $0.3\times0.07=0.021$ (American).

Recurring Decimals.—If we reduce $\frac{1}{6}$ to a decimal fraction, we have (using the British decimal point in this discussion) 0·1666, the 6 continually recurring. Such a fraction is called a *recurring decimal, circulating decimal*, or *repeating decimal*. This fraction may be written $0{\cdot}1\dot{6}$, the superposed dot indicating that the 6 is repeated indefinitely. We see, by division, that

$$\tfrac{16}{111}=0{\cdot}144144\cdots=0{\cdot}\dot{1}4\dot{4},$$

and $\tfrac{178}{55}=3{\cdot}2363636\cdots=3{\cdot}2\dot{3}\dot{6}$,

the dots being placed above the first and last figures of the *repetend*.

Considering the last of these cases, $3{\cdot}2\dot{3}\dot{6}$, the decimal $0{\cdot}0\dot{3}\dot{6}$ forms an infinitely decreasing geometric series, $0{\cdot}036+0{\cdot}00036+\cdots$, in which the first term is 0·036, the ratio is $\frac{1}{100}$ and the number of terms is infinite. The formula for S, the limit of the sum of this series, is $a/(1-r)$. Substituting

$$S=0{\cdot}036/(1-0{\cdot}01)=0{\cdot}036\div0{\cdot}99=\tfrac{2}{55},$$

and so $3{\cdot}2\dot{3}\dot{6}=3{\cdot}2+\frac{2}{55}=\frac{178}{55}$.

The following rule for the reduction to a common fraction is easily deduced: From the given number (3·236), considered as a whole number (3236), subtract the non-recurring part (32) and divide the result (3204) by a number composed of as many 9's as there are figures in the repetend with as many zeros annexed as there are figures between the repetend and the decimal point (that is, by 990). The result is the equivalent common fraction ($3204\div990=\frac{178}{55}$).

There is a considerable amount of theory connected with the recurring decimal, and the subject formerly found place in most of the elementary arithmetics.

THE INDEX NOTATION

Origin.—The need which modern science has created for decimal fractions to a large number of decimal places has led to the introduction of a new symbolism based upon the fact that $\frac{1}{10^n}=10^{-n}$, and hence that $\frac{1}{1000000}=10^{-6}$,—a shorter way of expressing the common fraction. For example, instead of saying that a millimicron is 0·000000001 of a meter, we may say that it is 10^{-9}m.; and instead of saying that a square millimeter is 0·00155 of 1 sq. in., we may say that it is $1{\cdot}55\times10^{-3}$ sq. in. or 155×10^{-5} sq. in. The index notation is also used in connection with very large numbers, as when we express 750,000,000,000,000 ultra violet waves per second as $7{\cdot}5\times10^{14}$ per second.

Advantages of the Index Notation.—The demands of astronomy and physics render it necessary to use numbers to represent such great and such small distances and lengths that the eye has difficulty in detecting their meaning when they are written. The index notation not only condenses the statement but it is particularly valuable when logarithms are to be used.

For example, in the case of $1{\cdot}55 \times 10^{-3}$ we see that the characteristic of the logarithm is -3, and in the case of $7{\cdot}5 \times 10^{14}$ it is 14. Since a fraction expressed in any one notation can be expressed in any other, it is immaterial what notation is used so far as the general principles of fractions are concerned.

BIBLIOGRAPHY.—On the general theory of fractions *see* E. Combette, *Cours d'Arithmétique,* 12th ed. (1904); A. Hofler, *Didnktik des mathematischen Unterrichts* (Leipzig, 1910) (foundation principles). On the history of the subject *see* J. Tropfke, *Geschichte der Elementar-Mathematik,* 2nd ed., vol. i, pp. 118–149 (Berlin, 1921); D. E. Smith, *History of Mathematics,* vol. ii. pp. 208–227, 418–420, 477–493. (Boston, 1925) (general development of the various types oi fraction, with facsimiles from early works). (D. E. S.)

FRACTIONAL DISTILLATION: *see* DISTILLATION.

FRACTIONATION, in chemistry, consists in separating into fractions materials which differ in rates of crystallization, boiling points or other characteristics, rendering possible a sharp separation. Gases may be separated by fractional combustion, as in burning oxygen out of the air to secure the nitrogen *(see* NITROGEN, FIXATION *OF).* Fractional crystallization requires conditions favourable for the crystallization of one component in a reasonably pure state. Further purification is obtained by redissolving and recrystallization. Various conditions, temperature and a choice of solvents are important, as well as a knowledge of the characteristics of the solids to be separated. Fractional distillation is dependent upon differences in boiling points, the best example being the concentration of alcohol *(see* ALCOHOL). Here the lower boiling point of the alcohol allows its removal in a high state of purity from the water with which it is admixed. Fractionating columns are of various designs, the object in all cases being to concentrate to a high purity with low heat consumption. Complex mixtures of liquids are often separated by several distillations, in the course of which one after another is removed, according to predetermined conditions. *(See* DISTILLATION.) Fractionation may also be applied to precipitation, where one material after another may be thrown out of a mixed solution, depending upon the reagents used.

FRACTURES AND DISLOCATIONS. The most common injuries involving the bones are fractures and dislocations. A fracture is a break in the normal continuity of a bone. A fracture is called simple when the overlying skin is not broken and the bone is not exposed to the air; it is called compound when the bone is exposed, either as a result of the injury destroying the skin over the bone or of the broken end of the bone piercing the skin. The terms transverse, oblique, spiral and T-shaped refer to the direction of the fracture line. A transverse fracture line goes directly across the bone, an oblique fracture line crosses it at an angle and a spiral fracture line winds around the bone. A T-shaped fracture line goes transversely across the bone near a joint and the smaller piece of bone near the joint is split longitudinally.

Incomplete, greenstick, complete, impacted and comminuted are terms that refer to the position the broken ends of the bone assume following the injury. An incomplete or greenstick fracture occurs when the bone appears to bend but does not completely break into two separate pieces, the latter condition being termed a complete fracture. An impacted fracture occurs when the broken ends of the bone appear to be jammed together by the force of the injury. A comminuted fracture is one in which the ends are shattered into many pieces. A pathological fracture results when a bone weakened by disease breaks from a minor injury.

A dislocation is a disruption of a joint leaving the ends of the bones that meet to form the joint out of contact with each other. In simple dislocation, the joint surfaces are not exposed to the air. When the joint surfaces are exposed by destruction of overlying skin or by the end of the bone being driven through the skin the dislocation is called compound. A congenital dislocation is present at birth and is the result of defective formation of the joint. An acquired dislocation results irom an injury. A recurrent or habitual dislocation is a repeated dislocation of the same joint. A pathological dislocation occurs as the result of a disease which weakens the capsule and ligaments about the joint.

Injuries which cause dislocations may cause a iracture of one or more of the joint surfaces at the same time. This condition is called a fracture-dislocation.

Causes. — Fractures are produced by an injury which is forceful enough to overcome the resistance, whether normal or weakened, of the involved bone. In direct external injuries the force is applied directly at the point of fracture, as in the case of fracture of the iorearm as the result of a blow with a weapon. In indirect external injuries the force is transmitted from a distance to the point of iracture, ior example, as in a iracture of the upper arm as the result of a fall on the outstretched hand. In internal injuries the force is provided by the pull of the muscles which attach to the fractured bone. An example of this injury is a fracture of the upper arm as the result of throwing a ball.

Conditions which weaken the bones and predispose to fractures may be classified as normal or pathological. The normal predisposition exists in infants and young children whose bones have not fully matured and in elderly people, especially women, who normally undergo a weakening of the bone with age. Many pathological conditions which involve the skeleton, most commonly the spread of cancer to the bones, result in weakening of the bones. In persons with such pathological conditions fractures may occur as a result of very minor injuries.

Dislocation of a joint is caused by an injury which is forceful enough to overcome the resistance of the ligaments, muscles and capsule which hold the joint in place. Dislocation of a normal joint most commonly follows an injury in which the iorce is transmitted along the length of the bone and thrusts the end of the bone through the tissues which surround the joint but it may also follow direct injuries in the region of the joint.

Habitual, or recurrent, dislocations are those that reappear following an original injury, as the result of improper healing of the tissues or of the joint being made defective by the original injury. Subsequent repeated dislocations may then occur with minor injuries or even with ordinary movements of the joint.

Pathological dislocations result irom diseases that weaken the capsule of the joint or make the joint defective; such dislocations frequently follow minor injuries.

Diagnosis. — The recognition of iractures and dislocations is based upon the history of the injury, the symptoms the injured person experiences, the visible signs of the injury and X-ray examination. The history of the manner in which the injury occurred is helpful in localizing the area oi the iracture or dislocation, particularly in the case of young children who may be unable to indicate the region in which the pain is felt. A history oi a minor injury causing a iracture or dislocation leads to a search ior an underlying cause. The most common symptoms of a fracture or dislocation are pain and tenderness to the touch at the site, a sensation of grating or grinding on attempting to use the injured limb and an inability to use the injured limb. The most irequently seen physical signs of a iracture are deformity of the injured part, swelling in the region of the iracture, discoloration of the overlying skin, abnormal mobility of the bone and a grating or crepitant sensation felt at the point of the fracture when the strength of the injured bone is tested. The physical signs present in most instances of a dislocated joint are deformed appearance of the injured joint, swelling of the tissue about the joint, discoloration of the overlying skin and the inability to use the injured limb or to move the dislocated joint. X-ray examination of the injured bone or joint is of great value in the diagnosis of iractures and dislocations and is also helpful in indicating the type of treatment to be given since it reveals the type and extent of the injury more accurately than does the physical examination.

Healing. — All fractures, regardless of cause, attempt to heal in the same iashion. The injured bone very quickly produces new tissue that extends across the iracture line and joins the broken pieces together. In the early stages of healing this new tissue is soft, puttylike in consistency and easily injured. As time passes the body deposits bone minerals in this new tissue and it gradually hardens and cements the broken pieces firmly together. At this stage the new tissue is called the fracture callus and by virtue of the minerals deposited in it is faintly visible on an X-ray film. In the latter stages of healing this hardening callus becomes transformed into mature bone. As the callus is gradually changing into bone the union between the broken pieces becomes firmer until the area of fracture has become transformed into one solid piece of bone.

Several factors may govern the healing of a iracture, including the type and severity of the injury. In severely injured bone or in certain types oi iractures the blood supply to the broken bone may be destroyed. This bone is then unable to produce new reparative tissue to heal the iracture. Proper realignment of the broken hone promotes prompt healing since it makes it possible ior the new reparative tissue to bridge the gap between the broken ends of the bone. If other tissues such as muscle or tendon have been driven in between the broken ends of the bone they must be removed so the ends of the bone may be brought together. Adequate immobilization of the broken bone is necessary to achieve union. When the hone has been realigned it must be maintained in one position and must not be allowed to move or else the new delicate iracture callus will be injured and will not cement the ends oi the bone together. If the immobilizing apparatus is removed before healing has united the broken ends, motion may weaken the callus and allow the ends of the bone to spring apart.

Despite proper realignment and adequate immobilization, infection about the broken bone may retard or prevent healing by killing the new reparative fracture callus tissue. Other factors such as diet, age, general health, vitamins, syphilis and race which are popularly thought to play important roles in fracture healing have been shown to be of only minor importance. A child's bone heals more rapidly than does an adult's but advancing age does not retard healing or make it more difficult.

Dislocations involve injuries to the muscles, ligaments, tendons and capsule of the joint which hold the ends of the bone in contact. The dislocations heal by forming a scar between the cut or torn edges of these soft tissues. This healing process will take place whether the bones have been replaced in their proper position or not. The injured joint tissues heal more quickly than do broken bones.

Fracture-dislocation injuries heal by a combination of the two processes just described.

Treatment.— The proper treatment of a fracture or dislocation is dictated by many interrelated factors. The patient's age, general health, associated injuries, occupation and the type and location oi the iracture must all be taken into consideration in the treatment of an individual patient although many of these features have no direct bearing on the healing of the fracture itself. The emergency care of injuries suspected of having caused fractures or dislocations consists of controlling heavy bleeding with bandages or tourniquets, bandaging with clean bandages areas where skin has been torn or badly cut, splinting the injured limb without trying to straighten the deformity and gently transporting the patient to a place where medical care may be given.

The treatment of simple fractures consists of realigning the broken ends of the bone if they have been displaced and then preventing motion between them until sufficient time has elapsed ior the fracture to heal. Minor fractures with no displacement of the broken ends of the bone require no realignment. Incomplete fractures, the majority of fractures in children, and fractures involving bones that do not have powerful muscles attached to them may frequently be realigned by manipulation. The broken bone is grasped with one hand on either side of the fracture and manipulated with the hands until the desired position is attained.

Fractures involving bones that have powerful muscles attached to them or iractures in which the bone is shattered into many pieces often require more extensive care to realign them. The pull of the muscles may cause the broken ends of the bone to be pulled apart. In these cases a steady, continuous pull is put on the injured limb to counteract the pull oi the muscles after the bone ends have been realigned by manipulation. The pull is applied by attaching weights to the injured limb and suspending them in such a iashion that gravity iurnishes the pull—the traction method of treatment. The traction is maintained until healing has progressed to the point where release of the pull will not allow the ends of the bone to be pulled apart. Certain iractures cannot be realigned either by manipulation or by traction. This condition usually is the result oi a shattering injury or iracture in which muscle and other tissue is driven between the broken ends of the bone and cannot be dislodged. In these instances a surgical operation is necessary to realign the bone after which it is immobilized in one of several ways.

Minor iractures may he held with simple bandages or slings. Fractures that require manipulation for realignment are immobilized by splints or casts made of rolls of plaster of paris. The limb is held in the proper position and the cast applied. Following hardening oi the plaster of paris, slings, canes or crutches are used by the patient to further protect the injured limb. When traction is utilized to hold the bone ends together sandbags, slings or casts may be used in addition. Fractures that are treated by surgical operation are many times fixed internally by means oi metal pins, wires, screws, rods. nails or plates. Frequently in these cases casts or splints are not necessary to maintain stability of the broken bone.

The immobilization is continued until the iracture callus is strong enough to maintain union of the broken bone without external support, as determined by gently testing the strength of the bone and by X-ray examination. Following removal of the splints or casts complete use of the injured limb may not be permitted until further healing has taken place.

As soon as healing permits, gentle exercises to strengthen the injured limb are begun. Hinged casts, removable splints, crutches, canes, walkers, hot water pools, slings and braces are all devices that are used to protect the partially healed broken bone at this stage. Violent exercises which cause pain are avoided. Complete use of the limb is allowed when the fracture callus has been transformed into bone and the bone is solidly united. If advisable, metal devices which have been used to fix a fracture may be removed by a second operation aiter healing is complete.

Compound fractures present a more serious problem than do simple fractures. The wound (*q.v.*) produced by the loss of skin over the bone or by the bone piercing the skin irequently becomes infected by germs introduced at the time of injury. If the iniection extends about the broken ends it will inhibit the ability of the bone to form the fracture callus and will prevent healing. Ordinarily healing will not take place until the infection has been cured.

When a patient is seen within the first few hours after a compound fracture an operation is indicated. The broken bone is realigned and all tissues about the wound that have been exposed to germs are cut away in an attempt to remove all contaminated tissue beiore an infection can become established. The wound is then sewed together or skin is grafted over it and the iracture is kept immobilized by closed methods (application of splints or casts). The patient is immunized against tetanus and treated with drugs in a iurther effort to prevent infection. If by these procedures iniection is avoided and the wound heals the fracture is then treated as a simple fracture.

In cases where these measures fail or where infection has developed before treatment can be started all treatment is directed against the infection. Healing infections about iractures is frequently a prolonged, serious and difficult procedure. The fracture is placed in the best possible alignment and maintained by closed methods. After the infection is cured the fracture may be treated as a simple iracture.

Another serious problem is a iracture which extends into a joint and destroys the normal smooth surface of the joint. If the surface is made rough and uneven by the injury and heals in this irregular alignment the joint will irequently be permanently stiff and painful. Unless the surface of the joint can be accurately realigned by manipulation or traction surgical operation is necessary.

Simple dislocations are treated by repositioning the dislocated ends of the bones in their proper position, usually by manipulation. Occasionally it may he necessary to employ traction. Following reduction of the dislocation the involved joint is immobilized by bandages, slings, splints or casts until healing of the torn tissues about the joint has occurred. Gentle motion of the joint is then begun. Forcing painful motion is avoided. Complete function of the injured limb is not permitted until partial painless motion has been restored.

Compound dislocations are treated in the same fashion as compound iractures. Recurrent dislocations and congenital dislocations are special problems which require in most instances surgical reconstruction of the defective joint. (See ORTHOPAEDIC SCRGERY.)

Fracture-dislocations are the result of severe injuries. Frequently a loose piece oi bone remains jammed between the ends of the dislocated bones and may have to be removed surgically before the dislocation can be reduced. Even if the fracture can be realigned and the dislocation reduced by manipulation or traction, motion of the involved joint must be restricted longer than in a simple dislocation to allow healing of the fracture.

Complications.— The major complications of a broken bone are failure to heal, healing oi the bone in a position that interferes with the limb's iunction and loss of the injured limb's function despite healing of the fracture in good position.

The iailure of broken bones to heal may be due to inadequate immobilization, infection, massive destruction of bone or injury resulting in loss of blood supply to major portions of the bone; in certain instances the fracture may fail to unite ior no knou-n reason.

Healing in an improper position, or malunion, with resulting deformit'y, is usually caused by iailure to realign the bone properly. Malunion results when injuries have destroyed large portions oi the bone so that in order to salvage a limb, deiormity must be accepted. Injuries to the growth centres of bones in children cause malunion and subsequent growth in a deiormed manner.

The loss of function in a limb despite healing of a iracture is usually caused by prolonged immobilization necessary to achieve healing of severe fractures, by heavy scarring following infection from compound fractures or by heavy scarring irom associated wounds while the limb is immobilized. Stiffness in joints may follow even minor injuries to a limb. The cause of this phenomenon is unknown.

The major complications of dislocations are stiffness and pain in the joint and development of a recurrent dislocating joint. The usual causes of the pain and stiffness are failure to reduce the dislocation, irreparable damage to the joint by injury, heavy scarring in the surrounding tissues during healing and prolonged immobilization. Recurrent dislocating joints are produced by improper healing of the surrounding tissues or damage to the joint surfaces which result in a defective joint.

Bone Grafting.— Bone grafting is a surgical procedure in which one or more pieces of bone are placed across or packed around the broken ends of bone which have failed to heal. *(See* ORTHOPAEDIC SURGERY.) This operation stimulates the ends of the broken bone to produce fracture callus, provides a framework for the callus to grow across the break, and the grafted bone is thought by some to produce callus of its own which aids healing. It has been shown that bone obtained from the patient himself makes a graft superior to bone obtained from another person, an animal or a "bone bank." Bone grafts are useful in bridging large deiects in severely damaged bone, correcting deformities and bringing about healing in fractures which have failed to unite by other methods. (W. F. E.)

FRAGONARD, JEAN HONORÉ (1732–1806), one of the best-known and most typical French painters of the 18th century, was born in Grasse on April 5, 1732, the son of a glovemaker. His father articled him to a notary, but he showed such talent for painting that his employer suggested a change of profession. He entered the studio of F. Boucher. was sent on to J. B. Chardin, and six months later, having learned little, returned to Boucher (1750) who this time gave him serious attention. In 1752 Fragonard won the Prix de Rome with a picture of "Jeroboam Sacrificing to the Idols" (École des Beaux-Arts, Paris), but before leaving for Rome he spent three years at the École des Elèves Proteges, where he studied under F. Lépicié, M. Dandré-Bardon and C. Vanloo. Finally. in 1756, he arrived in Rome.

Despite this wealth of tuition, Fragonard learned all he knew from Boucher and from his own studies from nature in the Roman Campagna. On the eve of his departure. Boucher warned him to avoid the old masters and to concentrate on artists with whom he had a temperamental affinity, such as F. Albani and G. B. Tiepolo. In Rome he became friendly with the landscape painter Hubert Robert, with whom he spent many long days sketching; in 1759 the rich Abbé de Saint-Non arrived from Paris and the three men passed the summer at the Villa d'Este. Saint-Non engraved Fragonard's red chalk drawings of the gardens (many of which are now in the museum at Besançon), and they won the approbation of his superiors at the French Academy in Rome. He returned to Paris via Venice in 1761 with his style completely formed.

In 1764 he was admitted to the French Academy on the strength of his "Corrésus et Callirhoé" (Louvre, Paris). The king bought the picture but did not pay for it until some time later. After 1767 Fragonard ceased to exhibit in the Salon and was no longer considered a "serious" artist by his contemporaries. He accepted commissions from rich financiers (who paid promptly) and from actresses and demimondaines, and worked mainly on decorative projects for, among others. Mme. de Pompadour. Mlle. Guimard, and Mme. du Barry, who commissioned from him in 1771 a series of panels for Louveciennes on the theme "Le Progrès de l'Amour dans le Coeur des Jeunes Filles" ("The Progress of Love in the Hearts of Young Girls," now in the Frick collection, New York city). The subject matter of his small paintings became slighter and more allusive. as "Le Baiser à la dérobée" ("The Furtive Kiss." Hermitage, Leningrad), "La Chemise enlevée" ("The Stolen Chemise." Louvre) and "La Balançoire" ("The Swing." Wallace collection. London) will testify.

In 1773 he was taken to Italy by one of his patrons, Bergeret de Grandcour. who has left a charming account of the journey. They visited all the main towns and returned to Paris via Vienna, Mannheim and Dresden. Fragonard was rich, happy and famous, but he was also closely identified with the way of life of the *ancien régime,* and his fortunes fell with the Revolution. Thanks to his former friendship for the young Jacques Louis David, whom he had chosen to complete his decorations for Mlle. Guimard. Fragonard was protected from reprisals and even appointed to the committee of the new Museum des Arts. He died in Paris on Aug. 22, 1806.

Fragonard is represented in the major French. British and American collections and notably in the Louvre. the Wallace collection. and at Chantilly, Besanqon, Amiens, Nantes, Grenoble, Avignon and Marseilles. His finest landscape, "La Fête a Saint-Cloud." is at the Banque de France in Paris. Of his few engravings, the most important is "L'Armoire" ("The Wardrobe," 1778).

FRAMINGHAM, a town in Middlesex county, Mass., 21 mi. S.W. of Boston. Settled in 1650, it was named after the English home (Framlingham) of Gov. Thomas Danforth who owned the land. It was incorporated in 1700. Power and rail developments assisted in limited industrial development in the 19th century. It is the site of the first normal school in the country, founded in 1839 in Lexington and moved to Framingham in 1853; in 1932 it was renamed State Teachers college. The State reformatory for women is located in the town. After World War II, increasing use of the automobile and the development of superhighways, particularly the Massachusetts turnpike, made the community a retail-industrial centre and residential area for the Greater Boston industrial complex. Among the firms introduced at this time mere scientific concerns and regional distributors to the industrial leaders: paper and allied goods, auto assembly, textiles and chemicals. Framingham was chosen for the site of the first suburban shopping centre in the nation, Shoppers World (but it was the second to be completed, in Oct. 1951). It retains unlimited town-meeting government. For comparative population figures *see* table in MASSACHUSETTS: *Population.* (R. C. Mo.)

FRAMLINGHAM, a market town in the Eye parliamentary division of East Suffolk, 88 mi. N.E. of London by road. Pop. of civil parish (19ʒ1) 1,943. The church of St. Michael is a Perpendicular and Decorated building of black flint surmounted by a tower 96 ft. high. Monuments include those of Thomas Howard, 3rd duke of Norfolk (d. 1554); Henry Howard. the famous earl of Surrey, who was beheaded by Henry VIII; and Sir Robert Hitcham. Dominating the little town are the remains of the castle: a splendid curtain wall 44 ft. high and 8 ft. thick with 13 towers more than 50 ft. high. The chimneys are mostly dummies added in the 17th century. The castle, originally founded in the 6th century, was captured by the Danes and retaken by the Saxons. In 1100 Henry I gave it to Roger Bigod whose son Hugh, the 2nd earl of Norfolk. built a masonry structure. About the end of the 12th century this was enclosed by the still-existing curtain wall with its towers, and a new hall on the west side replaced one built (c. 1150) on the east. In 1306, in default of heirs. the castle passed from the Bigods to the crown and was granted by Edward II to his half brother Thomas of Brotherton, created earl of Norfolk in 1312. From him it descended to the Mowbrays and then to the Howards. Town and castle followed the vicissitudes of the dukedom of Norfolk and after being alternately forfeited to the crown and restored it was sold in 1635 to Sir Robert Hitcham. In 1636 he left it to Pembroke college, Cambridge, on condition that "all the castle. saving the stone building, be pulled down" and that a poorhouse be provided. The curtain wall with its towers now encloses a grassy space measuring about zoo ft. by 300 ft. with a building which has in turn served as poorhouse, courthouse and drill hall. Scheduled as an ancient monument, the fabric is cared for by the ministry of works. Half a mile from the station is Framlingham college. founded by public subscription in 1864 as the memorial of Suffolk county to the prince consort.

FRAMPTON, SIR GEORGE JAMES (1860–1928), English sculptor and craftsman, the author of some noted public monuments, was born in London on June 16. 1860. He studied under W. S. Frith and at the Royal Academy schools, where he won a traveling studentship. During 1888–90 he studied in Paris under A. Mercié. by whom he was much influenced. At the beginning of the 1890s he was attracted by the arts and crafts movement (*q.v.*) and experimented with decorative sculpture, using various materials such as bronze, ivory, marble and jewels combined in one work. His principal statues include those of Mrs. Alice Owen at Owen's school, Islington. London; Queen Victoria at Calcutta, at Leeds, at Southport and at Winnipeg; and (all in London) Quintin Hogg in Langham place, Peter Pan in Kensington gardens and Edith Cavell (a conspicuous failure) in St. Martin's lane. Frampton became a royal academician in 1902 and was knighted in 1908. He died in London on May 21, 1928. (R. Gs.)

FRANC, originally a French coin but now also the title of a number of national currencies of different values, notably those of France, Belgium. Luxembourg. Switzerland and most French and Belgian overseas territories. The name was first applied to a gold coin, minted by King John II of France in 1360, because on one face was the legend *Johannes Dei gracia Francorum rex* ("John, by the grace of God, king of the Franks"). As this coin also carried an effigy of the king on horseback it was known as the *franc* a *cheval* to distinguish it from another coin of the same value subsequently issued by Charles V of France and labelled the *franc à pied* because the monarch was shown on foot. During the 16th century the minting of franc gold coins ceased, but the name was freely applied by the French public to the new unit of exchange then introduced—the livre tournois, a gold coin subdivided into 20 sols. In 1795, to symbolize the political changes that followed the revolution of 1789. the government of the republic introduced a new franc currency. The first coin was a 5-franc silver piece. but subsequently gold coins worth 20 francs (napoleonsj were produced in quantity. The livre tournois, which was exchangeable into the new currency at a rate of 81 livres to 80 francs, continued to circulate in France until 1834.

The franc was formally established as the monetary unit of France in 1799 and made divisible into 10 decimos and 100 centimes. Reaflirmed in this position by the more elaborate law of 1803 (which also introduced a fixed relationship of $15\frac{1}{2}$ to 1 between gold and silver in monetary uses), the franc has continued to form the basis of the French monetary system although subjected to stresses that have greatly reduced its international standing as well as its purchasing power. The decline of its status largely occurred after the opening of the 20th century. During the 19th century its stability, coupled with the tendency for France to dominate the continent of Europe politically and economically, led to its being widely used as the basis for the currencies of other countries. The currency system introduced in Belgium after that country gained its independence from the Netherlands in 1831 provided that the Belgian franc should be maintained at parity with the French franc and permitted French gold and silver coins to circulate freely. In 1850, following the reform of the constitution, the Swiss government decreed that the French franc should supersede all existing currency, while the new lira currency introduced in Italy in 1862, shortly after the unification, was directly linked to the French franc on a parity basis. Finally, in 1865, when France, Italy, Belgium and Switzerland joined together in a plan for strengthening European economic ties through the formation of the Latin Monetary union, the French franc was made the medium of exchange for external transactions. (*See* MONETARY AGREEMENT.) The union, which was later joined by Greece and, on a limited basis, by Spain, Venezuela and other countries, did not formally end until 1926, but for practical purposes it broke up during World War I. With its disintegration, the French franc lost its dominating position in the European currency field and thereafter there were no special links between the minor franc currencies.

French Franc. — The decline in the price of silver having forced France and other Latin Monetary union countries in 1873 to abandon the practice followed since 1803 of giving both a gold and a silver standard for currency purposes, France entered World War I with a gold standard currency only. The gold link was then severed, however. During the war period, the franc was pegged at the prewar levels of 25.22 to the pound sterling and 5.18 to the U.S. dollar. But after the exchange was freed in 1918 the franc fell until a level of 244 to the pound was reached in July 1926. At that point, with the country on the verge of financial collapse, the Poincaré ministry undertook reform with the result that it became possible to stabilize the franc on a gold basis in 1928 at rates of 124.2 to the pound and 25.51 to the dollar. Following the departure of Great Britain and other countries from the gold standard in the early 1930s, the French balance of payments deteriorated. This and internal financial crises led to the abandonment of the gold standard and three successive devaluations of the franc between Oct. 1936 and May 1938. From a level of 74.60 to the pound and 15.13 to the dollar at the end of 1935, the franc had fallen to 176.63 to the pound and 43.83 to the dollar four years later. During the German occupation a rate of 20 fr. to the reichsmark was maintained, which corresponded to a sterling rate of about 200 and a dollar rate of about 50. But the real value of the franc fell rapidly as a result of inflationary forces. Nevertheless, although black market quotations indicated that by the autumn of 1944 the franc had fallen to about 800 to the pound and 200 to the dollar, the new rates fixed after France was liberated were 200 to the pound and 49.63 to the dollar. This overvaluation of the franc, however, impeded postwar economic recovery and the exchange was therefore adjusted to the more realistic level of 480 to the pound and 119 to the dollar at the end of 1945. But the economic situation continued to deteriorate mainly because of inflationary stresses stemming from the budget deficit and rising wage rates. In consequence the franc had to be devalued twice in 1948 and again in April 1949 to 1,097 to the pound and 270 to the dollar.

When sterling was devalued in Sept. 1949, the franc was reduced again against the dollar to 350 but raised against the pound to 980. In Aug. 1957 tax changes for certain trade purposes and a new exchange rate for foreign tourists reduced the franc to 420 against the dollar although the official rate remained at 350.

Though most of the franc currencies circulating in French overseas territories depreciated substantially after World War I, they were not all devalued to the same extent as the metropolitan franc.

Belgian Franc. — In 1925 a first, abortive attempt was made to stabilize Belgian currency, which had depreciated severely after World War I. But a new attempt made in 1926 backed by an international loan of $100,000,000 proved successful on the basis of an exchange rate of 175 fr. to the pound and 36 to the dollar. To facilitate trade a new unit known as the belga, with a value of 5 fr., was then introduced to govern external business, but the franc was retained for internal purposes. The new gold standard currency came under pressure in the 1930s as a result of the devaluation of other currencies and had to be reduced in value in terms of gold. During the German occupation an exchange rate of 12½ fr. to the mark was enforced. After liberation in 1944 the currency system was wholly reformed. The belga was abolished and a new franc currency introduced with an exchange value of 176.6 to the pound and 44 to the dollar. The new rates structure overvalued the country's currency a little and advantage was taken of the world currency realignment of 1949 to reduce its gold value by 14%, establishing it at 50 to the dollar and 140 to the pound. Between 1950 and 1956 the Belgian external payments position was sound and the new structure was maintained without difficulty.

The Congolese franc used in the Belgian Congo is directly linked with the Belgian franc on a parity basis.

Luxembourg Franc.—Before World War I Luxembourg had a franc currency linked to the German mark at a value of 80 pfennigs. Since economic union with Belgium came into practical being in 1922, however, the duchy's currency has been directly linked to the Belgian franc on a parity basis and Belgian notes and coin have circulated freely.

Swiss Franc. — With the collapse of the Latin Monetary union, Switzerland began to mint Swiss francs on a large scale to end the former dependence on foreign currencies. Since then its currency has depreciated to a materially smaller extent than other leading world currencies, partly because of Switzerland's remaining neutral in both World Wars I and II and partly because of the sound monetary policies pursued by successive governments. It is also one of the few world currencies that, by the mid-1950s, had not had its freedom of movement restricted by exchange controls. During World War I it was maintained at 25.22 fr. to the pound and 5.18 to the dollar and these were the rates chosen when stabilization took place upon return to the gold standard in 1929. The gold value of the franc had to be reduced in 1936 because of the pressures imposed on Switzerland's balance of payments by the devaluation of many other currencies between 1931 and that year. In 1940 a slight increase was made in the gold value and the new level was maintained during and after World War II despite the fact that many other European currencies were considerably reduced in value. During 1950–56 it was quoted at a level of about 12.25 to the pound sterling and 4.35 to the U.S. dollar. (C. G. T.)

FRANÇAIS, FRANÇOIS LOUIS (1814–1897), French painter. was born at Plombières (Vosges). After a few years of hard struggle, during which he made a precarious living by drawing on stone and designing woodcut vignettes for book illustration, he studied painting under Gigoux, and subsequently under Corot, whose influence remained decisive upon Français's style of landscape painting. He exhibited first at the Salon in 1837 and was elected to the Académie des Beaux-Arts in 1890. Comparatively few of his pictures are to be found in public galleries, but his painting of "An Italian Sunset" is at the Luxembourg museum in Paris.

FRANCAVILLA FONTANA, a town and episcopal see of Apulia, Italy, province of Brindisi, 22 mi. E. by N. of Taranto by rail. 460 ft. above sea level. Pop. (1951) 24,743. It is in a fine situation. and has a massive square castle of the Imperiali family. to whom, with Oria, it was sold by Carlo Borromeo in the 16th century for 40.000 oz. of gold, which he distributed in one day to the poor.

FRANCE, ANATOLE (1844–1924), whose real name was Jacques Anatole Thibault, French man of letters, was born in Paris on April 16, 1844. For 30 years French literature was dominated in the eyes of all the world by the fame of Anatole France. It is true that his influence declined in the last period of his life and that his ideas were questioned: but not his style nor the services rendered by him to the language. In his old age he was revered as a genius and a patriarch. No reputation since Voltaire's has been found comparable with his.

The son of a bookseller called Thibault. this youth who was to make illustrious the pseudonym of Anatole France started his career quite humbly. He was fond of literature, he was studious and erudite, but negligently preferred reading to writing. He composed publishers' puffs and contributed a weekly article signed "Gérôme" to the *Univers Illustré*. For his own amusement he wrote verse, *Les poèmes dorés* (1875) and *Les noces corinthiennes* (1876), which showed learning, charm and taste. In 1879 he published his first volume of stories. *Jocaste et le chat maigre,* and in 1881 his first novel, *Le crime de Sylvestre Bonnard,* which was acclaimed by the discriminating as delightful.

In 1883 he first met Mme. Arman de Caillavet. with results that profoundly influenced his career. Mme. de Caillavet became his lifelong friend. She was clever and active; she had a host of acquaintances and her receptions were attended by the leading figures of literature and politics. She laboured for the fame of Anatole France and she forced him out of his inertia into composition. The extracts from her correspondence with him prove the important share she took in his writings, and in the dedication of *Crainquebille* (1904) Anatole France could say: "To Madame de Caillavet, this book which I should not have written without her help, for without her help I should write no books."

For 40 years Anatole France poured out a series of lively, solid, graceful and profound works. There are the pungent and mischievous short stories: *Balthazar* (1889), *L'étui de nacre* (1892), *Le puits de Sainte-Claire* (1895); the meditative and critical books, *Les opinions de Jérôme Coigaard* (1893), *La vie littéraire* (4 vol., 1883–92); a philosophical novel: *La rôtisserie de la Reine Pédauque* (1893); an historico-philosophic novel, *Thaïs* (1890), describing Alexandria at the beginning of the Christian era and contrasting the ideals of dying paganism with those of nascent Christianity; an admirable novel on the French Revolution and the Terror, *Les dieux ont soif* (1912); a society novel, *Le lys rouge* (1894), a powerful study of jealousy set amid the artistic treasures and lovely vistas of Florence; then the series of political satires. the four volumes of *L'histoire contemporaine—L'orme du mail* (1897), *Le mannequin d'osier* (1897), *L'anneau d'amkthyste* (1899), *M. Bergeret à Paris* (1901), where Anatole France creates the legendary figure of M. Bergeret and portrays society before and during the Dreyfus affair; novels of a revolutionary tendency, *Sur la pierre blanche* (1903), *L'île des Pingouins* (1908), *La révolte des anges* (1914), a biography of Joan of Arc (1909–10); lastly the reminiscences, *Le petit Pierre* (1918), *La vie en fleur* (1922). Such is the sum of this work admirable in its wealth and variety.

The philosophy of Anatole France developed during the course of his career. Until 1900 he was primarily a sceptic. As Voltaire's spiritual son he delighted in the play of ideas and observed without pity the stupidity and the silliness of men. He probed the past and the present and spared no example of human inconsistency, error or weakness. *Les opinions de Jérôme Coignard* gives the reader much pleasure, so witty and mischievous is the author, and gives him, too, a complete lesson in scepticism. The same remark may be passed on *Les dieux ont soif,* where Anatole France considers almost exclusively the failures of the French Revolution. At this time the author seems to have kept respect for beauty alone, the beauty of natural or artistic forms or of such superior intelligence as was shown in the great Greek and Latin writers. Meanwhile he beamed indulgently upon an imperfect universe. As he believed in nothing, he did not believe in a better or a worse. In the writings prior to 1900 may even be found conservative and aristocratic maxims. A supreme indifference inclined him to accept what is rather than risk what might be.

On the outbreak of the political crisis of 1900 his temper changed. He was then seen to show a preference for the progressive parties, and little by little went on to the revolutionary parties. which became honoured by his support. He was no orator; words came slowly, and neither his mind nor his phrases were of the kind likely to be popular. The part taken by him at public meetings was undistinguished, being limited to signing manifestos and applauding resolutions. especially those with an international objective. He was more powerful with his pen. An opponent of church and state, he seemed to put his faith in the people and to expect the world to be renewed by some kind of revolution. On this point his ideas remained rather vague. In one of his books. *Sur la pierre blanche,* he ends the description of future society with a dreadful cataclysm that destroys everything, and here he is nearer to nihilism than to socialism. World War I changed the trend of his thoughts. As he was too old to serve in the field he wanted at least to show his good will and asked to be employed in a Tours office. This great upheaval left him uncertain concerning the destinies of humanity. Perhaps extreme scepticism is not for long tolerable, and Anatole France felt the need of escape into a revolutionary faith which he refused to define, leaving it a mere aspiration.

What is indisputable is the quality of Anatole France's art. The younger generations, tried by war and witnessing the consequent political difficulties, ill comprehend the detachment of dilettante M. Bergeret. They need more moral discipline, they believe more in virtue and action. But they do not deny the master who charmed their elders with his graceful wit and magic phrases. As a storyteller, in lucidity of thought and form, Anatole France is incomparable. In his style, too, there is a sweetness, an almost voluptuous grace, which distinguishes his phrases from those of any other writer. He owed much to Voltaire, much to Renan, much to the old French romances, to memoirs and to chronicles. He had read and remembered much; but what he borrowed he made his own; all mas changed, and for the better, by his style and interpretation. He translated into a pungent idiom all that could delight or stimulate the intelligence of his cultured contemporaries. He was a deep admirer of classicism, and to the end of his life when he mentioned Molière, Racine or Stendhal his conversation or his writing attained their richest substance and most pleasant harmonies.

He makes another strong claim on the attention of posterity. He was the finest flower of the Latin genius. His knowledge of antiquity was great, and his work contained the essentials of Greek and Latin wisdom. He portrayed in *Thai's* characters who distil the philosophy of the ancients. He put into the mouth of Jérôme Coignard maxims which likewise represent the sum of the meditations and arguments common to antiquity.

Lastly, in all periods of his career, whatever his theories, he was a deep student of human nature. He expressed in magic words most of the wisdom that may be acquired from the observation of life and the reading of history. He created characters who persist in the memory—Jérôme Coignard, Jacques Tournebroche, M. Bergeret, Mme. Martin Bellème, Catherine. the laceworker, Paphnuce, Nicias, Evariste Gamelin. He described what was comic and evil in mortals. He described, too, what was august in man, sacred in man's labours and sufferings. Though he lacked enthusiasm and ardour, his critical intelligence did not prevent him from brooding over human misery, and in the story of Crainquebille he showed his heart. While humbling himself before the invincible forces of fate and lust, he dedicated his work now to irony—which brought brightness into his life—and now to pity—which at other times reminded him that life deserves a serious, a solemn attention. And so he became twice fortunate, for he was at once a subtle artist acclaimed by the critics and a universally respected publicist who influenced the simple-minded. He died at Tours, Oct. 13, 1924.

FRANCE, a country occupying part of the extreme west of the European continent, lies between 51° 9′ and 42° 23′ N. lat. and between 4° 38′ W. and 8° 10′ E. long. It comprises an area of 212.821 sq.mi. (including Corsica, *q.v.,* 3,367 sq.mi.) and, excluding the components of the Soviet Union, is the largest country in Europe. It is roughly pentagonal in shape. Its maximum length is about 621 mi. from Dunkirk on the north coast to the Pyrenees; its greatest breadth. from the western tip of Brittany to the Rhine, is roughly the same distance. The country is bounded everywhere by natural frontiers in the form of sea, mountains or rivers except on the northeast, where it marches with Belgium.

The country's northern frontier from the Belgian border to the western tip of Brittany is formed by the Straits of Dover and by the English channel. The coast is at first straight, flat and bordered by dunes, then rocky around the Pas-de-Calais, low and sandy along the province of Picardy, and rectilinear and flanked by high chalk cliffs to eastern Normandy. The coast of Normandy is occasionally indented and lined by a few low cliffs; farther west it juts out in the steep and rocky Cotentin peninsula. The northern Breton coast is rugged, hilly, serrated by numerous bays and bordered by reefs and islands.

The long western Atlantic border can be divided into three parts: the western Breton coast, broken by large bays and deep inlets, fringed by islets; the coast of Vendée, Aunis and Saintonge between the estuary of the Loire and the Gironde, flat with occasional low headlands, straight and bordered by dunes; and finally the flat rectilinear edge of Aquitaine, behind whose dunes lie numerous extensive lakes and marshes.

The southern frontier is constituted by the Pyrenees, which stretch in a continuous barrier from the Atlantic to the Mediterranean, by the Languedoc coast of this latter sea (mostly flat and studded with ponds enclosed within dunes) and by the high rocky fringe of Provence, up to the Italian border. The island of Corsica is the subject of a separate article.

On the east France is bounded, from the Mediterranean to Lake Geneva, by the Alps, which separate the country from Italy; then by the Jura mountains, which form its boundary with northwestern Switzerland; farther north by the Rhine, which divides France from Germany until the northeastern frontier leaves the Rhine plain near Rarlsruhe and, marching with the Saar. Luxembourg and Belgium. strikes the North sea east of Dunkirk (Dunkerque). On leaving the Rhine it runs through the foothills of the Vosges and Hunsriick ranges to Luxembourg; then through those of the Ardennes and finally through the featureless lowlands of Flanders.

Presenting broad faces to the North sea, to the Atlantic and to the Mediterranean, France is. therefore, a maritime state with access to important sea routes. By virtue of its long eastern border it is also linked closely with southeastern and with western central Europe.

PHYSIOGRAPHY

Geology. — The geological history of France can be briefly summarized as follows.

Two principal periods of mountain building have occurred in France since Archaean times. During the first. which took place toward the close of the Palaeozoic era, a mountain chain (part of a more extensive European one known as the Hercynian system) was raised, running from east to nest through the northern area of the country. A second system running from southwest to northeast was also created in the south and centre. A long period of erosion mostly reduced these two ranges of mountains to peneplains. The more uplifted remnants (now represented by the Vosges, the Ardennes, the Brittany uplands and the Massif Central) were subsequently covered by a thin layer of sedimentary rocks. Other areas of the country aere overlaid in greater thickness by deposits of limestones, sandstones, marls and clays left during the ages by the retreats of successive invading oceans. These are now the lowlands of the Paris and Aquitaine basins. the Flanders plain, the Rhône-Saône corridor and the Languedoc plain.

In mid-Tertiary times there took place a second period of folding, nhich created the Alps and the Pyrenees. During this folding the existing blocks of older rocks were further raised. The area of the Massif Central itself became a region of intense volcanic activity which created a new relief in the shape of plateaus or rugged crests. The more outlying areas of the north and west mere only gently folded by this new disturbance. Erosion, which followed in later Tertiary times, stripped much of the sedimentary cover from the older rocks and created valleys within their systems. This erosion reduced the northern area to a surface of low relief, diversified, honever, by bands of more resistant rocks. Into the low Aquitaine basin and the Rhône-Saône corridor Tertiary sediments were deposited by the mountain rivers. France escaped the ice sheets of Quaternary ages, but local icecaps in the country's mountains contributed to the creation of valleys and the deposit of additional debris into them and existing plains.

Thus, the principal and more surface geological divisions are briefly as follows: the Massif Central, of older crystalline rocks or more fertile volcanic and limestone; the Vosges and Ardennes, where granite is occasionally covered with sandstone; the peneplain of Brittany nhere granite is sometimes covered with slates or sandstones; and the folded Tertiary mountains of the Alps and pre-Alpine zones, created later and comprising high massifs of granite and crystalline rocks and lower ranges or plateaus of limestone and sandstone.

The chief lowland areas comprise: the Paris basin, varied and bordered by scarplands of limestone and sandstone, but mostly composed of sedimentary deposits laid down from Jurassic to Miocene times, in which alluviums, gravels and loam (loess, *limon*) predominate; the Flanders area, a district of clay, sand-capped ridges and chalk hills, under which lie the richest carboniferous strata of the country; and the Aquitaine basin of a later Tertiary formation than the Paris, where limestone is less frequent and sand or clay predominates and where gentle undulations replace scarplands. Other areas are the Languedoc plain of limestone and gravel in the south and the Rhône-Saône corridor, a structural depression between the Alps and the Massif Central, which has been filled in by Miocene and Pliocene sediments or glacial and fluvial deposits.

Natural Regions. — The surface of France is divided almost evenly between lowlands and hills or mountains. The principal lowland areas comprise a succession of valleys and plains interspersed with hills and plateaus which wheel in a deep rough arc from the Belgian border to the Pyrenees. Their base is the axis of mountains and outlying uplands from the Ardennes to the gate of Carcassonne which divides the southern tip of the Massif Central from the eastern Pyrenees. In the north and west the valleys run roughly from northwest to southeast and thus form natural arteries into the centre of the country. Access from the Mediterranean area is provided either to the east and to the centre by the Rhône and Saône corridor, which breaches the two great mountainous regions of the Alps and the Massif Central; or to the southwestern central areas by the gate of Carcassonne and the Garonne plain.

The most extensive and highest mountainous area is that of the Alps nhich occupies the southeast. There the highest massifs and peaks rise to more than 10.000 ft. (with Mont Blanc reaching 15,781). The Alps are, however, pierced by a number of great valleys leading to passes, which make them relatively easy to cross in all directions. The core of the Massif Central is composed rather of plateaus, with cones reaching heights of around 6,000 ft. Within its mountains spring the headwaters of some of France's largest rivers. The Pyrenees, dividing France from Spain, form on the French side a steep rampart dominating the plains of Aquitaine. Their highest peaks rise to more than 10.000 ft., and passes through the chain are relatively rare. The tno remaining mountainous areas in the east, the Jura (really part of the Alpine system) and the Vosges are lower (around 4,000 ft.), less extensive and of a more rounded and smoother relief than the other systems. When treating the geography of France in some detail, it is convenient to divide the country into various regions.

The Northeastern Region. — This region comprises the Flanders plain, part of the Ardennes and Lorraine. The Flanders plain stretches from the North sea southeastward for about 100 mi. The maritime area (Cap Blanc-Nez to the Belgian frontier) includes a low sandy coast bordered by dunes behind which lie reclaimed marshes and a flat clay plain. The hinterland is a rich agricultural region, linked to the ports of Calais, Dunkirk and Gravelines by canals. With its humid atmosphere and good soil it supports dairy cattle and horses. The maritime belt is succeeded by a low central plain, mostly of clay and relieved by occasional ridges. It is watered by various rivers and bounded on the southwest by the Artois uplands. There wheat, barley and hops are grown. To the southeast, the plain runs into the foothills of the Ardennes. Stretching through the centre is the most important coal field of France, to which metallurgical, engineering and textile industries are attached.

The foothills of the Ardennes limit the southeast of the plain (of the Ardennes, only the small southwestern area is in France). They rise into a plateau covered with forest and moors of peat and clay. The area is deeply cut by the gorges of the Meuse and its tributaries. A harsher climate and poorer wooded soil are general except in the deep river valleys nhere a varied agriculture is practised.

The southernmost part of the region comprises the limestone Lorraine plateau and plain, bounded on the nest by the scarplands of Champagne and on the east by the Vosges. The plateau, extensively wooded, is intersected by rivers (chief of which are the Saar, Moselle and Meuse) rising in the Vosges and in the lower border of southerly hills. Cultivation is practised, chiefly wheat, potatoes and beets and fruits together with stock raising. In the plateau area are found the rock salts and iron ore which support the Lorraine industry; in the Moselle valley coal deposits are being increasingly exploited.

The Paris Basin.—The Paris basin in the north and centre of the country roughly covers a geographic area of 110,000 sq.km. (42,471 sq.mi.) or about one-fifth of France. It is bounded on the northeast by the Artois hills, on the east by the Lorraine plateau and on the southeast by the Monts du Morvan and the plateau of Langres, which divide it from the corridor of the Sabne. To the south, the valleys of the central Loire, of the Cher and of the Indre may be included within the region; to the west, it merges into the eastern hills of Normandy; on the north it is bounded by the English channel. The principal artery is the Seine which, in its course, is fed by numerous rivers, especially from the east and southeast. Limestone is the predominant element and superficial deposits include clays, river alluvium and *limon,* the latter especially productive for cereal and root crops.

The basin itself can be divided into several areas, most of them covered nith a deep layer of linzon. The core (with Paris and its outskirts forming an urbanized and industrial centre) consists of various districts, each possessing many of the same economic characteristics. Brie, lying between the Marne and the Seine to the east of Paris, is a country of clay to the north and limestone to the south; it supports a varied agriculture, dairy cattle and sheep. Beauce, between the Seine and the Loire to the south, is a level expanse of limestone covered with limon and without important rivers; it is one of the granaries of France because of its fertile soil; and again cultivation is varied by the raising of cattle and sheep. The district watered by the Risle, Eure and Iton to the west of Paris is of similar soil but broken by deep river valleys and more nooded. That of Valois and the Soissonnais. lying to the north and to the northeast between the Oise and the Marne, is also a limestone area covered with limon, intersected by valleys and composed of rich farmlands.

The outer core of the Paris basin is composed of various districts. which stretch into the neighbouring provinces of Maine, Normandy, Picardy, Artois, Champagne and Berry. To the west lies the clayey bocage plateau of Perche, partly in Normandy and partly in Maine. This region is particularly celebrated for the breeding of horses. It merges to the north with the more open country of Neubourg and St. André, an agricultural area with an emphasis on the raising of young stock for export. To the north of the Seine lies the dissected chalk plateau of the Vexin, where agricultural pursuits are supplemented in the river valleys by a small-scale cotton and woollen industry; and the woodland and pastures of the clay soils of Bray, where flourishes particularly stock raising and dairy farming. Bordering the coasts lies the Ievel, open district of Caux, where a thick covering of limon supports arable farming and stock raising and where small textile towns are found in the valleys. Picardy, lying farther northeast, is a chalk upland, partly forested and divided by the valleys of the Somme, Authie and Canche. Where it is covered with limon intensive cultivation is found. Small towns specialize in sugar refining and distilling or in various branches of textiles. Farther north lie the bare chalk hills of Artois, bordered by the undulating meadow and woodland coastal area of the Boulonnais, again extensively cultivated or given over to stock raising.

The outer eastern area of the basin comprises the extensive Champagne plain. Its western fringe is composed of the Cbtes de Champagne, whose slopes, particularly south of Reims and around Epernay, form the vine-growing area of the province. In the extreme north bordering the Ardennes is a fertile area of cultivated and pasture lands. A large area of the north and northwest is, however, covered with forest, ponds and marshes.

Much of central Champagne (Champagne Pouilleuse) is a dry plateau of chalk without any covering of *limon* and with fertile areas only in the river valleys. Farther east is a wetter and richer district, supporting a mixed type of farming. In the southeast lies the more hilly, wooded and dry country of Bassigny. Weaving industries are found around Reims and Troyes, metallurgy in the St. Dizier-Joinville area.

The southeast of the Paris basin is enclosed by the Langres plateau and the Monts du Morvan. To the south bordering the northern limits of the Massif Central, lies a region of low hills and plains, which varies in character. Sologne, a little northwestward, is a sparsely populated district of sandy pine-covered soil or of marshland, capable in some places of supporting sheep; some attempt has been made to reclaim land there for agriculture. Farther south stretches the province of Berry. The Sancerrois in its northeast is a district of well-watered chalky hills which give a good pastureland. The centre of Berry comprises the wide loamy plain of the Champagne Berrichonne between the Loire and Chbteauroux. This offers a mixture of good arable land, sheep pasturages or wooded areas.

Farther southward and westward toward the northwest of the Massif Central lie the districts of Brenne, an area of sand and ponds, Boischaud, of fertile valleys, and the hilly Val Berrichon. In Berry extensive forests, abundant water power and the presence of iron ore formerly gave rise to a widespread metallurgical industry. This chiefly survives in Vierzon and its district.

Normandy.—Kormandy is divided into Haute Normandie and Basse Normandie. The former lies chiefly to the north of the Seine, and comprises the districts of the Vexin Normand, Caux and part of Bray, which have been considered as belonging to the Paris basin (see above). Along the coasts of Haute Normandie are the flourishing ports and fishing towns of Dieppe, St. Valéry, Fécamp and Le Havre.

Basse Kormandie is a much larger area, lying to the west and southwest and south of the province. Its more easterly plains, which may be said to fall geologically within the Paris basin, from the Campagne de Caen and Évrecy across the Lieuvin (around Lisieux) to Neubourg and St. André are widely covered nith *limon* and thus provide rich soils for the cultivation of grain crops and of fodders (for stock raising and fattening), fruit growing (*e.g.,* apples for cider or spirits) or for dairy production (*e.g.,* of cheeses, Camembert, Pont-l'Évêque, etc.). Farther west lie the areas of the Cotentin and the Bocage Normand. which belong geologically to the Armorican massif. The Cotentin peninsula is composed of central lowland and an extreme northern upland: the former comprises chiefly the Carentan plain and the Valognes basin, of alluvial soils, where drainage has considerably improved agricultural productivity; the upland resembles rather a bocage type of countryside. with coasts terminating in rocky headlands.

The whole area supports a scattered but relatively dense population, specializing particularly in stock raising and dairy farming. Western Normandy is chiefly composed of two parallel flat granite ridges, running from northwest to southeast, the Collines de Normandie (reaching about 1,200 ft.), each cut by the valleys of rivers or tributaries. Soils are chiefly clays or, in the higher parts, sands. The whole area is well wooded and chiefly devoted to rearing cattle and horses or to fruit growing.

Some industrial life is found within Basse Normandie. Mining and metallurgy are carried on around Caen and Cherbourg, weaving at Flers and Alençon and tanning and lacemaking on a small scale in various towns and villages.

Brittany.—Brittany, forming a peninsula to the west of Normandy, constitutes a peneplain out of which rivers have fashioned deep valleys; two parallel ranges of hills run from west to east within the interior. Locally, the province is divided into the "country of the sea" (Armor) and of "the woods" (Argoat). The former comprises an extremely indented rocky coast line. along which there is an intense maritime life, chiefly in numerous small ports situated on the estuaries. The sedentary element of the coastal population is occupied chiefly in the cultivation of vegetables. The interior of the province comprises the Rennes basin, an extensive area of lowland with fertile soil devoted chiefly to cereals, market gardening and stock raising; the Rohan plateau of moorland and woods in the centre; and. in the west, the Châteaulin basin, which is mainly a dairying region. Throughout the whole of the interior, vegetables, apples and the hardier grains are grown. Stock raising is intensively practised; in the east, horned cattle and in the west horses predominate.

The Provinces of the Lower Loire.—South of Normandy and Brittany lie the areas watered by the lower Loire and its tributaries the Mayenne, the Sarthe, the Vienne, etc. Maine, in the north. is divided into Haut and Bas Maine. The former and eastern part is a wooded region, interspersed with fertile soils which give rise to various agricultural pursuits. Bas Maine is country of a more bocage type. Throughout the whole province is a scattered population, practising stock raising and poultry rearing. Small deposits of iron ore, coal and slate are found, and, in addition, there exists some cultivation of linen and hemp. South of Maine lie the provinces of Anjou and Touraine, watered by the Loire and its tributaries. There a mild, sunny climate and fertile soil favour the cultivation of vines, fruits and various types of cereal. South of the Loire is the province of Poitou. Its western area, La Vendée, is, in the north, chiefly a dissected plateau of sandy and infertile soils whose vegetation is moor and gorse. or of a bocage type; but nearer the coast and to the south is a richer area supporting all types of cereal, stock and poultry.

The southwestern part of Poitou marches with the old maritime province of Aunis. The rest of the province comprises Bas Poitou, an area of plain and marshland where market gardening predominates; and the "gate" of Poitou. a low plateau between the northwestern outskirts of the Massif Central and the southeastern end of the Armorican massif, composed of chalk soils supporting livestock and crops and offering a ready means of access between the Paris and Aquitaine basins.

The Southwestern Plains.—A longitudinal expanse covering approximately one-seventh of France's surface begins south of Poitou. Its western border is the Bay of Biscay and its eastern the edge of the Massif Central. To the south it broadens eastward to include the wide valleys of the Dordogne, the Lot and the Garonne, so that its base stretches along the whole of the Pyrenees. In general, the area is one of varied agricultural occupations. Industries are chiefly found in the few large-sized towns.

The various geographical divisions of this extensive region are as follows: In the northwest, Angoumois on the east and Saintonge on the west form an area of limestone and marl, sloping gradually to the coast. Watered by the Charente and its tributaries, this area is one of open country, becoming somewhat swampy near the sea and the broad estuary of the Gironde, which forms its southwestern boundary. Much of the land is given over to arable farming, and there is extensive dairy farming. Along the eastern valleys between Saintes and Angoulême stretch the vineyards of the Cognac district.

To the southeast of Angoumois lie the plateaus of Périgord and Quercy. Périgord (with a general height of about 700 ft.) is of limestone and provides a poor cornland and pastures. The river valleys of the Dronne, Isle, Vézère and Dordogne, which cross it from east to west, offer, however, a much better soil on which a variety of cereals and fruits together with vines are grown. The still more southeasterly plateaus of Quercy are higher (reaching nearly 2,000 ft.), but their limestone has usually a poor productive soil, though the river valleys are wide and fertile.

From the western bank of the Gironde toward the Basses-Pyrénées and the Spanish border stretches the westernmost part of the ancient province of Guienne-et-Gascogne, a remnant of the former duchy of Aquitaine. This extensive area, now comprising the western and southern parts of the Gironde de'partement and the de'partement of the Landes, can be divided into several regions.

The whole of the long coastal belt is low, rectilinear and flanked by dunes. At its northern extremity, between the Bay of Biscay and the Gironde, lie the districts of Médoc and the Bordelais: there the coastal districts are marshy areas of sand or sandstone studded with ponds or covered with pines; inland the vines, fruits and vegetables are grown on low slopes. To the south of the Bordelais the coastal belt stretches monotonously in a flat broad plain behind the barrier of dunes. Formerly a waste of sand, swamps and dunes underlaid with an impervious deposit of "iron pan," large areas have been reclaimed by drainage and afforestation. Farther inland stretch the immense forests, chiefly pine, of the Grandes Landes. Large areas of these forests are composed of plantations, which have to a great extent curtailed the marshy pastures where herdsmen on stilts graze their flocks. The southern inland area of the Landes, the Chalosse, is a higher and more populated area, where is found the cultivation of wheat, maize and tobacco and certain mineral deposits.

East of the Landes stretches the broad Garonne valley, which forms the heart of Aquitaine. There is found the richest soil and the greatest density of population. In particular the Agenais, between the Lot and the Garonne, with its limestone soil yields good crops of wheat, vine and fruits.

South of the Agenais, across the Garonne, lies the district of Lomagne with its heavy and fertile soil favouring the cultivation of cereals and stock raising. Still farther south is Armagnac, an area of irrigated meadows of maize and wheat and vine-covered slopes. Again to the south, under the Pyrenees, stand the stony plateaus of Lannemezan and, westward, of Bigorre, arable or wooded in their lower areas but drier and affording a poor pasture higher up.

The Massif Central.—The Massif Central may be represented as an immense core around which the northern and western valleys and plains wheel. It covers roughly about one-sixth of France, and is the most important source of the country's rivers. The Massif Central itself can be divided into several well-defined areas.

The central area comprises the volcanic country of Auvergne, where cones or *puys* (*e.g.*, the Plomb du Cantal and Mont-Dore) rise up to around 6,000 ft. and massive plateaus are dissected by deep and often broad fertile valleys. The volcanic soils favour both cultivation and stock raising. The upper slopes of the mountains, snow covered in winter, offer a summer pasture which supports a migrant population. Cutting westward out of the volcanic mass run the headwaters of the great rivers which cross the Aquitaine plain, the Lot, the Dordogne and the Charente. To the east the Massif Central consists of a succession of south-north chains, divided principally by the river valleys of the Allier and the Loire, which broaden to the north and finally enter the southern borders of the Paris basin. The eastern boundary of the region is the Rhône valley.

In the southeast the Cévennes mountains form a dissected frame to the wide plain west of the Rhône delta. Along the valleys of the Cévennes grow wheat, olives and mulberries. Higher up are forests of beech and chestnut interspersed by summer pastures. South of the mountains of Auvergne lie the lava plateau of Aubrac and lower limestone plateaus (les Causses), cut by the headstreams of the Lot and of the Tarn. There sheep can be pastured and hardier cereals grown. The western and northwestern parts of the Massif constitute an extensive plateau deeply indented by the upper courses of numerous rivers. In the higher regions, the country consists of moors or poor grassland; in the lower, the soil supports intensive cattle raising and some production of cereals.

The Pyrenees.—The Pyrenees extend for about 300 mi. from the Bay of Biscay to the Mediterranean and form a natural frontier between France and Spain (roughly 60 mi. in depth at the centre, 20 in the west and 6 in the extreme east). Many of their peaks (particularly in the centre) rise to more than 10,000 ft., and passes through the barrier are relatively rare.

The chain can be divided into a western, a central and an eastern region. In the west, few dominating peaks are found; the mountains consist mostly of a high limestone plateau below 6,000 ft. Along the valleys grow vines and maize; on the lower slopes are woods of chestnut and ash; and good grazing land is common even in the higher levels. The central Pyrenees contain high massifs and peaks cut by transversal valleys and gorges through which the headwaters of the Garonne and its tributaries flow; the lower heights are covered by forests of ash and beech. In the eastern Pyrenees longitudinal valleys merge into basins or plains, and the influence of a warm climate is felt: vegetation on the mountain slopes is chiefly the cork oak and Mediterranean chestnut, broom and plants subsisting on a drier soil.

The *Mediterranean* Littoral.—From the eastern Pyrenees to the Italian border stretches the Mediterranean littoral. It can be divided into two areas: the low coastal Languedoc plain running eastward in a rough semicircle south of the Massif Central from the Roussillon valley to Marseilles; and the narrower band of Provence, where the southern Alps sometimes run down to the sea. Roussillon, an irrigated gravel vale, is an intensively cultivated area of vine and early vegetables, with marshes or ponds along the coast, from which in some cases land has been reclaimed. Along the coastal strip of the plain of Languedoc lie long belts of dunes enclosing lagoons; but farther inland are arid gravel lands, supporting extensive vineyards and backed by undulating limestone uplands nhich merge with the foothills of the Cévennes.

The lower Rhône valley and delta to the east of the plain comprise marshy lands such as the Camargue; drainage has turned much of the delta into rich farmland, pastures and market gardens, but the lower lands bordering the branches of the Rhône and its tributaries still remain swamp.

East of Marseilles begins the mountainous country of Provence. In the southernmost part of this province there is first a series of east-west limestone ranges and then the granitic Maures and Esterel mountains, between which lie broad plains. Agricultural production specializes in vines, wheat, fruits and flowers. To the northeast rise the Maritime Alps which at the eastern end of the littoral approach close to the coast. This is a higher dry area, sparsely populated except along the narrow coastal plain.

The Alps.—The French Alps stretch from Lake Geneva to the Mediterranean (about 248 mi.) and from the Rhône valley to the Italian border. They contain some of the greatest massifs and peaks of the Alpine system (Mont Blanc, 15,781 ft.) but are breached by wide valleys and passes.

The Alpine area can be divided into the lower limestone ranges stretching from Geneva to the Drôme valley, roughly the western section (Alpes de Savoie and du Dauphine). The eastern section comprises loftier granite and crystalline massifs of the western Alpes Pennines and Alpes Graies. where are to be found the highest peaks. Farther south lie the Alpes Cottiennes, crystalline massifs interspersed with limestone ranges; these higher ranges broken by deep narrow valleys offer little opportunity for' cultivation or even stock raising. At the southern end of the Alpine area are the Alpes Maritimes, chiefly of Jurassic and limestone rocks and, in general, of a poor soil supporting a scattered population.

Elevation governs to a large extent the economic value of this area. In the lower valleys (more common in the west) the soil produces cereals, fruits and vines. Above 2,500 ft. cultivation becomes rare, and vegetation chiefly comprises coniferous forests or extensive pasturages which form the greatest wealth of the Alps. These pasturages; many of which are summer ones, extend to the lower limits of perpetual snow (around 10,000 ft.); the lower slopes support cattle and the higher ones sheep or goats. Throughout the area is a scattered mineral wealth, \\-hich is only slightly exploited, but in the 20th century the numerous swift rivers were increasingly harnessed for the production of electric power.

The Rhône-Saône Valley.—The Rhône valley, dividing the Massif Central from the French Alps, extends from the Mediterranean to a point above Lyons. Thereafter the valley is continued northward by the broader plain of the Saône up to the Vosges mountains and the plateaus of eastern France. Thus, a continuous corridor about 340 mi. long leads to the eastern heart of the country. Easy access can also be obtained to the northwest through gaps between the north of the Massif Central and its northeasterly extensions. to the northeast through the Belfort gap and the north through the hlarne, Meuse and Moselle valleys.

From Avignon (the northern end of the Rhône plain), the corridor is relatively narrow. It is bordered by the poorly forested hills of Bas Dauphiné. Above Lyons the Saône cuts a wide band about 1 jo mi. in length and forms a fertile region of plains or low hills, watered by its various tributaries.

The Jura.—The Jura mountains form the eastern flank of the Saône plain and curve in an arc about 35 to 45 mi. broad for about 18; mi. to form the frontier between France and Switzerland. They are predominantly limestone ranges, rising to heights of 5,000 ft., and fall into two longitudinal sections known as the Folded Jbra and the Plateau Jura, the latter lying to the west and descending in stages to the SaBne plain. The whole area is relatively sparsely populated, with a poor soil.

The Rhine Valley.—The northern half of France's eastern border is formed by another broad river valley, the Rhine, stretching from the Swiss border to the German Palatinate and framed to the west by the Vosges. The alluvial plain in the extreme south is fertile, producing cereals, market-garden produce, hops and vines. Farther north around Mulhouse the soil becomes, however, gravelly, and toward the Rhine itself, forested. To the west, in the outlying valleys of the Vosges, is a considerable textile industry. The northern part of the plain is composed of very fertile soil, interspersed with small gravelly areas covered by forests. There are grown corn, sugar beets, tobacco, hops and fruits. Petroleum and mineral deposits give rise to various industries.

The *Vosges.*—The Vosges stretch northward in long rounded folds to the west of the plain of the Rhine, dividing it from Lorraine. They are divided into the Hautes Vosges in the south. a granite massif whose rounded tops rise to about 4,500 ft., and the Basses Vosges in the north, sandstone rocks of a lesser altitude. The former are breached by various low passes. They are well forested, and in their valleys stock raising is found side by side with textile and wood industries.

The Basses Vosges form a steep escarpment over the Rhine plain, but descend more gently eastward toward Lorraine. They also are well forested and supply wood for various minor industries. A more extensive occupation is that of glassmaking for numerous uses. Cultivation is mostly confined to potato growing for distillery and starch industries.

Vegetation. — The flora of France may be considered geographically as comprising four elements: the central European or continental, the oceanic or Lusitanian, the Mediterranean and the alpine.

In the northern and central regions of France, which include most of the country, the central European or continental type of vegetation is found. This consists, where the natural succession of plants has reached its climax, of deciduous summer forest, chiefly oak and beech. The valley of the lower Loire is marshy, but the highest hills south of the river are covered with moorland consisting largely of gorse and heather.

Part of the marshy plain between the Massif Central and the Loire has been planted with pines, birch and oak, but large tracts of gorse and bracken and areas of peaty moorland remain. Big stretches of oak and beech forest cover the upper slopes of the valleys of the Oise and lower Seine; the chalk land of Picardy, where tall poplars and willows line the banks of the Somme and where there is a marshy valley containing islands of market gardens which have to be reached by boat; the crest of a long ridge in the Pays d'Othe; the plateau of the Argonne, where the valleys are marshes with dense undergrowth; the southern part of Alsace, where there is also a great deal of marsh with willows and poplars; and the iimestone of Périgord, where truffles are found in the oakwoods. On the Jurassic limestone round Boulogne there is short-turfed downland, and on the rocks of the adjacent Marquise district gorse and heather predominate.

Along the Atlantic coast is the belt of oceanic or Lusitanian type of flora. There, in the wetter places, will be found moorland with willows, bog myrtle (*Myrica* gale). Sphagnum, *Pinguicula* lusitanica, two heaths, Erica *vagans* and E. ciliaris, etc. Where it is drier, scrub occurs with alder, stunted oaks (in the more sheltered parts), petty whin (genista anglica) and so on. On the uplands of Brittany and on the highlands south of the Loire are large tracts of moor and scrub. Behind the sand dunes of the Landes, farther south, the swamps have been drained and reafforested with pines.

The Mediterranean element occurs in the south, where olives, vines, mulberries and figs are common, with the strawberry tree (Arbutus *unedo*), laurels and the Mediterranean heath (Erica *mediterranea*). There the typical Mediterranean scrub communities, called maquis and garigue, are found. The former is low scrub, often dominated by the maritime pine (*Pinus pinaster*), with myrtle (*Myrtus communis*) and wild olive as its chief associates. The latter consists of discontinuous low scrub with large patches of bare soil: the kermes oak (Quercus coccifera) is often the dominant tree with broom and gorse, or there may be aromatic communities containing lavender, thyme, rosemary and other herbs. In Provence oranges are grown, and imported *Eucalyptus* and dwarf palms flourish in the hot sheltered places. Mediterranean conditions prevail in the Cévennes, where olives, mulberries and vines are grown in the valleys, while above them chestnuts have been planted for food, replacing the beeches; higher up still are grasslands. The forests of the south are largely of Aleppo pines (*Pinus halepensis*) and maritime pines with local woods of evergreen oaks, Spanish chestnut, etc. The eastern half of the Pyrenees bears forests of cork oak (*Quercus* suber) and kermes oak, Spanish chestnut and other Mediterranean types, while the western half supports a continental flora with forests of ash and beech on the lower slopes (see PYRENEES).

The alpine flora is found immediately below the snow line on the mountains. (See ALPS.) There grow the cushion plants such as *Silene acaulis,* Androsace, *Primula* and Saxifrage with mosses and lichens. Below the alpine zone comes the subalpine, where dwarf pines and juniper, bilberry and dwarf rhododendrons are among the flowering plants. Next below this, in the Alps, is a continuous belt of conifers, while on the lower slopes grow beeches, oaks and other deciduous trees. Large areas of forest have been turned into pastureland in the Alps. In the Vosges and the Jura there are extensive tracts of coniferous forest on the lower slopes with grassland, moorland and swamps higher up. Some of the higher parts of the Massif Central are covered with marsh and moorland, with woods of chestnut (grown for food) and beech.

Fauna. — Central European in character, the fauna of France includes about 90 species of mammals. The many fossil remains of prehistoric animals found show that the mammoth was once plentiful in the valleys of the Rhbne and the Sabne and in the Paris basin. The largest beast now living is the brown bear, still plentiful in the Pyrenees but in the Alps found only in the remoter forests. The wolf, very common up to 1880, became about 1900 in danger of disappearing from its haunts in the big stretches of forest scattered over the country, while the lynx completely disappeared. Other inhabitants of the forests include polecat and marten; the rarer wildcat, found in most of the big stretches of forest but not in Brittany or Normandy; the stoat, found in all but the southern forests; the rare sable of the east; the dormouse of the east and southeast; and the wild boar, especially common in the Haute-Marne and the Ardennes.

Roe deer live in nearly all the forests, in some of which they are protected, but red deer are much more restricted in their distribution. There are different species of chamois in the Alps and the Pyrenees, while the ibex, once very common in the Alps, was hunted out of the country. Among other beasts of the mountains are the alpine hare (*Lepus timidus*), which occurs above 5,000 ft.; the marmot, found up to 10,000 ft.; mountain varieties of bat, vole and shrew and, in the Pyrenees, a special kind of muskrat (*Galemys pyrenaicus*). The commonest mammals in the country are small insectivores, carnivores and rodents, including hedgehogs: shrews, moles, bats, foxes, weasels, squirrels, voles, mice and rabbits. Badgers are locally common, while hares are found chiefly in the northeast and hamsters are becoming increasingly rare. Most of the rivers contain otters, but beavers: once common in nearly all the rivers, are now found only in the Rhbne and the Camargue where they are protected. The brown rat (*Rattus norvegicus*) was introduced in 1750 and largely displaced the black rat (Rattus *rattus*), which probably came in at the time of the crusades. The mouth of the Somme is the home of a colony of seals, and there are porpoises and whales in the coastal waters.

A high proportion of the bird population of France consists of summer visitors which winter farther south. There are also many winter visitors and migrants. There are very few endemic species. In the Mediterranean region blackcaps, buntings, bee eaters and many others are common; terns nest in colonies along the south coast; in the Camargue stilts, flamingos, egrets and night herons breed; storks are seen especially in Alsace; eagles, falcons and vultures haunt the mountains, but the lammergeyer is only found in the Pyrenees. Wood pigeons visit the country in summer; pheasants became common after their introduction from Asia; red-legged partridges are found in the south and hazel hens in the eastern forests, but the capercaillie had almost disappeared by mid-20th century. The lapwing nests regularly, and curlews and kites are common when on migration. Woodcock and larks are frequently seen, and common everywhere are dunnocks, warblers, thrushes, tits, magpies, rooks and other passerines, owls, buzzards and harriers and waterfowl of various kinds. Round the coasts are numbers of oyster catchers. gulls and other sea birds.

Various species of frogs and toads, lizards, slowworms and snakes are found all over the country, but only in the south is the serpent lizard (*Chalcides* striatus) to be seen. Of river fish the most abundant are eels, chub. perch, pike. carp and roach. Salmon spawn in the Loire, Allier and Rhine and in the streams of the northnest. and trout live in the rivers of the north and in the lakes and streams of the Alps. Sturgeon, found in all river mouths in the middle ages, are now confined to the Rhbne and the Garonne; flounders, lampreys and mullet are caught round the coasts. Lobsters, crayfish, scorpions (in the Midi), insects and many other invertebrates are abundant.

Climate. — Two factors chiefly govern climatic conditions in France: the country's partly oceanic and partly continental position. and its variety of relief. Four broad types of climate can be distinguished: a western oceanic with moderate rainfall. less frequent in summer, and a relatively equable diurnal and annual temperature; a modified continental with more extremes of temperature and summer rain; a Mediterranean with hot dry summers and mild wetter winters; and a mountain one of cool summers and cold sunny winters.

Prevailing winds in winter are westerly and southwesterly in northern and western France. with periods of easterly over the northern area; and northwesterly in southern France. In summer they are westerly or northwesterly over most of the area. Two local winds which are experienced in the Mediterranean area are the mistral, a cold northerly one, sometimes of gale force and particularly common in the Rhône valley and in Languedoc; and the *marin,* a strong southeasterly which is also felt in the Garonne plain.

Temperature is governed by latitude, altitude and proximity to the sea. but no part of France is free from frost or snow except the most sheltered areas of the Mediterranean. In addition to this part of France, the coast of Brittany enjoys a temperate winter. In the higher areas of the centre and the east the mean winter temperature is below freezing and snow lies unmelted for considerable periods.

Rainfall is particularly heavy in the mountainous areas (more than 55 in. yearly) and in their adjacent hills and plateaus (31–55 in.) and also in Brittany, the Landes, the Cotentin and the hillier parts of Normandy and coastal areas of the northeast. Along the Mediterranean, the Garonne plain and large expanses of the centre it is between 23 and 31 in. with figures below 31 in. in certain districts.

TABLE I.—*Climate* Averages

		Brest	Paris	Strasbourg	Bordeaux	Marseilles
January	Temperature	44.8° F.	36.0° F.	31.5° F.	40.7° F.	43.4° F.
	Rainfall	3.2 in.	1.4 in.	1.3 in.	2.4 in.	1.9 in.
August	Temperature	62.6° F.	63.7° F.	63.9° F.	68.4° F.	71.1° F.
	Rainfall	2.0 in.	1.9 in.	2.7 in.	1.9 in.	0.9 in.

Table I gives some figures of temperature and rainfall representative of towns in different latitudes.

HISTORY

Geographically, France occupies a happy position between continent and ocean. Situated at one extremity of that indented peninsula known as Europe, France is closely united to the body of the continent—at once and equally a maritime and a land power.

If its position between north and south made it from earliest times the meeting place of peoples, it has also had the task of defending on the north and east an extended land frontier and long seacoast. Hence French governments have been ever torn between two essential but not always reconcilable policies.

The foundation of Marseilles about 600 B.C. by Greeks from Phocaea in western Asia Minor affords the first approximately accurate date in French history. At that time the Mediterranean coast and much of the hinterland of what is now France was inhabited by the Ligurians. A second and even more important invasion was that of the Celts or Gauls, a tall. blond race who came from beyond the Rhine and spread themselves throughout Gaul in successive waves of immigration during the course of two or three centuries until it became a Celto-Ligurian country. Settled in distinct tribes, the Gauls never achieved a centralized government. The victory of Caesar over the Gauls (57–52 B.C.) was, above all, the result of the fact that he never had to face a united Gaul until. after six years of spasmodic effort, it united for a day round Vercingetorix only to die heroically at Alesia.

The Roman conquest brought civilization in its train. The assimilation of a conquered people is an essential of successful conquest, and in this art Rome was a past master. Roman rule was a harsh but beneficial discipline, and Gaul speedily forgot its independence, although an attempt was made (A.D. 259–273) to establish a separate Gallic empire. The Pax Romana was seen to be preferable to the former anarchy: as a result of the existence for three centuries of a common policy, language, religion and administration, Gaul prospered under the Romans. *(See* also GAUL.)

Despite the benefits of the Pax Romana, the strongest bond uniting Gaul and Roman was their common fear of the barbarians who thrust themselves unceasingly against the eastern frontier. Many times already the storm had burst over Gaul. It had required a Marius to stem the torrent of the Cimbri and Teutoni (102 B.c.), a Caesar to hurl back the Germans under Ariovistus into their mountain fastnesses (58 B.C.). Then the western horizon brightened until the disaster to Varus wounded cruelly the pride of an Augustus. Abandoning the conquest of Germany, the Romans for two centuries entrenched themselves behind the fortified frontier line that ran from Cologne to Regensburg, affording a protection to which the Gauls gratefully acquiesced. But under the pressure of migrating tribes upon those already settled, the German invasion gradually penetrated across the frontier, now in the guise of colonization, now in that of war. Suddenly, at the beginning of the jth century, under a violent forward thrust of the German tribes, themselves subjected to the pressure of the Huns, the Rhine frontier, denuded of guards by civil wars. was swept away. For 70 years (405–475) the tempest raged over Gaul.

The barbarians were groups of tribes and not a single nation. For them there mas so little question of substituting a barbarian empire for that of Rome (for which they entertained a superstitious reverence) that their conquests seemed to them illegitimate without imperial ratification. When the first storm had passed, the Visigoths had established a powerful kingdom from the Loire to Andalusia. The Burgundians set up another in the valleys of the Rhône and Saône. Finally, the Franks, divided into two groups, settled in northern Gaul: the Ripuarians round Cologne and the upper Moselle; the Salians round Cambrai and the Somme. For a last time all the barbarians, auxiliaries of Rome, ranged themselves under Aetius in 451 to overthrow near Chblons the hordes of Attila. Then the empire of the west retreated over the Alps to die.

The Roman Church, which survived the empire, inherited to some extent the imperial attitude toward barbarian Europe. Gradually the "City of God" came to take the place of the Roman state as the guardian of civilization. That they might re-establish order and maintain it, the bishops sought from the barbarian kings the support that they had hitherto received from the empire in their contest with the Arian heresy and with the survivals of paganism. But the Visigothic and Burgundian kings were infected with Arianism, and to them the bishops were inevitably opposed. The Franks, who were to give to the land its permanent designation and who were to play so great a role in its history, seemed as yet far from such pre-eminence: they were less civilized than the Visigoths and Burgundians, and they were pagans: and by a double paradox, it was this that helped them. Their strength as fighters enabled them to extend their power and keep out fresh invaders; and, further. the church has always preferred pagans to heretics. The conversion of Clovis to the Catholic faith was a master stroke: at one and the same time it made his fortune and that of the Franks. A common faith was to become the token of a unified state and the foundation stone of Christian France.

THE MEROVINGIANS

Clovis.—Clovis was the king of only one of the tribes of Salian Franks who, under his iather Childeric, had come in search of new lands to cultivate in the rich valleys of the Somme and the Oise. When the victory of Soissons (486) over Syagrius, last representative of the fallen Roman power in France, had brought the power of Clovis to the Seine and then to the Loire, Remigius, archbishop of Reims, made a swift decision. To Syagrius. now a fugitive among the Visigoths. he preferred Clovis, who as an ally could be as useful as he would certainly be dangerous as an enemy. For his part Clovis well understood that he would never bring Gaul beneath his sceptre without the support of the church and of the Catholic Gallo-Romans who were tired of anarchy. Clovis laid the foundations of the French state by his conversion to Christianity, due to his wife, Clotilda, and to Remigius, rather than by his victory over the Alamanni at Tolbiac (496).

From that time forth his conquests took on the character of holy wars: after the victory of Dijon in 500, he became nominal overlord of the king of Burgundy; in 507, by his victory at Vouillé, he set free the whole of Aquitaine from the Arian Visigoths and drove them into Septimania (the march of Gothia) and Spain. In order to prevent a possible coalition of the Frankish tribes that had remained heathen, Clovis deposed and assassinated their kings. In these murders the church saw only the divine reward to a faithful soldier and convert from paganism and gave its consecration to his triumph by appointing him to preside over the council of Orléans (511). Clovis, like the Christian emperors before him, became for the church a new David. Finally, the eastern emperor Anastasius, by sending him the consular emblems, gave a legal sanction to his rule, even as the church had sanctified his military conquests. Thus the Merovingian dynasty was enabled to hold sway for two centuries and a half.

The Successors of Clovis **(511–751).**—After the death of Clovis, his house produced no monarchs worthy to rank with him. Neither the Roman law nor the influence of Christianity was strong enough to preserve the unity of the state. The Frankish custom of partitioning the royal domains at the death of each king to the exclusion of the female line, as though the kingdom were a private estate, coupled with the avariciousness of the princes, occasioned constant civil wars. Thus at the death of Clovis (511) his domains were divided into four kingdoms (Reims, Paris, Orléans and Soissons). For 50 years, indeed, his heirs sought to continue his work and to add to his dominions. From 523 to j32 they subdued Burgundy and Provence, and love of booty brought their armies into Italy and Spain. They even attempted the conquest of Germany. Because of the accident of Clotaire I's surviving his three brothers the dominions of Clovis were reunited from 558 to 561. But on the death of Clotaire, his kingdom was once more divided among his four sons, and during the years 567–613 domestic tragedies checked the progress of the Merovingian power and took the place of wars of aggrandizement and pillage. No trace is to be found of any political ideal in the wars between Chilperic and Sigebert. Chilperic's murder of his Visigothic wife Galswintha may have caused her sister Brunhilda, wife of Sigebert, to urge her husband to make war, though ambition was urge enough. After Sigebert's death Brunhilda carried on the strife. Her bitter rivalry with Fredegond, Chilperic's widow, is the thread on which the history of continuous war is hung. The central authority grew steadily weaker. It was further threatened by the growing power of the bishops and great nobles against whose aggressions Brunhilda strove all her life. Two landmarks in this struggle are the treaty of Andelot in 587 and the edict of Clotaire II in 614 by which benefices granted to the aristocracy of high officials mere made tenable only for life. But these exhibitions of strength were but momentary and could do little to arrest the steady development toward the feudal days (see FEUDALISM). The ordinary freeman, unprotected because of the weakness of royal power, was driven to commend himself to the local bishop or great noble.

The Mayors of the Palace.—From the 7th century onward, the mayor of the palace (see MAYOR; MAYOR OF THE PALACE) seriously weakened the already failing authority of the kings. The palace in those days as in the time of the empire and in mediaeval times, was the court of the king and the seat of his government. The mayors controlled this ambulatory court and in effect controlled the state; they sought not only to be independent but also to establish over the rest of the Frankish kingdom the supremacy of that division over which they ruled. Some tried to re-establish a unified Frankish monarchy and the rule of the state over the church; others, who were distrustful of the idea of a single kingdom, sought above all to assure their own independence. For a century (613–714) these two opposing tendencies can be traced. After a brief revival of the royal power under Dagobert (628–638) there ensued its long decadence with meaningless partitions, perpetual minorities, the ever-increasing power of the mayors over the rois *fainéants* and, finally, the duel between the Neustrians of the west and the Austrasians of the east (see AUSTRASIA; NEUSTRIA) and the great conflict between Ebroin, mayor of Neustria, and Archbishop Léger, who was all-powerful in Burgundy. The battle of Tertry (687) finally decided the struggle in favour of the Austrasians under Pippin of Héristal; but the death agony of the degenerate Merovingian dynasty was prolonged until 751.

THE CAROLINGIANS

Merovingian savagery and chaos ended in a general paralysis of the state. A new Clovis was needed and found in Pippin II of Héristal. In his person he united the two great houses, of Pippin and of Arnulf, archbishop of Metz. The Pippins, from father to son, had succeeded to the mayoralty of the palace in Austrasia from 61j to 655. They had at their back a great company of vassals and vast landed estates; above all they had patience—without which nothing lasting can be built. It took them nearly 100 years to supplant the Merovingian by the Carolingian dynasty.

Pippin of Héristal governed under four kings. A pioneer, he began all those tasks which his descendants were to carry to completion; he himself was precipitate in nothing. As warrior, he defended the frontiers that were threatened by the Frisians, the Alamanni and Bavarians; as a son of the church, the descendant of Arnulf, he brought in the train of his armies missionaries through whom the Carolingians were to consolidate their conquests. He died in 714 without having deemed it opportune, or without having found the occasion to sweep away the phantom kings whose sole utility was to date charters and diplomas.

Charles **Martel (714–741).**—With Pippin's son Charles began the greatness of Austrasia. He accomplished successfully a fourfold task. Although a bastard, he asserted his power in Austrasia where he deposed his half brothers from the mayoralty. He achieved the supremacy of Austrasia over Neustria and Burgundy by the victory of Vincy (717). Frankish unity was re-established. He then defended Gaul against the Frisians, the Alamanni and the Bohemians. Without being any more conscious of his mission than Clovis had been, Charles proved himself another soldier of the cross by repelling 'the Moorish invasion at Poitiers (732), which won for him his appellation of Martel—"the Hammer."

An alliance with Charles Martel, the pacifier of Gaul, the protector of St. Boniface and the vanquisher of the "infidels," became ever more necessary to Pope Gregory III, menaced as he was by the Lombards, and promised to be even more fruitful than was that of Clovis with Remigius. Unable to forget that the Lombards had aided him in expelling the Saracens from Provence, Charles contented himself with professions of zeal.

Pippin the Short **(741–768).**—Pippin the Short at once took over and continued his father's work. In 747 he became sole master of the kingdom, for his elder brother, Carloman, became a monk and Pippin compelled Childeric III, the last of the rois *fainéants*, to shave his royal locks. Grifon, Pippin's half brother, was also set aside. It only remained for Pippin to assume the royal title. Consulting Pope Zacharias on this matter and receiving the answer that "he who exercises the king's power should enjoy the king's title," Pippin had himself crowned at Soissons in Nov. 751, an act which was further consecrated in 754 by the grander coronation in St. Denis, whereby the church pronounced the new dynasty to be holy and its title indisputable.

The title of patrician, also conferred by the pope, still further attached the dynasty to Rome. But these rewards mere not unearned. During 754–756 it was Pippin who founded, at the expense of the Lombards, that temporal power of the papacy which was to endure till 1870, the bulwark of their spiritual authority. The price for his consecration paid, Pippin, between 758 and 768, assured the safety of his kingdom on the farther bank of the Rhine against the Germans and Slavs, and against the Arabs to the south of the Pyrenees. Moreover, by the alliance of the greatest material force of the age with the greatest moral authority, the way was opened up for a restoration of the western empire.

Charlemagne **(768–814).**—On the death of Pippin in 768 the kingdom was divided between his two sons. Charles and Carloman; but in 771 Carloman died, and the whole of this great inheritance was united under Charlemagne. Charles devoted his half-barbarian genius to the service of the church and of the traditions of Rome, and in realizing this ideal of his age, earned his appellation of "the Great." He attempted to found an empire after the Roman model. Prevented by the Moors from founding its capital on a Mediterranean site, he placed it in his own native land. Austrasia, with the intention of doing for Germany what Caesar had accomplished for Gaul. Christianity, which had been the weakness of the old empire, was to be the strength of the new. The victory of the soldiers was to be completed by the victory of the missionaries. And thus would a common, religion unite peoples otherwise separated by blood, language and customs.

The conquest of Gaul, from Brittany to Gascony (769–811) assured for his armies a reserve of soldiers that cost him nothing, since military service was obligatory upon all free men. The poor and the serfs cultivated the land. Between 774 and 777 he consolidated the patrimony of St. Peter by the destruction of the Lombard kingdom, whose iron crown he placed on his own brow. On the eastern frontier he turned his forces against the Saxons, but it took him 32 years (772–804) and 18 campaigns before he was at last victorious. But. unlike the Gauls, despite compulsory baptism, destruction of their idols and deportation or massacre. these heathens submitted themselves unwillingly to "the easy yoke of Christ." Charlemagne fortified his frontiers by marches, or military districts, but in multiplying these advance posts the Frankish empire came into contact with new peoples—each one a prospective enemy. In Spain Charlemagne suffered disaster at Roncesvalles (A.D. 778; see CHARLEMAGNE) and afterward he created the Spanish march as a defense for his southern borders. From their camp on the Hungarian plain, the tireless cavalry of the Avars had overrun Bavaria in the very year of its subjugation by Charlernagne (788), and it was not before the Danubian lands had been devastated that this new menace mas destroyed. Meanwhile, behind the Elbe and the Saale, the Slavs of Bohemia were engaged in an unceasing warfare with the Saxons. and in the north the Danish pirates raided the coasts of the North sea and the channel. After 47 years of warfare, the Carolingian empire stretched from the Elbe to the Ebro, and from the Eider to the Tiber—growing greater day by day, but also exposed increasingly to attack. Charlemagne's power extended farther than his frontiers. Christian princes from beyond the channel and the Pyrenees, Moorish amirs from Fez and Baghdad visited his palaces or offered him presents, as to the great Christian emperors. Through men like Alcuin and Peter of Pisa the church taught this German—still primitive in many ways—the traditions of Rome and Byzantium. Why should not he be the heir to the Caesars? Why should he not restore, in his own favour, the empire of the west? Nothing was wanting save the imperial crown.

In 797 the empress of Constantinople had deposed and blinded her son Constantine VI, and the imperial throne might be considered vacant. In 799 the pope had been driven from Rome by a revolt and only restored by a Frankish army. The time was ripe, and at Christmas 800 Charles was crowned emperor by Pope Leo III.

Of the reconstituted empire, Charlemagne wished to be himself the lawgiver. He was himself the ruler of his empire. He made his power felt to the farthest extremities of the empire by his missi *dominici,* or representatives, by his courts, military, judicial or political. Highhanded with his people in this violent world, the emperor believed that he was no less responsible for their eternal salvation in the next. The *missi* enforced his spiritual as well as his temporal authority. By this administrative hierarchy and centralization on the Roman model Charlemagne reconstituted the superstructure of the imperial monarchy; but in legalizing by his caoitularies the fief and the *beneficium* he undermined the foundations of the edifice which he believed himself to be strengthening; by requiring from the greatest in the land the oath of fealty, he admitted that the sovereign of all needed in addition to be definitely acknowledged as the direct overlord of his most powerful subjects; by the extension of *beneficia* the small freeholder gradually disappeared to make room for the feudal tenant (see FEUDALISM). The poor freemen gave up their freedom to win protection from the neighbouring lord or prelate. Unable to prevent this development Charlemagne systematized it. thinking himself strong enough to turn it to his own account. As long as he lived he was successful; but, even during his lifetime. the treason of Ganelon proved that he was not always served by a Turpin or a Roland. His authority, powerful and respected, decayed because it depended on him and him alone.

When, in 814, Charlemagne was laid in his tomb at Aix-la-Chapelle, his work was buried with him. There remained only a twofold legend—the religious one that made of him a saint; the other that made of him the hero of French epic. Twenty-nine years after the death of Charlemagne his empire was divided into three separate kingdoms by the treaty of Verdun; and division succeeded division as the 9th century drew to its close. France became no more than a scrap heap of almost independent states, out of which feudalism was springing. The seignorial system, which had at first aggrandized the Carolingians, had also prepared their ruin.

Louis the Pious **(814–840).**—The empire devolved upon Louis the Pious or Affable (le *Débonnaire*)—titles indicative of his characteristics. so valuable in peace, so calamitous in times of stress. From the beginning of his reign the clumsy machine of government was out of his control. As his predecessors had done, he kept the entire sovereignty in his own hands, but divided his benefices and offices between his three sons, Lothair, the eldest, whom he associated with himself in the empire, Pippin and Louis. A fourth. Charles, was born to him in 823 of a second marriage, and to him he gave a share also. War between the brothers resulted: the imperial dignity became a laughingstock and Louis himself was twice deposed and imprisoned in a monastery. Scarcely was he buried at Metz (840) before his sons rushed to arms. Lothair desired to preserve the unity of the empire and the patronage of all the fiefs in one hand. Louis the German and Charles the Bald leagued themselves against him by the oath of Strasbourg. the first treaty in the history of France and Germany to be written in the vulgar tongue. An amicable partition of the paternal property was, however, clearly desirable and this was presently effected by a treaty made at Verdun in 843.

The Treaty of Verdun **(843).**—The treaty of Verdun marks an important turning point in history. Louis received for his share the land which was to become Germany; Lothair the title of emperor, with Italy and the valleys of the Rhône, the Saône and the Meuse, in addition to the two capitals, Rome and Aix-la-Chapelle; Charles, called the Bald, found himself the possessor of the rest of Gaul. The unity of the Carolingian empire was definitely broken. The boundaries between the kingdoms were ill-defined. That of Lothair, without a national basis, soon split up into transient principalities, so that the vast and indeterminate territories of Burgundy, Lorraine and Provence (*qq.v.*) were to be the battleground of modern France and Germany.

Charles the Bald **(840–877).**—Charles the Bald was the first king of western France. Anxious as he was to maintain the traditions of Charlemagne, he was not strong enough. Rather a man of culture than a warrior, he was obliged to spend his life sword in hand, fighting against the Bretons, against the people of Aquitaine who had appealed to Louis the German, against the Norman raiders who were becoming more and more insolent; fighting always, but always without success. He even found himself obliged to entrust the defense of his patrimony to Robert the Strong, duke of the country between the Loire and the Seine and ancestor of the Capetian dynasty. Unable to defend his own kingdom of western France, Charles the Bald yet coveted other crowns and looked obstinately eastward. He succeeded in becoming. in turn. king of Lorraine. emperor of Germany and king of Italy: an accumulation indeed of titles, but not of strength.

Growth of the Feudal System.—The great vassals of the crown had remained faithful to Charlemagne because they had had need of his protection. Under Charles the Bald, and still more under his successors, it was the prince aho had need of the nobles. Thus was the feudal system turned against the throne, for the great vassals took advantage of it to perpetuate themselves in their offices and in their fiefs and to gain possession of lands and authority. Little by little the monarchy lost influence. since it no longer performed any services; hence, from the end of the reign of Charles the Bald, there was left only the appearance of royalty—administrative officialdom. No longer deeply rooted in the soil, a shadow without effective force, it hovered above the local powers which encroached upon it, seized its land and divorced it from its subjects. The king, the lord of lords, was poorer than his lords; while they were establishing themselves in strong principalities. he alone was creating no strong territorial basis for his power. The great vassals were confirmed in their new rights by the capitularies of Mersen (847), of Pitres (862) and of Quierzy-sur-Oise (877).

Vassalage could only be a disintegrating, not a unifying factor. That this disintegrating process did not go on indefinitely was because of the existence of 12 or 1; great military commands—Flanders, Burgundy, Aquitaine, etc. (*qq.v.*). The duchy of France, which Robert the Strong had received as a reward for his services, grew into a powerful fief, but it was not strong enough to withstand outside attack. In 911 King Charles the Simple gave to Rollo, a Danish chief, the lordship of the district surrounding the lower reaches of the Seine, land nominally under the rule of the dukes of the French. Rollo began to build up the Norman duchy (see NORMANDY). The ecclesiastical fiefs emancipated themselves in the same manner as the lay fiefs, and ceased to sustain the royal authority unless it was given into their control. Day by day the disparity became clearer between the vastness of the Carolingian empire and the feeble administrative control of its weak rulers over a society once again become barbarian and menaced by other barbarians. None obeyed an emperor whom all hoped perhaps to supplant. Each country developed its individual life and language. The races no longer understood one another, nor possessed common ideals.

The Last Carolingians.—The death struggle of the Carolingians lasted for a century. Royal power, hitherto hereditary, tended to become elective. It was given to Charles the Bald's son, Louis the Stammerer, only after election by the great magnates and bishops under the leadership of the successor of Robert the Strong. Since the kings were no longer rendering service, they could no longer claim service from others, as in the case of Charles the Fat who narrowly escaped deposition for his incapacity and cowardice in the face of the Normans. After many intrigues, Odo (Eudes), son of Robert the Strong, was chosen as king in 838 on account of his brilliant defense of Paris. Henceforth there ensued a long duel between the Robertians and the Carolingians in which three times the Robertians were chosen and might have taken the crown but three times deemed it more expedient to favour the restoration of the Carolingians, or more advantageous to have the power without the title. Thus heredity was asserted in favour of Charles the Simple in 893, of Louis IV in 936, of Lothair in 954 and of Louis V in 986. The difficulty indeed was not the taking of the crown but the keeping of it when once taken. The dukes of France had rivals (notably Herbert of Vermandois) capable of crushing them by forming coalitions; and if the Robertians had the support of Normandy, the Carolingians had that of Germany. Moreover the support of the archbishop of Reims, faithfully rendered to the Carolingians, gave to them more distinction than that of the bishop of Sens gave to the Robertians. Consequently, Hugh the Great (d. 956; son of Robert, count of Paris, and grandson of Robert the Strong) was content to remain the kingmaker of the Carolingians, even as Pippin's descendants had been of the Merovingian *rois fainéants*. But by waiting for the fruit to ripen, he almost lost the chance of gathering it. The Carolingians whom he had had elected—Louis IV and Lothair—displayed a fresh energy and capacity. Was it the last flicker of a dying light or the long-delayed return of their fortune? For 30 years none knew on which side the balance would dip; but on the death of Louis V after a reign of only one year, the assembly of Senlis eliminated from the succession the rightful heir, Charles of Lorraine, and elected Hugh Capet, son of Hugh the Great. The final struggle followed. The conflict raged between Laon, the royal capital. and Reims, the ecclesiastical capital. The one ensured the kingdom of France; the other the crown. Hugh Capet won the first in 985 and the second in 987; but the prestige of the Carolingians was still such that their fall seemed to presage the end of the world.

THE CAPETIANS OF THE DIRECT LINE

The same difficulties that confronted the last Carolingians confronted the first Capetians. They inherited all the strength and weakness of the feudal system. Their strength was their central situation in the kingdom—the Ile-de-France. Their weakness was the possession of a very small domain surrounded on all sides: on the west by the county of Blois and the powerful duchy of Normandy; on the north and east by the counties of Flanders and Champagne and by the duchy of Burgundy. Beyond this little belt stretched provinces almost impenetrable to the royal authority—Brittany, Aquitaine, Gascony, Toulouse and the Spanish march. Thus the kings lay stifling in the midst of a feudal jungle which thrust itself upon their horizon and forced them to establish their power in the only two towns of any importance in their kingdom—Paris. the capital of the future. and Orléans, the city of learning. Their first responsibility was, therefore, to gain breathing space, to give their energies to practical politics and, above all, to avert their eyes from that chimera of a restored empire which had ruined their predecessors. If from 987 to 1060 they had not carefully avoided unequal combats they might have forfeited the hope of acquiring for the royal house those titles, greater than any resulting from feudal rights, which their descendants were to establish. Thus the beginnings of the Capetians gave less an impression of regeneration than of a prolongation of the decadence of the Carolingians.

Hugh Capet (987–996), due to his diplomacy rather than to his military strength, contrived to maintain his independence despite the opposition of Charles of Lorraine (the last descendant of the Carolingians), the insubordination of the great lords and the hostility of a pope who favoured the empire. Above all, by associating his son, Robert the Pious (996–1031), with him in the royal power while he himself still lived, Hugh Capet secured the future of his dynasty by suspending the feudal right of election, an act of political sagacity that his grandson, Henry I (1031–60), copied in 1059 in favour of his own son, Philip I. But their system was still too like that of the Carolingians, and it became necessary to change it. Apart from their prudent opportunism, the greatest merit of the early Capetians was that they had sons, so that their dynasty endured without unduly long minorities and quarrels over partitions of territory.

Philip I (1060–1108).—Philip I accomplished little during his long reign of. 48 years beyond the essential son and heir, Louis the Fat, and a slight expansion of the royal domain. Absorbed in carnal and material pleasures and in love of money, he remained a total stranger to the great events of his time. The conquest of England in 1066 by William of Normandy was begun while he was a minor and could do nothing to prevent it, but for the moment it diminished the pressure of Normandy upon his kingdom. The first crusade was preached in 1096 by a French pope, Urban II. Philip, excommunicated the year before, played no part in it; but indirectly the monarchy benefited, for while it increased the prestige of France in the east, it also weakened the power of the feudal lords who either perished in or were ruined by it.

Louis VI the Fat (1108–37).—After a century of lethargy, the Capetian power awoke again under Louis the Fat, who concentrated his energy on extending his territory and rendering it obedient. The summit of his ambition was to effectively establish the king's highway from Paris to Orléans, and during 34 years of war he purged his domain of feudal brigandage. To become master in his own house he allied himself to a communal movement in Amiens against his rival Enguerrand de Coucy, but—sublimely an opportunist—he suppressed a similar movement in Laon because of the connection with it of his enemy Thomas de Marle. If he refused to admit feudal principles in his own affairs, or to his own disadvantage, he invoked them quickly enough against the great feudal lords who were more powerful than he. Little more than a mere police officer, he had the church on his side, but he did not allow it to dominate his actions.

His principal minister, Suger, began as a simple monk and became abbot of St. Denis. His other officials were all unimportant people, trustworthy and dependent on him. Thus, the Holy Roman emperor Henry V, who sought to invade the kingdom in 1125, soon fell back before the united strength of the vassals and townsfolk rallied under the oriflamme of St. Denis. The moral unity of the land had become a political factor.

Louis VII (1137–SO).—His successor, Louis VII, almost destroyed his work at the very moment when circumstances were conspiring in his favour. The two powers of greatest danger to his kingdom—England and Germany—were rent by civil distractions and disputed successions. His marriage, on the other hand, with Eleanor, heiress of the duchy of Aquitaine, had increased the area of his kingdom fivefold. Suger, his father's minister, continued to give him the support of his wise and moderate counsel. But unhappily the second crusade, undertaken despite Suger's warnings and the doubts of the pope, inaugurated a series of magnificent but fruitless exploits. Quarrels with his wife were even more disastrous, and the death of Suger in 1151 deprived Louis of his wisest counsellor at the moment when the annulment of his marriage (March 1152) was compromising the fortunes of the Capetians. Two months after that annulment Eleanor found a youthful candidate for her dowry in Henry Plantagenet who thus added to his county of Anjou and his duchy of Normandy the whole southwest of France. Two years later he obtained the crown of England (1154) as Henry II. Henry and Louis at once began the struggle between England and France which lasted till the middle ages were almost ended. Wedged between the Angevin power and the German kingdom of Frederick Barbarossa, it was little less than a miracle that the French dynasty escaped extinction. Twice the church saved its devoted son by the moral prestige given him by the presence in France of a refugee pope and by the interdict which was placed on Henry II after the assassination of Thomas Becket. Happily, after 28 years in which three successive wives had given him daughters only, Louis was presented in 1165 with a son, Philip, whose birth averted the prospect of a war of succession.

Philip Augustus (1180–1223).—The new king began to give proofs of his energy and calculating ambition before his 20th birthday: in five years (1180–86) he freed himself from the Flemish tutelage of Philip of Alsace and from that of the counts of Champagne. But his major problem was to destroy the Angevin empire. The battle was a long one. Abandoned by his sons, Henry II in the moment of death was brought to submission. but Philip Augustus found himself confronted by a new English king, his former ally Richard Coeur de Lion. If he accompanied him to the crusade, he did so less from a desire to go than from a wish to return. His one interest was Richard's kingdom, and the absence of his rival seemed to him to afford an opportunity to despoil it. When Richard was captured in Germany on returning from his crusade Philip allied himself with Richard's brother, John, and they tried to bribe the emperor, Henry VI, to keep Richard a captive; but Richard bought his liberty, and the "devil at large" cost Philip all the fruits of his intrigues and shut him off from Normandy by the strong fortress of Château Gaillard. But the arrow that carried off Richard at the siege of Châlus and the misfortunes of his brother and successor, John, restored the fortunes of the Capetians. Philip seized Normandy; then Anjou, Touraine, Maine and most of Poitou fell into his hands. He failed, however, to conquer Guienne and Gascony. Fortunately for the future of his dynasty, Philip, instead of seeking to conquer England, marched against the allies of John in the northeast, the counts of Boulogne and of Flanders (1211–12). The power of the Capetians was now clearly very dangerous, and a European coalition was formed to combat it. The king of England, the emperor Otto and all the great lords of Flanders, Belgium and Lorraine allied themselves together. But the whole country responded to the call of Philip Augustus to repulse a feudal reaction allied with foreign intervention. The national victory at Bouvines (1214) placed the Capetians in an unrivalled position.

Anxious not to risk his gains, but desirous' rather of consolidating them by organization, Philip left to others the toil and trouble of conquests, the advantages of which were not for them. In 1216, when his son Louis wished to wrest the crown of England from John, then fighting with his barons, Philip intervened without appearing to do so, supporting and disavowing his son by turns. Likewise, when the church and the needy and fanatical nobility of northern and central France began to destroy the feudal power of the counts of Toulouse and the rich civilization of Languedoc in the Albigensian crusade (1209–29), Philip took no part in order to avoid the odium that attached itself to this act of bloody oppression: but it was for the royal house that Simon de Montfort, although he knew it not, conquered Languedoc. Henceforth, except for the English power in Guienne and Gascony, there was but one royal France embracing the whole kingdom.

As in war, so in peace, Philip Augustus was an efficient sovereign. If he did not love feudalism he liked theocracy no better—as is evidenced by his quarrels with Innocent III. He allied himself to the church on the condition that it should comply with his designs. He took advantage of its weakness in the midst of a violent age and gave to it the protection of the royal power, even in lands beyond his authority. In setting the feudal lords against each other, the king and the church found a common advantage. In furthering his antifeudal policy Philip similarly exploited the wish for security and the instinct of independence among the townspeople who were demanding henceforth an assured position in the feudal hierarchy. By means of the communes (*q.v.*) he was able to make a breach in feudalism and to exercise his royal authority far beyond his own domain. He did more. He gave to the monarchy instruments of government of which it was still in need: in Paris, a council of men of humble birth, but wise and loyal; in his domains, *baillis* or seneschals, all-powerful against the great nobles but submissive to himself; a treasury filled by the harsh exploitation of private wealth; an army that was no longer a temporary feudal levy but a permanent royal force; and, finally, a fixed capital where the university sprang up about the towers of Notre Dame. So strong had the monarchy become that the son of Philip Augustus was the first of the Capetians who did not need to be consecrated in his father's lifetime.

Louis VIII (1223–26).—Louis VIII continued his father's work, acquiring southern Poitou and large parts of Guienne-Gascony from Henry III of England and Languedoc from the Albigenses. In distributing great appanages among his sons he avoided family quarrels such as had brought Henry II of England to submission, and he facilitated unity by encouraging French customs in the more distant parts of the kingdom. But he lacked the time to reveal his capacity, for he died suddenly in 1226, leaving a foreign wife and infant son, the future Louis IX, behind him.

Louis IX (1226–70).—The queen mother, Blanche of Castile, assumed the regency and undertook the guardianship of her son. For nine years she ruled with a strength of character and a farsightedness that frustrated the enemies of the kingdom, who had hoped to take their revenge for Bouvines. In 1230 she even got help from the malcontent barons of the east against Peter of Dreux, who had transferred his homage for Brittany to Henry III of England. Raymund VII of Toulouse made his submission in 1229. The marriage of Louis to Margaret of Provence in 1234, to be followed by that of his brother Charles to her sister Beatrix in 1246, frustrated imperial designs on the "kingdom of Arles" (*q.v.*).

But Blanche's greatest work was the education of her son. She imbued him with that high morality that inspired not only his private life but the whole conception of kingship to which he remained faithful. In Louis IX morality entered the domain of politics; his sole aim was the good of the whole world and the reconciliation of all Christians in the name of a general crusade. Not that Louis was a monk: well-balanced, he inherited and exhibited the qualities of his house—courage, skill and common sense. But he added to these a new element—religious fervour, the spirit of Christ. Sometimes, indeed, he was forced to fight, as when the small nobility of the south of France rebelled under the leadership of Raymund Trancavel, viscount of Carcassonne, in 1240 or when Henry III sought to restore the English hold on Poitou. After the double victory of Taillebourg and Saintes (1242) Louis imposed terms on Henry III. Then he left for his first crusade in Egypt, which was to end disastrously. Louis indeed preferred negotiations to battles. On his return from Egypt, in the treaty of Corbeil (1258), he concluded with James I of Aragon an agreement whereby France renounced Catalonia and Roussillon in return for Aragon's renunciation of Toulouse and Languedoc (except Montpellier). By the treaty of Paris (1259) with Henry III, in exchange for the recognition of the conquests of Philip Augustus, Louis agreed to recognize Henry as his vassal not only for the remnant of Aquitaine that the English were still holding but also for large parts of the dioceses of Limoges. Périgueux and Cahors, with further conditional claims in the Agenais and Saintonge.

He won for himself and his kingdom a moral authority that made of him a universal arbiter: the oak of Vincennes under which, as it is said, he delighted to administer justice, cast its shade over all his policy. The peace was established among the princes and justice decided no longer by battle but by law. He intervened in the interests of serfs; he granted privileges to townspeople; and the book of the Establissemens des *mestiers* offered protection to the workers against exploitation by the masters. Having accomplished all this and notwithstanding his former failure, against the advice of his mother and his counsellors and even of the pope himself, Louis IX embarked on the crusade to Tunis in which he met his death on Aug. 25, 1270.

Philip the Bold (1270–85).—His son and successor, Philip III, departed from the wise traditions of Capetian policy. The death of Alphonse of Poitiers on the way back from Tunis meant that, as well as the crown of France, Philip inherited Poitou, Auvergne, Toulouse and the marquisate of Provence. The death of Henry I of Navarre, who was also count of Champagne (*q.v.*) and Brie in 1274 left his heiress, a three-year-old girl, in Philip's hands. Champagne and Brie were annexed to the crown and a marriage between the heiress and the king's second son (Philip, later Philip IV) arranged. These successes and the temporary success of Charles of Anjou (see CHARLES I, of Naples) in southern Italy encouraged Philip to look outside the boundaries of France for conquests. But the Sicilian Vespers (see VESPERS, SICILIAN) ended the hopes of Charles in Italy in 1282 and Philip's attempt to win the crown of Aragon for his son Charles of Valois failed in 1285. Philip III died on his way back from Spain.

Philip the Fair (1285–13141.—The new king, by methods completely opposite to those of St. Louis, won for his kingdom a pre-eminent position in Europe. His policy was simple. He sought to bring feudalism and the papacy into subjection to the monarchy by means of a more and more centralized administration. In his realism and his prudent ambition, and still more in his method of government, Philip was a man of the modem world.

With him the French monarchy formulated its ambitions and changed by degrees its feudal and ecclesiastical character for a legal constitution. His progressive and aggressive policy and his ruthless financial legislation were carried out by those lawyers of Normandy or the south who had been brought up in the school of Roman law, in the universities of Bologna and of Montpellier, raising themselves little by little to the political stage, and who were now leading the king and filling his *parlement.* It was no longer on religion or on morals but on imperial and Roman law that the *chevaliers ès lois* based the omnipotence of the ruler. Nothing indicates more clearly the new tradition which was growing up than this fact: all the great events in the reign of Philip the Fair were given at any rate the appearance of legal process. The first of these was with the papacy. The famous quarrel between papacy and empire had ended in the victory of the former. A new quarrel was opened by Boniface VIII with the kings of France and England. As vicar of Christ, the pope insisted that the temporal princes should render him the same obedience as they owed to God—an obedience not only spiritual but temporal. And thus, in effect, he laid claim to the benefices of all Christendom and refused to admit that any king could demand tithes from the clergy without the consent of the pope. The quarrel began in 1296: the bull *Clericis laicos* definitely forbade the clergy to pay taxes to the lay power. The king, whose expenses had increased with his wars *(see* below) and who had no revenues beyond those derived from his domains, was always short of money. The feudal lords, ruined by the crusades, and the lower classes, fleeced by everyone, could give but little. As in all times of crisis, Philip forbade the export of gold or silver from the kingdom. Thus deprived of his revenues from the French clergy, Boniface protested in vain. Philip's expenses were constantly increasing and he took violent measures to improve his financial position. Everyone who had dealings with him resented the constant attempts to raise money by tampering with the coinage. He both issued bad money and ordered by proclamation the value that should be put on it. Papal pretensions to interference in any matters that touched Philip's financial or political position could not be borne by the king and he used the meeting of national representatives, the states-general, to support the national cause against the pope. In a meeting in 1302 protests against papal oppression were made. Boniface determined to win the support of a council against Philip, whose ministers replied with a display of freedom of thought that was centuries in advance of the age. Guillaume de Nogaret (*q.v.*) travelled to Anagni, where he seized the person of Boniface with the object of bringing him, in his turn, before a council (Sept. 1303). A month later the pope became insane and died: the Capetians had conquered where the Hohenstaufen had failed. The Roman theocracy, which had thought to see its dream realized in the jubilee of 1300, found itself confronted by the captivity of the papacy at Avignon.

The affair of the Templars, also a matter of money, was another legal process carried out by Nogaret. As a military and religious order, the Templars had no longer any *raison d'être;* further, the order had the misfortune to be international and to have sided with Boniface; but its greatest crime was its wealth—for great financial powers become speedily unpopular: the Jews and the Lombards had already aroused popular dislike and envy. Philip made use of this hatred among the people, and also of the weakness of his creature, Pope Clement V. The trial of the order, though disguised under the imposing names of religion and morality, was in truth a political affair (1307–13); and this astonishing conclusion to the crusades resulted in a vast scheme of secularization that was the precursor of those in the 16th and 18th centuries.

Philip's foreign policy had the same litigious character. He instituted suits against his natural enemies—the duke of Guienne (king of England) and the count of Flanders, the former as powerful as his suzerain, and the latter at once the vassal of two rival sovereigns, the king of France and the Holy Roman emperor. Philip began his reign by settling the Sicilian and Aragonese adventures that he had inherited from his father.

Philip then seized upon a quarrel between English and French sailors to institute his customary legal procedure: a citation of the king of England before the *parlement* of Paris and, in case of default, a forfeiture to be followed by execution, that is to say, by the seizure of Guienne (1294–95). A truce brought about through the mediation of Boniface VIII restored Guienne to Edward I, gave him Philip's sister as wife and promised him the hand of Philip's daughter for his son (1298).

By a still more prolonged and unhappy lawsuit Philip sought to incorporate Flanders within his kingdom (1297–1312). Guy of Dampierre, who was lord of the country, had desired to marry his daughter to the eldest son of Edward I without the permission of his suzerain. Arrested and imprisoned in the Louvre, he was forced to deliver up Flanders (1297); but when James of Châtillon attempted in the king's name to take possession he found himself confronted by a rising of powerful counts and of turbulent and haughty republics of merchants and weavers, who had need of English wool for weaving the cloth that was the staple product of the land. The Flemish infantry overthrew the chivalry of France at Courtrai (*q.v.*) in 1302. By the treaty of Athis-sur-Orge (1305), which was a veritable masterpiece of chicanery, this luckless venture for France was momentarily settled. Philip secured the French-speaking towns of Lille, Douai and Valenciennes, but Flanders remained independent.

The efforts of Philip the Fair to expand his territory eastward met with greater success. His marriage had brought him one of the five great French fiefs—Champagne with Brie. Hard cash enabled him to extend his influence over the county of Chartres, Bar, the Lorraine bishoprics and Franche-Comté and to acquire Lyons and the Vivarais. Thus he removed the threat of encirclement which had been the preoccupation of the early Capetians. Disdaining the dream of imperial honours that haunted the mind of his brother and the lawyers, he turned all his energies toward the, eastern frontier, the line of least resistance, which might have yielded to him but for his death at the age of 46 (1314).

The Sons of Philip the Fair, 1314–28.—Philip's three sons continued his work. Louis X mastered the feudal reaction provoked in 1314 by the terrorist methods of his father's jurists. But in order to save the administrative and political gains of his predecessors he was compelled to sacrifice Enguerrand de Marigny, his minister of finance, to the mob fury roused by taxation as severe as it was necessary. In 1316 Louis died, leaving a daughter, Joan; his posthumous son, John I, lived only five days. Philip V the Tall therefore succeeded to the throne, and Charles IV the Fair followed Philip V in 1322 because it was impossible to permit France to be brought as a dowry to a strange prince. This precedent came to be known as the Salic law, yet it amounted to nothing more than the feudal rule that the whole domain returned to the crown in default of a male heir.

Under these eventless reigns, and also because of troubles in Germany and England, the development of the kingdom went on apace. In particular, under that born organizer Philip V, the administration was improved by the development of the judicial and financial departments out of the *conseil du roi.*

But with these kings the first direct male line of Hugh Capet failed. For three centuries and a half they had laboured greatly in founding a kingdom, a kingship and administrative institutions. Under Hugh Capet in 987 the territory of France was scarcely as great as two French *de'partements* of the present day; by 1328 it was equal in extent to 59 *de'partements.* The political unity of the kingdom was no longer impeded by about 15 great seignorial districts, but by 4 isolated fiefs: Flanders in the north, Brittany in the west, Burgundy in the east and Guienne in the south. For a long time unsettled, the capital was now established in the Louvre, which had been fortified by Philip Augustus. Like the fiefs, feudalism had been broken into pieces. The Capetians, though not of royal origin, had known how to create around them an administrative system in order to achieve order and centralization—the royal treasury of the Louvre; the *chambre des comptes;* the *parlement* dealing out a justice common to the whole realm; a royal currency; local representatives, provosts, *baillis* or seneschals. Two adversaries alone might have been dangerous; but one, the church, was now a captive in Avignon, and the second, the people, although they protested strongly against the taxes, had greatly prospered (if one may judge from the great booty captured by the English) and were consenting to efface themselves in the states-general behind the royal will. This well-established authority was also aided by the memory of St. Louis, and it was through the strength of this ideal that the royal prerogative survived the Hundred Years' War, in the course of which a unified monarchy arose and feudalism met its death.

THE VALOIS DYNASTY

With the extinction of the direct line of the house of Capet, the crown passed to a cadet branch, the Valois. On the death of Charles the Fair his cousin Philip of Valois became king as Philip VI.

Philip VI (1328–50).—On the new king's accession no one seriously thought of pressing the claim of the English king Edward III, grandson of Philip the Fair, least of all Edward himself. The Hundred Years' War (*q.v.*), the first period of which was to constitute the major preoccupation of the new reign, was aggravated rather than caused by the existence of this English claim. It began as a feudal dispute between a suzerain and his vassal.

Beginnings of the Hundred Years' War.—Gradual French encroachment on the English king's Aquitanian fief, under cover of legal process, had been begun under Charles the Fair and was at first quietly continued by Philip VI. But a distinct quarrel between the French and English kings had meanwhile been emerging from the Flemish question. The Flemish communes depended for their industry on imports of wool from England and barely tolerated the rule of the count of Flanders or that of his suzerain, the king of France. But after the French victory at Cassel (1328) Philip VI's authority had been established over them. Then Robert of Artois, who had married Philip's sister but was bitterly aggrieved at being dispossessed of the county of Artois, fled to England (1334) and was very well received. Prompted by him, Edward at last countered Philip's successes by prohibiting the export of wool from England to Flanders. As this reduced the Flemish industrial towns to idleness, Jacob van Artevelde (*q.v.*) incited them to break with France. Philip now retaliated by declaring Edward to have forfeited Guienne, and war broke out (1337).

The first important engagement was a disaster. The French fleet, which had been neglected for years, was destroyed at the battle of Sluys (1340). The sea was thus closed to France, but the war continued spasmodically on land. Flanders was overrun after the murder of Artevelde (1345). A war of succession had meanwhile broken out in Brittany between John of Montfort and Charles of Blois, the nephew of Philip VI. Edward naturally supported Montfort, and war went on in Brittany. The capture of Montfort did not end the struggle. Edward, setting out with a large army, exceptionally well provided with archers and including a small train of artillery, turned aside at the suggestion of a Norman exile, Godfrey of Harcourt, to land in the Cotentin and ravage defenseless Normandy. He raided almost up to Paris itself and turned northward to join his ships and so avoid a pitched battle while securing his booty. Followed and overtaken at Crécy, Edward achieved a complete victory over the French (Aug. 26, 1346). The subsequent capture of Calais (1347) afforded him a permanent gateway into France. These military disasters were followed by the Black Death, and Edward forebore to press his advantage, partly from prudence and partly because of the heavy cost. Before he died in 1350 Philip VI at least had the good fortune to add Montpellier and Dauphiné to his domain—the latter the future appanage of the eldest son of the French kings.

John the Good (1350–64).—Philip's son, John the Good, has commonly been reproached for his extravagance, romantic restlessness. brutality and recklessness. In truth. however, on ascending the throne, he found treason surrounding him on all sides—first Harcourt, next the constable d'Eu and then, in his own immediate family, Charles the Bad of Navarre. He crushed the traitors. but was driven, in default of any sufficient revenue, like Philip IV, to abuse his right of coinage. He spent money recklessly to win over Charles the Bad, who had betrayed him. As soon as Charles was imprisoned in Chbteau Gaillard, his followers deserted openly to England and the war began again. Edward III needed money as badly as John the Good. Wealthy by reason of its commerce and industry, England could borrow from the Florentine bankers under the security of a monopoly upon wool. But in France, which was solely an agricultural country, recourse could only be made to the inadequate and dangerous expedients of confiscation, debasement of the currency and arbitrary taxation. Regularly levied taxes could alone fill the treasury. In Nov. 1355 John summoned the states-general, which voted him aids on condition that they should be levied upon all classes and that their collection and application should be regulated by definite guarantees. The principle was a good one and resulted in the setting-up in France of representative institutions analogous to those which were already established in England; the estates, however, were no more fortunate than had been the monarchy in inducing the taxpayers to pay their impositions.

Thus it was that John came to fight and be captured at Poitiers (1356) with a well-nigh empty treasury and with troops no better equipped or disciplined than those which had been defeated at Crecy. Revolution followed. Confronted by a dauphin who was not yet of age, and amid the ruins of a discredited council, the states-general reassembled and, at the instance of Robert Lecoq, bishop of Laon, and of Étienne Marcel, provost of the merchants of Paris, the leaders of the Parisian representatives refused to co-operate with the dauphin's counsellors and determined to take him under their own tutelage. But politics at once took the place of considerations for the public weal, and they demanded the release of Charles the Bad. The dauphin hesitated; but, threatened with a rising, was forced to give way. In Feb. 1357 the states-general reassembled and transformed themselves, by means of the Grand Ordinance, into a deliberative, independent and permanent assembly. The government, at first seized by the middle classes, was soon under the revolutionaries led by Étienne Marcel; but the support of a name and a cause was imperative. This Marcel obtained through the coup de main which liberated Charles the Bad. But the murder of the marshals of Champagne and Normandy under the eyes of the dauphin (Feb. 22, 1358) and the consequent flight of the latter provoked in the noblesse and the states-general at Compiègne a strong loyalist reaction. At the same time the burghers in the barricaded capital, shocked at these crimes, deserted the reformers with their foreign allies. Neither the peasant rising of the Jacquerie, which was crushed at Meaux, nor a last, but unheeded, appeal to the towns, nor the uncertain alliance of Charles the Bad, whom he offered to make king of France, availed to save Marcel from death at the hands of the royalist party in Paris (July 31, 1358). As a consequence of the reaction that followed his death, the crown inherited the financial administration which the states-general had erected as a protection against its extravagance. Instead of being the representatives of the estates the *élus* and superintendents became officials like the *baillis* and provosts. Taxes, such as the hearth tax and the tax on salt, voted provisionally to meet the expense of war, were to be levied throughout the entire reign of Charles V and to be added to his personal revenues. The opportunity to found political liberty on the right to grant and control taxation was lost.

Treaty of *Brétigny*.—Besides the re-establishment of order in Paris, it was important to put an end to the wars with England and Navarre. This was done in the treaty of Brétigny (*q.v.*) by which (1360) John ceded a third of his kingdom to Edward III; but in the final draft, signed at Calais, John retained sovereignty over the ceded lands. John further obtained his liberty at the price of the enormous sum of 3,000,000 gold crowns, which he was never able to pay in full, and he returned to his pleasant captivity in England, where he died in 1364. But in its suffering and sorrow France was gradually realizing itself. Vanquished, it felt far more strongly than its king the shame of defeat. Local patriotism, like municipal patriotism, grew up in the peasants as in the burghers, and in a common hatred of the English was gradually founded a national feeling.

Charles V (1364–go).—The treaty of Brétigny, however, did not bring peace to the kingdom. For ten years the stragglers of the English, Navarrese and Breton armies, banded together in what mere known as the great companies, ravaged France till Charles V, *durement subtil et* sage, succeeded in sweeping them away. He persuaded their chiefs to lead them off wherever there was any fighting to be done—to Alsace, Brittany, Spain. With the help of Bertrand du Guesclin, a Breton adventurer of military genius, who became constable of France, some were trained to form an army to fight the English when war should be renewed. At the same time Charles fortified the towns and cities. A great diplomat, he made it his object to nullify the treaty of Brétigny by alliances with Flanders, the heiress of which he married to his brother Philip, duke of Burgundy; with Ferdinand of Portugal and with the emperor Charles IV. His alliance with Henry of Trastamara, the usurping king of Castile, was an inducement to the Black Prince to support the exiled Peter the Cruel. Debts incurred in Spain forced the Black Prince to try to raise money from his lands in France; the Gascon lords appealed to Charles V. Summoned to appear before the courts in Paris, the Black Prince failed to obey, and war was renewed in Gascony, Poitou and Normandy.

But this time *(1369)* different tactics were used. As the English still held to the employment of great masses of cavalry, Charles gave orders that the towns were to be defended and that the enemy was to be harried without risking a general engagement. Because of the prudent constable Du Guesclin, and the admiral Jean de Vienne, Charles was able, sitting quietly at home, to win back, bit by bit, all that his predecessors had rashly lost on the field of battle. When he died in *1380* the English possessions in France were reduced to Bayonne, Bordeaux, Brest, Cherbourg and Calais.

Charles VI (1380–1422).—The death of Charles V and the dynastic quarrels in England brought the war with that country to a close, but inaugurated a civil strife that lasted 35 years. Charles V's brothers at once fell to fighting for the regency of Charles VI, a child of *12,* and in the place of a strong central power there arose a republic of princes divided among themselves and wholly concerned for their personal interests. The faithful and wise counsellors of Charles V, whom the princes derisively called the *marmousets,* were removed, and the bad government of the king's uncles aroused widespread and increasing discontent. When they claimed to levy the aides which Charles V had renounced on his deathbed, the populace of Paris, armed with mallets, sought to murder the tax collectors. The great towns followed the example set by Paris and the Jacquerie was renewed in Auvergne and the Vivarais; but the battle of Roosebeke (1382), won by a French army over Flemish burgesses, reacted on the situation in France, and the forces of feudalism and of monarchy triumphed.

When he came of age, Charles VI recalled his father's counsellors to power, and in two months they restored order. But they could not control the king's pleasures, nor his extravagance, and when he became insane their rule came to an abrupt end (Aug. 5, 1392). Once more the king's uncles assumed the government, but instead of lessening the evil consequences of the king's insanity, they aggravated them.

War Between Burgundians and *Armagnacs.*—This time the combat was fought between two branches of the royal house—Orléans and Burgundy. Philip the Bold, duke of Burgundy, uncle of the king, had over his rival, Louis of Orléans, the king's brother, the advantages of superior age, of alliances with England and Germany, of wealth and great territorial possessions. The two opponents did not represent two different political programs: what each sought was to be the master of the intermittently insane Charles VI in order to exclude his rival from the pillage of the royal treasury. The contest became still more bitter when John the Fearless succeeded to the dukedom of Burgundy in 1404. Up to this time the queen, Isabella of Bavaria, had been held in a sort of dependence by Philip of Burgundy, who had brought about her marriage to Charles VI. Less desirous of power than of money, she suddenly became favourable to the side of the duke of Orléans. Whether it was passion or policy, it cost the duke his life, for John the Fearless had him assassinated, (1407) and thus set loose against each other the parties known as the Burgundians and Armagnacs, the latter so-called because the son of the murdered duke, Charles of Orléans, was the son-in-law of the count of Armagnac (*q.v.*). Despite all efforts to effect a reconciliation, the whole country divided itself into two camps, the south and west supporting the Armagnacs and the north and east the Burgundians. Paris, with its tradesmen—above all the butchers—and its university, played a prominent part in the quarrel, for to be master of Paris was to be master of the king.

In *1413,* as a result of the rising of the Cabochiens (the butchers led by Simon Caboche), the duke of Burgundy gained the upper hand. Out of this daring combination of brute force and idealism sprang the famous Ordonnance *cabochienne,* a practical program of financial reform. Unhappily the time was lacking in which to give it effect,nor were the actions of its authors in accord with the spirit of the ordinance. The government was at the mercy of the mob which was itself terrorized by turbulent and incapable leaders. The conflict ended in a war of factions between the carpenters under Cirasse and the butchers under Caboche. John the Fearless fled from Paris, and the Armagnacs entered the city in his rear; from Dec. 12, 1413, until July *28,* 1414, the white terror took the place of the red. These disorders allowed Henry V of England to resume the offensive.

War With England: *Agincourt.*—A national disaster was the reward of these internecine feuds. At Agincourt (1415), as at Crécy and Poitiers, the chivalry of France was shown to be incapable of playing the soldier in real warfare. Charles of Orléans was taken prisoner and John the Fearless, who had held aloof from war. set out to return to Paris. The Armagnacs were discredited by defeat, but the duke of Burgundy did not take advantage of the situation.

An unnatural alliance between Burgundy and the queen led to a renewal of civil war, and Henry V, seizing his chance, occupied Normandy and in two years destroyed the work of Philip Augustus. No serious resistance was anywhere offered, and the common need urged the duke of Burgundy to seek alliance with the Armagnacs, in whose hands was the heir to the throne, the dauphin Charles. But the assassination of John the Fearless at the conference at Montereau in 1419 by members of the dauphin's household was a fatal mistake: the whole Burgundian party, with them the queen, made a close alliance with the English. This treacherous assassination gave renewed life to the feuds which were showing signs of dying a natural death in the face of foreign invasion. By the treaty of Troyes (1420) Henry V, who was to marry Catherine, daughter of Charles VI, was recognized as heir to the French throne instead of the dauphin Charles. When Henry V and Charles VI died in 1422, Henry VI, with the aid of the new duke of Burgundy, Philip the Good, was proclaimed in Paris as king of France and England. In 1423 the English held not only Guienne but also the whole of northern and eastern France; and the two chief institutions in the land—the university and the *parlement* of Paris—acknowledged the English king.

Charles VII (1422–61).—But the greatest weakness of the French was again the king himself, Charles VII, the "king of Bourges" as he was commonly called. This youth of *19,* born of a madman and a loose-living Bavarian princess, timorous and suspicious, was the symbol of France itself. After his victories of Cravant and Verneuil (1424), the duke of Bedford, regent for the young Henry VI, gave Charles a respite of four years. But Charles's favourites, Pierre de Giac and Georges de la Trémoille, solely occupied in lining their own pockets, surrounded the king with intrigues. The banishment of the constable Richemont, the one forceful man about Charles, was secured and the unhappy king faced the tragic hour when Orléans, the last bulwark of the south, besieged by the earl of Salisbury, was about to fall *(1428).* He had neither the desire nor the means of Philip VI or John the Good to undertake reckless military expeditions to defend his country. A policy of withholding his hand from a vain display of military strength which might easily be broken had served Charles V well, but Charles VII had not his grandfather's skill, nor was he acting on any well-thought-out plan.

Joan of Arc.—Help came to him from an unexpected quarter. The cruel, prolonged war had year by year stimulated the growth of a national feeling against the English. La *grande pitié* qui *était* au royaurne de France was suddenly incarnated one day in the person of a young girl from Domremy in the Barrois, inspired with a stubborn faith and an exalted spirituality. The timid counsels of the army commanders, the not disinterested doubts of the courtiers, the criticism of experts and the questions of the doctors, she countered and overcame by her "voices." They told her, she said, to raise the siege of Orléans and to lead the gentle dauphin to Reims for his coronation.

Her sublime folly was to prove itself wiser than all their wisdom. In two months (May–July 1429) she raised the siege of Orléans, destroyed the prestige of the English army at Patay and brought the hesitating and spiritless king, in spite of himself, to his coronation at Reims—an event that was to have an extraordinary political effect throughout France. Through her, Charles VII was accepted without question as "the man to whom the kingdom of France ought to belong." After Reims the Maid's first thought was of Paris and of completing the destruction of the English. A check outside Paris enabled the jealousy of La Trémoille to use the Maid for eight months in secondary operations until the day when, under the walls of Compikgne, she was captured by the Burgundians and sold by them to the English. She was placed on trial, condemned to death and was burned alive at Rouen on May 30, 1431. (See JOAN OF ARC.)

The End of the Hundred Years' War.—Her martyrdom paved the way for the realization of one of the Maid's dearest wishes: the reconciliation of the warring parties in France. The English regent, Bedford, had with difficulty kept the Burgundian alliance. It was strained by the duke of Gloucester's marriage with Jacoba of Hainault and the consequent quarrel between Burgundy and Gloucester. It was broken when on the death of his wife, Anne of Burgundy, Philip's sister, Bedford married a vassal of Burgundy, Jacquetta of Luxembourg. The overthrow of the favourite La Trémoille through the agency of the constable Richemont removed the last barrier to agreement. Hard though its terms were, the treaty of Arras enabled a united France to expel the English from the east and opened the way for the king's return to Paris (1436). During the next three years famine, plague, the atrocities of the *écorcheurs* or flayers and finally the aristocratic rising of the Praguerie completed the misery of the country. But during the truce with England Charles VII succeeded, with the aid of the brothers Bureau, in establishing the first permanent royal army (1445) and, with that of Jacques Coeur (*q.v.*), in paying for it by means of a permanent tax (1449). But he repaid his servants with the ingratitude that he had shown toward Joan of Arc, whose fame he rehabilitated only in 1450. Meanwhile the English, weakened by the death of Bedford, continued to wage war unsuccessfully and to lose their possessions. Normandy dropped from their hands at Formigny (1450); Guienne, which had been English since the 12th century, was lost at Castillon (1453). Calais alone remained to them, and now it was they who were ruled over by a madman, Henry VI. France emerged from the Hundred Years' War victorious, but ruined and depopulated. Her patriotism, in the broadest sense, had been stimulated by the menace of dismemberment. But the victory was, above all, a victory for absolutism. The distracted nation, preferring established order to insecure liberty, was content to abandon all attempt to control the government and to give itself up to the enjoyment of living in peace. The king and the nation, now more at one and trusting each other better. pursued a utilitarian and steady policy along lines set for them by the natural resources and extent of the kingdom. Thus, when England was engulfed in the Wars of the Roses and the menace of the Habsburg empire rose up behind the indeterminate frontiers on the east, Charles VII turned toward Lorraine and Alsace. Toul and Verdun claimed his protection; but the opportunity had passed for annexing them without grave difficulty. On the other hand the appanages that under the Capets had guarded the unity of the kingdom had given rise under the Valois to a new and powerful feudal baronage. (X.)

Louis XI (1461–83).—The second half of the 15th century, from the end of the wars with England, was a decisive period for France. Political problems that had existed for several centuries were solved; the social system of the middle ages was undergoing a rapid change; and a modern state was taking the place of the feudal monarchy. Under Louis XI these developments were accelerated, to some extent as a result of Louis's own designs.

Louis had simple tastes and a bourgeois outlook. Mistrustful of the nobles, he liked the common people. Opposed to luxury, he wore old-fashioned clothes decked with relics and holy medals. But his modest exterior went with a very clear idea of his own authority, which he imposed invariably without regard to methods. Modelling himself on the contemporary Italian despots, he was determined to proceed toward absolute government and applied all his resources to this end. Quick-witted and scheming, he preferred intrigue and secret diplomacy to war; but he was sometimes too imaginative to appreciate a situation correctly: His mistakes of judgment were enormous and laid him open to surprises which make one question his statesmanship; he lacked foresight and, indeed, political sense. Thus he owed his successes largely to his skill in extricating himself from a false position and, above all, to the surprising accidents which removed his opponents. His character, good and bad, is precisely summed up in the phrase *universelle* aragne (universal spider).

On his accession France was barely out of the Hundred Years' War, and there was no proof that it would have anything more than a truce to enjoy. The threat of invasion remained. At home the great feudal states, used to independence, were a menace to the kingdom—especially the duchy of Burgundy which, by a series of fortunate acquisitions, had become a formidable power in the no man's land of Lotharingia (still hanging between France and the empire). The dukes did not owe allegiance to the king of France even for their fiefs within his frontiers and usually joined his enemies or organized coalitions of princes against him. Philip the Good, who had solidified the power of Burgundy, was to be succeeded by Charles of Charolais (Charles the Bold), who was determined to withstand the king in France and to create a kingdom for himself. Louis XI would have to defend himself against more than one feudal coalition.

The first was provoked, from 1465, by certain measures of a clumsily severe or arbitrary character. This was the League of the Public Weal (Ligue du Bien Public), in which Charles of Charolais had the support of Francis II of Brittany, of John II of Bourbon and of Louis's own brother Charles of France. Louis had assisted at the birth of this league without suspecting anything. His army met the rebels at Montlhéry near Paris without any decisive result, and the matter was closed by the treaties of Conflans and St. Maur, whereby Louis granted favours and lands to the conspirators, in particular the Somme towns to the duke of Burgundy and the duchy of Normandy, in exchange for Berry, to his brother Charles.

In 1467 there was a new coalition in preparation. To resist it, Louis saw fit to arrange for a revolt to take place at Likge against the Burgundian domination at the very moment when he was to be negotiating in person with Charles the Bold on his own territory at Péronne. News of the revolt arrived when he was in the duke's hands; and he was kept a prisoner (1468) and had to give in, promising to fulfil all previous treaties and making further concessions; he even went with Charles to help in suppressing the revolt at Likge.

Yet another coalition was formed in 1472, this time with the backing of the English, who were preparing a new invasion of France. But Charles the Bold failed at the siege of Beauvais; and when Edward IV landed with a solid force of 20,000 men he found himself unable to join his ally, who was involved in an ill-advised enterprise on the Rhine. Louis managed to come to terms with Edward and induced him to sign the treaty of Picquigny, whereby Ed ard was satisfied with an indemnity (1475). The English peril seemed henceforth to be receding.

At the same time Charles the Bold was undertaking adventures that turned his attention away from France. He dreamed of conquests on the Rhine, in Lorraine and in Alsace—to unite his possessions in Burgundy with those in the Low Countries. The duke of Lorraine, the Swiss cantons and the Austrian Habsburgs were alike threatened by these ambitions, and Louis's diplomacy gathered all these powers into the Union of Constance, which was to deal definitively with his adversary. Charles seemed likely to be crushed by a general coalition; then Louis, by an unaccountable change of face, withdrew from the struggle and signed the truce of Souleuvres with him. Charles went to war against the Swiss, who defeated him at Grandson and Morat (1467), then against the duke of Lorraine. He was killed under the walls of Nancy (1477), and this chance occurrence gave Louis XI his victory.

Louis showed himself no better advised in settling the Burgundian succession, which devolved on Charles's only daughter Mary. He had the right to take all the provinces comprised within the kingdom by marrying the heiress to a prince of his own choosing, who could well have been the dauphin; and he was strong enough to be able to impose this solution. But he was pleased to make certain unco-ordinated acquisitions while Mary of Burgundy discovered a protector in the Austrian archduke Maximilian, the future emperor. The treaty of Arras (1482) conceded the duchy of Burgundy, Franche-Comté, Artois and Picardy to France. It was a gain, but a limited one; and it gave rise to the conflict that was to set Austria and France rgainst one another for 300 years.

Throughout his reign Louis had continually intrigued in Spain, with a view to the acquisition of Roussillon and Catalonia. There too he wasted his energies without understanding that his object could never be wholly realized. He got Roussillon, but by doing so precipitated the union of Aragon and Castile and the unification of Spain which, when it was joined with the power of Austria under Charles V, was to constitute a grave danger to the future of France. Within the kingdom Louis had to discipline his nobles and to extend the royal domain at the expense of the princes' territories. He sought to restore everywhere the order that had been compromised for a century by the decline of the king's authority. To this end he meant to break all resistance, laying the foundations of an absolute monarchy. The nobles were treated harshly, the king's enemies imprisoned or put to death; the Armagnac dynasty was annihilated; and on the death of King René the duchy of Anjou and the county of Provence were incorporated in the royal domain. The church was likewise under control: in reaction against the methods of Charles VII, who had issued the Pragmatic Sanction of 1438 (to exempt the clergy from all obligation toward the pope and to give it the right of free election of bishops and abbots), Louis signed a concordat which gave the pope the right to intervene in the bestowal of benefices. As for the states-general, they were convened not to formulate the demands of the nation but to approve the king's decisions.

Louis desired above all to have plentiful resources and a strong army. Pressure was put on the towns and on the provincial estates. The taille. a tax imposed by the king for the upkeep of the army, was quadrupled in the course of Louis's reign; and the personnel of the army was expanded through the *compagnies d'ordonnance* and the francs-archers. A quantity of artillery was provided. An army of this sort made sure of the submission of the nobility throughout the kingdom.

Louis also concerned himself with reviving economic activity after the devastations of the Hundred Years' War; towns had been depopulated, trade interrupted, the countryside left untilled. The restoration of the productivity of the land was an immense task and would call for the labour of more than one generation. Louis recognized these problems and took some effective measures: he tried to introduce a silk industry and inaugurated the Lyons fairs. But the peace within the kingdom which made it possible to resume work in safety throughout the rural areas was still more effective than these governmental undertakings. When Louis died in 1483 the kingdom was richer and the king's authority greater than when he came to the throne.

Charles VIII (1483–%).—The 13-year-old dauphin Charles was incapable of governing; nor was he ever to show any aptitude for it. He was physically degenerate and of poor intelligence. The reading of novels of chivalry confused his outlook and inspired the Italian expedition, an adventure gratuitously initiated and madly pursued.

In the first years of the reign government was in the hands of Charles's sister, Anne of Beaujeu (Anne of France) who had married Duke Peter II of Bourbon. Anne had the mind and the vitality required for her task in difficult circumstances, where moreover she had to resist the aristocratic reaction inevitable at the end of Louis XI's authoritarian reign. She and her husband, guardians of Charles VIII, begdn by making concessions. Certain agents of Louis's were sacrificed to the anger of the *parlement*, and lands were restored to hostile nobles, of whom the chief was Louis, duke of Orléans (afterward Louis XII of France), a son-in-law of Louis XI. They even authorized the states-general to meet at Tours (1484); and for the first time the country districts as well as the towns were represented there. The royal party, however, succeeded in making the states-general reject the duke of Orléans' demand that he should be regent and in packing the *conseil du roi* with their supporters. Once supplies had been voted, they could ignore such demands as the control of taxation and the summons of a meeting of the states-general every two years. The malcontent party next attempted to obtain by revolt what the estates had failed to secure. Thus began the "Mad War" in which the king had to fight the dukes of Orléans and Brittany supported by Henry VII of England and the archduke Maximilian. The war ended with the royal victory of St. Aubin-du-Cormier (1488).

This victory was decisive in solving the question of the Breton succession. Duke Francis II had only a daughter, Anne, whose marriage would determine the future of the duchy. It was Charles VIII who got her; and the marriage treaty, if it did not prescribe the annexation of Brittany, at least effected the personal union of the heads of the two states, from which the union of the states themselves was to result (1491).

After this success the kingdom was secure, and there was no cause for Charles to be drawn into new enterprises. But absurd ambitions now attracted him to Italy, where he wanted to give effectto the rights that he had inherited from the dukes of Anjou. For more than 50 years the French kings were to have to engage their armies and spend their money on adventures that made them the dupes of the Italian princes and gave them only a little vainglory to balance against some serious reverses.

In preparation for his campaign, Charles wanted to conciliate his adversaries by meeting their demands; he restored Roussillon to Ferdinand II of Aragon and Artois and Franche-Comté to Maximilian and paid a heavy indemnity to Henry VII. He raised an army at great expense, borrowing money right and left, and crossed Italy unopposed (1494), without suspecting that he was leaving enemies in his rear. He entered Naples in triumph but had to leave shortly afterward when a coalition threatened to cut his communications. He escaped with difficulty from the battle of Fornovo and had lost his conquests when he returned to France (1495). He was preparing another expedition at the time of his death (1498).

Louis **XII (1498–1515)**.—The crown passed to the duke of Orléans, who had taken part in every aristocratic rising of the previous reigns but had now had time to grow wiser; indeed his premature old age won him that reputation of "father of the people" which hired writers handed down to posterity — though in fact his rule was authoritarian and as costly and oppressive as that of his predecessors. He entertained Charles VIII's designs on Italy augmented by claims to the Milanese, representing himself as having inherited it through his grandmother Valentina Visconti.

Louis XII began by marrying Charles VIII's widow Anne of Brittany, as was necessary in order to keep Brittany united to France. To this end he had to divorce his first wife, Joan of France, which gave rise to great scandal. Simultaneously he concerned himself with Italian politics, aided by Georges Cardinal d'Amboise, his prime minister, who was ready however to use French policy to further his own ambition to become pope. Two successive campaigns (1499–1500) led to the conquest of the duchy of Milan. Then Louis allied himself with Ferdinand of Aragon for the partition of the kingdom of Naples. But Ferdinand deceived him, and in 1504 he finally had to abandon Naples, which was henceforth to be the object of repeated and always disastrous expeditions for his successors.

Louis next let Pope Julius II involve him in a league against the Venetian republic. This was the League of Cambrai, which pledged France to another costly and fruitless undertaking. After the victory of Agnadello (1509) Louis had to face the Holy league organized by Julius II to drive the French "barbarians" out of

Italy. Though Gaston of Foix was victorious at Ravenna, the French had to evacuate Italy (1512), while the Swiss threatened Dijon and the English landed on the continent.

Louis sought vengeance on the pope by raising the Gallican church against him. He revived the Pragmatic Sanction and summoned a council to depose him. But this dispute ended in a setback, and a pontifical council threatened to interdict France. Barren enterprises that promised the country no advantage had ruined its fortunes and endangered its renascent prosperity.

Francis I (1515–47).—The new king, Francis, was the son of Louis XII's first cousin Charles of Angoulême. Twenty years old, he charmed the court with his youth and his handsome bearing, which formed a contrast with his predecessor's appearance. He liked strenuous exercise, hunting and warfare; he had a ready tongue and enjoyed the company of men of letters, who made out that he had a great mind. In fact his intelligence was ordinary and his culture mediocre and he knew nothing of politics and religious matters, of which he let his advisers take care. Antoine Cardinal Duprat and the constable Anne de Montmorency were the two statesmen of the reign, if we omit the queen mother, Louise of Savoy, whose influence was considerable. From his accession Francis thought only of resuming his predecessor's Italian ventures. These took up his whole reign and eventually involved him in a struggle against the Austro-Spanish power that was to absorb all France's efforts for several centuries.

In 1515, with a magnificent army, Francis won the battle of Marignan (Melegnano) and reconquered Milan. The peace of Fribourg with the defeated Swiss (1516) and the concordat of Bologna with Leo X inaugurated a twofold alliance that was to last as long as the monarchy itself. But Italy, where hitherto the French had had no rivals but the Spaniards, was now to attract other powers; a sequence of lucky inheritances had raised the sovereign of the Burgundian Netherlands, the archduke Charles, to the throne of Spain at the death of Ferdinand of Aragon (1j16) and to the succession of the Austrian territories at the death of Maximilian (1519). Elected emperor despite Francis' competition, Charles V now controlled most of western Europe as well as the Mediterranean and the Spanish colonial empire. France could see itself threatened on every frontier, but on the plea of self-defense undertook an interminable struggle that finally developed into a fight for supremacy between two rival dynasties. In this contest Francis' principal object was the duchy of Milan, which he wanted either to attach to the kingdom or to bestow on one of his sons. Charles V had his eye mainly on Burgundy, for ancestral reasons. But the rivals pursued other interests as well: the French kings intervened in imperial affairs, profiting from the disputes that arose out of the Reformation.

The rivals looked for allies. Two presented themselves: the king of England, who, not having abandoned the conquest of the Plantagenets, could at any moment checkmate Francis I should the latter descend upon Italy; and the pope, who, seated between Milan and Naples, was invaluable to both but always feared the union of north and south. After the meeting on the Field of the Cloth of Gold (1520), where Francis had in vain sought an alliance with him, Henry VIII of England turned to Charles V. As for the pope, there remained the alliance made with France after Marignan; but the pope was potverless and would never give Francis any real support.

War began in 1521, in Navarre, on the northern frontier and in Milan. But Francis' endeavours were countered by the flight of Duke Charles of Bourbon, the constable of France, who passed to the emperor's service after the illegal sequestration of his lands. A further expedition ended disastrously at Pavia (1525), where Francis was made prisoner. Taken to Madrid, he signed a treaty relinquishing all territories that Charles V claimed-(1~26) but on recovering his freedom he refused to put it into effect. Charles had failed to profit from his victory and had been restrained by the astute diplomacy of Louise of Savoy, the regent of France. He could only take vengeance on Francis' allies and on the pope, who was besieged in Rome and made prisoner. Rome itself was sacked by Protestant troops under the constable Bourbon, who was killed (1527). To put a stop to this profitless warfare, the treaty of Cambrai was signed. This modified the conditions of the treaty of Madrid: Francis renounced Italy but kept Burgundy (1529).

The following years were spent in preparing for a new war, which in this case was to be extended beyond the contentious sphere of Italian politics. Francis was in secret communication with the Turks of Constantinople, who threatened simultaneously the southeastern frontiers of the empire and the Mediterranean coasts. He was in alliance with the Lutheran princes of Germany, who were forming the League of Schmalkalden (1531) to defend their religious freedom. Christendom was scandalized to see the "most Christian king" allied with infidels and heretics.

A new war was fought from 1536 to 1538 and eventually won by Francis, as a result of the defensive strategy of the constable Montmorency. The war that broke out in 1542 ended merely in a truce, the peace of Crépy-en-Laonnois (1544), since the two parties were alike incapable of winning a decisive victory and coming to a general agreement on matters in dispute between them. Francis was piling up money for another war when he died (1547).

Trend Toward *Absolutism*.—Francis I was of a commanding disposition, and the opposition was less formidable than in the previous reigns. To so brave and fiery a temperament, love and war were schools hardly likely to teach moderation in government. Italy not only inspired him with the love of literature and the arts but also furnished him an arsenal of despotic maxims; and his principles of government, based on his inclination to dominate, were applied by his great officersof state, men thoroughly learned in the law, such as the chancellors Antoine Cardinal Duprat and Guillaume Poyet, and by the jurists of the southern universities, who drew their inspiration from Roman legal maxims.

All worked successfully to distinguish the "greatness and super-excellence of the king" from the rest of the nation; to isolate the nobility amid the seductions of a court life full of pleasures and possibilities of favour and high places; and to win over the bourgeoisie, at first by bribery and afterward by the hereditary transmission of offices.

The states-general were never convened; the king put a stop to the system of moderated monarchy that hitherto had allowed the nation's representatives, convened in times of stress, a voice in affairs. Francis had his ordinances registered by the *parlements* regardless of the remonstrances addressed to him. Attempts at resistance met with harsh treatment: the Gallican church's opposition to the application of the concordat was brutally repressed.

Intervention by judicial commissions served to remove any officers who proved refractory to Francis or lost his favour for a time: for instance the constable Bourbon, the chancellor Poyet, the admiral Philippe Chabot and the surintendant des finances Jacques de Beaune. baron de Semblançay, as well as other heads of the finance department.

The concordat of 1516 strengthened the king's authority by its settlement of the system of benefices, which lasted until the end of the ancien *régime*. The king nominated the holders of consistorial benefices (bishops and abbots) and so could avail himself of the revenues of the church for his favourites and for public servants. This was very much to his advantage, as it assured him a faithful episcopate; but though some of these bishops were conscientious, the church not infrequently found itself governed by unworthy men who cared nothing for their apostolic duties.

Francis I's prime concern was to have enough to maintain his court and his army without recourse to his subjects or diminution of his authority. He achieved this by increasing the returns of the taille, by raising regular tithes from the clergy and, especially, by organizing a system of state credit consisting of loans from the towns and from the Italian and German bankers, who proved more obliging than the French financiers that he had shaken off. This system was at once useful and dangerous to the state, as the abuse of credit was later to cause formidable crises.

The Reformation.—From the end of the 15th century circumstances in France had favoured a reform of religion. The clergy was in general decadent, both morally and intellectually, and concerned primarily with worldly affairs; and the faithful satisfied themselves with a formal practice that left no place for religious sentiment. The theologians themselves, given over to the barren discussion of formal logic, were not interested in going back to the true sources of Christian thought.

At the same time the Gallican quarrels, which pitted the king against the papacy, exposed the Roman hierarchy to mistrust and criticism in men's minds. The circulation of ideas and the spread of printing, together with the closer study of the classics and the Scriptures, opened new vistas to the reformers, who at the beginning of the 16th century were dreaming of a regenerated church with dogma and hierarchy intact.

The first attempts were by mystics who wanted to revive religious life: for example Jean Standonck and, after him, Jacques Lefèvre d'Étaples (Faber Stapulensis) and his whole group of Christian savants at the Collège du Cardinal Lemoine. Erasmus contributed his ideal of humanism. At the beginning of Francis I's reign Guillaume Briçonnet, bishop of Meaux, tried to put this ideal into practice by preaching the Scriptures in a way that made them accessible to the faithful (this constituted the group of Évangéliques de Meaux). But this reformation, hitherto simply moral, ended with an attack on dogma: the study of the Bible and of the Pauline texts and contact with the Lutheran reformers of Germany led to the doctrine of justification by faith and to the limitation of ritual practices. At the same time social changes favoured a contumacious attitude toward the clergy and a revolt against the abuses of the church. The Rebeine rioting at Lyons (1529) was a movement aimed at the church. The reformist clergy had the support of the common townspeople.

Francis I at first favoured the ne ideas and the reformers. who had the protection of his sister Margaret of Angoulême, queen of Navarre. But he became hostile when he saw society threatened by the reformers; and the affair of the placards, when broadsides against the Mass were posted in the towns (1534), and the publication of Calvin's Christianae Religionis Institutio (1536) made him decide for repression. Henceforth edict followed edict proscribing the heretics, and the tribunals were ready with convictions.

Henry II (1547–59).—The new king's character was less pronounced than his father's. Of slight intelligence and rather narrow, given over to the strictest religious orthodoxy, Henry II exposed himself to the influence of the dominant factions of his entourage. These comprised his mistress Diane de Poitiers; the constable Montmorency, whom he regarded with an almost filial affection; and the princes of the house of Lorraine, Francis duke of Guise, the greatest soldier of his time, and his brother Charles, the cardinal of Lorraine.

The Italian campaigns that occhpied the previous governments were continued in the new reign, instigated chiefly by the Italian princes at court; and they conflicted more than ever with the interests of the kingdom. But new enterprises were developed, and the king's political and military fields of action were widened. To maintain the struggle against Charles V, Henry continued his father's practice of German Protestant alliances, which was all the more necessary since the victory at Mühlberg had assured Charles's supremacy throughout the empire and presented an indirect threat to France. With the consent of the German princes Henry in 1552 occupied the Three Bishoprics (Metz, Toul and Verdun) in Lorraine, which were part of the empire. Francis of Guise successfully withstood the siege of Metz by Charles V (1553), and Henry kept his acquisitions. The Three Bishoprics remained in French hands, and the treaties of Westphalia (1648) were finally to acknowledge their cession to the king of France. This was the first step forward in the policy of expansion toward the Rhine.

Warfare was continued after Charles V's abdication, either in Italy or in the Low Countries. Through Montmorency's lack of experience, French arms suffered a disastrous defeat at St. Quentin which might have left the road to Paris open if the victors had had the means to pursue the operation (1557). But Henry had his revenge on the English: Francis of Guise took Calais and all the continental territory that they had been occupying for 200 years (1558).

Meanwhile, however, the Protestant party in France was approaching the zenith of its power. Some reckon its membership at one-third of the population of the kingdom. Numerous churches had been organized after 1555, and there were now more than 2,000. Under ministers schooled for the most part at Geneva, they were grouped in synods and assemblies; a national synod took place in Paris in May 1559. The party moreover had changed as it grew. Whole peoples in certain provinces, particularly in the Midi, had become Protestant, including the rural population; and nobles had taken the leadership over from the theologians. Henceforth the leaders were the prince of Condé (Louis de Bourbon), the admiral Gaspard de Coligny and Antoine de Bourbon. king of Navarre, who was succeeded in 1562 by his son Henry III (afterward king of France as Henry IV). The party had its own policy, made alliances outside the kingdom (with the queen of England and the German princes) and hired foreign armies.

Repressive measures against Protestantism were even more severe under Henry II than under his father: in the first year of his reign he set up the chambre ardente in the *parlement* to judge the malsentans de la foi. But Henry's military enterprises abroad exhausted France and set it in opposition to Spain, the great Catholic power, and so prevented his devoting himself wholly to the struggle against the Reformation. He therefore decided that, in order to crush heresy, peace had to be restored and the Italian ventures, the sterility of which had become apparent, renounced. This change of policy culminated in the peace of Cateau-Cambrésis (April 1559). Henry totally and unconditionally gave up his claims on the Italian territories. He even relinquished his positions in Tuscany and also Savoy, which had been French for 20 years and seemed to have been definitively incorporated in the kingdom. The restored Franco-Spanish friendship was cemented by Philip II's marriage to one of Henry's daughters, Elizabeth. This way of ending the Italian wars was no more reasonable than the policy that had poured France's wealth and strength into them over the past 50 years. However, it enabled Henry to issue the Edict of Écouen (June 2), which seemed to envisage a real civil war against the Protestants and perhaps a campaign in alliance with Spain against Geneva. During the festivities in celebration of his daughter's marriage (June 30, 1559) Henry took part in a tournament and received a wound that proved fatal.

Francis II (1559–60).—The new king, Henry II's son. was a major but too young to govern, and the direction of policy was entrusted to the Guises, uncles of the young queen Mary Stuart, who was also queen of Scotland. Francis of Guise was commander in chief of the army and his brother the cardinal of Lorraine held the administration. Both were fervent Catholics, in opposition to the Protestant leaders Condé and Antoine de Bourbon. To overthrow the Guises Condé organized the conspiracy of Amboise (le *tumulte d'Amboise,* 1560), which miscarried and was rigorously put down. This was the first resort to violence. To make peace and to rehabilitate the country's finances, it was decided to summon the states-general at Orléans; but the sitting had only begun when Francis II died (Dec. 1560).

Charles IX (1560–74).—Francis' brother was a minor at his accession and his guardian was the queen mother, Catherine de Medici, an intelligent, cultured but primarily crafty Italian who was to take part in the government for nearly 30 years. Her main object was to preserve undiminished the authority of her sons Charles IX and, after him, Henry III. She cared nothing about the truth of any religion and had no solid political principles, striving rather to keep the factions in awe even if this called sometimes for treachery. Her methods, which she pursued ruthlessly, finally destroyed the authority that she meant to reinforce.

At first she thought toleration practicable, in which opinion she had the support of the chancellor Michel de l'Hôpital. She summoned the colloquy of Poissy (Sept. 1561), where the best theologians of either side gathered to propound their doctrine. It became obvious that conciliation was impossible for two religions with firm dogmatic systems and differences on essential points; and their encounter at Poissy made reciprocal opposition more pronounced, between Catholics under the triumvirat (Francis of Guise, Anne de Montmorency and the maréchal de Saint-André, Jacques d'Albon) and the Huguenots under Condé and Coligny.

Catherine de Medici tried, failing an agreement, to keep the peace by edicts that gave the Protestants a certain freedom in the exercise of their religion: that of Jan. 1562 allowed them the right of assembly outside the towns. This generous toleration could have saved the religious peace, but the Catholics thought it excessive and meant to oppose the application of the edict.

The peace had already been troubled in the provinces of the Midi. On March 1, 1562, an incident at Vassy between the duke of Guise's troops and the congregation of a Reformed church ended in a massacre. This was the beginning of the Wars of Religion, to which the government was, for nearly 40 years, powerless to put a stop.

These wars involved no great operations, and there were no decisive battles. Armed bands attacked towns or châteaux and indulged in looting and massacre—exploits which made famous the Protestant baron des Adrets and the Catholic Blaise de Montluc. The hostilities particularly affected the Loire provinces, round Orléans and Sancerre, where the Huguenots were numerous, Dauphiné and Vivarais in the southeast and Gascony and Périgord in the southwest, where the nobles were turbulent and impoverished.

The first war lasted a year. Threatened by an English invasion, which Coligny and Condé had purchased by ceding Le Havre, Guise captured Rouen by assault, but in the attack Antoine de Bourbon lost his life. At Dreux, fought to close the road to German reinforcements hastening to join the English, Saint-André was killed; but Montmorency (the victor) and Condé were taken prisoner. Guise was assassinated by Jean Poltrot de Méré as he was attacking Orléans (Feb. 1563). Freed from his uncomfortable tutelage and now head of a Catholic party of tried strength, Catherine was able to destroy the unity of the Huguenots with the peace of Amboise (March 1563), by which Condé demanded freedom of worship for the Protestant aristocracy only. Catholics and Protestants then united to drive the English out of Le Havre.

Within the next four years Charles IX attained his majority; but he left the direction of affairs in the hands of his mother Catherine de Medici. Catherine wanted to use the peace to bring her conciliatory policy to fruition and restore the country's finances and the king's authority. She travelled over the kingdom presenting Charles to his subjects to enhance his prestige and had a meeting uith Philip II of Spain at Bayonne, where plans were laid for joint opposition to the heretics. Her efforts were unsuccessful; the second civil war broke out, and in the course of it Montmorency was killed in the battle of St. Denis (1567).

The peace of Longjumeau (1568) was short-lived. The third war saw real military operations developed in the western provinces and in the Midi, between the royal army under the king's brother, the duke of Anjou, and the Protestant armies of Condé and Coligny. CondC was killed at the battle of Jarnac and Coligny defeated at Moncontour (1569). The ensuing peace (1570) was another compromise between the parties, but contained a clause of which later events were to reveal the importance: the king assigned to the Protestants four places de *sûreté*, which were to have a Protestant governor and a Protestant garrison and to constitute places of refuge for members of the Reformed religion who could not safely live elsewhere. This seriously affected the sovereignty of the king, and the Protestant party seemed to be threatening the unity of the state.

St. Bartholomew's Day.—To seal the peacemaking it was proposed that Henry of Navarre should marry Charles IX's sister Margaret of Valois; and a further development on the same lines took place when the king, weary of his mother's power over him, drew closer to Coligny in order to prepare for mar against Spain in the Netherlands. In 1572 a fleet was prepared and an army raised, while an alliance was made with England.

Catherine de Medici reacted to this threat with characteristic treachery. Taking advantage of the princess Margaret's wedding, for which numerous Protestants, including Coligny, had come to Paris, she arranged an attempt on Coligny's life (Aug. 22, 1572). Coligny, however, was only wounded; and Catherine, fearing a Protestant rising and an investigation that might have revealed the truth, prevailed on the king to order a general massacre. This massacre, begun in the early hours of Aug. 24, lasted several days in Paris and claimed hundreds of victims. Those who were spared, for instance Henry of Navarre, had to abandon their religion. Similar proceedings took place in the other principal towns of the kingdom, but they were not thorough enough to annihilate the Protestant party, which made use of these very happenings to feed the increased virulence of the propaganda conducted by such pamphleteers as François Hotman and Philippe de Mornay (Du-Plessis-Mornay). Henceforth this propaganda was aimed at the king himself, indicated as the murderer of his own subjects.

The massacre of St. Bartholomew's day aggravated the conflict between the two religions and provoked a new Protestant rising: several towns in the Midi and Sancerre and La Rochelle in the midland region took up arms, and the siege of La Rochelle was the principal feature of the fourth war of religion. Despite another treaty of peace, the disorders became increasingly serious; the Protestants, during the war, had organized themselves politically and militarily in the southern provinces, which mere now in fact detached from the scope of the king's authority and had their own assemblies (provincial and general), their own army and their own tribunals.

The *Politiques*.—Moreover, a section of the Catholics. anxious for peace's sake to allow the dissidents liberty of worship, joined the opposition: these constituted the party of the Politiques or Malcontents, who, as they drew closer to the Protestants, were also called *Catholiques* unis. At their head was the king's brother, the duke of Anjou, who shortly afterward left France to become king of Poland (May 1573), whereupon his brother Francis, duke of Alençon, took his place at the head of the Politiques. This attitude on the part of the princes made anarchy worse.

Henry III (1574–89).—Henry of Anjou returned from Poland to succeed his brother Charles but was no more capable of restoring the royal authority than he had been. Intelligent and cultured but, because of his sexual immorality, little respected, he was to try to govern amid the factions without having the strength of character for which the situation called—at times dominated by his adversaries, at others seeking to regain the ascendant by treachery or assassination. Moreover the situation was more critical than before: Henry III was childless, and the heirs presumptive were his brother Francis of Alençon, who was himself childless, and Henry of Navarre, chief of the Protestant party. The question of the succession was the greatest problem of the moment.

Henry III was hardly back in France when the fifth civil war broke out. Despite Guise's victory at Dormans. Henry conceded all that the Protestant-Catholic coalition demanded in the peace of Monsieur (May 6, 1576). Alençon received the appanage of Anjou, Touraine and Berry; Henry of Navarre, Guienne; and Condé, Picardy. The Protestants likewise obtained the restoration of their places de *sûreté* and liberty of worship throughout the kingdom except in the neighbourhood of Paris. Chambres *mi*-parties, composed of Protestants and Catholics, were created in all the *parlements*, to judge Protestants brought to trial. This was another step in the decline of public authority.

The Catholic reaction to this favouring of the Protestants, which they determined to prevent, was the formation of the Holy League, under the inspiration of Guise. Grouping several local associations of the same kind, it was composed of common townspeople and directed by parish priests with a few bourgeois, lawyers and officials. It demanded the restoration of Catholicism, the revival of the provincial liberties and control of the government by the states-general. It was a democratic and antidynastic movement. Henry thought that the cleverest defense was to declare himself head of the league and to run it in his own interest. Henry therefore convened the states-general at Blois, as he had promised (1576). As the Protestants refused to participate, the Catholic majority did as the king wished and agreed to demand the re-establishment of religious unity, thereby nullifying the last peace treaty. However. the moderates under Jean Bodin recovered the advantage by refusing the subsidies needed for a new war. War broke out nevertheless; and a brief campaign led to the peace of Bergerac (1577), which established, in a somewhat curtailed version, the terms of the previous peace. This was later renewed at

Fleix (1580) after the so-called "Lovers' War," which arose out of the intrigues of the wanton Margaret, wife of Henry of Navarre.

Meanwhile Henry had abolished all leagues, and his position seemed to be becoming less precarious. Then came the death of his brother Francis, which revived in more acute form the question of the succession: Henry III had no heir but Henry of Navarre, which meant that the crown would go to a Protestant prince. The two parties were more than ever at variance. The Huguenots found themselves again the supporters of the hereditary principle and the divine right of kings. The Catholics and the Guises, the latter with a selfish mental reservation, became the upholders of elective monarchy and the sovereignty of the people. Was it not unthinkable that the crown of the "eldest daughter of the church" should be allowed to pass to a relapsed heretic? In order to realize their possible succession to the throne the Guises, who had already fabricated a genealogy that led them back to Charlemagne, entered into an understanding at Joinville (Dec. 1584) with Philip II and the pope to set aside Henry of Navarre and to substitute for him Charles, the old cardinal of Bourbon, who on his death would leave the crown to Henry of Guise.

The Guises relied on the reconstituted League, which made rapid progress (1585). Its avowed intention was to resist by force those who sought "to ruin the Catholic religion and the state." Centred in Paris, it had a council and an organization that made it in fact a revolutionary government.

War therefore broke out again: Henry of Navarre, Henry of Guise and Henry III faced each other and sought help from abroad, from Elizabeth of England, from Philip and the pope and from the German princes and the Swiss, who supplied mercenary troops and *reîtres*. Henry of Navarre was victorious at Coutras, Guise at Vimory and at Auneau (Oct.–Nov. 1587); but these engagements were indecisive and left the king as helpless as ever between the Protestants and the League.

Events at Paris were decisive. The ever-increasing tension made the Leaguers afraid of a Protestant resort to force, and they called Henry of Guise to their aid. He entered Paris in defiance of the king's prohibition, and the Parisians put up barricades. Henry III took fright and fled, leaving Paris in the hands of a revolutionary council; and the Edict of Union (July 1588), whereby he adhered to the League, consummated his defeat. The states-general, on the League's demand, were summoned to Blois. But Henry III, to recover the ascendancy from a majority that outvoted him in the League's favour, decided on a resort to force: he had the duke of Guise and his brother Louis, cardinal of Guise, assassinated and the cardinal of Bourbon, pretender to the crown, thrown into prison (Dec. 23, 1588).

Far from restoring the power of the king, this coup finally destroyed it. Henry III had no choice but to ally himself with Henry of Navarre, and the two kings were preparing to take Paris when Henry III was assassinated by Jacques Clément (Aug. 1, 1589).

Economic and Social Developments, 1460–1589.—The Hundred Years' War had ravaged the country, disrupted commerce and spread pestilences in France. In the middle of the 15th century the land was untilled, some villages had disappeared and many houses in the towns themselves were dilapidated. The population was falling; in the regions that had suffered most the peasants had left their fields to take refuge in the towns, where the multitude of beggars contributed to the disorder. Workers were scarce and labour expensive. Monetary difficulties made things worse, as precious metals were vanishing while salaries generally rose. The return of peace was not in itself enough to revive the country's economy: the resumption of work and the restoration of lost wealth called for an immense effort.

The most urgent task was to revive agriculture. Of the great landowners who had survived many were bankrupt, and they set about restoring their domains with the help of new farmers, to whom they made very generous conditions; the serfs were emancipated, and land was granted for small dues, the rate being fixed once and for all. After half a century of effort the results made themselves felt: fallow land was recovered, and the forest receded. Villages were re-established, and the beginning of the 16th century was a period of real agricultural prosperity. But if the peasants profited from it, their overlords were no longer as well placed as before: tenants paid only low dues, the real value of which decreased as money became cheaper. It was the beginning of a serious crisis, which was to undermine the conditions that had made possible the existence of the rural nobility.

Simultaneously with agriculture, industry and commerce revived, largely because of foreign businessmen, especially Italians, who engaged both in trade and in banking, imported luxury articles and set the flow of international business in motion again.

By the last years of Charles VII's reign the progress brought about by Jacques Coeur, who sent his ships to trade in the Levant and exploited the mines in the midland of France, was already discernible. But this activity developed under Louis XI, who, without having any precise ideas, took an interest in commerce and obtained results: he re-established the Lyons fairs, tried to introduce the silk industry and to develop the wool industry and took measures, with success, to attract stable currency and to impose a sort of protectionism which seems to foreshadow Colbert. Were, too, progress was discernible at the end of the 15th century, and under the following kings prosperity continued. Louis XII took advantage of these favourable conditions, which in fact gave rise to the legend so long connected with his name.

The 16th century gave a new turn to this prosperity. Voyages of discovery increased the sphere of commercial enterprise: there was the traffic in exotic merchandise, whether brought home directly from the new world or purchased in the great international markets of Spain and Antwerp. The ports of the Mediterranean were not neglected, but those of the channel and the Atlantic saw a new activity. There was a considerable development of the great international fairs, for instance those at St. Denis and, particularly, at Lyons, which became the centre of commercial life in France. But the most important feature was the discovery of the gold and silver mines of America, which produced, mainly from 1550 onward, a quantity of precious metal that continued to accrue till the beginning of the 17th century. Imported gold and silver flowed from Spain into all the neighbouring countries, and the 15th-century shortage of currency was followed by a surfeit, with various results: trade was stimulated, prices rose and the buying power of money diminished.

Besides real estate, which hitherto had been the basis of wealth, reserves of specie began to be accumulated for use in the purchase of goods, in industrial enterprise and in credit operations. The banks made use of letters of credit, the deposit system and clearances to maintain the international movement of capital, the principal centres being the exchanges of Antwerp and Lyons. Loans at interest were profitable to those who made them, so profitable in fact that the institution of capitalism can be dated from this time.

The men who handled this money gave their help to the governments; the French kings, who were involved in the costly enterprises of the Italian wars, could not go on without more than the usual resources of the treasury. They had to borrow; and from the time of Francis I a system of public credit was built up whereby the needs of the state were met with the help of bankers (mainly Italians or Germans) and of the towns, which themselves borrowed from private persons.

The debt, on which the interest was heavy, grew continuously and, in spite of insolvencies that reduced the total, imposed a burden that obstructed all attempts to restore the state's finances. The efforts of Michel de l'Hôpital, under Charles IX, were wrecked by disorder in the administration and by ever-increasing requirements. Henceforth the government was to live only on loans from the partisans (members of syndicates of investors) who received allotments of the royal domain as concessions or the right to reimburse themselves by collecting public revenues.

This led to far-reaching changes in the various social classes. Those who lived on fixed incomes were affected by the depreciation of the coinage and by the rise in prices: the rural nobility, who had feudal rights that brought returns not liable to change, was declining fast; likewise the *rentiers*, whose rents came from houses or land. The workers were even more affected, since the rise in wages was always slower than the rise in prices. On the other hand, merchants and peasants were becoming richer by buy-

ing the lands that the rural nobility were obliged to sell. Fortunes were made by businessmen who bought seignorial domains with title of nobility and thus composed an aristocracy that was to bring new blood into the noble classes of the 17th century. The houses of Gondi (from Italy) and of Villeroi were parvenus of this kind.

Another consequence of the government's financial policy was the sale of offices. In previous centuries people had tolerated the king's functionaries' selling their charges or passing them on to their children. The kings themselves had sometimes sold public charges, but this was exceptional until Francis I made the system general and created public functions in order to make money out of them. These were the offices, which found buyers because merchants and capitalists were making fortunes that could be employed in raising their dignity and in getting them a share of authority in the state. Thus most of the judiciary or financial charges were turned into offices, which were the property of their holders, incorporated into their patrimony and handed down to their children. The king was thus losing his authority and could neither recruit capable functionaries nor impose the necessary discipline.

These difficulties were discernible by the middle of the 16th century and contributed much to the outbreaks of civil war; the ruined gentry, who could find no place in the army since peace had been signed, were no less susceptible to any political ferment than the destitute workers. But the radical causes of the disorders were to become more general as time went on; the vicious system of finance and the anarchy pervading the administration through the sale of offices became progressively worse even in periods of stability. These evils were, in 200 years' time, to encompass the ruin of the monarchy.

THE BOURBONS, TO 1789

Henry IV (1589–1610).—The new king was a remote cousin of Henry III. As king of Navarre he had only a small domain; and his life had hitherto been that of a Gascon gentleman soldiering at the head of the Protestant armies. However, his mind was of exceptional quality: he had an admirable understanding of politics and could see the significance of events and win the sympathy of all by an opportune admixture of cordiality and authority. A warrior born for action, with a distaste for sedentary work, he knew how to find capable collaborators to manage his finances and his diplomacy. If he contrived to bring back stability and to redirect the government toward absolutism, he wanted above all to return to the past, without putting into practice the far-reaching reforms that experience might have indicated to him. He it was in fact who created the monarchy of the *ancien régime* with the vices that led to its end in 1789.

His first task was to recover the kingdom. At his accession he controlled only a few strongholds and a small army, as numbers of the Catholic gentry refused to serve a heretic king. He had against him the League, which was all-powerful in the towns and controlled by Charles, duke of Mayenne, since the murder of his brother Henry of Guise. The people as a whole would not accept a Protestant king whom the clergy refused to anoint. This opposition rallied round Charles, the aged cardinal of Bourbon, who was incapable of governing and was, moreover, Henry IV's prisoner.

Henry tried to get possession of Paris through the west. He won victories at Arques (1589) and at Ivry (1590) over the League's armies, but failed before Paris. Neither side could prevail through the use of force. Mayenne thought that the time mas ripe for a meeting of the states-general to proclaim him king; and so the estates of the League were assembled in Paris (Jan. 1593). But agreement could not be reached, since the Spanish ambassador was present and proposed Philip II's daughter (who was French on the maternal side) as a candidate for the throne instead of Mayenne. The moderates of the League rejected these Spanish claims and were upheld by the *parlement* of Paris. The pamphlet of the *Satire Ménippée* finally destroyed all respect for the clearly powerless estates. Henry IV, on his part, made this reverse more serious by embracing Catholicism (July 25, 1593); and this conversion, the effect of which was immeasurable, assured his success. He was crowned at Chartres in Feb. 1594 and entered Paris on March 22. The pope gave him absolution in Sept. 1595; and several days later Mayenne himself made his submission. Gradually the heads of the League's government, the seigneur de Villeroi (Nicolas de Neufville) and Pierre Jeannin, went over to the king, and all the provinces recognized him one after the other. Only a few obstinate people kept themselves detached; it was these who inspired Jean Châtel's attempt on Henry's life.

Spain still had to be dealt with and Henry declared war in 1595. The victory of Fontaine-Française did not settle anything, and a Spanish offensive led to the capture of Amiens, which was liberated only after a long siege. But since the defeat of the Armada Spain had been weaker. and Philip II resigned himself to the treaty of Vervins (1598) which confirmed that of Cateau-Cambrésis and set its seal on the decadence of Spain. The duke of Savoy, Charles Emmanuel I, in his turn was forced to capitulate: the treaty of Lyons (1601) at last brought the frontiers of France to the southern Jura.

The Edict of Nantes.—At the same time the Edict of Nantes (April 13, 1598) put an end to religious conflicts. as a result of long negotiations with the assemblies of the Protestant churches. Protestants were given the right to live in the kingdom and equality of citizenship; their worship could be celebrated in the houses of *seigneurs haut-justiciers* (the greater nobles), in places where it was celebrated in 1597 or where its celebration had been permitted by the Edict of Poitiers (1577) and in two towns in every *bailliage* or *sénéchaussée*. Whereas all these terms constituted a state of toleration rather than freedom of conscience, there were additional privileges as well: *chambres mi-parties* in the *parlements,* the granting of 150 *places de sûreté* and the right to hold assemblies of the religion. The statute was put forward as provisional and so kept the Protestants in suspense but at the same time granted them privileges that amounted to governmental authority and were to prove useful to them as a basis for further insurrections. The Edict of Nantes was neither so reassuring nor so definitive as its appearance suggested; in fact it was registered only with difficulty, as public opinion rightly saw in it a source of future conflicts.

The Government Reorganized.—From 1598 onward, being at peace with the church and having guaranteed the Protestants their freedom, Henry could set about reorganizing the system of government. He wanted only to restore the state of affairs that had existed before the civil wars. Apparently of an easy disposition, he was nevertheless resolved to tolerate no opposition. Government became more absolute than under Francis I. The country moreover lent itself to this development, being tired of disorder and anxious only to work for recovery. Henry addressed the *parlements* and municipalities as their master and considered their leaders factious and prevaricating. He no longer convened the states-general, which had done nothing but stir up trouble since 1560, but summoned only an "assembly of notables" at Rouen, having chosen the members of it himself; even then he presented himself to them "with his sword in his hand."

For his government he relied on councils, which he convened regularly and in which the work of administration was done by a staff of jurists, *conseillers d'e'tat* and *maîtres des requites:* these comprised the *conseil des affaires,* the *conseil d'e'tat* and the *conseil des finances.* At the head of the principal departments were the *secrétaires d'e'tat,* the *chancelier* and the *surintendant des finances.* Finally, to safeguard his authority in the provinces, he appointed intendants, who hitherto had been employed only intermittently. These intendants were the king's representatives whose duty it was to keep the local administrators aware of his authority. Thus emerged the organs of administrative monarchy, which the succeeding reigns did but perfect.

In this way Henry eliminated all the disorders that were troubling the kingdom: he suppressed the brigandage that ravaged the countryside and also the conspiracies of the nobles (for example that of the duc de Biron, who had been in secret communication pith Spain and mas executed in 1602).

Henry's greatest obstacle was presented by the Protestants.
