troops suppressing the revolt, still less the distant frontier armies. Thus the only source of supply was the Riviera of Genoa: "Our connections with this district are imperilled by the corsairs of Oneglia (a Sardinian town) owing to the cessation of our operations afloat. The army is living from hand to mouth," wrote the younger Robespierre in Sept. 1793. Vessels bearing supplies from Genoa could not avoid the corsairs by taking the open sea, for there the British fleet was supreme. The Army of Italy began operations in April, and not only was Oneglia captured, but also the Col di Tenda. Napoleon Bonaparte served in these affairs on the headquarters staff. Meantime the Army of the Alps had possessed itself of the Little St. Bernard and Mont Cenis, and the Republicans were now (May) masters of several routes into Piedmont. But the Alpine roads merely led to fortresses, and both Carnot and Bonaparte—who had by now captivated the younger Robespierre and become the leading spirit in Dumerbion's army—considered that the Army of the Alps should be weakened to the profit of the Army of Italy, and that the time had come to disregard the feeble neutrality of Genoa, and to advance over the Col di Tenda.

Bonaparte in 1794.—Bonaparte's first suggestion for a rapid condensation of the French cordon, and an irresistible blow on the centre of the Allies by Tenda-Coni, came to nothing owing to the waste of time in negotiations between the generals and the distant Committee, and meanwhile new factors came into play. The capture of the pass of Argentera by the right wing of the Army of the Alps suggested that the main effort should be made against the barrier fortress of Demonte, but here again Bonaparte proposed a concentration of effort on the primary and economy of force in the secondary objective. About the same time, in a memoir on the war in general, he laid down his most celebrated maxim: "The principles of war are the same as those of a siege. Fire must be concentrated on one point, and as soon as the breach is made, the equilibrium is broken and the rest is nothing." These tactical ideas of concentration and breaking the equilibrium he had already carried into the sphere of policy and strategy on the same lines. "Austria is the great enemy; Austria crushed, Germany, Spain, Italy fall of themselves. We must not disperse, but concentrate our attack." Bonaparte argued that Austria could be effectively wounded by an offensive against Piedmont, and even more effectively by an ulterior advance from Italian soil into Germany. But the younger Robespierre perished with his brother in the coup *d'état* of 9th Thermidor, the advance was suspended, and Bonaparte, amongst other leading spirits of the Army of Italy, was arrested and imprisoned. Profiting by this moment, Austria increased her auxiliary corps, and the allied forces moved (in September) towards the Riviera. This threat to the French supplies was averted by the expedition of Dego, planned chiefly by Bonaparte, who had been released from prison and was at headquarters, though unemployed.

Schdrer and **Kellermann.**—In November 1794, Dumerbion was replaced by Schérer, who was soon transferred to the Spanish frontier, while the plan he left, as limited in scope as in force, was never put into execution, for spring had scarcely arrived when the prospect of renewed revolts in the south of France practically paralysed the army. This encouraged the enemy to deliver the blow that had so long been feared. Their combined forces, the Sardinians, the Austrian auxiliary corps and the newly arrived Austrian main army, advanced together and forced the French right wing to evacuate Vado and the Genoese littoral. But at this juncture the conclusion of peace with Spain released the Pyrenees armies, and Schérer returned to the Army of Italy at the head of reinforcements. He was faced with a difficult situation, but he had the means wherewith to meet it, as Bonaparte promptly pointed out. Up to this time, Bonaparte said, the French commanded the mountain crest, and therefore covered Savoy and Nice, and also Oneglia, Loano and Vado, the ports of the Riviera. But now that Vado was lost the breach was made. Genoa was cut off, and the south of France was the only remaining resource for the army commissariat. Vado must therefore be retaken and the line reopened to Genoa. But Bonaparte's mind ranged beyond the immediate future. He calculated that if the French advanced into the interior by the road Savona-Ceva, the Austrians would seek to cover Lombardy, the Piedmontese Turin, and this separation, already morally accomplished, it was to be the French general's task to accentuate in fact. Next, Sardinia having been coerced into peace, the Army of Italy would expel the Austrians from Lombardy and connect its operations with those of the French in South Germany by way of Tirol. The supply question, once the soldiers had gained the rich valley of the Po, would solve itself.

Loano.—This was the essence of the first of four memoranda on this subject prepared by Bonaparte in his Paris office. The second indicated the means of coercing Sardinia—first the Austrians were to be driven or scared away towards Alessandria, then the French army would turn sharp to the left, driving the Sardinians eastward and north-eastward through Ceva, and this was to be the signal for the general invasion of Piedmont from all sides. In the third paper he framed an elaborate plan for the retaking of Vado, and in the fourth he summarized the contents of the other three. Having thus cleared his own mind as to the conditions and the solution of the problem, he did his best to secure the command for himself. The measures recommended by Bonaparte were translated into a formal and detailed order to recapture Vado. To Bonaparte the miserable condition of the Army of Italy was the most urgent incentive to prompt action. In Schérer's judgment, however, the army was unfit to take the field, and therefore ex hypothesi to attack Vado, without thorough reorganization, and it was only in November that the advance was finally made. It culminated, thanks once more to the resolute Masséna, in the victory of Loano (Nov. 23–24). But Schérer thought more of the destitution of his own army than of the fruits of success, and contented himself with resuming possession of the Riviera. Meanwhile the mentor, whose suggestions and personality were equally repugnant to Schérer, had undergone strange vicissitudes of fortune—dismissal from the headquarters staff, expulsion from the list of general officers, and then the "whiff of grapeshot" of 13th Vendémiaire, followed shortly by his marriage with Josephine, and his nomination to command the Army of Italy. These events had neither shaken his cold resolution nor disturbed his balance.

Napoleon in Command.—The Army of Italy spent the winter of 1795–96 as before in the narrow Riviera, while on the one side, just over the mountains, lay the Austro-Sardinians, and on the other, out of range of the coast batteries but ready to pounce on the supply ships, were the British frigates. On Bonaparte's left Kellermann, with no more than 18,000, maintained a string of posts between Lake Geneva and the Argentera as before. Of the Army of Italy 10,000 watched the Tenda road and 12,000 the coast line. There remained for active operations some 27,000 men, ragged, famished and suffering in every way in spite of their victory of Loano. The Sardinian and Austrian auxiliaries (Colli), 25,000 men, lay between Mondovi and Ceva; a force strung out in the Alpine valleys opposed Kellermann; and the main Austrian army (commanded by Beaulieu) in widely extended cantonments between Acqui and Milan, numbered 30,000 field troops. Thus the short-lived concentration of all the allied forces for the battle against Schérer had ended in a fresh separation. Austria was far more concerned with Poland than with the moribund French question, and committed as few of her troops as possible to this distant and secondary theatre of war. As for Piedmont, "peace" was almost the universal cry, even within the army. All this scarcely affected the regimental spirit and discipline of the Austrian squadrons and battalions, which had now recovered from the defeat of Loano. But they were important factors for the new general-in-chief on the Riviera, and formed the basis of his strategy.

Bonaparte's first task was to grasp the reins and to prepare his troops, morally and physically, for active work. It was not merely that a young general with many enemies, a political favourite of the moment, had been thrust upon the army. The army itself was in a pitiable condition. Whole companies with their officers went plundering in search of mere food, the horses had never received as much as half-rations for a year past, and even the generals were half-starved. Thousands of men were barefooted and hundreds were without arms. But in a few days he had secured an almost incredible ascendancy over the sullen, starved, half-clothed army.

"Soldiers," he told them, "you are famished and nearly naked. The government owes you much, but can do nothing for you. Your patience, your courage, do you honour, but give you no glory, no advantage. I will lead you into the most fertile plains of the world. There you will find great towns, rich provinces. There you will find honour, glory and riches. Soldiers of the Army of Italy, will you be wanting in courage?"

He augmented his army of operations to about 40,000, at the expense of the coast divisions, and set on foot also two small cavalry divisions, mounted on the half-starved horses that had survived the winter. Then he announced that the army was ready and opened the campaign. If the present separation of the Allies continued, he proposed to overwhelm the Sardinians first, before the Austrians could assemble from winter quarters, and then to turn on Beaulieu. If, on the other hand, the Austrians, before he could strike his blow, united with Colli, he proposed to frighten them into separating again by moving on Acqui and Alessandria. Hence Carcare, where the road from Acqui joined the "cannon-road" over the Apennines to Ceva, was the first objective of his march, and from there he could manoeuvre and widen the breach between the allied armies. His scattered left wing would assist in the attack on the Sardinians as well as it could—for the immediate attack on the Austrians its co-operation would of course have been out of the question. In any case he grudged every week spent in administrative preparation. The delay due to this, as a matter of fact, allowed a new situation to develop. Beaulieu was himself the first to move, and he moved towards Genoa instead of towards his Allies. The gap between the two allied wings was thereby widened, but it was no longer possible for the French to use it, for their plan of destroying Colli *while Beaulieu was ineffective* had collapsed.

In connection with a plan for a Genoese loan, and to facilitate the movement of supply convoys, a small French force had been pushed forward to Voltri. Bonaparte ordered it back as soon as he arrived at the front, but the alarm was given. The Austrians broke up from winter quarters at once, and rather than lose the food supplies at Voltri, Bonaparte actually reinforced Masséna at that place, and gave him orders to hold on as long as possible, cautioning him only to watch his left rear (Montenotte). But he did not abandon his purpose. Starting from the new conditions, he devised other means, as we shall see, for reducing Beaulieu to ineffectiveness. The French advance to Voltri had not only spurred Beaulieu into activity, but convinced him that the bulk of the French army lay east of Savona. He therefore made Voltri the object of a converging attack, not with the intention of destroying the French army but with that of "cutting its communications with Genoa and expelling it from the only place in the Riviera where there were sufficient ovens to bake its bread." As the Sardinians and auxiliary Austrians were ordered to extend leftwards on Dego to close the gap that Beaulieu's advance on Genoa-Voltri opened up, and the furthest to the right of Beaulieu's own columns had orders to seize Monte Legino, the wings were therefore so far connected that Colli wrote to Beaulieu on this day "the enemy will never dare to place himself between our two armies." The event belied the prediction, and the proposed minor operation against granaries and bakeries became the first act of a decisive campaign.

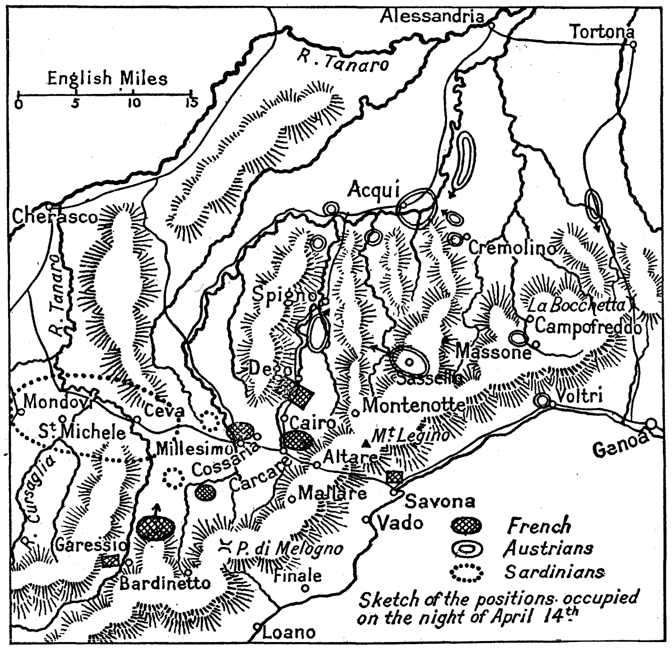
On the night of April 9 the French were grouped as follows: brigades under Garnier and Macquard at the Finestre and Tenda passes, Sérurier's division and Rusca's brigade east of Garessio; Augereau's division about Loano, Meynier's at Finale, Laharpe's at Savona with an outpost on the Monte Legino, and Cervoni's brigade at Voltri. Masséna was in general charge of the last-named units. The cavalry was far in rear beyond Loano. Colli's main force was around Coni and Mondovi-Ceva, the latter group connecting with Beaulieu by a detachment under Provera between Millesimo and Carcare. Of Beaulieu's army, Argenteau's division, still concentrating to the front in many small bodies, extended over the area Acqui-Dego-Sassello. Vukassovich's brigade was equally extended between Ovada and the mountain-crests above Voltri, and Pittoni's division was grouped around Gavi and the Bocchetta, the two last units being destined for the attack on Voltri. Farther to the rear was Sebottendorf's division around Alessandria-Tortona. On the afternoon of the 10th Beaulieu delivered his blow at Voltri, not, as he anticipated, against three-quarters of the French army, but against Cervoni's detachment. This, after a long irregular fight, slipped away in the night to Savona. Discovering his mistake next morning, Beaulieu sent back some of his battalions to join Argenteau. But there was no road by which they could do so save the détour through Acqui and Dego, and long before they arrived Argenteau's advance on Monte Legino had forced on the crisis. On the 11th (a day behind time), this general drove in the French outposts, but he soon came on three battalions under Col. Rampon, who threw himself into some old earthworks that lay near, and said to his men, "We must win or die here, my friends." His redoubt and his men stood the trial well, and when day broke on the 12th Bonaparte was ready to deliver his first "Napoleon-stroke."

Montenotte.—The principle that guided him in the subsequent operations may be called that of "concentrating a temporary superiority of force at the point of balance." Touch had been gained with the enemy all along the long line between the Tenda and Voltri, and he decided to concentrate swiftly upon the nearest enemy—Argenteau. Augereau's division, or such part of it as could march at once, was ordered to Mallare. Masséna, with 9,000 men, was to send two brigades in the direction of Carcare and Altare, and with the third to swing round Argenteau's right and to head for Montenotte village in his rear. Laharpe with 7.000 (it had become clear that the enemy at Voltri would not pursue their advantage) was to join Rampon, leaving only Cervoni and two battalions in Savona. Sérurier and Rusca were to keep the Sardinians in front of them occupied. The far-distant brigades of Garnier and Macquard stood fast, but the cavalry drew eastward as quickly as its condition permitted. In rain and mist on the early morning of the 12th the French marched up from all quarters, while Argenteau's men waited in their cold bivouacs for light enough to resume their attack on Monte Legino. About nine the mists cleared, and heavy fighting began, but Laharpe held the mountain, and Masséna with his nearest brigade stormed forward against Argenteau's right. A few hours later, seeing Augereau's columns heading for their line of retreat, the Austrians retired, sharply pressed, on Dego. The threatened intervention of Provera was checked by Augereau's presence at Carcare.

Montenotte was a brilliant little victory, and one can imagine its effects on the but lately despondent soldiers of the Army of Italy, but only two-thirds of Argenteau's force, and none of the other divisions, had been beaten, and the heaviest fighting was to come. Bonaparte, eager to begin at once the subjugation of the Piedmontese (for which purpose he wanted to bring Sérurier and Rusca into play) sent only Laharpe's division and a few details of Masséna's, under the latter, towards Dego. These were to protect the main attack from interference by the forces that had been engaged at Montenotte (imagined to be Beaulieu's main body), the said main attack being delivered by Augereau's division, reinforced by most of Masséna's, on the positions held by Provera. The latter, only 1,000 strong to Augereau's 9,000, shut himself in the castle of Cossaria, which, imitating Rampon, he defended against a series of furious assaults. Kot until the morning of the 14th was his surrender secured, after his ammunition and food had been exhausted.

Argenteau also won a day's respite on the 13th, for Laharpe did not join Masséna till late, and nothing took place opposite Dego but a little skirmishing. During the day Bonaparte saw for himself that he had overrated the effects of Montenotte. Beaulieu, on the other hand, underrated them, treating it as a mishap that was more than counterbalanced by his own success in "cutting off the French from Genoa." He began to reconstruct his line on the front Dego-Sassello, trusting to Colli to harry the French until the Voltri troops had finished their détour through Acqui and rejoined Argenteau. This, of course, presumed that Argenteau's troops were intact and Colli's able to move, which was not the case with either. Not until the afternoon of the 14th did Beaulieu place a few extra battalions at Argenteau's disposal "to be used only in case of extreme necessity," and order Vukassovich from the region of Sassello to "make a diversion" against the French right with *two* battalions.

Dego.—Thus Argenteau, already shaken, was exposed to destruction. On the 14th, after Provera's surrender, Masséna and Laharpe, reinforced until they had nearly a two-to-one superiority, stormed Dego and killed or captured 3,000 of Argenteau's 5,500 men, the remnant retreating in disorder to Acqui. But nothing was done towards the accomplishment of the purpose of destroying Colli on that day, save that Sérurier and Rusca began to close in to meet the main body between Ceva and Millesimo. Bloreover, the victory at Dego had produced its usual results on the wild fighting swarms of the Republicans, who threw themselves like hungry wolves on the little town, without pursuing the beaten enemy or even placing a single outpost on the Acqui road. In this state, during the early hours of the 15th, Vukassovich's



brigade,[1] marching up from Sassello, surprised them, and they broke and fled in an instant. The whole morning had to be spent in rallying them at Cairo, and Bonaparte had for the second time to postpone his union with Sérurier and Rusca, who meanwhile, isolated from one another and from the main army, were groping forward in the mountains. A fresh assault on Dego was ordered, and after very severe fighting, Masséna and Laharpe sutceeded late in the evening in retaking it. Vukassovich lost heavily, but retired steadily and in order on Spigno. The killed and wounded numbered probably about 1,000 French and 1,500 Austrians, out of considerably less than 10,000 engaged on each side—a loss which contrasted very forcibly with those suffered in other battles of the Revolutionary Wars, and by teaching the Army of Italy to bear punishment, imbued it with self-confidence. But again success bred disorder, and there was a second orgy in the houses and streets of Dego which went on till late in the morning and paralysed the whole army.

This was perhaps the crisis of the campaign. Even now it was not certain that the Austrians had been definitively pushed aside, while it was quite clear that Beaulieu's main body was intact and Colli was still more an unknown quantity. But Bonaparte's intention remained the same, to attack the Piedmontese as quickly and as heavily as possible, Beaulieu being held in check by a containing force under Masséna and Laharpe. The remainder of the army, counting in now Rusca and Sérurier, was to move westward towards Ceva. This disposition, while it illustrates the Napoleonic principle of delivering a heavy blow on the selected target and warding off interference at other points, shows also the difficulty of rightly apportioning the available means between the offensive mass and the defensive system, for, as it turned out, Beaulieu was already sufficiently scared, and thought of nothing but self-defence on the line Acqui-Ovada-Bocchetta, while the French offensive mass was very weak compared with Colli's unbeaten and now fairly concentrated army about Ceva.

On the afternoon of the 16th the real avalanche was begun by Augereau's division, reinforced by other troops. Rusca joined Augereau towards evening, and Sérurier approached Ceva from the south. Colli's object was now to spin out time, and having repulsed a weak attack by Augereau, and feeling able to repeat these tactics on each successive spur of the Apennines, he retired in the night to a new position behind the Cursaglia. On the 17th, reassured by the absence of fighting on the Dego side, and by the news that no enemy remained at Sassello, Bonaparte released Masséna from Dego, leaving only Laharpe there, and brought him over towards the right of the main body, which thus on the evening of the 17th formed a long straggling line on both sides of Ceva, Sérurier on the left, écheloned forward, Augereau, Joubert and Rusca in the centre, and Masséna, partly as support, partly as flank guard, on Augereau's right rear. Sérurier had been bidden to extend well out and to strive to get contact with Masséna, *i.e.,* to encircle the enemy. The line of supply, as an extra guarantee against interference, was changed from that of Savona-Carcare to that of Loano-Bardinetto. When this was accomplished, four clear days could be reckoned with certainty in which to deal with Colli.

The latter, still expecting the Austrians to advance to his assistance, had established his corps (not more than 12,000 muskets in all) in the immensely strong positions of the Cursaglia. Opposite this position the French arrived, after many delays due to the weariness of the troops, on the 19th. A day of irregular fighting followed, everywhere to the advantage of the defenders. Bonaparte, fighting against time, ordered a fresh attack on the 20th, and only desisted when it became evident that the army was exhausted, and, in particular, when Sérurier reported frankly that without bread the soldiers would not march. The delay thus imposed, however, enabled him to clear the "cannon-road" of all vehicles, and to bring up the Dego detachment to replace Masséna in the valley of the western Bormida, the latter coming in to the main army. Twenty-four thousand men, for the first time with a due proportion of cavalry and artillery, were now disposed along Colli's front and beyond his right flank. Colli, outnumbered by two to one, and threatened with envelopment, decided once more to retreat, and the Republicans occupied the Cursaglia lines on the morning of the 21st without firing a shot. But Colli halted again at Vico, half-way to Mondovi, and while he was in this unfavourable situation the pursuers came on with true Republican swiftness, lapped round his flanks and crushed him. A few days later (April 27), the armistice of Cherasco put an end to the campaign before the Austrians moved a single battalion to his assistance.

The Napoleon Touch.—The interest of the campaign lies in the "Napoleon touch" that differentiated it from other Revolutionary campaigns. Revolutionary energy was common to the Army of Italy and to the Army of the North. Why, therefore, when the war dragged on from one campaign to another in the great plains of the Meuse and Rhine countries, did Bonaparte bring about so swift a decision in these cramped valleys? The answer is to be found partly in the exigencies of the supply service, but still more in Bonaparte's own personality and the strategy born of it. Action of some sort was the plain alternative to starvation. He would have no quarter-rations on the Riviera, but plenty and to spare beyond the mountains. Strategical conditions and "new French" methods of war did not save Bonaparte in the two crises—the Dego rout and the sullen halt of the army at San Michele—but the personality which made the soldiers, on the way to Montenotte, march barefoot past a wagon-load of new boots. Later critics evolved from his success the theory of "interior lines," but actually the method was in many respects old. What, therefore, in the theory or its application was the product of Bonaparte's own genius and will? A comparison with Souham's campaign of Tourcoing will enable us to answer this question. To begin with, Souham found himself midway between Coburg and Clerfayt almost by accident, and his utilization of the advantages of his position was an expedient for the given case. Bonaparte, however, placed himself deliberately in an analogous situation at Carcare and Cairo. Then he swifty "concentrated fire, made the breach, and broke the equilibrium" at the spot where the interests and forces of the two allies converged and diverged.

[1] Vukassovich had'received Beaulieu's order to demonstrate with two battalions, and also appeals for help from Argenteau. He therefore brought most of his troops with him.

Relative Superiority.— Another guiding idea was that of "relative superiority." Whereas Souham had been in superior force (90,000 against 70,000), Bonaparte (40,000 against 50,000) was not, and yet the Army of Italy was always placed in a position of relative superiority (at first about 3 to 2 and ultimately 2 to 1) to the immediate antagonist. "The essence of strategy," said Bonaparte in 1797, "is, with a weaker army, always to have more force at the crucial point than the enemy. But this art is taught neither by books nor by practice: it is a matter of tact." In this he expressed the result of his victories on his own mind rather than a preconceived formula which produced those victories. But the idea, though undefined, and the method of practice, though imperfectly worked out, were in his mind from the first. As soon as he had made the breach, though preparing to throw all available forces against Colli, he posted Masséna and Laharpe at Dego to guard, not like Vandamme on the Lys against a real and pressing enemy, but against a *possibility*, and he only diminished the strength and altered the position of this protective detachment in proportion as the Austrian danger dwindled Later in his career he defined this system as "having all possible strength at the decisive point," and "being nowhere vulnerable," and the art of reconciling these two requirements, in each case as it arose, was always the principal secret of his generalship At first his precautions (judged by events and not by the probabilities of the moment) were excessive, and the offensive mass small But the point is that such a system, however rough its first model, had been imagined and put into practice.

The first phase of the campaign satisfactorily settled, Bonaparte was free to turn his attention to the "arch-enemy" to whom he was now considerably superior in numbers (35,000 to 2; 000). The day after the signature of the armistice of Cherasco he began preparing for a new advance and also for the rôle of arbiter of the destinies of Italy. Beaulieu had fallen back into Lombardy, and now bordered the Po right and left of Valenza. To achieve further progress, Bonaparte had first to cross that river, and the point and method of crossing was the immediate problem, a problem the more difficult as he had no bridge train and could only make use of such existing bridges as he could seize intact If he crossed above Valenza he would be confronted by one river-line after another. Milan was his objective, and Tortona-Piacenza his indirect route thither To give himself every chance he had stipulated with the Piedmontese authorities for the right of passing at Valenza. and he had the satisfaction of seeing Beaulieu fall into the trap and concentrate opposite that part of the river. The French meantime had moved to the region Alessandria-Tortona. Thence on May 6 Bonaparte set out for a forced march on Piacenza, and that night the advanced guard was 30m. on the way, at Castel San Giovanni, and Laharpe's and the cavalry divisions at Stradella, 10m. behind them. Augereau was at Broni, Masséna at Salo and Sérurier near Valenza, the whole forming a rapidly extending fan. jom. from point to point. If the Piacenza detachment succeeded in crossing, the army was to follow rapidly in its track. If, on the other hand, Beaulieu fell back to oppose the advanced guard, the Valenza divisions would take advantage of his absence to cross there. In either case, be it observed, the Austrians were to be evaded, not brought to action. On the 7th, the advanced guard under Dallemagne crossed at Piacenza,' and, hearing of this, Bonaparte ordered every division except Sérurier's thither with all possible speed. In the exultation of the moment he mocked at Beaulieu's incapacity, but the old Austrian was already on the alert. This game of manoeuvres he understood; already one of his divisions had arrived in close proximity to Dallemagne and the others were marching eastward by all available roads. But the mobility of the French enabled them to pass the river before the Austrians (who had actually started a day in advance of them) put in an appearance, and afterwards to be in superior numbers at each point of contact. The culmination Bonaparte himself indicated as the turning-point of his life. "Vendémiaire and even Montenotte did not make me think myself a superior being It was after Lodi that the idea came to me . . . that first kindled the spark of boundless ambition "

Lodi.—Abandoning his original idea of giving battle, Beaulieu retired to the Adda, and most of his troops were safely beyond it before the French arrived near Lodi, but he felt it necessary to leave a strong rearguard on the river opposite that place to cover the reassembly of his columns after their scattered march. On the afternoon of May 10, Bonaparte, with Dallemagne, Masséna and Augereau, came up and seized the town. But 200yds. of open ground had to be passed from the town gate to the bridge, and the bridge itself was another 250yds. in length. A few hundred yards beyond it stood the Austrians, 9,000 strong with 14 guns. Bonaparte brought up all his guns to prevent the enemy from destroying the bridge. Then sending all his cavalry to turn the enemy's right by a ford above the town, he waited two hours, employing the time in cannonading the Austrian lines, resting his advanced infantry and closing up Masséna's and Augereau's divisions. Finally he gave the order to Dallemagne's 4,000 grenadiers, who were drawn up under cover of the town wall, to rush the bridge. As the column, not more than 30 men broad, made its appearance, it was met by the concentrated fire of the Austrian guns, and half way across the bridge it checked, but Bonaparte himself and Masséna rushed forward, the courage of the soldiers revived, and, while some jumped off the bridge and scrambled forward in the shallow water, the remainder stormed on, passed through the guns and drove back the infantry This was, in bare outline, the astounding passage of the bridge of Lodi It was not till after the battle that Bonaparte realized that only a rearguard was in front of him. When he launched his 4,000 grenadiers he thought that on the other side there were four or five times that number of the enemy No aonder, then, that after the event he recognized in himself the flash of genius, the courage to risk everything, and the "tact" which, independent of and indeed contrary to all reasoned calculations, told him that the moment had come for "breaking the equilibrium," Lodi was a tactical success in the highest sense, in that the principles of his tactics rested on psychology—on the "sublime" part of the art of war as Saxe had called it long ago. The spirit produced the form, and Lodi was the prototype of the Napoleonic battle—contact, manoeuvre, preparation and finally the well-timed, massed and unhesitating assault. The failure to reap the strategical fruits mattered little Many months elapsed before this bold assertion of superiority ceased to decide the battles of France and Austria.

Milan.—Next day he set off in pursuit of Beaulieu, postponing his occupation of the Milanese, but the Austrians were now out of reach, and during the next few days the French divisions were installed at various points in the area Pavia-Milan-Pizzighetone, facing outwards in all dangerous directions, with a central reserve at Milan. Thus secured, Bonaparte turned his attention to political and military administration. This took the form of exacting from the neighbouring princes money, supplies and objects of art, and the once famished Army of Italy revelled in its opportunity. Now, however, the Directory, suspicious of the too successful and too sanguine young general, ordered him to turn over the command in Upper Italy to Kellermann, and to take an expeditionary corps himself into the heart of the peninsula, there to preach the Republic and the overthrow of princes Bonaparte absolutely refused, and offered his resignation In the end (partly by bribery) he prevailed, but the incident reawakened his desire to close with Beaulieu. This indeed he could now do with a free hand, since not only had the Milanese been effectively occupied, but also the treaty with Sardinia had been ratified. But no sooner had he resumed the advance than it was interrupted by a rising of the peasantry in his rear. The exactions of the French had in a few days generated sparks of discontent nhich it was easy for the priests and the nobles to fan into open flames Milan and Pavia as well as the countryside broke into insurrection, and at the latter place the mob forced the French commandant to surrender. Bonaparte acted swiftly and ruthlessly. Bringing back a small portion of the army with him, he

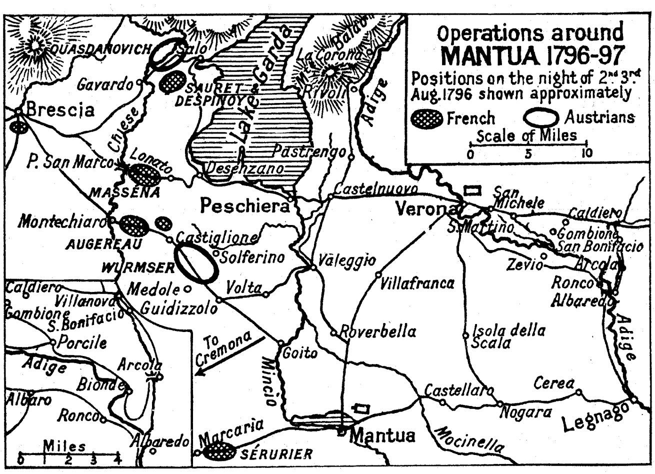
[1]On entering the territory of the duke of Parma, Bonaparte imposed, besides other contributions, the surrender of 20 famous pictures, and thus began a practice which for many years enriched the Louvre and only ceased with the capture of Paris in 1814.

punished Milan on the 25th, sacked and burned Binasco on the 26th, and on the evening of the latter day, while his cavalry swept the open country, he broke his way into Pavia with 1,500 men and beat down all resistance. Then he advanced to the banks of the Mincio, where the remainder of the Italian campaign was fought out, both sides contemptuously disregarding Venetian neutrality. It centred on the fortress of Mantua, which Beaulieu, too weak to keep the field, and dislodged from the Mincio in the action of Borghetto (May 30), strongly garrisoned before retiring into Tirol. Beaulieu was soon afterwards replaced by Wurmser who brought reinforcements from Germany.

At this point, mindful of the narrow escape he had had of losing his command, Bonaparte thought it well to begin the resettlement of Italy. The scheme for co-operating with Moreau on the Danube was indefinitely postponed, and the Army of Italy (now reinforced from the Army of the Alps) was again disposed in a protective "zone of manoeuvre." with a strong central reserve. Against hlantua no siege artillery was available till the Austrians in the citadel of Milan capitulated, and thus not till July 18 was the first parallel begun Almost at the same moment Rurmser began his advance from Trent with 55,000 men to relieve Mantua.

Siege of **Mantua.**—The protective system on which his attack would fall in the first instance was now as follows: Augereau (6,000) about Legnago, Despinoy (8,000) south-east of Verona, Masséna (13,000) at Verona and Peschiera, Sauret (4,500) at Salo and Gavardo Sérurier (12,000) was besieging Mantua, and the only central reserve was the cavalry (2 000) under Kilmaine. The main road to Milan passed by Brescia. Sauret's brigade, therefore, was practically a detached post on the line of communication, and on the main defensive front less than 30,000 men were disposed at various points between La Corona and Legnago (30m. apart), and at a distance of 1j to 20m. from Mantua. The strength of such a disposition depended on the fighting power and handiness of the troops, who in each case would be called upon to act as a rearguard to gain time. The lie of the country scarcely permitted a closer grouping, unless Bonaparte fell back on the old-time device of a "circumvallation." and shut himself up in a ring of earthworks round Mantua —and this was impossible for want of supplies.

As Wurmser's attack procedure has received almost universal condemnation, in justice it may be pointed out that the object of the expedition was not to win a battle by falling on the disunited French with a well-concentrated army, but to overpower



one, any one, of the corps covering the siege, and to press straight forward to the relief of Mantua. New ideas and new forces, undiscernible to a man of 72 years of age, obliterated his achievement by surpassing it; but such as it was—a limited use of force for a limited object—the venture undeniably succeeded.

The Austrians formed three corps, one (Quasdanovich, 18,000 men) marching round the west side of the lake of Garda. the second (under Wurmser, about 30,000) moving directly down the Adige, and the third (Davidovich, 6,000) making a détour by the Brenta valley and heading for Verona by Vicenza. On the 29th Quasdanovich attacked Sauret at Salo, drove him towards Desenzano, and pushed on to Gavardo and thence into Brescia. Wurmser expelled Masséna's advanced guard from La Corona, and captured in succession the Monte Baldo and Rivoli posts. The Brenta column approached Verona with little or no fighting. News of this column led Bonaparte early in the day to close up Despinoy, Masséna and Kilmaine at Castelnuovo; and to order Augereau from Legnago to advance on Montebello (19m. east of Verona) against Davidovich's left rear. But after these orders had been despatched came the news of Sauret's defeat, and this moment was one of the most anxious in Bonaparte's career. He could not make up his mind to give up the siege of Mantua, but he hurried Augereau back to the Mincio, and sent order after order to the officers on the lines of communication to send all convoys by the Cremona instead of by the Brescia road. More, he wrote to Sérurier a despatch which included the words "perhaps we shall recover ourselves . . . but I must take serious measures for a retreat." On the 30th he wrote: "The enemy have broken through our line in three places . . . and . . . captured Brescia. You see that our communications with Milan and Verona are cut." Early reports that day enabled him to "place" the main body of the enemy opposite Masséna, and this at least helped to make his course less doubtful. Augereau was ordered to hold the line of the Molinella, in case Davidovich's attack, the least-known factor, should after all prove to be serious: Masséna to hold Wurmser at Castelnuovo as long as he could. Sauret and Despinoy were concentrated at Desenzano with orders on the 31st to clear the main line of retreat and to recapture Brescia. On the Austrian side Quasdanovich wheeled inwards, his right finally resting on Montechiaro and his left on Salo, and Wurmser drove back Masséna to the west side of the Mincio. Davidovich made a slight advance.

In the late evening Bonaparte held a council of war at Roverbella. The proceedings of this council are unknown, but it at any rate enabled Bonaparte to see clearly and to act. Hitherto he had been covering the siege of Mantua with various detachments, the defeat of any one of which might be fatal to the enterprise. Thus, when he had lost his main line of retreat, he could assemble no more than 8,000 men at Desenzano to win it back. Now, however, he made up his mind that the siege could not be continued, and bitter as was the decision, it gave him freedom. At this moment of crisis the instincts of the great captain came into play, and showed the way to a victory that would more than counterbalance the now inevitable failure. Sérurier was ordered to spike the 140 siege guns which had been so welcome a few days before, and, after sending part of his force to Augereau, to establish himself with the rest at Marcaria on the Cremona road. The field forces were to be used on interior lines. On the 31st Sauret, Despinoy, Augereau and Kilmaine advanced westward against Quasdanovich. The first two found the Austrians at Salo and Lonato and drove them back, while with Augereau and the cavalry Bonaparte himself made a forced march on Brescia, never halting night or day till he reached the town and recovered his depots. Meantime Masséna had gradually drawn in towards Lonato, Sérurier had retired (night of July 31) from before Mantua, and Wurmser's advanced guard triumphantly entered the fortress (Aug. 1).

Lonato and **Castiglione.**—The Austrian general now formed the plan of crushing Bonaparte between Quasdanovich and his own main body. But meantime Quasdanovich had evacuated Brescia under the threat of Bonaparte's advance and was now fighting a long irregular action with Despinoy and Sauret about Gavardo and Salo, and Bonaparte, having missed his expected target, had brought Augereau by another severe march back to Montechiaro. Masséna was now assembled between Lonato and Ponte San Marco. Wurmser's main body, weakened by the detachment sent to Mantua, crossed the Mincio about Valeggio and Goito on the and, and penetrated as far as Castiglione, whence Masséna's rearguard was expelled. But a renewed advance of Quasdanovich, ordered by Wurmser, which drove Sauret and Despinoy back on Brescia and Lonato, in the end only placed a strong detachment of the Austrians within striking distance of

Masséna, who on the 3rd attacked and destroyed it, while at the same time Augereau recaptured Castiglione from Wurmser. On the 4th Sauret and Despinoy pressed back Quasdanovich beyond Salo and Gavardo, and Masséna annihilated an isolated column which tried to break its way through to Wurmser. Wurmser, thinking rightly or wrongly that he could not now retire to the Mincio without a battle, drew up his whole force, close on 30,000 men, in the plain between Solferino and Medole. The finale may be described in very few words. Bonaparte, convinced that no more was to be feared from Quasdanovich, called in Despinoy's division to the main body and sent orders to Sérurier, then far distant on the Cremona road, to march against the left flank of the Austrians. On the 5th the battle of Castiglione (*q.v.*) was fought. Closely contested in the first hours of the frontal attack till Sérurier's arrival decided the day, it ended in the retreat of the Austrians over the Mincio and into Tirol, whence they had come.

Thus the new way had failed to keep back Wurmser, and the old had failed to crush Bonaparte. In former wars a commander threatened as Bonaparte was would have fallen back at once to the Adda, abandoning the siege in such good time that he would have been able to bring off his siege artillery. Instead of this Bonaparte hesitated long enough to lose it, which, according to accepted canons, was a waste, and held his ground, which was, by the same rules, sheer madness. But revolutionary discipline was not firm enough to stand a retreat. Once it turned back, the army would have streamed away to Milan and perhaps to the Alps (*cf.* 1799). As to the manner of this fighting, even the principle of "relative superiority" failed him so long as he was endeavouring to cover the siege and again when his chief care was to protect his new line of retreat and to clear his old. In this period, viz., up to his return from Brescia on Aug. 2, the only "mass" he collected delivered a blow in the air, while the covering detachments had to fight hard for bare existence. Once released from its trammels, the Napoleonic principle had fair play. He stood between Wurmser and Quasdanovich, ready to fight either or both. The latter was crushed, thanks to local superiority and the resolute leading of Masséna, but at Castiglione Wurmser actually outnumbered his opponent till the last of Bonaparte's precautionary dispositions had been given up, and Sérurier brought back from the "alternative line of retreat" to the battlefield. The moral is, again, that it was not the mere fact of being on interior lines that gave Bonaparte the victory, but his "tact," his fine appreciation of the chances in his favour, measured in terms of time, space, attacking force and containing power. All these factors were greatly influenced by the ground, which favoured the swarins and columns of the French and deprived the brilliant Austrian cavalry of its power to act. But of far greater importance was the mobility that Bonaparte's personal force imparted to the French. Bonaparte himself rode five horses to death in three days, and Augereau's division marched from Roverbella to Brescia and back to Montechiaro, a total distance of nearly 50m., in about 36 hours. This indeed was the foundation of his "relative superiority," for every hour saved in the time of marching meant more freedom to destroy one corps before the rest could overwhelm the covering detachments and come to its assistance.

By the end of the second week in August the blockade of Mantua had been resumed, without siege guns. But still under the impression of a great victory gained, Bonaparte was planning a long forward stride. He thought that by advancing past Mantua directly on Trieste and thence onwards to the Semmering he could impose a peace on the emperor. The Directory, however, which had by now focussed its attention on the German campaign, ordered him to pass through Tirol and to co-operate with Moreau, and this plan, Bonaparte, though protesting against an Alpine venture being made so late in the year, prepared to execute. Wurmser was thought to have posted his main body near Trent, and to have detached one division to Bassano "to cover Trieste." The French advanced northward on the and, in three disconnected columns which successfully combined and drove the enemy before them to Trent. There, however, they missed their target. Wurmser had already drawn over the bulk of his army (22,000) into the Val Sugana, whence with the Bassano division as his advanced guard, he intended once more to relieve Mantua, while Davidovich with 13,000 (excluding detachments) was to hold Tirol against any attempt of Bonaparte to join forces with Moreau.

Thus Austria was preparing to hazard a second (as in the event she hazarded a third and a fourth) highly trained and expensive professional army in the struggle for the preservation of a fortress, and we must conclude that there were weighty reasons which actuated so notoriously cautious a body as the Council of War in making this unconditional venture. While Mantua stood, Bonaparte, for all his energy and sanguineness, could not press forward into Friuli and Carniola, and immunity from a Republican visitation was above all else important for the Vienna statesmen, governing as they did more or less discontented and heterogeneous populations that had not felt the pressure of war for a century and more. If we neglect pure theory, and regard strategy as the handmaiden of statesmanship—which fundamentally it is—we cannot condemn the Vienna authorities unless it be first proved that they grossly exaggerated the possible results of Bonaparte's threatened irruption.

Bassano.—When Masséna entered Trent on the morning of Sept. 5, Bonaparte became aware that the force in his front was a mere detachment, and news soon came in that Wurmser was in the Val Sugana about Primolano and at Bassano. This move he supposed to be intended to cover Trieste. He therefore informed the Directory that he could not proceed with the Tirol scheme, and spent one more day in driving Davidovich well away from Trent. Then leaving Vaubois to watch him, Bonaparte marched Augereau and Masséna, with a rapidity he scarcely ever surpassed, into the Val Sugana. Wurmser's rearguard was attacked and defeated again and again, and Wurmser himself felt compelled to stand and fight, in the hope of checking the pursuit before reaching the plains. Half his army had already reached Montebello on the Verona road, and with the rear half he posted himself at Bassano, where on the 8th he was defeated with heavy losses. Then began a strategic pursuit or general chase, and in this Bonaparte at first directed the pursuers so as to cut off Wurmser from Trieste, not fron Mantua. Late on the 9th, Bonaparte realized that his opponent was heading for Mantua via Legnago and despite the fresh cast his net closed so rapidly that Wurmser barely succeeded in reaching Mantua on the 12th, with all the columns of the French, weary as most of them were, converging in hot pursuit. After an attempt to keep the open field, defeated in a general action on the 15th, the relieving force was merged in the garrison, now some 28,000 in all. So ended the episode of Bassano, the most brilliant feature of which was the marching power of the French infantry. Between the 5th and the 11th, besides fighting three actions, Masséna had marched 100m. and Augereau 114.

Alvintzi was now appointed to command a new army of relief. Practically the whole of the fresh forces available were in Carniola, the military frontier, etc., while Davidovich was still in Tirol. Alvintzi's intention was to assemble his new army (29,000) in Friuli, and to move on Bassano. Meantime, Davidovich (18,000) was to capture Trent, and the two columns were to connect by the Val Sugana. All being well, Alvintzi and Davidovich, still separate, were then to converge on the Adige between Verona and Legnago. Wurmser was to co-operate by vigorous sorties. At this time Bonaparte's protective system was as follows: Kilmaine (9,000) investing Mantua, Vaubois (10,000) at Trent, and Masséna (9,000) at Bassano and Treviso, Augereau (9,000) and Macquard (3,000) at Verona and Villafranca constituting, for the first time in these operations, important mobile reserves. Hearing of Alvintzi':: approach in good time, he meant first to drive back Davidovich, then with Augereau, Masséna, Macquard and 3,000 of Vaubois's force to fall upon Alvintzi who, he calculated, would at this stage have reached Bassano, and finally to send back a large force through the Val Sugana to attack Davidovich. This plan miscarried.

By Nov. 7 Davidovich had forced Vaubois back to Rivoli, and Alvintzi pressed forward within 5m. of Vicenza. Bonaparte watched carefully for an opportunity to strike out, and on the 8th massed his troops closely around the central part of Verona. On the 9th, to give himself air, he ordered Masséna to join Vaubois, and to drive back Davidovich at all costs. But before this order was executed, reports came in that Davidovich had suspended his advance. The 10th and 11th were spent by both sides in relative inaction, the French waiting on events and opportunities, the Austrians resting after their prolonged exertions. Then on the afternoon of the 11th, being informed that Alvintzi was approaching, Bonaparte decided to attack him. On the 12th Alvintzi's advanced guard was assailed at Caldiero. But the troops in rear came up rapidly, and by 4 P.M. the French were defeated all along the line and in retreat on Verona. Bonaparte's situation was now indeed precarious. He was on "interior lines" it is true, but he had neither the force nor the space necessary for the delivery of rapid radial blows. Alvintzi was in superior numbers, as Caldiero had proved, and at any moment Davidovich, who had twice Vaubois' force, might advance to the attack of Rivoli. The reserves had proved insufficient, and Kilmaine had to be called up from Mantua, which was thus for the third time freed from the blockaders. Bonaparte chose a daring move on the enemy s rear in preference to the hazards of a retreat, though it was not until the evening of the 14th that he actually issued the fateful order.

The Austrians, too, had selected the 15th as the date of their final advance on Verona, Davidovich from the north, Alvintzi via Zevio from the south. But Bonaparte was no longer there; leaving Vaubois to hold Davidovich as best he might, he had collected the rest of his small army between Albaro and Ronco. His plan seems to have been to cross the Adige well in rear of the Austrians. to march north and establish himself on the Verona-Vicenza highway, where he could supply himself from their convoys. The troops passed the Adige in three columns near Ronco and Albaredo, and marched forward along the dikes, with deep marshes and pools on either hand. If Bonaparte's intention was to reach the dry open ground of San Bonifacio in rear of the Austrians, it was not realized, for the Austrian army, instead of being at the gates of Verona, was still between Caldiero and San Bonifacio, heading, as we know, for Zevio. Thus Alvintzi was able, easily and swiftly, to wheel to the south.

Arcola.—The battle of Arcola almost defies description. The first day passed in a series of resultless encounters between the heads of the columns as they met on the dikes. In the evening Bonaparte withdrew over the Adige, expecting every moment to be summoned to Vaubois' aid. But Davidovich remained inactive, and on the 16th the French again crossed the river. Masséna from Ronco advanced on Porcile, driving the Austrians along the causeway thither, but on the side of Arcola, Alvintzi had deployed a considerable part of his forces on the edge of the marshes, within musket shot of the causeway by which Bonaparte and Augereau had to pass, along the Austrian front, to reach the bridge of Arcola. In these circumstances the second day's battle was more murderous and no more decisive than the first, and again the French retreated to Ronco. But Davidovich again stood still, and with extraordinary resolution, Bonaparte ordered a third assault for the 17th, trying a fresh tactical move. Masséna again advanced on Porcile, Robert's brigade on Arcola, but the rest, under Augereau, were to pass the Alpone near its confluence with the Adige, and joining various small bodies which passed the main stream lower down, to storm forward on dry ground to Arcola. The Austrians, however, themselves advanced from Arcola, overwhelmed Robert's brigade on the causeway and almost reached Ronco. This was perhaps the crisis of the battle, for Augereau's force was now on the other side of the stream, and Masséna, with his back to the new danger, was approaching Porcile. But the fire of a deployed regiment stopped the head of the Austrian column; Masséna, turning about, cut into its flank on the dike; and Augereau, gathering force, was approaching Arcola from the south. The bridge and the village were evacuated soon afterwards, and Masséna and Augereau began to extend in the plain beyond. But the Austrians still sullenly resisted. It was at this moment that Bonaparte secured victory by a mere ruse, but a ruse which would have been unprofitable and ridiculous had it not been based on his fine sense of the moral conditions. Both sides were nearly fought out, and he sent a few trumpeters to the rear of the Austrian army to sound the charge. They did so, and in a few minutes the Austrians were streaming back to San Bonifacio. This ended the drama of Arcola, which more than any other episode of these wars, perhaps of any wars in modem history, centres on the personality of the hero. It is said that the French fought without spirit on the first day, and yet on the second and third Bonaparte had so thoroughly imbued them with his own will to conquer that in the end they prevailed over an enemy nearly twice their own strength.

The climax was reached just in time, for on the 17th Vaubois was completely defeated at Rivoli and withdrew to Peschiera, leaving the Verona and hlantua roads completely open to Davidovich. But on the 19th Bonaparte turned upon him, and combining the forces of Vaubois, Masséna and Augereau against him, drove him back to Trent. Meantime Alvintzi returned from Vicenza to San Bonifacio and Caldiero (Nov. 21), and Bonaparte at once stopped the pursuit of Davidovich. On the return of the French main body to Verona, Alvintzi finally withdrew, Wurmser, who had emerged from hlantua on the 23rd, was driven in again, and this epilogue of the great struggle came to a feeble end because neither side was now capable of prolonging the crisis. In Jan. 1797 Alvintzi renewed his advance with all the forces that could be assernbled for a last attempt to save Mantua. At this time 8,000 men under Sérurier blockaded Mantua. Masséna (9,000) was at Verona, Joubert (Vaubois' successor) at Rivoli with 10,000, Augereau at Lcgnago with 9,000. In reserve were Rey's division (4,000) between Brescia and Montechiaro, and Victor's brigade at Goito and Castelnuovo. On the other side Alvintzi's location was the reverse of that in the previous campaign, for while he had 9,000 men under Provera at Padua, 6,000 under BayaliE at Bassano, he himself with 28,000 men stood in the Tirol about Trent. This time he intended to make his principal effort on the Rivoli side. Provera was to capture Legnago on Jan. 9, and Bayalič Verona on the 12th, while the main army was to deliver its blow against the Rivoli position on the 13th.

Rivoli.—The first marches of this scheme were duly carried out, and several days elapsed before Bonaparte was able to discern the direction of the real attack. Augereau fell back, skirmishing a little, as Provera's and Bayalič's advance developed On the 11th, when the latter was nearing Verona, Alvintzi's leading troops appeared in front of the Rivoli position. On the 12th BayaliE, weakened by sending reinforcements to Alvintzi, made an unsuccessful attack on Verona, Provera, farther south, remaining inactive. On the 13th, Bonaparte, still in doubt, launched Masséna's division against BayaliE, who was driven back to San Bonifacio; but at the same time definite news came from Joubert that Alvintzi's main army was in front of La Corona. From this point begins the decisive, though by no means the most intense or dramatic, struggle of the campaign. Once he felt sure of the situation Bonaparte acted promptly. Joubert was ordered to hold on to Rivoli at all costs. Rey was brought up by a forced march to Castelnuovo, where Victor joined him, and ahead of them both Masséna was hurried on to Rivoli. Bonaparte himself joined Joubert on the night of the 13th. There he saw the watch-fires of the enemy in a semicircle around him, for Alvintzi, thinking that he had only to deal with one division, had begun a widespread enveloping attack. The horns of this attack were as yet so far distant that Bonaparte, instead of extending on an equal front, only spread out a few regiments to gain an hour or two and to keep the ground for Masséna and Rey, and on the morning of Jan. 14, with 10,000 men in hand against 26,000, he fell upon the central columns of the enemy as they advanced up the steep broken slopes of the foreground. The fighting was severe, but Bonaparte had the advantage. Masséna arrived at 9 A.M., and a little later the column of Quasdanovich, which had moved along the Adige and was now attempting to gain a foothold on the plateau in rear of Joubert, was crushed by the converging fire of Joubert's right brigade and by Masséna's guns, their rout being completed by the charge of a handful of cavalry under Lasalle. The right horn of Alvintzi's attack, when at last it swung in upon Bonaparte's rear, was caught between Masséna and the advancing troops of Rey and annihilated, and even before this the dispirited Austrians were in full retreat. A last alarm, caused by the appearance of a French infantry regiment in their rear (this had crossed the lake in boats from Salo), completed their demoralization, and though less than 2,000 had been killed and wounded, some 12,000 Austrian prisoners were left in the hands of the victors. Rivoli was indeed a moral triumph. After the ordeal of Arcola, the victory of the French was a foregone conclusion at each point of contact. Bonaparte refrained from striking so long as his information was incomplete, but he knew now from experience that his covering detachment, if well led, could not only hold its own without assistance until it had gained the necessary information, but could still give the rest of the army time to act upon it. Then, when the centre of gravity had been ascertained, the French divisions hurried thither, caught the enemy in the act of manoeuvring and broke them up. And if that confidence in success which made all this possible needs a special illustration, it may be found in Bonaparte sending Murat's regiment over the lake to place a mere 2,000 bayonets across the line of retreat of a whole army. Alvintzi's manoeuvre was faulty neither strategically in the first instance, nor tactically as regards the project of enveloping Joubert on the 14th. It failed because, apart from Bonaparte's genius, Joubert and his men were better soldiers than their Austrian opponents, and because a French division could move twice as fast as an Austrian division, and from these two factors a new form of war was evolved, the essence of which was that, for a given time and in a given area, a small force of the French should engage and hold a much larger force of the enemy.

The remaining operations can be very briefly summarized. Provera, still advancing on Mantua, joined hands there with Wurmser, and for a time held Serurier at a disadvantage. But hearing of this, Bonaparte sent back Masséna from the field of Rivoli, and that general, with Augereau and Sérurier, not only forced Wurmser to retire again into the fortress, but compelled Provera to lay down his arms. And on Feb. 2, 1797, Mantua, and with it what was left of Wurmser's army, surrendered. The campaign of 1797, which ended the war of the First Coalition, was the brilliant sequel of these hard-won victories. Austria had decided to save Mantua at all costs, and had lost her armies in the attempt, a loss which was not compensated by the "strategic" victories of the archduke. Thus the Republican "visitation" of Carinthia and Carniola was one swift march—politically glorious, if dangerous from a purely military standpoint—of Bonaparte's army to the Semmering. The archduke, who was called thither from Germany, could do no more than fight a few rearguard actions and make threats against Bonaparte's rear, which the latter, with his usual "tact," ignored.

On the Rhine, as in 1795 and 1796, the armies of the Sambre-and-Meuse (Hoche) and the Rhine-and-Moselle (Moreau) were opposed by the armies of the Lower Rhine (Werneck) and of the Upper Rhine (Latour). Moreau crossed the river near Strasbourg and fought a series of minor actions. Hoche, like his predecessors, crossed at Ddsseldorf and Neuwied and fought his way to the Lahn, where for the last time in the history of these wars, there was an irregular widespread battle. But Hoche, in this his last campaign, displayed the brilliant energy of his first, and delivered the "series of incessant blows" that Carnot had urged upon Jourdan the year before. Werneck was driven with ever-increasing losses from the lower Lahn to Wetzlar and Giessen. Thence, pressed hard by the French left wing under Championnet, he retired on the Nidda, only to find that Hoche's right had swung completely round him. Nothing but the news of the armistice of Leoben saved him from envelopment and surrender. This general armistice was signed by Bonaparte, on his own authority and to the intense chagrin of the Directory and of Hoche, on April 18, and was the basis of the peace of Campo Formio.

BONAPARTE IN EGYPT

Within the scope of this article, yet far more important from its political and personal than from its general military interest, comes the expedition of Bonaparte to Egypt and its sequel. (See also EGYPT: *History;* NAPOLEON I; etc.) Bonaparte left Toulon on May 19, 1798, at the same time as his army (40,000 strong in 400 transports) embarked secretly at various ports. Nelson's fleet was evaded, and, capturing Malta *en route,* the armada reached the coast of Egypt on July 1. The Republicans stormed Alexandria on the 2nd. Between Embabeh and Gizeh, on the left bank of the Nile, 60,000 Mamelukes were easily dispersed on the 21st (battle of the Pyramids), the French for the most part marching and fighting in the chequer of infantry squares that afterwards became the classical formation for desert warfare. While his lieutenants pursued the more important groups of the enemy, Bonaparte entered Cairo in triumph, and proceeded to organize Egypt as a French protectorate. Meantime Nelson, though too late to head off the expedition, had annihilated the squadron of Admiral Brueys. This blow severed the army from the home country, and destroyed all hope of reinforcements. But to eject the French already in Egypt, military invasion of that country was necessary. The first attempts at this were made in September by the Turks as overlords of Egypt. Bonaparte—after suppressing a revolt in Cairo—marched into Syria to meet them, and captured El Arish and Jaffa; at the latter place the prisoners, whom he could afford neither to feed, to release, nor to guard, were shot by his order. But he was brought to a standstill (March 17–May 20) before the half-defensible fortifications of Acre, held by a Turkish garrison and animated by the leadership of Sir Sidney Smith, In May, though meantime a Turkish relieving army had been severely beaten in the battle of Mount Tabor (April 16, 1799), Bonaparte gave up his enterprise and returned to Egypt, where he won a last victory in annihilating at Aboukir, with 6,000 of his own men, a Turkish army 18,000 strong that had landed there (July 25, 1799). With this tactical success to set against the Syrian reverses, he handed over the command to Kléber and returned to France (hug. 22) to ride the storm in a new *coup d'état,* the "18th Brumaire." Kléber, attacked by the English and Turks, concluded the convention of El Arish (Jan. 27, 1800), whereby he secured free transport for the army back to France. But this convention was disavowed by the British Government, and Kléber prepared to hold his ground. On March 20, 1800, he thoroughly defeated the Turkish army at Heliopolis and recovered Cairo, and French influence was once more in the ascendant in Egypt, when its director was murdered by a fanatic on June 14, the day of Marengo. Kléber's successor, the incompetent Menou, fell an easy victim to the British expeditionary force under Sir Ralph Abercromby in 1801. The British forced their way ashore at Aboukir on March 8. On the 21st Abercromby won a decisive battle, and himself fell in the hour of victory. (See ALEXANDRIA: *Battle of 1801.*) His successor, Gen. Hely Hutchinson, slowly followed up this advantage, and received the surrender of Cairo in July and of Alexandria in August, the dèbris of the French army being given free passage back to France. Meantime a mixed force of British and native troops from India, under Sir David Baird, had landed at Kosseir and marched across the desert to Cairo.

THE WAR OF THE SECOND COALITION

In the autumn of 1798, while Bonaparte's Egyptian expedition was in progress, and the Directory was endeavouring at home to reduce the importance and the predominance of the army and its leaders, the Powers of Europe once more allied themselves, not now against the principles of the Republic, but against the Treaty of Campo Formio. Russia, Austria, England, Turkey, Portugal, Naples and the pope formed the Second Coalition. The war began with an advance into the Roman States by a worthless and ill-behaved Neapolitan army (commanded, much against his will, by Mack), which the French troops under Championnet destroyed with ease. Championnet then revolutionized Naples. After this unimportant prelude the curtain rose on a general European war. The Directory, which now had at its command neither numbers nor enthusiasm, prepared as best it could to meet the storm. Four armies, numbering only 160,000, were set on foot, in Holland (Brune, 24,000); on the Upper Rhine (Jourdan, 46,000); in Switzerland, which had been occupied in 1798 (Masséna, 30,000); and in Upper Italy (Schérer, 60,000). In addition there was Championnet's army, now commanded by Macdonald, in southern Italy. All these forces the Directory ordered, in Jan. and Feb. 1799, to assume the offensive.

Stokach.—Jourdan, in the Constance and Schaffhausen region, had only 40,000 men against the Archduke Charles's 80,000, and was soon brought to a standstill and driven back on Stokach. The archduke had won these preliminary successes with seven-eighths of his army acting as one concentrated mass. But as he had only encountered a portion of Jourdan's army, he became uneasy as to his flanks, checked his bold advance, and ordered a reconnaissance in force. This practically extended his army while Jourdan was closing his, and thus the French began the battle of Stokach (March 25) in superior numbers, and it was not until late in the day that the archduke brought up sufficient strength (60,000) to win a victory. This was a battle of the "strategic" type, a wide-spread straggling combat in which each side took 15 hours to inflict a loss of 12% on the other, and which ended in Jourdan accepting defeat and drawing off, unpursued by the magnificent Austrian cavalry, though they counted five times as many sabres as the French.

The French secondary army in Switzerland u-as in the hands of the bold and active Masséna. The forces of both sides in the Alpine region were, from a military point of view, mere flank guards to the main armies on the Rhine and the Adige. But unrest, amounting to civil war, among the Swiss and Grison peoples tempted both Governments to give these flank guards considerable strength.

Masséna in Switzerland.—The Austrians in the Vorarlberg and Grisons were under Hotze, who had 13,000 men at Bregenz, and 7,000 commanded by Auffenberg around Chur, with, between them, 5,000 men at Feldkirch and a post of 1,000 in the strong position of the Luziensteig near Mayenfeld. Masséna's available force was about 20,000, and he used almost the whole of it against Auffenberg. The Rhine was crossed by his principal column near Mayenfeld, and the Luziensteig stormed (March 6), while a second column from the Zurich side descended upon Disentis and captured its defenders. In three days Auffenberg's division was broken up, Oudinot meanwhile holding off Hotze by a hard-fought combat at Feldkirch (March 7). But a second attack on Feldkirch made on the 23rd by Masséna was repulsed and the advance of his left wing came to a standstill. Behind Xuffenberg and Hotze was Bellegarde in Tirol with some 47,000 men. Most of these were stationed north of Innsbruck and Landeck, probably as a sort of strategic reserve to the archduke. The rest, with the assistance of the Tirolese themselves, were to ward off irruptions from Italy. Here the French offensive was entrusted to two columns, one from Masséna's command under Lecourbe, the other from the Army of Italy under Dessolle. Sjmultaneously with Masséna, Lecourbe marched from Bellinzona with 10,000 men. by the San Bernardino pass into the Splugen valley, and thence over the Julier pass into the upper Engadine. A small Austrian force under Loudon attacked him near Zernetz. but was after three days of rapid manoeuvres and bold tactics driven back to Martinsbrück, with considerable losses But ere long the country people flew to arms, and Lecourbe found himself between two fires, the levies occupying Zernetz and Loudon's regulars Martinsbrück. But though he had only some 5,000 of his original force left, he was not disconcerted, and by driving back the levies into the high valleys whence they had come, and constantly threatening Loudon, he was able to maintain himself and to wait for Dessolles. The latter, moving up the Valtelline, fought his way to the Stelvio pass, but beyond it the defile of Tauffers (south-west of Glurns), was entrenched by Loudon, who thus occupied a position midway between the two French columns, while his irregulars beset all the passes and ways giving access to the Vintschgau and the lower Engadine. In this situation the French should have been destroyed in detail. But as usual their speed and dash gave them the advantage in every manoeuvre and at every point of contact.

Operations in Tirol.—On the 2jth Lecourbe and Dessolles attacked Loudon at Nauders in the Engadine and Tauffers in the Vintschgau respectively. At Nauders the French passed round the flanks of the defence by scrambling along the high mountain crests adjacent, while at Tauffers, the assailants, only 4,500 strong, descended into a deep ravine, debouched unnoticed in the Austrians' rear, and captured 6,000 men and 16 guns. The Austrian leader with a couple of companies made his way through Glurns to Nauders, and there, finding himself headed off by Lecourbe, he took to the mountains. His corps, like Auffenberg's, was annihilated. This ended the French general offensive. Jourdan had been defeated by the archduke and forced or induced to retire over the Rhine. Masséna was at a standstill before the strong position of Feldkirch, and the Austrians of Hotze were still massed at Bregenz, but the Grisons were revolutionized, two strong bodies of Austrians numbering in all about 20.000 men had been destroyed, and Lecourbe and Dessolles had advanced far into Tirol. A pause followed. The Austrians in the mountains needed time to concentrate and to recover from their astonishment. The archduke fell ill, and the Vienna war council forbade his army to advance lest Tirol should be "uncovered," though Bellegarde and Hotze still disposed of numbers equal to those of Masséna and Lecourbe. Masséna succeeded Jourdan in general command on the French side and promptly collected all available forces of both armies in the hilly non-Alpine country between Basle, Zurich and Schaffhausen, thereby directly barring the roads into France (Berne-Neuchâtel-Pontarlier and Basle-Besançon) which the Xustrians appeared to desire to conquer. The protection of Alsace and the Vosges was left to the fortresses. There was no suggestion, it would appear, that the Rhine between Basle and Schaffhausen was a flank position sufficient of itself to bar Alsace to the enemy.

It is now time to turn to events in Italy, where the Coalition intended its principal effort. At the beginning of March the French had 80,000 men in Upper Italy and some 35,000 in the heart of the Peninsula, the latter engaged chiefly in supporting newly-founded republics. Of the former, 53,000 formed the field army on the Mincio under Schérer. The Austrians, commanded by Kray, numbered in all 84,000, but detachments reduced this figure to 67,000, of whom, moreover, 15,000 had not yet arrived when operations began. They were to be joined by a Russian contingent under the celebrated Suvórov, who was to command the whole on arrival, and whose extraordinary personality gives the campaign its special interest. Rray himself was a resolute soldier, and when the French, obeying the general order to advance, crossed the Adige, he defeatrd them in a severely fought battle at Magnano near Verona (March j). The war, however, was undertaken not to annihilate, but to evict the French, and, probably under orders from Vienna, Kray allowed the beaten enemy to depart.

Suvórov.—Suvórov appeared with 17,000 Russians on April 4. His first step was to set Russian officers to teach the Austrian troops—whose feelings can be imagined—how to attack with the bayonet, his next to order the whole army for ard. The Allies broke camp on April 17, 18 and 19, and on the 20th, after a forced march of close on 30m., they passed the Chiese. Brescia had a French garrison, but Suvórov soon cowed it into surrender by threats of a massacre, which no one doubted that he would carry into execution. At the same time, dissatisfied with the marching of the Austrian infantry, he sent the following characteristic reproof to their commander: "The march was in the service of the Kaiser. Fair weather is for my lady's chamber, for dandies. for sluggards. He who dares to cavil against his high duty is, as an egoist, instantly to vacate his command. Whoever is in bad health can stay behind. The so-called reasoners do no army any good. . . ." One day later, under this unrelenting pressure, the advanced posts of the Allies reached Cremona and the main body the Oglio. The pace became slower in the following days, as many bridges had to be made, and meanwhile Moreau, Schérer's successor, prepared with a mere 20,000 men to defend the Adda. On the 26th he was attacked all along the line. The moral supremacy had passed over to the Allies. Melas, under Suvórov's stern orders, flung tis battalions, regardless of losses, against the strong position of Cassano. The story of 1796 repeated itself with the rôles reversed. The passage was carried, and the French rearguard under Sérurier was surrounded and captured by an inferior corps of Austrians. The Austrians (the Russians at Lecco were hardly engaged) lost 6.000 men, but they took 7,000 prisoners, and in all Moreau's little army lost half its numbers and retreated in many disconnected bodies to the Ticino, and thence to Alessandria.

Everywhere the Italians turned against the French, mindful of the exactions of their commissaries. The strange Cossack cavalry that western Europe had never yet seen entered Milan on April 29, 11 days after passing the Mincio, and next day the city received with enthusiasm the old field-marshal, whose exploits against the Turks had long invested him with a halo of romance and legend. Here, for the moment, Suvorov's offensive culminated. He desired to pass into Switzerland and to unite his own, the archduke's, Hotze's and Bellegarde's armies in one powerful mass. But the emperor would not permit the execution of this scheme until all the fortresses held by the enemy in Upper Italy should have been captured. In any case, Macdonald's army in southern Italy, cut off from France by the rapidity of Suvórov's onslaught, and now returning with all speed to join Moreau by force or evasion, had still to be dealt with.

Suvórov's mobile army, originally 90,000 strong, had now dwindled, by reason of losses and detachments to sieges, to half that number, and serious differences arose between the Vienna Government and himself. If he offended the pride of the Austrian army, he was at least respected as a leader who gave it victories; but in Vienna he was regarded as a madman who had to be kept within bounds. But at last, when he was becoming thoroughly exasperated by this treatment, Macdonald came within striking distance and the active campaign recommenced. In the second week of June, Moreau, who had retired into the Apennines about Gavi, advanced with the intention of drawing upon himself troops that would otherwise have been employed against Macdonald. He succeeded, for Suvórov with his usual rapidity collected 40,000 men at Alessandria, only to learn that Macdonald with 35,000 men was coming up on the Parma road. When this news arrived, Macdonald had already engaged an Austrian detachment at hfodena and driven it back, and Suvórov found himself between hforeau and Macdonald with barely enough men under his hand to enable him to play the game of "interior lines." But at the crisis the rough energetic warrior who despised "raisonneurs," displayed generalship of the first order, and taking in hand all his scattered detachments, he manoeuvred them in the Napoleonic fashion.

The **Trebbia.**—On the 14th Macdonald was calculated to be between Modena, Reggio and Carpi, but his destination was uncertain. Would he continue to hug the Apennines to join Moreau, or would he strike out northwards against Kray, who with 20,000 men was besieging Mantua? From Alessandria it is four marches to Piacenza and nine to Mantua, while from Reggio these places are four and two marches respectively. Piacenza, therefore, was the crucial point if Macdonald continued westward, while in the other case nothing could save Kray but the energetic conduct of Hohenzollern's detachment, which was posted near Reggio. This, however, was soon forced over the Po, and Ott, advancing from Cremona to join it, found himself sharply pressed in turn. The field-marshal had hoped that Ott and Hohenzollern together would be able to win him time to assemble at Parma, where he could bring on a battle whichever way the French took. But on receipt of Ott's report he was convinced that Macdonald had chosen the western route and ordering Ott to delay the French as long as possible by stubborn rearguard actions and to put a garrison into Piacenza under a general who was to hold out "on peril of his life and honour," he collected what forces were ready to move and hurried towards Piacenza, the rest being left to watch Moreau. He arrived just in time. When after three forced marches the main body (only 26,000 strong) reached Castel San Giovanni, Ott had been driven out of Piacenza, but the two joined forces safely. Both Suvórov and Macdonald spent the 17th in closing up and deploying for battle. The respective forces were Allies, barely 25.000, French, 35,000. Suvórov believed the enemy to be only 26,000 strong, and chiefly raw Italian regiments, but his temperament would not have allowed him to stand still even had he known his inferiority. He had already issued one of his peculiar battle-orders, which began with the words: "The hostile army will be taken prisoners" and continued with directions to the Cossacks to spare the surrendered enemy. But Macdonald was too full of energy, and believed still that he could annihilate Ott before Suvórov's arrival. Thus the battle of the Trebbia (June 17–19) was fought by both sides in the spirit of the offensive. It was one of the most severe struggles in the Republican wars, and it ended in Macdonald's retreat with a loss of 15,000 men—probably 6,000 in the battle and 9,000 killed and prisoners when and after the equilibrium was broken—for Suvórov, unlike other generals, had the necessary surplus of energy, after all the demands made upon him by a great battle, to order and to direct an eflective pursuit. The Allies lost about 6,000. Macdonald retreated to Modena, harassed by the peasantry, and finally recrossed the Apennines and made his way to Genoa. The battle of the Trebbia is one of the most clearly defined examples in military history of the result of moral force—it was a matter not merely of energetic leading on the battlefield, but far more of educating the troops beforehand to meet the strain, of ingraining in the soldier the determination to win at all costs.

To return now to the Alpine region, where the French offensive had culminated at the end of March. Their defeated left was behind the Rhine in the northern part of Switzerland, the half-victorious centre athwart the Rhine between Mayenfeld and Chur, and their wholly victorious right far within Tirol between Glurns, Nauders and Landeck. But neither the centre nor the right could maintain itself. The forward impulse given by Suvórov spread along the whole Austrian front from left to right. Dessolles' column (now under Loison) was forced back to Chiavenna. Bellegarde drove Lecourbe from position to position towards the Rhine during April. There Lecourbe added to the remnant of his expeditionary column the outlying bodies of Masséna's right wing, but even so he had only 8,000 men against Bellegarde's 17,000, and he was now exposed to the attack of Hotze's 25,000 as well. The Luziensteig fell to Hotze and Chur to Bellegarde, but the defenders managed to escape from the converging Austrian columns into the valley of the Reuss. Having thus reconquered all the lost ground and forced the French into the interior of Switzerland, Bellegarde and Hotze parted company, the former marching with the greater part of his forces to join Suvórov, the latter moving to his right to reinforce the archduke. Only a chain of posts was left in the Rhine valley between Disentis and Feldkirch. The archduke's operations now recommenced.

Charles and Hotze stood, about May 15, at opposite ends of the lake of Constance. The two together numbered about 88,000 men, but both had sent away numerous detachments to the flanks, and the main bodies dwindled to 35,000 for the archduke, and 20,000 for Hotze. Masséna, with 45,000 men in all, retired slowly from the Rhine to the Thur. Pressed by the combined forces he continued to yield ground until at last he halted in the position he had prepared for defence at Ziirich. He had only 25,000 men in hand, owing to detachments, to cover his right and his left. These 25,000 occupied an entrenched position 5m. in length, against which the Austrians, detaching as usual many posts to protect their flanks and rear, deployed only 42,000 men, of whom 8,000 were sent on a wide turning movement and 8.000 held in reserve 4m. in rear of the battlefield. Thus the frontal attack was made with forces not much greater than those of the defence and it failed accordingly (June 4). But Masséna, fearing perhaps to strain the loyalty of the Swiss to their French-made constitution by exposing their town to assault and sack, retired on the 5th to the valley of the Aar between Baden and Lucerne. The archduke did not seek to press Masséna, and for two months operations were at a standstill.

Döttingen.—Ere mid-August, Lecourbe, who formed a loose right wing of the French army in the Reuss valley, was reinforced to a strength of 25,000 men, and pounced upon the extended left wing of the enemy, which had stretched itself, to keep pace with Suvórov, as far westward as the St. Gothard. The movement began on the 14th, and in two days the Austrians were driven back from the St. Gothard and the Furka to the line of the Linth, with the loss of 8,000 men and many guns. At the same time an attempt to take advantage of Masséna's momentary weakness by forcing the Aar at Dottingen near its mouth failed completely (Aug. 16–17). This was the end of the archduke's campaign in Switzerland. Though he would have preferred to continue it, the Vienna Government desired him to return to Germany. An Anglo-Russian expedition was about to land in Holland,[1] and the French were assembling fresh forces on the Rhine, and, with the double object of preventing an invasion of South Germany and of inducing the French to augment their forces in Alsace at the expense of those in Holland, the archduke left affairs in Switzerland to Hotze and a fresh Russian force under Korsákov, and marched away to the Black Forest. His new campaign never rose above the level of a war of posts and manoeuvres about Mannheim and Philippsburg.

Suvórov's last exploit in Italy coincided in time, but in no other respect, with the skirmish at Dottingen. Returning swiftly from the battlefield of the Trebbia, he began to drive back Moreau to the Riviera. At this point Joubert succeeded to the command on the French side, and against the advice of his generals, gave battle. Equally against the advice of his own subordinates, Suvórov accepted it, and won his last great victory at Novi on Aug. 13, Joubert being killed, and only a third of his army making good its retreat. This was followed by another rapid march against a new French "Army of the Alps" which had entered Italy by way of the Mt. Cenis. But immediately after this he left all further operations in Italy to Melas, and himself, with the Russians and an Austrian corps, marched away for the St. Gothard to combine operations against Masséna with Hotze and Korsákov. It was with a heavy heart that he left the scene of his battles, in which the force of his personality had carried the old-fashioned "linear" armies for the last time to complete victory. He had himself urged an advance into France, but the Vienna Government had been unwilling, for their interest was concentrated on Italy. The Tsar Paul I., annoyed with the Austrians, ordered Suvórov to bring back the Russian army, through Switzerland and thence to South Germany. The archduke had already left Switzerland, and was committed to a resultless warfare in the high mountains, with an army which was a mere detachment and in the hope of co-operating with two other detachments far away on the other side of Switzerland.

In loyalty to the formal order of his sovereign Suvórov prepared to carry out his instructions. Masséna's command (77,000 men) was distributed, at the beginning of September, along an enormous S, from the Simplon through the St. Gothard and Glarus, and along the Linth, the Züricher See and the Limmat to Basle. Opposite the lower point of this S, Suvórov (28,000 men) was about to advance. Hotze's corps (25,000 Austrians), extending from Utznach by Chur to Disentis, formed a thin line roughly parallel to the lower curve of the S, Korsákov's Russians (30,000) were opposite the centre at Zurich, while Nauendorff with a small Austrian corps at Waldshut faced the extreme upper point. Thus the only completely safe way in which Suvórov could reach the Zurich region was by skirting the lower curve of the S, under protection of Hotze. But this détour would be long and painful, and the ardent old man preferred to cross the mountains once for all at the St. Gothard, and to follow the valley of the Reuss to Altdorf and Schwyz—*i.e.,* to strike vertically upward to the centre of the S—and to force his way through the French cordon to Zurich; and if events, so far as concerned his own corps, belied his optimism, they at any rate justified his choice of the shortest route. For, aware of the danger gathering in his rear, Masséna gathered up all his forces within reach towards his centre, leaving Lecourbe to defend the St. Gothard and the Reuss valley and Soult on the Linth. On Sept. 24 he forced the passage of the Limmat at Dietikon. On the 25th, in the second battle of Zurich, he completely routed Korsákov, who lost 8,000 killed and wounded, large numbers of prisoners and 100 guns. All along the line the Allies fell back, one corps after another, at the moment when Suvórov was approaching the foot of the St. Gothard.

Suvórov in the Alps.--On the 21st his headquarters were at Bellinzona, where he made the final preparations. Expecting to be four days en *route* before he could reach the nearest friendly magazine, he took his supply trains with him, which inevitably augmented the difficulties of the expedition. On the 24th Airolo was taken, but when the far greater task of storming the pass presented itself before them, even the stolid Russians were terrified, and only the passionate protests of the old man, who reproached his "children" with deserting their father in his extremity, induced them to face the danger. At last after 12 hours' fighting the summit was reached. The same evening Suvórov pushed on to Hospenthal, while a flanking column from Disentis made its way towards Amsteg over the Crispalt. Lecourbe was threatened in rear and pressed in front, and his engineers, to hold off the Disentis column, had broken the Devil's bridge. Discovering this, he left the road, threw his guns into the river and made his way by fords and water-meadows to Goschenen, where by a furious attack he cleared the Disentis troops off his line of retreat. His rearguard meantime held the ruined Devil's bridge. This point and the tunnel leading to it, called the Urner Loch, the Russians attempted to force, with the most terrible losses, battalion after battalion crowding into the tunnel and pushing the foremost ranks into the chasm left by the broken bridge. But at last a ford was discovered and the bridge, cleared by a turning movement, was repaired. More broken bridges lay beyond, but at last Suvórov joined the Disentis column near Goschenen. When Altdorf was reached, however, Suvórov found not only Lecourbe in a threatening position, but an entire absence of boats on the Lake of the Four Cantons. It was impossible (in those days the Axenstrasse did not exist) to take an army along the precipitous eastern shore; and thus, passing through one trial after another, each more severe than the last, the Russians, men and horses and pack animals in an interminable single file, ventured on the path leading over the Kinzig pass into the Muotta Thal. The passage lasted three days, the leading troops losing men and horses over the precipices, the rearguard from the fire of the enemy, now in pursuit. And at last, on arrival in the Muotta Thal, Suvórov received definite information that Korsákov's army was no longer in existence. Yet even so it was long before he could make up his mind to retreat, and the pursuers gathertd on all sides. Fighting, sometimes severe, and never altogether ceasing, went on day after day as the Allied column, now reduced to 15,000 men, struggled on over one pass after another, but at last it reached Ilanz on the Vorder Rhine (Oct. 8). The Archduke Charles meanwhile had, on hearing of the disaster of Zurich, brought over a corps from the Neckar, and for some time negotiations were made for a fresh combined operation against Massitna. But these came to nothing, for the archduke and Suvórov could not agree, either as to their own relations or as to the plan to be pursued. Practically, Suvórov's retreat from Altdorf to Ilanz closed the campaign. It was his last active service, and formed a gloomy but grand climax to the career of the greatest soldier who ever wore the Russian uniform.

MARENGO AND HOHENLINDEN

The disasters of 1799 sealed the fate of the Directory, and placed Bonaparte, who returned from Egypt with the prestige of a recent victory, in his natural place as civil and military head of France. In the course of the campaign the field strength of the French had been gradually augmented, and in spite of losses now numbered 227,000 at the front. These were divided into the army of Batavia, Brune (25,000), the army of the Rhine, Moreau (146,000), the army of Italy, Masséna (56,000), and, in addition, there were some 100,000 in garrisons and depots in France. Most of these field armies were in a miserable condition owing to the losses and fatigues of the last campaign. The treasury was empty and credit exhausted, and worse still—for spirit and enthusiasm, as in 1794, would have remedied material deficiencies—the conscripts obtained under Jourdan's law of 1798 came to their regiments most unwillingly. Most of them, indeed, deserted on their way to join the colours. A large draft sent to the Army of Italy arrived with 310 men instead of 10,250, and after a few such experiences, the First Consul decided that the untrained men were to be assembled in the fortresses of the interior and afterwards sent to the active battalions in numerous small drafts, which they could more easily assimilate. Besides accomplishing the immense task of reorganizing existing forces, he created new

[1]For this expedition, which was repulsed by Brune in the battle of Castricum, *see* Fortescue's *History of the British Army,* vol. iv., and Sachot's *Brune en Hollande.*

ones, including the Consular Guard, and carried out at this moment of crisis two such far-reaching reforms as the replacement of the civilian drivers of the artillery by soldiers, and of the hired teams by horses belonging to the State, and the permanent grouping of divisions in army corps.

The Army **of** Reserve.—As early as Jan. 25, 1800, the First Consul provided for the assembly of all available forces in the interior in an "Army of Reserve." He reserved to himself the command of this army,[1] which gradually Came into being as the pacification of Vendée and the return of some of Brune's troops from Holland set free the necessary nucleus troops. The conscription law was stringently reinforced, and impassioned calls were made for volunteers (the latter, be it said, did not produce 500 useful men). The district of Dijon, partly as being central with respect to the Rhine and Italian armies, partly as being convenient for supply purposes, was selected as the zone of assembly. As for the process of assembling it, we can scarcely imagine one which required more accurate and detailed staff work—correspondence with the district commanders, with the adjutant-generals of the various armies, and orders to the civil authorities on the lines of march, to the troops themselves and to the arsenals and magazines. No one but Bonaparte, even aided by a Berthier, could have achieved so great a task in six weeks, and the great captain, himself doing the work that nowadays is apportioned amongst a crowd of administrative staff officers, still found time to administer France's affairs at home and abroad, and to think out a general plan of campaign that embraced Moreau's, Masséna's and his own armies.

The Army of the Rhine, by far the strongest and best equipped, lay on the upper Rhine. The small and worn-out Army of Italy was watching the Alps and the Apennines from Mt. Blanc to Genoa. Between them Switzerland, secured by the victory of Zürich, offered a starting-point for a turning movement on either side—this year the advantage of the flank position was recognized and acted upon. The Army of Reserve was assembling around Dijon, within 200m. of either theatre of war. The general plan was that the Army of Reserve should march through Switzerland to close on the right wing of the Army of the Rhine. Thus supported to whatever degree might prove to be necessary, Moreau was to force the passage of the Rhine about Schaffhausen, to push back the Austrians rapidly beyond the Lech, and then, if they took the offensive in turn, to hold them in check for 10 or 12 days. During this period of guaranteed freedom the decisive movement was to be made—a swoop along an immense arc on to the rear of the Austrians who had penned Masséna into the north-west corner of Italy. The Army of Reserve, augmented by one large corps of the Army of the Rhine, was to descend by the Splügen (alternatively by the St. Gothard and even by Tirol) into the plains of Lombardy. Magazines were to be established at Zürich and Lucerne (not at Chur, lest the plan should become obvious from the beginning), and all likely routes reconnoitred in advance. The Army of Italy was at first to maintain a strict defensive, and then to fix the Austrians until the entry of the reserve army into Italy was assured.

But Moreau was tardy in moving, and at the beginning of April the enemy took the offensive against Masséna. On the 8th Melas's right wing dislodged the French from the Mt. Cenis, and most of the troops that had then reached Dijon were shifted southward to be ready for emergencies. By the 25th Berthier reported that Masséna was seriously attacked and that he might have to be supported by the shortest route, *i.e.*, the more westerly passes. Bonaparte's resolution was already taken. He waited no longer for Moreau (who, indeed, so far from volunteering assistance, actually demanded it for himself). Convinced from the paucity of news that Masséna's army was closely pressed and probably severed from France, and feeling also that the Austrians were deeply committed to their struggle with the Army of Italy, he told Berthier to march with 40,000 men at once by way of the St. Bernard unless otherwise advised. Berthier protested that he had only 25,000 effectives, and the equipment and armament were still far from complete—as indeed they remained to the end—but the troops marched, though their very means of existence were precarious from the time of leaving Geneva to the time of reaching Milan, for nothing could extort supplies and money from the sullen Swiss.

Bonaparte's Plan **of** Campaign.—At the beginning of May the First Consul learned of the serious plight of the Army of Italy. Masséna with his right wing was shut up in Genoa, Suchet with the left aing driven back to the Var. Meanwhile Moreau had won a preliminary victory at Stokach, and the Army of Reserve had begun its movement to Geneva. With these data the plan of campaign took a clear shape at last—Masséna to resist as long as possible; Suchet to resume the offensive, if he could do so, towards Turin; the Army of Reserve to pass the Alps and to debouch into Piedmont by Aosta and Ivrea; the Army of the Rhine to send a strong force into Italy by the St. Gothard. Bonaparte left Paris on May 6. Gradually, and with immense efforts, Berthier's leading troops were passed over the snow-clad St. Bernard, drawing their artillery on sledges, on the 15th and succeeding days. Driving away small posts of the Austrian army, the advance guard entered Aosta on the 16th—and the alarm was given. Melas, committed as he was to his Riviera campaign, began to look to his right rear, but he was far from suspecting the seriousness of his opponent's purpose. Infinitely more dangerous for the French than the small detachment that Melas opposed to them, or even the actual crossing of the pass, was the unexpected stopping power of the little fort of Bard. The advanced guard of the French appeared before it on the 19th, and after three wasted days the infantry managed to find a difficult mountain by-way and to pass round the obstacle. Ivrea was occupied on the 23rd, and Bonaparte hoped to assemble the whole army there by the 27th. But except for a few guns that with infinite precautions were smuggled one by one through the streets of Bard, the whole of the artillery, as well as a detachment to besiege the fort, had to be left behind. Bard surrendered on June 2, having delayed the infantry of the French army for four days and the artillery for a fortnight.

The military situation in the last week of May, as it presented itself to Bonaparte, at Ivrea, was this. The Army of Italy under Masséna was closely besieged in Genoa, where provisions were running short and the population hostile. But Masséna was no ordinary general, and Bonaparte knew that while Masséna lived the garrison would resist to the last extremity. Suchet was defending Nice and the Var by vigorous minor operations. The Army of Reserve, the centre of which had reached at Ivrea the edge of the Italian plains, consisted of four weak army corps under Victor, Duhesme, Lannes and Murat. There were still to be added to this small army of 34,000 effectives, Turreau's division, which had passed over the Mt. Cenis and was aproaching Turin, Moncey's corps of the Army of the Rhine, which had at last been extorted from Moreau and was due to pass the St. Gothard before the end of May, Chabran's division left to besiege Bard, and a small force under Béthencourt, which was to cross the Simplon and to descend by Arona (this place proved in the event a second Bard and immobilized Béthencourt until after the decisive battle). Thus it was only the simplest part of Bonaparte's task to concentrate half his army at Ivrea, and he had yet to bring in the rest. The problem was to reconcile the necessity for time which he wanted to ensure the maximum force being brought over the Alps, with the necessity for haste, in view of the impending fall of Genoa. As early as May 14 he had informed Moncey that from Ivrea the Army of Reserve would move on Milan. On May 25 he ordered Lannes (advanced guard) to push out on the Turin road, "in order to deceive the enemy and to obtain news of Turreau," and Duhesme's and Murat's corps to proceed along the Milan road.

The March to Milan.—Very few of Bonaparte's acts of generalship have been more criticized than this resolution to march on Milan, which abandoned Genoa to its fate and gave Melas a week's leisure to assemble his scattered forces. But to hasten to Genoa would, in Bonaparte's eyes, have been playing the enemy's

[1] He aftenvards appointed Berthier to command the Amy of Reserve, but himself accompanied it and directed it, using Berthier as chief of staff.

game, for they would have concentrated at Alessandria, facing west "in their natural position." The course which he took gave his army the enemy's depôts at Milan, of which it unquestionably stood in sore need, and the reinforcement of Moncey's 15,000 men from the Rhine, while at the same time Moncey's route offered an "assured line of retreat" by the Simplon and the St. Gothard. Above all, it provided him with a "natural position" across Melas's rear—that strategic barrage which seems to have been the initial objective of most of his manoeuvres against the enemy's rear. For such a position, offering natural obstacles, afforded him a secure pivot from which to prepare a warm embrace for the enemy, whose natural tendency, when cut off from their line of retreat and supply, was to turn and flow back, often in driblets, towards him. Once possessed of Milan, Bonaparte says, he could have engaged Melas with a light heart and with confidence in the greatest possible results of a victory, whether the Austrians sought to force their way back to the east by the right or the left bank of the Po. Thus, we are justified in assuming that his object was not the relief of Genoa, but the most thorough defeat of Melas's field army, to which end, putting all sentiment aside, he treated the hard-pressed Masséna as a "containing force" to keep Melas occupied during the strategical deployment of the Army of Reserve. In the beginning he had told Masséna that he would "disengage" him, even if he had to go as far east as Trent to find a way into Italy. From the first, then, no direct relief was intended, and when, on hearing bad news from the Riviera, he altered his route to the more westerly passes, it was because he felt that Masséna's containing power was almost exhausted, and that the passage and reassembly of the reserve army must be brought about in the minimum time and by the shortest way. It was a *pis aller* forced upon him by Moreau's delay and Masséna's extremity, and from, the moment at which he arrived at Milan he did, as a fact, abandon it altogether in favour of the St. Gothard.

Bonaparte's immediate purpose, then, was to reassemble the Army of Reserve in a secure zone of manoeuvre about Milan. This was carried out in the first days of June. Lannes at Chivasso stood ready to ward off a flank attack until the main army had filed past on the Vercelli road, then leaving a small force to combine with Turreau (whose column had not been able to advance into the plain) in demonstrations towards Turin, he moved off, still acting as right flank guard to the army, in the direction of Pavia. On the morning of June 2 Murat occupied Milan, and in the evening the headquarters entered the great city, the Austrian detachment under Vukassovich (the flying right wing of Melas's general cordon system in Piedmont) retiring to the Adda. Duhesme's corps forced that river at Lodi, and pressed on with orders to organize Crema and if possible Orzinovi as temporary fortresses. Lannes reached Pavia, where, as at Milan, immense stores of food, equipment and warlike stores were seized. Bonaparte was now safe in his "natural" position and barred one of the two main lines of retreat open to the Austrians. But his ambitions went farther, and he intended to cross the Po and to establish himself on the other likewise, thus establishing across the plain a complete barrage between Melas and Mantua. Here his end outranged his means, as we shall see. But he gave himself every chance that rapidity could afford him, and the moment that a "zone of manoeuvre" had been secured between the Ticino and the Oglio, he pushed on his main body—or rather what was left after the protective system had been provided for—to the Po.

The Movements of **Melas.**—At this point the action of the enemy began to make itself felt. Melas had not gained the successes that he had expected in Piedmont and on the Riviera, thanks to Masséna's obstinacy and to Suchet's brilliant defence of the Var. These operations had led him very far afield, and the protection of his over-long line of communications had caused him to weaken his large army by throwing off many detachments to watch the Alpine valleys on his right rear. He was further handicapped by the necessity of supporting Ott before Genoa and Elsnitz on the Var, and hearing of Lannes' bold advance on Chivasso and of the presence of a French column with artillery (Turreau) west of Turin, he assumed that the latter represented the main body of the Army of Reserve—in so far indeed as he believed in the existence of that army at all. Next, when Lannes moved away towards Pavia, Melas thought for a moment that fate had delivered his enemy into his hands, and began to collect such troops as were at hand at Turin with a view to cutting off the retreat of the French on Ivrea while Vukassovich held them in front. It was only when news came of Moncey's arrival in Italy and of Vukassovich's fighting retreat on Brescia that the magnitude and purpose of the French column that had penetrated by Ivrea became evident. Melas promptly decided to give up his western enterprises, and to concentrate at Alessandria, preparatory to breaking his way through the network of small columns—as the disseminated Army of Reserve still appeared to be—which threatened to bar his retreat. But orders circulated so slowly that he had to wait in Turin till June 8 for Elsnitz, whose retreat was, moreover, sharply followed up and made exceedingly costly by the enterprising Suchet. Ott, too, in spite of orders to give up the siege of Genoa at once and to march with all speed to hold the Alessandria-Piacenza road, waited two days to secure the prize, and agreed (June 4) to allow Masséna's army to go free and to join Suchet. And lastly, the cavalry of O'Reilly, sent on ahead from Alessandria to the Stradella defile, reached that point only to encounter the French. The barrage was complete, and it remained for Melas to break it with the mass that he was assembling, with all these misfortunes and delays, about Alessandria. His chances of doing so were anything but desperate.

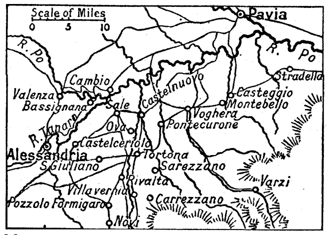
On June 5 Murat had moved on Piacenza, and stormed the bridge-head there. Duhesme pushed out on Crema and Orzinovi and also towards Pizzighetone. Moncey's leading regiments approached Milan, and Berthier thereupon sent on Victor's corps to support Murat and Lannes. Meantime the half-abandoned line of operations, Ivrea-Vercelli, was briskly attacked by the Austrians, who had still detachments on the side of Turin. On the 6th Lannes from Pavia, crossing the Po, encountered and defeated O'Reilly, and barred the Alessandria-Parma main road. Opposite Piacenza, Murat had to spend the day in gathering material for his passage, as the pontoon bridge had been cut by the retreating garrison of the bridge-head. Meantime the last divisions of the Army of Reserve (two of Moncey's excepted) were hurried towards Lannes' point of passage, as Murat had not yet secured Piacenza. On the 7th, while Duhesme continued to push back Vukassovich and seized Cremona, Murat at last captured Piacenza, finding there immense magazines. Meantime the army, division by division, passed over slowly, owing to a sudden flood, near Belgiojoso, and Lannes' advanced guard was ordered to open communication with Murat along the main road Stradella-Piacenza. "Moments are precious," said the First Consul. He was aware that Elsnitz was retreating before Suchet, that Melas had left Turin for Alessandria, and that heavy forces of the enemy were at or east of Tortona. He knew, too, that Murat had been engaged with certain regiments recently before Genoa and (wrongly) assumed O'Reilly's column to have come from the same quarter. Whether this meant the deliverance or the surrender of Genoa he did not yet know, but it was certain that Masséna's pinning action was over, and that Melas was gathering up his forces to recover his communications. Hence Bonaparte's great object was concentration. "Twenty thousand men at Stradella," in his own words, was the goal of his efforts, and with the accomplishment of this purpose the campaign enters on a new phase.

Bonaparte's Dispositions.—The army now being disseminated between the Alps, the Apennines, the Ticino and the Chiese, it was of vital importance to connect up the various parts into a well-balanced system. Duhesme was still absent at Cremona. Lechi was far away in the Brescia country, Béthencourt detained at Arona. Moncey with about 15,000 men had to cover an area of 40m. square around Milan, which constituted the original zone of manoeuvre, and if Melas chose to break through the flimsy cordon of outposts on this side (the risk of which was the motive for detaching Moncey at all) instead of at the Stradella, it would take Moncey two days to concentrate his force on any battlefield within the area named, and even then he would be outnumbered by two to one. As for the main body at the Stradella, its position was wisely chosen, for the ground was too cramped for the deployment of the superior force that Melas might bring up, but the strategy that set before itself as an object 20,000 men at the decisive point out of 50,000 available was, to say the least, hazardous. In truth, here, in contrast to his later campaigns, he had not the material to cement his strategic barrage. It is, however, clear from a letter to Carnot that Bonaparte counted greatly upon the union of Masséna and Suchet, with 18,000 men, to press Melas against the Army of Reserve. Another questionable feature was the order to Lannes to send forward his advanced guard, and to attack whatever enemy he met with on the road to Voghera. Bonaparte, in fact, calculated that Melas could not assemble 20,000 men at Alessandria before June 12. Acting on this order Lannes fought the battle of Montebello on the 9th. This was a very severe running fight, in which the French drove the Austrians from several successive positions, and it culminated in a savage fight at close quarters about Montebello itself. The singular feature of the battle is the disproportion between the losses on either side—French, 500 out of 12,000 engaged; Austrians, 2,100 killed and wounded and 2,100 prisoners out of 14,000. These figures are most conclusive evidence of the intensity of the French military spirit in those days, and also give a likely explanation of Bonaparte's apparent rashness in pushing Lannes forward. If, without endangering the bait, he could draw Melas towards the Stradella, he could thereby curtail the undue extent of his strategic barrage.

Meanwhile, Bonaparte had issued orders for the main body to stand fast, and for the detachments to take up their definitive covering positions Duhesme's corps was directed, from its eastern foray, to Piacenza, to join the main body. Moncey was to provide for the defence of the Ticino line, Lechi to form a "flying camp" in the region of Orzinovi-Brescia and Cremona, and another mixed brigade was to control the Austrians in Pizzighetone and in the citadel of Piacenza. On the other side of the Po, between Piacenza and Montebello, was the main body (Lannes, Murat and part of Victor's and Duhesme's corps), and a flank guard was stationed near Pavia. with orders to keep on the right of the army as it advanced (this is the first hint of an intention to go westward) and to fall back fighting should Melas come on by the left bank.

For a new idea, and doubt, had begun to form in his mind. Still believing that Melas would attack him on the Stradella side, and hastening his preparations to meet this, he began to allow for the contingency of Melas giving up his attempt to re-establish his normal line of communication, and retiring instead on Genoa, which was now in his hands and could be provisioned and reinforced by sea. On the 10th Bonaparte ordered reserve ammunition to be sent from Pavia, giving Serravalle, which is south of Novi, as its probable destination. Such reports as were available indicated no important movements whatever which happened to be true, but could hardly appear so to the French headquarters. On the 11th, though he thereby forfeited the reinforcements coming up from Duhesme's corps at Cremona, Bonaparte ordered the main body to advance to the Scrivia. Lapoype's division (the right flank guard) was called to the south bank of the Po, and the zone around Milan was stripped so bare of troops that there was no escort for the prisoners taken at Ilfontebello. The crisis was at hand, and influenced by the reports collected by Lapoype as to the quietude of the Austrians towards Valenza and Casale, Bonaparte and Berthier strained every nerve to bring up more men to the Voghera side in the hope of preventing the prey from slipping away to Genoa.

But Moncey, Duhesme, Lechi and Chabran were at a distance —and these represented almost exactly half of Berthier's command (30,000 out of 58,000), and even the concentration of 28.000 men on the Scrivia had only been obtained by practically giving up the "barrage" on the left bank of the Po Even now (the 12th) the enemy showed nothing but a rearguard, and the old questions reappeared in a new and acute form. Was bfelas still in Alessandria? Was he marching on Valenza and Casale to cross the Po, or to Acqui against Suchet, or to Genoa to base himself on the British fleet? As to the first, why had he given up his chances of fighting on one of the few cavalry battlegrounds in north Italy—the plain of Marengo—as he could not stay in Alessandria for any definite time? The second question had been answered in the negative by Lapoype, but his latest information was 36 hours old. As for the other questions, no answer whatever was forthcoming, and the only course open was to postpone decisive measures and to send forward the cavalry, supported by infantry, to gain information.



MAP SHOWING THE AREA ASSOCIATED WITH NAPOLEON'S ADVANCE AGAINST MELAS, JUNE 12–13, 1800

Marengo.—On the 13th, therefore, Murat, Lannes and Victor advanced into the plain of Marengo, traversed it without difficulty and carrying the villages held by the Austrian rearguard, established themselves for the night within a mile of the fortress. But meanwhile Bonaparte had taken a step that was fraught with the gravest consequences. He had, as we know, no intention of forcing on a decision until his reconnaissance produced the information on which to base it, and he had therefore kept back three divisions under Desaix at Pontecurone. But as the day wore on without incident, he began to fear that the reconnaissance would be profitless, and unwiiling to give Melas any further start, he sent out these divisions right and left to find and to hold the enemy, whichever may the latter had gone. At noon Desaix with one division was despatched southward to Rivalta to head off Melas from Genoa, and at 9 A.M. on the 14th, on the strength of a report, false as it turned out, that the Austrian rearguard had broken the bridges of the Bormida, Lapoype was sent back over the Po to hold the Austrians should they be advancing from Valenza towards the Ticino. Thus there remained in hand only 23.000 men when at last in the forenoon of the 14th the whole of Melas's army, 45,000 strong, moved out of Alessandria, not southward nor northward, but due west into the plain of Marengo (*q.v.*). The extraordinary battle that followed is described elsewhere. The outline of it is simple enough The Austrians advanced slowly and in the face of the most resolute opposition, until their attack had gathered weight, and at last they were carrying all before them, when Desaix returned from beyond Rivalta and initiated a series of counterstrokes These were brilliantly successful, and gave the French not only local victory but the supreme self-confidence that, coupled with their strategic position, enabled them to extort next day from Melas an agreement to evacuate all Lombardy as far as the Mincio. And though in this way the chief prize, Melas's army, escaped after all, Marengo was the birthday of the First Empire.

One more blow, however, was required before the Second Coalition collapsed, and it was delivered by Moreau. We have seen that he had crossed the upper Rhine and defeated Kray at Stokach. This was followed by other partial victories, and Kray then retired to Ulm, where he reassembled his forces, hitherto scattered in a long weak line from the Neckar to Schaffhausen. Moreau continued his advance, extending his forces up to and over the Danube below Ulm, and winning several combats of which the most important was that of Höchstädt, fought on the famous battlegrounds of 1703 and 1704, and memorable for the death of La Tour d'Auvergne, the "First Grenadier of France" (June 19). Finding himself in danger of envelopment, Kray now retired, swiftly and skilfully, across the front of the advancing French, and reached Ingolstadt in safety. Thence he retreated over the Inn, Moreau following him to the edge of that river, and an armistice put an end for the moment to further operations.

This not resulting in a treaty of peace, the war was resumed both in Italy and in Germany. The Army of Reserve and the Army of Italy, after being fused into one, under Masséna's command, were divided again into a fighting army under Brune, who opposed the Austrians (Bellegarde) on the Mincio, and a political army under Murat, which re-estahlished French influence in the peninsula. The former, extending on a wide front as usual, won a few strategical successes without tactical victory, the only incidents of which worth recording are the gallant fight of Dupont's division, which had become isolated during a manoeuvre, at Pozzolo on the Mincio (Dec. 25) and the descent of a corps under hfacdonald from the Grisons by way of the Splügen, an achievement far surpassing Bonaparte's and even Suvórov's exploits, in that it was made after the winter snows had set in.

Hohenlinden.—In Germany the war for a moment reached the sublime. Kray had been displaced in command by the young archduke John, who ordered the denunciation of the armistice and a general advance. His plan, or that of his advisers, was to cross the lower Inn, out of reach of Moreau's principal mass, and then to swing round the French flank until a complete chain was drawn across their rear. But during the development of the manoeuvre, Moreau also moved, and by rapid marching made good the time he had lost in concentrating his over-dispersed forces. The weather was appalling, snow and rain succeeding one another until the roads were almost impassable. On Dec 2 the Austrians were brought to a standstill, but the inherent mobility of the Revolutionary armies enabled them to surmount all difficulties, and thanks to the respite afforded him by the archduke's halt, Moreau was able to see clearly into the enemy's plans and dispositions. On Dec. 3, while the Austrians in many disconnected columns were struggling through the dark and muddy forest paths about Hohenlinden, Moreau struck the decisive blow. While Ney and Grouchy held fast the head of the Austrian main column at Hohenlinden, Richepanse's corps was directed on its left flank. In the forest Richepanse unexpectedly met a subsidiary Austrian column which actually cut his column in two. But profiting by the momentary confusion he drew off that part of his forces which had passed beyond the point of contact and continued his march, striking the flank of the archduke's main column, most of which had not succeeded in deploying opposite Ney, at the village of Mattempost. First the baggage train and then the artillery park fell into his hands, and lastly he reached the rear of the troops engaged opposite Hohenlinden, whereupon the Austrian main body practically dissolved The rear of Richepanse's corps, after disengaging itself from the Austrian column it had met in the earlier part of the day, arrived at Mattempost in time to head off thousands of fugitives who had escaped from the carnage at Hohenlinden. The other columns of the unfortunate army were first checked and then driven back by the French divisions they met, which, moving more swiftly and fighting better in the broken ground and the woods, were able to combine two brigades against one wherever a fight developed. On this disastrous day the Austrians lost 20,000 men, 12,000 of them being prisoners, and 90 guns.

Marengo and Hohenlinden decided the war of the Second Coalition as Rivoli had decided that of the first, and the Revolutionary Wars came to an end with the armistice of Steyer (Dec. 25, 1800) and the treaty of Lunéville (Feb. 9, 1801). But only the first act of the great drama was accomplished. After a short respite Europe entered upon the Napoleonic Wars.

Bibliography.—The most important modern works are A. Chuquet's *Guerres de la Révolution* (11 monographs forming together a complete history of the campaigns of 1792–93), and the publications of the French General Staff. Dupuis's *L'Armée du nord 1793;* Coutanceau's *L'Armée du Nord* 1794; Colin's *Éducation militaire de Napoléon* and *Campagne de 1793 en Alsace;* and de Cugnac's *Campagne de l'Armée de réserve 1800* may be specially named Among other norks of importance the principal are C. von B(inder)-K(rieglstein), *Geist und Stoff im Kriege* (Vienna, 1896); E Gachot's works on Masséna's career (containing invaluable evidence though written in a somewhat rhetorical style); Ritter von Angeli, *Erzherzog Karl* (Vienna, 1896); C. von Clausewitz, *Feldzug 1796 in Italien* and *Feldzug 1799* (French translations); H. Spenser Wilkinson's *The Defence of Piedmont* (1927) sheds valuable light on the mid-18th century campaigns which foreshadowed the strategy of 1796.

(C. F. A.; X.)

NAVAL OPERATIONS

The sweeping aims of the French Revolutionary government, to obtain for France her so-called natural limits—the Rhine, the Alps, the Pyrenees, and the Ocean—quickly provoked a coalition of many European Powers pledged to resist it. Of these powers, England proved the most implacable; and it became the object of the Revolutionary, and still more of the Napoleonic, government to reduce her to submission. The intensity of the struggle produced a series of naval campaigns extending over most of the world. In the earlier years of the war France was hampered by the excessively democratic spirit which spread amongst her fleets. Her crews were often mutinous, and some of her most competent admirals were guillotined, their places being filled by men hastily promoted from very junior ranks—for example, Villaret-Joyeuse was promoted straight from lieutenant to admiral. Such drawbacks mattered less in 1792 when operations were confined to giving some assistance to troops operating against Austria in north Italy, and to reducing Naples; but when the First Coalition was completed by the entry of England in Feb., and Spain in March 1793, the naval weakness of the French became manifest. This was seen in the operations in the Channel, where they were unable to maintain an effective force for some time. It is true that Lord Howe, commanding the British Channel fleet, did not attempt to blockade Brest throughout 1793–94—in this connection, the many calls on the British navy for commerce and colonial protection over the whole world must be remembered—and that this freedom enabled Villaret to cover the safe arrival of a large convoy bringing corn from America in 1794. But he himself—more important than the convoy—was caught by Howe in the process, and severely defeated at the Battle of the Glorious 1st of June, losingseven ships. This defeat effectually completed the disorganization of the French, and their engagements in the Channel for the next two years, such as those with Cornwallis and Lord Bridport in 179j, only served to emphasize this ineffectiveness. None the less, French successes on land added to the already heavy British commitments at sea. Having overrun Holland in 1794, the French compelled her to go to war with England in Jan. 1795; and England was thereafter forced to maintain a separate North Sea fleet to guard against invasion from the Texel.

In the meantime operations had been proceeding in various colonial waters and in the Mediterranean. In the former the British had, as early as 1793, seized various French stations in the East Indies, including Pondicherry. In 1793–94 they also achieved some success in the West Indies, capturing Tobago, French San Domingo, Martinique and Guadeloupe, though the last-named was retaken by the Terrorist. Victor Hugues. Later in the war St. Lucia and other islands were also taken. In 1795, Admiral Elphinstone. afterwards Lord Keith, began operations against the colonial possessions of the unfortunate Dutch, and took from them the Cape of Good Hope and their station at Malacca. The importance of these operations lay not only in the captures made, but in the destruction of French sea-borne commerce that they involved.

Lord Hood was given the British command in the Mediterranean and, with 21 ships, directed his energies to the reduction of Toulon, in which he was joined by Spanish and Neapolitan squadrons. The extreme dissension between the Jacobins and Girondists helped him to secure the surrender of the city and its great arsenal; but after the Jacobin triumph, lack of troops forced him to relinquish his hold. Over 30 French ships, including 13 of the line, were destroyed before the withdrawal; but, owing to the lukewarm support of the Spanish, a sufficient number were left intact to form, later, the nucleus of a Mediterranean fleet. Several thousands of the inhabitants were also taken off to escape the ferocious vengeance which was wreaked by the victorious Jacobins on their less fortunate countrymen left behind. From 1794–96 the British were mainly occupied in reducing Corsica and trying to help the Austrians in north Italy. Hood's successor, Hotham, failed to deal effectively with the Toulon squadron, though he was twice in action with it in 1795; on each occasion the French escaped serious damage, losing only three ships. Fortune, in the shape of the wind, assisted them; but Nelson held the opinion that Hotham's lack of energy did so too. Jervis, afterwards Lord St. Vincent, relieved Hotham at the end of 1795, and imparted a livelier spirit to the fleet; but in the following year Spain, who had made peace in 1795, re-entered the war on the French side. This gave England another long piece of coast-line to watch and forced her temporarily to withdraw from the Mediterranean.

From 1796 onwards French movements at sea became somewhat more purposeful; and in December they tried to strike at England by the time-honoured method of invading Ireland; but, though the expedition was allowed to sail from Brest, and some of the ships reached Bantry Bay, bad weather caused its failure, and the fleet returned in fragments to Brest. The year 1797 saw England standing alone against France and further embarrassed by the great naval mutinies at Spithead and the Nore, in which the sailors expressed their dissatisfaction with a state of affairs now admitted to have been disgraceful. None the less the gloom was relieved by the light of two great victories at sea, as a result of which Pitt was enabled to reopen negotiations for the formation of another coalition. In Feb. Jervis with 15 sail of the line encountered 27 Spaniards off Cape St. Vincent and, relying on Spanish inefficiency to counteract their advantage in numbers, attacked them and took four prizes. In Oct., Admiral Duncan in command of the North Sea fleet of 16 ships caught the Dutch at sea off Camperdown, also 16 strong. They tried to lure him on to the shoals, but he accepted the risk, chased them and took nine prizes.

In 1798, another, and slightly more successful, attempt was made to invade Ireland. General Humbert with 1,100 troops was actually landed; but, after some initial success, was compelled to surrender, while other forces were captured before they landed. But the most important movements were in the Mediterranean. Austria was willing to join a second coalition, but insisted on making the re-entry of the British into the Mediterranean a condition. Jervis, therefore, was ordered either to re-enter the Mediterranean himself, or, if he felt it necessary to continue the blockade of Cadiz, to detach a force thither. He replied that Nelson had already been detached to inquire into the nature of reported activities in Toulon, and he reinforced him with ten ships. The reported activities were the preparations for Napoleon's expedition to Egypt, the origin of which lay chiefly in his desire to keep himself in the public eye. The force succeeded in sailing from Toulon, covered by a fleet of 13 battleships commanded by Admiral Brueys, and in reaching Alexandria, where Napoleon was landed; but Nelson, discovering their whereabouts after a long search, came upon Brueys anchored in Aboukir Bay and destroyed his entire fleet with the exception of two battleships and two frigates, all of which were accounted for later. This placed Napoleon in a most awkward position. He advanced some distance, but was repulsed before Acre by Commodore Sir Sidney Smith, who had landed with Napoleon's own guns, taken at sea. The French tried to relieve his position, and Admiral Bruix succeeded in bringing the Brest fleet to the Mediterranean; but he did not venture far to the East and ultimately returned to Brest without having been brought to action. Napoleon came home as a fugitive, leaving his army to the mercy of the British, who followed up their victory at the Nile, and made further successes possible, by the capture of Minorca (1798) and Malta (1800). Some measure of success was also achieved in the autumn of 1799 by a combined Russian and British expedition, which proposed to attack the French army of occupation in Holland: Admiral Mitchell forced the entrance to the Texel and obtained the surrender of the Dutch fleet—the Dutch sailors showing little inclination to fight on behalf of their French conquerors. From the military standpoint, however, the affair was not so successful.

By this time Napoleon had become First Consul, and was responsible for the formation of the Armed Neutrality of the Northern Powers which brought about the last great expedition of the war. The Scandinavian Powers, Russia and Prussia pledged themselves to resist the right of search of the British, who were dependent for the very existence of their fleet on supplies of timber and hemp from the Baltic. The Neutrality had to be broken, and in March 1801, a fleet of 18 ships under Sir Hyde Parker, with Nelson as second-in-command, sailed to the Baltic for the purpose. It was decided that an attempt should first be made to detach Denmark from her allies, peaceably or forcibly. Peaceable methods failing, it became necessary to attack the Danish fleet that was anchored along the sea-front of Copenhagen, protected by shoals. Parker thought approach to it impossible; but Nelson with 12 ships solved the problem, smashed the Danish fleet, and the Armed Neutrality with it. By this time peace was near. The English people were sick of the war, while Napoleon needed a truce for the consolidation of his position and the preparation of new schemes. Consequently the Peace of Amiens ended the Revolutionary War in 1802, a peace that was to be the truce Napoleon intended, rather than anything more lasting.

FRENCH SOUTHERN OCEAN AND ANTARCTIC TERRITORIES (TERRES AUSTRALES ET ANTARCTIQUES FRANÇAISES), a group of islands in the southern part of the Indian ocean including a section of Antarctica. A separate administration for these territories was created by a decree of Sept. 18, 1956, with a senior administrator (administrateur *supérieur*), who resides in Paris, and is directly responsible to the minister for overseas France. From 1924 to 1956 these *terres australes* were administered from Madagascar (Malagasy Republic). The following islands are included in the new administrative unit: (1) two small volcanic islands, Saint Paul (*q.v.*) and Nouvelle Amsterdam; (2) the island of Kerguelen. with many adjacent smaller islands totalling about 2,703 sq.mi.; and (3) the Crozet Islands archipelago. Also included is Terre Adélie. (See ANTARCTICA.)

(Hu. DE.)

FRENCH WEST AFRICA (AFRIQUE OCCIDENTALE FRANÇAISE), a former federation of French overseas territories, comprised an area of 1,831,079 sq.mi. (approximately eight times the area of France and nearly one-sixth that of all Africa), extending from the central Sahara south ard to the Gulf of Guinea and from the Atlantic eastward to Lake Chad. It was bounded on the north by Rio de Oro, by the southern territories of Algeria and by Libya; on the east by former French Equatorial Africa; and on the south and the west by the Atlantic ocean, except where foreign enclaves (Gambia; Portuguese Guinea; Sierra Leone and Liberia; Ghana [Gold Coast] and the former trust territory of Togoland [Republic of Togo] ; and Nigeria) indent its coastal zone. French West Africa was a federation of eight territories: Mauritania, Senegal, Dahomey, French Sudan (renamed Mali Republic), Ivory Coast, Upper Volta, Niger and French Guinea. In 1958 the territories became autonomous republics, and in 1960 independent republics, within the French Community. Later, all but Senegal withdrew from the French Community. French Guinea in 1958 left the French Community and was renamed Guinea.

Physical Features.— The area of former French West Africa consists of gneisses and crystalline schists. There also occur at various points granites, old volcanic rocks, porphyries and diorites, old sedimentary deposits, schists and Silurian quartzites. Above these old folded formations are horizontal strata of nonfossiliferous sandstones which cover immense areas. Secondary and Tertiary marine formations (Cretaceous and Eocene) are met with in Senegambia and extend as far as Lake Chad. The Quaternary and Recent deposits include alluvial deposits, dunes and laterites, and ferruginous red clays which are often found in strata of great thickness and are the result of the decomposition of rocks in situ under the influence of the intertropical climate.

The country is in the form of a plateau, broken up by two systems of fractures, one running southwest and northeast, the other at right angles, northwest and southeast. The heights are domes of granite or diorite, which are remains of older chains of mountains now worn away; and the cliffs in which the plateau ends. The southern highland areas are the Futa Jallon (Fouta Djallon), the Nimba mountains and the Atakora highlands. The Futa Jallon is a much-dissected plateau region lying about 60 mi. inland in Guinea. It has a northwest-southeast length of nearly 500 mi. and averages 175 mi. in width; the maximum elevation reaches 4,675 ft. The Nimba mountains stand nearly on the boundary of Liberia and Ivory Coast; they rise to 6,069 ft. The Atakora highlands form a series of north-south ridges in northwestern Dahomey; their highest elevations rise to 2,146 ft. In the districts of the Sahara which are attached to Mauritania, Mali, and Niger there are three principal highland regions: the Adrar of Mauritania (2,628 ft.), the Adrar of Iforas (3,280 ft.) and the Aïr (5,905 ft.). The coast is straight and sandy from Cape Blanc to Cape Verde, which shelters the port of Dakar; after this it is cut up by estuaries, especially between Cape Verde and the island of Sherbro. After Cape Palmas the coast line runs from west to east and is bordered by unbroken beaches and lagoons.

Rivers.—The Niger (*q.v.*), the third longest river of Africa and the second in volume of water, is the main artery of former French West Africa. It rises at an altitude of 2,800 ft. not far from the frontier of Sierra Leone and at first flows from southwest to northeast and then takes a great bend which brings it into the Sahara in the neighbourhood of Timbuktu. After Bourem (Burem) it turns in a northwest-southeast direction and finally runs into the Gulf of Guinea. In its upper reaches, from its source to Koulikoro (Kulikoro), it receives tributaries from the right, particularly the Tankisso. In the middle reaches, from Koulikoro to Say, it receives a great tributary, the Bani or Bagoe, and spreads out into a sort of wide inland delta—a great area subject to flooding, which in the rainy season is about 90 mi. wide at Mopti and narrows in again after Tosaye and Bourem. The lower part of the river, from below Gaya to the sea, belongs to Nigeria; it is separated from the middle reaches by the Bussa rapids. The upper course of the Niger is subject to summer floods between June and September; the floods arrive gradually and late in the Timbuktu district, where the maximum is not reached until January. The middle reaches of the Niger are of great importance from the point of view of navigation, which is possible over a distance of 800 mi. from Koulikoro to Ansongo, as well as for irrigation. The most important of the coast rivers is the Senegal (*q.v.*), formed by the junction of the Bakoy (Bakhoy), with its tributary the Baoulé (Baule), and the Bafing; it is navigable up to Kayes in the wet season (Aug. 15 to Oct. 15) and up to Podor in the dry season. The Casamance, the Cavally, the Sassandra, the Bandama, the Comoé, the Volta and the Ouémé should also be mentioned.

Climate and Vegetation.—The climate varies from an equatorial type along the Gulf of Guinea coast to a desert type in the north. Temperatures are high the year around, with annual averages above 75° F. along the coast and above 80° in the interior. The range between the coldest month and the warmest is seldom more than 5° F. along the Guinea coast, but increases toward the north. From Dakar northward, there is a distinct cool season along the coast. On the whole, seasons are based not on temperature but rather on rainfall. Along the Gulf of Guinea, there are two rainy and two dry periods every year, the shorter dry season being in July and August. Northward. the rainy periods merge, eliminating the short dry season, while the other dry season becomes longer and more pronounced. As far north as the latitude of St. Louis there is an observable rainy season of three months and a dry season of nine months. Still farther north rain is uncertain at all times. The average yearly amount of rain exceeds 17j in. along the coast of Guinea and Ivory Coast but decreases inland and northward to less than 5 in. in northern Mauritania.

From the point of view of vegetation, a distinction may be drawn between the Saharan zone (rainfall of less than 8 in.); the Sahelian zone (rainfall of less than 24 in.), which is a region of steppes in which grow doum palms and narrow-leaved acacias; the Sudanese zone (rainfall from 24 in. to 60 in.), a country of savannas with forest belts, which is the principal agricultural region; and the Guinea zone (rainfall of more than 60 in.) which is occupied by the great forest: attaining a width of more than 180 mi. at Cape Palmas, and the characteristic feature of which is the oil palm (Elaeis guineensis).

For further physiographical information, see WEST AFRICA.

History.—The French were established early on the west coast of Africa; but, if a few attempts at colonization such as that of André Brue at the end of the 17th and beginning of the 18th century are excepted, their main object was the trade in slaves and gum, their practice being similar to that of other European states. Their two principal factories were at St. Louis and on the island of Gorée. which the English disputed with them till the early years of the 19th century. A new era was inaugurated by Col. Louis Faidherbe. who, in the decade of 1854–65, subdued the hinterland of Senegal and conceived the scheme of linking the upper Senegal with the upper Niger. From 1876 onward the coast settlements were considerably extended into the hinterland by a series of campaigns and missions, and at the same time the possessions of other European powers in the same region were reduced to the state of enclaves by a number of conventions. The most important events were: the campaigns on the upper Niger (1876–go), which resulted in the destruction of the upstart empires of Omar al-Haji (el-Hadj Omar) and Samory; L. G. Binger's mission to the Ivory Coast (1887–89); the campaigns of Dahomey (1889–94); the occupation of Timbuktu (1893); and the Franco-British conventions of 1890 and 1898. By about 1900 the period of expansion may be regarded as over, and the period of organization and development begun.

French West Africa was constituted in 1895 by the grouping of the several colonies under one governor general. Subsequently the development of the federation as a unit was promoted, while a large measure of autonomy was left to each territory (which had its own governor and its own territorial assembly). See below, Administration; and the articles on the individual territories.

Population.—There is no racial unity among the populations of the area. They differ in physique, in physiognomy, in manners and in dialect and are of very mixed stock. They have spread mainly in two directions, toward the south and toward the west. Some of them are not connected with the Negro races: for example, the Saharans, Moors and Tuaregs, and the Fulani (Fula, Peul), who, with their reddish-brown colouring and only slightly woolly hair, appear to be of Ethiopian or Hamitic, and some of Semitic stock. Among the strictly Negro populations, a distinction may be made between those of the region enclosed by the bend of the Niger and of Senegal on the one hand and those of the Gulf of Guinea on the other. The former include the great group of the Mandingo, which extends over the region of the upper courses of the Niger; it is subdivided into a number of tribes, including the Malinké, the Soninke, the Bambara and the Diula; then there are the Wolof and the Tukulor of Senegal, the Sonrhaï of the district of Gao and the Mossi of Upper Volta. The Negroes of the coast are generally shorter than the Sudanese; their heads are not so long and their colour is lighter. Of this type are the Fon of Dahomey; the Agni and the Baule of the eastern Ivory Coast and the Kru of the western; and the Susu (Soussou) of Guinea. In the middle region live naked Palaeo-Negritic peoples (Koniagui, Lobi, Bobo, Kabré, Samba).

The original religion of the Sudanese tribes is animism, or belief in the omnipotence of spirits. About one-half of the population is Moslem, in name at any rate; but the Negro manages to reconcile Islam with his ancient beliefs, and it is only the populations in the neighbourhood of the Sahara which have really been profoundly affected by Mohammedanism. The Guinea tribes, as well as the Mossi, have for the most part remained animists.

It was estimated. in 1951, that the total population of French West Africa amounted to 17,726.000, including 62,300 Europeans and foreigners (of whom 50,000 were metropolitan Frenchmen). The average density is 9.7 per square mile, but distribution is very irregular. In the coastal section of Dahomey there are about 250 people per square mile, while most of the area has less than 12 per square mile, the northern desert regions and some parts of the great forest having less than 1. Up to the beginning of the 20th century the country was depopulated by internecine warfare in the region enclosed by the bend of the Niger; and the slave trade had previously taken vast numbers from the Guinea coast.

In 1951 the population of the several territories (including that of their principal towns) was as follows: Mauritania, 560,000 (there are no towns, administration being from St. Louis in Senegal); Senegal. 2.158,000 (capital: St. Louis. 60,000; Dakar, capital of French Rest Africa, 229,200; Rufisque, 33,000; Kaolack, 37,600; Thiès, 31,500); French Sudan, 3,461,000 (capital:

Bamako, 68.197; Kayes, 19,605; French Guinea, 2,506,852 (capital: Conakry, 34,770); Ivory Coast. 2,485,086 (capital: Abidjan, 119,135; Bouake, 42,117); Upper Volta. 3,324,969 (capital: Ouagadougou. 32.077; Bobo-Dioulasso: 44,8jj); Dahomey, 1,614,633 (capital: Porto-Novo, 30,800; Cotonou, 28,064); Niger, 2,335,436 (capital: Niamey, 18,098).

Administration.—The eight territories of French West Africa were administered by governors, who were subordinate to a governor general (high commissioner) at Dakar. All the inhabitants were made French citizens in 1946. Each territory elected its own territorial assembly to vote the budget and to watch over the administration. The assemblies elected the members of the grand council, which met at Dakar. French West Africa likewise sent 20 deputies to the French national assembly. 20 senators to the council of the republic and 26 representatives to the council of the French Community in Paris. The territorial capitals and the major towns also elected their own municipal councils.

Communications.—The problem of communications in French West Africa has always been that of linking the interior with the coast. The earliest line of penetration was the Senegal river. the northernmost permanent stream south of the Sahara. From that stream's upper course access to the upper reaches of the Niger was relatively easy. Together, the streams were thought to form an east-west traffic corridor across a large part of west Africa. But they were never as effective as was originally hoped, because their flows vary markedly during the year; *e.g.*, the Senegal is navigable as far upstream as Kayes (600 mi.) for boats with a draught of 15 ft. from Aug. 1j to Oct. 1j; but for the rest of the year it is quite unsatisfactory save for very small craft, and during April and May it is unusable. The Niger is navigable from Kouroussa and Kankan (Guinea) to Bamako (Sudan) from August to December; from Bamako to Ansongo, by shallow-draught boats, for most of the year; and from Ansongo to Gaya (Niger), regularly. throughout the year.

With the expansion of French control from the coast, railways seemed to offer an effective means of access to the interior. The line from Dakar to St. Louis, 163 mi. long and the first to be built in West Africa, was completed in 1885. A line begun near Kayes on the Senegal in 1881 reached Bamako on the Niger in 1904. Meanwhile, lines toward the interior were begun at Conakry in 1900, at Cotonou in 1902 and at Abidjan in 1905. In 1907 a railway joined Dakar to Kayes, so that by 1923 there was a Dakar-Bamako line, connecting the Niger with the coast 800 mi. away. Previously. in 1914, the Conakry line had reached navigable water at Kouroussa on the upper Niger and at Kankan. In 1934, the Cotonou line reached Parakou. The Abidjan line, stopped for a long time at Bobo-Dioulasso, reached Ouagadougou in 1954. Meanwhile. roads which were motorable during most of the year connected the railway termini. Furthermore. there were three trans-Saharan bus routes. one going northward from Zinder (Niger) to Algiers, one northward from Gao (Sudan) on the Niger to Oran in western Algeria and the third. less used, north-northeastnard from St. Louis to Agadir in Rforocco.

Dakar has cable connections with Brest in France, with Fernando Noronha in Brazil. with Casablanca in Morocco and with Conakry. Abidjan and Cotonou within the federation. Regular steamship and air services link Dakar with Europe and with South and North America; and there are services linking all the major ports of the French West African coast. Air services connect all the capitals to Paris.

Dakar overshadowed all other ports in the federation. In 1953 tonnage cleared there amounted to 3,300,000 metric tons, as against 660.000 at Abidjan. 350,000 at Conakry and 150,000 at Cotonou.

Economy.— Since the latter part of the 19th century there has been a remarkable change in the economy of French West Africa. Ivory, bird plumage, rubber, cabinet woods and gum arabic n-ere among the more important items of commerce in the early days of French control. But these products are now less important. and agriculture. with the controlled use of natural resources, has come to supersede uncontrolled exploitation.

For the most part, agricultural development in French West Africa has differed from that in many tropical colonies. Plantation agriculture, which means alienation of the land from the natives, has been kept at a minimum. Few concessionary companies and individual colonists were allowed to establish themselves in Ivory Coast and French Guinea. Attention has been given to promoting sustenance crops for the Africans as well as crops destined for commerce. To speak broadly, the natives have retained control of the land and are the real producers.

The principal food crops are millets, rice and maize. Livestock is important in the grassland areas; above all in Senegal. in French Sudan, in Niger and in Mauritania. In 1953 sheep and goats together numbered 17,000,000; cattle. mostly of the humpbacked zebu variety. numbered about 8,500,000. There were more than 250,000 horses and about 250,000 camels.

By the middle of the 20th century the principal commercial crops were those yielding vegetable oils. Peanuts, originally a food staple, were the most important of these. The first consignment of them was shipped from Rufisque to Rouen in 1640, and after 1844 regular shipments to Marseilles were made from several West African ports. In 1954 output amounted to 700,000 metric tons unshelled (including 550,000 from Senegal) and 488,000 metric tons shelled. Palm kernels and castor-oil seeds are other sources of commercial vegetable oil. Both peanut oil and palm oil are exported in large amounts. Cacao, coffee and bananss. as well as cotton, sisal and kola (a source of caffeine and theobromine). were all likewise of increasing importance. All these products are cultivated in native plantations or gardens. Particular efforts have been made to stimulate cotton growing. As most native kinds were not suited to French manufacturing needs. agricultural experiments (including irrigation systems affecting 300 sq.mi. in the region of the middle Niger river) were undertaken. with the result that quality was improved and quantity raised. Output however was still far behind France's requirements.

Of the minerals, gold has been known to exist in the region since mediaeval times. but French West Africa is not one of the great producing countries, Salt has been important in the desert areas of Mauritania and Niger for nearly 1,000 years. There is manganese in Ivory Coast, iron and copper in Mauritania and iron and bauxite in French Guinea. By the middle of the 20th century the oil works at Dakar still constituted French West Africa's only large-scale industry. Native industries, leather and cotton goods, are of little external importance.

In 1953 French West Africa's imports amounted to 1,257,000 metric tons. with a value of 55,242,000,000 fr. C. F. .4. (1 franc C. F. A.=2 metropolitan French francs). Exports in the same year amounted to 1,806,000 metric tons. with a value of 46,761,000,000 ir. C. F. A., mainly peanuts and peanut oil {constituting more than 40% of the total value). coffee (about 21%), cacao (17%), almonds and palm oil (6%), bananas (3%) and timber (2%). By far the greater part of French West Africa's trade is with France and other countries of the French Community.

BIBLIOGRAPHY.—J. Richard-Molard, *Afrique Occidentale Française* (Paris, 1952); also the *Encyclopédie Maritime et Coloniale: Afrique Occidentale Française*, 2 vol. (Paris, 1949). (H. M. KL.; HU. DE.)

FRENEAU, PHILIP MORIN (1752–1832), U.S. poet, essayist and editor, known as the "poet of the American Revolution," was born of parents of French Huguenot descent in New York city on Jan. 2, 1752. After graduating from Princeton in 1771, he taught school and studied for the ministry until the outbreak of the American Revolution, when he turned his ready pen to vitriolic satire against British and Tories. Not until his return from two years in the Caribbean islands, where he produced two of his most ambitious poems, "The Beauties of Santa Cruz" and "The House of Night," did he become, however, an active participant in the war, joining the New Jersey militia in 1778 and sailing as a privateer to the West Indies. Captured and imprisoned by the British in 1780, he wrote bitterly, on his release, of *The British Prison-Ship* and with infectious enthusiasm of *American Independence*, and during the next several years wrote patriotic contributions to the *Freeman's Journal* in Philadelphia. The war over, he became a sea captain until 1790, when he again entered partisan journalism, ultimately as editor from 1791 to 1793 of the outspokenly republican *National Gazette,* in which he so effectively attacked Federalist policies that Thomas Jefferson credited him with saving the country when it was "galloping fast into monarchy." Ardently devoted to principles of liberty, but recognizing also the necessity of finding solitude for poetry, he alternated his time between quiet periods at sea and periods of active newspaper work as editor or contributor, until he retired early in the 19th century to his farm in Monmouth County, N.J., where he died on Dec. 18, 1832.

For more than 50 years his verse and prose appeared in periodicals and in something more than a dozen volumes; collected editions were published in 1786. 1788, 1795, 1809 and 1815. Well schooled in the classics and in antecedent English poetry. he strove for a fresh idiom which would be unmistakably American. hut except in a few poems he failed to avoid the influence of his models. He has been called the father of American poetry, anticipating Bryant and Poe in theme and technique. A dozen years before Wordsworth's influence was felt on English verse, Freneau looked with wonder on nature in such poems as "The Wild Honey Suckle" and "Stanzas Written on the Hills of Neversink" which, with "The Indian Burying Ground" and "To the Memory of the Brave Americans," deserve a place in any anthology of his period.

FRENSSEN, GUSTAV (1863–1945), German novelist: perhaps the most powerful of the school of writers of the *Heimatkunst* (*i.e.,* literature of particular regions). He was born at Barlt, Holstein. Oct. 19, 1863, took orders in 1890 and until 1902 was pastor at Hemme; but he had already for several years been known as a novelist, and after the success of *Jorn Uhl* (1901), he gave up his pastorate and devoted all his time to writing. He died at Barlt, April 11, 1945. His novels include *Die Sandgräfin* (1896); *Die drei Getreuen* (1898; Eng. trans.. *The Three Comrades,* 1907); *Hilligenlei* (1905; Eng. trans., *Holyland,* 1906); *Klaus Hinrich Baas* (1909); *Die Brüder* (1918); *Otto Babendiek* (1926); and *Der brennende Baum* (1931). He also published sermons (*Dorfpredigten,* 1899–1902) and plays. His novels give realistic and vivid descriptions of the peasantry and the countryside in north Germany. His great popularity was due partly to this and partly to the many subsidiary and propagandist elements associated with his work.

See N. Numsen, *G. Frenssen* (1940). (A. Gs.)

FREON. A trade name covering a family of chemicals containing fluorine and used as fluids in refrigeration compressors. The more commonly used are usually known by a code name; for example the substance CCl_2F_2 is known as either Freon-12 or F-12; similarly F-11 is CCl_3F; F-22 is $CHClF_2$; and F-114 is $CClF_2.CClF_2$. These compounds are economically manufactured by part replacement of fluorine for chlorine in inexpensive compounds such as carbon tetrachloride (CCl_4) or chloroform ($CHCl_3$); each of the replacements causes a drop of about 50° C. in the boiling point. so that CCl_4, which boils at 76° C., becomes CCl_3F (F-11) boiling at 25° C., then CCl_2F_2 (F-12) boiling at −29° C. The low boiling property makes the compound usable as a refrigerating fluid. In addition; the presence of a group of fluorine atoms causes a general tightening up of the molecular structure of the Freons, and this results in a much improved stability which permits the Freons to resist tenaciously any destructive physical or chemical factors; it also renders them physiologically inert. It is possible to inhale or be exposed to concentrations of these materials to as large as 10% to 20% for several hours with impunity. The practice of air-conditioning public places such as theatres! restaurants, trains and auditoriums requires the use of refrigerating fluids which! in case of accidents, would not create a fire hazard or be injurious to the audience, should they leak into the atmosphere; neither can the refrigerating fluids have a detectable odour. lest a panic be created in an audience detecting even an insignificant leakage. The importance of the Freons lies in the fact that they are so stable that they are entirely harmless. The Freons were first manufactured in 1930 and increased rapidly in commercial importance after 1934. During World War II they were adapted to the use of dispersing agents for insecticides. A solution of an insecticide such as pyrethrum or DDT in Freon-12 is carried in a steel container; by opening a valve, the solution is forced out as a fine spray: and the insecticide is thereby fully dispersed in a room, a tent or the space enclosed under the mosquito nets used in the tropics. The mist so created is harmless because it will neither burn nor injure the lungs and the space may be occupied while the fumigation proceeds.

See also REFRIGERATION. (A. L. HE.)

FREQUENCY. A term used in scientific work generally to denote the number of occurrences of some periodic phenomenon or quantity which occur in unit time.

In physics the term is applied to wave motions of all types, mechanical, sound (*q.v.*), light (*q.v.*), electromagnetic waves (*q.v.*) or oscillations generally. *See* ALTERNATING CURRENT; BROADCASTING; RADAR; RADIO; RADIO RECEIVER. (H. B. LM.)

FREQUENCY, RADIO, a term designating the portion of the electromagnetic energy spectrum that is useful in radio communication. The frequency of electromagnetic energy is the number of complete reversals of energy direction that take place in one second and is usually expressed in cycles per second (c.p.s.), kilocycles per second (kc.) or megacycles per second (mc.) where 1 kc. equals 1,000 c.p.s. and 1 mc. equals 1,000,000 c.p.s. The radio-frequency spectrum extends from the lowest frequency that can be efficiently radiated (about 3 kc.) to the lower edge of the infrared region (about 300,000 mc.).

It is often convenient to divide the radio-frequency spectrum into smaller ranges (or bands) which can be designated by appropriate abbreviations.

Radio-Frequency Classifications

Band number	Frequency range	Designation
4	3 kc.–30 kc.	Very low frequency (VLF)
5	30 kc.–300 kc.	Low frequency (LF)
6	300 kc.–3,000 kc.	Medium frequency (MF)
7	3,000 kc.–30,000 kc.	High frequency (HF)
8	30 mc.–300 mc.	Very high frequency (VHF)
9	300 mc.–3,000 mc.	Ultrahigh frequency (UHF)
10	3,000 mc.–30,000 mc.	Superhigh frequency (SHF)
11	30,000 mc.–300,000 mc.	Extremely high frequency (EHF)

The various portions of the radio-frequency spectrum are usually allocated, by law, to different types of radio service. For example. the familiar AM (amplitude modulation) broadcasting stations (540 kc.–1,600 kc.) are located in the MF band while FM (frequency modulation) and television broadcasting are allocated to the VHF band. The two lowest frequency bands (VLF and LF) are used for radiotelephone and radio navigation service while the SHF band is primarily for radar and microwave relay systems. The highest frequency band (EHF) is used largely for experimental purposes. *See* also RADIO. (G. R. CR.)

FRERE, SIR HENRY BARTLE EDWARD, 1ST BART., cr. 1876 (1815–1884), British administrator, born at Clydach in Brecknockshire on March 29, 1815, was the son of Edward Frere, and a nephew of J. H. Frere. of *Anti-Jacobin* and *Aristophanes* fame. After leaving Haileybury, Bartle Frere was appointed a writer in the Bombay civil service in 1834, and in 1835 assistant collector at Poona. In 1842 he became private secretary to Sir George Arthur, governor of Bombay. In 1844 he became political resident at the court of the raja of Satara, administering the province, on the raja's death in 1848, even after its formal annexation in 1849. In 1850 he was appointed chief commissioner of Sind.

On his return to India from leave in 1857 Frere learned at Karachi of the mutiny. He sent his only European regiment to secure the strong fortress of Multan against the rebels, and sent further detachments to aid Sir John Lawrence in the Punjab. For his services he received the thanks of both houses of parliament and was made K.C.B. In 1863 he was appointed governor of Bombay, where he effected great improvements, including the inauguration of the university buildings. He established the Deccan college at Poona, and a college for instructing natives in civil engineering. The prosperity, due to the U.S. Civil War. which rendered these developments possible, resulted in a speculative mania, leading eventually to the disastrous failure of the Bombay bank, for which Frere incurred severe and not wholly undeserved censure. In 1867 he returned to England and was made a member of the Indian council. In 1872 he was sent by the foreign office to negotiate a treaty with the sultan, Seyyid Burghash, at Zanzibar, for the suppression of the slave traffic. In 1875 he accompanied the prince of Wales to Egypt and India.

But the greatest service that Frere undertook on behalf of his country was to be attempted not in Asia, but in Africa. He landed at Capetown as high commissioner of South Africa on March 31, 1877. He had been chosen by Lord Carnarvon in the previous October as the statesman most capable of carrying his scheme of confederation into effect, and within two years it was hoped that he would be the first governor of the South African Dominion. The first year of his rule was marked by a Raffir war on the one hand and by a rupture with the Cape (Molteno-Merriman) ministry on the other. The Transkei Kaffirs were subjugated early in 1878 by General Thesiger (the and Lord Chelmsford) and a small force of regular and colonial troops. The constitutional difficulty was solved by Frere dismissing his obstructive cabinet and entrusting the formation of a ministry to Gordon Sprigg. Frere emerged successfully from a year of crisis, but the advantage was more than counterbalanced by the resignation of Carnarvon early in 1878, at a time when Frere required the steadiest and most unflinching support. He was convinced that there was a widespread insurgent spirit pervading the natives, which had its focus and strength in the celibate military organization of Cetywayo. Frere told the colonial office that this organization must be broken up, if necessary, by force. The colonial office appeared to agree, but when Frere sent, in Dec. 1878, an ultimatum to Cetywayo, the home government abruptly discovered that a native war in South Africa was inopportune and raised difficulties about reinforcements. Having entrusted to Lord Chelmsford the enforcement of the British demands, Frere's immediate responsibility ceased. On Jan. 11, 1879 the British troops crossed the Tugela, and 14 days later the disaster of Isandhlnana was reported; and Frere, attacked and censured in the house of commons, was but feebly defended by the government. Lord Beaconsfield, it appears, supported Frere; the majority of the cabinet were inclined to recall him. He was censured, but begged to stay on.

The Zulu trouble and the disaffection that was brewing in the Transvaal reacted upon each other in the most disastrous manner. Frere had had no part in the actual annexation of the Transvaal. which was announced by Sir Theophilus Shepstone a few days after the high commissioner's arrival at Capetown. The delay in giving the country a constitution afforded a pretext for agitation to the malcontent Boers, a rapidly increasing minority, while the reverse at Isandhlwana had lowered British prestige. Oning to the Kaffir and Zulu wars Frere had hitherto been unable to give his undivided attention to the state of things in the Transvaal, which he visited in 1879. A large camp, numbering 4.000 disaffected Boers, had been formed near Pretoria, and they were terrorizing the country. Frere visited them unarmed and practically alone. On the condition that the Boers disperse. Frere undertook to present their complaints to the British government, and to urge the fulfilment of the promises that had been made to them They parted with mutual good feeling, and the Boers did eventually disperse—on the very day upon which Frere received the telegram announcing the government's censure. But bad nens met him on his return to Capetown—on June 1. 1879, the prince imperial had met his death in Zululand—and a few hours later Frere heard that the government of the Transvaal and Natal, together with the high commissionership in the eastern part of South Africa, had been transferred from him to Sir Garnet Wolseley.

When Gladstone's ministry came into office in the spring of 1880, Lord Kimberley had no intention of recalling Frere In June, however, a section of the Liberal party memorialized Gladstone to remove him, and the prime minister weakly complied (Aug. 1, 1880). Upon his return Frere replied to the charges relating to his conduct respecting Afghanistan as well as South Africa, previously preferred in Gladstone's Midlothian speeches, and was preparing a fuller vindication when he died at Wimbledon from the effects of a severe chill on May 29, 1884.

His *Life and Correspondence, by* John Martineau, was published in 1895. *See* the article SOUTH AFRICA, UNION OF: *History.*

FRERE, JOHN HOOKHAM (1769–1846), English diplomat and author. was born in London. He was educated at Eton, where he met Canning, and at Caius college, Cambridge. He entered public service in the Foreign Office under Lord Grenville, and sat from 1796 to 1802 as M.P. for the close borough of West Looe in Cornwall. He and Canning were ardent supporters of Pitt, and contributors to the *Anti-Jacobin.* On Canning's removal to the board of trade in 1799 he succeeded him as under-secretary of state; in Oct. 1800 he was appointed envoy extraordinary and plenipotentiary to Lisbon; and in Sept. 1802 he was transferred to Madrid, where he remained for two years. He was made a member of the privy council in 1805; in 1807 he was appointed plenipotentiary at Berlin, but the mission was abandoned, and Frere was again sent to Spain in 1808 as plenipotentiary to the Central Junta. The condition of Spain rendered his position a very responsible and difficult one. When Napoleon began to advance on Madrid Frere wholeheartedly advised Sir John Moore not to retreat. After Corunna public opinion accused him of having endangered the army, and he was recalled.

Thus ended Frere's public life. In 1816 he married Elizabeth Jemima, dowager countess of Erroll, and in 1820, on account of her failing health, he went with her to the Mediterranean. There he finally settled in Malta, where he lived the rest of his life. He died at the Pietà Valetta on Jan. 7, 1846. Frere's literary reputation now rests entirely upon his spirited verse translations of Aristophanes, which remain in many ways unrivalled. The translations of *The Acharnians, The Knights, The Birds* and *The Frogs* were privately printed, and were first brought into general notice by Sir G. Cornewall Lewis in the *Classical Museum* for 1847.

Frere's complete works were published in 1871, with a memoir by his nephews, W. E. and Sir Bartle Frere, and reached a second edition in 1874. *See* also Gabrielle Festing, J. H. *Frere and his Friends* (1899).

FRÈRE-ORBAN, HUBERT JOSEPH WALTHER (1812–1896), Belgian statesman, was born at Liége on April 24. 1812. After studying law in Paris, he practised as a barrister at Liége, took a prominent part in the Liberal movement, and in June 1847 was returned to the chamber as member for Liége. He was minister of public works in the Rogier cabinet, and from 1848 to 1852 was minister of finance. He founded the Banque Nationale and the Caisse d'Épargne, abolished the newspaper tax. reduced the postage, and modified the customs duties as a preliminary to a decided free-trade policy. To facilitate the negotiations for a new commercial treaty, he conceded to France a law of copyright, which proved highly unpopular in Belgium, and he resigned office, soon followed by the rest of the cabinet. His work La *Mainmorte et la charité* (1854–1857), published under the pseudonym of "Jean van Damme," helped his party back to power in 1857, when he again became minister of finance. He now embodied his free-trade principles in commercial treaties with England and France, and abolished the *octroi* duties and the tolls on the national roads. He resigned in 1861 on the gold question, but soon resumed office, and in 1868 succeeded Rogier as prime minister. In 1869 he defeated the attempt of France to gain control of the Luxemburg railways. Defeated in 1870, he returned to office in 1878 as president of the council and foreign minister. He provoked the bitter opposition of the Clerical party by his law of 1879 establishing secular primary education, and in 1880 broke off diplomatic relations with the Vatican. Frère-Orban, while rejecting the Radical proposal of universal suffrage, conceded an extension of the franchise (1883); but the hostility of the Radicals, and the discontent caused by a financial crisis, overthrew the government at the elections of 1884. Frère-Orban continued to lead the Liberal opposition till 1894, when he failed to secure re-election. He died at Brussels on Jan. 2, 1896.

FRÉRET, NICOLAS (1688–1749), French scholar, was hardly 26 years of age when he was admitted as pupil to the Academy of Inscriptions. One of the first memoirs which he read mas *Sur l'origine des Francs* (1714). He maintained that the Franks were a league of South German tribes and not, according to popular legend, a nation of free men deriving from Greece or Troy. These sensible views excited great indignation in the Abbé Vertot, who denounced Fréret as a libeler of the monarchy. A *lettre de cachet* was issued, and FrCret was sent to the Bastille until March 1715. In Jan. 1716 he was received associate of the Academy of Inscriptions, and in Dec. 1742 he was made perpetual secretary. His memoirs, many of them posthumous, treat of history, chronology, geography, mythology and religion. He died in Paris on March 8, 1749.

FRERICHS, FRIEDRICH THEODOR (1819–1885): German pathologist, became professor of pathology at Gottingen (1848), at Kiel (1850), at Breslau (1852) and Berlin (1859). He developed scientific clinical teaching in Germany. He discovered leucin and tyrosin in the urine in cases of acute yellow atrophy of the liver (1855), made pathological studies of cirrhosis of the liver and of pernicious malarial fever and published works on Bright's disease (1851) and diseases of the liver (1858).

FRÉRON, ÉLIE CATHERINE (1718–1776), French controversialist, prominent mainly as the opponent of the *philosophes*, was born at Quimper in Brittany, Jan. 20, 1718. He was editor of *L'Année litte'raire,* founded by him in 1754, which gave a thorough survey of French literary production. Although submissive to authority, he was imprisoned at Vincennes in 1746, in the Bastille in 1757, and narrowly escaped a similar fate in 1765. He appears to have carried his opposition to the *Encyclopédie* to the length of denouncing the printers to the police. He was not without affability in his private life, but was bitterly attacked on many occasions by Voltaire, most notably in his comedy *L'Écossaise* (1760). He died in Paris, March 10, 1776.

See F. Cornou, *Élie Friron* (1922). (RT. S.)

FRÉRON, LOUIS MARIE STANISLAS (1765–1802), French revolutionist, son of Elie FrCron (*q.v.*), was born at Paris on Aug. 17, 1765. On the death of his father his name was attached to *Année littéraire,* which was continued until 1790 and edited successively by the abbés G. M. Royou and J. L. Geoffroy. On the outbreak of the Revolution Fréron, who was a schoolfellow of Robespierre and Camille Desmoulins, established the violent journal *L'Orateur du peuple.* With Barras in 1793 he repressed the opposition to the convention at Marseilles and Toulon, but both afterward joined the Thermidoriens, and Fréron became the leader of the *jeunesse dorée* and of the Thermidorian reaction. He brought about the accusation of Fouquier-Tinville and of J. B. Carrier, the deportation of B. Barère and the arrest of the last *Montagnards*. His paper became the official journal of the reactionists. He went in 1799 as commissioner to Santo Domingo and died there in 1802. He wrote *Mémoire historique sur la réaction royale et sur les malheurs du midi* (1796).

FRESCO (Ital. for *cool,* "fresh"), a term introduced into English, both generally (as in such phrases as *al fresco,* "in the fresh air"), and more especially as a technical term for mural painting on plaster. In the latter sense the Italians distinguished painting *a secco* (when the plaster had been allowed to dry) from *a fresco* (when it was newly laid and still wet). *See* FRESCO PAINTING and PAINTING.

FRESCOBALDI, GIROLAMO (1583–1644), Italian organist and composer, was born in Ferrara. He studied under the cathedral organist Luzzasco Luzzaschi, and owed his first reputation to his beautiful voice. He was organist at St. Peter's in Rome from 1608 to 1628. In 1628 he went to live in Florence, becoming organist to Duke Ferdinand II. Political troubles drove him back to Rome in 1633, and he was again organist at St. Peter's until March 1643. He died on March 2, 1644. Frescobaldi was perhaps the greatest organist of the 17th century. His compositions show the consummate art of the early Italian school, and his works for the organ are full oi the finest devices of fugal treatment. He also wrote numerous vocal compositions, such as canzoni, motets, hymns, etc., a collection of madrigals for five voices (1608) being among the earliest of his published works.

FRESCO PAINTING. Fresco is a method of painting on freshly applied, wet lime-plaster walls with colours made by grinding artists' dry powder pigments in pure water. The colours dry and set with the plaster and become a permanent part of the wall. The terms *buon fresco* and *a fresco* are sometimes used to distinguish true fresco from its substitutes.

Like other processes which have their roots in remote antiquity, it is basically simple and direct; it operates on the most commonplace of chemical reactions; and at the same time it demands of the painter thorough competence and familiarity with a multitude of details. The execution of a fresco should not be attempted by the inexperienced. The restrictions imposed in modern times by economic and other circumstances usually preclude the use of this most desirable kind of mural painting.

A mural is not merely a large-scale version of an easel painting. blown up and projected on a wall. No other, form has so many technical requirements. In addition to the restrictions common to all forms of painting, resulting from the artist's desire for maximum control of the paint and for permanence, mural painting has certain limitations peculiar to itself. The mural must be effective when viewed from any point in the room, whereas the easel painting may be effective only from the most favourable point. Ideally, the surface of the mural should be without glare under general illumination. It must have a "mural quality" — it should seem to be a part of the building rather than a superimposed en~bellishment.

From the early Renaissance to the present day, fresco has been the technique that has met all mural requirements in the most satisfying way; it has survived and retained its pre-,eminence as the most appropriate medium through every change in style.

History. — Nobody knows when or where fresco painting began. One theory was that it arose from the preparatory outlines drawn on the plaster for setting mosaics. The most accepted explanation points to the ancient use of stucco to cover rough or unsightly masonry: a smooth, flawless white finish was gradually developed, which was then tinted or coloured by the addition of pigments and eventually decorated with more intricate colours in the form of designs and pictures.

The Egyptians did not use fresco. Mud plaster was employed for building; lime was not used until its introduction by the Romans. Wall painting was prominent, however, throughout the long history of Egypt. Examples have survived because of the dryness of the climate and the 'protection of the tombs. Some of these paintings have simple water colour binders; after thousands of years they are still bright, but can be removed with a damp sponge. Others, particularly those used with carving, were mixed with a resinous binder.

True frescoes. of a high level of technical accomplishment. were a prominent feature of the prehistoric Minoan culture in Crete (before 1500 B.C.) discovered in the 20th century. Chemical analysis showed the lime and all the earth pigments of the Minoan frescoes to have been produced locally with the exception of an imported Egyptian blue frit. Some, not all, of the Etruscan wall paintings still to be seen in Italy, notably at Tarquinia, were painted in fresco. No wall paintings from ancient Greece have survived but writings suggest that fresco was a standard method there. Little is known about Greek painting from the artistic or stylistic viewpoint. or what relation it had to Roman wall painting, but it is known that the Romans were profoundly influenced by Greek methods and technical procedures.

Roman fresco painting is well-documented, especially in the books of Vitruvius and Pliny. Whole frescoed walls have been excavated in Pompeii and Herculaneum and fragments have been unearthed in nearly every Roman site.

In India the cave temples of Ajanta (200 B.C.–A.D. 600) contain a large number of frescoes skillfully executed with lime and pigments of local origin plus Afghan lapis lazuli blue. Considerable ingenuity and resourcefulness must have been used to overcome local difficulties. There is no indication of joins in these murals; a possible explanation is that the work was done by guilds or families rather than individual painters, so that a wall could be finished in one session. Another isolated find of ancient frescoes (5th–8th centuries A.D.) is a group of Buddhist decorations at Tun-huang, Kansu, in remote western China.

European artists from the 13th through the 17th centuries employed fresco as their major mural painting method, and this was its heyday, especially in Italy where it fulfilled the requirements of every conceivable personal technique and pictorial objective. From the 18th century, artists and chemists experimented widely with new methods designed to replace fresco with mediums more resistant to the polluted atmosphere of towns and cities, but technically, fresco remained the most desirable.

The demanding and formidable process does not conform to the exigencies of the 20th century, so it has been largely supplanted by inferior methods, such as *secco* and the traditional easel painting techniques—(*e.g.*, oil, casein, tempera). In the 1930s, during a period of extensive construction of public buildings, there was a widespread revival of fresco painting in the Cnited States and in Mexico.

See also PAINTING; MURAL PAINTING.

Technique.—Onto a brick, tile or metal lath wall, the artist or his plasterer trowels or "throws" three coats of specially made mortar composed of aged slaked lime-putty (quicklime which has been slaked with water and kept in storage for a year or more to improve its plasticity), sand and sometimes marble dust, each in its own carefully measured proportion. The first or scratch coat (trulisatio) and the second or brown coat (arricaccato) are applied and allowed to set. The artist, who has made enlarged full-scale cartoons completely finished in detail from his original drawings, then transfers them onto the mall in outline, usually by going over the lines of a tracing of the cartoon with a perforating wheel; while the tracing is held in place against the wall. a little cloth bag of dry powder pigment is tapped or pounced through the perforations. The final painting coat (*intonaco*) is then smoothly troweled on as much of the upper left-hand corner of the wall as can be painted in one session. The boundaries of this area are confined carefully along contour lines, so that the joins of each successive day's work are imperceptible. The perforated tracing is then held against the fresh intonaco and lined up carefully with the adjacent drawing; the pigment is then gently pounced over it once more.

If the wall has been correctly prepared the *intonaco* will hold its moisture for a long working period. When the painter freely dilutes his colours with water and applies them with deft brushstrokes. they will be drawn into, or imbibed by, the surface through capillary action. As the wall dries and sets; the pigment particles become bound or cemented along with the lime and sand particles. They are part of the same cementitious, porous mass; their colour permanence and resistance to aging is entirely due to their own chemical inertness and not to a transparent skin or binding medium as is the case with other forms of painting. The painting is actually part of the wall, not a superimposed layer of paint.

After the mortar reaches a certain degree of set or dryness, it will no longer take or absorb colours from the brush; as soon as this is observed, the painter must stop, and await the next fresh area of plaster, or else his colour will lie on the surface like dusty pastel instead of becoming incorporated into the rocklike mass.

Secco or limewash painting is a simplified offshoot of fresco which does away with the complex preparation of the wall with fresh plaster. Dry, finished walls are soaked with limewater and painted while wet with casein colours. The colours do not penetrate into the plaster but form a surface film like any other paint. Practised since early times, it has always held an inferior position to true fresco.

Pigments.—The fresco palette is more rigidly restricted than any other. The pigments not only must have the usual colour stability required of artists' pigments in general. but also must be completely alkali proof to resist the caustic action of the lime and sufficiently acid resistant to withstand concentrations of acid impurities existing in the atmosphere. As a routine check on the behaviour of his pigments, the fresco painter makes a plaster test block upon which his supply of pigments is tried so that he can check on their colour when dry, their ability to combine with the mortar and their resistance to the lime (six months' aging is necessary for this test).

The modern fresco painter uses the following pigments: white, either plain lime-putty, the traditional biartco *sangiovanni* (partially carbonated lime putty) or blanc fixe; Mars black; Indian red; light red; the umbers; the siennas; green earth; ochre (or Mars yellow); Mars violet; a special cementitious rosy-red earth called Pozzuoli red; chromium oxide green; viridian; cobalt blue; cerulean blue; phthalocyanine blue; and some specimens of cobalt violet (must be tested). Most painters reject vermilion, the cadmium yellows and reds and ultramarine blue, because they contain sulfides and are therefore extremely sensitive to the action of acids. These are used by others. however: on the theory that they are no more sensitive to acids than the calcium carbonate of the wall itself.

Three chemical reactions are involved: the making of lime. the slaking of lime and the hardening of mortar. Lime is obtained from kilns where limestone or marble or some other form of calcium carbonate is burned to form quicklime (calcium oxide). The slaking or mixing with water converts it into hydrated lime (calcium hydroxide). When the mortar is spread out and exposed to air, its lime is converted to calcium carbonate, chemically identical to the original limestone or marble. The carbonation is caused by carbon dioxide which is a constituent of the atmosphere. Calcium carbonate is a durable substance indoors, where plastered and frescoed walls have lasted for centuries and where marble retains a high polish. But it is too susceptible to the abrasion of rain and airborne particles and to acid conditions to be used outdoors or even in a semiexposed position.

Chemists rate fresco as a completely permanent indoor method but not sufficiently permanent outdoors. For exposure to outdoor or drastic conditions! some imperishable mural method must be chosen. for example. mosaic and terra cotta or one of the modern developments such as ethyl silicate or porcelain enamel.

Ser Olle Nordmark, *Fresco Painting* (1947); Ralph Mayer, *The Artist's Handbook of Materials and Techniques*, rev. ed. (1957), extensive bibliography. (RH. M.)

FRESENIUS, KARL REMIGIUS (1818–1897), German chemist and author of standard texts on chemical analysis, was born at Frankfurt-on-Main on Dec. 28, 1818. In 1836 he was apprenticed to an apothecary. He studied at Bonn in 1840 and at Giessen in 1841, where he acted as assistant in Justus von Liebig's laboratory, and in 1843 became *Privatdocent* in chemistry. In 1845 he was appointed to the chair of chemistry, physics and technology at the Wiesbaden Agricultural institution, and in 1848 he became the first director of the chemical laboratory and school for chemists which the Nassau government established there. This establishment. which was set up in his home. was augmented in 1862 with a pharmacy school, and in 1868 with an agricultural experiment station especially devoted to the wine industry. He established a bacteriologic institute in 1884. Fresenius occupied himself almost exclusively with analytical chemistry, and the fullness and accuracy of his textbooks on that subject (of which that on qualitative analysis first appeared in 1841 and that on quantitative in 1846) soon rendered them standard works. They passed through numerous editions and were translated into many languages. including Japanese.

Many of his original papers were published in the *Zeitschrift* fur analytische *Chemie*, which hc founded in 1862 and continued to edit until his death.

Fresenius died suddenly at Wiesbaden on June 11, 1897. His sons and brothers continued the laboratory and school.

(R. E. O.)

FRESHWATER, a seaside holiday town in the Isle of Wight, Eng., about 10 mi. S.W. of Newport by road. Pop. (1951) 3,423. It is a scattered township lying on the peninsula west of the river Yar at the western extremity of the island. Freshwater bay is separated from Alum bay on the west by the promontory between, with the group of detached rocks, known as the Needles, jutting from the sea. The cliffs are magnificent, rising 400–500 ft.

Farringford house in the parish was the home of Alfred, Lord Tennyson, who is commemorated by a tablet in All Saints' church and by a great cross on High down overlooking Freshwater bay. There are two golf links on the downs.

FRESNEL, AUGUSTIN JEAN (1788–1827), French physicist and pioneer in optical theory, was born at Broglie, Nor-

CEILING OF THE SISTINE CHAPEL

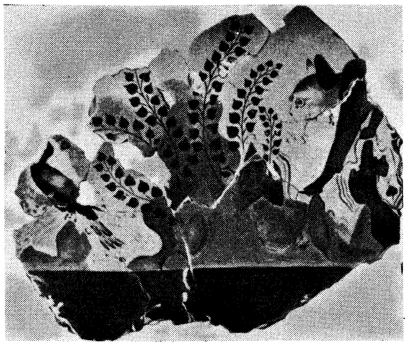
Among the most important series of frescoes were those painted by Michelangelo (1475–1564) on the ceiling of the Sistine chapel in the Vatican. This work, which took four and a half years to complete, is comprised of 343 figures grouped in scenes from the Book of Genesis. Bordering the central panels of the vaulted ceiling of the chapel are large, seated figures of prophets and sibyls md, interspaced with them, triangular spandrels depicting the ancestors of Christ and four miraculous salvations of the chosen people. The ceiling is enclosed in and divided by a painted framework

Top: The Fall of Man, om of the central panels, shows Adam and Eve taking the forbidden fruit and being expelled from the Garden of Paradise. The serpent, with the head of & woman, $ coiled around the Tree of Knowledge

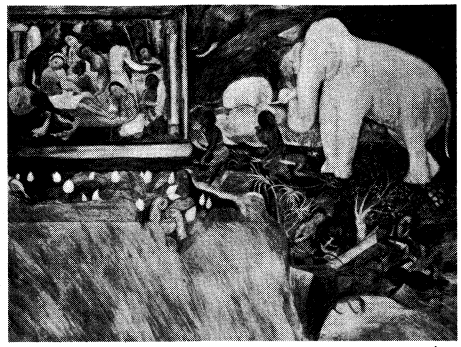
Bottom left: The Prophet Zacharias. The Genii of the intellect peer over the shoulders of the prophets md sibyls

Bottom right: The Delphic Sibyl. Five sibyls and seven prophets are depicted

FRESCO PAINTING



"Cat Hunting a Pheasant"; late Minoan period (c. 1500 B.C.) from Hagia Traida. Facsimile from original in Candia museum, Crete

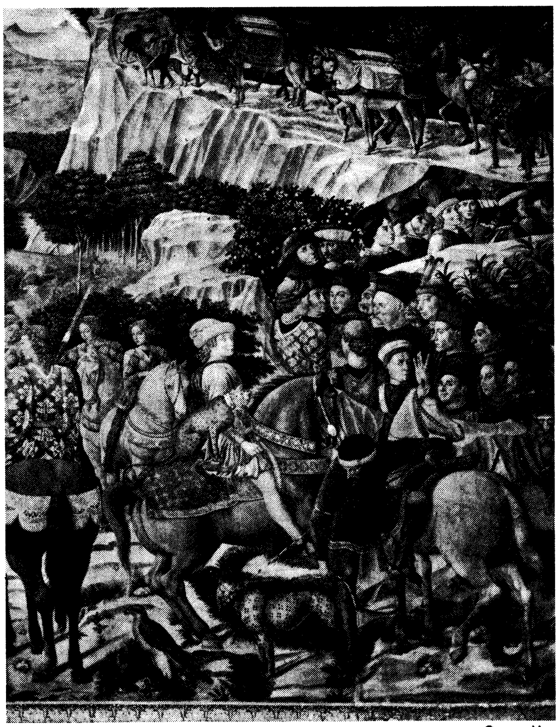


"Six-Tusked Elephant and the Queen of Benares," Indian fresco from Ajanta, cave XVII

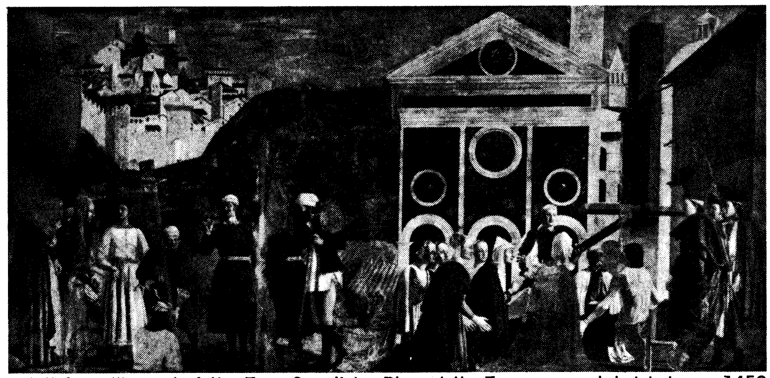
"Pieth" from "The Life of Christ and the Virgin" by Giotto; painted 1305–06. From the Arena chapel, Padua, Italy

"Lady Playing the Cithera," Roman fresco from Boscoreale, 1st century A.D.

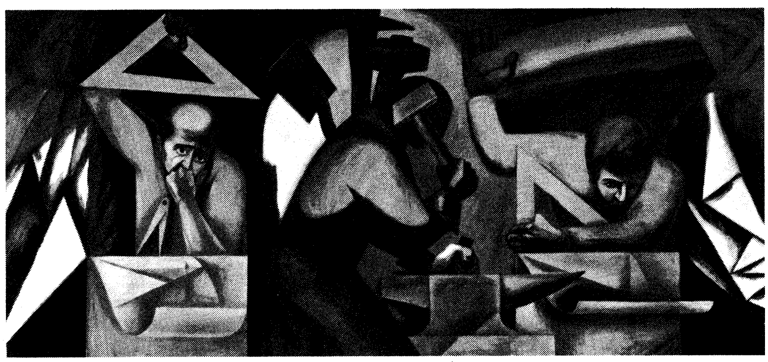
"Musicians," Etruscan wall painting of the 5th century B.C. Detail from the Tomb of the Leopards, Tarquinia



Detail of panel 1, "Procession of the Magi," by Benozzo Gozzoli; about 1460. From the Ricciardi-Medici palace, Florence, Italy



Detail from "Legend of the True Cross" by Piero della Francesca, painted between 1452 and 1466. Church of S. Francesco, Arezzo, Italy



"Creative Man" by José Clemente Orozco (1883–1949), Mexican. From a series at the New School for Social Research, New York city

FRESCO PAINTING OF VARIOUS PERIODS

BY COURTESY OF (SECOND ROW LEFT) METROPOLITAN MUSEUM OF ART. ROGERS FUND, 1903, (BOTTOM RIGHT) THE NEW SCHOOL PHOTOGRAPH BY PETER JULEY & SON; PHOTOGRAPH, (BOTTOM LEFT) ALINARI mandy, on May 10. 1788. He was educated at the École Centrale in Caen, the École Polytechnique, and finally went to the École des Ponts et Chaussées. He served as an engineer in several departments, but lost his appointment in 1814 because he opposed Napoleon's return from Elba. On the second restoration he obtained a post as engineer in Paris. His researches in optics appear to have been begun about 1814, when he prepared a paper on the aberration of light, which, however, was not published. Fresnel's work on interference did a great deal to establish the wave theory of light. and various devices for producing interference fringes bear his name. He applied mathematical analysis to his work and removed a number of objections to the wave theory. With D. F. J. Arago he studied the laws of the interference of polarized rays. Circularly polarized light he obtained by means of a rhomb of glass, known as "Fresnel's rhomb." He was a pioneer in the use ot compound lenses instead of mirrors for lighthouses. He was a member of the Académie des Sciences and a foreign member of the Royal society. He died at Ville-d'Avray, near Paris, on July 14, 1827.

Fresnel's labours in the cause of optical science received during his lifetime only scant public recognition, and some of his papers were not printed by the académie until many years after his death. But, as he wrote to Thomas Young, the English scientist. in him "that sensibility, or that vanity, which people call love of glory" had been blastcd. "All the compliments," he said, "that I have received from Xrago, Laplace and Biot never gave me so much pleasure as the discovery of a theoretic truth, or the confirmation of a calculation by experiment."

See *Oeuvres Complètes* **(1866–70).**

FRESNILLO (FRESNILLO DE GONZÁLEZ ECHEVERRÍA), a town of the state of Zacatecas, Mex., 37 mi. N.W. of Zacatecas city. Pop. (1950) 29.908. Fresnillo is located on a plain between two ranges of mountains, about 7,700 ft. above sea level. It has a generally temperate climate but is often swept by cold winds. Five miles northeast is a station of the Mexican National railroad linking the town with Mexico City and with El Paso, Tex. Fresnillo is on the central highway and has an airport.

The town was founded in 1554 by Francisco de Ibarra. It has been an important silver mining centre since 1569, when rich mines were discovered in the neighbouring Proaño hill. A school of mines was founded in 1853. Gold, copper, lead and zinc are produced in limited quantities.

The region served by Fresnillo has become important agriculturally. Limited irrigation facilities have been instrumental in increasing grain and vegetable production and the livestock industry dates from the colonial period. (J. J. J.)

FRESNO, a city of California, U.S., near the geographical centre of the state, is the chief city of the San Joaquin valley and the seat of Fresno county. It is the commercial and mercantile centre of an area extending from the Sierra Nevada to the Coast range. and for 100 mi. to the north and south. The population, which in 1900 was 12.470. increased rapidly. Pop. (1960) city 133.929; standard metropolitan statistical area (the entire county) 365.945; for comparative population figures see table in CALIFORNIA: *Population.* The chief national groups are Armenians. Mexicans and Russian Germans. the last-named being the descendants of German colonists who in the 18th century settled in Russia and in the late 19th and early 20th centuries emigrated to the U.S. The city presents the aspects of a large farm town; it is the focus for the processing of farm products as well as the distributing point for farm labour and machinery.

Fresno was settled in 1872 as a station on the newly opened line of the Central (now Southern) Pacific railway, in an arid and flat area which up to that time had supported only a sparse population; the name (Sp., "ash tree") comes from the name of the county, so called because of the ash trees in the foothills, not at the townsite. The introduction of irrigation canals in the 1870s and 1880s made intensive agriculture possible and encouraged settlement. The seat of Fresno county was transferred from Millerton to Fresno in 1874 and the city was incorporated in 1885.

The climate of Fresno is characterized by summers of high temperature and almost complete absence of rainfall; the low humidity moderates the effects of the temperature, and the nights are cool. About 87% of the annual rainfall occurs in the six months from November to April, when the temperature rarely falls below freezing. The mean annual temperature is 63° F., and the mean annual rainfall 9.52 in. A fertile soil and favourable climatic conditions have made Fresno county one of the richest agricultural counties in the United States. The chief crops are cotton. grain. alfalfa and fruits (especially raisin grapes. figs, peaches and melons). There is little industry apart from wine making and the drying and packing of fruit.

Higher education is provided by Fresno State college (established 1911) and Fresno City college. a junior college established in 1910. There is a philharmonic orchestra and Roeding park has a zoological garden. Three national parks—Yosemite, Sequoia and Kings Canyon—are nithin 90 mi. of the city. (HE. M. M.)

FRET, in decorative art and architecture, is any one of several types of running or repeated ornament consisting of lengths of straight lines or narrow bands. usually connected and at right angles to each other in T. L or square-cornered G shapes, so arranged that the spaces between the lines or bands are approximately equal to the width of the bands. Occasionally the system is arranged so that the lines intersect or interlace. as in the common "swastika (*q.v.*) fret." As the fret is one of the simplest and most natural decorative forms that can be produced in textiles: it is one of the most widely spread and is found alike from early times in all the continents. Thus it was a favourite decoration for the ceilings of Egyptian tombs from the fourth dynasty on, in later examples combined with rosettes, scarabs and the lotus into patterns of great richness.

In America. it is found in early Peruvian textiles, it is frequent in sculpture and architecture in the Maya and Aztec remains in Middle America; and it is one of the most universal of pottery decorations among American Indians. It was highly developed by both Chinese and Japanese for textiles as well as for architectural ornament; it occurs not only as a band but as a complicated allover pattern. sometimes with acute and obtuse angles instead of the more usual right angles. But its most important development was that by the Greeks (hence the common name "Greek fret"), who used it not only for pottery, but painted on architectural members, such as the abaci of capitals, and later carved it.

Like so many Greek motives it was widely used by the Romans particularly in Syria (*e.g.,* the *propylaea* at Damascus and the great temple at Baalbek) and occurs in Byzantine and Romanesque work.

"Fretwork" has a wider significance and is the most often used .of any small-scale repeated ornament in which geometrical forms occur, especially if in low relief or pierced. (T. F. H.; X.)

FREUD, SIGMUND (1856–1939), founder of psychoanalysis. was born of Jewish parents at Freiberg in Moravia on May 6, 1856. From the age of 4 until the age of 82 he lived in Vienna. As a student he found it difficult to decide on a profession. Though he was greatly impressed by the work of Darwin and other scientists of that period, he also was attracted to the history of culture and to philosophy; one volume of the German edition of John Stuart Mill's collected works was translated by Freud. In his preliminary studies he was interested in chemistry, but finding that he was not particularly gifted in that field he turned for a time to physiology and anatomy, in which he did some original research work in his student days. He was not primarily interested in the therapeutic aspects of medicine, preferring scientific research. Still, he finally decided to study medicine, as many of the great physiologists had done.

Freud worked for several years in the physiological laboratory of E. W. von Bruecke and later in the psychiatric clinic, then under the, direction of the brain anatomist T. H. Meynert. But his financial condition did not allow him to follow a career in research, particularly after he decided to get married. Thus he came to start practice as a neurologist (1886). In the following years he made some important contributions to neurology, his studies on aphasia and on the cerebral paralyses of children remaining highly regarded by neurologists. But in that period the interests that n·ere to become the centre of his lifework were already in the ascendancy.

In 1885 Freud studied in Paris under the neurologist Jean Charcot, who strengthened his determination to investigate hysteria from a psychological point of view. But the decisive influence in his turning to problems of psychopathology and psychology came from another source. An outstanding Viennese physician and thinker, Josef Breuer, had told him of an extraordinary experience in which he had cured symptoms of hysteria by getting the patient to recollect in hypnosis the circumstances of their origin and to express the emotions accompanying them. After his return from Paris. Freud suggested to Breuer that they publish the case, together with some others Freud had in the meantime treated with the same method, and with an added chapter on the theoretical conclusions that could be drawn from their observations. This book about what they called the "cathartic" method of treatment (*Studien über Hysterie,* 1895) was the starting point of what later became psychoanalysis.

Soon afterward: however, Freud took the decisive step of replacing hypnotism by the method of free association. This allowed him to isolate and study the phenomena of resistance (which the patient opposes to the uncovering of repressed experiences) and transference (the patient's emotional ties to the analyst). These two factors have ever since remained central in the technique of psychoanalysis. From this change from catharsis to free association the beginning of psychoanalysis (in the sense that the word is used today) is generally dated.

The development of Freud's psychological thinking also greatly benefited when, beginning in 1897, he had the courage to use his newly acquired knowledge for a study of his own unconscious mental processes. The degree of insight that he achieved in this way is accessible by the method of self-analysis only to the very few. But from this pioneering experience grew the demand that the student of analysis undergo, as part of his training, a personal analysis conducted by an experienced psychoanalyst.

In Freud's work the clinical, theoretical and technical aspects are closely interrelated. His method of free association is essential lo the therapeutic technique and also a powerful tool of psychological research. Freud, who had been reluctant to abandon research for medical practice, discovered a practically efficient method of treatment that was at the same time to satisfy what he considered the main endeavour of his life: "To infer or to guess how the mental apparatus is constructed and what forces interplay and counteract in it." (E. Jones) *The Life and Work of Sigmund Freud,* New York: Basic Books, London: Hogarth Press, 1953, vol. 1. p. 45.) This led to radical progress in the understanding of neurosis, psychosis, perversion and, of course, the normal mind. Some fundamental aspects of this are: (1) the dynamic effect of unconscious processes on consciousness and action; (2) the central role of mental conflict not only in pathology but also in normal development — part of this was the insight into the various mechanisms of defense by which instinctual tendencies are either excluded from consciousness and action (as in repression) or modified (as in sublimation); (3) the structural aspects of personality; (4) the motivating force of the instinctual drives (sexuality and aggression); and (5) more specifically, the existence and importance of infantile sexuality. (For the Oedipus conflict, *see* PSYCHOANALYSIS.)

Freud's first classical contribution to normal psychology was *Die Traumdeutung (The Interpretation of Dreams,* 1900), which he considered his greatest book. It was followed by studies of the parapraxes and of wit, by analytic interpretations of works of literature and by the application of psychoanalysis to anthropology and to the psychology of religion.

Freud's work contains striking discoveries; it is also the expression of a powerful mind, capable of extracting the fullest meaning from his discoveries. His unfailing intellectual courage allowed him to face previously unknown aspects of the human mind. The characteristic elements of his style of thinking and his creativity remained unimpaired either by age or by a disease process that started when he was 67 and led to his death 16 years later. He wrote one of his most lucid and significant papers at the age of 80. His last book *Moses and Monotheism* (1939) was written at 83; in this he uses his full mastery of the method and science he had created to elucidate one of those questions of the history of culture that had fascinated him as a young man.

Freud's discoveries particularly his findings about the sexuality of children, from the beginning met opposition, misunderstanding and abuse. This reaction did not surprise Freud, after he had learned from his work the role played by opposition to the uncovering of unconscious motivations. Recognition of analysis was slow to come. Freud, though he had the title professor, was never made a full professor at the University of Vienna. Only in his last years, and partly under the influence of the comparatively broad acceptance of analysis in the United States. did the opposition to analysis also in other countries assume a less vehement character. In 1930 he received the Goethe prize and in 1936 he was elected to the Royal society.

For ten years Freud had worked alone at psychoanalysis. About 1906 he was joined by a number of colleagues who met in 1908 at the first International Congress of Psychoanalysis, and two years later the International Psychoanalytic association was founded.

Freud was married to Martha Bernays in 1886. They had six children, the youngest. Anna Freud, became a famous psychoanalyst in her own right. In 1938, after the annexation of Austria by Nazi Germany, Freud moved to London, where he died on Sept. 23, 1939

Freud s works have been translated into many languages. An English standard edition of his complete works is edited by J. Strachey, thirteen volumes of which had been published by 1960.

FREY, ADOLF (1855–1920), Swiss poet. literary historian and critic, son of Jacob Frey, was born at Aarau on Feb. 18, 1855, and died at Ziirich on Feb. 12. 1920. He became professor of German literature, first at Xarau and then at Ziirich. His chief claim to attention is his keen and profound interpretation of Swiss literature and art, as shown in his book on *Schweizer Dichter* (1919), and in his monographs on *Albert von Haller* (1879), *Gottfried Keller* (enlarged edition, 1893), *C. F. Meyer* (1900), *Böcklin* (1903), *Koller* (1906), *Welti* (1908), *Hodler* (1922) and others.

He wrote also two vigorous historical novels, *Die Jungfer von Wattenwil* (1912) and *Bernhard Hirzel* (1918). *A* final selection of his best *Poems* was issued in 1922. His lyrics are graceful, and his dialect poems were especially popular. His dramas (*e.g., Erni Winkelvied,* 1893) are less important.

See C. F. Wiegand, *Das Adolf Frey Buch* (1920); L. Frey, *Adolf Frey: sein Leben und Schassen (1923).*

FREY, son of Njord, one of the chief deities in the northern pantheon and the national god of the Swedes. He is the god of fruitfulness, the giver of sunshine and rain. His sister Freyia, the most prominent goddess in northern mythology, shares his characteristics.

See TEUTONIC PEOPLES.

FREYBERG, BERNARD CYRIL FREYBERG, 1ST BARON (1889–), of Wellington, New Zealand, and of Munstead, Surrey, commander in chief of the New Zealand forces in World War II and governor general of New Zealand from 1946 to 1952, was born in London on March 21, 1889. Two years later he emigrated with his parents to New Zealand and was educated at Wellington college and at the New Zealand university. He joined the army in New Zealand in 1909. In 1914 he took part in the Mexican revolution on the side of Pancho Villa.

Early in World War I he served in a British naval division in the retreat from Antwerp and took part in the operations in Gallipoli from the landing to the evacuation. Later in France he took part in many of the fiercest battles and was awarded the Victoria cross (Dec. 16, 1917). He was promoted to brigadier general at 27, then the youngest of that rank in the British army. He commanded the 29th division in 1917–18.

Freyberg was nine times wounded, and his bravery became legendary.

Between the wars he held senior staff appointments and a command in England. In World War II, as major general, he commanded the New Zealand Expeditionary force, and the Allied forces during the battle of Crete, in 1941. Later in the war he fought in the western desert and in Italy under Montgomery and Alexander. During the latter campaign he received a third bar to his Distinguished Service Order. In 1942 he received a knighthood. Freyberg in 1946 became governor general of New Zealand, an appointment he held for six years. He was created a baron in 1951, and in 1953 was appointed lieutenant governor of Windsor castle. (E. B. Bn.)

FREYCINET, CHARLES LOUIS DE SAULCES DE (1828–1923), French statesman, was born at Foix on Nov. 14. 1828. He was educated at the École Polytechnique, and entered the government service as a mining engineer. He was sent on a number of special missions, among which, one to England, on which he wrote a *Mémoire sur le travail des femmes et des enfants dans les manufactures de l'Angleterre* (1867). On the establishment of the Third Republic in Sept. 18 jo, he offered his services to Gambetta, was appointed prefect of the department of Tarn-et-Garronne, and in October became chief of the military cabinet. It was mainly his powers of organization that enabled Gambetta to raise army after army to oppose the invading Germans. In 1871 he published a defence of his administration under the title of *La Guerre en province pendant le sikge de Paris.* He entered the senate in 1876. and in Dec. 1877 became minister of public works in the Dufaure cabinet. He retained his post in the ministry of Waddington, whom he succeeded in Dec. 1879 as president of the council and minister for foreign affairs. He passed an amnesty for the Communards. but in attempting to steer a middle course on the question of the religious associations, lost the support of Gambetta, and resigned in Sept. 1880. In Jan. 1882 he again became president of the council and minister for foreign affairs. His ministry resigned on the rejection of his plan to occupy the Isthmus of Suez. He returned to office in April 1885 as foreign minister in the Brisson cabinet, and retained that post when, in Jan. 1886, he succeeded to the premiership. He came into power with an ambitious program of internal reform; but except that he settled the question of the exiled pretenders. his successes were won chiefly in the sphere of colonial extension. His ministry fell on Dec. 3, 1886.

In April 1888 he became minister of war in the Floquet cabinet —the first civilian since 1848 to hold that office. His services to France in this capacity were the crowning achievement of his life. He held his office without a break for five years through as many successive administrations—those of Floquet and Tirard, his own fourth ministry (March 1890–February 1892), and the Loubet and Ribot ministries. He introduced the three-years' service and established a general staff, a supreme council of war, and the army commands. He failed to clear himself entirely of complicity in the Panama scandals, and in Jan. 1893 resigned the ministry of war. In Nov. 1898 he once more became minister of war in the Dupuy cabinet, but resigned office May 6, 1899. He published, besides the works already mentioned. *Traitd de mécanique rationnelle* (1858); *De l'analyse infinitésimale* (1860, revised ed., 1881); *Des pentes e'conomiques en chemin de fer* (1861); *Emploi des eaux d'égaut en agriculture* (1869); *Principes de l'assainissement des villes* and *Trait4 d'assainissement industriel* (1870); *Essui sur la philosophie des sciences* (1896); *La Question d'Égypte* (1905); besides some remarkable "Pensées" contributed to the *Contemporain* under the pseudonym of "Alceste." He died on May 14, 1923 in Paris.

FREYCINET, LOUIS CLAUDE DE SAULCES DE (1779–1842), French navigator and explorer of the southern hemisphere, was born at Montélimar. Drôme, on Aug. 7, 1779. In 1793 he entered the French navy. In 1800. after taking part in several engagements against the British, he and his brother Louis Henri Freycinet (1777–1840) joined the expedition sent out under Capt. Baudin in the "Naturaliste" and the "Géographe" to explore the south and southwest coasts of Australia. Much of the ground already gone over by M. Flinders was revisited, and new names were imposed by this expedition. In 1805 Freycinet returned to Paris and prepared the maps and plans of the expedition; he also completed the narrative entitled *Voyuge de de'couvertes aux terres australes* (1807–15). In 1817 he commanded the "Uranie," in which Jacques Arago, the French novelist and dramatist, went to Rio de Janeiro, on a scientific expedition. During the three-year voyage Freycinet visited Australia, Marianne Island, the Sandwich (Hawaiian) and other Pacific islands, South America and other places. Notwithstanding the loss of the "Uranie" on the Falkland Islands during the return voyage, he returned to France with fine collections in all departments of natural history, and with voluminous notes and drawings. The results of this voyage were published under Freycinet's supervision as *Voyage autour du monde sur les corvettes "l'Uranie" et "la Physicienne"* (1824–44).

Freycinet was one of the founders of the Paris Geographical society (1821). He died at his estate of Freycinet, near Loriol (Drôme), on Aug 18, 1842.

FREYSSINET, (MARIE) EUGÈNE (LÉON) (1879–), French civil engineer, chiefly renowned for his successful development of prestressed concrete. was born at Objat, Corrèze, on July 13. 1879. After studying at the École Polytechnique and the École Nationale des Ponts et Chaussées, he was appointed bridge and highway engineer at Moulins in 1905. From then until 1914 he designed and built many reinforced concrete bridges, including one of goo-ft. span. After World War I he worked for a firm of contractors until 1928. In the late 1920s he built Plougastel bridge. with three 600-ft. spans, the largest reinforced concrete bridge to be constructed up to that time. After 1928 he devoted his time to the development of prestressed concrete and also to the making of high-strength concrete. His most significant contribution was the quantitative assessment of creep and shrinkage and the realization that only a high-strength steel at a high stress would achieve a permanent prestress in concrete. At first little recognized, Freyssinet's methods, successfully applied at the Gare Maritime at Le Havre in 1933, were gradually adopted. After his invention in 1938 of a practical tool to stress wires his methods were used all over the world. (F. Wy.)

FREYTAG, GUSTAV (1816–1895), German novelist, was born at Kreuzburg, in Silesia, on July 13, 1816. He studied philology at Breslau and Berlin, and in 1838 took the degree with a remarkable dissertation, *De initiis poëseos scenicae apud Germanos.* In 1839 he settled at Breslau, as *Privatdocent* in German language and literature. His comedy *Die Brautfahrt, oder Kunz von der Rosen* (1844), had some success, but he made his name by his comedy *Die Journalisten* (1853), one of the best German comedies of the 19th century, the subject of which was drawn from his own experience. In 1847 he edited, with Julian Schmidt, *Die Grenzboten,* a weekly journal which, founded in 1841, now became the leading organ of German and Austrian liberalism. Freytag helped to conduct it until 1861. and again from 1867 until 1870. when for a short time he edited a new periodical, *Im neuen Reich.* His fame became universal with the publication in 1855 of his novel of the counting house, *Soll und Haben,* which was translated into almost all the languages of Europe. It was certainly the best German novel of its day, impressive by its sturdy but unexaggerated realism. Its main purpose is the recommendation of the German middle class as the soundest element in the nation. His powerful advocacy of the hegemony of Prussia in his *Grenzboten* gained him the friendship of the duke of Saxe-Coburg-Gotha, whose neighbour he had become on acquiring the estate of Siebleden near Gotha. At the duke's request Freytag was attached to the staff of the crown prince of Prussia in the campaign of 1870, and was present at the battles of Worth and Sedan. Before this he had published another novel, *Die verlorene Handschrift* (1864), a description of Leipzig society, in which he endeavoured to do for German university life what in *Soll und Haben* he had done for commercial life. His *Bilder aus der deutschen Vergangenheit,* a popular account of the history and manners of the Germans, has been compared to Green's *Short History of the English People.* In 1872 he began a work with a similar patriotic purpose, *Die Ahnen,* a series of historical romances in which he unfolds the history of a German family from the earliest times to the middle of the 19th century. His other works include an autobiography (*Erinnerungen aus meinem Leben,* 1887); *Gesammelte Aufsätze,* chiefly reprinted from the *Grenzboten*

(1888) ; *Der Kronprinz und die deutsche Kaiserkrone; Erinnerungsblatter* (1889). He died at Wiesbaden on April 30, 1895.

BIBLIOGRAPHY.—Freytag's *Gesammelte Werke,* 22 vol. (Leipzig, 1886–89). His *Vermischte Aufsätze* have been edited by E. Elster, 2 vol. (Leipzig, 1901–03). On Freytag's life *see,* besides his autobiography mentioned above, the lives by C. Alberti (Leipzig, 1890) and F. Seiler (Leipzig, 1898). *See* also *Flugschriften-sammlung G. Freytag* (1925), published by the city library of Frankfort-on-Main; and A. Kohut, *Gustav Freytag als Patriot und Politiker* (1916).

FRIAR, the English generic name for members of the mendicant religious orders (from Lat. *frater* through Fr. *frère*). Formerly it was the title given to individual members of these orders, as Friar Laurence (in *Romeo and Juliet*), but this is not now common. In England the chief orders of friars were distinguished by the colour of their habit: thus the Franciscans or Minors were the Grey Friars; the Dominicans or Preachers were the Black Friars (from their black mantle over a white habit), and the Carmelites were the White Friars (from their white mantle over a brown habit): these, together with the Austin Friars or Hermits, formed the four great mendicant orders—Chaucer's "alle the ordres foure." Detailed information on these orders and on their position in England is given in separate articles. The difference between friars and monks is explained in article MONASTICISM.

See Fr. Cuthbert, *The Friars and How They Came to England,* pp. 11–32 (1903) ; also F. A. Gasquet, *English Monastic Life,* pp. 234–249 (1904), where special information on all the English friars is conveniently brought together.

FRIARBIRD, the name given to several Australian birds of the honey eater family, from their ruff of feathers on the head and their sober plumage. The best-known species is *Tropidorhynchus corniculatus,* also known as pimlico and as four-o'clock, after its loud cry. Friarbirds are bold and noisy, haunting trees in small flocks. The forms inhabiting some of the islands of the Malay archipelago are mimicked by orioles.

See HONEY EATER; ORIOLE.

FRIAR'S BALSAM, known also as compound tincture of benzoin, appeared in the *Pharmacopoeia Londinensis* of 1746 as traumatic balsam and for many years it was held in wide repute in the treatment of wounds and infections. It is now used mainly as an inhalent in the treatment of bronchitis and laryngitis, its efficacy being due to the presence of benzoic acid in a volatile form.

FRIBOURG (Ger. *Freiburg),* one of the Swiss cantons, in the western portion of the country, taking its name from the town around which the various districts that compose it gradually gathered. Its area is 645 sq.mi. of which 568 sq.mi. are classed as productive. It is a hilly region, the highest summits (of which the Vanil Noir, 7,838 ft., is the loftiest) rising in the Gruyère district at its southeastern extremity, the best known being probably the Moléson (6,568 ft.) and the Berra (5,640 ft.). It is the heart of pastoral Switzerland and is famed for its cheese and cattle. It is watered by the Sarine or Saane river (with its tributaries the Singine or Sense and the Glâne) that flows through the canton from north to south, and traverses its capital town. The upper course of the Broye (like the Sarine, a tributary of the Aar) and that of the Veveyse (flowing to the Lake of Geneva) are in the southern portion of the canton. A small portion of lakes Neuchâtel and Morat belong to the canton, wherein is the Lac Noir or Schwarzsee. There are sulphur springs near the lake, and at Montbarry and Bonn. The main line from Lausanne to Berne past Fribourg runs through the canton with important branch lines in all directions. Pop. (1930) 143,230; by 1960 census 159,194; most of whom are Roman Catholics. The canton is on the linguistic frontier in Switzerland, the line of division running nearly due north and south through it, and even through its capital. The German-speaking inhabitants are found chiefly in the northwestern (Morat region) and northeastern (Singine valley) portions, as well as in the upper valley of the Jogne or Jaun in the southeast. Besides the capital, Fribourg (*q.v.*), the only villages of importance are Bulle, Chbtel St. Denis, Morat (*q.v.*) or Murten, Romont and Estavayer le Lac or Stäffis am See.

The canton is pre-eminently a pastoral and agricultural region, tobacco, cheese and timber being its chief products. Its industries include watchmaking (Semsales), papermaking (Marl)) and chocolate manufacturing. It forms part of the diocese of Lausanne and Geneva, the bishop living since 1663 at Fribourg. It is a stronghold of Roman Catholicism aith monasteries and nunneries, such as those of the Carthusian monks at Valsainte. and the Cistercian nuns at La Fille Dieu and at Maigrauge.

FRIBOURG (Ger. *Freiburg*), the capital of the Swiss canton of that name. It is built almost entirely on the left bank of the Sarine, the oldest bit (the Bourg) being just above the river bank, flanked by the Neuveville and Auge quarters, these with the Planche quarter on the right bank of the river forming the *Ville Basse.* On the steep ground to the west of the Bourg is the Ouartier des Places, beyond which. to the west and south-west. is the still newer Pérolles quarter, with the railway station and university; all these (with the Bourg) constituting the *Ville Haute.* In 1960 the population of the town was 32.583. In 1921 the French-speaking numbered 12,831 and the German-speaking 6,921. these last being mainly in the Ville Basse. Founded as a German town. French became the official language during the 14th and 1jth centuries, but when it joined the Swiss Confederation in 1481 German influence came to the fore, and German was the official language from 1483 to 1798. From 1798 to 1814, and again from 1830 onward, French prevailed, as at present. Fribourg is on the main line from Berne (20 mi.) to Lausanne (41 mi.).

The town was founded in 1157 by Berchthold IV, duke of Zahringen. The spot was chosen for purposes of military defense, and was situated in the *Uechtland* or a aste land between Alamannian and Burgundian territory. The oldest existing charter of the town dates from 1249. In 1218, the lands passed to Anna, the sister of the last duke and wife of Count Ulrich of Kyburg. The line became extinct in 1264. Their heiress married Eberhard, count of Habsburg-Laufenburg, who sold Fribourg in 1277 to his cousin Rudolf, the head of the house of Habsburg. The town had to struggle for its existence against Berne and the count of Savoy, between 1448 and 1452. Abandoned by the Habsburgs, and desirous of escaping from the increasing power of Berne, Fribourg in 1452 finally submitted to the count of Savoy. In the 15th century Fribourg exported much leather and cloth to France, Italy and Venice. When Tolande, dowager duchess of Savoy, entered into an alliance with Charles the Bold, duke of Burgundy, Fribourg joined Berne, and helped to gain the victories of Grandson and of Morat (1476).

In 1477 the town was finally freed from the rule of Savoy, while in 1481 (with Soleure) it became a member of the Swiss Confederation. In 1475 the town had taken Illens and Arconciel from Savoy, and in 1536 won from Vaud much territory, including Romont, Rue, Chhtel St. Denis, Estavayer, St. Aubin, as well as Vuissens and Surpierre, which still form outlying portions (physically within the canton of Vaud) of its territory, while in 1537 it took Bulle from the bishop of Lausanne. In 1502–04 the lordship of Bellegarde or Jaun was bought, while in 155j it acquired (jointly with Berne) the lands of the last count of the Gruyère, and thus obtained the rich district of that name. From 1475 it ruled (with Berne) the bailiwicks of Morat, Grandson, Orbe and Echallens, just taken from Savoy, but in 1798 Morat was incorporated with (finally annexed in 1814) the canton of Fribourg, the other bailiwicks being then given to the canton of Léman (later of Vaud). From the 16th century the democratic government gave place to an oligarchy which continued till the French occupation of 1798.

From 1803 (Act of Mediation) to 1814, Fribourg was one of the 19 cantons of the Swiss Confederation. But, on the fall of the new regime, in 1814, the old patrician rule was partly restored. In 1831 the Radicals secured a more liberal constitution. In 1846 Fribourg joined the Sonderbund and, in 1847, had to surrender to the Federal troops. The Radicals came back to power. In 1857 the Conservatives secured the adoption of a new cantonal constitution, and have since maintained their power.

The principal building in the town is the collegiate church of St. Xicholas, of which the nave dates from the 13th–14th centuries. while the choir was rebuilt in the 17th century. It has a lofty bell tower (1jth century). The town hall dates from the 16th century. In the Lycée is the Cantonal museum of fine arts.

On the Pérolles plateau is the International Catholic university founded in 1889. A dam built to the north of the town forms a sheet of water known as the Lac de Pérolles.

FRICK, HENRY CLAY (1849–1919), U.S. industrialist, art collector and philanthropist, was born at Rest Overton, Pa., Dec. 19,1839. He organized the firm Frick and Company (1871), acquired extensive coal deposits, built about 12,000 coke ovens and supplied the Pittsburgh steel mills with the coke that city required for its steel and iron industry. During the Homestead (Pa.) steel strike of 1892 Frick was shot and stabbed by Alexander Berkman, an anarchist, but survived. He was chairman of the board of Carnegie Brothers (1889–92), and a director of a number of railroads and of U.S. Steel corporation.

Frick died in New York city on Dec. 2, 1919. He left a park to Pittsburgh with an endowment and established the H. C. Frick Educational foundation. He bequeathed his New York town house to that city with numerous paintings, bronzes and enamels. He also endowed many hospitals and educational and charitable institutions. (J. n. 0.)

FRICTION is the resistance which is offered to the sliding of one solid body over another. From earliest times man has made ingenious attempts to diminish it to as small a value as possible. The development of the wheel helped considerably; since rolling friction is less than sliding friction it is easier to pull a cart along the ground than to pull a sledge of the same weight. It is not so much the work done in overcoming the friction—the power loss—which is important, although this can be considerable. In a motor car about 20% of the power is so wasted, in an airplane piston engine about 9% and in a turbojet engine about 1% to 2%. The most important aspect is the damage which is done by friction—the wear or seizure of some vital parts of the machine.

The two main experimental laws which govern the friction of sliding solids are simple. The first states that the friction is independent of the area of the solids. If a brick is pulled along a table the frictional force is the same whether the brick is lying flat or standing on its end. The second law is that the friction is proportional to the load (W) between the surfaces. If the load is doubled by putting a second brick on top of the first, the force required to cause sliding is twice as great. If a pile of three bricks is used the friction would be three times as great and so on. This means that for any particular pair of surfaces, the ratio of

$$\frac{\text{friction } (F)}{\text{load } (W)}$$

is constant and this constant is called the coefficient of friction (μ). In the case of a brick sliding on a clean wooden table, the coefficient of friction (y) is about 0.5 (*i.e.,* a force equal to one-half the weight of the brick is required to pull it along). The coefficient of friction varies widely for different solids. For ice sliding on ice, for example, it is about 0.02, so that a pull equal to about $\frac{1}{50}$ of the weight of the ice block will cause sliding. With copper sliding on copper, the coefficient of friction is about 0.8 to 1.0 and. if the metal is carefully cleaned so that all traces of surface contamination are removed, it may rise to a much higher value still.

These two laws were formulated by Leonardo da Vinci and rediscovered by the French engineer G. Amontons in 1699. Amontons' observations were verified in 1785 by C. A. Coulomb, who made a clear distinction between the static friction (the force required to start sliding) and kinetic friction (the force required to maintain it). He showed that kinetic friction could be appreciably lower than static friction.

Coulomb concluded that friction was due to the interlocking of the surface asperities and represented the work of lifting the load over these asperities. Modern work suggests, however, that it is due primarily to a local adhesion between the surfaces.

Area of **Contact.**—A detailed examination of the contours of solid surfaces by electron microscopy and other delicate methods has shown that it is almost impossible, even with the best modern methods. to make a surface which is truly flat. To a person the size of an atom an optically polished mirror surface would look like country consisting of valleys and rolling hills differing in height by a hundred atoms or more. Most of the engineer's best

FIG. 1.—OBLIQUE SECTION OF FINELY ABRADED STEEL SURFACE. THE SECTION GIVES A VERTICAL MAGNIFICATION OF TEN THOUSAND AND A HORIZONTAL MAGNIFICATION OF ONE THOUSAND

surfaces have irregularities which are much greater than this and may be thousands of atoms high: they may be compared with Alpine peaks rather than hills (see fig. 1). Putting two solids together is rather like turning Switzerland upside down and standing it on Austria, and the area in intimate contact will be relatively small.

Measurements of the electrical conductivity across metal surfaces placed together confirm that the real area of contact is indeed very small. It varies with the load. but for flat steel surfaces it may be less than $\frac{1}{10\,000}$ of the apparent area. Such experiments are also Interesting in that they show that the real area of contact is almost independent of the size of the surface. It is little influenced by the shape and degree of roughness of the surfaces It depends mainly on the load which is applied to them and is in fact directly proportional to the load

The general behaviour is consistent nith the view that the surfaces are held apart by small irregularities. This means that even with lightly loaded surfaces, the local pressure at these small points of contact is very high and may be sufficiently great to cause the hardest metals to flow plastically. Although the stresses will cause elastic deformation of the metal in the vicinity of the points of contact. the experiments suggest that the summits of irregularities on which the bodies are supported flow plastically and are crushed down until their cross section is sufficient to enable them to support the applied load. The real area of contact A is given by

FIG. 2 — OBLIQUE SECTION OF STEEL SURFACE OVER WHICH A COPPER SURFACE HAS SLID ONCE, RESULTING IN A HEAVY PLUCKING OF COPPER (DARK), A FRAGMENT OF WHICH IS ATTACHED TO THE STEEL. THE JUNCTION IS SO STRONG THAT THE COPPER HAS PULLED THE STEEL ABOYE ITS ORIGINAL LEVEL

$A = W/p_m$, where W is the load and p_m is the yield pressure of the metal.

Mechanism of Friction.—There is strong evidence that the friction of metals is due, in large measure! to adhesion at these contact regions and represents the force necessary to shear these small junctions. In addition, if one surface is harder than the other the surface irregularities on the hard surface may plow their way through the softer surface and some of the friction will arise from this. In general the plowing term is small and the shearing term is predominant so that the friction may be written $F = A.s$, where s is the shear strength (per unit area) of the junctions, and A the real area of contact.

This offersa simple explanation of the two laws of friction. (1) Since A the real area of intimate contact is independent of the area of the surfaces, the friction will be independent of it also. (2) Since the real area of contact A is proportional to the load W the friction will be also. The formation and shearing of junctions is a primary cause of wear. If slip were to occur at the interface, wear would be negligibly small. Unfortunately, this is rarely the case—the adhesion at the surface is strong. When shearing takes place it frequently occurs at a small distance from the interface so that a small fragment of one metal is torn away and may be welded onto the other metal (*see* fig. 2). These wear fragments are very small! but may be revealed by making one of the metals radioactive by irradiating it in a pile and using it as a slider. The radioactive fragments adhering to the other surface can then be detected photographically (*see* fig. 3). In a running engine these wear fragments would accumulate in the lubricating oil so that a determination of the radioactivity of the oil can provide a sensitive test of engine wear.

FIG. 3.—AUTORADIOGRAPHIC RECORD OF METALLIC TRANSFER PRODUCED BY SLIDING

A radioactive copper surface with a load of 2 kg. is slid at a low speed over a clean steel surface. A photographic plate is then placed in contact with the steel so that radioactive copper fragments attached to the steel sensitize the photographic emulsion. When developed' an autoradiograph is obtained. The pick-UP consists of small fragments and corresponds to about one-millionth of a gram of copper per centimetre of track

Friction of Nonmetals.—So far the discussion has dealt mainly with metals but the friction of nonmetallic solids is governed by the same general principles. If the solids are deformed plastically (as a metal is) it obeys the same two frictional laws, This is true for the solids popularly known as plastics or polymers (*e.g.*, polymethyl methacrylate, polyethylene or nylon). The coefficientof friction for these solids is in the region of $\mu = 0.3–0.6$. An interesting exception is the solid polytetrafluroethylene (Teflon) which gives a much lower friction $\mu = 0.05–0.1$.

If an elastic solid such as rubber is used the real area of contact is no longer proportional to the load W but to $W^{\frac{2}{3}}$. The coefficient of sliding friction μ should not therefore be constant. It should decrease as the load is increased, and it can be shown that μ should be proportional to $W^{-\frac{1}{3}}$. Experiment confirms this and shows that in addition an appreciable part of the friction is due to elastic hysteresis loss inside the rubber when it is deformed (see *Rolling Friction* below). The friction of wood is also due partly to adhesion at the surface and partly to internal deformation hysteresis loss inside the wood.

Diamond, which is the hardest of solids, is elastically deformed even under the heaviest loads so that its friction also obeys the elastic laws. It is interesting to note that the friction of a diamond crystal depends on the direction of sliding. The crystallographic directions which give the highest friction are those in which the diamond is mostly easily polished or abraded.

The friction of ice ($\mu = 0.02$) is remarkably low and there is evidence that this is due to the presence of a water film at the surface. This may be formed by "pressure melting" if the temperature is close to freezing or by frictional heating if the sliding speed is appreciable. There is evidence that this frictional melting can play an important part in the sliding of skis on snow.

Effect of Surface Films.—It has been assumed that the surfaces dealt with are clean. In fact metal surfaces exposed to the air are always covered with a film of oxide and adsorbed gas or vapour. This may be only a few molecules thick and invisible, but it may have a profound effect on the friction for it can enormously reduce the strength of adhesion at the points of real contact. It is difficult to get rid of these films, but if the metals are put in a vacuum and the last molecular layer is removed, it is found that the friction rises to an enormous value; in fact, complete seizure of the two metal surfaces occurs. It is only when a trace of air or other contaminating material is allowed to enter the apparatus that the friction falls to its usual everyday value. The friction of most nonmetals is also increased if these surface films are removed in a high vacuum.

Temperature of Sliding Surfaces.—Another important factor comes into play when the surfaces slide at an appreciable speed. The work done against friction is dissipated mainly in the form of heat and quite simple calculations suggest that the rise of temperature at the surface may be high. This is confirmed by experiments which show that the tiny points of sliding contact may be red hot or even white hot, although to ordinary observation there is no sign of this and the metal appears quite cool. These high temperatures can cause a local softening or melting at the points of contact of the metal surfaces, even at moderate speeds of sliding. The upper limit of temperature is fixed by the melting point of the metal since the surface temperature will not, in general, rise above this. When metal surfaces are rubbed together at high speeds (1,000 m.p.h. or 2,000 m.p.h.) a thin film of the metal is melted which can act as a lubricant so that the friction falls to a very low value. A shell leaving the muzzle of a gun may rub against the barrel at this speed, but in ordinary engineering the rubbing speeds are, of course, much lower.

These high surface temperatures may also be important in lubrication. At elevated temperatures lubricant films cease to be effective and a temperature flash at a rubbing hot spot may lead to failure of the lubricant precisely at the region where its protective properties are most needed.

Since the major source of friction and wear arises from interaction between the rubbing surfaces, the most effective way of reducing them is to keep the rubbing surfaces apart. The simplest way of doing this is to put a layer of oil or some other fluid between the surfaces. Under appropriate conditions an air or gas film can be used. If the lubricant layer is a thick one the conditions are those of fluid lubrication or a hydrodynamic lubrication. If the lubricant layer is only a few molecules in thickness it is termed boundary lubrication. Boundary lubricated surfaces obey the two frictional laws mentioned above and there is evidence that some metallic or solid contact usually occurs through the boundary films.

See LUBRICATION.

Rolling Friction.—There are two main types of rolling. The first occurs for example when a driving wheel rolls over a road in a motor car or over a rail in a train. Here considerable tangential forces are involved in pulling the vehicle along and the conventional frictional grip between the wheel and the surface is of great importance. There is, however, another type of rolling which involves only a minute tangential traction—this is the type of rolling that occurs when a wheel or a ball or a cylinder rolls freely over another surface. We may call this "free" rolling and its most common application is in ball bearings and roller bearings (*see* BEARINGS). The resistance to rolling in these cases is phenomenally low, corresponding to a coefficient of friction of perhaps less than $\frac{1}{1,000}$. A ball bearing was designed by C. Varlo in 1772.

The source of rolling friction has long been a matter of speculation. The first basic study was by Osbome Reynolds in 1875. He showed that when a metal cylinder rolls over a rubber surface it moves forward a distance less than its circumference in each revolution of the cylinder. This is because the cylinder measures out its circumference over a stretched portion of rubber. Reynolds suggested that this stretching was not uniform over the region of contact so that minute slipping between cylinder and rubber occurs. Another type of microslip, of far greater importance than the Reynolds' slip, occurs when a hard ball rolls in a groove. This was first pointed out by H. L. Heathcoate in 1920 and arises from the fact that the central band on the ball measures out its full circumference in each revolution whereas the bands at the edge of the groove measure out a length smaller than their circumference. Consequently some slip must occur within the ellipse of contact.

Although there is little doubt that both types of slip can occur, D. Tabor has shown that in many cases the friction arising from this is minute and constitutes only a small fraction of the total observed rolling friction. The reason for this is relatively simple. In rolling, any interfacial junctions that are formed are peeled apart, whereas in sliding they must be sheared. The peeling action is a very easy one so that little work is necessary to break the junctions during rolling. Thus interfacial frictional effects are of secondary importance. This is confirmed by the observation that lubricants which greatly reduce the sliding friction have little effect on the rolling friction.

Lubricants may play a useful and important part in reducing surface attrition or wear and it is probable that this is one of their main functions in ball and roller bearings. In addition they help to reduce corrosion and diminish sliding friction between the rolling elements and the cage in the assembled bearing.

The main source of friction in free rolling appears to be due to deformation losses in the rolling materials. If the rolling of a hard sphere over a somewhat softer surface is considered the material ahead of the sphere is deformed elastically, and work is done on it. As the sphere rolls forward the deformed material emerging behind it recovers elastically and urges the ball fonvard. If the material were ideally elastic the energy restored as the material recovered behind the ball would be exactly equal to the energy stored in the front region and no net force would be required to roll the ball.

However, in practice all solids lose some energy when they are deformed elastically. This effect is known as internal friction or elastic hysteresis. It is this loss which is reflected in the work required to roll the ball along. Hysteretic properties vary enormously and there is a corresponding variation in rolling resistance. Some types of rubber which are "soggy" or "dead" have high hysteresis losses and with these materials the free rolling friction may be relatively large. Even so the rolling friction will be much less than the sliding friction. On the other hand, with hard steels, such as those used in ball bearings, the elastic hysteresis losses are small and the rolling friction is correspondingly low. In ball and roller bearings these hysteretic losses are not only important in determining the rolling friction but they are also closely associated with the fatigue life of the bearing material. As seen above the elastic hysteresis loss can also play a part in sliding friction if the solid is deformed by the sliding process.

FRIED, ALFRED HERMANN (1864–1921), Austrian writer and leader of the peace movement, was born in Vienna, Nov. 11, 1864. After a brief career as bookseller and publisher in Berlin, he dedicated himself in 1891 to the propagation of peace and became in 1894 a free-lance journalist and writer. He founded a number of periodicals concerned with international understanding and interstate organization. The aim of the peace movement he led was not merely to condemn war but to spread the understanding of the process of interstate organization, which he defined as voluntary co-operation between independent states for the realization of common purposes.

Fried's contributions to peace were recognized by the award of the Nobel peace prize in 1911, which he shared with Tobias Asser. During World War I he lived in exile in Switzerland. He died at Vienna on May 4, 1921. (L. Gs.; X.)

FRIEDEL, CHARLES (1832–1899), French chemist and mineralogist, best known as a co-discoverer of the chemical process known as the Friedel-Crafts reaction *(q.v.),* was born at Strasbourg on March 12.1832. In 1854 he entered C. A. Wurtz's laboratory, and in 1856 was appointed conservator of the mineralogical collections at the École des Mines. In 1871 he began to lecture at the École Normale, and in 1876 he became professor of mineralogy at the Sorbonne, but on the death of Wurtz in 1884 he exchanged that position for the chair of organic chemistry. He died at Montauban on April 20, 1899. Friedel worked both in mineralogy and organic chemistry. He collaborated from 1879 to 1887 with Émile Edmond Sarasin (1843–90) on the formation of minerals by artificial means. He also devoted much attention to the pyroelectric phenomena of crystals, to the determination of crystallographic constants, and to the study of the ketones and aldehydes. Friedel was associated with Wurtz in editing the latter's *Dictionnaire de chimie,* and undertook the supervision of the supplements issued after 1884. He was the chief founder of the *Revue générale de chimie* in 1899. His publications include a *Notice sur la vie et les travaux de Wurtz* (1885), *Cours de chimie organique* (1887) and *Cours de minéralogie* (1893).

FRIEDEL-CRAFTS REACTION. The reaction is commonly considered as the process of uniting two or more organic molecules through the formation of carbon-to-carbon bonds under the influence of certain strongly-acidic metal halide catalysts, such as aluminum chloride, boron fluoride, ferric chloride, zinc chloride, etc. The useful applications of the reaction include such typical examples as aromatic alkylation *(e.g.,* the formation of cumene from benzene and isopropyl chloride), aromatic acylation *(e.g.,* the formation of acetophenone from benzene and acetyl chloride), aliphatic alkylations *(e.g.,* the formation of isooctane from isobutane and isobutylene) and polymerizations *(e.g.,* the formation of butyl rubber from isobutylene and isoprene), all effectively catalyzed by aluminum chloride.

The Friedel-Crafts reaction was discovered in 1877 by Charles Friedel and James Mason Crafts, working at the Sorbonne in Paris. In the amazingly short period of six weeks, they proceeded from the observation of a vigorous reaction between amyl chloride and aluminum foil to a remarkably clear definition of the scope of aluminum chloride and similar metal halides as catalysts for alkylation, acylation, polymerization and cracking. The typical reactions catalyzed by aluminum chloride, which they reported in a series of publications in 1877 and subsequently, and which now bear the general name of Friedel-Crafts reactions, have proven to be among the most versatile and useful reactions in all of organic chemistry.

One indication of the scope and utility of the reaction is the fact that a definitive monograph on the subject, appearing in 1941, encompassed 963 pages (Charles Allen Thomas, *Anhydrous Aluminum Chloride in Organic Chemistry,* American Chemical

Society Monograph no. 87). Investigations of extensions and applications of the Friedel-Crafts reaction have been the subject of literally thousands of scientific publications and patents since 1877.

Aromatic **Alkylation.**—Among the earliest examples of the Friedel-Crafts reaction, reported in the original papers in 1877, were cases of alkylation of benzene to give toluene, ethylbenzene and amylbenzene. Perhaps the most useful applications of this reaction are in the large-scale commercial preparation of ethylbenzene and cumene (isopropylbenzene).

$$\underset{\text{benzene}}{C_6H_6} + \underset{\text{ethyl chloride}}{CH_3CH_2Cl} \xrightarrow{AlCl_3} \underset{\text{ethylbenzene}}{C_6H_5CH_2CH_3} + HCl$$

$$\underset{\text{benzene}}{C_6H_6} + \underset{\text{isopropyl chloride}}{(CH_3)_2CHCl} \xrightarrow{AlCl_3} \underset{\text{cumene}}{C_6H_5CH(CH_3)_2} + HCl$$

In each instance only small amounts of aluminum chloride are required. The reaction may be conveniently carried out either by mixing the benzene and organic chloride and then adding the aluminum chloride portionwise, or by mixing the benzene and aluminum chloride and then adding the organic chloride portionwise. The reactions proceed vigorously at room temperature or slightly above.

The above organic chlorides are prepared commercially by the addition of hydrogen chloride to ethylene and propylene, and, in fact, the Friedel-Crafts reactions are frequently carried out directly on the olefin.

$$\underset{\text{ethylene}}{CH_2 = CH_2} + HCl \longrightarrow \underset{\text{ethyl chloride}}{CH_3CH_2Cl}$$

$$C_6H_6 + CH_2 = CH_2 \xrightarrow{AlCl_3} C_6H_5CH_2CH_3$$

$$C_6H_6 + \underset{\text{propylene}}{CH_2 = CHCH_3} \xrightarrow{AlCl_3} C_6H_5CH(CH_3)_2$$

One of the major modifications of the Friedel-Crafts reaction, not encompassed in the original publications, is the use of sulphuric acid in place of aluminum chloride. Thus, the reaction of propylene (or isopropyl alcohol) with benzene in the presence of concentrated sulphuric acid produces cumene.

$$C_6H_6 + CH_2 = CHCH_3 \xrightarrow{H_2SO_4} C_6H_5CH(CH_3)_2$$

$$C_6H_6 + \underset{\text{isopropyl alcohol}}{(CH_3)_2CHOH} \xrightarrow{H_2SO_4} C_6H_5CH(CH_3)_2$$

Because of the similarity of the action of sulphuric acid to that of the metal halides originally discovered by Friedel and Crafts, this modification is frequently referred to as a reaction of the Friedel-Crafts type.

Ethylbenzene is prepared commercially by the syntheses outlined above on a large scale for dehydrogenation to styrene, a component of GRS synthetic rubber and "Styron" and related plastics.

$$C_6H_5CH_2CH_3 \xrightarrow{\text{catalyst}} \underset{\text{styrene}}{C_6H_5CH = CH_2} + Hz$$

Cumene was prepared in large amounts during World War II as a component of high test aviation fuels and is the starting point for an economical synthesis of phenol and acetone.

$$\underset{\text{cumene}}{C_6H_5CH(CH_3)_2} \xrightarrow{O_2} \underset{\text{hydroperoxide}}{C_6H_5\underset{OOH}{\underset{|}{C}}(CH_3)_2} \xrightarrow[\text{or } HCl]{AlCl_3} \underset{\text{phenol}}{C_6H_5OH} + \underset{\text{acetone}}{(CH_3)_2C = O}$$

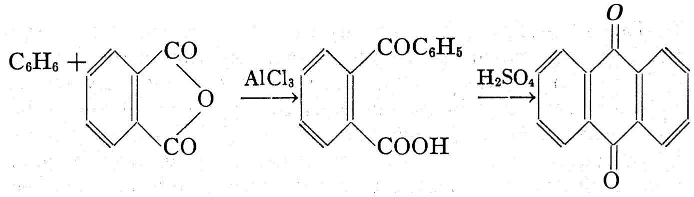
The intermediate, cumene hydroperoxide, also is utilized as a catalyst in the production of GRS synthetic rubber.

Aromatic **Acylation.**—When acyl halides are substituted for alkyl halides in the Friedel-Crafts reaction, ketones are produced in good yield.

$$C_6H_6 + CH_3\overset{O}{\overset{\|}{C}}-Cl \xrightarrow{AlCl_3} C_6H_5\underset{CH_3}{\underset{|}{C}} = O\cdot AlCl_3 \xrightarrow{H_2O} \underset{\text{acetophenone}}{C_6H_5\overset{O}{\overset{\|}{C}}CH_3}$$

In this application, it is found that the ketones which are produced form a molecular compound with the aluminum chloride, necessitating the use of one molecular equivalent of the aluminum halide. This complex must be hydrolyzed by water to recover the ketone produced. Acetophenone is a useful article of commerce, finding particular application in the perfume industry.

Acid anhydrides also undergo the Friedel-Crafts reaction. A particularly useful example is that of phthalic anhydride.



phthalic anhydride o-benzoylbenzoic acid anthraquinone

Anthroquinone is produced synthetically in this way for use as a useful intermediate in the dye industry.

Aliphatic **Alkylation.**—Although the very first observation of Friedel and Crafts concerned the action of aluminum on a simple alkyl halide, useful application of the Friedel-Crafts reaction to nonaromatic systems was delayed nearly 50 years. By mid-20th century the application to petroleum reactions was perhaps the most important volume use of the Friedel-Crafts catalysts. One example was the condensation of two olefin molecules.

$$2CH_2 = C(CH_3)_2 \xrightarrow[\text{or } H_2SO_4]{AlCl_3} \underset{\text{diisobutylene}}{(CH_3)_3CCH = C\begin{matrix} CH_3 \\ CH_3 \end{matrix}} \xrightarrow{H_2}$$

$$\underset{\text{isooctane}}{(CH_3)_3CCH_2CH(CH_3)_2}$$

Isooctane, the standard for high-test antiknock gasoline, was once made industrially by the above procedure. In the 1950s it was made by direct reaction of isobutylene with isobutane.

$$(CH_3)_3CH + CH_2 = C(CH_3)_2 \xrightarrow[\text{or } H_2SO_4]{AlCl_3} (CH_3)_3CCH_2CH(CH_3)_2$$

The reverse of the above reaction, the "cracking" of large, saturated molecules in the presence of Friedel-Crafts catalysts, is also an extremely important reaction in petroleum refining.

Polymerization.— One other important reaction catalyzed by aluminum chloride, and recognized in the original work of Friedel-Crafts. is polymerization. The most important commercial application has been in the conversion of isobutylene to high molecular weight polymers.

$$CH_2 = \underset{CH_3}{\underset{|}{\overset{CH_3}{\overset{|}{C}}}} \xrightarrow[-80^\circ]{AlCl_3} -CH_2\underset{CH_3}{\underset{|}{\overset{CH_3}{\overset{|}{C}}}} - \left(CH_2\underset{CH_3}{\underset{|}{\overset{CH_3}{\overset{|}{C}}}} \right)_n - CH_2\underset{CH_3}{\underset{|}{\overset{CH_3}{\overset{|}{C}}}} -$$

For moderate values of n, these materials are widely used to improve the viscosity characteristics of motor oil. By incorporating minor amounts (1%) of isoprene in the formulation, and carrying the polymerization to values of n in excess of 1,000, one obtains butyl rubber, from which highest quality automobile inner tubes are made.

FRIEDJUNG, HEINRICH (1851–1920), Austrian historian, who combined historical studies with a keen interest in politics and whose reputation as a historian suffered because of his political views and his involvement in a sensational trial. He was born at Rostin, Moravia, Jan. 18, 1851, of Jewish parents. He studied at Prague, Berlin and Vienna, was at the Institut fur Österreichische Geschichtsforschung (1871–75) and taught at the Handelsakademie in Vienna (1873–79). Friedjung favoured strengthening the German character of Austria and wanted close economic connection between the two countries; he was thus unsympathetic to Slav and Magyar nationalist movements in the dual monarchy. He also wanted a centralized and liberal government. His *Der Ausgleich mit Ungarn* (1877), based on these views, led to dismissal from the Handelsakademie. He then became a political journalist. associated with the nationalist Georg von Schönerer until Schonerer's anti-Semitism made Friedjung break away.

Despite editorship of the *Deutsche Wochenschrift* (1883–86) and the *Deutsche Zeitung* (1886–87), in which he expressed his German nationalist views, Friedjung found time for historical studies. His chief historical work is *Der Kampf um die Vorherrschaft in Deutschland* (1897–98; 10th ed., 1916–17). *Das Zeitalter des Imperialismus, 1884–1914* (1919–22), unfinished at his death, was completed by A. F. Pribram, but was soon superseded by publication of important documents. His other works, dealing mainly with the period 1848–66, include *Österreich von 1848–60* (1908–12), also unfinished.

During the Bosnian crisis of 1909, Friedjung published an article based on documents supplied by the Austrian foreign office accusing leaders of the Serbo-Croat movement of treasonable practices. The men attacked sued Friedjung and the trial that followed showed that the documents were forgeries. Friedjung had used them in good faith but without adequate scrutiny and his reputation as an historian suffered. He died in Vienna, July 14, 1920.

See H. von Srbik in *Deutsches Biographisches Jahrbuch* (1917–20).

FRIEDLAND (Russian PRAVDINSK), a town of former East Prussia, after 1945 in the U.S.S.R., on the Alle, 27 mi. S.E. of Kaliningrad (Königsberg), famous as the scene of the battle fought between the French under Napoleon and the Russians commanded by Gen. Levin Bennigsen, on June 14, 1807 *(see* NAPOLEONIC CAMPAIGNS). The Russians had on June 13 driven the French cavalry outposts from Friedland to the westward, and began to occupy the town in the night.

The army of Napoleon was set in motion for Friedland, and the corps of Marshal Jean Lannes as general advanced guard was first engaged in front of Posthenen (2:30–3 A.M. on June 14).

After more than 1j hours of fighting, the more mobile French forced the Russian defenders into a congested area with their backs to the Alle river. The French guns were then brought up and a withering fire of case shot was poured into the massed enemy. It was the first example of the terrible artillery preparations of modern warfare, and the Russian defense collapsed in a few minutes.

The losses incurred by the Russians in retreating over the river at Friedland were very heavy, many soldiers being drowned. The losses of the French were reckoned at 12,100 out of 86,000, or 14%, those of the Russians at 10,000 out of 46,000, or 21%.

FRIEDRICH, CASPAR DAVID (1774–1840), German landscape painter and engraver of the romantic school, was born at Greifswald on Sept. 5, 1774. He studied under J. G. Quistorp, the university drawing master of his native town, and from 1794 to 1798 at the academy in Copenhagen. He then settled at Dresden, where he was a member of an artistic and literary circle of friends, which included Philip Otto Runge, Ludwig Tieck and Novalis. His drawings in sepia, executed in his neat early style, won Johann Goethe's approval and a prize from a Weimar art society in 1805. His first important oil painting, dated 1807, was an altarpiece for the castle of Graf Thun in Teschen, representing a "Crucifix in Mountain Scenery." Other notable works were the "Graveyard in Snow" (1810), "Alpine Scenery" (1828), "Two Men Contemplating the Moon" (1819) and "Rest in a Hayfield" (1835). In 1824 he was made professor of the Dresden academy. He died May 7. 1840, at Dresden. For a long time his work was forgotten; but it was revived in 1906 in a Berlin exhibition. His influence made itself felt in the work of his pupils and friends, K. G. Carus, G. Kersting, K. F. Lessing, F. Olivier, E. Öhme, the Norwegian J. K. C. Dahl and others.

FRIEDRICHSHAFEN, a town of Germany, in the *Land* of Baden-Württemberg on the east shore of Lake Constance, at the junction of railways to Bretten and Lindau. Pop. (1950) 20.501. It consists of the former imperial town of Buchhorn and the monastery and village of Hofen. Buchhorn is mentioned (as Buachihorn or Puchihorn) in documents of 837, and in the 12th century passed through the hands of the Welfs to the Hohenstaufen.

In 1275 it was made a free imperial city by King Rudolph I. In 1802 it was assigned to Bavaria, and in 1810 to Wiirttemberg. The monastery of Hofen was founded in 1050 as a convent of Benedictine nuns, but was changed in 1420 into a provostship of monks, was suppressed in 1802, and in 1805 came to Wiirttemberg. King Frederick I, who caused the harbour to be made, amalgamated Buchhorn and Hofen under the new name of Friedrichshafen.

Zeppelins were built there before World War II. Other industries established there include motor cars, tanning and aeroplanes. The town was bombed during World War II.

FRIENDLY SOCIETY, in British usage, a mutual association whose chief purpose is to provide its members with money allowances during incapacity for work resulting from sickness or infirmity, and with money payments on the death of a member or of his wife. Many societies also provide other benefits or services for their members. In addition a number of societies exist, known as collecting friendly societies, which have a large aggregate membership. The facts that their contributions are collected by agents at the houses of members, and that in Great Britain they are subject to the Industrial Assurance act, 1923, distinguish these societies from the ordinary friendly society, with which alone the present article is concerned.

By the National Insurance act, 1911, the friendly societies in Great Britain became associated with the administration of national health insurance. A friendly society could, under that act, become an "approved society" for national health insurance and at the same time carry on its wholly voluntary operations as a friendly society. This arrangement was terminated by the National Insurance act, 1946, which came into force in July 1948. The friendly societies then ceased to be concerned with national insurance.

The Friendly Societies act, 1896, described them as organizations whose purpose was to provide, by voluntary subscriptions, their members, with or without the aid of donations, for:

1. The relief or maintenance of the members, their husbands, wives, children, fathers, mothers, brothers or sisters, nephews or nieces, or wards being orphans, during sickness or other infirmity, whether bodily or mental, in old age (which shall mean any age after 50) or in widowhood, or for the relief or maintenance of the orphan children of members during minority; or
2. Insuring money to be paid on the birth of a member's child, or on the death of a member, or for the funeral expenses of the husband, wife or child of a member, or of the widow of a deceased member, or, as respects persons of the Jewish persuasion, for the payment of a sum of money during the period of confined mourning; or
3. The relief or maintenance of the members when on travel in search of employment, or when in distressed circumstances, or in case of shipwreck or loss or damage of or to boats or nets; or
4. The endowment of members or nominees of members at any age; or
5. The insurance against fire, to any amount not exceeding £15, of the tools or implements of the trade or calling of the members; or
6. Guaranteeing the performance of their duties by officers and servants of the society or any branch thereof;

Provided that a friendly society which contracts with any person for the assurance of an annuity exceeding £104 per annum, or of a gross sum exceeding £500, shall not be registered under this act.

These objects were widened by the Friendly Societies act, 1955, which among other things gave to any registered friendly society the power to lend funds, in certain circumstances, to other friendly societies, to invest funds in housing associations and to offer new forms of benefit, such as marriage endowments.

History. — Sickness and death benefit societies existed in early times. Burial societies and guilds of working and professional people which provided death benefits were common in Rome and the provinces of the Roman empire (see M. I. Rostovtsev, Social and Economic History of the Roman Empire, p. 178). In Great Britain similar functions were included in the objects of medieval guilds, from which the modern friendly society movement may be descended, though no definite historical links have apparently been traced.

A few societies still existing in Britain at mid-20th century were founded before the end of the 17th century; but during the 18th the system became widely established and considerable literature exists on the subject dating from the latter years of the 18th century. Thus Sir F. M. Eden's Observations on Friendly Societies for Maintenance of the Industrious Classes During Sickness, Infirmity, Old Age and Other Exigencies (published in 1801) referred to returns obtained for more than 5,000 societies enrolled under the act of 1793 (the first general statute relating to friendly societies). He concluded that the total number of societies then in existence was about 7,200. But many of them were financially unsound and much of the literature referred to (which included several reports of committees of the house of commons) was highly critical of them.

Most of these societies were purely local, drawing their membership from a single village or a restricted area in a town. But two other types of society began to develop in the early years of the 19th century. One was the so-called "county" friendly society, promoted by the rural gentry and clergy (the clergy were also active in the promotion of village friendly societies). This type was generally run on sounder financial principles than the local societies and covered a wider area, generally the greater part of a county. Several still existed at mid-20th century.

Much more important was the rise of the orders. Little is known about their origins, but it is probable that they began to take shape in the second half of the 18th century as offsprings of freemasonry, whose ceremonial and fraternal aims they imitated. One of the earliest was the Independent United Order of Mechanics, established in 1756 or 1757. The United Ancient Order of Druids was established in 1781.

Earlier than either were the Oddfellows, of which a lodge is known to have been in existence in 1745. This was the ancestor of many existing orders calling themselves Oddfellows, of which the largest is the Independent Order of Oddfellows, Manchester Unity. This order was established in 1813 and spread rapidly first through the industrial north of England and then through the whole country. In the late 1940s it had more than 4,000 branches with over 750,000 members in Great Britain, and many others elsewhere. Of the other large orders, the Ancient Order of Foresters was established in 1834, the Independent Order of Rechabites in 1835 and the Loyal Order of Ancient Shepherds, Ashton Unity, in 1826.

During the middle and latter part of the 19th century the orders were the most important, indeed the typical form of British friendly society. Their ceremonial and their fraternal aspirations made them social and convivial bodies meeting a need which was not otherwise well met for the lower middle class and the artisans who comprised the membership. Furthermore, they were, on the whole, much better administered and financially sounder than were the small local societies, because of the supervision which could be exercised over the branches by the headquarters of the order. Indeed, the Independent Order of Oddfellows, Manchester Unity, led the friendly societies in submitting itself to an actuarial valuation.

During the latter half of the 19th century, however, other varieties, which unlike the orders were essentially centralized, came into greater prominence. Thus there was the large centralized accumulating type, of which a leading example is the Hearts of Oak Benefit society. Founded in 1842, it met with early and continued success and by 1872 its membership had grown to 32,000; in the late 1950s it was more than 500,000.

The deposit societies form another group which came into prominence in the 1860s and 1870s and has achieved a continued success. The leading example, the National Deposit Friendly society, was established in 1868. By 1899 its membership numbered 46,000; in the latter 1950s it was more than 650,000.

Types of Society. — Like other English institutions, friendly societies sprang from insignificant origins and developed in a great measure independently of one another. Consequently a great variety of practice arose among them, rendering a simple classification impossible. At least three separate and overlapping classifications must be made:

General and Specialized Societies. — The typical friendly society is one assuring payments to the member during incapacity for work due to sickness, together with a lump sum on the death of the member or of his wife. The sickness benefit is generally from 10s. to 20s. a week, although many of the larger societies have introduced higher rates of contribution and benefit which members may take at their option. Sickness benefit at the full rate is usually payable for 26 or 52 weeks, after which, if incapacity still continues, it is reduced by one half. Sometimes, after a similar period, there is a further reduction. In most societies, the premiums are graduated according to age at entry in accordance with actuarial tables.

The great bulk of friendly societies offer these assurances and many provide nothing else. But in addition to these, many societies exist which have more specialized objects. These include societies offering medical or institutional treatment only, societies assuring endowments or annuities and pensions, societies for widows and orphans and a considerable number of small burial societies.

Centralized Societies and Societies With Branches. — Many friendly societies, including some very large ones, consist of a head office only, or of a head office with a number of local agencies. These agencies do not maintain any separate funds and usually have little or no control over their finances. In contrast to these there are the societies with branches, or, as they are also called, the affiliated orders. An order consists essentially of a number of local branches, all more or less closely linked by common traditions and all subject to the general rules of the order and to the central governing body. The local branch, which is called the lodge in the Oddfellows, the court in the Foresters and by other names in other orders, is the link with the individual member. He joins the branch, pays his contribution to its funds and out of its funds, as a rule, his benefits are provided. But the branches are, at any rate with the larger orders, grouped in districts on a geographical basis.

Above the district is the central authority of the order. Every branch is subject to the general rules of the order and though it has its own rules these must comply with the rules of the superior body. Branches are likewise subject to the district under which they are grouped and districts are subject to the central authority.

Often, too, districts will reinsure certain benefits in order to protect the financial stability of branches. But each branch and district must be separately registered under the act, if the order of which it is a branch is registered. If the order is unregistered no subsidiary may be registered as a branch, though it can be registered as a separate society. The domestic affairs of the branch are legally subject to the control of its own elected committee of management. The branch elects its delegates to the district meeting, at which the district committee of management is elected, and districts appoint representatives to the annual meeting of the order, at which the committee of management of the whole order is elected. Thus the typical order combines a close connection with the individual members with much of the financial stability typical of a large insurance society.

Accumulating Societies and Societies With Dividend. — This basis of classification cuts across the preceding. Thus some centralized societies are accumulating societies, while others are societies giving a dividend. Societies of the accumulating type make provision for the increasing liability to sickness as age advances by fixing the premiums for lower age groups at a figure somewhat higher than is necessary to cover the estimated sickness claims at those ages and to accumulate the surplus to form a reserve to meet sickness claims of higher age groups.

On the other hand, societies with dividend depart from this orthodox practice. In this class there are three main subdivisions, generally called "deposit," "Holloway" and "dividing" societies. All three combine some kind of savings system with the ordinary insurance. Under the deposit plan, which enjoys the widest popularity, the members are in general required to contribute monthly an amount equal to what they desire to receive daily in sickness benefit. Thus a contribution of 2*s.* a month is payable in respect of a sickness benefit of 12*s.* a week. Part of the contribution so paid is put to the member's personal savings on deposit account, part to the common fund for sickness benefit; the governing body of the society fixes the proportions in which the contributions shall be divided, but normally the proportion allocated to the deposit is considerable. Whatever sick benefit a member may claim is drawn in part from the common fund and in part from his deposit.

If, as a result. his deposit becomes exhausted, sick benefit ends and is replaced by "grace pay" at a lower rate for a limited period, but no member is allowed to resort to "grace pay" more than once in five years. If the member's deposit account is not exhausted, he may draw upon it, subject to certain restrictions, as if it were a savings bank account. He has also the option of making extra deposits to it.

The second class of society with dividend, known as Holloway societies because the idea originated with George Holloway, later member of parliament for Stroud, Gloucestershire, came into existence about 1874. These societies also achieved considerable popularity.

The principle of this system was to require a high contribution, relative to the insurance value of the benefits offered and to increase it as the member passes from age to age between 30 and 65, when sickness benefit terminates; the object of this condition is to provide, in the absence of specific reserves for sickness benefit, for the growing liability the member brings as his age increases. The claims of each year constitute a first charge on the contribution income of the year and in normal circumstances are wholly met from this source, there being no recourse to the personal account of a member in respect of his own demands for sickness benefit and no limitation on the amount of benefit that he may draw, such as the deposit system involves. The balance of the income of each year, after meeting sickness claims, is divided among the members and credited to their personal accounts.

The third type of society with dividend is known as the dividing society. Among registered friendly societies this class was declining in importance by mid-20th century. In the dividing society the member pays a periodical subscription, the rate of which, like the rates of benefit, is usually fixed arbitrarily. After payment of benefits, the surplus on the year's working, or a large part of it, is distributed as a cash dividend to members. In "slate clubs" members pay small sums periodically toward accumulating a fund to be shared out at a special time (*e.g.*, at Christmas).

Legislation. — Numerous acts of parliament for the encouragement and regulation of friendly societies were passed between 1793 and 1895, but practically everything of permanent value in these measures was incorporated in the Friendly Societies act, 1896. The latter act is administered by the Registry of Friendly Societies at the head of which is the chief registrar, who, by the statute (as amended by the Friendly Societies act, 1924), must be a barrister of 12 years' standing or have been an assistant registrar for at least five years. The privileges which the act confers are restricted to those societies which register under it, and most, though not all, of the conditions which it imposes apply to these societies only. Unregistered friendly societies are subject, of course, to common law, but the registry office exercises no functions in regard to them. The privileges of registration apply to workingmen's clubs and to societies operating under special authorities as well as to friendly societies.

The condition of registration is the adoption of rules providing, among other things, for the following matters:

The objects of the society, which must be chosen from among the objects specified in the act; terms of admission of members; conditions entitling a member to benefit; mode of holding meetings and right of voting; manner of making, altering or rescinding rules; appointment and removal of trustees, committee of management and other officers; provision, if the society is one with branches, for the composition of the central body and the conditions under which a branch may secede from the society; investment of funds; keeping of accounts and audit thereof; annual returns to registrar; manner of settling disputes (decisions arrived at in accordance with the rules are binding, are not removable into any court of law and may be enforced on application by the county court); provision for expenses of management; and quinquennial valuation.

The rules set out the conditions of the contract which the members of a friendly society make with one another and of the remedies which the law provides to secure its fulfillment. But, although the society must state in its rules what are its benefits and the conditions under which they are payable, few conditions are imposed upon it. Thus there is no compulsion to adopt an actuarially sound table of contributions. except for the insurance of annuities.

Again, while every society is compelled to submit its accounts to an annual audit and to submit its financial position to valuation at quinquennial intervals (unless exempted by the registrar on the ground that valuation is inapplicable to its undertakings), there is no compulsion on the members to employ professionally qualified actuaries (though nearly all societies do so) or to take steps to rectify any unsoundness which the valuation may reveal. The registrar may do (and does) much, through the influence which his position enables him to exercise, to ensure that societies are run on sound lines, but he has no power to order an inquiry into a society's affairs except on the application of a specified proportion of the members as laid down in the act.

The more important privileges attaching to a registered friendly society are:

It can legally hold land and other property in the names of its trustees. It also has various privileges in respect of the transference of property from one trustee to another.

It is exempt from income tax, corporation property duty and stamp duty on certain kinds of documents

Disputes with the society can be settled in any manner for which the rules provide, thus avoiding the cost of litigation.

The period from 1910 to World War II saw great changes in the friendly societies, largely because of the advent of national insurance, with the administration of which they were closely concerned until 1948. In 1910 the number of societies (including branches of orders) was 26,877, but membership was only 6,637,000 and funds £49,802,000. In 1945 societies numbered about 18,000, but membership was over 8,700,000 and funds over £200,000,000. Sickness benefits amounted to about £5,000,000 and death benefits to about £2,000,000 annually.

After 1945, numbers of societies and of members progressively declined. This decline was attributable largely to the comprehensive national social security schemes instituted shortly after World War II. These, together with full employment and the rise in money incomes, made the old friendly society schemes of insurance less attractive. Experience of the period 1948-54 suggested that the stronger friendly societies would develop new kinds of business, including endowments and perhaps those objects permitted them by the act of 1955 (see above).

Commonwealth and Other Countries. — In the dominions settled from England, friendly societies are similar to the English in their structure; many are branches of English orders. In Australia there is a Friendly Societies act for each state, with a registrar to administer it. All societies must be registered and submit annual returns to the registrar. From the returns available in 1950 (which referred to different years in the different states) it appeared that there were more than 200 societies and 5,800 branches, having more than 600,000 members.

In New Zealand there is a Friendly Societies act providing for the compulsory registration of societies, of which there were about 1.000, with 90,000 members. In South Africa there is no general Friendly Societies act. but more than 100 societies were listed, with some 300,000 members.

UNITED STATES

The term "friendly societies" has never gained currency in the United States, but it may be used here to describe a group of more than 100 U.S. fraternal insurance bodies organized around a system of financial benefits for members. Often these bodies are embellished by ritualistic features, but fraternal insurance is their mainstay. Thus the groups. analogous to the friendly societies of Great Britain, remain distinct from many larger familiar orders. such as the Masons, which exist primarily for social reasons and offer financial benefits, if at all, only incidentally. The insurance societies are organized around a co-ordinating agency known as the National Fraternal Congress of America.

In spite of the background afforded by the friendly societies of Great Britain, founders of the United States system of benefit insurance were ignorant of British prototypes. It was not until after the middle of the 19th century that fraternal insurance orders began to proliferate in the United States. There had been earlier societies, among them the Improved Order of Red Men, established in 1833. But fraternal insurance as a movement dates from the work of John Jordan Upchurch, who organized in 1868 the Ancient Order of United Workmen. The A.O.U.W. grew rapidly and was followed by numerous other insurance societies. So popular was the movement that some of the older orders followed suit and for a time added benefit features of their own. By 1905 there were 148 national benefit orders with almost 5,000,000 members carrying insurance of $6,500,000,000.

Some of these societies fell by the wayside; members were often admitted without proper reference to age or health. Even so, the societies made remarkable adjustments by lowering benefits and increasing rates, so that they became a solid feature of United States business. Not one of the fraternal insurance societies collapsed under the pressures of 1933. By mid-20th century new fraternal insurance was being written at the rate of $1,000,000.000 annually. Membership amounted to 7,500,000, and the societies were paying out more than $100,000,000 each year in benefits. Low costs in management and in the writing of policies were factors in the financial success of the societies. Though appearing exclusive, many conducted vigorous membership campaigns.

Among the leading fraternal insurance societies at mid-20th century were the Fraternal Order of Eagles, with more than 1,300.000 members; Loyal Order of Moose, more than 900,000; and Modern Woodmen of America and Woodmen of the World, each with more than 400,000 members.

For a more complete discussion of fraternal organizations, the name by which friendly societies are known in the United States, see FRATERNAL ORGANIZATION.

FRIENDS, SOCIETY OF, a body of Christians commonly called Quakers, originating in 17th-century England, whose members are found in small numbers in many parts of the world. Their distinctive character arises from emphasis on a measure of God's spirit being given to all men and women. which issues in a church order based on the priesthood of all believers, and a social outlook based on the sacredness of every personality. This article summarizes their history, surveys their faith and practice in the middle of the 20th century and concludes by considering the specific activities of the U.S. branch.

HISTORY

The 17th Century. — George Fox (*q.v.*; 1624–91), the founder of the society, was the son of a Leicestershire weaver. He mas brought up within the Puritan wing of the Church of England. After a long period of seeking within and without the Anglican Church, he had a vivid inward personal experience of 'God, and began a public ministry directing people inwardly to the Spirit of Christ and asserting that God's grace is given freely to every man. This twofold message came as a release to many who were finding the elaborate doctrinal structure of contemporary Calvinism feeding their minds but not their spirits, and to whom a doctrine of potential universal salvation was in joyful contrast with the doctrines of election and reprobation. Though he did not originally intend to establish another denomination. Fox's message attracted large numbers who met together for worship and soon created a church life.

The early Friends quickly found a unity of fellowship, belief and practice, which led to testimony in word and deed. Their basic belief was in the Light of Christ in every man. This led in worship to abandoning a separate ordained ministry and to meeting in unprogrammed silent worship in which anyone, man or woman, could take vocal part. They accepted the Bible as inspired by God, but declared that it was, in the words of Robert Barclay (*q.v.*; 1648–go), their best-known apologist, "a secondary rule. subordinate to the Spirit," and that it must be interpreted in the light of the Spirit of God. Their belief in the Light of Christ in every man, confirmed by their reading of the New Testament. led them to Christian pacifism. They refused to take oaths because they mere forbidden by the New Testament. Their belief in the sacredness of personality led them to refuse conventions which differentiated between superior and inferior "classes," and they accordingly refused to give "hat honour" to the upper class and to address them with the plural pronouns while reserving the singular form for equals or inferiors. This led to the retention of "thou" and "thee" by Friends long after they had lapsed from common social usage. They testified to simplicity (but not to asceticism) in putting first things first, and this led *inter* alia to a testimony against "the changeable nature of vain fashions"; and so, as fashions changed, the Quaker costume remained the same and became unintentionally a distinctive uniform. They were as much concerned with social righteousness as with personal piety. and George Fox was but the first of a long line of Quaker social reformers. At the end of the 17th and early in the 18th century, John Bellers (1654–1725) was the outstanding example in this field.

Friends came into sharp opposition with church and state. With the former, there were doctrinal controversies; but in particular the Friends' testimony against what they called "a hireling ministry" aroused violent opposition. After the restoration of Charles II in 1660, a series of laws against nonconformity led to serious conflict between Friends and the state, particularly over freedom to worship, freedom from oaths, tithes and military service and, to a lesser extent, freedom to teach. The consequent persecution led to something like 15,000 Friends' suffering various legal sentences before 1689, many of them many times; and 450 are known to have died in prison. Their steady open defiance of the Conventicle acts in particular, even meeting to worship in the street if the soldiers had locked them out of their meeting rooms, was a powerful influence leading to the Toleration act of 1689, and their persistent refusal to take judicial oaths led to the Affirmation act of 1696.

By the end of the 17th century there were probably 50,000 Friends in Great Britain and a similar number in the West Indies and other American colonies, with small groups in Ireland, Holland. Germany and Danzig.

The 18th Century.— The Toleration act of 1689 put an end to the worst suffering of Friends in Great Britain and legalized their way of worship. But the Test and Corporation acts remained, virtually excluding nonconformists from sharing in parliamentary and local government; and Oxford and Cambridge universities had no room for dissenters until 1871. Consequently Friends were debarred from a number of professions and were primarily found in industrial and commercial enterprise, where they played a very important role in Great Britain, particularly in banking and in the iron industry. In their religious thinking they were quietistic, and much of their energy was directed to maintaining the purity of their own witness rather than to evangelizing the world. They became traditionalist, so that, for example, a positive testimony for simplicity was then expressed in a complex series of prohibitions and in the manufacture of dress to conform with an outmoded fashion. Numbers declined in Europe though they increased in America.

The testimonies of the society were maintained, but added to them was a testimony against the slave trade and, from the middle of the century, against slavery itself. By 1787. largely as the result of the concerned leadership of men such as the Americans John Woolman (*q.v.*; 1720–72) and Anthony Benezet (1713–84), probably no Friend owned a slave. and Friends were campaigning steadily for the abolition of both the slave trade and slavery, being the founders in 1783 of the first abolition society in Britain. This became interdenominational in 1787.

At the end of the century Friends opened at York, Eng., the first hospital for the treatment of the insane by humane methods, believing that the Light of Christ is given to all men, including the mentally deranged, an act of faith which influenced the attitude toward mental disease all over the world. This hospital. called the Retreat. was still under the management of Friends in the mid-20th century.

The 19th Century.— The conservative quietism of the 18th century encountered the quickening influence of the evangelical movement early in the 19th century, and the theological colour of the society was soon changing under the leadership of such men as Joseph John Gurney (1788–1847), a brother of Elizabeth Fry (*q.v.;* 1780–1845), and Stephen Grellet (1773–1855), a French-born American Friend. The change was largely one of emphasis, from the inward, present, personal experience to the outward, objective historic fact of Jesus Christ. The new thought soon was in tension with the old, and in controversy each party was driven to an extreme position so that these points of emphasis were made irreconcilable alternates instead of being held firmly together as the double reality of Christian experience. The result was a serious division in United States Quakerism in 1827 and the following years (see *United States,* below). In Great Britain the Society of Friends as a whole tended toward evangelicalism without a major division, though a small number of Friends of extreme evangelical views seceded in 1836 under the leadership of Isaac Crewdson (1780–1844).

In the middle of the 19th century a further source of tension was found within the evangelical groups. This was partly a revival of the older theology (a return to greater emphasis on the inward Light of Christ) and partly a reaction against the "modernism" which allowed some of the traditional differentia (plain speech, Quaker costume, etc.) to lapse. This led to separations in the United States establishing the "conservative" Friends. and to a similar small separation in England which established the Fritchley General Meeting of Friends, which maintained close link with the "conservative" Friends in the United States.

The evangelical movement quickened the social conscience of each denomination, and Friends like others were led into great movements of social reform, sometimes as pioneers. The abolition of slavery has already been mentioned. In Great Britain Joseph Sturge (1793–1859) and in the United States the poet John Greenleaf Whittier (*q.v.;* 1807–92) were outstanding abolitionists, but the whole society was involved in this cause. This was part of a wider concern for right race relations springing directly from the Friends' belief in the Light of Christ being given to every man. Many aspects of penal reform claimed their ardent support: the first society for the abolition of capital punishment in Great Britain was formed partly by Friends in 1808, and Elizabeth Fry, supported by other Friends, initiated reforms in prisons and convict ships which quickly revolutionized both. The movement for universal education derived much of its impetus from Joseph Lancaster (*q v.;* 1778–1838) and the British and Foreign School society which sprang from his activity in opening schools on the monitorial system; in this society Friends played a prominent part. The British and Foreign Bible society had Friends among its founders, and they continued to support it. Friends were involved in founding the London Peace society to educate public opinion to the renunciation of war as an instrument of policy. The temperance movement received much support from Friends from before the middle of the century onward. In yet another field, George Cadbury (*q.v.;* 1839–1922) and Joseph Rowntree (1836–1925) were outstanding examples of industrial employers who introduced the concept of "welfare" into factory management and workers' housing, destined to have far-reaching effects all over the world.

In Britain, the repeal of the Test and Corporation acts in 1828 allowed Friends to enter local government and parliament and to serve as magistrates. They quickly found their way into these areas of service, John Bright (*q.v.;* 1811–89) being the second Friend to enter parliament. The removal of denominational tests from Oxford and Cambridge in 1871 and the growth of other universities allowed Friends increasingly to find their way into the professions.

Hesitation on the ground of their testimony against a separated ordained ministry delayed Friends from entering upon long-term residential missionary service in non-Christian countries until the second half of the 19th century, but then British and U.S. Friends committed themselves to such service, and missions were established in several parts of Asia, Africa and Central America and in Alaska. Meanwhile a strong home missionary movement arose, and in England Friends were the prime movers in the Adult School movement founded in its modern phase by Joseph Sturge in 1845.

From the earliest days Friends had made provision for the education of their children. George Fox himself was actively concerned in this, and directed that the girls in one of the schools set up in the London area should be instructed in "whatsoever things were civil and useful in the creation." Though some of the existing schools under the care of the society date from the 18th century, most were founded in the 19th. In their schools and colleges Friends have been pioneers in coeducation, the teaching of science and the encouragement of hobbies.

The 20th Century.— The turn of the century brought new theological currents into the Society of Friends as it did to all other Christians. For many, a more liberal attitude toward the Bible took the place of the earlier fundamentalism, and though this was a change fraught with tension and heart searching, it probably came more easily to Friends than to some because of their original stress on the Bible as secondary in authority to the Spirit of God known directly.

A parallel modernism invaded Friends in other ways. Their origin among Puritans had left them a heritage of puritanical opposition to music, the theatre and certain other arts. This was now seen to be an accident rather than an essential of faith, and within a generation the attitude of most Friends changed to an appreciation of the value of the arts. It may be noted here that while this distrust of the arts has prevented Friends from producing many eminent artists, a surprisingly large number of eminent scientists have been found among them from the 18th century onward.

Another development was the growth of world Quakerism. The missionary movement established groups of Friends in the middle east. India. China and Japan; in East Africa, Pemba and Madagascar; in the West Indies, Central America and Alaska. Emigration established Friends in South Africa, Australia and New

Zealand; and groups grew up in all the countries of northwest Europe except Belgium and Luxembourg. This last development was in part an indirect and unexpected outcome of widespread relief work undertaken during and after World War I. Though many of these groups are small, Quakerism has ceased to be Anglo-American but contains within its ranks men and women from most parts of the world. This fact led to the holding of world conferences of Friends in 1920, 1937 and 1952, and the establishment of the Friends' World Committee for Consultation in which the many autonomous groups find a common meeting ground.

The existence of the world committee enabled Friends to be recognized by the Economic and Social council of the United Nations as a nongovernmental organization having "consultative status." This allowed them to be present at meetings of the assembly of the United Nations, where their concern for reconciliation and peacemaking found opportunities for expression.

Throughout the history of the society, service in various fields has been rendered by its members. Relief work following disaster (flood, famine and war) has been undertaken by Friends repeatedly.

Several of the 20th-century developments are closely associated with Rufus M. Jones (1863–1948), to whose long life of inspiring leadership the society owes much. His influence was outstanding in bringing the society to a new theological outlook, in fostering a sense of world fellowship, in promoting unity among United States Friends and in creating and guiding the American Friends' Service committee (see United States, below). He also edited and wrote most of the "Rowntree Series of Quaker Histories," the standard history of the Society of Friends up to 1900.

Figures prepared for the world conference in 1952 showed a total of 174,000 Friends distributed roughly as follows: Africa, 24,000; the Americas, 124,000; Asia, 1,000; Australia and New Zealand, 1,000; Europe, 24,000 (of whom 23,000 were in Great Britain and Ireland).

FAITH AND PRACTICE

With so many autonomous groups there is very considerable variety of faith and practice among Friends. This article takes London Yearly Meeting, the parent body, as the norm, and refers to significant divergences.

Friends are Christians. Their distinctive characteristics arise from their emphasis on the fact of God's making Himself directly known in the heart of every man and woman. This experience they refer to as the Light of Christ, believing that in Christ the character of the Light is shown uniquely and supremely. But they believe that the Light is given in measure to every one, including those who lived before the coming of Jesus Christ, and those who are unacquainted with His appearance in history.

Consequently, the primary religious authority for them is the Light made known in the heart. This will be recognized and checked by the knowledge of God given in the Bible, and supremely in the person of Jesus Christ, but the Bible is secondary in authority to the Spirit.

Friends have not made any creed obligatory on their members, though many United States Yearly Meetings have accepted the Richmond Declaration of Faith (1887) as an outline of their doctrine. But the primary emphasis on experience of the Light and an early reaction from "notions" about religious experience have made them shy of creeds. They have found that membership can be based on a general acceptance of Christian experience without demanding a particular credal declaration. For this reason, some (but not all) branches of the Society of Friends have not joined the World Council of Churches, whose basis of membership involves acceptance of a brief credal statement.

Believing that God speaks directly to each one, Friends plan their worship to allow the maximum opportunity for this. They meet together in unprogrammed silent prayer. from which anyone present may speak to the congregation or offerspoken prayer on its behalf. Spontaneous Bible reading or singing may also occur, though less frequently. A modification of this pattern originated in parts of the United States in the latter part of the 19th century, and some of the groups in Asia and Africa have similarly developed a pastoral system involving partially or wholly programmed worship led by a pastor.

Friends' reaction against "forms" of religious practice from which the life easily departs was in part responsible for their disuse of the celebration of the Lord's Supper and baptism in the 17th century. They believed these to be essentially spiritual experiences to which the outward elements of bread, wine and water were unnecessary adjuncts. In a few of the more fundamentalist meetings of United States Friends the celebration of sacraments has been reintroduced, and this has also happened in certain areas of the mission field for reasons of ecumenical polity.

Another and more basic reason for disuse of the sacraments was Friends' emphasis on the sacredness of every part of life, or the potentially sacramental nature of the whole of life. They refuse to separate life into sacred and secular. For example, early Friends refused to call Sunday the Lord's Day, because every day is the Lord's; and they refused to celebrate Christmas chiefly because they claimed that Christ must be born anew in our hearts every day. (Most modern Friends celebrate Christmas.) Similarly they refused to celebrate the special occasion of the sacraments, trying instead to make every meal a reminder of the Last Supper and to know repeatedly the baptism of the Spirit.

Their emphasis on the Light of Christ in each one led them to give equal place to women and men in the religious life. Margaret (*née* Askew) Fell (1614–1702), widow of Thomas Fell, who married George Fox in 1669, gave outstanding service to the infant society from 1652 onward, making her home the geographical headquarters of the society. Women Friends were the first to preach the Quaker understanding of the gospel in London, Oxford and Cambridge, and on the American continent; and of 59 British Friends known to have visited America between 1656 and 1663, 27 were women. Women take as much vocal part in worship as men; they share equally in the whole system of church government; and they make equal and similar promises to those made by the men in marriage. This has led to the women of the society often playing a public role, and the movement for the emancipation of women owes not a little to Friends.

Belief in the Light of Christ in every man, experience of "that life and power which took away the occasion of all wars" (George Fox) and study of the gospels led Friends early to adopt the Christian pacifist position, and they have maintained this peace testimony collectively since 1660. Originally the testimony was for the Christian way of life in all circumstances and only incidentally against war. This positive aspect has continued, and led Friends to active attempts to bind up the wounds of war by relief work given entirely according to need. It has led to attempts in many ways to lessen international tension and to promote reconciliation; it has led Friends actively to support the causes of arbitration, world organization and disarmament and to oppose military conscription. Many Friends have suffered imprisonment, and in some cases worse, as conscientious objectors to military service.

On the social side, Friends have been concerned for many social reforms because they believe that every person should have the fullest opportunity to give expression to the Light within him. A number of such reforms with which the society has been collectively identified have already been mentioned.

The church government of the society is transacted in a series of meetings for church affairs. Each local congregation meets together once a month to transact its congregational business in a preparative meeting. A number of such congregations in a limited area are gathered together into a Monthly Meeting. This is the most important meeting, being responsible for admission to and termination of membership, the recording of births, marriages and deaths, the appointment of elders and overseers, the care of property, etc. Elders are responsible for the right holding of meetings for worship and the provision of opportunities for the religious education of the members. while overseers are responsible for the pastoral care of the members. Several neighbouring Monthly Meetings are gathered together into a Quarterly Meeting, the Quarterly Meetings are gathered into a Yearly Meeting which takes decisions and acts on behalf of the society as a whole in a given area. (This system is simplified in areas where meetings are less closely situated than in Britain, in which case the business of preparative and monthly meetings is combined. This is particularly true of South Africa and Australia, the continent of Europe and parts of the United States.)

At each meeting for church affairs every Friend may attend and has a responsibility to do so if he can. Friends believe that the Light in each one will lead into unity if faithfully followed. Consequently, no vote is taken. The meetings begin and conclude with worship, and a period of worship may be introduced in the course of the meeting. After discussion, the clerk records what he believes to be the judgment of the meeting in a written minute which he reads to the meeting, and which must be accepted by the meeting, after modification if necessary, before further business is taken. In practice the method is sometimes slow, but it avoids outvoted minorities.

The central offices of the Society of Friends in Great Britain are at Friends' house, Euston road, London, N.W. 1, from which the addresses of Friends in any part of the world can be obtained.

UNITED STATES

The Colonial Period.—Between 1656 and 1658 Quaker missionaries arrived in Massachusetts Bay, Rhode Island, New Amsterdam, Maryland and Virginia, where they made converts and established meetings. The visit of George Fox to America in 1672 gave fresh impetus to the movement. By 1700 the Friends had acquired New Jersey and Delaware, founded Pennsylvania, were politically powerful in Rhode Island. North Carolina and Maryland, had organized meetings in all the colonies except Connecticut and South Carolina and had established six Yearly Meetings.

Friends were persecuted in all the non-Quaker colonies except Rhode Island. In New England and Virginia this was primarily the result of their religious nonconformity. Four Friends were hanged on Boston common in 1659 and 1660, and one died in Virginia as the result of flogging and subsequent neglect in prison. Their refusal to pay tithes, take oaths or render military service brought on them fines and civil disabilities in most of the colonies. Pennsylvania was founded by William Penn in 1682 as a "holy experiment" in the application of Quaker ideals to the state, but the Friends were not able to give their principles a full expression in Pennsylvania because the crown imposed limitations on the colony's policy.

The later settlers were hostile to the Quaker ideals, and at the outbreak of the French and Indian War the Friends voluntarily gave up control of the Pennsylvania government. They used their influence to keep peace with the Indians and to protect them from fraud and debauchery. They worked for popular education, peace, temperance and democracy and championed effectively the cause of religious liberty. Chiefly through the patient work of John Woolman the society had cleared itself of slavery, without a war or division, before 1800.

By the end of the colonial period Friends had retired from public life generally, and during the next century, chiefly because of the neglect of higher education and the prevailing quietism, the society declined in numbers and in influence. But Friends pioneered in prison reform, the care of the insane and the antislavery movement.

Migrations.—Between 1725 and 1775 there were considerable migrations of the Quaker population from New England, Pennsylvania and New Jersey southward into North and South Carolina. Toward the end of the 18th century large numbers of southern Friends, finding it difficult to live in a slaveholding society after freeing their own slaves, emigrated to the free territories of Ohio and Indiana.

Divisions.—In 1827–28 came the great disruption of the society, caused by the clashing of new forces which made themselves felt after the Revolutionary War.

Elias Hicks (*q.v.*), alarmed at the intolerant spirit and new methods of the newly felt evangelical influences, became the champion of the older quietism. In the effort to rationalize and defend the sufficiency of the doctrine of the Inner Light, he built a theology of his own. The opposition of the city elders to his views made him the champion of the democratic opposition to their authority, particularly on the part of the country Friends. The result was a division in five of the Yearly Meetings. The resulting groups are commonly, but not officially, called Orthodox and Liberal (Hicksite). Originally the Hicksites outnumbered the Orthodox by more than two to one, but since the westward migrations were mainly from the undivided Yearly Meetings of Virginia and North Carolina, which sided with the Orthodox, the latter greatly outstripped the Liberals in numbers. In 1955 the Orthodox and Hicksite Yearly Meetings in the Philadelphia and New York areas and in Canada were reunited.

The Liberal Yearly Meetings never adopted the theology of Elias Hicks, their position being that theology is not the essence of Christianity but a matter of individual opinion. In 1902 they united in the Friends General conference, which meets biennially but has no legislative authority. The conference carries on continuous work through standing committees in the fields of religious education, peace and social order, Christian unity, education and the advancement of Friends' principles. The central offices are in Philadelphia. The total membership by the latter 1950s was about 29,000.

Among the Orthodox Friends the evangelical tendencies developed most readily in the new western Yearly Meetings, and they were powerfully stimulated by the visit of Joseph John Gurney, a prominent English Friend, in 1837. He laid emphasis on the authority of the Scriptures, favoured Bible study and Bible schools and gave an impetus to higher education. The opposition of John Wilbur of New England to his work led finally to small separations in New England and Ohio. The resulting groups are unofficially called Orthodox (Gurneyite) and Conservative (Wilburite). After the Civil War a great revival movement began among Orthodox Gurneyite Friends. The leaders introduced innovations in methods and in theological expression. In consequence there were small conservative separations in Iowa, Kansas, western and Canada Yearly Meetings (1877–84) and later in North Carolina (1905).

These Conservative Yearly Meetings "recognized" one another and by the 1950s had an estimated membership of 2,700, of whom about 1,000 belonged to the Ohio Yearly Meeting.

Reorganization.—Among the western Orthodox Gurneyite Friends the evangelical emphasis on the outward authority of the Bible and other influences produced a movement toward the practice of water baptism, especially in the Ohio Yearly Meeting. To consider this tendency, a conference of the Orthodox Yearly Meetings in America and Great Britain was held at Richmond, Ind., in 1887. It issued a Declaration of Faith which reaffirmed the historic position of the society in opposition to outward ordinances and restated its doctrinal position in mildly evangelical terms. The great revival occasioned marked changes in the Gurneyite Yearly Meetings. The peculiarities of dress and speech were abandoned almost entirely. Music was introduced into the public worship, which conforms closely to the general type of "low church" Protestantism, without, however, using a fixed liturgy or abandoning the theory of Spirit-led worship. Pastors are generally employed to preach. By the 1950s mission stations were maintained in Africa, Asia, Central America and the West Indies.

In 1902 a Five Years Meeting was organized with consultative and administrative rather than legislative powers, to which all the Orthodox Yearly Meetings belong except Ohio, Oregon and Kansas. The work of this body is carried on through the following boards: Christian education, evangelism and church extension, missions, peace and social concerns, publications and education. The central offices are at Quaker hill, Richmond, Ind., where the official organ, the *American Friend,* is published. The Five Years Meeting is a member of the National Council of the Churches of Christ in America and of the World Council of Churches. The membership of the 11 Yearly Meetings belonging to the Five Years Meeting on the North American continent was approximately 69,000 in 1956; three other constituent Yearly Meetings in Cuba, Jamaica and East Africa brought the total membership to approximately 90,000.

Education and Philanthropy.—The Quaker pioneers usually established elementary schools and academies in their communities, which had a marked influence in shaping the public school systems in North Carolina, Ohio, Indiana and Kansas. In the eastern Yearly Meetings Friends of both the larger branches still maintain both elementary and high schools. By the 1950s there were ten Quaker colleges and one graduate centre for religious and social study (Pendle hill, Wallingford, Pa.).

In 1869, at the request of Pres. U. S. Grant, Friends of both branches began to take charge of many of the Indian agencies. This work was finished in 1885, but missions and schools for the Indians continued to be maintained in Oklahoma and elsewhere. Friends were active in work on behalf of freed slaves after the Civil War and contributed much to Negro education.

In 1917 Friends of all branches united in forming the American Friends Service committee, with headquarters in Philadelphia, for war relief and reconstruction work. The committee's work was carried on in the first instance by conscientious objectors furloughed from the army. In co-operation with British Friends it helped in the restoration of the devastated districts in northern France, Poland and Serbia; provided hospitals in France and Russia and orphanage schools for the children of war victims in Serbia, Poland and Syria. It co-operated with the American Relief administration in feeding the Russian peasants in the Volga basin and supervised the feeding of 2,000,000 German children.

At home in the 1920s and 1930s the committee carried on peace education, sought to further interracial understanding, set up volunteer work camps in areas of social need or tension and worked in the depressed coal fields, feeding children of unemployed miners and promoting self-help housing projects. During and after World War II, while keeping up and expanding these activities, the committee again undertook relief and reconstruction work in Europe and Asia. It has rendered service all over the world through international seminars and technical assistance projects. In 1947 the committee received, jointly with the Friends Service Council of England, the Nobel peace prize. (E. Rl.; F. B. T.)

FRIERN BARNET, an urban district, comprising Friern Barnet, most of Whetstone and part of Muswell Hill, in the Finchley parliamentary division of Middlesex, Eng., 7 mi. N. of London. The Great North road forms part of its western and East Barnet its northern and northeastern boundary. Pop. (1951) 29,163. Area 2.1 sq.mi. The manor was held by the brothers of the Order of St. John of Jerusalem, hence the name Friern. Campes almshouses were founded in 1612. The many old trees in Friary park (23 ac.) and on the North Middlesex golf course are reminiscent of the time when the land was afforested. Friern hospital (formerly Colney Hatch) is in the district, which is now a residential area.

FRIES, the name of a Swedish family distinguished for its botanists. The most eminent members are:

Elias Magnus Fries (1794–1878) was famous for his outstanding contributions to the study of fungi. Born at Femsjö, Småland, on Aug. 15, 1794, he was educated at Lund university where he became junior professor in 1824. In 1834 he became professor of practical economy in the University of Uppsala and was professor of botany during 1851–59. He was also director of the botanical garden and museum from 1851 to 1863. He died on Feb. 8, 1878. Although the author of many important works on the botany of higher plants, he is mostly known for his contributions to mycological taxonomy on which he was regarded as the greatest authority of his time.

Among his many publications are *Novitiae florae svecicae,* 7 parts (1814–24; 2nd ed., 1828); *Observationes mycologicae,* 2 vol. (1815–18); *Systema mycologicum,* 3 vol. (1821–32); *Elenchus fungorum,* 2 vol. (1828); *Epicrisis systematis mycologici* (1836–38; 2nd ed., 1874); and *Icones selectae Hymenomycetum nondum delineatorum,* 2 vol. (1867–75; 1877–84). The last mentioned work was seen to completion by Oscar Robert Fries.

Theodor (Thore) Magnus Fries (1832–1913) was noted as a lichenologist, but more especially for his studies on Linnaeus. The eldest son of Elias Magnus, he was born at Femsjö on Oct. 28, 1832, and educated at Uppsala, where, eventually, he was professor of botany and practical economy, 1877–99. He took part in the scientific exploration of arctic regions as a botanist in the expeditions of Baron N. A. E. Nordenskjöld to Spitsbergen, in 1868, and Greenland, in 1870. He also studied the vegetation of Finnmark in 1857 and 1864. He died in Uppsala on March 29, 1913.

Theodor was prominent in the fields of lichenology, mycology, arctic plant life and botanical history. His fundamental 20 years' work on the life of Linnaeus is a monument to his industry and energy.

Among others, his publications include *Lichenographia scandinavica,* etc., 2 pt. (1871–74); and *Linné, lefnadsteckning af,* 2 pt. (1903).

Oskar Robert Fries (1840–1908), son of Elias Magnus, was born at Uppsala on April 5, 1840. After training in medicine at Uppsala, he practised in Göteborg, devoting all his spare time to mycological studies. He died at Uppsala on July 18, 1908.

Among his mycological works are *Synopsis Hymenomycetum Regionis gothoburgensis* (1889); *In Synopsin . . . additamentum scripsit* (1900).

Klas Robert Elias Fries (1876–   ), a well-known botanical explorer and taxonomist, and the eldest son of Theodor Magnus, was born at Uppsala on July 11, 1876. He was educated at Uppsala university, where he became in 1913 instructor of biology and chemistry. In 1915 he was appointed professor of botany and director of the Bergian Botanical garden at Stockholm. He traveled widely, and wrote many important works on the flora of South America and central and east Africa, being especially interested in Annonaceae and contributing greatly to the study of this family. His interests, following the Linnean traditions of his father and grandfather, have also included the taxonomy and cytology of fungi.

His publications include *Zur Kenntnis der alpinen Flora im nördlichen Argentinien* (1905); "Beiträge zur Kenntnis der Flora des Kenia, Mt. Aberdare und Mt. Elgon," with T. C. E. Fries, 14 pt., *Notizbl. bot. Gart. Berl.,* vol. viii–xi (1924–30); *A Short History of Botany in Sweden* (1950).

Thore Christian Elias Fries (1886–1930), was best known for his botanical explorations. The son of Theodor Magnus, he was born at Uppsala on Nov. 2, 1886, and educated at the university there; he became conservator of the Botanical museum in 1920 and docent in botany in 1925. In 1921–22 with his elder brother, K. R. E. Fries, he explored Kenya and Uganda, particularly Mt. Kenya and the Aberdare mountains. In 1927 he was appointed professor of botany and director of the Botanical museum at Lund. In 1930 he led an expedition to the Transvaal and Southern Rhodesia and died in Umtali, S. Rhodesia, on Dec. 31, 1930. He was author of papers on arctic and alpine floras, and published with his brother valuable works on the flora of central and east Africa.

His publications include *Botanische Untersuchungen im nördliclzsten Schweden, ein Beitrag zur Kenntnis der alpinen und subalpinen Vegetation in Torne Lappmark* (1913) and *Über die regionale Gliederung der alpinen Vegetation der fennoskandinavischen Hochgebirgen* (1917).

BIBLIOGRAPHY.—For more complete biographical and bibliographical data on all members of the Fries family see *Svensk. bot Tidskr*, vol xxv (1931) and *Bot Notiser* (1931). *See* also V. B. Wittrock, *Catalogus illustratus zconothecae botanzcae . . . bergzani*, etc. (1903–05) and T. O. B. N Krok, *Bibliotheca botanica suecana . . .* (1925).

FRIES, JAKOB FRIEDRICH (1773–1843), German philosopher, was born at Barby, Saxony, on Aug. 23, 1773. Having studied at Leipzig and at Jena, he became professor of philosophy and elementary mathematics at Heidelberg in 1805. His attitude toward contemporary philosophies is set forth in *Reinhold, Fichte und Schelling* (1803; reprinted 1824 as *Polemische Schriften), System der Philosophie als evidente Wissenschaft* (1804) and *Wissen, Glaube und Ahndung* (1805). His important *Neue oder anthropologische Kritik der Vernunft* (3 vol.. 1807) attempted to give a new foundation of psychological analysis to the critical theory of Kant, which he sought to reconcile with the philosophy of F. H. Jacobi. His *System der Logik* appeared in 1811. In 1816 Fries accepted the chair of theoretical philosophy at Jena. In politics he was a strong Liberal and a believer in a united Germany and did much to inspire the organization of the *Burschenschaft*. In 1816 he published *Von Deutschem Bund und Deutscher Staatsverfassung,* and his influence gave a powerful impetus to the agitation which in 1819 led to the issue of the Carlsbad decrees. He was condemned by the Mainz commission, and the grand duke of Weimar was compelled to deprive him of his professorship. In 1824 he was recalled to Jena as professor of mathematics and physics, and in 1838 the right of public lecturing on philosophy was restored to him. He died at Jena on Aug. 10, 1843.

The most Important norks of his Jena professorate were the *Handbuch deu praktischen Philosophie* (1818–32), *Handbuch der psychischen Anthropologie* (1820–21). *Dze mathematische Naturphilosophie* (1822), *System der Metaphysik* (1824) and *Die Geschichte der Philosophie* (1837–40).

FRIES, JOHN *(c.* 1764–1825), U.S. insurgent leader, was born in Pennsylvania of German descent about 1764. As an itinerant auctioneer he became well acquainted with the Germans in the southeast part of Pennsylvania. In July 1798, during the troubles between the United States and France, congress levied a direct tax (on dwelling houses, lands and slaves) of $2,000,000, of which Pennsylvania was called upon to contribute $237,000. There were very few slaves in the state, and the tax was accordingly assessed upon dwelling houses and land, the value of the houses being determined by the number and size of the windows. The inquisitorial nature of the proceedings aroused strong opposition among the Germans, and many of them refused to pay. Fries, assuming leadership. organized an armed band of about 60 men, who marched about the country intimidating the assessors and encouraging the people to resist. At last the governor called out the militia (March 1799) and the leaders were arrested. Fries and two others were twice tried for treason (the second time before Samuel Chase) and were sentenced to be hanged, but they were pardoned by Pres. John Adams in April 1800, and a general amnesty was issued on May 21. The affair is variously known as the "Fries rebellion." the "Hot-Water rebellion" — because hot water was used to drive assessors from houses — and the "Home Tax rebellion." Fries died in Philadelphia in 182j.

FRIESE-GREENE, WILLIAM (1855–1921), British photographer and inventor of the first practical motion-picture camera, was born at Bristol on Sept. 7, 1855. He took out almost 70 patents, that for the camera being in 1889. This camera used celluloid film.

The previous year the Photographic Society of Vienna had awarded him the Daguerre medal for a moving-picture camera using paper film with perforated edges. In 1889 he wrote to Thomas Alva Edison (*q.v.*) describing his camera and suggesting that it should be combined with the phonograph to make "talkies." He was a pioneer in stereoscopic and colour motion-picture making, and experimented with electrical inkless printing and radio direction of moving objects.

He died in London on May 5, 1921. A memorial in Highgate cemetery is' inscribed "William Friese-Greene, the Inventor of Kinematography."

See Leslie Wood, *The Miracle of the Movies* (London, 1947); Ray, Allister, *Friese-Greene, Close-Up of an Inventor* (London, 1948).

(R. ALL.)

FRIESLAND (VRIESLAND), a province of the Netherlands, bounded southwest, west and north by the Northeast polder, the IJsselmeer (Zuider Zee) and the North sea, east by Groningen and Drente, southeast by Overijssel; occupied by Germany in World War II. It includes the islands of Ameland and Schiermonnikoog *(see* FRISIAN ISLANDS). Area, 1,251 sq.mi.; pop. (1957 est.) 471,153. The soil of Friesland falls naturally into three divisions consisting of sandy clay in the north and northwest, of a median belt of low fen between the southwest and northeast, and of a comparatively small area of high fen in the southeast. The clay and low fen furnish good meadowland for the world-famed breed of Frisian cattle, noted especially for butter production. Horse breeding is also practised. In the high fen district peat digging is still important. but cultivation remains difficult. Droughts are specially serious in the absence of flowing rivers, and this difficulty interferes seriously with milk production at times. The water system is entirely canalized, and there is a vast network of canals, waterways and lakes in the whole north and west. The principal lakes are Tjeuke Meer, Sloten Meer, De Fluessen and Sneeker Meer. The tidal range being small on the north coast, the Waterstaat provides for the largest removal of superfluous surface water into the Lauwers Zee. The drainage problem has always been a peculiarly difficult one. The population of the province is evenly distributed in small villages. The principal centres are Leeuwarden, Sneek. Bolsward, Franeker, Dokkum and Heerenveen. With the exception of Franeker and Heerenveen all these to ns originally arose on the inlet which became the IJsselmeer. The seaport towns of Stavoren, Hindeloopen, Workum, Harlingen and Makkum are more or less decayed as a result of the increased draft of modern vessels. For history *see* FRISIANS.

SAWDERS FROM CUSHING

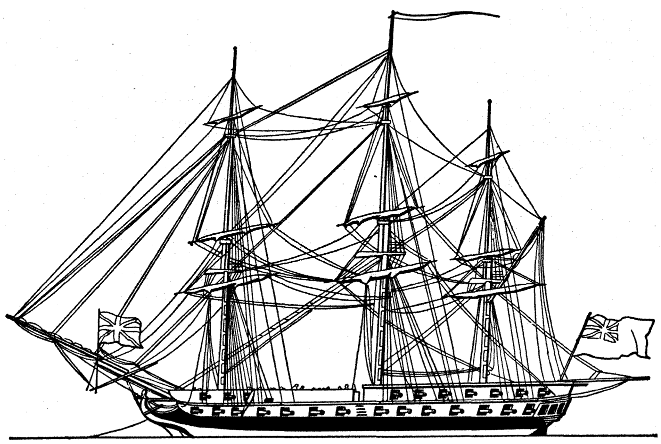
STREET SCENE AT LEEUWARDEN. CAPITAL OF FRIESLAND

FRIEZE, in architecture, the middle of the three divisions of a classic entablature (*q.v.*), above the architrave and below the cornice *(see* ORDER); also any long, narrow, horizontal panel or band used for decorative purposes. The frieze probably developed from the necessity of carrying the crossbeams of a ceiling upon the tops of the architrave beams, but below the cornice eaves.

The stone triglyphs of the Doric frieze are reminiscent of the beam ends of a primitive wood construction. In the Ionic. Corinthian and Composite orders the frieze has no architectural membering but is frequently richly ornamented. In Greek work this ornamentation consists of figures, as in the treasury of the Cnidians at Delphi (early 5th century B.C.) or the monument of Lysicrates at Athens (310 B.C.). In Roman and Renaissance work it consists of anthemions, acanthus foliage or garlands, as in the temple of Vesta at Tivoli (*c.* 80 B.C.) and the Maison Carrée at Nimes (early 1st century A.D.). In late Roman work and many Renaissance examples the profile of the frieze is a convex curve and is known as a pulvinated frieze. The most famous of decorative friezes is undoubtedly that carved on the top of the outer wall of the cella of the Parthenon (*q.v.*), just under the ceiling of the portico.

This frieze, 40 in. high and 525 ft. long, bearing a representation of the ritual procession of the Panathenaic festival, is characterized by superb rhythmic design and faultless execution. Sculptured probably from the designs and under the supervision of Phidias, it is a perfect expression of Greek sculpture of the mid-5th century B.C. and one of the best examples of architectural sculpture of all time.

FRIGATE, in ancient times, a small, swift, undecked vessel, propelled by oars or sails, in use on the Mediterranean. The word was also applied to small. fast vessels used by the Spanish and Portuguese during the 16th and 17th centuries. The French first applied the term to a particular type of warship during the second quarter of the 18th century. The Seven Years' War (1756–63) marked the definite adoption of the "frigate" as a standard class



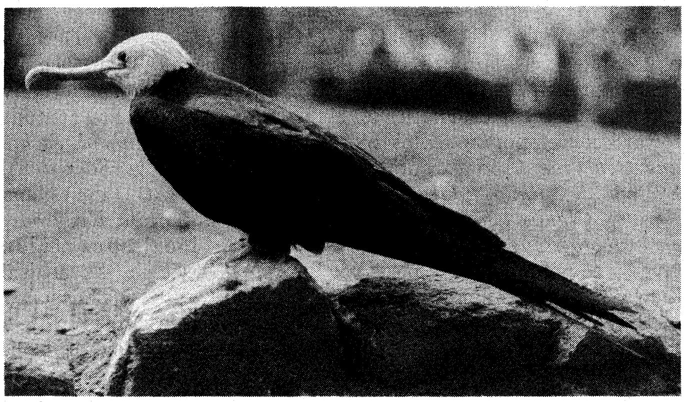
FROM "THE KING'S SHIPS," BY COURTESY OF COMMANDER H. S. LECKY, R.N.

THREE-MASTED FRIGATE. THE "CRUISER" OF SAILING-SHIP DAYS

of vessel, coming next to ships of the line and used for cruising and scouting purposes. They were three-masted, fully rigged, fast vessels, with the main armament carried on a single deck and additional guns on the poop and forecastle. The guns varied from 24 to 50, but between 30 and 40 guns was the usual number carried. The frigate "Constitution" (*q.v.*), nicknamed "Old Ironsides," won undying fame in the early years of U.S. history. "Frigate" continued in use throughout the period of transition from sail to steam but gradually gave way to "cruiser" (*q.v.*).

During World War II, in 1942, Great Britain revived the name frigate by assigning it to a particular category of warship. In 1943 the United States also revived the term and applied it to about 70 vessels each having a full load displacement of about 2,400 tons, a speed of 20 knots and 3-in. dual-purpose guns. By 1955, however, the United States had disposed of all these vessels except 22 on loan to other countries, and had placed in the frigate classification the "Norfolk" and four destroyer leaders in commission as well as six others under construction. Great Britain meanwhile retained frigates of varying size, speed and armament, designed for various purposes. Built or building, the U.S navy had also 20 frigates carrying guided missiles. in 1960. Other nations employed the term frigate in such a manner that it had no precise meaning in international usage. (J. B. HN.)

FRIGATE BIRD, large sea birds of the genus Fregata, constituting the family Fregatidae in the order Pelecaniformes. ranging throughout tropical and subtropical oceans. They are known also as man-o'-war birds because of their aggressive and piratical behaviour. Frigate birds are related to the pelican, cormorant. gannet, snakebird and tropic bird (*qq.v.*), and are about the size of a hen, with extremely long slender wings, the span of which may



BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

MAN-O'-WAR-BIRD (FREGATA MAGNIFICENS ROTHSCHILDI)

reach $7\frac{1}{2}$ ft., and scissorlike tail. The black plumage is relieved by an orange throat pouch in the male and by a white breast in the female. Other distinguishing characters are the almost helpless feet with four toes webbed, and a long hooked' bill, used in attacking and robbing other sea birds, particularly boobies, of their fish.

Although they fly singly or in pairs, they nest in colonies, building nests of sticks in mangroves and on rocky islets, laying a single white egg. The nestlings are matted with soft white down, but the black wing feathers soon appear. The adults, without oil glands to waterproof the plumage, never alight on the water but are unbelievably fast and skillful in the air, soaring effortlessly and often diving to recover falling fish dropped aloft by panic-stricken boobies. Despite their flying ability frigate birds are usually found within 100 mi. of land. F. *aquila* is confined to Ascension Island in the Atlantic, F. *andrewsi* to Christmas Island and Cocos Keeling southeast of Java, the Anambas northeast of Singapore, wandering to nearby coasts, as far as India. F. minor, with six races, breeds on islands in the Indian, Pacific and Atlantic (south Trinidad) oceans; F. ariel has races similarly distributed. The magnificent man-0'-war bird, F. *magnificens,* breeds on the Galapagos and Pearl islands and ranges the eastern Pacific; with a race (F. *m. rothschildi*) breeding in the West Indies and along the coasts of the Caribbean and northern and eastern South America, wandering to the Gulf states, and another race in the Cape Verde Islands. (G. F. Ss.; X.)

FRIGG, the wife of the god Odin (Woden) in northern mythology, was known also to other Teutonic peoples, as Friia in German and Frea in Langobardic; in English her name still survives in the word Friday.

FRIIS, JOHAN (1494–1570), Danish statesman, was born in 1494 and was educated at Odense and at Copenhagen, completing his studies abroad. He was one of the first of the magnates to adhere to the Reformation and its promoter King Frederick I (1523–33). Friis, who made a fortune out of the church lands, succeeded Claus Gjoodsen as imperial chancellor in 1532, and held that dignity till his death. He promoted the election of Christian III (1533–59), but in the course of the "Count's War" he was taken prisoner by Count Christopher, the Catholic candidate for the throne, and forced to do him homage. He made his escape to Germany and then rejoined Christian III. He was one of the plenipotentiaries who concluded peace with Liibeck at the congress of Hamburg, and subsequently took part in the national reconstruction necessitated by the Reformation, acting as mediator between the Danish and the German parties that were contesting for supremacy during the earlier years of Christian III. Friis was a patron of learning. He encouraged Hans Svaning to complete Saxo's history of Denmark, and Anders Vedel to translate Saxo into Danish. Under King Frederick II (1559–88), Friis was well-nigh omnipotent. He was largely responsible for the Scandinavian Seven Years' War (1562–70), which did so much to exacerbate the relations between Denmark and Sweden. Friis died on Dec. 5, 1570, a few days before the peace of Stettin.

FRILLED LIZARD (*Chlamydosaurus* kingi), a tropical lizard of Australia and New Guinea, belonging to the family Agamidae, remarkable for the large erectile frill round the neck and for its ability to run on its hind legs. It is arboreal and insectivorous.

FRIMLEY AND CAMBERLEY, an urban district in the Woking parliamentary division of Surrey, Eng., on the London-Exeter trunk road, 29 mi. W.S.W. of London by road. Pop. (1951) 20,386. Area 12.1 sq.mi. The district includes York Town and Frimley Green. A healthful climate, a picturesque situation in the sandy heath district and military associations have contributed to its growth as a residential township. The land rises 200 ft. from the Blackwater river in the west to the heights of Chobham ridges overlooking Bagshot heath in the east, and coniferous trees and rhododendrons abound. In Camberley is the army's staff college and nearby is the Royal Military academy, Sandhurst.

Bret Harte, the writer, is buried at Frimley parish church. Since World War II several light industries have been established in the district.

FRINGE TREE, a common name for the genus Chionanthus of the olive family, comprising two species of shrubs or small trees that may reach to 30 ft. and bear deciduous leaves and fluffy clusters of snow-white flowers, followed by dark-blue, olivelike fruits. The American fringe tree or old-man's-beard (C. *virginica*), native from Pennsylvania and Florida to Texas, is widely planted as an ornamental while the Chinese species (C. retusa), although introduced into America, did not attain equal popularity. (J. M. Bl.)

FRINGILLIDAE, a family of small perching birds (order Passeriformes) comprising the buntings, finches and grosbeaks (*qq.v.*).

FRINTON AND WALTON, an urban district in the Harwich parliamentary division of Essex, Eng., on the east coast about 17 mi. E.S.E. of Colchester by road. Pop. (1951) 8,451. Area 9.8 sq.mi. The district comprises the parishes of Frinton-on-Sea and Walton-on-the-Naze, both seaside towns with sands, and the rural .parishes of Kirby-le-Soken and Great Holland. Walton came into existence as a seaside resort about 1830; it has a ½-mi.-long pier, a Martello tower of the Napoleonic period and a late 18th-century beacon tower. This portion of the coast has in the past suffered from sea encroachment. About 2 mi. to the northeast is the Naze promontory; local low cliffs exhibit fossiliferous Red Crag formations. Frinton grew up as a seaside resort at the end of the 19th century; the old church of St. Mary dates partly from the early 16th century. Apart from the tourist industry there is some local agriculture and a small foundry at Walton.

FRISCHES HAFF (Vistula Lagoon; Pol. Zalew Wislany; Rus. Vislinski Zaliv), a lagoon on the Baltic coast, between Danzig (Gdansk) and Konigsberg (Kaliningrad). It is 56 mi. in length, from 5 to 12 mi. broad, 324 sq.mi. in area and is separated from the Baltic by a narrow spit, the Frische Nehrung. This barrier was torn open by a storm in 1510, and the channel thus formed, now dredged out to a depth of 22 ft., affords a navigable passage for vessels. Into the lagoon flow the Nogat, the Elbing, the Pasleka, the Pregel and the Frisching.

FRISCHLIN, PHILIPP NIKODEMUS (1547–1590), German philologist. poet and commentator on Vergil. and one of the last of the humanists, was born Sept. 22, 1547, at Balingen, Wiirttemberg. He was educated at Tiibingen, where he became (1568) professor of poetry and history. In 1575 for his comedy Rebecca, which he read at Regensburg before the emperor Maximilian II, he was rewarded with the laureateship, and in 1577 he was made a count palatine.

In 1582 he had to leave Tubingen, and spent two years teaching at Laibach. Shortly after his return to Tübingen in 1585, he was threatened with a criminal prosecution for immoral conduct, and fled to Frankfurt-am-Main (1587). For 18 months he taught in Brunswick and he appears also to have lived at Strasbourg, Marburg and Mainz. From Mainz he wrote libelous letters, which led to his arrest in March 1590. He was imprisoned in the fortress of Hohenurach. near Reutlingen. where, on the night of Nov. 29/30, 1590, he was killed by a fall in attempting to let himself down from the window of his cell.

In his Latin verse Frischlin often successfully imitated classical models. His Latin comedies have freshness and vivacity, and his commentaries on the *Georgics* and *Bucolics* of Vergil were important contributions to the scholarship of his time. He also wrote plays in German.

See his *Operum poeticorum,* 4 vol. (1585–1602); D F. Strauss, *Leben und Schrijten des Dichters und Philologen Frischlin* (1856); G. Berbermeyer, *Tübinger Dichterhumanisten* (1927).

FRISIAN ISLANDS, a chain of islands, lying from 3 to 20 mi. from the mainland and stretching from the IJsselmeer east and north as far as Jutland, along the coasts of the Netherlands and Germany. They are divided into three groups: (1) West Frisian; (2) East Frisian; and (3) North Frisian. The islands mark the outer fringe of the former continental coast line, and are separated from the mainland by shallows, known as *wadden.* Notwithstanding the protection afforded by sand dunes and artificial embapkments, the Frisian Islands are slowly disappearing through marine erosion. Many of the Frisian legends and folk songs deal with submerged villages and hamlets. The German and Dutch governments annually spent large sums for the protection of the islands, and in some cases the erosion on the seaward side is counterbalanced by the accretion of land on the inner side, fine sandy beaches being formed well suited for sea bathing, attracting many visitors in summer.

The inhabitants support themselves by seafaring, pilotage, grazing of cattle and sheep, fishing and a little agriculture, chiefly potato growing.

West Frisian. — The West Frisian Islands belong to the Netherlands, and embrace Texel (62 sq.mi.), Vlieland (13 sq.mi.), Terschelling (37 sq.mi.), Ameland (22 sq.mi.), Schiermonnikoog (10 sq.mi.), as well as the much smaller islands of Boschplaat and Rottum, which are practically uninhabited. The northern end of Texel is called Eierland, or "Island of Eggs," in reference to the large number of sea birds' eggs which are found there. It was joined to Texel by a sand dike in 1629–30 and is now undistinguishable from the main island. Texel was already separated from the mainland in the 8th century. but remained a Frisian province and countship, which once extended as far as Alkmaar in North Holland, until it came into the possession of the counts of Holland. Germany occupied all the West Frisians in 1940.

The island of Terschelling once formed a separate lordship, but was sold to Holland. As early as the beginning of the 9th century Ameland was a lordship belonging to the Cammingha family. who held immediately of the emperor, and in recognition of their independence the Amelanders were in 1369 declared to be neutral in the fighting between Holland and Friesland, while Cromwell made the same declaration in 1654. The castle of the Camminghas in Ballum remained until 1829. This island is joined to the mainland of Friesland by a stone dike built in 1873 to promote the deposit of mud. Schiermonnikoog has a village and a lighthouse. Rottum was once the property of the ancient abbey at Rottum, 8 mi. N. of Groningen, of which there are slight remains. West Frisian Islands have a total area of 145 sq.mi. and a pop. (1957 est.) of 17,460.

East Frisian. — The East Frisian group belongs to Germany and comprises Borkum (13½ sq.mi.), Memmert, Juist (6 sq.mi.), Norderney (10 sq.mi.), Baltrum, Langeoog (7 sq.mi.), Spiekeroog (5 sq.mi.) and Wangeroog (2 sq.mi.). All these islands are visited for sea bathing. Many have lighthouses and lifeboat stations. In the beginning of the 18th century Wangeroog comprised eight times its present area. Borkum and Juist are two surviving fragments of the original island of Borkum (computed at 380 sq.mi.), known to Drusus as *Fabaria*, and to Pliny as *Burchana*, which was rent asunder by the sea in 1170. Neuwerk and Scharhorn are situated off the mouth of the Elbe, the former contains some marshland protected by dikes and has two lighthouses and a lifeboat station.

North Frisian.—About the year 1250 the area of the North Frisian Islands was estimated at 1,065 sq.mi.; by 1850 this had diminished to only 105 sq.mi. This group embraces the islands of Nordstrand ($17\frac{1}{4}$ sq.mi.), which to 1634 formed one larger island with the adjoining Pohnshallig and Nordstrandisch-Moor; Pellworm ($16\frac{1}{4}$ sq.mi.), protected by a circle of dikes and connected by steamer with Husum on the mainland; Amrum ($10\frac{1}{2}$ sq.mi.); Fohr (32 sq.mi.); Sylt (38 sq.mi.); Rom (16 sq.mi.), with several villages, the principal of which is Kirkeby; Fanö (21 sq.mi.); and Heligoland ($\frac{1}{4}$ sq.mi.). With the exception of Fanö and Rom which are Danish, these islands belong to Germany, which also occupied the former two in 1940. In the North Frisian group there are also several smaller islands called Halligen, rising generally only a few feet above the level of the sea.

FRISIANS, a people who in the first century of our era were found by the Romans in occupation of the coast lands stretching from the mouth of the Scheldt to that of the Ems. The first historical notices of the Frisians are found in the *Annals* of Tacitus. They (or a portion of them) were rendered tributary by Drusus, and became *socii* of the Roman people, but soon after A.D. 47 the emperor Claudius ordered the withdrawal of all Roman troops to the left bank of the Rhine. In 58 the Frisians tried unsuccessfully to appropriate certain districts between the Rhine and the Yssel and in 70 they took part in the campaign of Claudius Civilis. Ptolemy states that they inhabited the coast above the Bructeri as far as the Ems. Tacitus speaks of them as adjacent to the Rhine. But there is some reason for believing that the part of Holland which lies to the west of the Zuider Zee was at first inhabited by a different people, the Canninefates, whose name is perhaps preserved in the name Kennemerland or Kinnehem formerly applied to the same district.

In connection with the movements of the migration period the Frisians are hardly ever mentioned, though some of them are said to have surrendered to the Roman prince Constantius about the year 293. Procopius speaks of the Frisians as one of the nations which inhabited Britain in his day, but we have no evidence from other sources to bear out his statement. In Anglo-Saxon poetry mention is frequently made of a Frisian king named Finn, the son of Folcwalda, who came into conflict with a certain Hnaef, a vassal of the Danish king, Healfdene, about the middle of the 5th century. The incident is obscure, but it is worth noting that Hnaef's chief follower, Hengest, may quite possibly be identical with the founder of the Kentish dynasty. About the year 520 the Frisians are said to have joined the Frankish prince Theodberht in destroying a piratical expedition which had sailed up the Rhine under Chocilaicus (Hygelac), king of the Götar. Toward the close of the century they begin to figure much more prominently in Frankish writings. It is probable that the Frisians were to some extent associated with the Angles and Saxons in the invasion of Britain. In any case, the Frisian language, by its close resemblance to English, proves an ancient and intimate connection between these peoples.

The northward extension of Frankish dominion brought on a collision with the Frisians. Under the protection of the Frankish king Dagobert (622–638), the Christian missionaries Amandus (St. Amand) and Eligius (St. Eloi) attempted the conversion of the southern Frisians, but farther north the building of a church by Dagobert at Trajectum (Utrecht) at once aroused the fierce hostility of the heathen tribesmen of the Zuider Zee. Utrecht was attacked and captured, and the church destroyed. Wilfrid, bishop of York, who visited Frisia in 678 was allowed to preach Christianity by Aldgils, then king. Radbod, his successor, who was hostile to Christianity. was beaten by Pippin of Heristal in the battle of Dorstadt (689), and was compelled tp cede west Frisia from the Scheldt to the Zuider Zee to the conqueror. Although Frankish supremacy over Frisia was not completely established until the time of Charles the Great, it was under Frankish protection that Christianity was established in Frisia by the Englishman Willibrord, between 690 and 739. The see of Utrecht which he founded has remained the chief see of the northern Netherlands from his day to our own, though many Frisians were still heathen when the more famous English missionary Boniface was martyred at Dokkum in Frisia shortly after 750.

Charles the Great granted the Frísians important privileges under a code known as the *Lex Frisionum,* based upon the ancient laws of the country. In this text three districts are clearly distinguished: West Frisia from the Zwin to the Vlie; Middle Frisia from the Vlie to the Lauwers; East Frisia from the Lauwers to the Weser. At the treaty of Verdun (843) Frisia became part, of Lotharingia; at the treaty of Mersen (870) it was divided between the kingdoms of the East Franks and the West Franks; in 880 the whole country was united to the latter; in 911 it fell under the dominion of Charles the Simple, king of the West Franks, but the districts of East Frisia asserted their independence and for a long time governed themselves after a very simple democratic fashion. The history of West Frisia gradually loses itself in that of the countship of Holland and the see of Utrecht (*see* HOLLAND, COUNTY *AND* PROVINCE OF; UTRECHT).

The influence of the Frisians during the interval between the invasion of Britain and the loss of their independence must have been greater than is generally recognized. They were a seafaring people and engaged largely in trade, especially perhaps the slave trade, their chief emporium being Wyk te Duurstede. During the period in question there is considerable archaeological evidence for intercourse between the west coast of Norway and the regions south of the North sea, and it is worth noting that this seems to have come to an end early in the 9th century. Probably it is no mere accident that the first appearance, or rather reappearance, of Scandinavian pirates in the west took place shortly after the overthrow of the Frisians.

Besides the Frisians discussed previously, a people called North Frisians inhabited the west coast of Schleswig. In historical times these North Frisians were subjects of the Danish kingdom and not connected in any way with the Frisians of the empire. It seems not unlikely that the original settlers were Frisians who had been driven northward by the Franks in the 8th century. The inhabitants of the neighbouring islands, Sylt, Amrum and Föhr, who speak a kindred dialect, have apparently never regarded themselves as Frisians, and it is the view of many scholars that they are the direct descendants of the ancient Saxons.

In 1248 William of Holland, having become emperor, restored to the Frisians in his countship their ancient liberties in reward for the assistance they had rendered him in the siege of Aachen; but in 1254 they revolted, and William lost his life in the contest which ensued. After many struggles west Friesland became completely subdued, and was henceforth virtually absorbed in the county of Holland. But the Frieslanders east of the Zuider Zee obstinately resisted repeated attempts to bring them into subjection. In the course of the 14th century the country was in a state of anarchy, which favoured the attempts of the counts of Holland to push their conquests eastward. but the main body of the Frisians was still independent when the countship of Holland passed into the hands of Philip the Good of Burgundy. Philip laid claim to the whole country, but the people appealed to the protection of the empire, and Frederick III, in Aug. 1457, recognized their direct dependence on the empire. The marriage of Maximilian of Austria with the heiress of Burgundy produced a change in the fortunes of that part of Frisia which lies between the Vlie and the Lauwers. In 1498 Maximilian reversed the policy of his father Frederick III and gave it to Albert of Saxony, who thoroughly crushed out all resistance. In 1523 it passed with all the rest of the provinces of the Netherlands to the emperor Charles, the grandson of Maximilian and Mary of Burgundy.

The part of Frisia which lies to the east of the Lauwers had a divided history. The portion which lies between the Lauwers and the Ems after some struggles for independence had, like the rest of the country, to submit itself to Charles. It became ultimately the province of the town and district of Groningen (*q.v.*). The easternmost part between the Ems and the Weser, which had since 1454 been a county was ruled by the descendants of Edzard Cirksena, and was attached to the empire. The last of the Cirksenas, County Charles Edward, died in 1744 and in default of heirs male the king of Prussia took possession of the county.

The province of Friesland was one of the seven provinces which by the treaty known as the Union of Utrecht bound themselves together to resist the tyranny of Spain. From 1579 to 1795 Friesland remained one of the constituent parts of the republic of the United Provinces, but it always jealously insisted on its sovereign rights, especially against the encroachments of the predominant province of Holland. It maintained throughout the whole of the republican period a certain distinctiveness of nationality, which was marked by the preservation of a different dialect and of a separate stadtholder. Count William Lewis of Nassau-Siegen, nephew and son-in-law of William the Silent, was chosen stadtholder, and throughout the 17th and 18th centuries the stadtholdership was held by one of his descendants. Frederick Henry of Orange was stadtholder of six provinces, but not of Friesland, and even during the stadtholderless periods which followed the deaths of William II and William III of Orange the Frisians remained stanch to the family of Nassau-Siegen. Finally, by the revolution of 1748 William of Nassau-Siegen, stadtholder of Friesland (who by default of heirs male of the elder line, had become William IV, prince of Orangej, was made hereditary stadtholder of all the provinces. His grandson in 1815 took the title of William I, king of the Netherlands. The male line of the "Frisian" Nassaus came to an end with the death of King William III in 1890.

FRIT FLY (*Oscinella frit*), a small, shining black fly destructive to oats, rye, barley and wheat in Europe and North America. The creamy white larvae live in the developing grains, and within the stems, causing the central leaf to milt. (*See* DIPTERA.)

(C. H. CN.)

FRITH or FRYTH, **JOHN** (c. 1503–1533), English Reformer and Protestant martyr, was born at Westerham, Kent. He was educated at Eton and King's college, Cambridge, where Gardiner, afterward bishop of Winchester, was his tutor. At the invitation of Thomas Cardinal Wolsey, after taking his degree he migrated (Dec. 1525) to the newly founded college of St. Frideswide or Cardinal college (now Christ Church), Oxford. The sympathetic interest which he showed in the Reformation movement in Germany caused him to be suspected as a heretic, and led to his imprisonment for several months. Subsequently he appears to have resided chiefly at the newly founded Protestant university of Marburg, where he became acquainted with several scholars and reformers of note, especially Patrick Hamilton (*q.v.*). Frith's first publications were printed at Marburg. His *Disputacyon of Purgatorye,* a treatise in three books, against John Rastell, Sir Thomas More and John Fisher (bishop of Rochester) respectively, was published at the same place in 1531. While at Marburg, Frith also assisted William Tyndale, whose acquaintance he had made in England, in his literary labours. In 1532 he ventured back to England. Warrants for his arrest were almost immediately issued at the instance of More, then lord chancellor! and he ultimately fell into the hands of the authorities as he was on the point of escaping to Flanders. Frith was examined by the king's order; he was afterward tried and found guilty of having denied that the doctrines of purgatory and transubstantiation were necessary articles of faith. On June 23, 1533, he was handed over to the secular arm; and was burnt at the stake at Smithfield on July 4. During his captivity he wrote a reply to More's letter against his own "lytle treatise"; also two tracts entitled *A Mirror or Glass to know thyself,* and *A Mirror or Looking-glass wherein you may behold the Sacrament of Baptism.*

FRITH, WILLIAM POWELL (1819–1909), English painter of large, crowded scenes, was born at Aldfield, Yorkshire, on Jan. 9, 1819. He trained first at Henry Sass's school in London (1835) and then in 1837 entered the Royal Academy school. In 1840 he exhibited there his first picture "Malvolio Before the Countess Olivia." His earlier works included portraits and subject pieces in the tradition of D. Wilkie and W. Mulready, but .he developed a preciseness of technique akin to that used by the Pre-Raphaelites.

He quickly gained wide popularity. Elected associate of the Royal Academy in 1845 and a member in 1852, he established his reputation with a succession of large compositions of everyday English life, the first of which, "Ramsgate Sands" (exhibited 1854), was bought by Queen Victoria. There followed "The Derby Day" (18j8, Tate gallery, London); "Claude Duval" (1860); "The Railway Station" (1862); and "The Marriage of the Prince of Wales" (1865) painted for Queen Victoria.

Frith later turned to moralizing works exemplified by the series of five paintings—"The Race for Wealth" (1880). He died in London. Nov. 2, 1909. Commemorative exhibitions were held at Whitechapel Art gallery (London) and at Harrogate in 1951.

See Nevile Wallis (ed.), *Victorian Canvas: Memoirs,* from Frith's autobiographical writings (19j7). (D. L. FR.)

FRITILLARY (*Fritillaria*), a genus of hardy bulbous plants of the family Liliaceae (*q.v.*), containing more than 70 species widely distributed in the northern hemisphere. About 15 species are native to western North America, chiefly California, and mostly with handsome flowers, among which are the white fritillary (*F. liliacea*), the yellow fritillary (*F. pudica*), mission bells (*F. lanceolata and mutica*), brown bells (*F. parviflora*) and the chocolate lily (*F. biflora*).

J HORACE MCFARLAND COMPANY

FRITILLARY OR SNAKE'S-HEAD (FRITILLARIA MELEAGRIS)

The genus is represented in the southern half of England by the fritillary or snake's-head (*F. meleagris*), which occurs in moist meadows. A much larger plant is the crown imperial (*F. imperialis*), a native of western Asia and well known in gardens. This grows to a height,of about three feet, the lower part of the stoutish stem having leaves, while near the top is developed a crown of large pendent flowers surmounted by a tuft of bright green leaves. The flowers are bell-shaped, yellow or red, and in some of the forms double. The plant grows freely in good garden soil, preferring a deep well-drained loam.

Fritillary is also the name of several species of butterfly.

FRITZLAR, a town in the *Land* of Hesse, on the left bank of the Eder, 16 mi. S.W. from Cassel by rail. Pop. (1950) 6.851. As early as 732 Boniface, the apostle of Germany, established the church of St. Peter and a small Benedictine monastery at Frideslar.

Among the earlier scholars of the famous monastery school were Sturm, abbot of Fulda, and Megingod, second bishop of Würzburg. Boniface later entrusted the office to Wigbert of Glastonbury, who thus became the first abbot of Fritzlar. In 774 the little settlement was burnt by the Saxons, but soon recovered. Soon after 786 it was the seat of the bishopric of Buraburg, founded by Boniface in 741. At the diet of Fritzlar in 919 Henry I was elected German king. Early in the 13th century the village received municipal rights. As a principality Fritzlar continued subject to the archbishopric of Mainz till 1802, when it was incorporated with Hesse. In 1866 it passed with Hesse-Cassel to Prussia.

FRITZSCHE, OTTO FRIDOLIN (1812–96), German theologian, was born on Sept. 23, 1812, at Dobrilugk. and studied at Halle. From 1837 to 1893 he was professor of theology at the University of Zurich, where he died on March 9, 1896.

His chief publications were his edition of the Apocrypha of the Old Testament (1871) and his *Kurzgefasstes exegetisches Handbuch zu den Apokryphen des Alten Testamentes* (6 vol., 1851–60). For his other works, including his text editions, *see* Herzog's *Realencyklopädie.*

FRIULI, a district at the head of the Adriatic sea, partly included in Venetia proper (province of Udine) and partly in Venetia Julia (province of Gorizia). In the north and east Friuli includes portions of the Julian and Carnic Alps, while the south is the alluvial plain of the Isonzo, Tagliamento, and lesser streams which come down in floods after rain or thaw. The inhabitants, known as Furlanians or Friulani, speak a dialect with Celtic elements, one of the Latin dialects (others being those of the Dolomite valleys and of the Engadine). Silkworms are bred.

Friuli derives its name from the Roman town of Forum Iulii, or Foroiulium, the modern Cividale del Friuli (*q.v.*). In the 2nd century B.C. it was subjugated and became part of Gallia Transpadana. During the Roman period, besides Forum Iulii, its principal towns were Concordia and Aquileia. The Lombards (6th century) made it one of their 36 duchies, the capital being Forum Iulii or, as they called it. Civitas Austriae. The discovery of the grave of Gisulf (d. 611) at Cividale is an interesting proof of the veracity of Paulus Diaconus' *Historia Langobardorum.* In the 11th century the ducal rights over the greater part of Friuli were bestowed by the emperor Henry IV on the patriarch of Aquileia; but toward the close of the 14th century the nobles called in the assistance of Venice, which, after defeating the archbishop, secured possession of the country for itself in 1420. The eastern part of Friuli was held by the counts of Gorizia till 1500, when on the failure of their line it was appropriated by Maximilian I, and became the possession of the house of Austria. By the peace of Campo Formio in r797 the Venetian district also came to Austria, and on the formation of the Napoleonic kingdom of Italy in 1805 the department of Passariano was made to include the whole of Venetian and part of Austrian Friuli, and in 1809 the rest was added to the Illyrian provinces. The title of duke of Friuli was borne by Marshal Géraud Duroc. In 1815 the whole country was recovered by the emperor of Austria, who himself assumed the ducal title and coat of arms. In 1866 the Venetian portion was again ceded to Italy by the peace of Prague, and the rest came under Italian domination in 1918. Under the Italian peace treaty of 1947 the eastern part of the district was given to Yugoslavia.

FRIULIAN: *see* RAETO-ROMANCE DIALECTS.

FROBEN or FROBENIUS, **JOANNES** (c. 1460–1527), German printer and scholar, was born at Hammelburg in Bavaria. After completing his university career at Basel, where he made the acquaintance of the famous printer Johannes Auerbach (1443–1513), he established there about 1491 a printing house which had a European reputation for accuracy and for taste. In 1500 he married the daughter of the bookseller Wolfgang Lachner, who entered into partnership with him. He was a friend of Erasmus (*q.v.*), who not only had his own works printed by him, but superintended Frobenius' editions of St. Jerome, St. Cyprian, Tertullian, Hilary of Poitiers and St. Ambrose. His *Neues Testament in Greek* (1516) was used by Luther for his translation. Frobenius employed Hans Holbein to illuminate his texts. It was part of his plan to print editions of the Greek fathers. He did not, however, live to carry out this project, but it was very creditably executed by his son Jerome and his son-in-law Nikolaus Episcopius. Frobenius' work in Basel made that city in the 16th century the leading centre of the German book trade. An extant letter of Erasmus gives an epitome of his life.

FROBENIUS, LEO (1873–1938), German explorer and ethnologist, came to be regarded in his day as one of the world's greatest authorities on prehistoric art. He was born in Berlin, June 29, 1873, the son of a retired army officer. In ethnology he favoured extreme theories of diffusion, attributing a common origin to the cultures of Oceania and west Africa. Frobenius led 12 expeditions into Africa and explored centres of prehistoric art in the Alps, Norway, Spain, the Libyan and Sahara deserts, Trans-Jordan, Southern Rhodesia and the Bushman caves of South Africa. He wrote 60 books and numerous pamphlets and articles. In 1910 he announced that he had conclusive proof of the existence of Atlantis, the mythical lost continent in Africa. He died at Lake Maggiore, Intra, It., on Aug. 9, 1938

FROBISHER, SIR MARTIN (c. 1539–1594), English navigator and explorer, was the son of Bernard Frobisher of Altofts, Normanton, Yorkshire. In 1553 and in 1554 he went on voyages to Guinea and was there imprisoned for a time by the Portuguese. About 1559 he was in Barbary. During the 1560s he was privateering in the channel and was in trouble for piracy. In 1571–72, however, he was in the queen's service off the Irish coast. He married in 1559. As early as 1560 or 1561 Frobisher is said to have become interested in the possibility of finding a northwest passage to Cathay and India, and in 1576, by help of the earl of Warwick, he was put in command of an expedition consisting of two tiny barques, the "Gabriel" and "Michael," and a pinnace. He set sail from Blackwall on June 15 by way of the Shetland Islands. The pinnace was lost in a storm and the "Michael" deserted; but on July 20 the "Gabriel" sighted the coast of Labrador. Some days later the mouth of Frobisher bay was reached and, a farther advance northward being prevented by ice and contrary winds, Frobisher determined to sail westward up this passage (which he conceived to be a strait) to see "whether he mighte carrie himselfe through the same into some open sea on the backe syde." Butcher's Island was reached on Aug. 18 and some natives then decoyed away five of his men. After vainly trying to get them back, Frobisher turned homeward and reached London on Oct. 9.

Among the things Frobisher's men brought back was some "black earth," arid a rumour arose that this was gold ore. The result was that the next year a much more important expedition than the former was fitted out, the queen lending the "Aid" from the royal navy and subscribing £1,000. A company of Cathay was established and Frobisher was appointed high admiral of all lands and waters that might be discovered by him. On May 26, 1577, the expedition, consisting, besides the "Aid," of the "Gabriel" and "Michael" with pinnaces and 120 men, including miners, left Blackwall and reached Hall's Island at the mouth of Frobisher bay on July 17. The time was spent in collecting ore, and very little discovery was achieved. The return was begun on Aug. 22, and the "Aid" reached England on Sept. 23; the "Gabriel" and "Michael" later. Frobisher was received by the queen at Windsor. She believed in the value of the territory, and it was resolved to send out a larger expedition and establish a colony. On May 31, 1578, the expedition, consisting of 15 vessels. left Harwich and reached the south of Greenland on June 20. On July 2 the foreland of Frobisher bay was sighted. but stormy weather and dangerous ice drove the fleet unwittingly up a new (Hudson) strait. After proceeding about 60 mi. up this "mistaken strait" Frobisher turned back, and the fleet at last came to anchor in Frobisher bay.

Some attempt was made at founding a settlement, and a large quantity of ore was shipped; but the venture was not a success, and on Aug. 31 the fleet set out for England, which was reached in early October.

The ore was eventually proved to contain neither silver nor gold, and a proposal to send Frobisher out again in 1581 came to nothing.

In 1580 he commanded the "Foresight" in operations off Munster during the Desmond rebellion and took part in the capture of Smerwick. In 1585 he went in the "Primrose" as vice-admiral of Sir Francis Drake's expedition to the West Indies. He was again at sea during the vain attempts to relieve Sluys in 1587. and next year in the "Triumph" played a prominent part in the Armada campaign, being knighted during the operations. In the winter of 1588–89 he commanded a squadron guarding the Narrow Seas and in the following autumn he took another small force to the Spanish coast and the Azores. He was off the Azores again in the summer of 1590. Next year he married a second time and for a short while settled in Yorkshire, but for most of the summer of 1592 he lay off the Spanish coast with one part of a fleet fitted out by Sir Walter Raleigh. His last command was of a squadron sent in 1594 to assist in defending Brest against a Spanish force established at Fort Crozon.

In the final assault on the fort he received a wound from which he died at Plymouth on Nov. 22. Though he appears to have been somewhat rough in his bearing, and too strict a disciplinarian to be much loved, Frobisher was undoubtedly one of the most able seamen of his time.

Frobisher Knight* (1878); J. A. Williamson, *Age of Drake* (1938); P. F. Alexander (ed.), *The North-west and North-east Passages, 1576–1611* (1915). (R. B. WM.)

FROCK, originally a long, loose gown with broad sleeves, worn by members of the religious orders. The word is derived from the O.Fr. *froc*, of obscure origin. The formal stripping off of the frock became part of the ceremony of degradation in the case of a condemned monk; hence the expression "to unfrock." In the middle ages "frock" was also a long loose coat worn by men, or a coat of mail, and the word survived into the 19th century for a coat with long skirts. the "frock coat." It is now chiefly used in English-for a child's or young girl's dress.

FRODING, GUSTAF (1860–1911), one of the most outstanding Swedish lyrical poets, was born at Alster, Varmland, Aug. 22, 1860. His parents came from cultured and gifted families but both showed mental instability. He studied at Uppsala university, 1880–83, and again in 1885, but did not take a degree. At first he staved off depression by working for a liberal paper and was for ten years a journalist at Karlstad. Varmland, though forced to spend long periods in sanatoriums for treatment of nervous disorders. Stimulated by the revolt against naturalism at the end of the 1880s, in 1891 he published his first collection of poems, *Guitarr och dragharmonika* (Eng. trans., *Guitar and Concertina*, containing also later poems, 1925). It was followed in 1894 by *Nya dikter* and in 1896 by *Stank och flikar*. These three volumes contain the essential Fröding. Passages in the last led to his prosecution for pornography, and although he was acquitted, the experience was disastrous to a man so scrupulous and oversensitive. He managed to publish two more small books of poems, *Nytt och Gamnzalt* (1897) and *Gralstank* (1898), before his final breakdown. From 1898 to 1905 he was a patient in a mental hospital at Uppsala and, although he recovered a measure of sanity, he never recovered his health and died at Stockholm, Feb. 8, 1911. A collection of verse and prose, *Efterskord*, was published in 1910, and a posthumous collection, *Reconvalescentia*, appeared in 1913. Fröding also wrote humorous dialect sketches, literary essays and newspaper causeries.

Although Fröding never altogether abandoned the realism and social compassion which had first inspired him, he partly shared the neoromanticism of the 1890s, nostalgically looking back to an idealized, old-world country life. In outlook he remained a radical, involved in contemporary discussions inspired by the ideas of such writers as Tolstoy and Nietzsche, but as a poet he was influenced more by the great romantics: Goethe, Scott, Byron, Heine. He wrote a little book on Burns (1892) and translated several of his poems. His poetic style showed a virtuosity new to Swedish literature and unusual technical perfection. By uniting colloquial language with a rich musical form, he liberated Swedish verse from traditional patterns. He was a master of humorous verse, and his drolleries are as effective as the bitter pathos or evocative magic of his serious poetry. Readers were first attracted by the poems inspired by the scenes, characters and folklore of his native Värmland, but even in his early work there was also a strong personal note of melancholy, despair and revolt and a pathetic quest for a philosophy capable of resolving life's discords. One of Froding's answers to this quest was humour; another was a monistic mysticism. reconciling good and evil. His popularity as a poet was enhanced by the appeal of his personality, which remained essentially kind, noble and upright, despite the tragedy of his life.

Froding's collected writings, edited by R. G. Berg, appeared in 16 volumes, 1917–22. English translations include *Poems*, translated by A. Björck (1903) and *Selected Poems*, translated by C. W. Stork (1916).

FROEBEL (FRÖBEL), **FRIEDRICH (WILHELM AUGUST)** (1782–1852), German founder of the kindergarten and influential educational reformer of the 19th century, was born on April 21, 1782, in the Thuringian village of Oberwiessbach, where his father was pastor. His mother died when he was very young, and he was neglected as a child until an uncle gave him a home and sent him to school. For two years he was apprenticed to a forester and this influenced his future development. He acquired a thorough knowledge of plants and natural phenomena while at the same time beginning the study of mathematics and languages.

Froebel's love of nature led him to take a course at Jena, but lack of funds cut short his university career. He incurred small debts and was imprisoned for nine weeks. He tried various kinds of employment until his meeting with Anton Gruner, a pupil of Johann Pestalozzi and head of the Frankfurt am Main model school, convinced him of his vocation as a teacher. After two years as assistant to Gruner, he went to Yverdon, Switz., where he came into close contact with Pestalozzi. Though he learned much at Yverdon, he quickly discovered the weakness of organization which characterized Pestalozzi's work. He entered the University of Gottingen, where military service soon interrupted his studies. During the campaign of 1813 he formed a lasting friendship with H. Langethal and W. Middendorff, who became his devoted followers and who joined him at a school he opened at Griesheim in Thuringia in 1816. Two years later the school moved to Keilhau, also in Thuringia, and it was there that Froebel put into practice his educational theories. He and his friends and their wives formed a kind of educational community. To this period belongs Froebel's most important treatise, *The Education of Man* (1826; Eng. trans. 1885). In 1831 he left Keilhau to his partner and accepted the invitation of the Swiss government to train elementary teachers. His experience at Keilhau and as head of a new orphan asylum at Burgdorf, Switz., impressed him with the importance of the early stages of education. On returning to Keilhau in 1837 he opened his first *kindergarten*, or "garden of children," in the neighbouring village of Blankenburg. The experiment attracted widespread interest and other kindergartens were started. Unfortunately, because of a confusion with the socialist views of Froebel's nephew, the Prussian government proscribed the kindergarten and the ban was not removed until after 1860, several years after Froebel's death at Marienthal on June 21, 1852.

One of Froebel's most enthusiastic disciples, Baroness Bertha von Marenholtz-Biilow. was largely responsible for bringing Froebel's ideas to the notice of educators in England, France and the Netherlands. Later they were introduced into other countries, including the United States. The first kindergarten in London was opened in 1851 under the supervision of Madame Bertha Ronge and her sister, both pupils of Froebel. Charles Dickens visited the school and wrote a full and sympathetic account of the work in *Household Words*. The later growth of the movement in England was mainly the result of the work of Madame E. Michaelis, who was instrumental in founding the Froebel society in 1875. English teachers were attracted by the practical ideas of Froebel but at first failed to grasp the importance of his theory. It was in the United States that the Froebelian movement achieved its greatest success. Thus John Dewey adopted Froebel's principles in his experimental school at The University of Chicago. It was not until the 20th century that they were thoroughly understood by English teachers. The English nursery-school movement originated by Margaret and Rachel McMillan owed much to Froebel's ideas.

Though not himself a great philosopher, Froebel was influenced by the outstanding German thinkers of his age and by Rousseau and Pestalozzi. He was a sincerely religious man who, because of his belief in the underlying unity of all things, tended toward pantheism and has been called a nature mystic. An important contribution to educational theory was his belief in self-activity and the essential factor of play in child education. This resulted in the introduction of a series of toys or apparatus known as the "gifts," devised to stimulate learning through well-directed play accompanied by songs and music. The modern "playway" in education is much indebted to Froebel.

In addition to the *Education of Man,* Froebel wrote the *Pädagogik d. Kindergartens; Kleinere Schriften* and *Mutter-und Koselieder.* Collective editions were edited by W. Lange (1862) and F. Seidal (1883). There are English editions of the *Autobiography of Friedrich Froebel,* new ed. (1903), *Froebel's Chief Writings on Education* (1912) and the *Mother's Songs, Games and Stories* (1920).

FROESCHWILLER, BATTLE OF. The name given by the French to the battle of Wörth in the Franco-German War (*q.v.*), which is the name commonly adopted.

FROG, a name of wide application, strictly for an animal belonging to the family Ranidae, but also used properly for any representative of the order Salientia of the class Amphibia (*q.v.*). It is a deficiency of the English language that there is no vernacular name in general use for the tailless amphibians as a whole.

Frogs proper are typified by the common European species, *Rana temporaria,* the edible frog, *R. esculenta,* and by the American leopard frog, *R. pipiens* and the bullfrog, *R. catesbeiana.* The genus *Rana* includes in all about 200 species.

Some of the species are permanently aquatic and have fully webbed toes, while others are terrestrial, except during the breeding season. On the other hand, other species are adapted for burrowing, by means of the much-enlarged and sharp-edged tubercle at the base of the outer toe, while not a few have the tips of the digits dilated into discs by which they are able to climb on trees.

Some frogs grow to a large size. The bullfrog of eastern North America grows to nearly eight inches from snout to vent, *R. guppyi* of the Solomon Islands to eight and one-half inches and *R. goliath,* of the South Cameroons, to ten inches. Among species belonging to other genera of the family may be mentioned the hairy frog of west Africa, *Trichobatrachus robustus,* some specimens of which have the sides of the body and of the hind limbs covered with long villosities, and its ally *Gampsosteonyx batesi,* in which the last phalanx of the fingers and toes is sharp and claw-like and perforates the skin. *Dimorphognathus,* from west Africa, is the unique example of a sexual dimorphism in the dentition, the males being provided with a series of large sharp teeth in the lower jaw, which in the female is edentulous. The curious horned frog of the Solomon Islands, *Ceratobatrachus guentheri,* has teeth in the lower jaw in both sexes, while a few forms, such as *Cardioglossa,* have no teeth.

A closely allied family, the Rhacophoridae, includes the arboreal genus *Rhacophorus* of eastern Asia, some species of which are remarkable for the extremely developed webs which are believed to act as a parachute (flying frog of A. R. Wallace). Some species have been observed to make aerial nests between leaves overhanging water, a habit shared by the closely related *Chiromantis* of tropical Africa. (K. P. S.)

FROGBIT, in botany, the English name for a small rootless plant with floating leaves known botanically as *Hydrocharis morsus-ranae,* a member of the family Hydrocharitaceae. The plant has rosettes of roundish floating leaves, and multiplies like the strawberry plant by runners, at the end of which new leaf-rosettes develop. Staminate and pistillate flowers are borne on different plants; they have three small green sepals and three broadly ovate white membranous petals. The fruit is fleshy. The plant occurs in ponds and ditches in England.

FROGMEN, the popular name for members of the U.S. navy's underwater demolition teams in World War II. Their efforts reduced troop losses and facilitated the landing of men and supplies on enemy shores. Before an amphibious landing was made, frogmen reconnoitered the beach area. They measured the actual depths of the water, detected natural or man-made obstructions under the surface and observed the enemy's defensive positions close to the water's edge. One of their most important functions was to destroy dangerous underwater obstructions. Frogmen were carefully chosen volunteers who were intensively trained and worked without weapons. The explosive charges they used for demolitions, their boats, tools, equipment and clothing were developed by test and war experience.

About 1,000 frogmen prepared the way for the invasion of Okinawa, working for three days in very cold water, after the mine-sweepers had done their work. The frogmen dealt with a few beaches at a time, beginning by taking soundings on the reefs offshore and examining the extensive obstructions which the enemy had erected. This was followed by the demolition work and a final recheck. The frogmen, protected by heavily concentrated gunfire and by aerial strikes, lost only a few men. *See* also DIVING APPARATUS.

See Francis Douglas Fane and Don Moore, *The Naked Warriors* (1956). (J. B. HN.)

FROGMOUTH, a name, in reference to the broad, froglike gape, for birds comprising the family Podargidae, in the order Caprimulgiformes, which also contains the nightjar, nighthawk, whippoorwill and oilbird (*qq.v.*). There are about 12 species of frogmouths, including *Batrachostomus auritus* of the Malay peninsula and Sumatra and Borneo, *B. septimus* of the Philippines and *B. moniliger* of India; others occur in southeastern Asia and the Malays. The genus *Podargus* of Australia and the Malays is usually called morepork (*q.v.*). Owlet frogmouths, intermediate in appearance to owls and nightjars, belong to the family Aegothelidae. (G. F. Ss.; X.)

FRÖHLICH, ABRAHAM EMANUEL (1796–1865), a Swiss poet, pastor and professor, was born at Brugg, Feb. 1, 1796, and died at Baden, Dec. 1, 1865. His earliest literary work was in the form of versified apologues (*Fabeln,* 1825), which achieved great popularity for their satirical humour and sound morality. Among his other works were *Hymns,* the ultra-Protestant epics of *Ulrich Zwingli* (1840) and *Ulrich von Hutten* (1845), and *Der Junge Deutsch-Michel* (1846), an attack on the youth of his day. Fröhlich was highly conservative and orthodox in his views.

FROHMAN, CHARLES (1860–1915), U.S. theatrical manager, a star maker who developed, among others, Maude Adams, Ethel Barrymore, Julia Marlowe, Billie Burke, William Gillette and Otis Skinner, was born in Sandusky, O., on June 17, 1860. In his early youth his family moved to New York city, and Charles became interested in theatrical activities through his elder brothers, Daniel (*see* below) and Gustave. After several years of part-time positions with local newspapers and theatres, Frohman, in 1883, managed the Wallack Theatre company on tour. He later opened a theatrical booking office in New York and laid the foundation of the Theatrical Syndicate, which for several years controlled U.S. theatres. Frohman's first real success was Bronson Howard's *Shenandoah* in 1889. In 1892 he engaged John Drew (*see* DREW) as his star and established the Empire Stock company. Frohman's encouragement of such playwrights as Clyde Fitch, David Belasco and Augustus Thomas was indicative of his ability to perceive theatrical talent. He dominated the U.S. theatre during 25 of its most exciting years, and when he died with the sinking of the "Lusitania," May 7, 1915, an era ended. Frohman never married.

His brother, DANIEL FROHMAN (1851–1940), was an important theatrical producer from the 1880s to his retirement in 1912. At various times he managed the Fifth Avenue, the Madison Square, the Lyceum, the New Lyceum and Daly's theatres, and was president of the Actor's Fund of America. He died Dec. 26, 1940. (S. W. H.)

FROHSCHAMMER, JAKOB (1821–1893), German theologian and philosopher, was born at Illkofen, near Regensburg, on Jan. 6, 1821. He studied theology at Munich and in 1847 became a priest. In 1850 he published Beitriige *zur Kirchengeschichte*, which was placed on the Index Expurgatorius, and in 1854, his Uber den *Ursprung* dcr menschlichen Seelen, which maintained that the human soul was not individually created, but was the result of a secondary creative act on the part of the parents, and that soul like body was subject to the laws of heredity. This was supplemented in 1855, the year in which he became professor of philosophy in Munich, by Menschenseele und *Physiologie*. The Einleitung in die Philosophie und *Grundriss* der Metaphysik of 1858 assailed the doctrine of Thomas Aquinas, that philosophy was the handmaid of theology. In 1861 appeared Uber die Aufgabe der Naturphilosophie und ihr *Verhältnis zur Naturwissenschaft,* and Uber die Freiheit der *Wissenschaft,* in which he declared the independence of science from authority, and reproached the excessive respect for the latter in the Roman Church. In 1862 he founded Atheniium as the organ of liberal Catholicism, writing for it the first adequate German account of the Darwinian theory of natural selection. Excommunicated in 1871, he replied with Der Fels Petri in Rom (1873), Der *Primat* Petri und des Papstes (1875) and Das *Christentum* Christi und das Christentum des Papstes (1876). Of his later works, the most important are: Die Phantasie *als Grundprincip* des Weltprocesses (1877), Uber die Genesis der Menschheit (1883) and Uber die Organisation und *Cultur* der menschlichen Gesellschaft (1885).

Frohschammer died at Bad Kreuth, Bavaria, on June 14, 1893.

BIBLIOGRAPHY.—His autobiography was published in A. Hinrichsen's Deutsche Denker (1888). See also E. Reich, Weltanschauung und Menschenleben; Betrachtungen uber die Philosophie J. Frohschammer (1894); B. Munz, J. Frohschammer (1894), Briefe *von* und uber J. Frohschammer (1897); J. Friedrich, J. Frohschammer (1896).

FROISSART, JEAN (1338–1410?), French chronicler and raconteur, historian of his own times. His forefathers were *jurés* (aldermen) of the little town of Beaumont, lying near the river Sambre, to the west of the forest of Ardennes. His father, who seems to have been a painter of armorial bearings, migrated to Valenciennes. The date generally adopted for his birth is 1338. His native city of Valenciennes was rich in romantic associations. Not far from its walls was the western fringe of the great forest of Ardennes, sacred to the memory of Pepin, Charlemagne, Roland and Ogier. Along the banks of the Scheldt stood, one after the other, not then in ruins, but bright with banners, the gleam of armour, and the liveries of the men at arms, castles whose seigneurs, now forgotten, were famous in their day for many a gallant feat of arms. The castle of Valenciennes itself was illustrious in the romance of Perceforest. There was born that most glorious and most luckless hero, Baldwin, first emperor of Constantinople. All the splendour of mediaeval life was to be seen in Froissart's native city: on the walls of the Salle le Comte glittered — perhaps painted by his father — the arms and scutcheons beneath the banners and helmets of Luxembourg, Hainaut and Avesnes; the streets were crowded with knights and soldiers, priests, artisans and merchants; the churches were rich with stained glass, delicate tracery and precious carving; there were libraries full of richly illuminated manuscripts on which the boy could gaze with delight; every year there was the fete of the *puy d'Amour* de Valenciennes, at which he would hear the verses of the competing poets; there were festivals, masques, mummeries and moralities.

The moon, he says, rules the first four years of life; Mercury the next ten; Venus follows. He was 14 when the last goddess appeared to him in person, as he tells us, after the manner of his time, and informed him that he was to love a lady, "belle, *jone,* et *gente.*" Meanwhile he was placed in some commercial position which he very soon abandoned, for he had resolved on becoming a learned clerk. He then naturally began to make verses, like every other learned clerk, and fell in love. He found one day a damoiselle reading a book of romances. It was the romance of Cleomades. He remarks the singular beauty of her blue eyes and fair hair, while she reads a page or two, and then — one would almost suspect a reminiscence of Dante — "Adont *laissames nous le* lire." She was rich and he was poor; she was nobly born and he obscure; it was long before she would accept the devotion, even of the conventional kind, which Froissart offered her.

In England. — He was 18 years old when he left Valenciennes for the court of England, taking with him letters of recommendation from the king of Bohemia and the count of Hainaut to Queen Philippa, niece of the latter. He was well received by the queen, always ready to welcome her own countrymen; he wrote ballades and virelays for her and her ladies. But after a year he began to pine for another sight of "la *très douce,* simple, et *quoie,*" whom he loved loyally. Good Queen Philippa gave him his *congé* on the condition that he was to return. The conclusion of his single love adventure is simply and unaffectedly told in his Trettie de *l'espinette* amoureuse. It was a passion conducted on the well-known lines of conventional love; it ended with calumny and a complete rupture. The damoiselle not only scornfully refused to speak to her lover or acknowledge him, but even seized him by the hair and pulled out a handful. Nor would she ever be reconciled to him again.

Perhaps to get healed of his sorrow, Froissart began those wanderings in which the best part of his life was to be consumed. He first visited Avignon in 1360, and in 1361 he returned to England after an absence of five years. He brought with him as a present to Queen Philippa a book of rhymed chronicles of the wars of his time written by himself. The queen now made young Froissart one of her secretaries, and he began to serve her with "beaux *dittiés* et traite's amoureux." She seems to have suggested to him the propriety of travelling in order to get information for more rhymed chronicles. It was at her charges that Froissart travelled to Scotland, where he was well received by King David, William of Douglas and the earls of Fife, Mar, March and others. His travels in Scotland lasted for six months. Returning southward he rode along the whole course of the Roman wall, showing the true spirit of an archaeologist; he thought that Carlisle was Carlyon, King Arthur's capital; he calls Westmorland, where the common people still spoke the ancient British tongue, North Wales; he rode down the banks of the Severn, and returned to London by way of Oxford — "l'escole *d'Asque-Suffort.*" In London Froissart entered the service of King John of France as secretary, and probably acquired at this period that art, in which he has probably never been surpassed, of making people tell him all they knew. He liked the story of a battle from both sides and from many points of view; he wanted the details of every little cavalry skirmish, every capture of a castle, every gallant action and brave deed. And he forgot nothing.

At the age of 29, in 1366, Froissart left England for Brussels, where there was a great concourse of minstrels from all parts, from the courts of the kings of Denmark, Navarre and Aragon, from those of the dukes of Lancaster, Bavaria and Brunswick. Froissart received a gift of money, as appears from the accounts: "*uni* Fritsardo, dictori, qui est cum regina Angliae, *dicto* die, VI. mottones." He then went to Brittany, where he heard from eyewitnesses details of the battles of Cocherel and Auray, the great day of the Thirty and the heroism of Jeanne de Montfort. Windsor Herald told him something about Auray, and a French knight, one Antoine de Beaujeu, gave him the details of Cocherel. From Brittany he went southward to Nantes, La Rochelle and Bordeaux, where he arrived a few days before the visit of Richard (afterward Richard II). He accompanied the Black Prince to Dax, and hoped to go on with him into Spain, but was dispatched to England on a mission. He next formed part of the expedition which escorted Lionel, duke of Clarence, to Milan, to marry the daughter of Galeazzo Visconti. Geoffrey Chaucer was also one of the prince's suite. At the wedding banquet Petrarch was a guest sitting among the princes. From Milan Froissart, accepting gratefully a cotte hardie with 20 florins of gold, went to Bologna, and met Peter, king of Cyprus, from whose follower and minister, Eustache de Conflans, he learned particulars of the king's exploits. He accompanied Peter to Venice, where he left him after receiving a gift of 40 ducats. At Rome he learned of the death of his friend, King Peter of Cyprus, and of the good Queen Philippa, of whom he writes, in grateful remembrance—

Propices li soit Diex à l'âme!
J'en suis bien tenus de pryer
Et ses larghesces escuyer,
Car elle me fist et créa.

Philippa dead, Froissart returned to Flanders and presented himself, with a new book in French, to the duchess of Brabant, from whom he received the sum of 16 francs, given in the accounts as paid *uni Frissardo dictatori.* Froissart may also have found a patron in Yolande de Bar, grandmother of Ring René of Anjou. In any case he received a substantial gift from someone in the shape of the benefice of Lestines, a village near Binche. He was placed upon the duke of Brabant's pension list, and was entitled to a yearly grant of grain and wine, with some small sum in money. Froissart was not the man to sit down at ease to discharge the duties of parish priest, to say mass, to bury the dead, to marry the villagers and to baptize the young. From time to time he repaired to the court of Coudenberg, and became '*(moult frère et accointé"* with the duke of Brabant. And then came Gui de Blois, one of King John's hostages in London in the old days. He had been fighting in Prussia with the Teutonic knights, and now proposed to settle down for a time in his castle of Beaumont. This prince, in emulation of his grandfather, the patron of Jean le Bel, advised Froissart seriously to take in hand the history of his own time.

THE CHRONICLE

He began his career by rewriting the work of the chronicler Jean le Bel; Gui de Blois, among others, supplied him with additional information. His own notes, taken from information obtained in his travels, gave him more details, and when in 1374 Gui married Marie de Namur, Froissart found in the bride's father, Robert de Namur, one who had himself largely shared in the events which he had to relate. He, for instance, is the authority for the story of the siege of Calais and the six burgesses. Froissart remained for 12 years at Lestines, or at Beaumont, arranging and writing his chronicles. During this period, too, he composed his *Espinette amoureuse,* and the *Joli Buisson de jonesce,* and his romance of *Méliador.* He also became chaplain to the count of Blois, and obtained a canonry of Chimay. After this appointment we hear nothing more of Lestines, which he probably resigned,

In 1386 his travels began again, when he accompanied Gui to his castle at Blois, in order to celebrate the marriage of his son Louis de Dunois with Marie de Berry. He wrote a *pastourelle* in honour of the event. Then he attached himself for a few days to the duke of Berry, from whom he learned certain particulars of current events, and then, becoming aware of what promised to be the most mighty feat of arms of his time, he hastened to Sluys, where the French were collecting an enormous fleet, and making preparations to repeat the invasion of William the Conqueror. But there was no invasion of England. In Flanders Froissart met many knights who had fought at Rosebeque. and could tell him of the troubles which in a few years desolated that country, once so prosperous. He stayed at Ghent, among those ruined merchants and mechanics, for whom, as one of the same class, he felt a sympathy never extended to English or French, perhaps quite as unfortunate, and he devotes 300 chapters to the Flemish troubles, This portion of the chronicle was written at Valenciennes. During this residence in his birthplace his verses were crowned at the *puys d'amour* of Valenciennes and Tournay.

This part of his work finished, he determined on making a journey to the south of France in order to learn something new. On this occasion he rode first to Blois; on the way he fell in with two knights who told him of the disasters of the English army in Spain; one of them also informed him of the splendid hospitality of Gaston Phoebus, count of Foix, on hearing of which Froissart resolved to seek him out. Arrived at Foix he discovered that the count was at Orthez, whither he proceeded in company with a knight named Espaing de Lyon, who, Froissart found, had not only fought, but could describe.

The account of those few days' ride with Espaing de Lyon is the most charming, the most graphic, and the most vivid chapter in the whole of Froissart. Every turn of the road brings with it the sight of a ruined castle, about which this knight of many memories has a tale or a reminiscence. The whole country teems with fighting stories. Froissart never tires of listening nor the good knight of telling. "Sainte Marie!" cries Froissart in mere rapture. "How pleasant are your tales, and how much do they profit me while you relate them! And you shall not lose your trouble, for they shall all be set down in memory and remembrance in the history which I am writing." Arrived at length at Orthez, Froissart introduced himself to the count as a chronicler. He heard much from the count, and there was a good deal, too, to be learned of people about the court. One knight recently returned from the east told about the Genoese occupation of Famagosta; two more had been in the fray of Otterbourne; others had been in the Spanish wars.

Leaving Gaston at Iength, Froissart assisted at the wedding of the old duke of Berry with the youthful Jeanne de Bourbon, and was present at the reception given to Isabeau of Bavaria by the Parisians. He then returned to Valenciennes, and sat down to write his fourth book. While engaged in the events of the year 1385 he found that his notes taken at Orthez and elsewhere on the affairs of Castile and Portugal were incomplete. He hastened to Bruges, where, he felt certain, he should find someone who would help him. There was, in fact, at this great commercial centre, a colony of Portuguese. From them he learned that a certain Portuguese knight, Dom Juan Fernand Pacheco, was at the moment in Middelburg on the point of starting for Prussia. He instantly embarked at Sluys, reached Middelburg in time to catch this knight, introduced himself and conversed with him uninterruptedly for the space of six days, getting his information on the promise of due acknowledgment. During the next two years he seems to have had trouble with his seigneur Gui de Blois, and even to have resigned his chaplaincy. He next calls Robert de Namur his seigneur, and dedicates to him, in a general introduction, the whole of his chronicles. We then find him at Abbeville, trying to learn all about the negotiations pending between Charles VI and the English. He was unsuccessful, either because he could not get at those who knew what was going on or because the secret was too well kept. He next made his last visit to England, where, after 40 years' absence, he naturally found no one who remembered him. He stayed in England several months, seeking information on all points from his friends Henry Chrystead and Richard Stury, from the dukes of York and Gloucester and from, Robert the Hermit.

On his return to France, he found preparations going on for that unlucky crusade, the end of which he describes in his *Chronicle.* It was headed by the count of Kevers. After him floated many a banner of knights, descendants of the crusaders, who bore the proud titles of duke of Athens, duke of Thebes, sire de Sidon, sire de Jericho. They were going to invade the sultan's empire by way of Hungary; they were going to march south; they would reconquer the holy places. And presently we read how it all came to nothing, and how the slaughtered knights lay dead outside the city of Nikopoli. In almost the concluding words of the *Chronicle* the murder of Richard II of England is described. His death ends the long and crowded *Chronicle,* though the pen of the writer struggles through a few more unfinished sentences.

The Man and His Work.—The rest is vague tradition. He is said to have died at Chimay in 1410 and to have been buried at the church of St. Monegunda. It is further said that he died in poverty so great that his relations could not even afford to carve his name upon the headstone of his tomb; not one of his friends, not even Eustache Deschamps, writes a line of regret in remembrance; the greatest historian of his age had a reputation so limited that his death was no more regarded than that of any common monk or obscure priest. Among his friends were Guillaume de Machault, Eustache Deschamps and Cuvelier, a follower of Bertrand du Guesclin. It is probable that he knew Chaucer, with whom Deschamps maintained a poetical correspondence; there is nothing to show that he ever made the acquaintance of Christine de Pisan.

The selection of Froissart's own poems published by Buchon in 1829 includes the *Dit dou florin;* the *Débat dou cheval et dou levrier,* written during his journey in Scotland; the *Dittie de la flour de la Margherite;* a *Dittie d'amour* called *L'Orlose amoureus,* in which he compares himself. the imaginary lover, with a clock; the *Espinette amoureuse,* which contains a sketch of his early life, freely and pleasantly drawn, accompanied by rondeaux and virelays; the *Buisson de jonesce,* in which he returns to the recollections of his own youth; and various smaller pieces.

There has never been any difference of opinion on the distinctive merits of his *Chronicle.* It presents a vivid and faithful drawing of the things done in the 14th century. No more graphic account exists of any age. No historian has drawn so many and such faithful portraits. There are, it is true. portraits of men as they seemed to the writer, not of men as they were. Froissart was uncritical; he accepted princes by their appearance. Who, for instance, would recognize in his portrait of Gaston Phoebus de Foix the cruel voluptuary, stained with the blood of his own son, which we know him to have been? Froissart, again, had no sense of historical responsibility; he was no judge to enquire into motives and condemn actions; he was simply a chronicler. He has been accused by French authors of lacking patriotism. Yet it must be remembered that he was neither a Frenchman nor an Englishman, but a Fleming. He has been accused of insensibility to suffering. Indignation against oppression was not, however, common in the 14th century; why demand of Froissart a quality which is rare enough even in our own time? Yet there are moments when, as in describing the massacre of Limoges, he speaks with tears in his voice.

As regards his personal character, Froissart depicts it himself for us. Such as he was in youth, he tells us. so he remained in more advanced life; rejoicing mightily in dances and carols. in hearing minstrels and poems; inclined to love all those who love dogs and hawks; pricking up his ears at the uncorking of bottles, "Car au voire prens grand plaisir"; pleased with good cheer, gorgeous apparel and joyous society, but no commonplace reveller or greedy voluptuary — everything in Froissart was ruled by the good manners which he set before all else; and always eager to listen to tales of war and battle. As has been said above, he shows, not only by his success at courts, but also by the whole tone of his writings, that he possessed a singularly winning manner and strong personal character.

Froissart lived wholly in the present, and had no thought of the coming changes. Born when chivalrous ideas were most widely spread, but when the spirit of chivalry itself, as inculcated by the best writers, was in its decadence, he is penetrated with the sense of knightly honour, and ascribes to all his heroes alike those qualities which only the ideal knight possessed.

BIBLIOGRAPHY.—The first edition of Froissart's *Chronicle* was published in Paris. It bears no date; the next editions are those of the years 1505, 1514, 1518 and 1520. The edition of Buchon, 1924, was a continuation of one commenced by Dadier. The best modern editions are those of Kervyn de Lettenhove (1863–77) and Siméon Luce (1869–88); for bibliography *see* A. Potthast, *Bibliotheca hist. medii aevi,* i (1896). An abridgment was made in Latin by Belleforest, and published in 1672. An English translation was made by Bourchier, Lord Berners, and published in London, 1525. *See* the "Tudor Translations" edition of Berners (1901), with introduction by W. P. Ker; and the "Globe" edition, with introduction by G. C. Macaulay (1913). The translation by Thomas Johnes was originally published in 1802–05. For Froissart's poems *see* Scheler's text in K. de Lettenhove's complete edition; *Méliador* has been edited by A. Longnon ior the Société des Anciens Textes (1895–99). *See* also Mme. Agnes Darmesteter (Duclaux), *Froissart* (1894). *Froissarts Cronycles,* translated from the French by Sir John Bourchier, Lord Berners, 7 vol. (1927–28).

FROME (pron. "Froom"), a market town and urban district in the Wells parliamentary division of Somerset, Eng., 17½ mi. E.N.E. of Wells by road. Pop. (1951) 11,298. Area 1.9 sq.mi. It is unevenly built on high ground above the Frome river, and the country round is richly wooded and picturesque. The early version of its name was Froom.

The parish church of St. John the Baptist, with its fine tower and spire, was rebuilt in the 13th and 14th centuries and much restored in the 19th. Bishop Thomas Ken (*q.v.*) who died at Longleat (4 mi S.E.) is buried there.

There are the Literary and Scientific institution, with a museum, a school of art and science, and a grammar school founded under Edward VI. The George hotel in the market square is one of many old houses. Selwood forest, now diminished, on whose border the town once stood, was long a favourite haunt of brigands and highwaymen. The Saxon occupation is the earliest in Frome of which there is evidence, the settlement being the result of the foundation of a monastery by St. Aldhelm. A witenagemot was held there in 934 and at the time of the Domesday survey the manor was owned by William I. Frome was not represented in parliament until given one member by the Reform act of 1832; its separate representation was merged in that of the county in 1885.

A charter of Henry VII to Edmund Leversedge. then lord of the manor, granted the right to have two fairs, and in the 18th century two others nere held.

An agricultural show and cheese fair is held on the third Wednesday in September. The industries include plastics. die-stamping and hot pressing and paint manufacture. One of the oldest is cloth making. The town is an agricultural centre.

About 3 mi. west of Frome is the village of Mells. where the manor house is associated with the rhyme of "Little Jack Horner."

FROMENTIN, EUGÈNE (1820–1876), French painter and author, best known for his pictorial scenes of Algeria, was born at La Rochelle on Oct. 24, 1820. He studied under Louis Cabat, the landscape painter. The land and people of Algeria suggested the subjects of most of his works.

Among his more important early works are "Moisson en Algérie"; "Diffa, reception du Soir"; "Chasse à la gazelle"; and "Enterrement maure." They are somewhat stiff in design and execution. His second period extends until 1859 and includes the following works: "Les Bateleurs nkgres"; "Le Sirnoun"; and "La Lisikre d'oasis." They are grey in tone and were executed under the influence of Jean-Baptiste Carot.

After 1860 Fromentin's colour becomes bright and luminous: "Fauconnier arabe"; "Chasse au héron"; "La curée"; "Centaures et centauresses"; here Fromentin was influenced by Eugène Delacroix. Fromentin's paintings show only one side of a talent that was perhaps even more felicitously expressed in literature; "Dominique," first published in the *Revue des deux mondes* in 1862, and dedicated to George Sand, is remarkable among the fiction of the century for imaginative observation. Fromentin's other literary works are *Visites artistiques* (1852); *Simples Pèlerinages* (1856); *Un Été dans le Sahara* (1857); *Une Année dans le Sahel* (1858); and *Les Maîtres d'autrefois* (1876). He died at La Rochelle on Aug. 27, 1876.

FROMMEL, GASTON (1862–1906), Swiss theologian, professor of theology in Geneva from 1894 to 1906. An Alsatian by birth, he belonged mainly to French Switzerland. He may best be described as continuing the spirit of Alexandri Vinet (q v.) amid later mental conditions. Like Vinet, he derived his philosophy of religion from a deeply personal experience of the Gospel of Christ as meeting the demands of the moral consciousness; but he developed even further than Vinet the psychological analysis of conscience and the method of verifying every doctrine by direct reference to spiritual experience. Both made much of moral individuality or personality as the criterion of reality, believing that its correlation with Christianity, both historically and philosophically, was most intimate. But while Vinet's stress was on the liberty from human authority essential to the moral consciousness, the changed needs of the age caused Frommel to develop rather the aspect of man's dependence on God's spiritual initiative, "the conditional nature of his liberty." "Liberty is not the primary, but the secondary characteristic" of conscience; "before being free, it is the subject of obligation."

Frommel claimed that a deeper analysis carries us beyond the subjectivity of Immanuel Kant's categorical imperative, since consciousness of obligation was *"une expérience imposée sous le* *mode de l'absolu." By imposée* (Solomon Malan's phrase) he emphasized the priority of man's sense of obligation to his moral consciousness either of self or of God. He appealed to the psychology of the subconscious for confirmation of his analysis, insisting on priority to self-conscious thought as a mark of metaphysical objectivity in the case of moral, no less than of physical experience. He found in the Christian revelation the same characteristics as belonged to the universal revelation in conscience, viz. God's sovereign initiative and his living action in history. From this standpoint he argued against a purely psychological type of religion (*agnosticisme religieux,* as he termed it) —a tendency to uhich he saw even in A. Sabatier and the *symbolofidéisme* of the Paris school—as giving up a real faith. Like Vinet, Frommel was a man of letters and a penetrating critic of men and systems: *see* his *Études litteraires et morales* (1907).

BIBLIOGRAPHY.—G. Godet, *Gaston Frommel* (Neuchâtel, 1906), *a* sketch, mith citation of sources; for a complete edition of his writings see *Oeuvre Systematique* (Neuchâtel, 1910–16); *The Psychology of Christian Faith* (London, Stud. Chr. Mov., 1928), a selection in English with introductory study. (J. V. B.)

FRONDE, THE, the name given to a civil war in France which lasted from 1648 to 1652, and to its sequel, the war with Spain in 1653–59. The word means a sling. and mas applied to this contest from the circumstance that the windows of Jules Cardinal Mazarin's adherents were pelted with stones by the Paris mob. Its original object was the redress of grievances, but the movement soon degenerated into a factional contest among the nobles, who sought to reverse the results of Armand Cardinal Richelieu's work and to overthrow his successor Mazarin. In May 1648 a tax levied on judicial officers of the *parlement* of Paris was met by that body, not merely with a refusal to pay, but with a condemnation of earlier financial edicts and even with a demand for the acceptance of a scheme of constitutional reforms framed by a committee of the *parlenzent.* This charter was somewhat influenced by contemporary events in England. But there is no real likeness between the two revolutions, the French *parlement* being no more representative of the people than the Inns of Court were in England. The political history of the time is dealt with in the article FRANCE: *History,* the present article being concerned chiefly with the military operations of what was perhaps the most costly and least necessary civil war in history.

The military record of the first or "parliamentary" Fronde is almost blank. In Aug. 1648, strengthened by the news of Louis II. prince of Condé's victory at Lens, Mazarin suddenly arrested the leaders of the *parlement,* whereupon Paris broke into insurrection and barricaded the streets. The court, having no army at its immediate disposal, had to release the prisoners and to promise reforms, and fled from Paris on the night of Oct. 22. But the signing of the peace of Westphalia set free Condé's army, and by Jan. 1649 it was besieging Paris. The peace of Rueil was signed in March, after little blood had been shed. The Parisians, though still and always anticardinalist, refused to ask for Spanish aid, as proposed by their princely and noble adherents, and having no prospect of military success without such aid, submitted and received concessions. Thenceforward the Fronde becomes a story of sordid intrigues and halfhearted warfare, losing all trace of its first constitutional phase. The leaders were discontented princes and nobles—Monsieur (Gaston of Orléans, the king's uncle), the great Condé and his brother Armand de Bourbon, prince of Conti, the duc de Bouillon and his brother the vicomte de Turenne. To these must be added Gaston's daughter, Mlle. Anne Marie de Montpensier (La grande Mademoiselle), Condé's sister, Mme. Anne de Longueville, Mme. Marie de Chevreuse, and the astute intriguer Paul de Gondi, later Cardinal de Retz. The military operations fell into the hands of war-experienced mercenaries, led by two great, and many second-rate, generals, and of nobles to whom war was a polite pastime. The feelings of the people at large were enlisted on neither side.

This peace of Rueil lasted until the end of 1649. The princes, received at court once more, renewed their intrigues against Mazarin, who, having come to an understanding with Monsieur, Gondi and Madame de Chevreuse, suddenly arrested Condé, Conti and Longueville (Jan. 14, 1650). The war which followed this coup is called the "Princes' Fronde." This time it was Turenne, before and afterward the most loyal soldier of his day. u-ho headed the armed rebellion. Listening to the promptings of his Egeria, Madame de Longueville, he resolved to rescue her brother, his old comrade of Freiburg and Nordlingen. It was with Spanish assistance that he hoped to do so; and a powerful army of that nation assembled in Artois under the archduke Leopold, governor general of the Spanish Netherlands. But the peasants of the countryside rose against the invaders, the royal army in Champagne was in the capable hands of César de Choiseul, comte du Plessis-Praslin, and the little fortress of Guise successfully resisted the archduke's attack. Thereupon. however, Mazarin drew upon Plessis-Praslin's army for reinforcements to be sent to subdue the rebellion in the south, and the royal general had to retire. Then, happily for France, the archduke decided that he had spent sufficient of the king of Spain's money and men in the French quarrel. The magnificent regular army withdrew into winter quarters, and left Turenne to deliver the princes with a motley host of Frondeurs and Lorrainers. Plessis-Praslin by force and bribery secured the surrender of Rethel on Dec. 13, 1650, and Turenne, who had advanced to relieve the place, fell back hurriedly. But he was a terrible opponent, and Plessis-Praslin and Mazarin himself, who accompanied the army, had many misgivings as to the result of a lost battle. The marshal chose nevertheless to force Turenne to a decision, and the battle of Blanc-Champ (near Somme-Py) or Rethel was the consequence. Both sides were at a standstill in strong positions. Plessis-Praslin doubtful of the trustworthiness of his cavalry. Turenne too weak to attack. when a dispute for precedence arose between the *Gardes françaises* and the *Picardie* regiment. The royal infantry had to be rearranged in order of regimental seniority, and Turenne, seeing and desiring to profit by the attendant disorder, came out of his stronghold and attacked with the greatest vigour. The battle (Dec. 15, 1650) was for a time doubtful, but Turenne's Frondeurs gave way in the end, and his army, as an army, ceased to exist. Turenne himself, undeceived as to the part he was playing in the drama, asked and received the young king's pardon, and meantime the court, with the *maison du roi* and other loyal troops, had subdued the minor risings without difficulty (March–April 1651). Condé, Conti and Longueville were released, a few months of hollow peace followed, and the court returned to Paris. Mazarin. an object of hatred to all the princes, had already retired into exile. *"Le temps est un galant homme,"* he remarked, *"laissons le faire!"* and so it proved. His absence left the field free for mutual jealousies, and a state of anarchy soon reigned. In December Mazarin returned with a small army, the war began again, and this time Turenne and Condé were pitted against one another. After the first campaign, as we shall see, the civil war ceased, but for several other campaigns the two great soldiers were opposed to one another, Turenne as the defender of France, Condé as a Spanish invader. Their personalities alone give threads of continuity to these seven years of wearisome manoeuvres, sieges and combats, though for a right understanding of the causes which were to produce the standing armies of the age of Louis XIV and Frederick the Great the military student should search deeply into the material and moral factors that here decided the issue.

The debut of the new Frondeurs took place in Guyenne (February–March 1652), while their Spanish ally, the archduke Leopold William, captured various northern fortresses. On the Loire, whither the centre of gravity was soon transferred, the Frondeurs were commanded by intriguers and quarrelsome lords, until Condé's arrival from Guyenne. His bold trenchant leadership brought initial success in the action of Bléneau (April 7, 1652), but fresh troops came up to oppose him, and from the skilful dispositions made by his opponents Condé felt the presence of Turenne and broke off the action. The royal army did likewise. Condé invited the commander of Turenne's rearguard to supper. chaffed him unmercifully for allowing the prince's men to surprise him in the morning, and by way of farewell remarked to his guest, *"Quel dommage que des braves gens comnce nous se coupent la gorge pour un faquin"*—an incident and a remark that thoroughly justify the iron-handed absolutism of Louis XIV.

There was no hope for France while tournaments on a large scale and at the public's expense were fashionable amongst the *grands seigneurs.* After Bléneau both armies marched to Paris to negotiate with the *parlement,* de Retz and Mlle. de Montpensier, while the archduke took more fortresses in Flanders, and Charles IV, duke of Lorraine, with an army of plundering mercenaries, marched through Champagne to join Condé. But Turenne manoeuvred past Condé and planted himself in front of the mercenaries, and their leader, not wishing to expend his men against the old French regiments, consented to depart with a money payment and the promise of two tiny Lorraine fortresses. A few more manoeuvres, and the royal army was able to hem in the Frondeurs in the Faubourg St. Antoine (July 2, 1652) with their backs to the closed gates of Paris. The royalists attacked all along the line and won a signal victory in spite of the knightly prowess of the prince and his great lords, but at the critical moment Gaston's daughter persuaded the Parisians to open the gates and to admit Condé's army. She herself turned the guns of the Bastille on the pursuers. An insurrectional government was organized in the capital and proclaimed Monsieur lieutenant general of the realm. Mazarin, feeling that public opinion was solidly against him, left France again, and the *bourgeoisie* of Paris, quarrelling with the princes, permitted the king to enter the city on Oct. 21, 1652. Mazarin returned unopposed in Feb. 1653.

The Fronde as a civil war was now over. The whole country, wearied of anarchy and disgusted with the princes, came to look to the king's party as the party of order and settled government, and thus the Fronde prepared the way for the absolutism of Louis XIV. The general war continued in Flanders, Catalonia and Italy wherever a Spanish and a French garrison were face to face, and Condé with the wreck of his army openly and definitely entered the service of the king of Spain. The "Spanish Fronde" was. except for a few outstanding incidents, a dull affair. In 1653 France was so exhausted that neither invaders nor defenders were able to gather supplies to enable them to take the field till July. At one moment, near Péronne, Condé had Turenne at a serious disadvantage, but he could not galvanize the Spanish general Count Fuensaldana, who was more solicitous to preserve his master's soldiers than to establish Condé as mayor of the palace to the king of France, and the armies drew apart again without fighting. In 1654 the principal incident was the siege and relief of Arras. On the night of Aug. 24–25 the lines of circumvallation drawn round that place by the prince were brilliantly stormed by Turenne's army, and Condé won equal credit for his safe withdrawal of the besieging corps under cover of a series of bold cavalry charges, led by himself as usual, sword in hand. In 1655 Turenne captured the fortresses of Landrecies, Condé and St. Ghislain. In 1656 Condé revenged himself for Arras by storming Turenne's circumvallation around Valenciennes (July 16), but Turenne drew off his forces in good order. In the campaign of 1657 a body of 6,000 British infantry, sent by Oliver Cromwell in pursuance of his treaty of alliance with Mazarin, took part. The presence of the English contingent and its very definite purpose of making Dunkirk a new Calais, to be held by England forever, gave the next campaign a character of certainty and decision which is entirely wanting in the rest of the war. Dunkirk was besieged promptly and in great force, and when Don Juan of Austria and Condé appeared with the relieving army from Furnes, Turenne advanced boldly to meet them. The battle of the Dunes (*q.v.*) fought on June 14, 1658, was the first real trial of strength since the battle of the Faubourg St. Antoine, ended in Turenne's victory. Here the redcoats made their first appearance on a continental battlefield, under the leadership of Sir W. Lockhart, Cromwell's ambassador at Paris, and astonished both armies by the stubborn fierceness of their assaults, for they were the products of a war where passions ran higher and the determination to win rested on deeper foundations than in the *dégringolade* of the feudal spirit in which they now figured. Dunkirk fell, as a result of the victory, and flew the St. George's cross till Charles II sold it to the king of France. A last desultory campaign followed in 1659—the 25th year of the Franco-Spanish War—and the peace of the Pyrenees was signed on Nov. 5. On Jan. 27, 1660, the prince asked and obtained at Aix the forgiveness of Louis XIV. The later careers of Turenne and Condé as the great generals—and obedient subjects—of their sovereign are described in the article DUTCH WARS. (For their earlier careers see THIRTY YEARS' WAR.)

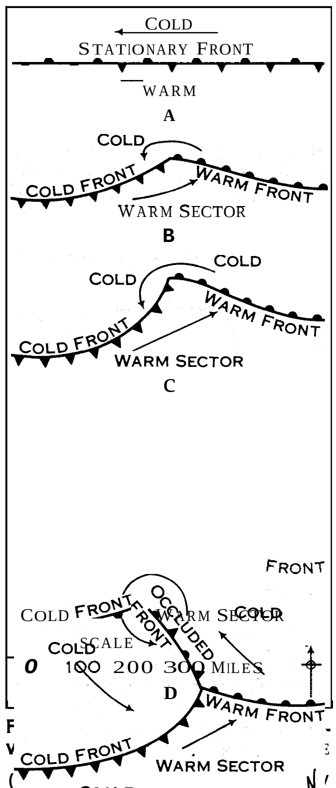
FRONT. When two great masses of air forming part of the atmosphere lie side by side, each horizontally uniform in air density but with appreciable differences in density between them at each height, the heavier air lies as a thin wedge under the lighter air. The differences in density are associated with horizontal differences in temperature and humidity (*q.v.*) between them, and are accompanied by differences in air motion and transparency. The sloping area of contact of the two air masses is known as a frontal surface. The line marking the intersection of such a frontal surface with a horizontal surface, more particularly the earth's surface, is called a front. In middle latitudes such fronts, generally in motion, extend continuously for hundreds and often for thousands of miles over the earth. The interplay of great air masses at fronts results in some of the most dramatic types of weather, and the study of such interplay is therefore of primary importance in the science of meteorology.

Near the end of the 19th century H. Helmholtz pointed out that two currents of air having different densities could flow side by side with different speeds and with little mixing between them. H. Bigelow in 1902 stated that the centres of the low-pressure systems known as cyclones are to be found along the line marking the boundary between adjacent warm and cold air currents. Similar conclusions were later reached by S. Hanzlik, by Sir Napier Shaw and R. G. K. Lempfert and by H. von Ficker. However, it was not until the end of World War I that the behaviour of these frontal surfaces and fronts during the development of a cyclone of middle latitudes was described in detail, and an integrated picture presented by the Norwegian meteor-

[illegible]

aspects of the wave motion of a frontal surface. Further descriptive and theoretical investigations of frontal cyclones have been made, largely by the Norwegian school of meteorologists under the leadership of the two Bjerkneses.



front, (B) the pressure falls: cyclonic air flow commences along the front, accompanied by a wavelike deformation of the front; (C) the deformation increases; (D) finally the cold front overtakes the warm front, resulting in an occluded front; thereafter the cyclone wanes

Their approach to the problem may be briefly described as follows. There are two main types of air masses found in middle latitudes: polar air masses which have their origin at higher latitudes and are therefore cold and dry, and tropical air masses which originate at lower latitudes and are therefore warm and moist. The front marking the line of contact of these two main air masses is the polar front. The development of most cyclones of middle and higher latitudes occurs at the polar front and is associated with a deformation of it. Four stages of a typical development in the northern hemisphere viewed from above are shown in fig. 1.

Frontal Stages. — Stage A. — Initially there is a straight stationary or slowly moving front extending in an east-west direction; a cold polar air mass lies to the north and a warm tropical one to the south. In the warm air the wind is west, as indicated by the arrow; in the cold air the wind may be east, as shown, or west but with a smaller speed than that of the wind in the warm air.

Stage *B*.—The pressure starts to fall near a section of the front, cyclonic (counterclockwise in northern hemisphere) rotation of the air commences, and simultaneously the front undergoes a wavelike perturbation. The forward edge of an advancing warm-air mass with receding cold air ahead of it is a warm front; that of an advancing cold-air mass before which warm air recedes is a cold front. To the west of the centre of low pressure the black triangles on the southern edge of the front indicate that it is a cold front moving southward; to the east the black semicircles on the northern side of the front indicate that it is a warm front moving northward. The warm air between the two fronts is known as the warm sector.

Stage C.—As the pressure fall continues, the wavelike deformation of the front increases. The cold front moves more rapidly than the warm one, and as a result near the centre the warm sector becomes narrower. During stages B and C the wave moves rapidly eastward along the front, with the lowest pressure at the crest of the wave.

Stage D. — Finally, near the centre of low pressure the cold front overtakes the warm front to produce an occluded front. By this stage the pressure has ceased to fall and may have started to rise, and the eastward rate of motion of the centre has decreased. The cyclone is now past its prime, and its last hours are spent as a circular vortex of decreasing strength in which the occluded front gradually loses its identity as such. From birth to death, the life span of such frontal cyclones is from one to three days.

Cyclones of this type sometimes occur in families. One cyclone grows and then dies as it moves eastward along a front; another develops on the same front, generally to the south of the birthplace of the first, and goes through the same cycle. Three or four cyclones developing at intervals of several days may make up a family. Not all cyclones reach the unstable state represented by the occlusion phase. Some cease to develop at stage B, and thereafter move rapidly along the front as stable waves until they dissipate.

FIG. 2.— VERTICAL CROSS SECTION THROUGH A COLD FRONTAL SURFACE. SHOWING ASSOCIATED CLOUDS AND PRECIPITATION

It must not be inferred from the foregoing that all cyclones of middle latitudes have a frontal structure, although the great majority do. A few cyclones develop without discernible fronts in them.

Vertical Structure. — A knowledge of the vertical structure of fronts is essential in understanding the weather phenomena which accompany them. The cold air lies as a thin wedge under the warm air. A cold frontal surface (shown in fig. 2 by a vertical cross section in a plane perpendicular to the surface front) has an average slope of about 1 in 50. The frontal surface is steeper near the ground because the roughness of the latter produces a frictional drag which retards the air just above it. Often the warm air just

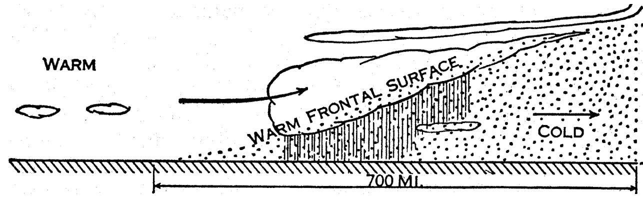


FIG. 3.— VERTICAL CROSS SECTION THROUGH A WARM FRONTAL SURFACE. SHOWING ASSOCIATED CLOUDS AND PRECIPITATION

ahead of the frontal surface rises as the cold-air mass advances. When the rate of ascent of this warm air is small, not much cloud develops at the frontal surface. With rapid ascent, however, heavy towering clouds (fig. 2), perhaps giving showers or even thunder and lightning, may result. One often hears a comment on how a certain thunderstorm has cleared the air. When this happens, the clearing of the air is caused by the arrival of the cooler and drier air mass which replaces the sultry air; the thunderstorm merely develops at the cold front. A thunderstorm unaccompanied by a cold front affords only temporary relief. In addition, as the cold front passes, the wind suddenly veers, perhaps from southwest to northwest, and freshens. the visibility improves and the barometric pressure starts to rise.

A warm frontal surface (fig. 3) has a smaller slope, about 1 in 175. Frictional forces retard the cold air near the earth's surface, and the slope there is less than at higher levels. Usually the warm air moves more rapidly normal to the front than the cold air ahead of it, and therefore overruns the latter. Clouds form in and just below this ascending warm air. Hundreds of miles ahead of the surface warm front, wispy. hooked cirrus clouds (mares' tails) made up of ice crystals are seen. As the front approaches, the cloud, now of the layer type, becomes thicker and lower, and finally rain or snow falls steadily from it. Frequently there are two or more layers of stratified cloud, with clear air between them (fig. 3). Occasionally thunderstorms develop ahead of the warm front, but not so frequently as at a cold front, for the rate of ascent of the warm air is less. The passage of the aarm front is marked by a gradual temperature rise, a decrease in the rate of pressure fall, a veering of the wind, perhaps from south to southwest, and a decrease in the amount of cloud and a change in its type.

The vertical structure of an occluded front (or occlusion, as it is often called) has several interesting features (fig. 4). When the cold front overtakes the warm front. the warm air which was previously between them (fig. 1 [C]) is carried aloft, and only cold air is left at the ground. There are two types of occlusions, depending on whether the air behind the cold front is colder or less cold than the air ahead of the warm front. When the air behind is colder than that ahead (fig. 4 [A]), the former undercuts the latter, and the system displays many of the characteristics of a cold front. It is therefore known as a cold-front type of occlusion. At the forward part of the system, the clouds are similar to those which accompany a warm front. Under suitable conditions, the warm air just above the advancing cold air may ascend so rapidly that towering clouds form in it and showers or even thunderstorms occur. The warm-front type of occlusion develops when the air ahead of the warm front is colder than that behind the cold front and consequently the latter overruns the former (fig. 4 [B]), in the same way that warm air overruns cold at a warm front. Precipitation generally falls from the extensive cloud system near the frontal surfaces, but may evaporate during its descent through drier air below. and never reach the ground. The two cold air masses are sometimes so similar in physical properties that little change in temperature and humidity is noted as an occlusion passes. The chief indications of passage are the cessation of the pressure fall and the beginning of a rise and a veering of the wind, usually from southwest to northwest.

A type of front known as an upper front is associated with occlusions. but also occurs independently of them. In the cold-front type of occlusion (fig. 4 [A]). the surface front is of the cold type and only the original narm front appears aloft. The line of discontinuity aloft along which the three air masses meet acts as a warm front, and is therefore called an upper warm front. Similarly, in the warm-front type of occlusion (fig. 4 [B]), there is a surface front of the warm type, but a cold front aloft; *i.e.*, an upper cold front. An upper front may also develop independently of occlusions. This type is especially prevalent to the east of an extensive mountain range lying in a north-south direction and located at the western side of a continent. It occurs when air advances eastward from the adjacent ocean over the mountain range and at the same time east of the range there is a stagnant mass of cold air near the surface (fig. 5). Frequently the maritime air is colder than the air aloft over the continent, so that it undercuts the latter, and the front is an upper cold front (fig. 5). The maritime air, being not so cold as the lower continental air, moves along aloft without disturbing it, just as if the upper boundary of the lower air were an elevated land surface. Clouds are usually present near the leading edge of the advancing cold maritime air, and rain or snow may fall from them. Upper warm fronts of this type (not illustrated) occur less frequently than the corresponding type of upper cold fronts. Upper fronts often travel for hundreds of miles before dissipating or reaching the earth's surface and becoming ordinary fronts. The chief manifestations of upper fronts observable at the ground are the associated cloud types and precipitation, and a variation in the rate of pressure change as the upper front passes.

Frontogenesis and **Frontolysis.**—A field of air motion which brings two large air masses with differing properties into closer proximity promotes the formation of a front between them or the intensification of an existing front there, a process known as frontogenesis. Initially there may be a relatively uniform variation of temperature or some other property in a broad zone of transition, perhaps several hundred miles wide, between the t o air masses. However, a change of air flow may occur which brings the warm and cold air masses closer together, so that the zone of transition narrows. As this process continues, the zone narrows until it becomes a true front; *i.e.*, frontogenesis has occurred. The horizontal mixing between the air masses prevents the zone from ever becoming less than several miles in width, and it is usually much wider than that. In general, near the surface, cold fronts are more sharply marked, with a narrower zone of transition, than warm fronts.

New fronts form mainly in polar air masses. The process of development occurs between their northern portions, which remain relatively cold and dry, and their southern sections, which have become warmer and moister during their journey southward. Fronts increase in intensity most frequently near the eastern coasts of the continents.

In the northern hemisphere during winter there are five main zones of frontogenesis: (1) near the east coast of North America; (2) near the east coast of Asia; (3) in the North Pacific; (4) to the east of Greenland; and (5) along the Mediterranean. In summer there are three main zones only: (1) across Canada; (2)

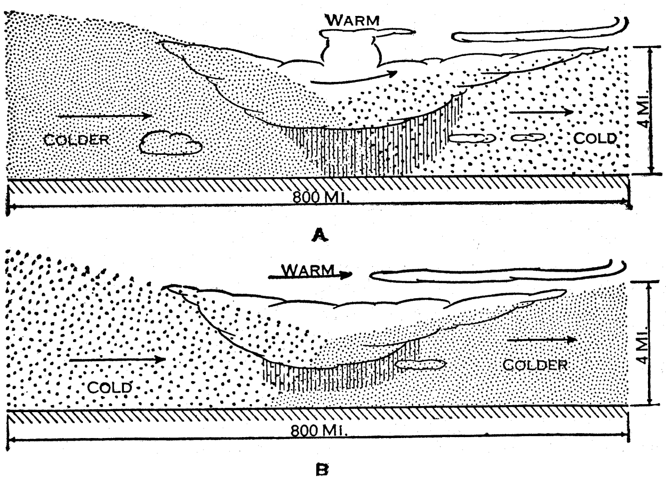

FIG. 4.— DETAILS OF OCCLUSIONS, SHOWN BY VERTICAL CROSS SECTIONS
(A) Cold-front type of occlusion; (B) warm-front type of occlusion

across northern Europe; and (3) from northeast Russia to Alaska. In the southern hemisphere the main zones lie between latitudes 30° and 50° at all seasons. During both summer and winter there are zones of frontogenesis over the ocean to the west and east of South America and to the east of South Africa; in January (summer) there is a zone to the southeast of Australia and in July (winter) one to the southwest.

As the zone of transition between two air masses broadens and the front between them weakens or dissipates, frontolysis is said to occur. In the absence of frontogenesis, the horizontal mixing between the two masses slowly produces this result. In other cases, the air flow may change and cause a decrease in the sharpness of the contrast of properties between them.

Slope.—It is well known that in a state of equilibrium a lighter liquid rests on top of a heavier one; *e.g.*, oil lies on top of water.

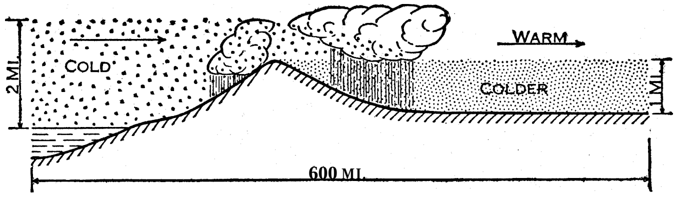

FIG. 5.— AN UPPER COLD FRONT, SHOWN IN A VERTICAL CROSS SECTION. THIS TYPE OCCURS MAINLY TO THE EAST OF AN EXTENSIVE MOUNTAIN RANGE

Similarly, in the atmosphere warmer and therefore lighter air tends to rest above colder and therefore heavier air. But because of the rotation of the earth, the state of equilibrium is attained not when the frontal surface is horizontal, but nhen it makes a slight angle with the horizontal. In 1906, Max Margules developed a formula which expresses the slope of a frontal surface in terms of the latitude at which it is found, and the winds and temperatures in the adjacent air masses. Other factors being equal, the slope is less at low latitudes than at high ones. For example, a frontal surface at latitude 60° will have a slope 50% greater than one at latitude 35° if the distribution of temperatures and minds near each frontal surface is the same. The slope of a frontal surface is relatively large when the temperature difference between the two air masses is small, and small when the temperature contrast is large. When the difference in wind components parallel to the frontal surface in the two air masses is large, its slope is greater than when the difference is small. Margules' formula is chiefly valuable in providing general criteria, such as those outlined above.

Arctic and Equatorial Fronts.—The main frontal systems of the earth are the polar fronts of the northern and southern hemispheres; these, although not continuous around the globe, nevertheless extend for thousands of miles. Of secondary importance in temperate latitudes are the arctic and antarctic fronts. These systems occur at high latitudes. and chiefly affect the weather of the polar and subpolar regions; cyclones sometimes form along these fronts.

Near the equator, true fronts are rarely if ever found. The zone along which the trade wind systems of the northern and southern hemispheres converge, known as the doldrums, has sometimes been called the intertropical or equatorial front. A closer study of this system has revealed, however, that there is little difference in physical properties across it and little undercutting or overrunning by the air masses involved, in contrast with frontal systems of middle and high latitudes. Rather it is a region over which there is a general ascent of air which results from the horizontal convergence of the trade winds. It has therefore been given the more appropriate name of the intertropical convergence zone. Heavy cloud formations, frequently accompanied by showers and thunderstorms, occur in this zone. The width of the zone itself varies widely, being small at times, and at others very large.

The mean position of the intertropical convergence zone changes with the seasons: in August the farthest northward displacement occurs, with the zone at latitude 5° N. over South America and at latitude 25° N. over southern China; its maximum southward displacement occurs in February, when it lies near the equator between South America and western Africa, and at latitude 15° S. over northern Madagascar and over northern Australia. The violent tropical disturbances known as tropical hurricanes or typhoons develop at or near this convergence zone when at these positions of maximum displacement.

(E. W. HE.)

FRONTENAC ET PALLUAU, LOUIS DE BUADE, COMTE DE (1620–1698), French-Canadian statesman, governor and lieutenant general for the French king in La *Nouvelle France* (Canada), son of Henri de Buade, colonel in the regiment of Navarre, was born in the year 1620. Louis de Buade served in 1635 under the prince of Orange in Holland, and fought in many engagements in the Low Countries and in Italy. His service seems to have been continuous until the conclusion of the peace of Westphalia in 1648, when he returned to his father's house in Paris and married Anne de la Grange-Trianon, a girl of great beauty, who later became the friend and confidante of Anne Marie de Montpensier. Incompatibility of temper led to a separation, the count retiring to his estate on the Indre, where by an extravagant course of living he became hopelessly involved in debt. In 1669, when France sent a contingent to assist the Venetians in the defense of Crete against the Turks, Frontenac was placed in command of the troops on the recommendation of the vicomte de Turenne. In this expedition he won military glory; but his fortune was not improved.

At this period the affairs of New France claimed the attention of the French court. Frontenac was appointed to succeed Rémy de Courcelle as governor, and arrived in Quebec on Sept. 12, 1672. It was immediately evident that he proposed to pursue a policy of colonial expansion, and to exercise an independence of action that did not coincide with the views of Louis XIV, or of his minister Jean Colbert. One of the first acts of the governor, by which he sought to establish in Canada the three estates—nobles, clergy and people—met with the disapproval of the French court, and measures were adopted to curb his ambition by increasing the power of the sovereign council and by reviving the office of intendant. Frontenac soon became involved in quarrels with the intendant touching questions of precedence, and with those priests who ventured to criticize his proceedings. The church in Canada had been administered for many years by the religious orders; for the see of Quebec had not yet been erected. But three years after the arrival of Frontenac a former vicar apostolic, François Xavier de Laval-Montmorency, returned to Quebec as bishop, with a jurisdiction over the whole of Canada. In him the governor found a vigorous opponent who was determined to render the state subordinate to the church. Frontenac had issued trading licences which permitted the sale of intoxicants. The bishop, supported by the intendant, endeavoured to suppress this trade, and sent an ambassador to France to obtain remedial action. The views of the bishop were upheld, and henceforth authority was divided. Troubles ensued between the governor and the sovereign council, most of the members of which sided with the one permanent power in the colony—the bishop; while the intrigues of the intendant, Duchesneau, were a constant source of strife. At last both governor and intendant were recalled to France in the year 1682.

During Frontenac's first administration many improvements had been made in the country. The defenses had been strengthened, a fort was built at Cataraqui (now Kingston), Ont., bearing the governor's name, and conditions of peace had been fairly maintained between the Iroquois on the one hand and the French and their allies, the Ottawas and the Hurons, on the other. The recall of the governor was ill-timed. The Iroquois were assuming a threatening attitude toward the inhabitants, and Frontenac's successor, A. J. L. La Barre, was quite incapable of leading an army against such cunning foes. At the end of a year La Barre was replaced by the marquis de Denonville, a man of ability and courage, who, though he showed some vigour in marching against the western Iroquois tribes, angered rather than intimidated them, and the massacre of Lachine (Aug. 5, 1689) must be regarded as one of the unhappy results of his administration.

The affairs of the colony were now in a critical condition, and Louis XIV once more sent out Frontenac. He arrived in Quebec as governor for the second time on Oct. 15, 1689, and confidence was at once restored. But on Oct. 16, 1690, several New England ships under the command of Sir William Phipps appeared off the Island of Orleans, and an officer was sent ashore to demand the surrender of the fort. Frontenac repulsed the enemy and prepared to follow up his advantage by an attack on Boston from the sea, but his resources were inadequate for the undertaking. In 1696 Frontenac, now 76 years of age, decided to take the field against the Iroquois. On July 6 he left Lachine for the village of the Onondagas, where he arrived a month later. In the meantime the Iroquois had abandoned their villages, and as pursuit was impracticable the army commenced its return march on Aug. 10. Frontenac died on Nov. 28, 1698, at the Chbteau St. Louis after a brief illness, deeply mourned by the Canadian people. He was fearless, resourceful and decisive, and triumphed as few men could have done over the difficulties and dangers of a most critical position.

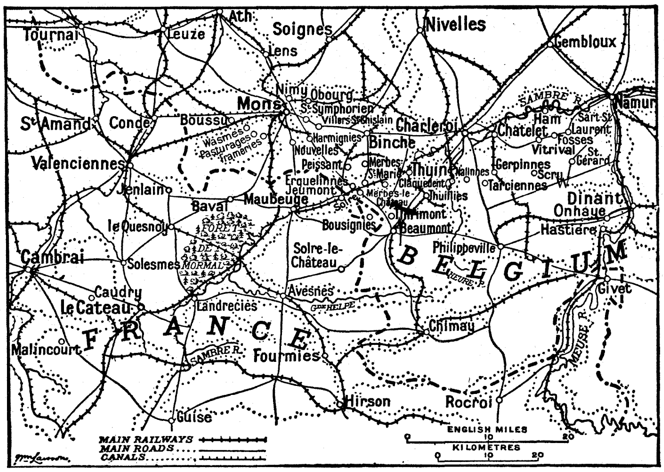
FRONTIER, BATTLES OF THE. The generic name of "battles of the frontier" covers the whole of the actions fought at the opening of World War I in Aug. 1914, on or near the French frontiers. For convenience, these are here divided into six sections, each of which deals with a more or less distinct part of the series of operations. These are: I. Early battles in Upper Alsace; II. First battles in Lorraine; III. Battle of the Ardennes; IV. Charleroi and Mons; V. Le Cateau; and VI. Guise.

I. EARLY BATTLES IN UPPER ALSACE

It was laid down in the original French plan (*see* WORLD WAR) that the action of their right wing would be much assisted by a preliminary operation in Upper Alsace to be carried out by the 7th corps and 8th cavalry division; this force was to advance by Mulhouse on Colmar, so holding fast the hostile forces in that area, besides encouraging the Francophile elements of the population to throw off the German yoke. In accordance with this plan, Gen. Dubail, commanding the 1st army on the right of the French line, issued orders on Aug. 5 for this operation to commence on the 7th, and by the evening of Aug. 8 the French had secured Mulhouse and taken up a defensive position around that town, the weak German covering troops falling back before them to the east bank of the Rhine. Their success, however, was short-lived; Gen. Josias von Heeringen, commanding the 7th German army, was already planning a counter offensive with the 14th and 15th corps. then detraining in the area Colmar-Breisach, and on Aug. 10 the French, heavily attacked by these superior forces, were forced to evacuate Mulhouse and commence a retreat which by the 12th had brought them back to within 10 mi. of Belfort. On neither side had the conduct of the operations been a model of skill, but the Germans had at least the satisfaction of having scored the advantage in the first clash of arms.

The French high command now decided to entrust the execution of the task in which the 7th corps had so completely failed to a newly formed army of Alsace under Gen. Paul Pau, comprising, besides that corps, one additional regular division, and three reserve divisions. The concentration of this new army and the preparations for a renewed advance could not be completed before Aug. 14, by which date the 7th German army, in expectation of the main French offensive in Lorraine, was concentrating all its forces to the north, leaving in Upper Alsace only three weak brigades of second-line troops. These were, of course, easily driven back by Pau's army, which by Aug. 20 had reoccupied Mulhouse, together with Munster to the north and Altkirch to the south, and had cleared Upper Alsace entirely of the enemy. But the object of holding important hostile forces and so assisting Dubail's army now engaged in the main offensive had not been achieved;



MAP OF "BATTLES OF THE FRONTIER" **IN** WORLD WAR I, SHOWING MONS, **CHARLEROI** AND LE CATEAU. WHERE ENGAGEMENTS OCCURRED IN AUG. 1914

nor could Pau from his present position even cover its right flank effectively. It was therefore decided to withdraw him. On Aug. 20 the short-lived Army of Alsace was dissolved, the troops comprising it being placed under Dubail or dispatched to other parts of the front. The early French operations in Upper Alsace had been unproductive of either political or military advantage and had absorbed forces which might have found more useful employment elsewhere. (E. W. S.)

II. FIRST BATTLES IN LORRAINE

The first French plan (General Instruction No. 1 of Aug. 8, 1914) was purely offensive. It proposed to seek action with all forces united with the right on the Rhine. The two armies of Lorraine (1st and 2nd) were to lead, the 1st (Gen. Augustin Y. E. Dubail) in the direction of Saarburg, after having thro n back the 7th German army toward Strasbourg and Lower Alsace, while an isolated corps would make a diversion to the east of the Vosges. The 2nd army (Gen. Edouard de Castelnau), covering itself from Metz, was to attack in the direction of Saarbriick, pivoting on Dubail's in the neighbourhood of Étangs. . The two left corps were to the west of the Moselle, with a view to their eventual employment in the north.

Disposition of **Forces.**—In front of Dubail's and De Castelnau's armies the Germans had approximately equal strength (6th and 7th armies). They would at first keep to the defensive, acting as a pivot to the huge wheel being made by their centre and right. The rapidity of the invasion of Belgium determined the French to hasten the operations in the east in order to make a diversion. On Aug. 13 Dubail's army had two corps on the Meurthe (8th and 13th). Dubail counted besides on the cooperation of the two right corps of De Castelnau's army and on that of the 21st corps descending from the Vosges on his right. On Aug. 16 the 2nd cavalry corps was placed under his orders. The final concentration of the complete fighting force, however, could not be complete until the 18th. Nevertheless. the 13th and 8th corps moved on the 14th, and on the 15th entered Cirey and Blamont, pushing back the 1st Bavarian corps, which retired toward Saarburg.

By the evening of the 17th the two French corps had reached the line Vasperveiller-Aspach-St.' Georges, and the 21st extended the line toward the Vosges. The 2nd cavalry corps had orders to go ahead on the 18th toward Saarburg, which was entered after a skirmish. The 21st corps pushed to the northeast as far as Walscheid; the 13th held the heights north and east of Saarburg; the 8th, marching on Heming, seized the passage of the Marne-Rhine canal and entered Saarburg. The 2nd cavalry corps bivouacked toward Diane-Capelle, in liaison with De Castelnau's army, which had reached the line Bisping-Château Salins. The Germans held entrenched positions on a front of 40 mi., from the neighbourhood of Dobbenheim to Biberkirch.

Dubail's Offensive.—It was decided that Dubail's army should attack with its left northwest of Saarburg, its centre and right standing fast to repulse an eventual counterattack in the Vosges. The 2nd cavalry corps was to move on Saar-Union in order to operate south of the Saar. On Aug. 19 the 8th corps commenced the attack before dawn, gained the terrain northwest of Saarburg, and repulsed a counterattack. On the 20th it resumed the offensive, but during the morning it became evident that it was incapable of opening a passage for the cavalry corps; indeed. it was necessary to bring back a division on the canal with heavy losses. In the centre and on the right the French were more fortunate. The 21st corps met no resistance on the 19th, and the 13th had not yet been engaged.

On Aug. 20, the 21st corps, attacked by the German 14th corps, inflicted on it a serious check near Walscheid; the 13th corps, coming into line, attacked to the northeast of Saarburg, disengaging the right of the 8th corps. which held the town until nightfall. Dubail's intention was to entrench on the front Kerprich-Soldatenkopf, and to undertake afterward a methodical advance; but the check to De Castelenau's army led Joffre to direct a retreat in Lorraine. On the morning of Aug. 21 Dubail's army retired slowly toward Blamont. Afterward it was necessary to accelerate the movement on account of the rapidity of De Castelnau's retreat. On the evening of the 23rd, Dubail held a front from Dames-aux-Bois to the Col du Bonhomme. His army had suffered heavy losses, the casualties in the 8th corps amounting to more than 50%.

De Castelnau's **Offensive.**—The offensive of De Castelnau's army had been still less fortunate. On Aug. 14 the 16th and 15th corps moved in the direction of Avricourt, uith the bulk of the 20th, the remainder covering the front to the north. In the evening the army faced to the northeast on the high ground at Gondrexon, the 15th corps alone having been stopped by the enemy at Rfoncourt. On Aug. 15 the advance still suffered a brake by the condition of the 1 jth corps, which had suffered heavily, but the 16th and 20th corps made fair progress. The 9th corps remained on the Grand Couronné east of Nancy and sent out detachments toward the northeast.

On Aug. 16 the Germans continued their retreat and the French followed rapidly as far as Morhange, northwest of Donnelay. On the 17th the army was to swing around to the northwest toward Delme-Chateau Salins-Dieuze. The 16th corps progressed without difficulty; the 1 jth occupied Marsal, but could not bring its main body beyond the Seille; the 20th corps, in possession of Château Salins, reconnoitred toward the north. Rearguard fights only were expected, but on Xug. 18 the 16th corps from the early morning met the enemy in strength. The German artillery held the 15th corps in the valley of the Seille and prevented it from occupying Dieuze. The 16th corps had to fall back on Angviller, and only the 20th advanced to the north of Morville-les-Vic and Chbteau Salins. In spite of the loss of the 9th corps, sent to the 4th army on Aug. 18. De Castelnau ordered for the 19th the continuation of the offensive in the direction of Loudrefing, Bensdorf and Morhange.

Retreat: Aug. 19–20.—From the morning of Aug. 19 the 16th corps was stopped on the Salines canal; the 1 jth could not pass Zommange and Vergaville; and only the 20th could make a real advance, pushing a brigade as far as Morhange. The 68th reserve division, which had relieved the 9th corps, insufficiently covered the left of the 20th corps. De Castelnau ordered for Aug. 20 a combined attack by the two other corps on the line Cutting-Dommon-Bassing; the 20th was to consolidate its positions, ready to march to the north or northeast. On the 20th the corps on the right, instead of progressing, was attacked and even thrown back. The 20th, having attacked and not having improved its position. was stopped by De Castelnau, but the Germans, taking the offensive in turn, threw the left back on Chbteau Salins. The right followed this movement on Lidrequin and the 65th division resumed its position of the previous day. At 4 P.M. the general ordered a retirement, which began during the night and continued through Aug. 21 under the protection of the 20th corps and the 68th division. In spite of the arrival of two new reserve divisions and the 2nd cavalry corps. De Castelnau had to retire to the west of the Meurthe, his left to St. Nicholas. To the north. three divisions held the Grand Couronné.

Dubail's Action. — On Aug. 23, Dubail's army commenced a three-weeks' battle destined to stop the enemy and aid De Castelnau, who was heavily attacked. To effect this it took the offensive on Aug. 24 and 25, while De Castelnau's army threw back the Germans to the northeast. From the 28th to the 31st the Germans held up Dubail's advance, and their 6th and 7th armies even aimed at forcing "the gap of Charmes," in such a manner as to carry out an enveloping movement to the west of the Vosges. This action was helped by the French 21st corps being dispatched to take part in the battle of the Marne.

From these circumstances there resulted a series of very confused fights extending over a large front between the Grand Couronné and the Vosges. On Sept. 6 the 7th German army, facing Dubail, was broken up, divided between the 6th army, and the main German right wing was then engaged on the Ourcq against Gen. Michel Joseph Maunoury. But Dubail's army was also enfeebled by the removal, westward also, of the 13th corps; and at the same time De Castelnau lost the 18th division and the 15th corps. Clearly both sides had given up the idea oi striking seriously in Lorraine. After having gloriously held its positions to the east of Nancy and on the Meurthe, De Castelnau's army was itself to be broken up. to be reconstituted on the left of the French armies in the "race to the sea."

Thus, after checks resulting from an inopportune offensive, Dubail's and De Castelnau's armies had been first able to stop the German progress, then to throw the enemy back to the frontier. Moreover, their merit was all the greater as they had been constantly weakened by the withdrawal of their best units. During the battle of the Marne they provided the unshakable pivot of the vast movement undertaken by the Allies. It was because of their efforts that that movement succeeded. But they had paid the price. A single reserve division between Aug. 24 and Sept. 12 lost 140 officers and more than 5,000 men.

III. BATTLE OF THE ARDENNES

On the outbreak of World War I, the 3rd, 4th and 5th French armies concentrated toward the frontier. west of the Meuse. On hearing of the German attack on Liége, Gen. Joseph Joffre decided to post the 5th army (Gen. Charles Louis Lanrezac) toward the Sambre and to direct the 4th army, which he had grouped between Vitry-le-François and Sainte-Menehould, in the region of Stenay. The concentration, which had scarcely begun on Aug. 8, was nearly finished on the 14th. Until the commander in chief had all his iorces at hand, the covering troops were not to be drawn into an important action. The German high command had made a similar decision, hence the battle of the Ardennes was the "battle of the two blind men."

French Plan of Attack. — The German plan of operations placed the 5th army between Thionville and Tintigny, the 4th between Tintigny and the Meuse de Dinant (the Meuse between Mezières and Namur), the 3rd army between Dinant and the Sambre, the and on the Sambre, and the 1st in the neighbourhood of Mons. The 3rd army was still in the Ardennes behind the 4th and the 1st army was hastening toward Brussels and Antwerp, when on Aug. 22 Joffre decided to attack. It was certainly a strategic success to bring about a battle with all his forces in the Ardennes, while the 3rd German army was unable to take part in it. Joffre had disposed his 3rd and 4th armies in echelon. the left in front. so that he could face the north or east as he wished. On Aug. 16 he decided to attack toward the north with these two armies massed, while the 7th cavalry division reconnoitred toward Thionville. and the 4th and 9th cavalry divisions to the north toward the Meuse. The result was that in front, and almost everywhere, the army corps had only weak and insufficient cavalry for reconnoitring purposes.

During the night of Aug. 20–21 the whole mass moved forward. The only instructions given by Joffre were "to attack the enemy wherever met." He estimated that the 4th army would have almost nothing in front of it, and yet it was precisely there that the Germans had their 4th and 3rd armies. the 3rd being behind the 4th. The French Lorraine army. which consisted of groups of reserve divisions. was placed under the command of General Maunoury with orders to defend the Hauts de Meuse. or eventually, in the event of the advance of the 3rd army, to besiege Metz and Thionville. These reserve divisions were mobilized after the active forces, the men were elderly, they had few officers, and their staffs were inexperienced, so that the 3rd army could get little help from them.

On the evening of Aug. 21, after a long period, during which only patrols had been encountered, the 3rd army arrived on the line Conz-Lagranville-Tellancourt-Virton. At Virton, the left corps tried to get in touch with the right of the 4th army. The line continued by Villers-la-Loue, Geronville, Florenville and the Semoy. The 4th army (De Langle de Cary) was to push on toward the north, while the 3rd army was to cover its right against any attack coming from the north or east. Everywhere the advance was made in divisions except for one corps, which marched entire on a single road.

On Aug. 22 all the columns started in a fog at a very early hour for a long march with the idea of "attacking the enemy wherever met." To march quickly rather than to take precautions was the order of the day, and almost every\\-here the presence of the Germans was only discovered by receiving shell fire. In the 3rd army. the jth corps sent its infantry to the attack without the support of artillery. and it suffered such terrible losses that the leaders became completely unnerved, and Gen. Paul Grossetti, chief of the staff, had to intervene to prevent a precipitate retreat. In the 4th army the Colonial corps exposed a division a column-of-route to the German guns. The 17th corps also suffered from a sanguinary surprise. But the most serious danger arose on the right wing of the 4th army, uncovered by the premature check of the 4th corps at Virton, and on the exposed right wing of the 3rd army.

Fortunately, the 2nd corps was in a single column, so that the rear division was able to make up for the absence of the 4th corps. On the right of the 3rd army there was a leader, General Hache. who with his heroic division gained the necessary time for the other divisions to fall back. The Germans did not exploit their tactical success but remained practically stationary in their positions. This battle of the Xrdennes taught the French the necessity for co-operation of all arms in the field of battle. On Aug. 23, 24 and 25 the two armies retired slowly without being disturbed.

Lorraine Army Dissolved.——On the morning of Aug. 25, the right of the 4th army retired between the Chiers and the Meuse; the 3rd ariny also approached the Meuse facing eastward. Thus the two armies practically became one, and it is regrettable that from this time they were not placed under one leader. On the same day, the 4th corps (3rd army) suffered a severe reverse at Marville and they feared they would lose their corps artillery, but the 2nd corps came to their assistance and convoyed this artillery to Stenay, where they crossed the Meuse. This shows how intimate was the co-operation between the two armies. It was on Xug. 25 also that Joffre decided to reinforce the left of the Allied armies and to lose ground in order to gain the necessary time for his strategic plans. The Lorraine army was dissolved; one group of divisions was to defend the Hauts-de-hleuse; the jjth and 56th divisions were entrained for Montdidier. Gen. Maunoury had in these two divisions the nucleus of that 6th army which determined the victory of the Marne.

On the morning of Aug. 26 the entire 4th army was on the left bank of the Meuse, with cavalry connecting it with the 5th army. On its right flank it was in immediate contact with the 3rd army. So much feared was the envelopment of the 3rd army's right, that a cavalry division was sent to the rear to Dombasle, between

Verdun and Clermont, as if an extensive enemy movement was expected to take place south of Verdun. The 3rd army took no part in the battle of the bleuse.

Defense of the Meuse.—On Aug. 26 the orders ran: "From tomorrow the 4th army will fight a decisive battle on the Meuse . . . The corps will make every effort to prevent any attempt of the enemy to cross the river." Generally speaking, this army was some distance from the left bank. Its object was to carry out vigorous counterattacks against German infantry who had passed the river before its artillery could come to its support. The colonial corps was somewhat driven back by the Germans. who had crossed at Inor and Pouilly, but the arrival of reinforcements from the 2nd corps soon checked this. The struggle was severe on the whole front. On the right wing the 2nd corps had decided successes, three times throwing the Germans back into the river at Cesse and Luzy. On the left wing, the success was still more marked.

There the 11th corps, reinforced by two reserve divisions, gained the battle of La Marfée. A German division, making the same mistake as did the French at the battle of the Ardennes, advanced in massed formation without artillery and was crushed.

On the evening of Xug. 27, De Langle de Carp gave the following order: "At all costs the Germans must be thrown back into the river Meuse." However, Aug. 28 was not so active as the previous day; the Germans scarcely attacked at all, and the orders given by Joffre for the coming retirement to the Xisne kept the 4th army to its ground. On the 29th the retirement towards the Aisne commenced—the battle of the Meuse was ended. The French 4th army had repulsed the German 4th army.

Battle of **Signy l'Abbaye.**—The French 5th army, having been beaten by the German and army on Aug. 22 and 23, had to retreat, leaving a gap 25 mi. wide between it and the 4th army. The Germans of Hausen's 3rd army poured into this open space. Gen. Dubois was ordered to fill up this gap and to cover the left of the 4th army, and was given command of the 9th corps, composed of the 17th division, the Moroccan division: and the 9th cavalry division. Two roads led to the region occupied by the Germans at Rethel. The road Mezières-Rethel was barred by the 17th division and the 9th cavalry division at Guignicourt, the road from Rocroi to Rethel by the Moroccan division at Signy l'Abbaye and Launois.

On Aug. 28, the 17th division, hearing the guns from La Marfée, had its attention drawn in that direction. On the same day, at 3 A.M., the advanced posts of the Moroccan division were attacked by the 12th (Saxon) corps. At 11 A.M. the Moroccan division was turned in the west by the enemy, who seized Signy l'Abbaye and so opened up the way to Rethel. But the Germans did not exploit their success and allowed themselves to be checked at Novion-Porcien. The battle manoeuvres lasted through Aug. 29 and 30. Dubois, by clever movements, brought his forces to the north of Rethel, having thus accomplished his difficult mission.

(L. E. V. C.)

IV. BATTLES OF CHARLEROI AND MONS

The series of encounters between the Allied left and German right wings in southern Belgium during the third week in Aug. 1914 may be subdivided into the battle of Charleroi, in which the French jth army was attacked and defeated by the German 2nd and 3rd armies, and the battle of Mons. subsequent to which the British expeditionary force retired southward before the German 1st army.

1. THE PRELUDE TO THE BATTLES

(a) German Movements Prior to the Battles.—The German plan of campaign in 1914, which in its general lines followed that drawn up some ten years before by Schlieffen, the then chief of the great general staff, involved an advance with a strong right wing through Belgium. so as to turn the fortresses on the French eastern frontier, and with the centre through the Belgian Ardennes and Luxembourg, pivoting on the fortified area Thionville-Metz. The three German right-wing armies concentrated in the area between the German western frontier with Holland, Belgium and Luxembourg, and the line of the lower Rhine and Moselle from Duisburg to Treves. The 1st army (Kluck) on the extreme right, compr'ising four first-line corps and two second-line corps, assembled to the northeast of Aix-la-Chapelle; the and army (Bülow) on its left, comprising three first-line corps and three second-line corps, to the east and south of Aix-la-Chapelle; the 3rd army (Hausen), comprising three first-line corps and one second-line corps, to the east of the line St. Vith-Bitburg. Two cavalry corps were also allotted to the right wing, together with certain ancillary troops. In all, the three armies therefore comprised 20 first-line and 12 second-line infantry divisions and j cavalry divisions, and their concentration was completed by Aug. 14. The fall of the last forts of Liége early on the 16th having opened the way for their advance, the 1st and 2nd armies crossed the Meuse between the Dutch frontier and Huy during the course of the next few days, and came into contact with the main body of the Belgian army deployed behind the line of the Geete between Diest and Tirlemont. By the evening of the 20th the Belgians had been forced to seek shelter in Antwerp; the 1st army had occupied Brussels and the country to the south as far as Waterloo; the 2nd army on its left continued the line southeastward toward the Belgian fortress of Namur, nhich its two left-wing corps were observing; and the 3rd army east of the Meuse, having made its way through the northern Ardennes, was approaching the line of that river between Namur and Givet. At the headquarters of Bulow, who had been placed in general control of the operations of both the 1st and 2nd armies, it was believed that strong French forces (about five corps) were moving forward into the angle between the Sambre and the Meuse. that the British would shortly complete their landing at Boulogne and move thence on Lille, though their arrival in the near future was not to be expected. On the morning of the 20th Bülow received orders from the German supreme command that his two armies should co-operate with the 3rd army in an attack on the French forces west of Namur; the details of the combined attack were left to be mutually arranged between him and Hausen.

(*b*) French Movements Prior to the Battle of **Charleroi.**—The French 5th army, the role of which as laid down in plan 17, was to act offensively in conjunction with the 4th and 3rd armies on its right, to the north of the line Verdun-Metz against the enemy right wing, concentrated on the Franco-Belgian frontier between Longwy and Hirson; it comprised four corps (each of two divisions), two Algerian divisions, and a cavalry corps of three divisions.

The army commander. Gen. Lanrezac. from the first believed that the main strength of the forces opposed to him was to be expected north of the Meuse. and that the projected offensive across that river through the Ardennes would therefore be impracticable, and he took every opportunity of impressing this view on Gen. Joffre. The latter, on the other hand, adhered to his plan for an offensive across the Meuse into the Ardennes, nhich he estimated would break in the enemy's centre, nullify any advantage gained by their right wing in Belgium, and even force its withdrawal. All he considered necessary was to extend the left wing of Lanrezac's army to the north toward Namur and place a group of three reserve divisions behind it around Vervins. A hostile attack on Dinant on Aug. 14 and increasing evidence of the great German strength north of the Meuse finally induced him, while still maintaining his project for an offensive by the 3rd and 4th armies, to move Lanrezac's army northward to the area Mariembourg-Philippeville, so as to be in a position to meet the danger from the north.

Between Aug. 16 and 20, therefore, Lanrezac's army carried out a change of front and a flank march which brought it to a new position south of the Sambre between the western defenses of Namur and Thuin, with advanced guards holding the bridges, and one corps (1st) facing east along the Meuse between Givet and Namur to guard its right flank. Its further action as laid down by Joffre on the 18th nas, in conjunction with the British and Belgian armies, either directly to oppose a hostile advance astride the Meuse betneen Givet and Brussels, or, if the main enemy strength lay south of that river, to act against his right flank in the northern Xrdennes. On the zoth, however, it became known that the Belgian army was in full retreat on Antwerp, while Sir John French had informed Lanrezac at an interview on the 17th that the British expeditionary force would not be ready for action before the 24th. As regards the enemy, Lanrezac believed them to have nine or ten corps available for active operations against him north of the Meuse and another two in the angle southeast of Namur. His intention was now to close up his army on the 21st and 22nd, establish himself in a defensive position, and cross the Sambre early on the 23rd.

(*c*) British Movements Prior to the Battle of **Mons.**—The mobilization of the British expeditionary force (B.E.F.) was completed by Aug. 9 and the transport across the channel of its four infantry divisions and five cavalry brigades took place without interruption betneen the 12th and 17th. Field Rlarshal Sir John French, the commander in chief, had received instructions to co-operate with the French but as an independent commander only, and to be cautious of exposing his small and precious force to serious danger or losses. After a series of conferences with Joffre and Lanrezac, it was agreed that the B.E.F. should take part in Lanrezac's offensive, moving on the left of Lanrezac by Soignies on Nivelles, and as a preliminary should move forward from its concentration area east of the general line Maubeuge-Landrecies-Bohain to a position of assembly about Mons.

2. THE BATTLE OF CHARLEROI

(a) Aug. 21.—During the 21st .the German 1st army continued its southwesterly advance and the 3rd army closed up to a line a few miles east of the Meuse. Bdlow's orders for the 21st were that the and army on the 21st would continue its advance to the Sambre, but as the 3rd army was not yet in position, it was agreed between the two commanders that the combined attack by the two armies against the enemy southwest of Namur should not take place until the 23rd. The right wing of the 2nd army reached the line of the Canal du Centre west of Gosselies, driving back the French cavalry. while the left began operations against the eastern forts of Namur. The centre, however, early in the afternoon came into contact with the right of the French 5th army on the line of the Sambre and forced its way across the river. Thus on the evening of the 21st the German 2nd army secured the crossings both of the Canal du Centre and of the Sambre, and was in position ready to carry out its part in the combined attack arranged with the 3rd army for the 23rd.

The French right on this evening had taken up a new defensive position running from Fosse to Marchienne au Pont. The left was approaching Thuin. with the cavalry covering its western flank. Of the group of three reserve divisions which had detrained around Vervins, one was on its way to relieve the 1st corps. still guarding the army right on the Meuse south of Namur; the other two were moving north and had reached Avesnes. In these positions Lanrezac decided to await further hostile attacks.

(6) **Aug.** 22.—Buloa's orders for the zznd envisaged nothing more than a general closing up of the and army on the north bank of the Sambre and preparations for an advance across that river on the 23rd, so as to open the passage of the Meuse for the 3rd army. The 1st army was directed to close up to a position whence it could support the right of the 2nd army. News which arrived at 2nd army H.Q. in the course of the morning, however, caused a radical change of plan; it appeared from this that the French immediately south of the Sambre were chiefly cavalry and that their main forces were no farther north than the line Beaumont-Philippeville. Bülow, faced with the alternative of throwing overboard his prearranged scheme of co-operation with the 1st and 3rd armies, or of losing so apparently favourable a chance of securing the passage of the Sambre at little cost, decided about noon to attack forthwith. Orders were accordingly issued to all corps; the 3rd army was asked also to push forward.

The right of the 2nd German army encountered no very serious opposition, and by the evening, had succeeded in setting foot on the right bank of the river. In the centre, however, the struggle was much more severe. In the early morning the French right wing launched a series of counterattacks in the hope of regaining the ground lost on the 21st; these met with only partial success, and were finally beaten back with heavy loss. A stand was made on the line Fosse-Gerpinnes; where for some hours the fight swayed to and fro without any decided success on either side.

Finally, however, the Germans succeeded in breaking into the positions held by the French, who were driven back once more to the line St. Gerard-Nalinnes, where they reorganized and prepared for a new defense on the morrow. Their left wing was not seriously attacked and maintained its positions.

For the 22nd, the German 3rd army had been ordered merely to close up on the east bank of the Meuse, and began preparations for the passage of the river on the morrow. During the day news came in to Hausen that the and army, contrary to its commander's previous arrangement with him, had crossed the Sambre that day and asked urgently for his co-operation by an advance across the Meuse. Orders were therefore issued for the 3rd army to force the passage of the river early on the morrow.

(c) Aug. 23.—The morning of the 23rd passed without any renewal of fighting on the French 5th army front; Biilow was apparently waiting till the effects of the 3rd army attack should make themselves felt. It was not till afternoon that his centre began to work forward toward Mettet and forced back the French line some little distance by nightfall. Fighting on the left was more serious and sustained; the Germans forced the passage of the Sambre in this sector, and after repeated attacks drove back their opponents some miles to the south, On the extreme left the troops of the reserve divisions, relieving the cavalry, came into line along the south bank of the Sambre between Merbes le Chateau and Maubeuge.

Despite the progress made by the 2nd army during the fighting of the last three days, the view of the situation taken at Biilow's headquarters on this evening was gloomy. The expected co-operation of the 1st army had failed to materialize, and that of the 3rd army seemed to have had little effect. The enemy was believed to be in superior force on the army front; he had fought well and might be expected at any time to undertake a general counteroffensive, which the German troops, exhausted by three days' incessant fighting, could hardly hope to resist. Nevertheless, the army orders for the 24th laid down a continuance of the attack.

The 3rd army had begun its attack east of the Meuse early in the morning. The French positions were strong and well adapted for defense, and their resistance stubborn; but before noon the German left had effected a crossing and observed signs of a hostile retirement, which were attributed to the effect of the 2nd army's victorious advance. In accordance, therefore, with an order from the German supreme command, Hausen instructed his left to move on Fumay so as to cut off the hostile retreat to the south. But the task of the army was far from accomplished; its centre met with fierce resistance at Dinant and only got across late in the day; the left, pushing forward to Onhaye, was counter-attacked and driven back by part of the 1st French corps, sent back to restore the threatening situation on this front; while the column sent toward Fumay, by reason of the natural difficulties of the route, failed to reach its objective. Still, the 3rd army was across the Meuse, and Hausen had ordered it to undertake a pursuit next day in a southwesterly direction, when a staff officer from the 2nd army arrived bearing an urgent request for his assistance in the form of an advance due west against the flank of the 5th French army. To this alteration of his plan Hausen consented and issued new orders directing his right wing on Mettet.

Meanwhile, Lanrezac, on his side, in view of the threat to his flanks and rear afforded by the fall of Namur, the advance of the 3rd army and the defeat of the French in the Ardennes, fearing for his left where the B.E.F. had been engdged all that day, with superior enemy forces, and realizing the state of moral and material exhaustion among his own troops, decided that he had no choice but to retreat. Orders were issued that morning for a withdrawal to the line Givet-Philippeville-Merbes-le

Chateau; which was carried out on the 24th unmolested by the Germans. Their 2nd army advanced only a few miles to the southward; the right of their 3rd army, advancing due west, found no enemy before it, and its left column, resuming its advance on Fumay, was unable to cross the Meuse there until the 28th, when it was too late to interfere with the French retirement.

The battle of Charleroi had thus terminated in a definite German success, the scope and effects of which, however, were so unduly exaggerated in the reports of army and corps commanders, as to assume, quite without warrant, the dimensions of a decisive victory.

3. THE BATTLE OF MONS

On Aug. 21 the British expeditionary force began its advance into the line of battle. The cavalry preceded the advance, followed by the 2nd corps (Smith-Dorrien) and the 1st corps (Haig) in that order. Reports from aircraft and cavalry on the 21st and 22nd established the presence of hostile cavalry about Nivelles. and of the main enemy forces between Enghien and Charleroi. In rear of the cavalry the British corps closed up to the line Binche-Mons-Condé canal, the 1st corps on the right as far as Villers St. Ghislain, the 2nd corps on the left behind the canal line; one cavalry brigade covered the right of the army, while later in the morning the cavalry division fell back from before the front to a new position southeast of Condé in rear of its left. Sir John French knew on the evening of the 22nd that the French on his right, after heavy fighting, had been forced back from the line of the Sambre, and that strong enemy forces, reckoned at three or four corps, were approaching his own front; he therefore determined to abandon all idea of an offensive, and to stand for battle next day in the positions then held by his army. In view of this, a request from Lanrezac for a British counterstroke against the flank of the enemy then attacking him could not be complied with; the most that French could promise was that he would hold his ground for at least 24 hours.

On the German side the 1st army, on the evening of Aug. 21, received orders from Bulow to be prepared next day to afford direct support to the 2nd army. To this scheme Kluck saw serious objections in view of the uncertainty as to the whereabouts of the British, and a prolonged discussion took place which resulted in the 1st army commander yielding his point, and agreeing to swing his army on the zznd more to the south to the line Lessines-Soignies. During this day contact was established, as has already been related. with the British cavalry and Kluck now realized that the B.E.F. was advancing to join the left of the French on the Sambre. Once more there arose a divergence of views; Kluck wanted to carry out a wide turning movement to envelop the British left; while Bulow considered he could not dispense with his direct support on the Sambre. Eventually orders were issued for the 1st army to advance on the 23rd across the Canal du Centre to the general line north of Maubeuge, northeast of Condé, a movement which was bound to bring them into conflict with the British.

Early on the morning of the 23rd, the latter had taken up their positions for battle—the 1st corps on the right facing northeast between the Sambre and the Haine southeast of Mons, the 2nd corps and the 19th infantry brigade facing north along the line of the Canal du Centre from Mons to just east of Condé (which was held by part of the 84th French territorial division), and the cavalry division in rear of the 2nd corps left. The whole front was a very long one—about 27 mi.; the ground along the line of the canal was enclosed and much built over, but the heights to the southeast of the Haine afforded strong second positions farther in rear. About 9 A.M. the battle opened on the 2nd corps' right, but it was not till 11 A.M. that the action became general all along its front. This pause was due to the fact that early in the morning Kluck, alarmed by a false report that strong hostile forces were detraining at Tournai, well out on his right flank, had ordered his army to halt until the situation there was cleared up—which did not occur till about midday. The German attack at first made little progress and suffered heavy casualties from the effective British fire, but in the early afternoon the right of the British corps was forced to evacuate Mons and the canal bend north of it, and retire to its second position, while a gap in its centre also caused some temporary anxiety. By nightfall it had every here fallen or was about to fall back to this new position about 2 mi. south of the canal. Neither the 1st corps on the right nor the 19th brigade and the French on the extreme left had been seriously attacked during the day, since the German right wing, which was moving on Condé, failed to reach the battlefield; the British losses had been slight and the morale was excellent. Nonetheless. Sir John French, on receipt of news from the French G.O.C. and Lanrezac's French army of the situation on his flanks and the greatly superior enemy force available for use against him, realized that he could not continue to hold his position, and issued orders for a retirement next day to a line running east and west through Bavai, with its right covered by the fortress of Maubeuge.

This withdrawal, commencing before dawn on the 24th, was successfully executed, though not without local fighting in which the B.E.F. actually suffered more heavily than in the previous day's battle. The 1st corps and the right of the 2nd corps fell back unmolested, but at Frameries and Elouges the centre and left of the 2nd corps and cavalry divisions were hard pressed by the enemy, who succeeded in cutting off and capturing the greater part of one battalion at Elouges after a gallant resistance. Nevertheless, by the morning of the 24th the B.E.F. stood, wearied but intact, on the line allotted to it on either side of Bavai. The German 1st army, apart from its pressure on the rear guards of the 2nd corps, made little attempt to follow up or molest the retirement. Kluck believed the British would stand fast on this day and await his further attack, arrangements for which he had laid down in his orders issued late on the 23rd; it was not till next morning that he realized the true position, and then it was too late to carry out that enveloping movement with his right wing which alone could have enabled him to secure decisive success. In fact, the results of the two days' fighting around Mons were, from the German point of view, disappointing; the retirement of the British before it was mainly attributable to the course of events elsewhere and in particular to the ill success of the French 5th army farther east, and there was at no time any question of a true tactical victory on the German 1st army front.

General Considerations.—The operations above described had thus resulted in a serious Allied defeat which laid open the whole northern frontier of France to invasion. The weight and velocity of the German offensive had been too great and unexpected for the French countermeasures to be effective in stemming its progress; such a result was only to be expected in view of the fact that on this sector of the front the Germans had a numerical superiority of 11 divisions (28 as against 17). The Allies, moreover, were incompletely concentrated for battle and the arrangements for co-operation between them were by no means satisfactory. The 5th army moved forward to the Sambre too late to assist the Belgians and too soon to be able to count on British support, and became involved in an encounter battle before it had time to establish itself in a suitable defensive position. Moreover, its indifferent tactical handling allowed the Germans to make full use of their superior armament, which took heavy toll of the hasty and ill-prepared attacks in which the French at this period of the war were too prone to indulge. The French failure at Charleroi, moreover, nullified the effect of the temporarily successful resistance of the British at Mons against an enemy who had ample additional troops at hand to continue his offensive. The immediate retreat of the whole Allied left wing therefore became the only means of escape from a critical situation.

Fortunately for the Allies, the Germans on their side failed to reap the full fruits of a success so real that it might well have been made decisive. This failure must be attributed to several causes: inadequate information, which lead them unduly to disperse their forces prior to and during the battles; defective organization of command, which placed the general control of the operations in the hands of one army commander who was bound to be unduly influenced by events on his own immediate front; and faulty leadership, which indulged in sudden and ill-considered changes of plan, and let slip its chance of completely destroying its weaker adversary.

It seems that while the Allies were fortunate to escape as lightly as they did, for the Germans Charleroi and Mons were at once a real victory and a lost opportunity.

V. BATTLE OF LE CATEAU

In view of the withdrawal of the whole of the French centre and left wing which Sir John French had been informed was to be continued on Aug. 28, the British commander in chief ordered on the evening of the 24th a further retirement of the B.E.F. from the Bavai area to a position on either side of Le Cateau. In order to carry out this movement it was necessary to split the army and send the 1st corps to the east and the 2nd corps and cavalry to the west of the great Mormal forest, which lay right across the line of retreat and through which no practicable roads were believed to exist. The 1st corps completed its movement unmolested by the enemy, though not without difficulty and trouble owing to the great heat and the presence of French troops along its allotted route, and went into quarters for the night around Landrecies. Here late in the evening a collision took place with German advance guards, which after some confused fighting were beaten off.

On the other flank, however, the 2nd corps and the cavalry, who were joined in the afternoon by the 4th division, just detrained at Le Cateau, had considerable fighting.

The commander of the German 1st army, who had expected the British to stand for battle, realized in the early morning that they were in fact retiring, but concluded as the result of an erroneous air report that the direction of their retreat was not southwestward but eastward with a view of seeking shelter under the guns of Maubeuge—a course of action which Sir John French had in fact considered, but on recollection of the fate of Bazaine in similar circumstances in 1870, had rejected. As a consequence of this inaccurate appreciation of the situation, the 1st army column was switched off from 'its first direction of advance southwestward toward a new southward direction, and it was not till the afternoon that the error was recognized and the original direction resumed. By that time, as we have seen, the British 1st corps had got a good start of its adversaries; but the 2nd corps and cavalry, partly owing to the passage of the French 1st cavalry corps across their rear to the new position allotted to it on their left, were much delayed in starting their retirement, and the German 2nd and 4th corps early got contact with their rear guards; so that the retreat of the British left wing resolved itself into a running fight with a vigorously pursuing enemy. The 4th division, which had just arrived from England and had taken up a position north of Solesmes, effectively assisted the withdrawal, but the bulk of the troops of the 2nd corps were unable to reach the positions allotted to them west of Le Cateau until late that night, and some not even till next morning. The 4th division and the cavalry were in little better position, the former, which was deficient of many essential units, being unable to fall back from Solesmes to its new positions till long after dark, while the cavalry, being scattered on both flanks of the 2nd corps, was much exhausted.

About 9 P.M. General Smith-Dorrien, G.O.C. 2nd corps, received orders from British G.H.Q. that the army was not to stand to fight on its present position next day, as expected, but was to continue its retreat to the area Busigny-Beaurevoir-Le Catelet. He now found himself called on to make a critical decision. According to reports from his subordinates, his force could not possibly resume its retreat till well after dawn on the 25th; and as the enemy were, according to information from the cavalry, in force close to his front, to attempt a retirement by daylight and over roads encumbered with transport and refugees would probably lead to a disaster. Moreover, the 1st corps was believed to be engaged with the enemy, and the 2nd corps, by falling back, would expose its flank and rear. To continue his retirement next day, as ordered, he therefore considered impossible. By standing to fight in conjunction with the 4th division and the cavalry he might hope to check the hostile advance for a time and utilize the first opportunity to resume his withdrawal before he could be attacked and overwhelmed by greatly superior forces. On this latter course, therefore, Smith-Dorrien eventually decided; and in this decision G.H.Q. concurred. Accordingly, orders were got out for the British left wing to stand for battle, on the heights south of the Le Cateau-Cambrai high road between Le Cateau and Esnes.

The German 1st army halted for the night of the 25th–26th on the general front, east and south edges of Mormal forest—Solesmes-Bouchain, and its orders for the morrow were to continue the pursuit southwestward so as to cut off the British line of retreat between Cambrai and St. Quentin. About 6 A.M. on the 26th, the 4th division was suddenly attacked by German cavalry and suffered severely before it could effect it withdrawal to its battle position on the line Ligny-Esnes, and there check the German progress. Meanwhile, on the opposite flank the 5th division in and west of Le Cateau were as suddenly assailed and forced back to the heights southwest and west of the town. An attempt to get round its right in the Selle valley was, however, foiled with the help of the cavalry on that flank; and with the assistance of troops sent up from corps reserve the British positions were maintained intact in this part of the field till noon. The 3rd division in the centre had not been seriously attacked. Before Iong, however, the situation became serious, one fresh German corps, moving west from about Landrecies, was approaching the field and threatened to envelop the British right; while on the left another uhich had arrived on the field to support the cavalry, resumed the attack in the sector held by the 4th division. Under these circumstances Smith-Dorrien, at 1:40 P.M., ordered a general retirement commencing with the right, and as soon as these orders reached the troops, about 3 P.M., the withdrawal commenced. On the 5th division front considerable difficulties were encountered. and some guns had to be abandoned but the bulk of the troops succeeded in getting away. The 3rd division had no difficulty in effecting their retreat, and the 4th little more, since the attention of the German 2nd corps, which, after driving back French territorial troops through Cambrai, was preparing to fall on the British left, was distracted by the opportune arrival about Crèvecoeur, of the French cavalry corps, whose artillery effectively prevented the German attack from developing till the 4th division had got well away to the south. On the whole front small parties which had not received orders to retire or had received them too late, fought on till finally overwhelmed, and their stubborn resistance prevented any pursuit of the main bodies by the enemy. Marching far into the night despite its intense exhaustion and great congestion and confusion on the various lines of retirement, Smith-Dorrien's command finally halted in the area between Bohain and Le Catelet. It had lost nearly 8.000 men and 38 guns, but was still a fighting force. Its escape from the critical position in which it stood on the morning of the battle may be attributed partly to its adversaries' failure to exploit to the full their great superiority in numbers and means; partly to the invaluable help rendered first by the French territorials and later by their cavalry corps in securing its exposed left flank thoughout the day; but most of all to the fine qualities of its leadership and its own soldierly virtues, which made of Le Cateau an episode more creditable than many a victory.

With the conclusion of the battle the crisis through which the B.E.F. had passed since Mons may be said to have ended. Its retreat was continued on the 27th and 28th unmolested by the German 1st army, which now had to swing westward to deal with a new enemy in the shape of French forces assembling in the Somme valley. The 2nd corps, 4th division and cavalry moved via St. Quentin and Ham behind the line of the Somme and then behind the Oise, where touch was established with the 1st corps, which, after a series of rear-guard encounters with the right wing of the Germany 2nd Army, had successfully effected its retreat by may of Etreux and Guise. Thus, on the 29th, the whole of the B.E.F. stood once more united on the south bank of the Oise between La Fere and Noyon, where it was afforded a short respite to reorganize and refit.

VI. THE BATTLE OF GUISE

Between Aug. 24 and 27 the French 5th army carried out a steady retirement southward from the area south of the Sambre to south of the Oise, and on the evening of the 26th stood with outposts on the line of that river and the Thon between Aubenton and Guise, and its main bodies farther back. The German 2nd army, which had bought its victory at Charleroi at a heavy price in casualties, had followed it up and had reached on a line from east of Bohain to La Capelle; it was now reduced to four corps, the other two having been sent off to the eastern front, where the situation had become menacing for the Germans. No serious contact had taken place between the adversaries during this period.

Meanwhile Joffre, in view of the Allied failure in the frontier battles and the rapid progress of the German right wing, proposed to strengthen his own left wing by the formation of a new 6th army about and south of Amiens, to check the enemy advance on the general line Laon-La Fere-St. Quentin-the Somme, and ultimately assume the offensive with the 5th, 6th and British armies. But the retreat of the B.E.F. as a result of Le Cateau rendered it necessary in his opinion for some immediate assistance to be given to it if it were to be kept in being as a fighting force, and on the 27th the 5th army received orders for an immediate attack northwestward toward St. Quentin against the enemy who were following up the British on the west bank of the Oise. Accordingly, the French corps on the 28th closed to their left in preparation for the attack on the 29th, the left wing facing northwest along the Oise between Origny and Mons, the right guard facing north between Guise and Rumigny. The co-operation of the British 1st corps had been asked for and promised by its commander, but Sir John French Intervened to forbid this. Meanwhile, Biilow, as before the battle of Charleroi, had come to the conclusion early on the 28th that he had only strong rear guards in front of him south of the Oise. On the 28th, therefore, he pushed his left wing up and over that river between Guise and Étréaupont, while his right was sent off far to the southwestward beyond St. Quentin toward the upper Somme so as to keep touch with the 1st army and assist it to cut off the retreat of the British. His orders for the 29th dealt mainly with the preparatory measures for the attack on the out-of-date fortress of La Fkre, the importance of which seems to have obsessed him unduly; the right wing, however, was to continue its advance southwestward.

The French advance across the Oise toward St. Quentin thus came as a complete surprise to the Germans; and their right wing, thus menaced on its left flank, was at once checked in its progress and faced hurriedly southeastward to meet the unexpected threat. At first only part of one corps was available to stave off the advancing French, who got to within 4 mi. of St. Quentin, while the wide gap between Bulow's wings for a time caused him grave anxiety. Eventually the arrival of the remainder of his right wing relieved the German situation in this part of the field; the French having received orders that the attack on St. Quentin was not to be pressed, maintained their ground till nightfall, and then fell back east of the Oise.

The reason for this order lay in the changed situation on the northern part of the field, where the German left wing, advancing southward, had driven in the French forward troops opposed to them, and menaced the flank of columns about to cross the Oise about Mt. d'Origny. Lanrezac's reserve was thrown in; a general counterstroke took place which not only put a stop to the enemy's advance, but forced him to give ground; and by nightfall the progress of the German left wing had been checked definitely.

The object of the French counteroffensive having been achieved, Joffre ordered Lanrezac to resume his retreat on the 30th, to the line originally laid down, and this movement, which commenced early in the morning, was safely completed under cover of strong rear guards. The Germans did not attempt to resume their attack during the morning, but their right wing, having called up to its assistance a division of the 1st army, advanced in force later in the afternoon across the Oise and established itself on the east bank by nightfall; the left wing also moved forward level with it, By this time the French main bodies had got clear away and no pursuit was undertaken, the 2nd army, which was much exhausted, was ordered a rest day on the 30th, leaving to the 1st army the task of following up the retiring enemy by an advance across the Oise south of La Fkre

In truth the battle of Guise, if a *victoire sans lendemain* for the French, was a bad setback for the Germans, and in it was to be found a presage of the turn of the tide a week later on the Marne.

FRONTINUS, SEXTUS JULIUS (c. A.D. 35–c. 103), Roman soldier and writer, was the author of the *De aquis urbis Romae,* a history and description of the water supply of Rome, including the laws relating to its use and maintenance and other matters of importance in the history of architecture. In 70 he was city praetor, and about five years later succeeded Petilius Cerealis as governor of Britain. He subdued the Silures, a tribe in southeast Wales, and held the other tribes in check until he mas superseded by Agricola (78). In 97 he was appointed superintendent of the aqueducts *(curator aquarum)* at Rome. His treatise *De re militari* is lost. His *Strategematicon libri iii.* is a collection of examples of military stratagems from Greek and Roman history; a fourth book, the plan and style of which is different from the rest (more stress is laid on the moral aspects of war; *e.g.,* discipline), is the work of another writer known as Pseudo-Frontinus. Extracts from a treatise on land surveying ascribed to Frontinus are preserved in C. Lachmann's *Gromatici veteres* (1848).

Herschel, *The Two Books on the Water Supply of the City of Rome,* with Eng. trans. and explanatory chapters, 2nd ed. (1913); M. B. McElwain (ed.), *The Stratagems and the Aqueducts of Rome,* with Eng. trans., "Loeb Series" (1925).

FRONTO, MARCUS CORNELIUS (c. A.D. 100–170), Roman grammarian, rhetorician and advocate, was born of an Italian family at Cirta in Numidia. He came to Rome in the reign of Hadrian, and soon won fame as an advocate and amassed a large fortune. Antoninus Pius appointed him tutor to his adopted sons Marcus Aurelius and Lucius Verus. In 143 he was consul for two months, but declined the proconsulship of Asia on the ground of ill health. His talents were greatly admired by his contemporaries, a number of whom formed themselves into a school called after him Frontoniani, whose avowed object it was to restore the ancient vigour of the Latin language. The authors recommended include Ennius, Plautus and Sallust. Till 1815 the only extant works ascribed (erroneously) to Fronto were two grammatical treatises, *De nominum verborumque differentiis* and *Exempla elocutionurn* (the last being really by Arusianus Messius). In that year, however, Angelo Mai discovered in the Ambrosian library at Milan a palimpsest manuscript from St. Columba at Bobbio (and, later, some additional sheets of it in the Vatican), on which had been originally written some of Fronto's letters to his royal pupils and their replies. These were published at Rome in 1823. The correspondence with Antoninus Pius, Marcus Aurelius and Lucius Verus shows their character in a very favourable light. The collection also contains letters of recommendation to friends, treatises on eloquence, some historical fragments and literary trifles on such subjects as the praise of smoke and dust, of negligence, and a dissertation on Arion. Fronto's style is "a laborious mixture of archaisms, a motley cento," the forerunner of the Latin of Apuleius.

The best edition of his works is by S. A. Naber (1867), with an account of the palimpsest; *see* also G. Boissier, "Marc-Aurèle et les lettres de F.," in *Revue des deux mondes* (April 1868); R. Ellis. in *Journal of Philology* (1868) and *Correspondence of Fronto and M.*

Aurelius (1904); and the full bibliography in the article by Brzoska in the new edition of Pauly's *Realencyklopadie der classischen Altertumswissenschaft,* iv, pt. i (1900). Edition with English translation by C. R. Haines, Loeb series (1919); *see* also *M D* Brock, *Studies in Fronto and His Age,* Girton Coll. Studies, V (1911)—a more favourable view of Fronto's style.

FROSINONE, a town of Italy (anc. Frusino) and the capital of a province, 53 mi. E.S.E. by rail from Rome. Pop. (1951) 14,035. The town is picturesquely situated on a hill of 955 ft. above sea level, but contains no buildings of interest. It was a Volscian, not a Hernican, town; a part of its territory was taken from it and sold about 306–303 B.C. by the Romans, later becoming an unimportant colony. It was situated a little way above the Via Latina.

FROSSARD, CHARLES AUGUSTE (1807–1875), French general, was born on April 26, 1807, and entered the army from the École Polytechnique in 1827, being posted to the engineers. Napoleon III made him in 1867 chief of his military household and governor to the prince imperial. He was one of the superior military authorities who in the period 1866–70 foresaw and endeavoured to prepare for the inevitable war with Germany, and at the outbreak of mar he was given by Napoleon the choice between a corps command and the post of chief engineer at headquarters. He chose the command of the 2nd corps. On Aug. 6, 1870, he held the position of Spicheren against the Germans until the arrival of reinforcements for the latter and the nonappearance of the other French corps compelled him to retire. He took part in the battles around Metz, and was involved with his corps in the surrender of Marshal A. F. Bazaine's army. General Frossard published in 1872 a *Rapport sur les opérations du 2 corps.* He died at Château-Villain, Haute-Marne, on Aug. 25, 1875.

FROST, EDWIN BRANT (1866–1935), U.S. astronomer, specialist in stellar spectroscopy, was born in Brattleboro, Vt., on July 14, 1866, and graduated from Dartmouth college, Hanover, N.H., in 1886. In 1898 he became professor of astrophysics at The University of Chicago and astrophysicist at the Yerkes observatory, Williams Bay, Wis., of which he served as director for the period 1905–32.

Frost's chief contributions were in the field of stellar spectroscopy, especially the spectrographic determination of velocities of stars.

FROST, ROBERT LEE (1874–), U.S. poet, might never have become "the poet of New England" had not his father made a dying request to be buried in his native New England. So it happened that Mrs. William Prescott Frost took her son Robert, born in San Francisco, Calif., March 26, 1874, and a younger daughter Jeanie, across the continent from San Francisco to Lawrence, Mass., for the interment of her husband in 1885. No funds were available for the return trip and the widow settled with her children in Salem, N.H., where Mrs. Frost earned a living for several years by teaching school.

Entering Dartmouth college in the fall of 1892, Robert Frost so intensely disliked formal study that he remained there less than one semester. During the next two years, he earned a living in miscellaneous ways while sending poems to uninterested editors. In 1894, to celebrate his first sale of a poem ("My Butterfly"), he privately printed six of his poems in a booklet entitled *Twilight,* an edition limited to two copies, one for his affianced, Elinor White, and one for himself.

After his marriage in 1895, Robert Frost taught for two years at his mother's private school in Lawrence and then spent the next two years as a special student at Harvard. In 1900, for reasons of health, he moved to a small farm in Derry, N.H.. and conducted a small poultry business there until 1905. Failing as a farmer, he taught various subjects in the Pinkerton academy at Derry from 1905 to 1911 and then moved to Plymouth, N.H., where he taught psychology for a year in the New Hampshire State Normal school.

Still intent only on achieving success as a poet, he sold his Derry farm and with the proceeds took his family to England, where he devoted his time entirely to writing. During that extremely important three-year stay in England (1912–1915), he published his first two books of poetry: *A Boy's Will* (1913) and *North of Boston* (1914). The cordial praise given those poems by British men of letters won him lasting friendships in England and attracted the surprised attention of critics and editors in his native land. When he returned to the United States in 1915, his first two books had been reissued in New York, and *North of Boston* soon became a best seller.

Although the Frost family bought and settled on a small farm in Franconia. N.H., immediately after the return from England, the poet found himself in unexpected demand for public readings and lectures. Thus began the habit which gradually made his genial personality as well known and loved as his poetry. When he found that not even success as a poet afforded adequate financial returns, he accepted various invitations to teach' from colleges and universities—Amherst (1916–20, 1924, 1926–38, 1949–), Michigan (1921–23, 1925), Harvard (1939–43) and Dartmouth (1943–49). He was awarded the Pulitzer prize for poetry in 1924, 1931, 1937 and 1943.

After his first two works mentioned above, his major works include *Mountain Interval* (1916), *New Hampshire* (1923), *West-Running Brook* (1928), *A Further Range* (1936), *A Witness Tree* (1942), *A Masque of Reason* (1945), *A Masque of Mercy* (1947), *Steeple Bush* (1947) and *Complete Poems* (1949).

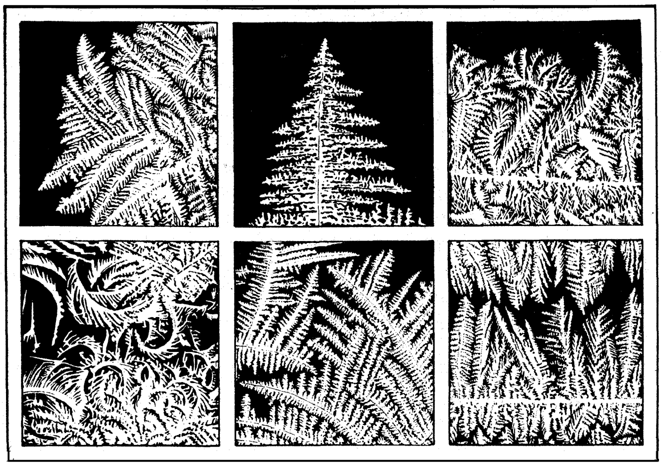
FROST, a term used in two senses: (1) atmospheric water directly crystallized on the ground and on exposed objects; and (2) the occurrence of subfreezing temperatures affecting plants and crops. Frost crystals, often called hoarfrost in the aggregate, form by the passing of the invisible water vapour of the atmosphere into the ice crystal phase without going through the liquid phase. Hoarfrost lightly covers fields and roof tops under conditions that would form dew (*q.v.*) if the temperature were above freezing at the point of formation. Sometimes the freezing temperature will be reached after dew has already formed, producing frozen dew, but this usually cannot be readily distinguished because crystals ordinarily will start forming at about the same time the freezing starts. Pertaining to plant culture, frost refers to the freezing of the aqueous solutions in the plant cells causing these to burst and destroy the plant. Only plants containing plentiful and dilute solutions in their leaves, fruits, etc., are easily damaged. The occurrence of a killing frost without a hoarfrost deposit is sometimes popularly called a black frost.

In physiography and technology the term frost is applied to a variety of freezing processes. Thus, one speaks of the depth of frost penetration in the soil, meaning depth of frozen ground, frost action in the erosion of rocks, frost heaving of soils, frosting of surfaces by other vapours as well as nater, frost damage to structures, newly laid cement, etc.

The most important aspect of frost in relation to plants is its determination of the length of the growing season, which is defined as the period from the last killing frost in spring to the first killing frost in autumn, with reference to the tenderest crop plants. There are regions of the earth mhere the season reaches critically short proportions for the maturing of most usable crops and others where the season is so long that more than one planting of such crops as corn (maize) and alfalfa can be brought to harvest. In regions where frost is rare or absent, other factors take on more importance.

One of the most critical situations for frost is encountered in the citrus fruit regions. There the few killing frosts likely each winter are combated by heating the groves with crude oil heaters called smudge pots or by mixing the air with huge fans to prevent the cold air from settling down. The smoke from the smudge pots reduces the heat losses of outgoing radiation to some extent but the smoke nuisance in most localities offsets this advantage and local legislation or campaigns are directed toward use of cleaner, more efficient burners.

In citrus growing regions the government meteorological offices developed special frost-warning services with a high degree of usefulness to growers in the United States. In the Pacific coast fruit regions the service was extended to make it possible to prevent frost damage to deciduous fruit crops such as peaches, apricots, almonds, pears and even apples during the period of blossoming both in the United States and in Canada. Protection of orchards was undertaken less extensively in the eastern deciduous fruit regions. Atlantic coast and Wisconsin cranberries are protected from frost at critical times of the growth cycle by flooding



SOME OF THE FORMS ASSUMED BY HOARFROST ON WINDOWPANES

the cranberry bogs n·ith water.

The crystalline and other forms of frost deposit are a subject of aesthetic as well as scientific interest. The structures differ in some respects from those of snow (*q.v.*). Granular forms Froduced by the freezing of droplets of liquid water carried in the air at temperatures below freezing, technically called supercooled droplets, form rime. It is best developed on mountain tops enveloped in supercooled clouds.

Rime is a common form of icing on aircraft. It also occurs in steam fogs around open springs, streams, lakes or ponds in very cold weather and in extreme conditions around chimneys from the water vapour condensed in the flue gases. True crystalline hoarfrost is of two classes, that which assumes columnar forms and that which assumes tabular forms. Generally the crystals of these two classes do not occur together on a single night; rather, one or the other will greatly predominate. Columnar forms usually comprise the majority of hoarfrosts of spring and autumn. The columns are. in their best-preserved state, hexagonal in cross section. hollow and variable in size and slenderness.

Tabular or platelike hoarfrost crystals are most common at low temperatures such as those of midwinter. They resemble snow plates, but since they must grow outward in segments from some supporting object they rarely assume the perfect symmetry of many snow crystals. Over ice-covered ponds and rivers, beautiful clusters or rosettes of fernlike or jewel-like frost collect on the surface of the ice. At very low temperatures cubical crystals are sometimes found.

Children and adults alike in cold climates have been fascinated by the beautiful and varied frost forms found on the inner surfaces of windowpanes in buildings. In most cases with heated rooms the vapour condenses as a liquid first. but if the conditions are right, such as in an unheated room, the delicate pure crystalline forms are predominant. These will resemble fairy forests of fir trees, ferns, starry skies and castles or submarine gardens with corals. starfish and plants. Some of the designs. especially those that form along otherwise obscure scratches or strictions in the glass, are repeated from one occasion to the next. Factors affecting the design are the presence of films, dust particles, oily marks and irregularities on the glass. The tiny eddy currents of air over the glass and the nearness of other frost crystals also have an effect. (H. R. B.)

FROSTBITE is an injury to the skin or underlying tissues or both. resulting from exposure to cold of such severity and duration that actual freezing (ice formation) occurs. Air temperatures must be below 32° F. for frostbite to occur. Unprotected areas of skin exposed to very cold mind can freeze in less than one minute. but usually freezing occurs only after longer exposure. Parts of the body most commonly frozen are toes, fingers; ears and nose. Mild true frostbite produces only swelling and reddening of the skin; severe frostbite may affect deep tissues, including bone, and may culminate in gangrene (*q.v.*) and loss of the frozen part. Reddening or blanching of the skin from mere chilling instead of freezing should not be called frostbite. Cold injuries without actual freezing, such as chilblain (*q.v.*), immersion foot and trench foot, are frequently confused with true frostbite; these injuries occur as the result of exposure for many hours in air or water at temperatures above freezing. Experiments conducted during World War II and later showed that frostbite should be treated by very rapid thawing of the still frozen part in warm water. The frozen part should never be rubbed with snow. (F. A. FN.)

FROSTWEED (*Helianthemum canadense* or *Crocanthemum canadense*), a North American plant of the rockrose family (Cistaceae). which is native to dry rocky places and sandy soils from Maine to Ontario and Wisconsin southward to North Carolina and Missouri.

It is a slender, sparsely branched, slightly woody perennial, with small, narrow, nearly stalkless leaves and showy yellow flowers, $\frac{3}{4}$ in. to $1\frac{3}{4}$ in. across. usually borne singly or rarely two together, the petals soon falling. These are followed later by small short clusters of cleistogamous (self-fertilized in the bud stage, or at least without opening) flowers. without petals. borne in the axils of the leaves. The plant is remarkable in that late in autumn crystals of ice sometimes shoot from the fissured bark at the base of the stem, whence the popular name.

The hoary frostweed (H. *majus* or *C. majus*), a similar species but of more western and southern range, exhibits the same peculiarity.

FROTTOLA, an Italian choral form, popular about 1490–1530. consisted of four parts: the melody in the highest voice: a bass harmonic and two inner parts of lesser importance. Sometimes a lute or other instrument took one of the minor parts, but usually the frottola was unaccompanied. The same music was repeated for several verses in a fashion simpler than the madrigal proper. which succeeded it. The music of the frottola was less contrapuntal than that of the madrigal, and the words usually were humorous or sentimental.

O. Petrucci of Venice published 11 books of frottole from 1504 to 1514, 10 of which remain.

FROUDE, JAMES ANTHONY (1818–1894), English historian, son of K. H Froude, archdeacon of Totnes, was born at Dartington, Devon, on April 23, 1818. He was educated at Westminster and Oriel college. Oxford, then the centre of the ecclesiastical revival, and was elected a fellow of Exeter college *(1842)*. Froude joined the High Church party and helped J. H. Newman, aftenvard cardinal, in his *Lives of the English Saints*. He was ordained deacon in *184;* By that time his religious opinions had begun to change, he grew dissatisfied with the views of the High Church party and came under the influence of Thomas Carlyle's teaching. Signs of this change first appeared publicly in his *Shadows of the Clouds* (1847), published under the pseudonym of "Zeta." and his complete desertion of his party was declared a year later in his *Nemesis of Faith*.

On the demand of the college he resigned his fellowship at Oxford. The first two volumes of his *History of England from the Fall of Wolsey to the Defeat of the Spanish Armada* appeared in 1856, and the work was completed in 1870. Froude held that the office of the historian was simply to record human actions and that history should be written as a drama. Accordingly he gives prominence to the personal element in history. His work is often marred by prejudice and incorrect statements. The keynote of his *History* is contained in his assertion that the Reformation was "the root and source of the expansive force which has spread the Anglo-Saxon race over the globe." Hence he overpraises Henry VIII and others who foruarded the movement, and speaks too harshly of some of its opponents. A strong anticlerical prejudice is manifest in his historical work generally, and is doubtless the result of the change in his views on church matters and his abandonment of the clerical profession. Carlyle's influence on him may be traced both in his admiration for strong rulers and strong government, which led him to write as though tyranny and brutality were excusable, and in his independent treatment of character. His rehabilitation of Henry VIII was a useful corrective, but his representation of him as the minister of his people's will is founded on the false theory that the preambles of the acts of Henry's parliaments represented the opinions of the educated laymen of England. He was not a judge of evidence, and seems to have been unwilling to admit the force of any argument or the authority of any statement which militated against his case. He worked diligently at original manuscript authorities at Simancas, the record office and Hatfield house; but he used his materials carelessly, and evidently brought to his investigation of them a mind already made up as to their significance. He was constitutionally inaccurate. and seems to have been unable to represent the exact sense of a document which lay before him, or even to copy from it correctly.

Few more brilliant pieces of historical writing exist than Froude's description of the coronation procession of Anne Boleyn through the streets of London, few more full of picturesque power than that in which he relates how the spire of St. Paul's was struck by lightning; and to have once read is to remember forever the touching and stately nords in which he compares the monks of the London Charterhouse preparing for death to the Spartans at Thermopylae. Proofs of his power in the sustained narration of stirring events are abundant; his treatment of the Pilgrimage of Grace, of the sea fight at St. Helena and the repulse of the French invasion, and of the murder of David Rizzio are among the most conspicuous examples of it. Nor is he less successful when recording pathetic events, for his stories of certain martyrdoms and of the execution of Mary queen of Scots are told with exquisite feeling and in language of well-restrained emotion. And his characters are alive. We may not always agree with his portraiture, but the men and women whom he saw exist for us instinct with the life with which he endows them and animated by the motives which he attributes to them. His successes must be set against his failures. At least he wrote a great history, one which can never be disregarded by future writers on his period, be their opinions what they may, and which attracts and delights a multitude of readers and is a splendid example of literary form and grace in historical composition.

On the death of his adversary E. A. Freeman in 1892, Froude was appointed to succeed him as regius professor of modern history at Oxford. His lectures on Erasmus and other 16th-century subjects were largely attended. He died on Oct. 20, 1894. His long life had been full of literary work. For 14 years he was editor of *Fraser's Magazine.*

Froude was one of Carlyle's literary executors, and brought some sharp criticism upon himself by publishing Carlyle's *Reminiscences* and the *Memorials of Jane Welsh Carlyle,* for they exhibited the domestic life and character of his old friend in an unpleasant light. Carlyle had given the manuscripts to him, telling him that he might publish them if he thought it well to do so, and at the close of his life agreed to their publication. He also wrote *Thomas Carlyle: a History of the First Forty Years of His Life* (1882) and *Thomas Carlyle, a History of His Life in London* (1884); *Short Studies on Great Subjects* (1867–82); and a historical novel, *The Two Chiefs of Dunboy* (1889).

Froude was taice married. His first wife, a daughter of Pascoe Grenfell and a sister of Mrs. Charles Kingsley, died in 1860. His second wife, a daughter of John Warre, M.P. for Taunton, died in 1874.

See H Paul, *Life of* **J.** *A. Froude* (1905).

FROUDE, WILLIAM (1810–1879). English engineer and naval architect, who founded the modern science by which the forces on a ship are predicted from experiments with geometrically similar models, was born at Dartington, Devon, on Nov. 28, 1810. He was educated at Westminster school and Oriel college, Oxford. He worked as a railway engineer until 1846, after which he began the pioneer work on ship hydrodynamics for which he is famous. In 1868 he served on a committee appointed by the British association to study naval design. The other committee members were agreed that tests with models could not be relied upon for predicting the performance of ships, but Froude advocated a more thorough investigation of the laws governing the extrapolation from model to full scale. He was invited to explain his proposals to the admiralty, and this led, in 1870, to a grant for the construction of a ship model testing tank. This, the forerunner of the model tanks which are now to be found in all maritime countries, was built at Froude's home near Torquay. Here he found that the chief components of resistance to motion were skin friction and wave formation, and showed how the total resistance of a ship could be extrapolated from the results of model experiments.

His methods in all probability inspired pioneers in aerodynamics to adopt model testing and thus contributed to the rapid development of aircraft design. In 1870 he was elected a fellow of the Royal society, whose royal medal he received in 1876. He died on May 4, 1879, while on a visit to South Africa. His many published papers were reprinted in one volume by the Institution of Naval Architects in 1955. (S. J. P.)

FRUGONI, CARLO INNOCENZO (1692–1768), the most prolific of the Italian Arcadian poets *(see* ITALIAN LITERATURE). Born at Genoa, Nov. 21, 1692, he took monastic vows at the age of 17. In 1716 he formed an Arcadian society and was later recommended by Cardinal Cornelio Bentivoglio as poet laureate to Antonio Farnese, duke of Parma. He dedicated sonnets to the duchess of Parma, Philip V of Spain and, in 1734, a pindaric ode to the French ambassador. Having obtained remission of his monastic vows, he lived in Venice in great poverty, but after the peace of Aix-la-Chapelle was appointed poet of the court theatre in Parma. He died at Parma, Dec. 20, 1768.

Frugoni wrote over 1,000 sonnets and 250 lyrical odes besides a large number of poems in free verse. His work was admired less for its originality than for its facility and elegance. He was also known for his translations from the French and for his librettos for two operas by Tommaso Traetta, adapted from the librettos of Rameau's *Hippolyte et Aricie* and *Castor et Pollux.*

Frugoni's works were published in 10 vol. (1779) and 15 vol. (1779–80). *See* also C. Calcaterra, *Storia della poesia frugoniana* (1920); A. Equini, *C. I. Frugoni alle covti dei Farnesi e dei Borboni di Parma* (1919–20).

FRUIT, in its popular sense is any product of the soil that can be enjoyed by man or animals; in the Bible the word is often extended to include the offspring of man and of animals; *e.g.,* in such expressions as "the fruit of the womb." "fruit of thy cattle" in the Authorized Version of the Bible (Deut. xxviii, 4). More often it is employed to denote a group of edible parts of plants, as contrasted with another group termed vegetable. But the term is a loose one, including, for example, the stalks of the rhubarb.

In its strict botanical sense the fruit is developed from the ovary of the flower as a result of the fertilization of the contained ovule or ovules. In a somewhat broader sense the fruit of angiosperms consists of the mature ovary and any closely associated parts. Fertilization induces various changes: the anthers and stigma wither, the petals drop off and the sepals may be shed or undergo modifications; the ovary enlarges and the ovules develop into seeds, each containing an embryo plant. Normally no fruit is produced unless fertilization is effected; but in certain plants, mostly cultivated varieties, this is not the case (*e.g.,* the seedless orange and grapes, the banana and the cucumber).

The production of fruit without fertilization is known as parthenocarpy, and as early as 1902 attempts were made to develop such fruits artificially by treating the pistil with pollen extracts and with various chemicals. After 1934, considerable progress was made in this work, and successful results were obtained with the tomato, petunia, pepper, gladiolus, holly and salpiglossis. Among the compounds that gave promise in inducing parthenocarpy experimentally are naphthalene acetic acid, indoleacetic acid, indolebutyric acid and B-naphthoxyacetic acid.

Functions of Fruit.—The fruit protects the developing seeds and may aid in their distribution when mature. This latter function is very important, and numerous devices secure a wide and effective dispersal. These may be classified according to the agents employed as animate and inanimate. To the second group belong those methods by which the plant itself propels the seed forcibly from the fruit. Some plants employ a combination of the two. Thus in the gorse the seeds are shot out by the splitting and curling of the pod in which they are contained, and they must then be buried by ants in order to germinate. Violent dehiscence occurs in many plants (fig. 28). In the squirting cucumber the walls of the pericarp exert pressure on the pulpy contents in which the seeds are placed. In the balsam (Impatiens) also, the seeds are actively expelled. Other inanimate agents are water and wind. Fruits or seeds are sometimes sufficiently buoyant to float for a long time in water. Thus the coconut may be carried hundreds of miles in the sea; the fruits and seeds of West Indian plants are sometimes throun up by the Gulf stream on the coasts of Europe and will often germinate; in the water lily and many other aquatic plants, the seeds float for a time before sinking to the bottom. In many cases the wind plays a part in distrtbution. In the poppy and many Caryophyllaceae (figs. 6, 7) there is a capsule opening by pores borne on a long stalk which sways in the wind. thus jerking out the seeds. In the pine, sycamore (fig. 22), ash (fig. 1) and many others, there is a winglike development; in numerous Compositae the fruit is crowned by a plumose pappus (*e.g*, dandelion, thistle); in the clematis, the style becomes feathery, while the seeds of the willow and poplar bear tufts of silky hairs. The fruit of the bladder senna (Colvtea) is easily rolled by the mind, while in the rose of Jericho (*Anastatica hierochuntica*), the whole plant dries up after developing its fruits and forms a mass, easily rolled over the dry ground by the wind A notable example of dissemination of seed by the whole plant is the Russian thistle (Salsola Kali var. *tenuifolia*). Introduced into the United States in 1873 with flaxseed, it invaded a large part of the western states.

Birds and mammals are also utilized as dispersal agents by plants. The mistletoe develops a sticky layer around the seeds which stick to the bill of the bird that eats the berries; these may be wiped off on the bark of trees, thus transporting the embryo to a new host. More commonly, the fruit develops hooks which become entangled in the fur or feathers. Such are the fruits of cleavers (Galium *aparine*), *Ranunculus arvensis* (fig. 21), etc. In some cases the inner portion of the fruit, the endocarp, forms a hard covering surrounding the seed while the remainder of the pericarp is succulent and often brightly coloured. Thus the seed can pass through the alimentary tract of an animal without injury; *e.g.*, plum, cherry (fig. 5). The true fruit may be provided with stiff hairs, which cling to the beak of the bird which eats the fleshy receptacle; *e.g.*, rose (fig. 3).

Classification and Structure.— There are several systems of classifying fruits. On the basis of the texture of the pericarp, and accessory parts when present, they may be classified as dry, dry-fleshy or fleshy. In the dry types the pericarp becomes desiccated as it matures; while in the fleshy forms it becomes wholly or in part succulent. In the intermediate dry-fleshy types. part of the pericarp becomes desiccated and frequently hardened while the other portions of the ovary wall are fleshy and succulent. The dry types are called indehiscent if they do not open at maturity, and dehiscent if the pericarp opens in some manner to liberate the mature seeds. The former are usually single-seeded, the latter commonly contain two to many seeds. These types may be further subdivided on the basis of the number of carpels and accessory structures that comprise the fruit (see Table I).

The principal indehiscent dry fruits are the caryopsis or grain, the achene, the schizocarp and the nut. The caryopsis contains a single seed and develops from one or more carpels. In its development the integuments become so closely appressed to the pericarp that the two structures cannot be separated readily in the mature fruit. The fruits of cereal crops and other members of the Gramineae belong in this group. In the achene the pericarp is closely applied to the seed but can be separated from it. This type of fruit may develop from a single carpel. as in the Ranunculaceae, or from two carpels, as in the Compositae. in which the receptacle is also a part of the fruit. Achenes are borne singly in the dock; aggregated in the buttercup (fig. 21); on a fleshy receptacle, which may be convex as in the strawberry (fig. 2) or concave, as in the rose (fig. 3). Thus what is popularly called the fruit of these last three is really the enlarged receptacle with the carpels. In Clematis the style, and in many Compositae the specialized calyx remain adherent to the fruit. The limb of the floral tube is frequently plumose and is then termed the pappus. The schizocarp consists of two or more carpels, each of which forms an indehiscent achenelike fruit known as a mericarp and contains a single seed. Examples of this are found in the Geraniaceae, in which the mericarps separate from below upward (fig. 19) and in the Umbelliferae, in which the ripe mericarps are usually suspended from a unique structure called the carpophore. Rlericarps or achenes in which the pericarp is extended to form a winged appendage, as in the ash (fig. 1) and sycamore (fig 22), are called samaras or key fruits. A nut has a hardened pericarp often surrounded by bracts at its base formed from the involucre as in the acorn (fig. 27). Other examples are the hazelnut and chestnut. The term has been popularly applied to other fruits (almond, walnut); to seeds (Brazil nut); and to legumes (peanut) which do not belong to this type on the basis of structure.

The principal dehiscent dry fruits are the follicle, the legume or pod, the capsule, the silique and the silicle. In the follicle, there is a single line of dehiscence which usually occurs along a suture on the adaxial surface. The fruit is formed from a single carpel, but usually several fruits are aggregated; e g., columbine (figs. 28, 29). A legume or pod differs in dehiscing along both sutures. This is characteristic of leguminous plants. such as the pea (fig. 8). A few legumes are indehiscent as in the peanut, *Arachis*, nhere the fruit is developed underground. Hedysarum and others have a pod that separates transversely into single-seeded mericarps (fig 18); such a structure is called a lomentum and may be regarded as a specialized indehiscent legume. In Erythrina monosperma there is only one seed. In the Cruciferae (wallflower, cabbage, shepherd's-purse) the characteristic fruit is

Table I.—*Classification of* ***Fruits***

Major Types	Structure			
	One carpel	Two or more carpels	Two or more carpels plus stem axis or floral tube	Carpels plus stem axis or floral tube and accessory parts
Dry Indehiscent	Caryopsis (grain) corn, wheat, grasses Achene buttercup, anemone Legume peanut	Silique radish Samara (key-fruit) ash, elm, maple Nut acorn, hazelnut, chestnut	Achene aster, sunflower, dandelion Schizocarp carrot, fennel	
Dry Dehiscent	Follicle milkweed, columbine, marsh marigold Legume pea, bean	Capsule onion, lily, poppy Silique rock cress, cabbage Silicle shepherd's-purse, pepper-grass	Capsule iris	
Dry-Fleshy	Drupe plum, peach, almond, cherry	Drupe coconut	Pome apple, pear, quince, hawthorn Aggregate raspberry, strawberry	Multiple (pseudocarp) fig, mulberry
Fleshy	Berry May apple	Berry tomato, grape Hesperidium orange, lime	Inferior berry blueberry Pepo squash, cucumber, pumpkin, watermelon	Multiple pineapple

Dry one-seeded dock fruit. **21.** Achene of *Ranunculus* arvensis. **22.** Samara of maple. **23.** Section of wheat grain. **24.** Comfrey fruit. 25. Ovary of Foeniculum officinale. 26A and **26B.** ***Carum carvi*** fruit. **27.** Quercus ***aegilops,*** acorn. **28.** Columbine fruit. **29.** Single follicle. **30.** Section of gooseberry. **31.** Section of apple. **32.** Section*of melon. 33. Honesty, septum of fruit: **34. Silicle** of shepherd's-purse. **35.** Asclepias seed a silique which is long and narrow; if short and broad it is termed a silicle (fig. 34). In both of these types carpels dehisce by two valves from below upward, the valves separate from the placentas and leave them united by a false septum. In a few cases (radish) the fruit is indehiscent. The capsule is formed from two or more carpels and may include a portion of the axis as in Iris (fig. 12). The dehiscence of the capsule may occur by means of pores as in the poppy (fig. 7) and *Campanula,* or by means of a lid as in the pimpernel (fig. 17).

The dry-fleshy fruits include the drupe, aggregate, pome and some of the multiple forms. To this group belong many edible fruits. In the drupe, as shown by the cherry (fig. 5), plum, etc , the endocarp is usually hard and the mesocarp pulpy and succulent, though in the almond it is tough and in the coconut fibrous. In the aggregate fruit, such as the raspberry and strawberry, several small drupes or achenes develop on the receptacle which in the case of the latter is fleshy and edible. In the pome the fleshy outer portion consists of the undiverged floral parts which are more or less adnate to the carpels. Examples of this type are the apple (fig. 31), pear and quince. The multiple fruit or pseudocarp differs from the aggregate fruit in that it results from the conjoint development of several flowers while the latter is the product of several pistils of a single flower. Thus in the mulberry the fruit is formed by the coalescence of a spike of flowers. Each flower produces a fruit that is nutlike and surrounded by fleshy floral parts. In the fig (fig. 4) the whole inflorescence is within a hollow receptacle nhich may contain both staminate and carpellate flowers, each of the latter forming a true fruit. The pineapple is a fleshy type of multiple fruit in which the entire inflorescence is involved; the individual pomelike fruits are borne in the axils of more or less fleshy bracts, and the axis of the inflorescence is also somewhat fleshy.

The principal fleshy types are' the berry, hesperidium (specialized berry), and the pepo (inferior berry). The berry has a fleshy pericarp at maturity. It develops from an hypogynous flo er which often has two or more carpels as in the tomato, but it may be produced from a single carpel as in the May apple, *Podophyllum.* The hesperidium is a specialized berry in which the dorsal walls of the carpels form a thick rind and from the inner surface of which fleshy succulent hairs arise and more or less fill the carpellary cavities. The citrus fruits, orange, lemon, lime, etc., belong in this group. The pepo develops from an epigynous flower and is similar in structure to the pome except that the outer portions frequently become very hard as in some squashes and pumpkins. The edible part consists of the carpels and a portion of the enveloping receptacle. See ANGIOSPERMS; FLOWER; SEED. (H. E. HD)

Dwarf Fruit Trees. — In horticultural practice the dwarf fruit tree is produced by grafting a variety of apple, peach, pear or plum to a closely related and compatible plant, called the rootstock, which inherently makes small growth and in a corresponding manner restricts the growth of the variety grafted on it. A fruit tree can also be dwarfed by restricting root development; *e.g.,* by growing the tree in a pot.

Rootstocks used to dwarf fruit trees originate from individual seedlings having dwarfing tendencies and are propagated by vegetative means, as by layering or by taking cuttings and rooting them. Each plant propagated from the original is identical with it. In the production of dwarf apple trees two rootstocks are used, Malling No. IX and Malling No. VII. The former has the greater dwarfing ability and induces the tree to bear fruit at the earliest age. Pear trees are dwarfed by grafting the variety to a quince rootstock. *Prunus* besseyi and a selected plum stock known as St. Julien Malling Selection A serve as dwarfing stocks for peach and plum varieties.

Dwarf trees are grown as various forms. The bush tree, having a go-in.-long trunk nith several lateral branches arising from it, is the most popular and easiest to grow. The pyramid type, with a central stem 8 ft. long from which branches arise in successive tiers 20 in. apart, is more difficult to train. The cordon, consisting of a single stem 10 ft. in length on which the fruit spurs are arranged, is grown in a vertical position or can be trained to grow at an angle. The espalier trained on trellises or walls has a central stem from which arise horizontal tiers of branches that carry the fruit spurs. The fan-trained tree has a permanent framework of branches arranged in the shape of a fan when training is completed. The bush tree is adapted to all the different tree fruits, whereas pyramids. cordons and espaliers are best suited for apples and pears. The fan-trained tree is preferred for growing peaches and plums against walls or trellises. (K. D. B.)

FRUIT BAT: see BAT; FLYING-FOX.

FRUIT COOKERY. Though certain fruits. *e.g.,* breadfruit, dates, figs, form the staple food of various tropical peoples, fruits are used by nations in the temperate zones mainly as an agreeable means of introducing liquid into the system; for their mixture of salts and vegetable acids; *e.g.,* tartaric, malic, citric; for their slight laxative properties; as an antiscorbutic; and as a valuable medium for supplying the body with vitamins. Fruits can be classified as small fruits, including currants, raspberries, blackberries, strawberries, etc.; apricots, plums, cherries, etc.; citrus fruits; *i.e.,* oranges, tangerines, lemons, grapefruit, etc.; orchard fruits, apples, pears, etc.; vine (grapes) ; and a few fruits which do not come into any of these categories, as for instance, pineapple, avocado, olive. etc. Fresh fruit is used as a first course and as dessert and for fruitades.

Methods of Cooking. — There are innumerable ways of serving fruit. and because of the great variety of fruits at the disposal of mankind it is possible to employ every known method of cookery in preparing fruit dishes (see PRESERVING AND BOTTLING).

Stewed Fruit. — A great number of fruits can be cooked by stewing either by a waterless method or with the addition of a little water and sugar. By the waterless method the fruit is placed in a stone jar (with or without sugar according to taste) in a pan of boiling water. In this way, all the juices of the fruit are conserved without loss of flavour. Where water is added this should be as little as possible with due consideration for the amount of water (generally about 80%) already contained in the fruit. If desired to keep the fruit whole it is wiser to boil the sugar and water before adding the fruit. All fruit should be stewed slowly. Overheating causes the pectin in fruit to jelly. Dried fruits should be soaked before stewing in order to restore the water.

Baked Fruits. — Apples may be cored, filled with sugar and cooked in a baking dish. A compote of fruit is baked fruit to which is added a sugar syrup.

Fried Fruit. — A number of fruits may be dipped in batter and fried in deep fat and served as fritters. In this case, the fruit, if large, is cut into suitable portions, or if small. is left whole in a sugar syrup for a short time before frying. Certain fruits may be sliced and pan fried as a vegetable.

Fruit Salads. — These may be sweet or savoury and are made by mixing different fruits together with certain flavourings, *e.g.,* liqueurs, essences, oil, vinegar, etc., to form a salad. When raw fruits are used they are usually soaked in a marinade of their own juices and the flavourings for some time before dishing.

Fruit Molds. — When hot stewed fruit is thickened with a liaison of corn flour, tapioca, sago, etc., or when mixed with jelly powders, gelatin, agar agar, etc., it can be turned out into a wet mold and allowed to cool and served as a blancmange. Dried fruits may be thickened with starch liaisons but it is best to use gelatin or jelly for setting soft small fruits, as this does not spoil the colour of the fruit.

Fruit Ices. — These differ from ice creams in that they possess no cream or custard foundation and are made with a fruit syrup which may, in some cases, be thickened with gelatin to give a smooth appearance. (J. A. SI.)

FRUIT FARMING. The subject of fruit farming deals with the intensive culture of perennial plants whose fruits have economic significance. It is a part of the subject of horticulture (*q.v.*), which also encompasses vegetable growing and the production of ornamentals and flowers. This article places further arbitrary limitations — it takes in neither perennial nut crops, nor a number of very important perennial fruit crops including the coconut and oil palms, vanilla, coffee, cacao and the tung tree (whose problems were once considered beyond the pale of horticulture) which are dealt with in separate articles, as NUT; OIL PALM: etc., and in the articles on OIL PLANTS and TROPICAL AGRICULTURE. See also separate articles on the various fruits discussed in this article. as BANANA; PINEAPPLE. etc.

The first section of this article deals nith fruit farming from the standpoint of economics and geography, and the second section with basic problems and practices of fruit farming.

ECONOMICS AND GEOGRAPHY

Table I gives information on the world production of some of the most important fruit crops. The data are very incomplete because they can only be concerned with commercial movement. Many fruits are used locally in large quantity without going beyond the village markets; mango and banana are examples of such fruits and both are of crucial importance in the diets of very large populations in the regions of production. It seems reasonably certain, however, that the five most important fruits are grape, orange, banana, apple and mango. In second rank of importance are olive, pear, peach and plum; and these are followed by date. fig. pineapple, apricot, avocado, strawberry. the brambles and bush fruits and many others of lesser significance.

TABLE I.—*World Commercial Production of 15 Major Fruits*

Climatic zones of production and fruits grown	Average annual production (000 tons)		Ratio × 100 1955/previous

Table I illustrates the general increase in world fruit production that has taken place in the middle of the 20th century and shows the dramatic rise in importance of commercial fruit growing in the tropics and subtropics, due largely to increases in output of bananas and citrus fruits. Improvements in technology and consolidation of the industries in the most favoured climates have been responsible for a steady increase in yield per unit of land during this period, so that the total acreage devoted to fruit crops has not risen in proportion to the rise in production.

The geography and main products of the more important of these varied enterprises are briefly discussed below.

FRUITGROWING ENTERPRISES OF THE TROPICS

Although the principal perennial fruit plants of these warm regions differ in many ways. most of them are evergreen and are seriously injured or killed by temperatures below freezing.

Banana.—The banana. which originated in southeastern Asia, is now cultivated throughout the torrid tropics (see Table II for principal regions of production). The ease with which this giant herb may be propagated from pieces of rhizome (rootstock) has made it possible for vast acreages of a few seedless varieties to be planted in widely separate regions. Important among these varieties are Gros Michel. Cavendish and Mysore. Although the fruit is very perishable, its ability to develop good eating quality after having been harvested green has permitted the growth of intricately co-ordinated plantation, shipping and marketing agencies that bring bananas to the temperate zone cities of the western world throughout the year. Perhaps three-quarters of the bananas for these distant markets originate in Central America, northern South America and the islands of the Caribbean. Dried banana "figs" and other palatable products are made, but most of the fruit is sold for consumption unprocessed.

Pineapple. — The pineapple is indigenous to the warm regions of northern South America and has been distributed around the norld in the humid tropics during relatively recent times (Table II). A small semiherbaceous perennial with the drought-resistant leaves of an epiphyte, or air plant, it can be cultivated successfully in somewhat drier and cooler tropical areas than the banana. Easy vegetative propagation from slips or suckers has permitted heavy concentration on a few seedless varieties, the most important of which are Smooth Cayenne. Red Spanish and Queen. At present about half the norld's commercial production originates in the Hawaiian Islands and a third in the Caribbean islands, Central America and northern South America. Although shipments of the fresh fruits, harvested a little green, are considerable the canned fruit is the most important commercial product for distant markets, accounting for practically all of the Hawaiian output.

Mango. — The mango tree probably originated in southern India and has been under cultivation in the tropical areas there, in Malaya and in Africa for many centuries. In India alone. there were about 2,200,000 ac. occupied by mango trees in the second half of the 20th century. During the past two centuries the mango has been introduced to the Philippines and to the American and Australian tropics; in the 20th century a small industry was begun in the United States in southern Florida. This large evergreen tree is most apt to be productive in tropical regions with a considerable dry season which coincides with the annual period of bloom. Many varieties have been selected and propagated by graftage: among the most important of which are Mulgoba, Saigon, Carabao: Haden and Julie. In spite of its great importance as a food and dessert in the regions where it is grown there are no reliable statistics on world production. The extreme perishability of the fresh fruit, and special problems with harvesting and storage curtailed its exploitation as a crop for shipment to distant markets. In the second half of the 20th century no appreciable volume of the fruit was processed commercially as a canned or frozen product. although considerable quantities were used for preserves and chutney.

Avocado. — The avocado tree is native to the cool tropical regions of Central America. and was under primitive culture at the time of the Spanish conquests, hoth on the isthmus and on some of the Caribbean islands. During the 20th century intensive selection of superior varieties formed the basis for small commercial industries producing 40,000 to 50,000 tons annually in the United States. in southern California and Florida. These selections are now distributed widely throughout the tropics and may result in further exploitation oi this nutritious salad fruit. Narrow limitations in climatic adaptability and inherent problems of harvesting and postharvest care may continue to limit the avocado's commercial outlets to the luxury bracket, insofar as distant markets are concerned. Among the most important varieties in the second half of the 20th century were Fuerte, Zutano, Lula and Booth 8.

FRUITGROWING ENTERPRISES OF THE SUBTROPICS

Perennial fruit species successful in subtropical regions are able to develop some resistance to injury from freezing temperatures during the winter months, and are benefited in one way or another by the slight seasonal periodicity of the climate. Like species of the tropics they are usually evergreen.

Date. — The majestic date palm is native to the oases in the desert region of the Persian gulf and for thousands of years the fruit has been an essential part of the diet of indigenous populations living in suitable climates of the eastern Mediterranean basin and North Africa. Although the palm has been distributed widely in modern times, nine-tenths of the commercial production emanates from the areas of ancient culture (see Table III). This may result largely from three circumstances: (1) a desert climate with no rainfall during most of the period of fruit development is essential for a marketable product, yet there must be ample soil moisture during this same period; (2) the product is stable and there is a sufficient output in the indigenous region to satisfy most of the world demand at moderate prices; (3) propagation of the superior varieties must be by offshoots from relatively young palms, and the supply is so limited as to make establishment of new date gardens in distant countries very slow and expensive. In spite of these facts a small industry based on old-world varieties, of which Deglet Noor is the most commonly planted, was established in the Coachella valley desert region of California during the 20th century.

Date varieties selected over the past centuries may be divided into three classes according to their physical properties and their sugar content. Dry dates. sometimes called "bread" dates. which are firm and relatively low in sugars are important locally in the old-world desert regions for daily nourishment; the variety Thoory is an example. Semidry varieties soften at maturity, but being firm enough to pack and ship well. are the most important commercially; Deglet Noor, Dayri and Zahidi are examples of this type. Soft dates, used mainly as confection, are most difficult to handle; examples of this kind are Barhee, Khadrawy and Hayany.

Citrus. — Introduced to the western world by traders from southeastern Asia over the period from the 1 nth to the 18th century A.D., the most important citrus fruits are now produced in large quantity in the subtropics and tropics throughout the world. Orange, mandarin (tangerine) and grapefruit trees are most productive and develop the best quality in regions where there is some seasonal periodicity of climate. Since they are able to withstand exposure to a few degrees below 32° F. in midwinter, they may be intensively cultivated in regions n-here occasional light frosts occur as well as in the milder subtropirs. Table III summarizes the statistics on production, showing the great importance of the orange industry on all the continents. Grapefruit, on the other hand, is mainly significant in the United States and the Caribbean region, close to the point of its probable hybrid origin in Jamaica. The lemon and lime are less able to nithstand freezing temperatures than the orange; as a result they are planted in more protected parts of the subtropics, and a larger proportion of lemons and limes are found in the tropics than of oranges.

In the United States, commercial citrus growing is confined largely to central Florida, southern and central California, southern Texas and Arizona. In Florida, which produces 60% of the nation's oranges, the four principal varieties are Parson Brown, Hamlin, Pineapple and Valencia; the first two are sent to the early fresh-fruit market whereas perhaps half of the Pineapple and Valencia crops are sold for fresh fruit and the rest are processed for frozen concentrate. California is responsible for most of the rest of the orange crop, with the two varieties, Washington Navel and Valencia accounting for practically all the acreage. Most of these oranges are sold as fresh fruit. Grapefruit production comes from four states: Florida. Texas, California and Arizona. The main varieties are Marsh Seedless, Foster. Ruby and Duncan. About half the crop is marketed fresh and the rest is either processed for canned sections or for juice. Practically all the mandarins are produced in Florida and are of one variety, the Dancy tangerine. The small lime industry of the United States is located in southern Florida, and has depended in recent years on two relatively large-fruited varieties, Tahiti and Barss; the "Key" lime. grown extensively on the Florida Keys has gradually disappeared as a dominant factor. Lemons are produced almost exclusively in the more protected citrus areas of southern California. The main varieties are Lisbon, Eureka and Villafranca. Most of the fruit is sold fresh but an increasing proportion of it has been processed for frozen concentrate or canned juice.

FRUITGROWING ENTERPRISES OF THE WARM TEMPERATE ZONE

Most of the perennial fruit species adapted to the warm temperate zone are deciduous, passing the winter leafless, although a few, of nhich the olive is one, are evergreen. Practically all of these species are capable of developing resistance to temperatures below 20° F. during winter dormancy. Most of them cannot be grown commercially in the subtropics or tropics because exposure to a considerable period of chilling temperatures below 45° F. is required for normal growth and flowering. On the other hand, this chilling requirement is relatively short, winter hardiness is not great and a long, warm growing season may be necessary for satisfactory productivity and fruit quality; hence, they are not well adapted to the cooler temperature regions.

Grape. — The old-world grapevine (*Vitis* vinifera) is by far the most important perennial fruit plant. It has been cultivated for thousands of years in the Mediterranean basin and southwestern Europe. Although, as Table IV shows, more than two-thirds of the world's grapes still come from those areas, there is now important production on all continents in the milder parts of their temperate zones, whether north or south latitude (see Table IV). In the United States practically all the vinifera grapes are produced in the great central valley of California, with small acreages in the southern part of the state and in Arizona.

The fruit from this species may be consumed fresh, dried for raisins or used for wines and alcoholic distillates. By far the largest part of the European and Mediterranean production goes to the mine press and only a small proportion is eaten fresh or as raisins. The California vinifera industry, on the other hand. dries more than half its production, ships 10% to 15% as table and canning stock and uses the remaining third for fermented products. The important varieties differ in their versatility for these uses. Sultanina (Thompson Seedless) and Muscat of Alexandria are grown in quantity for all three purposes; the Flame Tokay and several others are used both for fresh fruit and for specialty wines.

On the other hand. Zante currant is grown only for its raisins. and a number of varieties including Zinfandel. Carignane and Alicante Bouche are produced exclusively for fermentation.

Several species native to North America contribute to two other grape growing enterprises of the United States. The larger of these accounts for about 10% of the total U.S. production and is based on hybrids between V. vinifera and native species. Most important varieties of this labruscana group are Concord, Delaware and Catawba. They are hardier than vinifera varieties and less subject to humid climate diseases; hence the industry is centred in New York and Michigan. The principal product is unfermented Concord grape juice, with some outlet for wines. In addition, in the Gulf states the native species V. *rotundifolia* is the basis for minor production of grapes, mainly for muscadine wine. See also WINE.

Olive.—The olive tree was under cultivation in the warm temperature parts of the eastern Mediterranean basin 3,000 years ago and its spread into North Africa and southern Europe was undoubtedly completed during the Arab invasions if not before. Introductions to the new world were made by Spanish colonists and have resulted in small industries in South America and California, but as Table IV shows the world's supply of this important fruit and its oil depends almost entirely on the countries bordering the Mediterranean. Although evergreen and able to grow normally under subtropical conditions, the tree does not flower unless exposed to temperatures below 45° F. for a considerable period of time. The unusual tolerance to freezing winter temperature, hot summer weather and rather severe moisture deficiency have caused it to be planted in many situations not suitable for other fruit crops. The principal outlets for the fruit are as olive oil (*q.v.*), pickled in brine or canned ripe. Most of the European production is used for olive oil, although in Spain, particularly, there is substantial production of pickled olives. Because of high labour costs, olive oil is mostly considered a by-product market of the small United States industry and the major concentration is on production for ripe canned or for pickled olives. Examples of important olive varieties are: Manzanillo, Barouni and Mission. Only varieties high in oil are useful for extraction, and the others are processed as fruit.

Fig.—Like the olive and grape, the fig tree was under cultivation in the warm temperate climate of the Mediterranean basin long before the time of Christ. Some of the varieties of that region have probably been carried down to modern times by vegetative propagation for over a thousand years. Table IV shows that practically all of the commercial production still comes from the area of ancient culture with the United States contributing about 7% of the total and small additional production from Australia. Italy, Spain, Turkey, Greece and Algeria are the leading producing countries.

The tree is able to withstand cold temperature to 15° F. but has a relatively short chilling requirement; in fact some varieties grow and fruit satisfactorily in the tropics. Where the crop is sun-dried after harvest and because the maturing fruit is subject to infection from fungus and bacterial diseases, the most favourable climate is semiarid with available irrigation water and no rain during the period of fruit maturation and drying. Some varieties are grown under humid conditions, however, for local sale or to be used in canning. Thus, in the United States the main production area is the irrigated central valley of California nith rainfall ranging from 10 in. to 20 in. annually, and a long hot growing season. The most important varieties of that region are Calimyrna (Lob Injir), Adriatic, Mission and Kadota (Dottato). The first two of these varieties constitute three-quarters of the production and practically all are dried. Mission may be dried or marketed fresh and Kadota is canned in light sirup. In the Gulf states—Louisiana. for instance—the varieties Brunswick and Celeste are dominant. In that humid climate most of the limited production is marketed fresh and a small proportion is canned.

Apricot, Peach, Plum and Prune.—These three kinds of fruit grow on small deciduous trees of the genus *Prunus* whose climatic requirements are satisfied in the warm temperate zone and whose culture extends to the milder parts of the cool temperate zone. All of them are cultivated widely in the climatic regions of the world to which they are adapted, as Table V shows.

The apricot is somewhat more restricted climatically than the other two partly because it has a shorter chilling requirement and therefore blooms earlier, and partly because its great susceptibility to a fungus disease (brown rot) makes culture difficult in regions where rainfall is high during the growing season. In the United States and Canada most of the apricots are found in semiarid districts of the coastal and interior valleys from California to British Columbia. Local climatic conditions determine whether the main outlets are for fresh fruit, drying or canning; these outlets. in turn may determine the varieties and cultural practices. Thus in limited areas of California where an early harvest season gives the industry opportunity to exploit a premium market for fresh fruit, the main variety has been Royal (similar to Blenheim). In the semiarid hot California regions that have midseason harvest the drying outlet predominates and the Tilton variety has been most important. In the cooler, more northern sections where canning and late market are the dominant outlets, Moorpark, and Large Early Montgamet are important.

Although peach varieties adapted to climates ranging from the subtropics to the milder parts of the cool temperate zone are available, the most important peach regions of the world have long hot growing seasons and mild winters lasting at least three months during which freezing temperatures occur frequently. In the United States these conditions occur in the semiarid central valley of California and along the coastal plain and the lower piedmont region of the east, from northern Georgia to Maryland; California, Georgia and South Carolina produce more than half the nation's

peaches. As with apricots there are three outlets for this fruit and varieties differ in accordance with them. Clingstone varieties of which Phillips. Paloro and Halford are examples, are used exclusively for the large canning industry of California. Although drying is also a by-product or distress outlet for other varieties in California, Muir and Lovell are especially desirable because of their relatively high dry matter content. The fresh-fruit market is served by a long list of delicious freestone varieties including Elberta, Halehaven and Golden Jubilee.

The world's plum and prune industries are based mainly on two species of different origin and adaptation. The Japanese plum, *Prunus salicina,* is a small, vegetative tree with approximately the same climatic requirements as the apricot. It is most successful in semiarid irrigated warm-temperate climates. Because the fruit is very high in moisture and soft, it is not useful for canning. Difficulties of handling and storage limit the opportunities for large-scale exploitation in fresh fruit markets. The principal European species, *Prunus domestica* is responsible for most of the commercial plum and prune production of the world. The climatic adaptability of the tree straddles the warm and cool temperate zones, and it is tolerant both to semiarid and humid climates. The most important varieties produce fruit that may be harvested in a firm condition and that has storage and shelf life of a month or more. Some varieties are very high in total solids and may be dried for prunes.

In the United States practically all the Japanese plums are grown in the irrigated valleys of California. Examples of important varieties are Beauty, Santa Rosa and Duarte. European plums are an important crop in Oregon, Idaho and Washington, as well as California. California produces all of the dried prunes of the United States; the variety French Prune accounts for most of them. Italian Prune is the main plum variety in the northwestern states for use in canning and fresh-fruit markets. Other varieties including President and California Blue are also shipped for fresh fruit.

In the south of England, several varieties of the Green Gage group are prized for their dessert qualities and such varieties as Czar, Giant Prune and Victoria are used for culinary and dessert purposes.

Fruitgrowing Enterprises of the Cool Temperate Zone

The perennial fruit species best adapted to this zone are deciduous and have relatively long chilling requirements, are able to withstand subzero (F.) temperatures when dormant and can produce fruit of satisfactory quality in a growing season of six months or less.

Apple.——As Table VI indicates, the apple tree is grown commercially in cool temperate climates throughout the world. Over the centuries of culture thousands of varieties have been named and the selections that are now cultivated in different countries represent the tastes of their citizens and conform to the climatic and commercial requirements of each area. In the United States, about one-quarter of the total production originates in the irrigated semiarid valleys of Washington. There the varieties Red Delicious and Winesap are most important. Tno eastern regions are responsible for another quarter of the crop. They are: (1) the slopes of the Shenandoah-Cumberland valleys from Virginia to Maryland mhere Stayman Winesap and Red Delicious dominate; and (2) the New York and New England areas where McIntosh and Rhode Island Greening are most important. Perhaps one-quarter of the United States production is canned or frozen and the rest moves in fresh-fruit markets.

In the United Kingdom most of the apples are grown in the south of England; in Kent, Sussex and Essex, the varieties Cox's Orange, Allington Pippin and Bramley Seedling are very important. Most of these apples go to the fresh-fruit market for dessert or culinary uses. In addition there is a thriving cider apple industry which uses large quantities of varieties suitable for production of a sparkling fermented cider.

Pear. — The European pear tree, *Pyrus communis* is most successful in the milder apple regions and in regions climatically adapted to prune culture. It is extremely susceptible to bacterial fire blight and this limits opportunity for culture of the best varieties in humid climates mhere the causal organism is established—as, for instance, in eastern Sorth America. Table VI shows that there is significant commercial production on all the continents, with Europe and North America most important. More than 90% of the pears grown in the United States are found in the irrigated region5 of California, Oregon and Washington and one-half the total are produced in California. Bartlett (Williams Bon Chrétien) is the dominant variety with significant production of Beurre Bosc and Buerre d'Anjou. Because the Japanese sand pear, P. *serotina,* has marked resistance to fire blight, it has been hybridized with the European pear and several varieties, among them Kieffer, have been found to have increased resistance and to be acceptable for processing in these humid regions. About one-half the Bartlett crop of California is canned commercially, the rest and other varieties are sent to fresh-fruit markets.

In the United Kingdom pears are grown in the same areas in the south of England as apples and plums. The varieties Conference, Williams Bon Chrétien and Comice are important. On the continent, there is large production of a number of varieties of local origin for fresh-fruit consumption. A special group of varieties contributes the fruit for a fermented cider called perry.

Cherry. — The sweet and sour cherry also are found in the milder apple regions throughout the world (*see* Table VI). Because sweet cherry fruits are subject to cracking damage if exposed to rain at the end of the maturation period, orchards of that species are more limited to semiarid climates than are sour cherry orchards. In the United States sweet cherry production is about 45% that of sour cherry. Some 85% of the sweet cherries are grown under irrigation in California, Washington, Oregon and Idaho, whereas more than 90% of the sour cherry production originates in New York, Michigan and Wisconsin. The principal sweet cherry varieties are Bing, Lambert, Windsor and Napoleon (Royal Ann); all but the last, which is used mostly for canning and artificial maraschino cherries, are sold chiefly in the fresh-fruit markets. Montmorency is the basis of the sour cherry industry; frozen and hot-pack preservation for pie stock stabilizes the greatest part of this crop for year-round marketing.

Cherry culture in England is concentrated mostly in Kent where the summer rainfall atmospheric conditions are reasonably favourable; there are venerable sweet cherry orchards whose trees date back more than 100 years in that locality. Practically all of the fruit is consumed fresh. 'The most important varieties include Early Rivers, Napoleon and Noir de Guben.

Strawberry. — The cultivated strawberry, probably the most cosmopolitan of all perennial fruit plants, is cultivated from the cool tropics to the arctic zone. Its great climatic range results partly from the fact that it is evergreen but at the same time so small that it can be protected from the coldest winter temperatures, and partly from the fact that different varieties exhibit special adaptabilities to the various environmental conditions in this broad area. No summary of the production over the world is available.

Table VII groups the main producing areas by harvest seasons. While it is impossible to assert that one climate or another is the best for strawberries the fact that annual yields of more than ten tons per acre are obtained from plantings of the variety Lassen in the Watsonville area of California suggests that this may be the ideal climate for the species. On the other hand, as the table shows, strawberry growing is a sound commercial business in the cooler parts of the United States and in the United Kingdom. It is also a good business on the continent as far north as Denmark, Sweden and Norway. In the United States there are two principal outlets: as fresh fruit and for frozen pack. The perishability of the fresh fruit and the excellence of the frozen pack caused the latter to increase in importance greatly as this industry perfected its procedures. In addition appreciable quantities of strawberries are preserved as jams and some are canned. The following varieties are very important: winter and early spring, Missionary and Klonmore; mid-spring, Blakemore and Temple and (from California) Lassen and Shasta; late spring, Catskill and Sparkle. In the United Kingdom, Royal Sovereign and Climax are examples of important varieties.

Raspberry and Blackberry.—Raspberries and blackberries (*see* Table VII) are produced by a number of deciduous species of the genus *Rubus* called biennial because the canes fruit in their second growing season, and then die. These canes may require support by trellis or stake or they may be erect. The different species vary in climatic requirements but the most important belong in temperate regions that do not have either extremely hot summers or extremely cold winters. For this reason they do very well in the south of England and on the western slope of the coast range in Oregon and Washington in the United States and in British Columbia. Some species are also cultivated in Europe as far north as Denmark, Sweden and in other similar climates. Red raspberry varieties of importance in the United Kingdom are Lloyd George and Norfolk Giant. In the United States, Cuthbert, Washington and Newburgh are excellent varieties. The black and purple raspberry are less common, and their culture is mostly confined to eastern United States. All these fruits are marketed fresh locally and are processed frozen or in preserves. Several trailing and semitrailing blackberry species are important in Europe and hybrids among them or with raspberry have contributed large fruited, juicy berries very satisfactory in preserves and canned. Among the most exploited of these are the Himalaya berry, the Oregon Evergreen blackberry, Boysenberry and Youngberry.

Currant and Gooseberry.—Currants and gooseberries are hardy deciduous bushes well adapted for fruitgrowing in the cool temperate zone. Their culture is particularly important in Great Britain, as Table VII indicates, but there are small industries in most countries with suitable climates. These fruits are used primarily in preserves, but gooseberry also is an important culinary fruit in Britain and on the continent, and black currant juice has special dietary uses. Among the important varieties are: red currant, Wilder, Red Lake; black currant, Mendip Gross, Seabrook's Black, Baldwin; gooseberry, Poorman, Careless. Lancashire Lad.

Blueberry.—Several species of blueberry indigenous to North America are harvested in the wild and a rapidly expanding intensive industry developed during the 20th century, based on varieties of a hybrid of the two hardiest of them, *Vaccinium corymbosum* and *V. pennsylvanicum* (*see* Table VII). Although these bushes have rather special soil requirements productive plantings have been established in New Jersey, North Carolina, Michigan and western Washington. Examples of important varieties are Concord, Jersey, Stanley and Dixi.

Cranberry.—The cranberry is the smallest intensively cultivated perennial fruit plant, and one species, *Vaccinium macrocarpon,* is the basis of a unique fruitgrowing enterprise of North America. Culture is confined to drained bogs whose substratum is acid in reaction; the most productive of these bogs may be flooded at will in order to give control over temperature and certain pests. Commercial acreages are found in Massachusetts, New Jersey, Wisconsin apd western Washington (*see* Table VII). Among the important varieties are Early Black and Howes.

BASIC PROBLEMS AND PRACTICES OF FRUIT FARMING

Although fruitgrowing enterprises cover great ranges of climates and plant materials their technologies are bound together by problems and practices that have much in common. The most significant of these are discussed below.

THE VARIETY, ITS PROPAGATION AND IMPROVEMENT

The first step in establishing a fruitgrowing industry is the selection of individual plants having high productivity and with fruit of superior acceptability in the market place. Such an individual is a horticultural variety. If it is multiplied vegetatively from rooted cuttings, from root pieces that throw shoots or by graftage, the entire group of resulting plants is a single clone, each plant identical with the others. All perennial fruit crops considered in this article are clonally propagated; *i.e.,* their varieties are multiplied vegetatively by one means or another.

Many important varieties of fruit plants were selected generations ago, and some are hundreds of years old. The Sultanina (Thompson Seedless) grape, the Lob Injir (Calimyrna) fig and the Gros Michel banana are examples of fruit varieties of obscure origin, planted by the millions since selection, with each subsequent specimen actually a vegetative continuation of the selected individual growing on an independent root system. But regardless of the age of a fruitgrowing industry or the perfection of some of the selected varieties continuing search for new varieties is essential because there is always room for improvement in climatic adaptability, in insect and disease resistances and in the solution of special horticultural or marketing problems.

Not only is varietal selection and improvement a continuing need. but so also is the maintenance of existing varieties. Although vegetative mutation of a variety is exceptional, the opportunities for accidental multiplication of degenerate mutants increase in proportion to the number of specimens of the variety. As a result, care is taken to propagate a clone only from superior individuals and in the case of citrus where mutation is unusually common, further precautions are necessary. There are, of course, occasional mutations that improve a variety and these may be selected and propagated.

The most effective technique of vegetative propagation varies with the kind of fruit plant. Date, banana and pineapple are multiplied by use of offshoots or suckers. Grape. fig, olive, currant and blueberry are usually propagated from cuttings. Strawberry and black raspberry reproduce vegetatively by special organs—the former are stolons, the latter tip layers. Many kinds of fruit tree must be grafted or budded on specially grown rootstocks because the species to be multiplied self-root with difficulty; apple, pear, peach, mango and citrus are examples of this group. *See* also ARBORICULTURE; PLANT PROPAGATION.

With most fruit species a period of one to two years intervenes between the time that a cutting is rooted and the plant is ready for setting in the field, or between graftage or budding and field planting. During this interval the plants are held in a nursery where they can be given intensive culture in rows. Strawberry, raspberrry, pineapple and banana planting materials do not require the intervention of a period in the nursery before field planting, however.

The grower's problem in choosing varieties of the fruits he intends to produce has two aspects: (1) to recognize the relative adaptabilities of available varieties to the climatic and soil conditions of his farm; and (2) to select from those best adapted to his conditions a group that satisfy both his management needs and the market demands. For instance, an apple producer in northeastern United States may depend on four varieties: Milton, McIntosh Red, Red Delicious and Rome Beauty. The main harvest seasons for these succeed each other at about two-week intervals, and this helps him to extend the period of harvest. The first two cross-pollinate satisfactorily, and so do the last two. The first of these varieties is usually marketed without storage, and the cold-storage seasons of the others are of increasing length; this helps him to exterid the marketing period.

The Site

The site of a fruitgrowing enterprise is as significant in determining its success as the varieties grown on it. In fact, variety and site together set the ceiling of productivity and profit that may be attained under the best management. In most developed fruit regions microclimatic and soil conditions, that is, climatic conditions as influenced by slight differences in soil, soil covering and elevation. and soil conditions are the two components of a site that determine its desirability for a fruitgrowing enterprise. Sometimes, particularly with very perishable fruits, transportation problems must also be considered.

Local conditions of a site exposing it to unusual frost hazard are as detrimental to citrus in Florida as they are to peach trees in New Zealand and apple trees in the south of England. In regions and sites where temperatures during the season of concern may drop no more than 4° or 5° F. below freezing, artificial frost protection is sometimes used (see FROST).

For highest productivity most fruit trees need to be able to root extensively to a depth of four feet or more. Heavy subsoil or other conditions causing imperfect internal drainage may result in shallow, weak root systems that are unable to exploit the soil efficiently for water and nutrients. In semiarid and arid regions it is not uncommon for accumulation of saline salts in a subsurface layer to limit rooting of fruit trees as well as to cause leaf scorching and abnormal defoliation symptoms. Tiling and surface ditching help to decrease the accumulation of water in poorly drained subsoils, and are beneficial in dealing with wet spots in otherwise satisfactory sites. Special control of irrigation procedures and periodic leaching may alleviate the worst salt effects in saline soils. Choice of tolerant species, varieties and rootstocks may make exploitation of imperfectly drained or mildly saline sites economic, but it is rare that the performance of the plants is up to that on sites free from these inherent difficulties.

Once a site is selected it is prepared by clearing and cultivation of the surface and installation of such permanent drainage, irrigation and road systems, as may be required. In rolling or sloping terrain where contour planting is needed to control erosion and conserve moisture, the locations of the plant or row positions are determined by the contour intervals established. In old lands, where there are residual nematode or other pest populations that make fumigation desirable, this must also be done before the new plants are set. In very infertile sites or where the physical condition of the surface soil is poor, it is sometimes useful to apply fertilizer and lime and to grow a succession of leguminous cover crops for a year or more before planting.

Planting and Spacing Systems

Growth, flowering habits and light requirements on the one hand, and management problems on the other, determine the most satisfactory planting plan for a fruitgrowing enterprise.

Such crops as strawberry and pineapple having compact plants close to the ground are usually managed in beds containing several rows or in less formal matted rows. In an acre of strawberries, 200,000 or more plants may occupy the matted rows. A pineapple plantation with two-row beds, having plants a foot apart in rows two feet apart contains 15,000 to 18.000 plants per acre. Intense competition within such dense populations for light, water and nutrients causes the production of the individual plant and the size of the average fruit to be less than they would be if more space were provided; but the total yield per unit of land is usually greater than it would be with lower plant numbers. There may also be indirect benefits from these high populations; for instance, the problem of hand weeding or hoeing may be substantially decreased by the shading effects of the fruit plants.

The spacing of grapevines along a trellis row, and of trees in an orchard involves the same group of problems. Maximum vineyard production frequently results with vine distances of 8 to 9 ft. (600 per acre). Peach trees set 20 ft. apart (100 per acre) and apple trees 40 ft. apart (27 per acre) are apt to attain maximum acre yields at full maturity.

With those species and varieties that require cross-pollination by the agency of insects, the planting plan must take their special pollination needs into account. This is a problem with apple, pear, plum and sweet cherry orchards. At least two varieties that cross-pollinate successfully must be planted in association with each other.

Training and Pruning

Pruning, the removal of parts of a plant in order to influence growth and fruitfulness of the rest, is an essential fruitgrowing practice. In the first few years after fruit trees or vines are planted, primary attention is given to form, because that may influence the strength and longevity of the mature plant as well as the efficiency of other practices; this kind of pruning is called training. Subsequently, as the plant approaches maximum fruitfulness and fills its alloted space. maintenance pruning for various purposes becomes increasingly important.

The grape responds favourably to heavy pruning by one of two groups of training systems: those that involve cutting the growth of the previous season (canes) to short spurs and those that permit the canes to remain relatively long. Whether a spur system or a long cane system is to be followed depends on the flowering habit of the particular variety (see GRAPE). Relatively small trees that respond favourably to severe annual pruning, such as the peach, apricot and Kadota fig are usually trained to systems creating an open-centred tree with a scaffold of four or five main branches that originate on a short trunk constituting the head of the tree. These main branches are in turn branched a number of times so that they permit fruiting. Annual renewal pruning can be reasonably efficient under these circumstances. Larger trees which do not respond favourably to heavy annual pruning may often be best trained to systems which encourage the original main leader branch to grow erect to a height of eight to ten feet, with four or five main branches at intervals on its sides forming the scaffold which carries fruiting wood up and out; this is called a modified leader system.

The principal reasons for maintenance pruning are: (1) to permit efficient spraying and harvesting operations; (2) to maintain satisfactory light exposure for most of the leaves; (3) to create a satisfactory balance between flowering and leaf surface. Maintenance pruning to regulate crop size is largely confined to species whose fruitfulness is directly related to vegetative vigour. The grape is this kind of a plant, and pruning of it is primarily to regulate crop size; peach and apricot are also pruned heavily in order to reduce the number of fruits. See also ARBORICULTURE: PRUNING.

Soil Management, Irrigation and Fertilization

Two soil management practices, clean cultivation and permanent sod culture, illustrate contrasting purposes and effects. In clean cultivation, the surface soil is stirred periodically throughout the year in order to prevent establishment and growth of vegetation that competes with the fruit crop for nutrients, water and light.

The stirring increases the decomposition rate of soil organic matter and thereby releases nitrogen and other nutrients for the use of the fruit crop. It may also provide transient improvement in water penetration. On the other hand, laying bare the soil surface exposes it to erosion; destruction of organic matter results in lowered fertility and degeneration of structure. Sod culture minimizes the destructive processes and may permit modest increase in fertility, but the sod itself competes with fruit plants for water and nutrients and may compete for light. As a result, permanent sod culture is practical only with tree crops that are normally rather low in vegetation — apple, sweet cherry and mango, for instance; and competition from established sod is detrimental with extremely vegetative fruit plants like grape. peach and raspberry.

Because each of these soil management systems has advantages and disadvantages, three modifying or complementary practices are used under many circumstances: cover cropping: mulching and chemical control of vegetation. Cultivation combined with winter cover cropping is used widely in grape, peach, cherry, bush fruit and citrus plantings, as well as with other species. Mulching is the addition of undecomposed plant materials such as straw, hay or processors' refuse to the soil in the fruit planting. In orchards mulching materials are most often applied under the branches of trees maintained in permanent sod. Chemical control of vegetation has come into increasing use as a supplement to or substitute for cultivation.

In semiarid and arid regions irrigation is necessary. Probably the maximum demand occurs in date gardens, because they expose a very large leaf surface the year around. under conditions of very high evaporation and practically no rainfall. Irrigation in humid climates is generally limited to shallow-rooted fruit crops such as strawberry and blueberry. There are a few exceptions, however, and the banana appears to be one. Large acreages of this species are irrigated on coastal lowlands of the torrid tropics where annual rainfall exceeds 60 in. Various procedures for irrigation are used in fruit plantings; of these furro , basin or sprinkler systems are most common. *See* IRRIGATION.

Needs of perennial fruit plants for fertilizers depend partly on the natural fertility of the soil supporting them and partly on their special requirements. Of the essential elements, supplemental nitrogen is almost always needed and potassium supplements may be commonly needed. Although phosphorus responses of strawberry. grape and a few fruit tree species have been reported occasionally, phosphorus deficiency is rather rare, and it is evident that perennial fruit plants are more efficient in absorption of this element than are many other plants. Calcium deficiency has seldom been reported. even in very acid soils, but limestone and hydrated lime are sometimes desirable because of indirect benefits. Lack of magnesium, on the other hand, has been noted by workers studying a wide range of fruit species. Of the trace elements, zinc, iron and boron are most apt to be lacking. Iron deficiency is difficult to control in orchards in soils of high pH, or acidity. Three other trace element nutrients, manganese, copper and molybdenum, are sometimes deficient in fruit plantings. *See* also FERTILIZERS AND MANURES.

POLLINATION

The stimulus of pollination and seed formation are needed for normal development of most of the fruits. (Banana, pineapple and some citrus and fig varieties are exceptions.) Transfer of pollen from anthers to stigmas is accomplished in nature either by movement in air or by agency of insects. With the possible exception of olive and grape and some varieties of citrus and fig, the perennial fruit plants considered here are benefited either by insect pollination or by artificial or hand-pollination. *See* POLLINATION and articles on individual species, as APPLE; FIG; etc.

THINNING

Removal of flowers of young fruits (thinning) is done for two purposes: (1) to permit the remaining fruits to grow more rapidly and (2) to prevent the development of so large a crop that the plant is unable to flower in subsequent years.

Thinning may be done by hand or chemically. With date, the pistillate flower cluster is reduced in size at the time of hand-pollination. In the case of certain table grape varieties, some clusters may be removed shortly after they appear, and in addition parts of clusters may be cut off. Young peach fruits may be thinned by striking the branches with a padded pole. Hand thinning of young apple and peach fruits once was also a common practice, but because of the expense and difficulty there has been increasing use of chemical sprays as a substitute. Two kinds of treatment may be used: (1) mildly caustic sprays applied during bloom and (2) sprays of growth-regulating substances applied shortly after bloom. These two kinds of treatment have been used with varying success but they have been successful enough to permit chemical thinning to find a place as one of the supplementary fruit growing practices. *See* SPRAYS AND DUSTS IN AGRICULTURE.

PEST CONTROL

In many fruit enterprises, pest control is the most expensive and time-consuming occupation of the grower, and where the concentration of fruit farms in an area warrants it, individual efforts are complemented by legislative measures including quarantine regulations and by technical and advisory services from public agencies. Sometimes the most economic control procedures are biological in nature. Selection of varieties that are immune, resistant to attack or tolerant to specific pests is a biological control procedure widely used. Parasites or other enemies of pests also have been used to control those pests. Chemical control procedures, however, are relied on most heavily. For discussion of these measures of pest control *see* ENTOMOLOGY: *Principles of Insect Control;* FUMIGATION; PLANT QUARANTIXE; SPRAYING AND DUSTING MACHINERY; SPRAYS AND DUSTS IN AGRICULTURE.

HARVESTING AND POSTHARVEST PRACTICES

The different fruits vary greatly in the way they ripen both as to the specific changes that take place during maturation and the rates at which they occur. Each kind of fruit has a characteristic pattern of cumulative increase in volume, and by the time physiological maturity has been reached the rate of growth is relatively slow. As this time is approached the colour changes to that of the mature fruit, and the ultimate chemical composition is approached. There is a tendency for the fruit of many species, including apple, pear, orange, lemon and grapefruit, to drop from the tree during the last part of the maturation period. Preharvest drop of these fruits is delayed by application of dilute sprays of growth regulating substances like naphthalene acetic acid. These same sprays increase the rate of ripening somewhat.

Most kinds of fruit are harvested as close to the time that they are eating ripe as possible so that they will attain the best quality when they do ripen. But a few, of which banana and pear are outstanding, may be harvested very immature and still ripen satisfactorily. Orange, grapefruit and some varieties of avocado may be held on the tree for several months after they attain good quality; this property is helpful in permitting convenient storage over a long marketing period.

The actual harvesting for these fruits involves hand-picking, except for prunes to be dried and olives for processing ripe. Thus mechanization can only be used to improve the efficiency of the handling operation after the fruit is off the plant. With soft or easily bruised kinds, rather little can be done to speed the handling procedures. With citrus, however, bulk handling has helped to reduce handling costs appreciably; large open containers on trailers are used for collecting fruit from pickers, and mechanized lifting equipment empties them into trucks which in turn are emptied by gravity.

The maximum life of the fresh fruit after harvest varies greatly depending on the kind and on the storage' conditions. Strawberries last for no more than two weeks in the best storage environment whereas apples or lemons can he held for more than six months. Cold temperature storage is the most common means of prolonging the life of fruit. Most temperate zone fruits can be held safely at 32° to 35° F., but many subtropical and tropical fruits, including the lemon, avocado, banana and mango, show chilling injury after prolonged exposure to temperatures below 40° to 45° F. Storage life is extended on several fruits, including apple, pear and banana by holding them in sealed refrigerated rooms in which internal atmospheres are modified to contain less oxygen and somewhat more carbon dioxide than normal air. For some apple varieties storage in an atmosphere containing 2% oxygen and 5% carbon dioxide by volume increases the life several months. Another important way of extending the storage life of some fruits is the removal of ethylene and other volatiles from the atmosphere.

Drying is a standard means of stabilizing dates, figs, raisin grapes, prunes and apricots; canning is of paramount importance to the pineapple, peach and pear industries; and freezing is a means of stabilizing some of the most perishable fruits including strawberry, raspberry and blueberry. *See* also CROP DRYING AND PROCESSING; COCOA; COFFEE; VANILLA; and articles on other individual plants.

FRUIT FLY, any member of the families Trupaneidae and Drosophilidae of the order Diptera (*q.v.*). The Trupaneidae (Trypetidae, Tephritidae) contain many species of economic importance. Most damage is caused by the larvae living in fruits. The Mediterranean fruit fly *(Ceratitis capitata)* infested Florida in 1929, and its eradication required several years. The pest reappeared in that state in 1956, however. The Mexican fruit fly, *Anastrepha ludens,* attacks citrus fruits in Central America and south Texas. *Rhagoletis pornonella,* the apple maggot or railroad worm, and *R. cingulatus,* the cherry fruit fly, cause enormous damage. Other species attack walnuts. The currant and gooseberry fruit fly and the melon fly are sometimes serious pests in North America. In Europe the asparagus fly, *Platyparea, poeciloptera,* destroys the edible shoots of asparagus. In Australia, *Chaetodacus tryoni,* the Queensland fruit fly, is a serious pest, while the olive fly. *Dacus oleae,* attacks olives in the Mediterranean region and in Africa. Control of these pests is difficult and varied according to the habits of each. Against some, use of poisoned bait to kill the adults, destruction of infested fruit and clean cultural methods are effective. The celery fly of Europe and the parsnip leaf miner of North America make mines in the leaves of umbelliferous plants; species of *Eurosta* and allies make galls on the stems and roots of goldenrod; others bore in stems or live in the developing seeds of the Compositae, especially of thistles and goldenrods. The Drosophilidae. now generally called small fruit flies, are attracted to fermenting sap, decaying vegetation and ripe fruit. They are believed to feed chiefly upon fungus developing in such places. Several species are used in the study of heredity. *(See* GENETICS; DROSOPHILA.) (C. H. CN)

FRUIT SUGAR: *see* CARBOHYDRATES; SUGAR.

FRUMENTIUS (*c.* 900–c. 360), the founder of the Abyssinian church. traditionally identified in Abyssinian literature with Abba Salama or Father of Peace *(see* ETHIOPIA, ORTHODOX CHURCH OF*)*, was a native of Phoenicia. According to Rufinus (x, 9), who gives Aedesius as his authority. a certain Tyrian, Meropius, accompanied by his kinsmen Frumentius and Aedesius, set out on an expedition to "India." but fell into the hands of Ethiopians on the shore of the Red sea and was put to death. The two young men were taken to the king at Axum, where they obtained. in time, great influence. With the help of Christian merchants who visited the country Frumentius gave Christianity a firm footing. In 326 he was consecrated bishop of Axum by Athanasius of Alexandria who in his *Epistola ad Constantinum* mentions the consecration and gives details of Frumentius' work.

FRUNDSBERG, GEORG VON (1473–1528), German soldier. was born at Mindelheim on Sept. 24, 1473. He fought for the German king Maximilian I against the Swiss in 1499, and in the same year was among the imperial troups sent to assist Ludovico Sforza, duke of Milan. against the French. Still serving Maximilian, he took part in 1504 in the war over the succession to the duchy of Bavaria-Landshut, and afterwards fought in the Netherlands. Frundsberg assisted Maximilian to organize the *Landsknechte* (*q.v.*), and at the head of bands of these formidable troops he was of great service to the empire and the Habsburgs. In 1509, 1513 and 1514 he gained fresh laurels against the Venetians and the French. When the struggle between France and the empire was renewed he took part in the invasion of Picardy (1521), and proceeding to Italy brought the greater part of Lombardy under the influence of Charles V through his victory at Bicocca in April 1522. He was partly responsible for the great victory over the French at Pavia in February 1525, and, returning to Germany, assisted in suppressing the Peasants' Revolt, using on this occasion, however, diplomacy as well as force. He died at Mindelheim on Aug. 20, 1528. Frundsberg was a capable and chivalrous soldier, and a devoted servant of the Habsburgs. With his grandson the family became extinct.

FRUNZE (formerly PISHPEK), the chief town of the Kirghiz A.S.S.R., situated on the Chu river in 42° 45' N. lat.. 74° 45' E. long. Its chief industries are brewing and the manufacture of tobacco *(makhorka)*.

A branch line from the Chkalov-Tashkent railway, passing through Chimkent and Aulie-ata, reaches the town. In 1928 a line to the densely peopled Tokmak region, northwest of Lake Issyk-kul, was commenced, and the Turksib (Turkistan-Siberian) railway linking Frunze and Semipalatinsk was completed in 1930. This opened up the corn-growing region round Lake Balkhash, and enabled the Central Asiatic republics to depend on imported instead of homegrown grain and thus to increase the area under cotton. Pop. (1959) 223,831

FRUSTRATION. The technical, psychological meaning of the term frustration has much in common with its more general lay meaning. In both cases, frustration refers to the interruption of an episode of behaviour before its completion. However, not every interruption of behaviour is frustrating. A man hard at work on a hot afternoon will not usually be frustrated if his employer interrupts him and says, "I want you to quit now, but I'll pay you for a full day's work." To define frustration more adequately requires a brief consideration of a point in psychological theory.

Some kinds of behaviour can be explained only in terms of such a concept as motive (or desire, purpose, want, need. instinct, sentiment or psychological tension). Motive refers to an inferred state of the individual that is presumed to organize and direct behaviour in relation to existing conditions until a more-or-less particuiar goal is reached. When such an episode of behaviour is interrupted before an appropriate goal is achieved, frustration results. Interruptions of behaviour that do not interfere with goal attainment, or which expedite it, are not frustrating.

During the operation of a motive the individual is active, his behaviour is organized, and, when the motive is conscious, he experiences a hunger for the goal. When the goal is attained, the individual experiences satisfaction or satiation. If the goal-directed behaviour is interrupted. *ie.,* if frustration occurs, a great variety of behaviour resultants may appear.

The basic fact about frustration is that it has effects which are often widespread. The behaving person is not like a rolling billiard ball which, when its movement is stopped. remains motionless. The interruption of a directed action changes behaviour but does not stop it. What the changes are depends upon a number of factors, some of which are the following:

Source of Frustration.— The chief causes of behaviour interruption are: (1) motor, intellectual or perceptual inadequacies; (2) physical obstacles or social prohibitions; and (3) conflict of motives.

Completeness of the Interruption.—Interruption of goal-directed behaviour may be complete and irrevocable as when a beloved person dies, or it may appear to be equivocal as when an attractive apple is barely out of reach on the tree.

Distance to the Goal.—Interruption of a directed action may occur at any point in the temporal course of the episode. immediately after beginning the action, intermediate in the action or just before its completion.

Nature of the Motivating State.—Three factors of importance are: (1) whether the motive is fundamental to the personality (often unconscious), or is of superficial importance (usually conscious); (2) the strength or degree of the motive; and (3) the content of the goal behaviour to which the motive directs behaviour.

Strength of Restraining and Control Mechanisms.—There are great differences in the ability of persons to organize and control the forces of motives. Terms such as strength of character, self-control, superego and force of habit are used to describe these differences.

Exploratory **Behaviour.**—An immediate effect of frustration, whatever its source and whatever the nature of the motive. is the occurrence of exploratory behaviour. This may be overt behaviour, as when a person searches for an opening in a wall which obstructs his path, or argues with a traffic officer who will not allow him to enter a certain street. If the exploration is successful, a detour is discovered and the directed action proceeds on its course. If the detour is short and simple, it may be learned immediately and become a permanent part of the individual's repertoire of behaviour; if it is long or complicated, it will be more slowly learned; and if it is too difficult, it will never be learned.

Thinking and **Planning.**—If immediate overt physical or social exploration is not successful, it is followed by subjective exploration; *i.e.*, thinking, planning, analyzing and problem solving. This behaviour is functionally similar to overt exploration.

Phantasy.—If frustration is long-continued, is of obscure origin or involves strong motives, phantasy frequently occurs. Phantasy is closely related to planning and thinking, but it differs from them in that the solutions and substitutes it provides cannot be achieved overtly. Phantasy reflects motives less distorted by external conditions than either thinking or overt exploration; in phantasy a person is free.

Substitute **Behaviour.**—The acceptance of more-or-less satisfying substitutes for inaccessible, original goals frequently occurs.

Dissociation.—When an individual is unable to achieve goals that are highly regarded by his social group, he may continue to avow his acceptance of them while making no effort to achieve them. Such dissociation of motive from directed! overt behaviour provides considerable social acceptance; merely subscribing to socially approved goals brings social prestige.

Emotional Reactions.—Emotional behaviour accompanies many of the other behavioural resultants of frustration. The stronger and the more basic the motive, the more extreme the emotional accompaniments. In some cases, complete disruption of goal-directed behaviour occurs.

Regressive **Behaviour.**—Under conditions of strong and persisting frustration, behaviour becomes primitive in many respects; it becomes like behaviour which normally occurs at an earlier developmental level. Regression occurs in connection with behavioural techniques used to achieve goals (instrumental regression); it occurs with respect to goals (goal regression); and it occurs in connection with motives (motivational regression). Much neurotic and psychotic behaviour involves goal and motivational regression, usually implemented by unconscious mechanisms.

Lowering Aspiration Level.--One kind of goal regression has been subject to successiul experimental study. In cases of relatively superficial and weak motives it has been found that a goal of high attractiveness but impossible of attainment for the individual may be abandoned ior a goal of lower attractiveness which is within the range of the individual's abilities. This is a common occurrence when the source of the frustration is attributed by the individual to his own lack oi ability; *i.e.*, when the individual experiences failure. This kind of regression, or lowering of the level of aspiration, as it has been called, has an important mental-hygiene significance. It means that great numbers of people are able to experience success in most of their efforts, ior when they do not experience success they change their goals to a level appropriate to their ability. Lowering the level of aspiration is not usually pathological (neurotic or psychotic).

Abandonment.—One common reaction to irustration, particularly when motives are superficial and weak and when the interruption occurs early in the behaviour episode, is the abandonment oi the course of action and the relinquishment of the possibility of achieving the goal. This is probably not possible with basic motives that ramify widely throughout hehaviour. Such motives cannot be abandoned without a drastic change in mode of living which is resisted by the social group in which the person lives and by his other motives.

Withdrawal.—During frustration temporary ceasing of goal-directed actions and turning to other activities without abandoning the motivating state is frequent.

Repression.—Frustration of fundamental motives may be too painful for the person to iace, or a social prohibition may be so strong that even the admission of the motive to transgress it may be impossible. In these cases the motive may he obliterated irom consciousness. It mas one of the great discoveries of the early 20th century that motives can be consciously avoided, yet continue to influence hehaviour. Repression of strong central motives is considered to be one oi the principal sources of neurotic and psychotic behaviour.

Lowered Attractiveness of Goals.—One way of avoiding the pain oi irustration is to depreciate the value oi the unobtainable goal, for serious frustration is not experienced in relation to unimportant things. The "sour-grapes" reaction is an important self-protective adjustment to frustration.

Enhanced Attractiveness of Goals.—When goal-directed behaviour is interrupted, but not irrevocably so, the value oi the goal may be enhanced. A considerable number of iolk sayings describe this phenomenon: "the grass on the other side of the ience is greener"; "absence makes the heart grow fonder."

Aggressive **Behaviour.**—The initial reaction to an interruption of goal-directed behaviour is frequently an energetic effort to proceed in spite of the interruption. This will take the form of physical, social or intellectual effort depending upon the nature oi the interruption. Such "aggressive" hehaviour may be one aspect oi exploration in its early stages; *i.e.*, a testing of the strength of the obstacle. If the individual becomes emotional or regresses, his behaviour will become more primitive and this often involves violent, direct physical and social approaches which will commonly he described as aggressive.

The reactions to frustration given above are not mutually exclusive or independent; they are on quite different levels of significance. An important problem of scientific psychology is to describe them more adequately and systematically, and to determine their causation.

FRUSTUM, a term in geometry for the part of a solid figure, such as a cone or pyramid, cut off by a plane parallel to the base or lying between two parallel planes; and hence in architecture a name given to the drum of a column.

FRY, ELIZABETH (1780–1845), English philanthropist, and, after Howard, the chief promoter of prison reform in Europe, was born in Norwich on May 21, 1780. Her father, John Gurney, afterwards of Earlham Hall, a wealthy merchant and banker, represented an old family which for some generations had belonged to the Society of Friends. While still a girl she showed the benevolence of disposition, clearness and independence of judgment, and strength of purpose, for which she was afterwards so distinguished. In Aug. 1800 she became the wife of Joseph Fry, a London merchant.

Amid increasing family cares she was unwearied in her attention to the poor and the neglected of her neighbourhood; and in 1811 she was acknowledged by the Society of Friends as a "minister." She had made several visits to Newgate prison as early as February 1813, but the great public work of her life dates effectively from the formation of the association for the improvement of the female prisoners in Newgate in April 1817. Its aim was the much-needed establishment of some of what are now regarded as the first principles of prison discipline, such as entire separation of the sexes, classification of criminals, female supervision for the women, and adequate provision for their religious and secular instruction, as also for their useful employment. The ameliorations effected by this association, largely by the personal exertions of Mrs. Fry. led to a rapid extension of similar methods to other places. In 1818 she, with her brother, visited the prisons of Scotland and the north of England. The publication (1819) of the notes of this tour, and the cordial recognition of the value of her work by the house of commons committee on the prisons of the metropolis, led to an extensive correspondence with persons interested in prison reform in Italy, Denmark and Russia. Through a visit to Ireland, which she made in 1827, she was led to direct her attention to other houses of detention besides prisons; and her observations resulted in many important improvements in the British hospital system, and in the treatment of the insane.

In 1838 she visited France, where she conferred with many of the leading prison officials, and personally visited most of the houses of detention in Paris, Rouen, Caen and other places. In 1839 she obtained an official permit to visit all the prisons in that country; and her tour, which extended from Boulogne and Abbeville to Toulouse and Marseilles, resulted in a report which was presented to the minister of the interior and the prefect of police. Before returning to England she had included Geneva, Ziirich, Stuttgart and Frankfort-on-Main in her inspection. The summer of 1840 found her travelling through Belgium, Holland and Prussia on the same mission; and in 1841 she also visited Copenhagen. In 1842, through failing health, Mrs. Fry was compelled to forego further travels, but she had the satisfaction of hearing from almost every quarter of Europe that the authorities were giving increased practical effect to her suggestions. She died on Oct. 12, 1845. She was survived by a numerous family, the youngest of whom was born in 1822.

Two interesting volumes of *Memoirs, with Extracts from her Journals and Letters*, edited by two of her daughters, were published in 1847. *See* also G. King Lewis, *Elizabeth Fry* (1910).

FRY, ROGER ELIOT (1866–1934), British art critic and painter, was born in London, and educated at Cambridge university. He studied painting under Francis Bate and then in Paris. His landscapes are marked by deep feeling for form and a scholarly sense of design and technique. An active member and exhibitor of the London group, he gave an exhibition of his paintings in 1920. With his wide knowledge and acute sensibility. Fry became a recognized art critic in England and abroad. He published a study of *Bellini* (1899) and edited Reynolds' *Discourses* (1905), but is best known by his championship through much opposition and prejudice, of Cézanne and the Postimpressionists. His *Cézanne* (1927) is a study of the master. Among other publications are *Vision and Design* (1920); *Architectural Heresies of a Painter* (1921), a book of travel impressions; *A Sampler of Castile* (1923); and *Transformations* (1926). In 1933 he was appointed Slade professor of fine art at Cambridge.

See Virginia Woolf, *Roger Fry:* a *Biography* (1940); and E. M. Forster, *Abinger Harvest* (1936; 1955), which contains an essay on Fry.

FRYATT, CHARLES (1872–1916), British seaman, was born at Parkeston, Essex, on Dec. 2, 1872. He entered the service of the Great Eastern Railway Co., and in 1904 became chief officer in their service of vessels plying between Harwich and Rotterdam. In 1913 he was promoted captain. At the end of July 1916, it was announced that his ship, "Brussels" had been captured and the captain himself arrested and tried by court martial. on a charge of having attempted, on March 28, 1915, to ram a German submarine. The German authorities stated that Captain Fryatt had confessed that he had acted under orders from the British admiralty; but the trial was hurried and secret, no intervention on the part of neutrals being allowed. The captain was condemned to death and shot at Bruges on July 27, 1916. The body was, on July 7, 1919, brought from Belgium to England and was buried at Dovercourt, near Harwich.

FRYDLANT or FRIEDLAND, an old town in Liberec, Czech., occupied in 1938 by Germany. It has local administrative functions supplemented by small but thriving textile and engineering factories, paper mills and pottery works. The old castle situated on a small hill commanding the town epitomizes its stormy history. Pop. (1950) 4,447. It must be distinguished from Frydlant in Ostrava, a small town of about 4,000 inhabitants.

FUAD I (1868–1936), king of Egypt, born at Gizeh palace, Cairo, on March 26, 1868, was the youngest son of the khedive Ismail. After his father's deposition he went to Italy, returning permanently to Egypt only in the 1890s when he became aide-de-camp to the khedive Abbas II. He remained quietly in Egypt, occupying himself largely with charitable activities. When, in 1914, Egypt was declared a British protectorate, Abbas deposed and the khediviate abolished, Fuad's elder brother, Husain Kiamil, became ruler with the title of sultan. The sultan's son, Prince Kemal ed-Din, having renounced his rights of succession, Fuad became sultan on his brother's death in 1917. On May 25, 1919, he married the princess Nazli, daughter of Abdel-Rehitn Sabri Pasha, who gave birth on Feb. 11, 1920, to an heir, Prince Farouk.

When Great Britain relinquished the protectorate and acknowledged Egypt as an independent kingdom, Fuad was proclaimed king (March 16, 1922) and became at once an important factor in Egyptian politics. The popular demand for an even greater degree of national independence was sponsored principally by the Wafd, the major political party; and after 1922 Egyptian political life was largely dominated by the struggle for power between the Wafd and the new palace parties centred around the king. In this duel the British government made a number of interventions, some favourable to the Wafd (since it was anxious to negotiate a settlement which would not be repudiated by the most popular party), others to the palace (by reason of the periodic outbreaks of anti-British violence to which the Wafd-inspired nationalist enthusiasm gave rise). *(See* EGYPT; *History.)*

Fuad retained his active interest in charitable and, particularly, in educational matters and was a prime mover in establishing the first Egyptian university of the western type, the Fuad I university in Cairo (1925). In 1927 he paid state visits to London and Rome. He died on April 28, 1936.

See G. A. Lloyd, Baron Lloyd of Dolobran, *Egypt since Cromer,* 2 vol. (1933–34); Ikbal 'Ali Shāh, *Fuad, King of Egypt* (1936).

(H. S. D.)

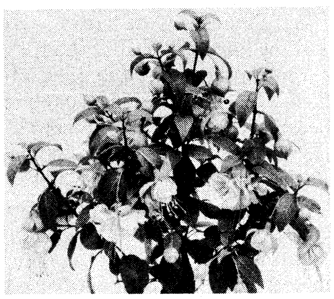
FUAD PASHA (1815–1869), Turkish statesman, was the son of the poet Kechéji-zadé Izzet Molla. He was educated at the medical school and was at first an army surgeon. He became secretary of the embassy in London; was employed on special missions in the principalities and at St. Petersburg (1848), and was sent to Egypt as special commissioner (1851). He was five times foreign minister. During the Crimean War he commanded the troops on the Greek frontier and distinguished himself by his bravery. He was Turkish delegate at the Paris conference of 1856; was charged with a mission to Syria in 1860; grand vizier in 1860 and 1861, and also minister of war. He died at Nice in 1869. Generally regarded as the partisan of a pro-English policy, he served his country well by his able management of foreign affairs, and not least by his efficacious settlement of affairs in Syria after the massacres of 1860.

FUCHOW: *see* FOOCHOW.

FUCHSIA, a genus of plants of the family Onagraceae (*q.v.*), characterized by entire, usually opposite leaves, pendant flo ers, a funnel-shaped, brightly coloured, quadripartite, deciduous calyx, four petals, alternating with the calycine segments, eight, rarely ten, exserted stamens, a long filiform style, an inferior ovary and fruit, a fleshy ovoid many-seeded berry. All the members of the genus, except a few New Zealand species, are natives of Central and South America—occurring in the interior of forests or in damp and shady mountainous situations. The various species differ not a little in size as well as in other characters; some, as F. *parviflora,* being dwarf shrubs; others, as F. *arborescens,* attaining a height of 12 to 16 ft.; while others are treelike and have stems several inches in diameter.

F. coccinea was the first species cultivated in England, where it was long confined to the greenhouse. The numerous hybrid fornis now existing are the result chiefly of the intercrossing of long-flowered with globose-flowered plants. In some varieties the blossoms are variegated, and in others they are double. There appears to be little limit to the number of forms to be obtained by careful cultivation and selection.

Ripe seed is sown either in autumn or about February or March in light, rich, well-drained mold, and is thinly covered with sandy soil and watered. A temperature of 70° to 75° F. has been found suitable for raising. The seedlings are pricked off into shallow pots or pans, and when three inches in height are transferred to three-inch pots, and are then treated the same as plants from cuttings. Fuchsias may be grafted readily, preferably by the splice or whip method, the apex of a young shoot being employed as a scion; but the easiest and most usual method is by cuttings.



BY COURTESY OF CHICAGO NATURAL HISTORY MUSEUM

FUCHSIA (FUCHSIA)

Among the more hardy or half-hardy plants for borders in California and southern England are varieties of F. *magellanica,* a tree up to 20 ft. high, but lower as cultivated. A native from Peru to southern Chile, it is the parent of most garden varieties.

For greenhouse culture may be mentioned F. *corymbiflora* (Peru), q to 6 ft. high, with scarlet flowers nearly 2 in. long in long terminal clusters; F. *julgens* (Mexico), 4 to 6 ft.. with drooping apical clusters of scarlet flowers; F. *procumbens* (New Zealand), a pretty little creeper, the small flowers of which are succeeded by oval magenta-crimson berries which remain on for months, and F. *splendens* (Mexico and Guatemala), 6 ft. high, with very showy scarlet and green flowers. These wild species, however, cannot compare in beauty or freedom of blossom with the numerous horticultural varieties.

The berries of some fuchsias are subacid or sweet and edible. From certain species a dye is obtainable.

The so-called native fuchsias of southern and eastern Australia are plants of the genera *Correa* and *Epacris.*

FUCINO, a lake bed of the Abruzzi, Italy (Lat. Lacus Fucinus), in the province of Aquila, 2 mi. E. of the town of Avezzano. The lake was 37 mi. in circumference and 6j ft. deep. From the lack of an outlet, the level of the lake was subject to great variations. As early as A.D. 52 the emperor Claudius. realizing a project of Julius Caesar, constructed a tunnel 33 mi, long, with 40 shafts at intervals, by which the surplus waters found an outlet to the Liris. No less than 30,000 workmen mere employed for 11 years in driving this tunnel. In the following reign the tunnel was allowed to fall into disrepair, but was repaired by Trajan. Still preserved in modern times, it is, however, no longer in use.

Various attempts to reopen it from 1240 onward were unsuccessful. By 1852 the lake had gradually risen until it was 30 ft. above its original level. In 1854–75 Prince Alessandro Torlonia, the Roman banker, drained the lake at the cost of about £1,700,000, becoming proprietor of the site in return. The outlet by which it was drained was 4 mi. long and 24 sq.yd. in section.

FUEL CELL. The idea of using electrochemical processes for generating and for storing electrical energy in flashlight batteries and storage batteries is familiar to most people; the conception of deriving electrical energy directly from normal oxidizable fuels is not so familiar. From the time of Sir Humphrey Davy the idea has attracted attention since the prize to be won is the generation of electricity without using any form of the heat engine with its thermodynamic and mechanical losses. It is theoretically possible to achieve very high conversion efficiencies with a corresponding saving in fuel.

Thermodynamics. — Provided the energy change in a fuel cell resulting from the chemical reaction of oxidation takes place with the production of electrical energy and no liberation of heat and in a thermodynamically reversible manner, then it may be represented by the Gibbs-Helmholtz equation:

$$\Delta H = \Delta G - \frac{T\,\delta(\Delta G)}{\delta T}$$

where T is the absolute temperature, ΔH is the heat of combustion and ΔG is the free energy change representing the maximum energy available. Free energy changes are known from many reactions and consequently efficiencies can be calculated. For example, the reaction $C + O_2 = CO_2$ has a value of ΔG at 25° C. which is equal to 94.2 kg.cal. per gram molecule or 4.136 kw.hr. per pound of carbon. At 1,000° C. this value is only altered by 0.0270. Thus the second term in the Gibbs-Helmholtz equation is negligible and the theoretical efficiency of conversion of heat of chemical energy to electrical energy is nearly equal to the heat of combustion. The voltage per cell is of the order of one volt on open circuit, falling as current is drawn from the cell.

Applications. — The fuel cell holds promise of application in industry. Since direct current is produced it would not seem feasible for large-scale power generation in competition with high-voltage alternating current. The characteristic of the fuel cell is falling efficiency with increasing load, which is favourable for traction applications where full load is only required for starting and climbing gradients. The good torque characteristics of direct-current motors can be used immediately. For local use the fuel cell's generation of direct current at low voltage is favourable for electrometallurgical and electrochemical processes, particularly if it is fed with industrial or natural gas.

Modern Developments. — Most progress was made after World War II in Great Britain, the U.S.S.R. and western Germany. The main work was on industrial gases rather than solid or liquid fuels. Three main types of cell were investigated: (1) the cell in which aqueous electrolyte is fed between the electrodes, the fuel gas being fed to one electrode and oxygen to the other; (2) the fused salt cell in which molten salt is used as the electrolyte; this is commonly based on carbonates having ionic conductivity; ionic solid electrolytes were also considered; and (3) the redox ("reduction-oxidation'!) cell in which oxidation of the fuel by one redox agent and oxidation of another redox agent by oxygen or air both take place outside the cell, the two redox agents providing the necessary electrical energy when brought together in the cell, but separated by a semipermeable membrane.

The Bacon team at Cambridge university developed a hydrogen-oxygen cell in which the electrolyte is a caustic potash solution. The cell operates at about 200° C. and 600 pounds per square inch with treated nickel electrodes, and gives varying outputs up to 1,000 amp, per square foot for long periods. In Germany E. Justi reported success on a low-pressure hydrogen-oxygen cell and fused carbonate cells using carbon monoxide and hydrogen. Following the work of E. Baur in Zürich, Switz., O. K. Davtyan in the U.S.S.R. reported promising results on high-temperature cells using alkali carbonates. These results were improved upon in the Netherlands and Great Britain.

FUELING STATIONS, NAVAL: *see* BUNKERING OF SHIPS.

FUELS. Fuel is a term applied to materials used to produce heat by combustion in air. Man alone among living creatures has discovered ways of creating heat and power by the use of fuel. He has thereby improved his means of procuring food, has adapted himself to live and flourish on almost the entire area of the globe and has secured an immeasurably increased standard of comfort. Modern civilization could not exist if fuel supplies failed or became exhausted.

Following are the main divisions of this article:

I. FUEL CONSTITUENTS

Generally speaking, the bulk of natural fuels such as coal, wood, peat, oil and natural gas are made up of compounds of carbon, hydrogen and oxygen in association with small proportions of nitrogen and sulfur, in addition to moisture and mineral ash but in special circumstances such elements as phosphorus and the more readily oxidizable metals such as magnesium and aluminum may be utilized as fuel.

When the constituent elements of a fuel burn or unite with oxygen, heat is evolved, and a fuel is completely burned only when all of its combustible components are oxidized to the highest possible degree. In the process a definite quantity of heat is produced which can be calculated approximately from the chemical composition of a fuel. Thus one pound of carbon in complete combustion to carbon dioxide (CO_2) produces about 14,500 B T U. (British thermal units), but only about 4,400 B.T.U. are produced in burning to the lower oxide. carbon monoxide (CO). If, however, this is subsequently burned to CO_2, the balance of about 10,100 B.T.U. is liberated. Hydrogen burns to water vapour, about 62,000 B.T.U. being produced per pound of hydrogen burned. The value of a fuel depends primarily upon its potential heat-producing capacity per unit mass or calorific value. but the calorific intensity, or the temperature to which this amount of heat can raise the products of combustion without excess air, is also important. The impurities in a fuel affect both its calorific value and calorific intensity.

II. SOLID FUELS

Solid fuels may be divided into two main groups, natural and manufactured. In the former category are coal. wood, peat and other vegetable matter, and in the latter such products as coke and charcoal, obtained by destructive distillation (heating the raw material in the absence of air, by which gas and tar are also produced). Such processes form the basis of the manufacture of both metallurgical coke and gas, two important industries.

A. Coal and Related Fuels

The reserves of coal; which may be expected to last more than 1,000 years at the rate of consumption in the early 1960s, are far above those of any other combustible. Coal is a stratified sedimentary rock that has been formed by the action of decay, heat and pressure upon accumulations of vegetable and woody or cellulosic matter laid down in bygone ages. It varies widely in composition and properties. Although the proportions of the elements present in any particular variety of coal and its behaviour under various forms of treatment are known, the fundamental causes of the differences between the different types have not yet been placed upon a really rational basis. A knowledge of the true constitution of coal: which is being sought by many research workers, could not fail to be of great assistance to those responsible for the proper utilization of a vast but irreplaceable store of fuel.

1. Classification. — Many classifications of coal have been suggested — by geologic age, coking properties, commercial application, chemical composition, etc. There is, however, no sharp distinction between any one coal and its nearest relation, but rather an innumerable family with characteristics changing gradually from one extreme to the other. Four main divisions are given in the classification of the American Standards association: (1) anthracite; (2) bituminous; (3) subbituminous; and (4) lignite and brown coal.

Table I.—Approximate Chemical Composition of Solid Fuels
(moisture free)

Fuel	Carbon (C)	Hydrogen (H)	Oxygen (O)	Nitrogen (N)	Sulfur (S)	Ash
Cellulose (forms the bulk of plant structure)	44.4	6.2	49.4	...	...	...
Wood	48.5	6.0	43.5	.5	...	1.5
Peat	58.0	6.3	30.8	.9	Trace	4.0
Lignite	67.0	5.1	19.5	1.1	1.0	6.3
Coal (bituminous)	77.0	5.0	7.0	1.5	1.5	8.0
Coal (anthracite)	90.0	2.5	2.5	.5	.5	4.0

From Table I it will be seen that the transition from cellulose to anthracite is marked by elimination of oxygen and a corresponding increase of carbon.

Henri Victor Regnault and E. Gruner were among the first to formulate methods for the classification of types of coal. which they grouped according to flaming characteristics and the nature of the coke residue. S. W. Parr proposed a classification by rank (in the natural series from anthracite to lignite) based upon the heat value of the true coal substance "unit coal," free from ash or sulfur, that is, mineral matter-free (mm-free), according to fixed carbon on the dry basis or B.T.U. on the moist basis. The Parr formula for the latter is:

$$\text{Moist, mm-free B.T.U.} = \frac{\text{B.T.U.} - 50S}{100 - (1.08A + 0.55S)} \times 100$$

where S and A are the percentages of sulfur and ash, respectively. Another method of classification is that of C. A. Seyler, in which coals are divided according to their hydrogen content into five groups uhich are further subdivided according to the carbon content. This classification has been used by the British geological survey in publications on the coals of south Wales.

For carbonization purposes one of the most important properties of bituminous (soft) coals is their ability to form coherent coke and the extent to nhich they swell or shrink during this process. This behaviour forms the basis of a useful subclassification of such coals. S. R. Illingworth and others classed coals according to the temperatures at which certain constituents decompose.

2. Tests on Carbonaceous **Materials.**—Accurate tests are available for such characteristics of coal as its calorific value or ultimate chemical composition. and independent determinations of these should agree closely. Tests of an empirical nature, such as proximate analysis, and special tests. such as determinations of the free-swelling index or caking characteristics, are less specific but equally important. Since in such cases variation of method might produce divergent results, the same procedures must be adopted by different workers.

In 1920 the British Fuel Research board appointed a committee to examine methods of analysis, including (1) proximate and (2) ultimate analysis, (3) determination of caking index and (4) measurement of calorific value. The following methods of analysis, which have since been essentially followed, were adopted:

Proximate Analysis.—This consists of the determination of moisture, ash. volatile matter and fixed carbon in a sample of coal ground to pass a standard sieve of 60 meshes to the inch and air-dried.

1. Moisture. This is given by the loss in weight of one to two grams of coal when heated for one hour at a temperature of 105°–110° C. Coals especially liable to oxidation should be heated in a current of dry nitrogen.

2. Ash. One to two grams of the coal in a platinum or silica dish are heated gradually in air to about 800° C. When combustion is complete the residue is cooled and weighed.

3. Volatile matter. One gram of the coal is heated for seven minutes at about 925° C. in a platinum crucible of special shape closed by a well-fitting lid. The loss of weight is taken conventionally to represent the volatile matter.

4. Fixed carbon. The value of fixed carbon is obtained by subtracting the sum of the percentages of ash, volatile matter and moisture from 100.

Ultimate Analysis.—This consists of determining the proportions of the various constituent elements of the coal. The carbon and hydrogen are determined by the combustion of 0.2 g. of coal in a current of oxygen. The products of combustion are passed over copper oxide at 800° C. and then over granular lead chromate at 600° C. to absorb sulfur compounds. The carbon dioxide and water produced are weighed separately and from these weights are calculated the percentages of carbon and hydrogen in the coal. Nitrogen is determined by digesting one gram of coal with sulfuric acid according to the method of J. Kjeldahl. The nitrogen is thereby changed into ammonia, which after distillation is titrated with standard solutions. The sulfur is determined by conversion into sulfate by heating the coal gently with a fusion mixture of lime and magnesia (Eschka's method). Detailed procedures for carrying out these tests, as later modified, are covered in *A.S.T.M.* Standards *on* Coal *and* Coke (American Society for Testing Materials, 1957).

Caking Index.—There is no laboratory test that will give completely satisfactory information as to the caking or coking action of coal in its utilization. The free-swelling index, however, gives valuable guidance on many utilization problems. This smelling test consists in heating one gram of pulverized coal in a silica crucible over a gas flame under prescribed conditions to form a coke button. which is compared in size and shape with a series of standard profiles numbered one to nine. These profiles are intended to cover the size and shape of buttons obtained from coals covering a wide range in plastic properties. The number of the standard profile with which the maximum cross-sectional area of the button most nearly corresponds is recorded as the swelling index.

Calorific Value.—The heat evolved by complete combustion of a fuel may be determined in various ways, but the most accurate method uses the bomb calorimeter. One gram of finely powdered coal is pressed into a cylindrical pellet, accurately weighed and inserted in a strong metal bomb with an airtight cover. This is filled nith oxygen to a pressure of about 25 atm. and immersed in a calorimeter vessel containing water.

The pellet is ignited by passing a momentary current of electricity through a thin wire within the bomb; the heat evolved by combustion of the coal is measured by the rise in temperature produced, proper cooling corrections being applied. The accuracy obtainable is of the order of two or three units in the fourth significant figure. The calorific value of dry coal varies from 10.000 to 15,000 B.T.U. per pound, according to the type. Approximate values in the same units for dry fuels may be taken as: wood 8,000; peat 10,000; lignite 11,000; bituminous coal 13,800; and anthracite 13.500.

The heat obtainable from a fuel is always less in practice than in theory, since losses caused by imperfect combustion and by heat carried away in the flue gases, in clinkers and in ashes can never be entirely avoided. Further, in fuels containing hydrogen the calorific value measured in the calorimeter and used generally for scientific purposes (the gross calorific value) is higher than that obtainable under working conditions (the net calorific value) by an amount equal to the latent heat of vaporization of the water formed.

3. Constitution **of** Coal.—Since coal is derived from vegetable matter, it is to be expected that among its major constituents will be degradation products of cellulose and lignin, together with small proportions of resinous bodies and compounds containing nitrogen and sulfur. The more important methods employed in investigating the constitution of coal may be briefly enumerated as: (1) extraction by solvents; (2) action of reagents (*e.g.,* controlled oxidation, hydrogenation, chlorination. methylation, etc.); (3) carefully regulated destructive distillation; (4) microscopic examination of thin sections or etched surfaces; and (5) examination by X-rays.

One investigation has been to determine the effect of hydrogen under high pressure upon the coal substance, by which it has been found possible to confer caking properties on coals that are normally noncaking. Even anthracite has yielded to this treatment, and the substance of certain types of coal has been converted into a mineral oil. By extracting coal with benzene under high pressure. F. Fischer in Germany and W. A. Bone in England were able to separate the constituents in which the caking properties of a coal appear to reside. Similar results were obtained by Parr in the U.S. by the use of phenol and xylene as solvents.

Bone obtained a considerable yield of mellitic and other benzene carboxylic acids in the oxidation products of the residue from the benzene extraction, and concluded that a considerable proportion of the coal substance has a six-carbon ring structure; each carbon atom of the ring is connected to other carbon atoms.

According to R. V. Wheeler, bituminous coal consists essentially of insoluble ulmins (organic substances) in which organized plant tissues are dispersed. By mild oxidation (for example, with hydrogen peroxide or with air at 100°–150° C.) the ulmins are rendered soluble in alkali and may thus be separated from the organized plant remains. Fossil plant cuticles and other tissues have been recognized in this residue. The ulmins, when oxidized by dilute nitric acid, yield oxalic, succinic, picric and pyromellitic acids. indicating that the ulmin molecules consist of benzenoid groupings linked by such structures as pyrrole and furan or their derivatives.

The results of the destructive distillation of coal have proved difficult to interpret from the point of view of the constitution of the coal substance because of overlapping of the various decomposition processes taking place. Examination of the oils produced by hydrogenation of coal seems to confirm the views of Bone and Wheeler on the six-carbon ring structure of the coal substance. By microscopic study of thin sections, Marie Stopes identified four main ingredients in British banded bituminous coal, which she designated vitrain, clarain, durain and fusain. G. Thiessen, on the other hand, considered that U.S. coals contain three main ingredients which he termed mother of coal, attritus and anthraxylon. Seyler applied the methods of metallography (*q.v.*) to microscopic examination of coal surfaces and nas able thereby to identify directly many forms of plant tissue in the coal.

4. Peat.—Vast accumulations of peat occur in Europe, North America and northern Asia, but the industry has been developed only in regions deficient in coal. In Ireland millions of tons are consumed annually; the U.S.S.R. Sweden, Germany and Denmark also produce and use considerable quantities, and peat is used locally in England and Scotland. Peat bogs are formed chiefly in temperate humid climates by the accumulation and partial decomposition of vegetable remains under conditions of deficient drainage. in which the immersion excludes air and prevents complete decay.

Winning of Peat.—A chief use of peat is as a domestic fuel, usually hand cut, although progress has been made in the excavation and spreading of peat by mechanical methods. In many bogs roots and tree trunks are found, but such obstructions do not necessarily preclude the successful application of mechanical winning. Peat is cut by spade in the form of blocks which are spread out on the bog to dry, and when dry weigh from three-quarters of a pound to two pounds each. In one method of machine winning a dredger or excavator digs the peat from the drained bog and delivers it to a macerater which extrudes the peat pulp through a rectangular opening; the pulp is then cut into blocks. which are spread upon the surface of the bog. After a meek or two these are collected into small piles or footings and after further drying are built in open order into small clamps. Maceration tends to more uniform shrinkage and a denser and tougher fuel; it also accelerates drying under unfavourable weather conditions.

Hydraulic excavating can also be used and is especially applicable to bogs containing roots and tree trunks, the peat being washed down by a jet of water under a pressure of about 150 lb. per square inch and the pulp run to a sump. There. after slight maceration, it is pumped to a draining ground in a layer about nine inches thick. which, after partial drying, can be cut up. Complete drying is effected in the usual manner.

Composition of Peat.—Peat varies from a light. spongy material mainly composed of sphagnum moss in the upper layers to a dense, brown, more humified substance at the bottom of thick bogs. In its natural state it contains 90% to 95% water, but by draining this may be reduced to 88% or 91%. The water ratio (the ratio of water to dry peat substance) of peat containing 95% water is 19:1, that of peat containing 90% water; 9:1. The latter will thus contain more than twice as much solid matter although its water content has only been reduced by 5%. The moisture may be reduced by: (1) air-drying; (2) evaporation by heat with partial heat recovery; (3) mechanical pressure; or (4) electrical osmosis. Many methods involving combinations of these have been tried. but air-drying is used in all schemes working on a commercial basis. By air-drying the water may be brought down to about 25%, the calorific value then being about 7.000 B.T.U. Peat thoroughly dried by heat takes up about 16% of water on exposure to air; it is thus useless to dry it artificially below this limit. The density of air-dried cut peat is about 0.5; that of macerated machine-cut peat is 0.85 to 1.0.

The ash in peat varies considerably, from about 1% to 8%. and usually increases with depth. The nitrogen likewise increases with the depth, from 1% to 2%. The proximate analysis of a good Irish peat, air-dried, may be taken as: moisture 20.2%; organic volatile matter 49.5%; fixed carbon 26.8%; and ash 3.4%. Peat burns readily with a smoky flame and a characteristic odour. The ash is powdery and light. except in certain varieties high in ash through the inclusion of sand, etc. Peat is used for domestic purposes and forms a fuel suitable for boiler firing in either the briquetted or pulverized form; it also has been used in gas producers, and the coke from carbonized peat forms a suitable fuel for small producers such as are sometimes used for motor-transport purposes.

5. Lignite.—It has been estimated that about 50% of the world's total coal reserves are lignitic. Being inferior in some ways to bituminous coal, these reserves have not been exploited to anything like the same extent. However, in some areas the growing urgency of the fuel problem led to extensive developments, especially in Germany, where the production of lignite has exceeded that of bituminous coal. Schemes for its utilization. particularly by hriquetting, have received attention in Australia, Canada, the United States. New Zealand and other countries.

Lignite is intermediate in properties between peat and bituminous coal, containing when dry about 60% to 75% of carbon and a variable proportion of ash. Raw lignite conforms to two types, brown or amorphous and black or pitchlike; it is characterized by a high water content, which may amount to as much as 60% in the brown varieties. Upon weathering, a proportion of this moisture is given up; and disintegration or crumbling of the material occurs, reducing its value as a fuel. Lignite tends also to disintegrate during combustion; hence the losses through a grate may be relatively high. It requires special care in storing, is uneconomical to transport long distances and is liable to spontaneous combustion. Against these drawbacks, many of the beds lie close to the surface and are of great thickness, sometimes more than 100 ft.; they are. therefore, easily worked, and the cost of production is low. (See also LIGNITE.)

6. Subbituminous Coals.—These coals are a gradation between lignitic and bituminous coals. They are noncoking, weather readily and have a B.T.U. value on a moist mineral matter-free basis of from 8,300 to 13,000. In general, such coals are utilized in about the same manner as noncoking bituminous coals but are more difficult to store.

7. Bituminous Coals.—A large variety of coals are included under the term bituminous. These coals have more than 14% volatile content on a dry mineral matter-free basis (which causes them to burn with a smoky yellowish flamej and in general resist weathering. The moisture content is lower than that of the subbituminous and lignitic coals, often being as low as about 3%. There are noncoking and coking varieties, the latter serving for metallurgical-coke manufacture. Such coals vary over a wide range in ash content, in hardness and in their tendency to heat spontaneously.

8. **Anthracite.**—Anthracites are characterized by their low percentage of volatile matter and high carbon content. Their lack of smoke production and relatively slow speed of burning make them particularly adaptable for domestic use. They are also used for steam raising and are often mixed with bituminous coals to reduce smoke production; they are blended in small percentages with coking bituminous coals for coke manufacture.

9. **Coke.**—When a raw carbonaceous fuel is distilled or carbonized by heating it in the absence of air, gas and tar vapours are evolved and a residue known as coke remains. The characteristics of a coke vary with the type of coal treated, the temperature and time of carbonization and the peculiarities of the plant in which the operation is carried out. Coke may, however. be broadly divided into two classes—metallurgical and gas. The former is the main product of the carbonization of coal at about 2.000° F. in coke ovens. the tar and gas obtained usually being considered as by-products. It is used for the reduction of iron ore and for various other metallurgical processes, its essential property being strength to withstand the heavy loads placed upon it in the blast furnace. The properties desired in coke are frequently obtained by blending coals having properties complementary to each other. At about 2.000° F. gas coke is also the most important by-product of carbonization of coal in vertical or horizontal retorts for gas manufacture. Its chief uses are as a metallurgical furnace fuel and in the production of gas. It is also used for steam raising and to a small extent for domestic fuel.

TABLE 11.—*Analyses of* ***Coke*** *Types*

Ingredient	Metallurgical coke	Gas coke: Horizontal	Gas coke: Vertical	Lon-tern-perature coke
Proximate analysis:				
Moisture	.7	.9	.6	2.0
Volatile matter	2.6		3.5	7.5
Fixed carbon	88.2	86.9	86.4	80.0
Ash	8.5	6.5	9.5	10.5
Ultimate analysis (dry coke):				
C	88.0	85.8	85.4	78.7
	.5	.6	.8	2.5
H	1.0	1.2	1.2	1.5
N	.9	1.9	1.8	1.0
S	.9	.6	1.0	j.6
Ash	8.7	9.9	9.8	10.7

Production of coke by carbonization at about 1,100° F. has attracted considerable attention This low-temperature coke retains about 10% to 15% of volatiles compared nith only 1% or 2% in gas or metallurgical coke. and so can be readily ignited, burning freely. It thus forms an excellent smokeless substitute for household coal but it is lighter and more friable than ordinary cokes. The gas yield is less from Ion-temperature carbonization than from high, but the tar yield is increased.

From one ton of coal the yields of coke vary widely; a rough approximation is as follows:

Metallurgical by-product coke	
Gas coke	1,300 to 1,400 lb.
Low-temperature coke	1,400 to 1,500 lb.

The analyses given in Table II are typical of cokes produced by the three methods under conditions of proper quenching. If the coke has been badly quenched or stored in the open the moisture will be much greater.

The physical characteristics of coke have an important bearing upon its suitability for different uses. The cell structure of coke appears to be due to the formation of bubbles during the fusion of certain portions of the coal substance and their subsequent perforation. Its exact nature depends largely upon the conditions of heating, the type of coal dealt with and the fineness to which it is ground before carbonization. Thus the dense coke made from finely divided coal of suitable coking properties consists of minute cells of uniform structure; but dense cokes can. be produced, even from strongly swelling coals, by blending or by pressure during carbonization.

In addition to the chemical tests already described, which are applicable to any solid fuel, certain special tests have been devised for investigating other properties of coke. Those most usually relied upon are determinations of specific gravity (apparent and true) and porosity. Strength is measured by the shatter test in which 50 lb. of two-inch screened coke are dropped four times from a height of six feet onto an iron plate and the proportion broken determined. Reactivity to carbon dioxide is also important.

10. Briquettes. — Fuels prepared from fines and dust by molding under pressure either with or without a binding material are called briquettes. Pitch and coal tar are the binders commonly used, the amount required depending upon the characteristics of the coal. usually somewhere between 6.5% and 10%. An expensive factor in the preparation of briquettes is the cost of binder; hence; materials such as clay, tar, crude oil, peat, silicate of soda, molasses: sulfite liquor, starch, etc., have been tried. Binders have also been prepared by the fermentation of waste straw, farmyard manure or seaweed; the last has the advantage of being smokeless but is difficult to make waterproof. In Europe large quantities of briquettes are made from lignite by pressure alone.

Briquetting offers a means of utilizing quantities of small coal which, though of good quality, is unsalable because of its fine size. Special processes are required for absolutely noncoking materials, such as anthracite fines, since these disintegrate on the fire through the melting out and burning of the binder. Germany occupies first place in the briquetting industry, using mainly brown coal; but briquetting is also carried on in France; Austria, the United States and Wales. Coal briquettes are used for domestic and industrial purposes; lignite briquettes, which do not stand transport well, are chiefly employed as household fuel in the neighbourhood of their manufacture.

Briquettes may be rectangular, varying in weight up to about 28 lb. Smaller egg-shaped or ovoid briquettes are produced in roll presses for domestic purposes. High-quality briquettes are uniform in composition and weight, of high calorific value, strong, waterproof and able to bear transport or storage without disintegration. Density is about 1.3, the same as that of lump coal. The ash content where pitch or a similar binder is used is less than that of the original coal, but when inorganic binders such as clay or lime are adopted the incombustible constituents of the binder are added to the ash of the coal. The calorific value is affected by the binder, but in pitch briquettes the calorific value is slightly greater than that of the raw coal.

Briquetting under pressure, either at ordinary temperatures or at temperatures high enough to cause incipient fusion of some of the constituents, is sometimes adopted as a preliminary process in the carbonization of blends of finely ground coal. It not only aids production of a homogeneous fuel but simplifies the retorting process. (C. H. L.; L. C. McC.)

11. Pulverized Coal. — When solid fuels such as coal are finely pulverized and suspended in air, they can be burned in much the same manner as atomized liquid fuels. The technique of burning pulverized coal progressed so rapidly after 1920 that by the second half of the 20th century this method of firing was universally employed for large furnaces such as cement kilns and central station steam generators. Attempts to burn pulverized coal at high rates in very restricted spaces, such as diesel-engine cylinders, locomotive fireboxes and marine boilers, met with little success because of the harmful effects of the ash inherent in all types of coal.

The burning rate of solid fuels depends primarily upon the amount of surface exposed to oxygen. A one-pound lump of bituminous coal (approximately 22 cu.in.) would have about 48 sq.in. of surface area. If the lump is pulverized until all of the fragments pass through a 200-mesh sieve (.0029-in. opening), more than 1,000,000,000 particles will result, and their surface area will exceed 50,000 sq.in. The lump would require many minutes to burn completely, whereas the pound of powder, suspended in approximately ten pounds of air and injected into a large, hot furnace, would burn in a fraction of a second.

The procedure of burning powdered coal includes: (1) pulverizing the coal; (2) conveying the pulverized coal to the furnace in a stream of "primary air"; (3) mixing the fuel with additional "secondary air" in a burner; and (4) blowing the mixture into the furnace where it is burned in suspension. Ignition is accomplished with an auxiliary oil or gas flame, which can be extinguished after the coal flame is established.

Since coal does not occur naturally in particles fine enough to be burned efficiently, it must be pulverized at some point between the coal seam and the furnace. Drying is also necessary in most applications, since wet coal is difficult to handle in bunkers, feeders and pulverizing mills. Drying and pulverizing are usually done at the point of use, because of the cost and complexity of transporting and storing powdered coal. The first successful installations, such as those at the Lakeside station of the Milwaukee Power and Light Co. (1924), used the bin-and-feeder system, in which the coal was dried, pulverized and stored in large bunkers from which it was conveyed to the furnace as required. Virtually all modern plants use the unit pulverizer system, in which the coal is dried and pulverized in the mill and conveyed to the furnace immediately by preheated air, thus eliminating the need for pulverized-coal collectors, bunkers, air cleaners, etc.

Many types of mechanical and pneumatic mills have been developed to pulverize lump coal by impact and attrition among the coal particles and the mill elements. Mechanical mills are almost universally employed because of their relatively low power consumption, 10 to 20 kw.hr. per ton of coal pulverized. The fineness required for good combustion depends largely upon the volatile content of the coal; increased fineness is required for low-volatility fuels. By proper choice of fineness, burner and furnace, coals of any volatile content, from anthracite to lignite, can be burned satisfactorily.

Pulverized coal burns with such intensely hot and radiant flames that ordinary refractory furnace linings must be replaced by specially cooled walls. In the early days of pulverized-coal firing, erosion or melting of firebrick linings was a major limitation. This difficulty was overcome by lengthening the flame path, increasing the furnace volume and circulating boiler feed water through the furnace walls. Modern steam generators with water-cooled walls burn more than 75 tons of coal and produce more than 1,500,000 lb. of steam per hour.

Ash, always present in coal to some extent, constitutes the major problem in pulverized-coal combustion. In a pulverized-coal flame, the ash exists in the form of tiny molten spheres, which freeze into fly ash as the flame is chilled below the ash-fusion temperature. If the flame impinges upon a surface, the spheres coalesce and become slag. In cement kilns, the ash is discharged with the cement, but in boiler furnaces the ash constitutes a nuisance which cannot be ignored. The fusion temperature of coal ash ranges from 1,800° to 2,900° F., depending upon the chemical analysis of its constituents. Coals with low ash-fusion temperatures are usually burned in "wet-bottom" furnaces, from which much of the ash is drawn off as molten slag. For coals with high ash-fusion temperatures, "dry-bottom" furnaces are used in which the ash is chilled and carried out of the furnace by the combustion gases. Precipitators are required to prevent the fly ash from being discharged to the atmosphere.

Pulverized-fuel firing has a number of advantages over other methods of burning solid fuel in large furnaces. Greater flexibility of fuel choice is a major asset, as is the fact that a powdered-coal furnace can also burn gas or heavy oil with little modification. Time required for starting up and shutting down is relatively short, and load changes can be made almost instantaneously. Since relatively little excess air is needed for complete combustion, and the air can be preheated to a high temperature, boiler efficiency is higher than with stoker firing. Finally, there is virtually no limitation on furnace capacity, since any desired number of mills and burners can be used to supply a single steam generator. (J. I. Y.)

B. Wood

1. Wood as a Fuel.—Although in industrial countries the use of wood as fuel has been almost entirely superseded by the use of coal, oil and gas, large quantities are still employed in less developed or outlying areas. Wood cannot be economically transported great distances by rail, and its use is generally contingent upon its being at hand more or less in a waste form, as, for example, in portions of woodlands unsuitable for timber. Large quantities of waste wood are produced in the process of converting timber into lumber; some of it is used for producing industrial power or for domestic purposes or is distilled for making charcoal, acetate of lime and wood alcohol.

The structural basis of wood is cellulose, of which the simplest form may be given as $C_6H_{10}O_5$. The composition of wood tissue has been expressed by E. Schultze and N. Schuppe as "an aggregate of cellulose and a lignone complex," $5C_6H_{10}O_5$, $C_{19}H_{18}O_8$ or, in percentage composition, C = 49.66, H = 5.74, O = 41.60. The water content of green wood ranges from 50% to more than 200% of the weight of dry fibre; in other words, wood may contain as much as two parts of water to one part of fibre, according to the species, the position in the tree and age. On air-drying this is reduced to about 15% to 20%, or still further by artificial drying. Dried wood, however, may under certain conditions reabsorb moisture.

Both the inflammability and the calorific value of wood are greater in the soft resinous varieties such as pine, fir and spruce than in hardwoods like oak and elm, the calorific value after air-drying varying from 6,500 to 9,000 B.T.U. per pound. The temperatures attained, however, are comparatively low because of the high moisture and hydrogen content. On this account raw wood is unsuitable for metallurgical operations, but before the days of coke manufacture large quantities of wood charcoal were used in the iron industry.

2. Charcoal.—Charcoal is the solid residue of the destructive distillation of wood. Formerly it was manufactured for smelting purposes by the charring process, in which large heaps of wood, covered with earth and turf and provided with flues, were set on fire and allowed to smolder until the volatile matter was completely driven off, no by-products being recovered. In many countries of Europe and Asia charcoal was still prepared in earth kilns into the second half of the 20th century. Where concentrated supplies of waste wood are available it is prepared in retorts. In such instances the charcoal becomes practically a by-product of the wood alcohol and acetic acid industries.

Charcoal is a brittle, porous material retaining the original shape of the wood while its microstructure preserves the vegetable cell structure. It is used for heating and coking and for cooking, in the U.S. especially for grilling, barbecuing, etc., out of doors; other uses are for the manufacture of gunpowder, absorbent and decolorizing agents and heat-insulating materials and for hop drying, casehardening steel, etc. (see also CHARCOAL). Good charcoal is deep black and breaks with a bright fracture. It rings when struck and burns without smoke. In the dry state the apparent specific gravity ranges from about 0.11 for a softwood to 0.20 for a hardwood. The true specific gravity of charcoal substance varies between 1 and 2. Charcoal is comparatively low in ash and ranges from 12,000 to 14,000 B.T.U. in calorific value. The charcoals prepared at low temperatures are exceedingly inflammable, imperfectly charred pieces often being used in Europe for kindling purposes.

C. Utilization of Solid Fuels

Because of the great differences in uniformity, composition and characteristics of the various solid fuels and of any individual type of solid fuel, the problem of efficient utilization has involved years of technological study of composition and structure, experimental work and development of equipment. Tests on quantities from one gram to thousands of tons have been made. From this work, besides knowledge of the fuel, many different types of equipment and operating procedures have been evolved. This work has had a great impact on the commercial movement of fuel, its proper choice, specifications and methods of purchase and the relative competitive position of the various types. Since the actual amount of heat that can be produced and utilized is usually the main objective, the B.T.U. value of a fuel is given prime consideration. However, other characteristics have great bearing on how much of the heat produced can be utilized and also on how rapidly the heat can be produced.

The annual world production of bituminous coal, anthracite and lignite was more than 2,000,000,000 tons in the 1950s. An idea of its relative consumption by different users in a large industrial country can be gained from the following statistics on use of coal in the United States. These figures are fairly typical, although the proportions vary from year to year: electric power utilities 33%; coke plants 25%; other industries 22%; retail deliveries 13%; railroads 4%; cement mills 3%; steel and rolling mills 1%.

1. The Combustion of Solid Fuel.—The combustion of a solid carbonaceous substance is an exceedingly complex process, taking place in several stages and involving the interaction of gases, water vapour and solid carbon. The theoretical amount of air necessary to burn a fuel completely to carbon dioxide and water vapour can be calculated from a knowledge of its ultimate analysis by the use of the equations: (1) $C + O_2 = CO_2$; and (2) $2H_2 + O_2 = 2H_2O$. From (1) it follows that 12 lb. of carbon will require 32 lb. of oxygen and from (2) that 1 lb. of hydrogen will require 8 lb. of oxygen for complete combustion; thus, to burn the carbon and hydrogen in 1 lb. of coal of composition

$$C = 73.1\%,\ H = 5.5\%,\ O = 8.7\% \quad (\text{net } H = 5.5 - \frac{8.7}{8} = 4.4\%)$$

will take $\frac{0.731 \times 32}{12} + 0.044 \times 8 = 2.30$ lb. of oxygen or about 9.9 lb. of air.

In a similar manner, the percentage of carbon dioxide in the flue gases corresponding to the theoretical proportion of air can be calculated. The equations, however, tell nothing regarding the manner in which gases are given off from the raw material and interact among themselves and with oxygen and water vapour before the final products of complete combustion are formed. The mechanism of combustion is still a matter for research.

A complex mixture is involved, containing simple gases, such as hydrogen and carbon monoxide, in addition to molecules of greater complexity which are less directly acted upon by oxygen than the simpler ones. The combustion of the heavier hydrocarbons presents great difficulty, since the action of heat causes them to form still denser aggregates. Even the combustion of such a comparatively simple gas as methane (CH_4) was shown by Bone to proceed in stages involving the entry of successive atoms of oxygen. Methyl alcohol is first formed, but this is subsequently oxidized to an unstable compound which breaks up into formaldehyde and steam. Under certain conditions of slow combustion further stages are involved before complete oxidation is effected, but under high-temperature conditions the formaldehyde is decomposed into carbon monoxide and hydrogen, which then burn directly to carbon dioxide and steam.

In the lower layers of a fuel bed, it is not definitely known whether solid carbon burns directly to carbon dioxide or whether it proceeds first to carbon monoxide (CO) and so to carbon dioxide (CO_2). Three possible reactions are involved:

$$C + O_2 = CO_2$$
$$C + \tfrac{1}{2}O_2 = CO$$
$$CO_2 + C = 2CO$$

An older theory held that the carbon mas first burned to carbon dioxide which was subsequently reduced to carbon monoxide by contact with heated coke. Later studies indicate that carbon monoxide is the initial product.

By circulating air or oxygen at temperatures from 100° to 900° C. over purified nood charcoal, T. F. E. Rhead and R. V. Wheeler were led to the conclusion that CO, and CO are formed simultaneously from an unstable physicochemical complex, C_xO_y, which is the first product of the action of oxygen on carbon (see CARBON, OXIDES OF). Irving Langmuir's experiments appear to show that the first gaseous product of the interaction between carbon and oxygen is carbon dioxide, as he was unable to detect the presence of carbon monoxide. On passing upward the two oxides, in the presence of carbon, react upon each other in accordance with the reversible reaction $C + CO_2 \rightleftharpoons 2CO$; the final products are formed in definite relative proportions that depend upon the conditions, such as temperature and concentration of the various gases present, and also upon nhether enough time has elapsed for equilibrium to be established. In the reaction quoted above, equilibrium is established at 8j0° C., when the percentages of CO_2 and CO are 6.23 and 93.77, respectively. and at 1,200° C., when they are 0.06 and 99 94. Cnder perfect fuel-bed conditions the gas leaving the incandescent bed will thus be composed almost entirely of carbon monoxide. With coal firing this carbon monoxide is consumed. nith the gases of distillation, by the secondary air; but even a coke fire, although smokeless, may give off carbon monoxide if the supply of secondary air should be deficient or badly distributed.

When a raw carbonaceous material is burned, it must first be heated to the point of decomposition. The gases evolved at this stage vary in composition but consist chiefly of hydrocarbons, hydrogen. carbon monoxide, water and tarry vapours, mixed with a certain amount of solid carbon in a finely divided state. As the combustion proceeds, the fuel is freed from volatile matter and converted into coke.

Distillation takes place in the upper layers of an ordinary fuel bed, and to burn the gas and smoke secondary air must be supplied at some point above the fire bed. The solid coke burns in the loner portions of the fire, primary air for this purpose passing through the bed from under the grate. Thus, combustion of both solid carbon and volatile matter is involved. Special devices are sometimes used to force the volatile products through the incandescent coke; for example, by downdraft in which the flue gases are drawn anay below the grate or by downward combustion in which the raw fuel is introduced at the bottom of the fire. In practice, air in excess of that theoretically necessary for complete combustion is required. In best boiler practice 20% of excess air is about the minimum necessary to ensure absence of smoke and fairly complete combustion. Too much air is undesirable, since by cooling donn the gases it may retard combustion, aggravate the production of black smoke and increase heat losses. Best furnace conditions are obtainable with mechanical methods of continuous firing in which the air supply is under more exact control than can be obtained when the firing door has to be opened frequently for hand charging.

2. Solid Fuel for Domestic Purposes.—The manner of use of solid fuels for domestic purposes, such as heating. hot water and cooking, varies widely according to climate and custom. All types of such fuel are used. In Great Britain, nhere extremes of temperature are rare but rapid changes common, the open-grate fire persists. but to cope with the more severe winters of parts of North America and Europe, closed stoves or central heating are widely used. There are many types of fireplaces and central-heating furnaces. Solid fuels are hand fired to some extent, but automatic fuel-burning equipment for central heating is preferred by many householders. Some of this equipment has been developed to feed the fuel from the bin. automatically controlling the fire and depositing the ashes into a container.

3. Solid Fuel for Industrial Purposes.—All types of solid fuel are burned for industrial purposes. Automatic fuel-burning equipment permits great saving in fuel and labour. Such equipment for burning coal takes many forms, depending upon the quantity of fuel to be burned per hour and many other factors. such as the fuel most cheaply available, the size and type of the boiler. load conditions, the area in which the plant is located and the type of labour available. Types of equipment include traveling-grate stokers, underfeed stokers, spreader stokers, cyclone furnaces and pulverized-fuel-burning equipment (see also Pulverized Coal, above). Stokers using bituminous coal usually burn slack coal which is run-of-mine coal with the larger sizes removed; under some conditions, particularly with the smaller stokers, small-sized coal nith the fines removed is used. The largest boilers use the cyclone furnace or pulverized-fuel-burning equipment. Coal for the cyclone furnace, a furnace where burning takes place in a relatively small cylindrical furnace, is ground to pass a small-size screen. Coal for pulverized-fuel-burning equipment is ground to a fine powder and burns somewhat as a gas does.

4. The Blast Furnace.—Coal and coke are used not only for heat production but also for chemical purposes, such as the smelting of iron ores. where carbon effects the removal of oxygen. so producing metallic iron. The process is an ancient one, but until the middle of the 18th century the fuel used was charcoal. By far the greater proportion of smelting furnaces have. however, adopted coke. The blast furnace in which pig iron is produced consists of a hollow shaft with an internal diameter increasing from the top and bottom to the centre. At the bottom is a hearth upon nhich the superincumbent column of coke and iron ore rests. The exact lines of a blast furnace are important and vary with the types of ore. Heated air under pressure is blown in through tuyères (nozzles) in the lower portion of the furnace.

The ores used may be either oxides or carbonates of iron. The reactions occurring are complex. In the lower portion of the furnace near the tuyères the fuel is burned by the blast to carbon monoxide, nhich effects the reduction of the ore in the upper portion of the shaft where spongy iron impregnated with carbon and carbon monoxide is produced in a series of reactions of which the following is the resultant: $Fe_2O_3 + 3CO = 2Fe + 3CO_2$ (ferric oxide and carbon monoxide react to form iron and carbon dioxide). This spongy iron is melted as it passes through the lower layers and can be drawn off from time to time through tapping holes. Limestone is added to the charge to assist in fluxing.

Blast-furnace practice mas greatly influenced by the work of Sir Lowthian Bell, who in 1872 applied the laws of mass action to the reactions in the blast furnace and came to the conclusion that the practical limit for the ratio of CO to CO_2 in the gases leaving the furnace could not be reduced below 2:0. In modern blast furnaces a ratio of 1:7 has been reached, but in average practice a ratio of 3.0 is more common. Bell's argument, however, remains valid, although imperfections in scientific measurement affected the accuracy of his calculation. It will thus be seen that fuel economy in iron and steel practice depends essentially upon finding uses for the combustible gases (having about 90 to 100 B.T.L.) uhich are necessarily rejected in large quantities from the shaft. These may be used either for heating the blast or for power and heat requirements in the subsequent treatment of the pig iron. Concentration of coke ovens, blast furnaces and steelmaking in the same works permits the fuel consumption per ton of finished steel to be reduced to a minimum, from 2,000 to 2.600 lb. of coal per ton of finished steel. (See also BLAST FURNACE.)

III. LIQUID FUELS

Liquid fuels made from vegetable oils, animal oils and petroleum were used in ancient times to provide light and sometimes heat. They were so used to a limited extent until early in the 19th century, when the sperm-oil lamp came into wide use. Whaling fleets provided the supply of oil for several years, but needs increased beyond the ability of whalers to supply them. The modern oil industry began about 1847, when James H. Young took out a patent for making oil from oil shales, or oil rocks, in Scotland. By 1859 numerous companies in continental Europe, England and the U.S. were producing illuminating oil (coal oil) from shale, from coal and from petroleum found in seepages. In 1859 the United States saw the beginning of the petroleum era in the drilling of an oil well in Pennsylvania. The rapid development of the petroleum industry stopped most production of oil from shale and coal, although some was obtained from these solids in the second half of the 20th century in a number of places including Scotland, Europe. Africa and South America. The quantity is insignificant in total volume when compared with liquid fuels from natural petroleum.

A. Petroleum

Natural petroleum, or crude oil, as it is widely known, is the basis of practically all industrial liquid fuels. The advent of internal-combustion engines and motorcars meant an ever-increasing demand for fuels. The availability of the heavier portions of crude oil at a cheap price fostered their use for heating purposes. Lubricating oils for all kinds of machinery also come from crude oil.

Petroleum is a mixture of hundreds of different hydrocarbons—compounds composed of hydrogen and carbon—together with small amounts of other elements such as sulfur: oxygen and nitrogen. The carbon content of most crude oils varies from 84% to 88% by weight, hydrogen from 11.5% to 14.5% and the total minor constituents from 0.5% to 4.5%.

Petroleum, usually associated with water and natural gas, is found in voids or open spaces in porous sedimentary rock where the geological formation is such as to allow the oil to collect from a wide area. Impervious rock usually overlies the petroleum-containing formation in the form of an anticline (concave downward), with natural gas above the oil and dissolved in the oil and water below the oil. Other oil deposits occur in other kinds of formations in sedimentary shales, limestones and sandstones.

Recovery of crude oil through oil wells never reaches 100% of the oil present in the formation. Some fields yield only 20% of this oil, others will produce 50% or more of the oil in place, and injection under pressure of air, gas or water in certain instances can allow production of more oil than the oil field could ever produce naturally. Some heavy, thick oils will not flow through wells to the surface and can be recovered by mining, as is done in a number of countries; *e.g.,* France. Oil is produced in more than 51 countries throughout the world.

1. Petroleum **Resources.**—World production of crude petroleum was in excess of 7,000,000,000 bbl. of 42 U.S. gallons annually by the end of the 1950s, continuing the steady increase shown in nearly every year since 1859. The United States was producing about 37% of the world total, followed by the middle east countries (combined). Venezuela and the U.S.S.R. Other important producers were Canada, a newcomer to the large producing areas, Mexico, Indonesia, Columbia, British Borneo and Argentina. Estimates of the amount of oil already discovered and available for production continue to increase from year to year. When the cost of finding and producing petroleum becomes too high, oils can be produced from oil shales, oil sands and coal in quantities greater than the present known resources of petroleum.

2. Preparation of Fuel Oils.—In the early days of oil, the average refining plant made only a few products and processed only about 100 bbl. of crude oil a day. A large modern refinery can handle 400,000 bbl. a day and can furnish more than 1,000 separate products. Few refineries handle less than 10,000 bbl. a day. The larger plants are huge and complex and cost many millions of dollars to build. The principal products are few in number but account for more than 95% of the total. These are gasoline (motor spirits or petrol), kerosene, distillate fuels, residual fuel oils. lubricating oils and asphalt. Gasoline remains the big volume product, accounting for 40% of total refinery output. Kerosene and the distillate fuel oils take about 25%, with another 25% in the heavy residual fuels. Lubricating-oil requirements are satisfied with less than 2% of the total production.

Crude oil, after some preliminary treatment to remove water and other undesirable substances such as sulfur, is fractionated by distillation in the refinery into portions according to a distillation temperature range, leaving an undistilled portion as a residual. Some of these fractions are used directly as the finished product but most of them are subjected to additional refinery processes.

The heavier distillates can be cracked by heating to high temperatures to yield gasoline fractions or can be catalytically cracked or reformed by passage at elevated temperatures over catalysts, generally solid particles that hasten and direct the change of the heavier hydrocarbons into lighter and more volatile hydrocarbons. The residual material likewise can be cracked to produce more desirable materials and coke; it can be used directly as industrial fuel oil or certain types can be treated to produce asphalt (used principally for road or highway surfaces). The ultimate goal of the refinery is the production of tailored products of the highest quality in the proper amounts according to seasonal demand. Gasoline production decreases and fuel-oil production for heating increases in winter.

Most countries have adopted standard specifications for all types of petroleum products, including seasonal variations to ensure proper fuels at the proper times. International co-operation in fixing these standards ensures, as an example, that airplanes can refuel anywhere in the norld with assurance of uniform quality of product.

The gross calorific value of fuel oils ranges from about 18,500 to 20,000 B.T.U. per pound. The calorific value varies according to the hydrocarbon type composition. so that an oil of high specific gravity and comparatively low calorific value may produce more energy per unit volume than one of low specific gravity and high calorific value. Where storage space is at a premium. as in airplanes, the high-specific-gravity fuels may be the more desirable. Calorific value is related almost directly to specific gravity.

The flash point of an oil is the temperature at which, under specified conditions, a momentary flash is produced when a flame is passed over the oil surface. Gasolines have flash points below atmospheric temperatures. Standards and laws generally set a minimum flash point of 125° F. for distillate fuels and burner oils. Kerosene, the lighter burner oils and diesel fuels for light diesel equipment, such as buses, have flash points of 125°–130° F. The medium-weight burner oils and diesel fuels for heavier moving equipment and for railroad diesel engines have flash points near 145° F., and the heavier oils range upward in flash point from 170° F. The temperature of a liquid fuel that will vaporize enough oil to support continuous combustion. known as the fire point, is generally about 20° F. higher than the flash point.

The viscosity of oil, which changes rapidly with temperature, is determined by its resistance to flow as measured by the amount passing through a standard orifice in a prescribed time. The formation of solid paraffins or waxes may cause difficulty in pumping oil through pipes at low temperatures. Some crudes and fuels even at atmospheric temperature must be preheated to reduce their viscosity to allow ready atomization in the burner.

Further information on petroleum production and resources will be found under Petroleum.

B. Substitute Liquid Fuels

Several processes are feasible for converting solid and gaseous fossil fuels to products that are interchangeable with liquid fuels of petroleum origin. Although large plants have been built, they have not always been commercially successful, especially where petroleum is plentiful. However, interest in such processes is increasing, not only for supplying motor fuel for certain areas or for emergency use, but also as sources of organic chemicals.

1. Carbonization.—Destructive distillation at low temperatures of solid fuels (coal. lignite, oil shale, tar sand, gilsonite) yields crude tars and oils that may be converted to liquid fuels. Carbonization processes recover only about 15% of the total energy of coal in producing 20 gal. of crude oil per ton, compared with the recovery of about three times as much energy and up to

80 gal. of crude oil from other methods described below. Thus, low-temperature carbonization of coal is more efficient for producing combustible gases and by-products other than liquid fuels.

Commercial distillation of oil shale was first practised in France (1838), followed by Scotland (1850), Canada (1860) and Australia (1865). Industrial shale retorts are operated in France, Germany, China, the U.S.S.R., Scotland, South Africa and Sweden. The oil yield from shales in these countries varies between 10 and 130 gal. per ton. Highly mechanized underground mining procedures, applicable to massive deposits, have been developed in the United States. Crushed shale is fed into retorts that crack the organic material (kerogen) with gas or steam at 350° to 500° C. to produce crude oil similar in character to petroleum but containing higher percentages of sulfur, nitrogen and oxygen. Underground retorting, without mining except for preparing adits, also has been practised. Finished products are refined, by methods similar to those developed for treating petroleum, for use in internal-combustion engines. Sulfur and nitrogen compounds and waxes are valuable by-products, and the spent shale may be used in building aggregates.

2. Gas Synthesis.—A mixture of hydrogen and carbon monoxide (synthesis gas) may be reacted catalytically to make predominantly liquid fuels, combustible gas, waxes or organic chemicals. The synthesis gas may be made by reforming methane (CH, from natural or refinery gases), but large-scale installations normally gasify coal with steam according to the water-gas reaction, $C + H_2O \rightleftharpoons CO + H_2$. A number of methods have been studied, of which the Fischer-Tropsch synthesis and its variants have received the greatest attention. In this process synthesis gas at about 230° to 330° C. and 1 to 20 atm. is contacted with a suitably prepared catalyst that may contain predominantly cobalt, nickel or ruthenium, although iron is the usual major constituent. Fixed beds of catalyst (dry or submerged in oil), slurries of fine catalyst in oil and fluidized beds have been used, the main engineering problem being quick removal of the heat of reaction. In isosynthesis, a German laboratory development of World War II, the same gas is passed over metal oxides (for example 85% thoria and 15% alumina) at 400° to 450° C. and 300 to 600 atm. to produce primarily isobutane and isobutene, raw materials for aviation gasoline.

3. Coal **Hydrogenation.**—F. Bergius first investigated a process of adding hydrogen to coal at elevated temperatures and pressures. thus splitting the coal molecules and adding enough hydrogen to increase the hydrogen-carbon ratio of at least a fraction of the coal to that prevailing in petroleum. As carried out on a large scale in Germany before the end of World War II, coal hydrogenation consisted of two steps: (1) liquid-phase hydrogenation at about 200 atm. and 450° C. of a coal and oil paste to which a catalyst (usually a compound of tin or iron oxide) was added; and (2) vapour-phase hydrogenation of middle oil—the major product from the first step—under similar conditions of pressure and temperature on a bed of catalyst such as molybdenum sulfide, tungsten sulfide or (later) ammonium sulfomolybdate impregnated on a carrier. Later, hydrogenation in a single step at about 510° C. and also in a fluidized bed of coal at only 60 atm. were studied in laboratory equipment. A commercial plant in West Virginia adopted a modification of the liquid-phase process as a source of aromatic chemicals. Hydrogenation of U.S. bituminous coal making primarily gasoline yields about 4.3 bbl. of gasoline and 0.8 bbl. of liquefied petroleum gases per ton of moisture- and ash-free coal.

C. Utilization of Liquid Fuels

Liquid fuels derived from petroleum may be utilized either by combustion in furnaces or to produce energy directly in the cylinders of internal-combustion engines. Both light and heavy oils are applicable to the internal-combustion engine; the former can be ignited by a flame or spark while, with heavier oils, vaporization and ignition are effected by the high temperature developed on the compression stroke.

In furnaces oil must be changed from the liquid to the gaseous state before actual combustion. In general, a mixture of heavy and light gaseous hydrocarbons is formed and for smokeless combustion these must be brought into contact with a large enough supply of air to allow complete burning at the best efficiency. It requires 18 to 20 lb. of air per pound of fuel oil to burn the oil. best results generally being obtained when 10% to 20% excess air is used.

1. Oil Burners.—Oil-burner types are classified as vaporizing or atomizing. Each of these types can be used with a natural air draft or with a mechanical forced-air draft. Domestic burners for home heating use the light distillate oils and can be manually or automatically controlled. Commercial burners for space heating in commercial buildings, apartment houses and the like use the light and middle distillate oils—sometimes the residual oils. Industrial burners for industrial or power steam generation ordinarily use any heavy grade of oil to supply the heat. In many industrial installations the burners are designed to be fired with coal or oil or even with coal, oil or gas. This allows the choice of the most economical fuel from year to year.

Mechanical draft burners use a fan or blower to supply the air needed for combustion and can be of the vaporizing or the atomizing type.

Atomization breaks the fuel into fine particles that mix with the combustion air, giving a clean flame and good burning. Atomization allows the use of heavier, cheaper grades of fuel oil and is well adapted to large industrial burners, although it does require power to produce the atomizing and first costs are comparatively high. Some burners use steam to assist atomization because of simple design requirements, low installation cost, ability to use heavy oils and flexibility of operation.

2. Advantages of Liquid Fuels.—Liquid fuel has many advantages over solid fuel. It weighs about 30% less per unit volume than coal and occupies only 50% of the space required for an equivalent amount of coal. Liquid fuels are usually readily available. can be stored conveniently, produce high heats in less furnace space, begin to burn instantly and cleanly, require little or no ash removal and need relatively little attention. For marine use, these and other advantages are readily apparent.

3. Fuels for **Light** Internal-Combustion Engines.—Motor gasolines are rather complex mixtures of light-hydrocarbon blending stocks tailored for best utilization in all motorcars in all seasons and climates. The refiners change the characteristics to fit these requirements. Motor gasolines distill within the temperature range of 100° to 400° F. Aviation gasolines are simpler blends of high-octane-number stocks produced to rigid specifications and boil in the 100° to 325° F. range. Four grades supply the requirements of virtually all conventional aircraft. These four grades are based on the octane-number requirements of the various aircraft engines. Fuels for jet turbine engines boil in the 100°–600° F. range and have no octane-number requirement.

The above fuels) except for the jet turbine, are vaporized more or less completely and mixed with air in their passage through carburetors in the engines, and are distributed to the individual engine cylinders through suitable manifolds. The efficiencies obtained in these internal-combustion engines are a function of compression ratio, engine design and fuel characteristics. "Knocking" in such engines indicates some unbalance in the three factors indicated above and generally results from too low an octane number in the fuel used. After the 1920s octane numbers for motorcar gasolines increased from about 50 to more than 90. Small quantities of the metallo-organic compound tetraethyl lead (one to three millilitres per gallon) are used to achieve part of this increase in octane number; the rest has come through improved refining processes. *(See* also Gasoline.)

4. Liquid Fuels for Heavy Engines.—The diesel engine, unlike the gas or gasoline engine, draws in air during the suction stroke without mixture with oil. Oil is injected mechanically in the form of a spray and mixes with the air already in the combustion chamber; the resultant mixture is ignited from the heat generated by the compression stroke of the engine. The diesel engine is the most efficient liquid-fuel engine. Modern developments in metal strengths and engine design allowed increased use of diesel engines in buses, trucks and small prime movers; diesel-engine

application by railroads led to sharply decreased operating costs. Such engices are ideal for marine installations and many large stationary engine requirements. Stationary diesel equipment can be designed to use either oil or gas or a combination as economics dictates.

Standard specifications in world-wide use allow refiners to satisfy 90% of fuel requirements with not more than four grades of diesel fuel. Fuel composition and boiling range, plus cetane number, are important fuel' characteristics. Cetane number is a measure of the time required for the fuel to ignite after fuel injection. A short delay period is indicated by a cetane number from 40 to 70, a long delay by a cetane number below 40, on an empirical scale from 0 to 100. Most engines operate satisfactorily on fuels in the 40 to 50 cetane-number range. The boiling range for the light distillate oils is 350° to 550° F., for the medium diesel oils 370° to 650° F. and for the heavier fuels 400° to 700° F.

IV. GASEOUS FUELS

A. Types of Gaseous Fuels

Before final combustion all liquid and most solid fuels are first converted to the gaseous state. In this section fuels that already exist as gases at room temperature and atmospheric pressure will be considered separately. Gaseous fuels are composed of one or more simple gases in varying proportions and may also include some inert gases and oxygen. The simple combustible gases are most commonly hydrogen (H_2). carbon monoxide (CO), rntthane (CH_4), ethane (C_2H_6), ethylene (C_2H_4), propane (C_3H_8), propylene (C_3H_6), butane (C_4H_{10}), butylene (C_4H_8), benzene (C_6H_6) and acetylene (C_2H_2); the inert gases are generally carbon dioxide (CO_2) and nitrogen (N_2). As the once important use of gas for illuminating purposes lost its significance, the development of gas cooking and heating made calorific value by far the most important criterion for evaluating gaseous fuels. The most common commercial gases are described below more or less in the order of increasing calorific value.

1. Blast-Furnace Gas.—In blast-furnace operations a gas is derived from the various reactions occurring throughout the furnace. The principal combustible constituent is carbon monoxide, resulting from the partial combustion of the coke in accordance with the reaction: $2C + O_2 = 2CO$. The gas contains relatively high percentages of inert gases. Depending on the quality of the coke, as well as on the other materials charged to the furnace, the gas may range in calorific value between 90 and 110 B.T.U. per cubic foot. A typical percentage composition of the gas is: CO_2, 11.5; H,, 1.0; CO, 27.5; and N_2, 60.0; with a gross calorific value of 92 B.T.U. per cubic foot and a theoretical flame temperature of 2,650° F. with no excess air. A modern blast furnace producing 1,000 tons of iron a day and consuming 1,800 lb. of coke per ton of iron produces about 127,000,000 cu.ft. of gas a day. Because it has the lowest heating value of all commercial gases. blast-furnace gas cannot be economically transported long distances. Accordingly, it is used in the steel mills for preheating the air required for the blast, as fuel for driving the blowers, underfiring the coke ovens. generating steam, heating the soaking pits and other miscellaneous purposes.

2. Producer Gas.—Outside of the steel mills, producer gas is perhaps the cheapest to manufacture for many industrial purposes. It is produced by blowing air or a mixture of air and steam through an incandescent fuel bed, which may be composed of coke, coal, lignite, peat or wood. When air alone is blown through incandescent carbon, the principal reactions are $C + \frac{1}{2} O_2 = CO$, $CO + \frac{1}{2} O_2 = CO_2$ and $CO_2 + C = 2CO$. For each volume of oxygen, 3.76 vol. of nitrogen are introduced with the air. If all of the carbon dioxide were converted to carbon monoxide, the resulting gas would be composed of CO, 34.5% and N_2, 65.5% and would have a maximum calorific value of 110 B.T.U.per cubic foot. In practice complete conversion of carbon dioxide to carbon monoxide does not take place and the gas, sometimes referred to as Siemens's gas, generally has a lower calorific value. This, coupled with operating difficulties frequentiy encountered by the excessive liberation of heat, is a serious disadvantage. As the reaction of incandescent carbon mith steam according to the equations $C + H_2O = CO + H_2$ and $C + 2H_2O = CO_2 + 2H_2$ absorbs heat, a sufficient quantity of steam is added to the air so that the heat liberated by the carbon-oxygen reactions is balanced by the carbon-steam reactions. A secondary reaction of considerable importance in producer-gas operation is $CO + H_2O = CO_2 + H_2$.

The quality of the gas depends largely on the kind of fuel charged to the producer and ranges from 120 to 180 B.T.U. per cubic foot. Typical percentage compositions of producer gas are as follows. With buckwheat anthracite, CO_2, 8.0; O_2, 0.1; CO, 23.2; H_2, 17.7; CH_4, 1.0; and N_2, 50.0. The gross calorific value is 143 B.T.U. per cubic foot and the theoretical flame temperature 3,040° F. With bituminous coal, CO_2, 4.5; O_2, 0.6; CO, 27.0; H_2, 14 0; CH_4, 3.0; and N_2, 50.9. The gross calorific value is 163 B.T.U. per cubic foot and the theoretical flame temperature 3,175° F. With coke, CO_2, 6.4; O_2, 0.0; CO, 27.1; H_2, 13.3; CH_4, 0.4; and N_2, 52.8. The gross calorific value is 135 B.T.U. per cubic foot and the theoretical flame temperature 3,010° F.

Producer gas. because of its low calorific value, cannot be transported economically over any appreciable distances. Its use is therefore generally for industrial operations, such as for underfiring coke ovens, heating open-hearth furnaces, glass-melting furnaces, lime kilns, brick kilns, ceramic kilns and the like, where the producer plant is integrated with the industrial plant.

3. Blue Gas or Water Gas.—Blue gas or water gas is produced by alternately blasting an incandescent fuel bed with air and with steam. The respective reactions between the carbon and air and the carbon and steam are similar to those taking place in producer-gas operation but follow each other cyclically instead of occurring simultaneously. The cycle is balanced so that the heat liberated during the air blast and stored in the fuel bed is enough to provide the heat absorbed during the steam blast. The gases produced during the air blast, containing the nitrogen admitted with the air, are discharged to the atmosphere, while the gases generated during the steam blast provide the useful fuel gas. Depending on the character of the fuel, blue gas ranges in calorific value from 285 to 335 B.T.U. per cubic foot. A typical blue gas produced from coke has a percentage composition of CO_2, 5.4; O_2, 0.7; CO, 37.0; H_2, 47.3; CH_4, 1.3; and N_2, 8.3. The gross calorific value is 287 B.T.U. per cubic foot and the theoretical flame temperature 3,670° F. Blue gas may also be produced in continuous operation by substituting oxygen for air in gas producers. This results in a producer gas that is practically nitrogen-free. Blue gas as a fuel is used industrially in large manufacturing establishments for heating in forge-welding operations, but the major uses of blue gas. without enrichment, are as synthesis gas for the production of ammonia and methanol and other chemical operations.

4. Carbureted Water Gas.—For domestic and commercial cooking and heating, blue gas or water gas is usually enriched with hydrocarbon gases produced by thermal cracking of oil which takes place simultaneously mith the blue-gas production. The principal components of a carbureted water gas machine are the generator, carburetor, superheater and wash box or seal. The blue gas is produced in the generator. During the air blast the gas leaving the generator is burned in the carburetor arid superheater to heat the malls and checker-brick provided for storing the heat. As the products of combustion leaving the superheater retain an appreciable quantity of heat, they may be passed through a waste-heat boiler for steam generation. or they may be discharged directly to the atmosphere. During the steam blast. oil is vaporized in the carburetor and partly cracked in the stream of blue gas flowing frorn the generator, and the mixture then flows through the superheater in nhich the hydrocarbon vapours are fixed—that is, converted to permanent gases—and finally through the wash box or seal to a gasholder. Depending on the availability of natural gas or liquefied petroleurn gases, the heating value of blue gas is frequently increased by what is known as cold enrichment by mixing with these gases in their normal state. The degree of enrichment of carbureted water gas is controlled by the relative amount of oil, natural gas or liquefied petroleum gas used under the particular conditions of operation. The calorific value of carbureted water gas ranges from 425 to 57j B.T.U. per cubic foot. A typical per-

centage composition of carbureted water gas is CO_2, 4.3; C_2H_4, 4.7; C_6H_6, 2.3; O_2, 0.7; CO, 32.0; H_2, 34.0; CH_4, 15.5; and N_2, 6.5. The gross calorific value is 534 B.T.U. per cubic foot and the theoretical flame temperature 3,700° F. Carbureted water gas is widely distributed in city gas mains for general use either alone or in a mixture with other gases with which it is interchangeable.

5. Coal Gas.—Coal gas is produced by destructive distillation of bituminous coal, during which it is heated in retorts in the absence of air. Coal-gas retorts vary considerably in design and may be horizontal, inclined or vertical.

The quality and yield of gas vary with the type of coal, the temperature and time of carbonization, the type of retort and other factors. A typical gas from horizontal retorts has the percentage composition: CO_2, 2.4; C_2H_4, 1.32; C_6H_6, 1.73; O_2, 0.75; CO, 7.35; H_2, 47.95; CH_4, 27.15; and N_2, 11.35. It has a gross calorific value of 542 B.T.U. per cubic foot and a theoretical flame temperature of 3,600° F. Vertical retorts are often operated with the introduction of steam for the purpose of producing blue gas by the reaction with the hot coke. This in effect cools the coke before discharging and provides a larger yield of gas, although the calorific value of the gas is lower than that of straight coal gas. A typical percentage composition of gas from steamed vertical retorts is: CO_2, 3.0; C_2H_4, 1.5; C_6H_6, 1.3; O_2, 0.2; CO, 10.9; H_2, 54.5; CH_4, 24.2; and N_2, 4.4. It has a gross calorific value of 532 B.T.U. per cubic foot and a theoretical flame temperature of 3,645° F.

6. Coke-Oven Gas.—This is gas produced by the distillation of bituminous coal (see COKE, COKING AND HIGH-TEMPERATURE CARBONIZATION). A typical coke-oven gas has the percentage composition: CO_2, 2.2; C_2H_4, 3.5; C_6H_6, 0.5; O_2, 0.8; CO, 6.3; H_2, 46.5; CH_4, 32.1; and N_2, 8.1. It has a gross calorific value of 574 B.T.U. per cubic foot and a theoretical flame temperature of 3,610° F. The distillation products leaving the coke ovens are drawn through hydraulic mains and coolers by exhausters and passed through tar extractors. saturaters, light-oil scrubbers, purifiers and other equipment designed for successively removing the tar, ammonia, light oil and sulfur compounds. (See also COAL TAR.) The specific procedures for the recovery of individual constituents vary from plant to plant.

7. Oil Gas.—Gas may be made entirely from the cracking of oil by innumerable methods and variations of equipment. A typical method of producing oil gas employs cyclic operation. in which oil atomized by steam is sprayed on previously heated checker-brick, where the oil is cracked and the steam reacts with some of the deposited carbon to form water gas, the resulting mixture being similar to carbureted water gas. The checker-bricks are heated by the combustion of oil with an excess of air, which also consumes the carbon that failed to react with the steam. This method permits the production of gases having a very wide range of calorific values. 525 to 1,100 B.T.U. per cubic foot. The operation can therefore be adjusted to produce gas which may be interchangeable with carbureted water gas, coal or coke-oven gas or natural gas. Oil gas may also be produced by catalytic cracking methods either in continuous or in cyclic operation. In continuous operation oil vapours and steam flow through a bed of catalyst inside of externally heated tubes. In cyclic operation the catalyst is alternately heated by the combustion of some of the oil and cooled by the cracking of the oil and the reaction of the carbon with the steam. Oil gas may also be generated continuously by partial combustion with air or oxygen.

8. Reformed Natural Gas.—Natural gas is frequently decomposed by thermal or catalytic cracking or partial combustion processes to lower its heating value to render it suitable for mixing with carbureted water gas, oil gas, coal or coke-oven gas. Thermal cracking may be done in the fuel bed of a blue-gas generator or in the checker-brick of an oil-gas generator. Catalytic cracking or partial combustion is accomplished in equipment essentially similar to that employed for the cracking or partial combustion of oil. A typical percentage composition of reformed natural gas is: CO_2, 1.4; C_2H_4, 1.3; C_3H_6, 0.8; O_2, 0.2; CO, 9 7; H_2, 46.6; CH,, 37.1; and N_2, 2.9. The gross calorific value is 599 B.T.U. per cubic foot and the theoretical flame temperature 3,615° F.

9. Natural Gas.—Natural gas is the ideal fuel gas where it is available for use in homes, buildings and industries or where industries can be located economically at the source of supply. It is usually found associated uith crude petroleum or in areas where petroleum has been found. Geologic conditions favourable for oil generally are favourable for natural-gas occurrence. Exploration for oil in the United States led to the discovery and utilization of vast quantities of gas. Other natural-gas deposits have been found in Canada. Argentina, Mexico, France, the U.S.S.R., the middle east and elsewhere. Only in the United States has the immense supply available been put to full use. Thousands of miles of steel pipelines carry natural gas to virtually all parts of the country.

The predominant hydrocarbon in natural gas is methane, and many natural gases can be used without treatment as they are produced at the well. Others must be processed to remove the heavier hydrocarbons present (yielding large quantities of liquefied petroleum gases) and to remove other undesirable constituents such as carbon dioxide, hydrogen sulfide and other sulfur compounds. The calorific values can vary between 700 and 1,500 B.T.U. per cubic foot. In commercial pipeline operations, these variations reduce to from 900 to 1,200 B.T.U. A typical delivered natural gas has a percentage composition: CH_4, 83.4; C_2H_6, 15.8; and N_2, 0.8. Its gross calorific value is 1,129 B.T.U. per cubic foot and the theoretical flame temperature 3,562° F.

See also GAS INDUSTRY; NATURAL GAS.

10. Acetylene.—Acetylene for fuel purposes is produced by the chemical reaction of calcium carbide and water; $CaC_2 + 2H_2O = C_2H_2 + Ca(OH)_2$. Acetylene has a gross calorific value of 1,499 B.T.U. per cubic foot. When burned with air the theoretical flame temperature is 4,210° F., but when burned with 1.4 vol. of oxygen for each volume of acetylene, as in welding operations, the calculated flame temperature is 6,000° F.

Acetylene gives a highly luminous flame and is used to furnish emergency, temporary or portable lighting needs. Acetylene burned in air is used in soldering and brazing operations and with oxygen for cutting and welding operations in which the highest flame temperature of any known mixture of gases is of great advantage. Acetylene is distributed to small users in cylinders under pressure but is generated directly and distributed through pipes on the premises of large consumers. Acetylene is also used widely for producing a variety of chemicals. For this purpose, the acetylene is frequently produced by the conversion of natural or refinery gases. (See also ACETYLENE.)

11. Liquefied Petroleum Gases.—Liquefied petroleum gases (LP gases) are derived from gases produced in petroleum-refining operations or from natural gas (*q.v.*). Propane, C_3H_8, has a gross calorific value of 2,572 B.T.U. per cubic foot and a theoretical flame temperature of 3,660° F. A typical commercial butane is composed of 93% butane (C_4H_{10}) and 7% propane and has a gross calorific value of 3,225 B.T.U. per cubic foot and a theoretical flame temperature of 3,640° F. For efficient transportation, storage and use, propane and butane are liquefied under pressure. Liquefied petroleum gases are distributed in cylinders to isolated consumers for domestic water heating, cooking, refrigeration and space heating. In small communities liquefied petroleum gases are distributed from a central point in place of manufactured gas.

B. UTILIZATION OF GASEOUS FUELS

1. Combustion of Gases.—The advantages of gaseous fuels are: (1) ease of distribution; (2) high thermal efficiency of utilization; (3) no smoke or ash; and (4) ease of control giving either oxidizing or reducing flames and flames of varying temperatures.

The general question of combustion has already been dealt with, but certain special considerations are applicable to gaseous combustion. In the burning of gases both rapidity of combustion and length of flame can be controlled by suitable adjustment of the gas rate and the primary and secondary air supplies.

2. Gas Burners.—Gas burners vary widely, but most types can be divided into two main classes, according to whether or not air is mixed with gas before it reaches the point of combustion. A relatively long flame, which may be suitable for certain types of

furnace work, is produced by burning gas without primary air. On the other hand, burners of the well-known Bunsen type can, if desired, be adjusted to give a rapid rate of combustion with relatively short flames, such as are necessary where the combustion space is limited or maximum flame temperatures are required.

3. Submerged Combustion. — With a view to obtaining increased efficiency in water or steam heating. attempts have been made to develop a type of burner in which gas can be consumed under water. For such submerged combustion it is obviously essential that enough primary air for complete combustion should be intimately mixed with the gas.

4. Surface Combustion. — Sir Humphry Davy, in the early 19th century, discovered that a warmed platinum wire when introduced into a nonexplosive mixture of air and coal gas became incandescent and continued to glow until virtually all of the oxygen mas consumed. Further experiments, particularly by P. L. Dulong, T. Thomson and J. W. Döbereiner, showed that many other substances had the same power. Before commencing work on this subject in 1902, Bone proved: (1) "that the power of accelerating gaseous combustion is possessed by all surfaces at temperatures below the ignition point in varying degrees, dependent upon their chemical characters and physical texture": (2) "that such an accelerated surface combustion is dependent upon an absorption of the combustible gas, and probably also of the oxygen by the surface, whereby it becomes 'activated' (probably ionized) by association with the surface"; and (3) "that the surface itself becomes electrically charged during the process." Bone also pointed out that "there are experimental grounds for the belief that not only does the accelerating influence of the surfaces rapidly increase with the temperature, but also that the differences between the catalyzing powers of various surfaces, which at low temperatures are often considerable, diminish with ascending temperatures until at bright incandescence they practically disappear." This accelerated combustion nas applied by Bone to various industrial heating appliances as a means of increasing the efficiency of heating operations In these a mixture of air and gas in correct proportions is caused to burn without flame in contact with incandescent surfaces. The advantages are: (1) accelerated combustion; (2) concentration of combustion where required; (3) minimum excess air; (4) high temperature; (5) rapid heat transfer by radiation. Surface combustion has been applied to some extent to gas furnaces, gas cookers and heaters, etc., gas and air being forced by slight pressure through a porous diaphragm of refractory material, the mixture burning on the exit surface and maintaining it at incandescence without flame.

For further information reference should be made to the following articles. Under COAL AND COAL MINING will be found a general survey of the world's coal resources and of the methods of coal mining; cognate articles will be found under COKE. COKING AND HIGH-TEMPERATURE CARBONIZATION; CARBONIZATION, LOW-TEMPERATURE; LIGNITE; and PEAT. Mineral oil is treated under PETROLEUM; SHALE, OIL; GASOLINE; and KEROSENE. *See* also GAS INDUSTRY; NATURAL GAS. (C. H. L.; L. C. McC.)

V. ATOMIC FUELS

Atomic or nuclear fuels are substances capable of producing heat (in conjunction with other forms of energy such as radiation) as the result of the splitting or fission of their atomic nuclei. In this respect they differ from the conventional fuels such as coal, mood, petroleum and gas, which furnish heat through the chemical process of combustion. The energy which can be obtained from nuclear processes is in vastly greater concentration than that which can be obtained from ordinary combustion, a pound of the fissionable material uranium-235 being capable of producing 3.3×10^{10} B.T.U. or roughly 2,600,000 times the amount of heat produced from burning a pound of coal. For further discussion *see* ATOMIC ENERGY; NUCLEAR ENGINEERING: Fuels and Fuel *Recovery*. (W. L. C.)

VI. ROCKET AND OTHER HIGH-ENERGY FUELS

Special fuels with performance characteristics superior to those shown by hydrocarbon fuels are required to send rocket-powered vehicles into space and to propel aircraft and missiles faster, farther and with heavier pay loads. Aircraft and missiles powered by air-breathing jet engines require a fuel having one set of properties. Rocket-propelled vehicles must travel in space containing no oxygen shortly after launching; their fuel requirements are different and provision must be made to carry both fuel and oxidant aboard the vehicle.

TABLE III.—*Energy Content of Some High-Energy Fuels Compared With Jet Fuel*

*Liquid †Gas ‡Solid

Fuel requirements for high-performance jet aircraft involve prime consideration of energy content on the basis of both unit volume and unit weight. Other factors such as ease of handling, inflammability limits. corrosiveness, toxicity and availability also must be considered, and may be of overriding importance. A listing of the energy content of some chemical fuels is shown in Table III with JP-4 hydrocarbon jet fuel included for purposes of comparison. Research by the armed forces in co-operation with industry has resulted in the selection of boron compounds as the base for high-energy fuels for jet-propelied weapon systems. The exact nature of the fuels is classified, but it is known that the toxic and explosive nature of the boranes has been reduced by the substitution of carbon-containing groups for some of the hydrogen, as illustrated by the alkylboranes.

For rocket systems, performance is based on the parameters of size, pay load, velocity at burnout and distance of travel, vertical or horizontal. All of these are related to fuel performance, which is measured in terms of a common factor, specific impulse. Specific impulse is defined as the pounds force of thrust developed per unit mass of propellant per second. The thrust developed by a rocket engine depends not only on the type and energy content of the fuel, but also on the type of oxidizer used and the average molecular weight of the combustion gases issuing from the rocket nozzle. In the mathematical expression of specific impulse, the important term is contributed by the ratio of the combustion-chamber temperature to the average molecular weight of the combustion products. Some examples are listed in Table IV.

TABLE IV.—*Examples of Performance Factors of Liquid Fuel-Oxidizer Systems*

*Operating pressure, 500 lb per square inch.

The use of hydrogen as a fuel and fluorine as an oxidant offers theoretical advantages, including combustion products of low molecular weight. However, difficulties of keeping hydrogen in liquid form and the corrosiveness of fluorine present formidable problems.

Solid-fuel rockets are used chiefly for short and intermediate ballistic missiles. Development for long-range missiles has been handicapped by the lower thrust of available solid fuels and by difficulties of controlling their burning rate. A solid rocket propellant is made up of oxidizer particles dispersed in a binder that serves as the fuel. The binder is usually a plastic, resin or synthetic rubber compound. The specific impulse for solid propellant systems is in the range of from 180 to about 225 pound-seconds per pound. Advantages of solid-fuel rockets are their high reliability, convenience in storage and quick availability.

FUENTERRABÍA (formerly sometimes FONTARABIA; Lat. FONS RAPIDUS), a town in north Spain, Guipúzcoa province, near the Bay of Biscayand on the French frontier. Population of the municipality (1950) 7,334. It is on a hillside on the left bank of the Bidassoa, near the point where its estuary begins, and it became popular near the end of the 19th century as a resort for visitors from the interior of Spain. The town has a tiny harbour and makes cider, fishing tackle and pickles fish.

Fuenterrabia formerly possessed considerable strategic importance, and it has frequently been taken and retaken in wars between France and Spain. Unsuccessful attempts to seize Fuenterrabia were made by the French troops in 1476 and again in 1513. In 1521 they captured it but it was retaken in 1524. The prince of Condé sustained a severe repulse under its walls in 1638, and the town then received from Philip IV the rank of city, a privilege which involved some measure of autonomy. In 1719 Fuenterrabia surrendered to the duke of Berwick and his French troops and in 1794 it again fell to the French, who so dismantled it that it has never since been reckoned by the Spaniards among their fortified places. It was by the ford opposite Fuenterrabia that the duke of Wellington, on Oct. 8, 1813, forced a passage into France. Severe fighting also took place there during the Carlist War in 1837 and early in the civil war of 1936–39.

FUERO, a Spanish term, derived from the Latin *forum* (*q.v.*). The Castilian use of the word in the sense of a right, privilege or charter is perhaps to be traced to the Roman *conventus juridici* (assize towns), also known as *jurisdictiones* or *fora,* in Pliny's time already numerous in the Iberian peninsula. In each of these provincial *fora* the Roman magistrate paid all possible deference to the established law of the district; and every free subject could demand that he should be judged in accordance with the customs and usages of his proper forum. It is highly probable that the old administrative arrangements of the provinces: and especially of the towns, remained practically undisturbed at the period of the Gothic occupation of Spain.[1] The Theodosian Code and the Breviary of Alaric alike seem to imply a continuance of the municipal system established by the Romans; the later *Lex Visigothorum* does not appear to have contemplated any marked interference with the former *fora.* During the Arab occupation the Christians were, sometimes at least, judged according to their own laws in separate tribunals presided over by Christian judges;[2] and the mere fact of the preservation of the name *alcalde* (*q.v.*), an official whose functions corresponded so closely to those of the *judex* or *defensor civitatis,* suggests that the old municipal *fora,* if much impaired, were not even then in all cases wholly destroyed. When the word *forum* (or *forus,* Ducange) begins to appear in documents of the 10th century in the sense of a liberty or privilege, it is generally implied that the thing so named is nothing new.

The earliest extant written fuero is probably that granted to the province and town of León by Alfonso V in 1020. It emanated from the king in a general council of the kingdom of León and Castile, and consists of two parts, the "fuero general" applying to the kingdom at large and the "fuero municipal," a mere municipal charter. The "fuero general" does not profess to supersede the *consuetudines antiquorum jurium* or Chindaswint's codification of these in the *Lex Visigothorum;* the "fuero municipal" is for the most part but a resuscitation of usages formerly established. Almost contemporaneous with it was that granted to Nájera by Sancho el Mayor of Navarre (d. 1035), and confirmed, in 1076, by Alfonso VI.[3] In the fuero of Cardefia, granted by Ferdinand I in 1039, reference is made to a previous forum Burgense (Burgos), which, however, has not been preserved, if, indeed, it ever had been reduced to writing at all. The fuero of Sepúlveda (1076) points back to a remote antiquity. Among the later fueros of the 11th century, the most important are those of Jaca (1064) and of Logroño (1095). The former, unusually large in its concessions, rapidly extended to many places in the neighbourhood, while the latter, given also to Miranda by Alfonso VI, was extended in 1181 by Sancho el Sabio of Navarre to Vitoria, thus constituting one of the earliest written *fora* of the "Provincias Vascongadas." In the 12th and 13th centuries the number of such documents increased rapidly; that of Toledo, granted to the Mozarabic population in 1101, but enlarged and extended by Alfonso VII (1118) and later sovereigns, was the basis for many other Castilian fueros.

Latterly the word fuero came to be used in Castile in a wider sense, as a general code of laws; thus about the time of Saint Ferdinand the old *Lex Visigothorum* was translated into the vernacular and called the Fuero Juzgo; and among the compilations of Alfonso the Learned were an *Espejo de Fueros* and the *Fuero de las leyes,* or *Fuero Real.* The famous code known as the *Ordenamiento Real de Alcald,* or *Fuero Viejo de Castilla,* dates from a later period. As the power of the Spanish crown mas gradually concentrated and consolidated the local fueros slowly yielded before the force of imperialism; and only those of Navarre and the Basque provinces *(see* BASQUE) managed to survive. At the death of Ferdinand VII in 1833, these rights were set aside by Castaños. The result was a'civil war, which terminated in a renewed acknowledgment of the fueros by Isabel II (1839). The provisional government of 1868 also promised to respect them, and similar pledges were given by the governments which succeeded. In consequence, however, of the Carlist rising of 1873–76, the Basque fueros were finally extinguished in 1876. The history of the *Foraes* of the Portuguese towns! and of the *Fors du Béarn,* is analogous to that of the fueros of Castile.

FUERTES, LOUIS AGASSIZ (1874–1927), U.S. artist and naturalist who specialized in portraying bird life, was born at Ithaca, N.Y., on Feb. 7, 1874. He was educated at Cornell university and received art training from Abbott H. Thayer. As a painter of birds he was pre-eminent in the U.S. during a period of 30 years from 1897 to 1927. Enthusiastic and industrious, he produced abundantly, mainly as an illustrator of popular and technical ornithological books. He painted also a limited number of large pieces, some of which are owned by the New York Zoological society. His most extensive work was a series of large plates illustrating "The Birds of New York," published by the state and covering practically every species of eastern North America. A similar work for the state of Massachusetts was incomplete at his death. His work is characterized by a fidelity to nature involving not only objective but subjective accuracy. His genius lay in the power to reproduce subtle, fleeting and intangible qualities of birds which reflected their individuality to a remarkable degree. This was quite as much the result of a highly sympathetic and very extensive knowledge of birds in their haunts as it was of technical skill. His travels covered a wide field in North America,

[3] "Mando et concedo et confirmo ut ista civitas cum sna plebe et cum omnibus suis pertinentiis sub tali lege et sub tali foro maneat per saecula cuncta. Amen. Isti sunt fueros quae habuerunt in Naxera in diebus Sanctii regis et Gartiani regis." (I order and permit and confirm that this town with its people and all that pertains to them shall remain under such law and such *forum* for all time. Amen. These are the fueros which they held in Naxera in the days of King Sancho and King Garcia.)

Mexico, West Indies, South America, Europe and Africa. His field experience, therefore, was of the widest.

He died on Aug. 22, 1927, at Unadilla, N.Y.

FUERTEVENTURA, an island in the Spanish archipelago of the Canary islands (*q.v.*). Pop. (1950) 14,229; area 666 sq.mi. Fuerteventura lies between Lanzarote and Grand Canary. It has a length of 52 mi., and an average width of 12 mi. Lava streams and other signs of volcanic action abound, but there has been no igneous activity since the Spaniards took possession. The highest peak reaches 2,500 ft. In external appearance, climate and productions, Fuerteventura greatly resembles Lanzarote. La Oliva (pop. 2,875 [mun.]) is a small town. Cabras (pop. 4,029 [mun.]) on the eastern coast is the chief port.

FUGGER, the name of a famous German family of merchants and bankers. The founder of the family was Johann Fugger, a weaver at Graben, near Augsburg, but its real greatness was established by his grandsons, Andreas and Jakob, who greatly extended the business in Augsburg, which they inherited from their father. Andreas, called the "rich Fugger," had several sons, among them being Jakob, who was granted the right to bear arms in 1452, and who founded the family of Fugger vom Reh, which died out in 1583. Jakob Fugger died in 1469, and three of his seven sons, Ulrich (1441–1510), Georg (1453–1506) and Jakob (1459–152j), men of great resource and industry, inherited the family business and added enormously to the family wealth. In 1473 Ulrich obtained from the emperor Frederick III. the right to bear arms for himself and his brothers, and about the same time he began to act as the banker of the Habsburgs, a connection destined to bring fame and fortune to his house. Under the lead of Jakob the Fuggers were interested in silver mines in Tirol and copper mines in Hungary, while their trade in spices, wool arid silk extended to almost all parts of Europe. Their wealth enabled them to make large loans to the German king, Maximilian I., who pledged to them the county of Kirchberg, the lordship of Weissenhorn and other lands, and bestowed various privileges upon them. Jakob built the castle of Fuggerau in Tirol, and erected the Fuggerei at Augsburg, a collection of 106 dwellings, which were let at low rents to poor people and which still exist. Jakob Fugger and his two nephews died without direct heirs, and the family was continued by Georg's sons, Raimund (1489–1535) and Anton (1493–1560), under whom the Fuggers attained the summit of their wealth and influence.

Jakob Fugger's florins had contributed largely to the election of Charles V. to the imperial throne in 1519, and his nephews and heirs maintained close and friendly relations with the great emperor. In addition to lending him large sums of money, they farmed his valuable quicksilver mines at Almaden, his silver mines at Guadalcanal, the great estates of the military orders which had passed into his hands, and other parts of his revenue as king of Spain; receiving in return several tokens of the emperor's favour. In 1530 Raimund and Anton were granted the imperial dignity of counts of Kirchberg and Weissenhorn, and obtained full possession of these mortgaged properties; in 1534 they were given the right of coining money; and in 1541 received rights of jurisdiction over their lands. Continuing their mercantile career, the Fuggers brought the new world within the sphere of their operations, and also carried on an extensive and lucrative business in farming indulgences. Both brothers found time to acquire landed property, and were munificent patrons of literature and art. Before this time the total wealth of the family had been estimated at 63,000,000 florins. The Fuggers were devotedly attached to the Roman Catholic Church. Jakob had been made a count palatine *(Pfalzgraf)* and several members of the family had entered the church; one, Raimund's son, Sigmund, becoming bishop of Regensburg.

In additicn to the bishop, three of Raimund Fugger's sons attained some degree of celebrity. Johann Jakob (1516–1575), was the author of *Wahrhaftige Beschreibung des osterreichiscken und habsburgischen Nahmens,* which was largely used by S. von Bircken in his *Spiegel der Ehren des Erzhauses Österreich* (Nuremberg, 1668), and of a *Geheim Ernbuch des Fuggerischen Geschlechtes.* He was also a patron of art, and a distinguished counsellor of Duke Albert IV. of Bavaria. Another of Raimund's sons was Ulrich (1526–1584), who became a Protestant and took refuge in the Rhenish Palatinate; greatly interested in the Greek classics, he occupied himself in collecting valuable manuscripts, which he bequeathed to the university of Heidelberg. Raimund's other son was Georg (d. 1579), who inherited the countships of Kirchberg and Weissenhorn, and founded a branch of the family which still exists, its present head being Georg, Count Fugger of Kirchberg and Weissenhorn (b. 1850).

Anton Fugger left three sons, Marcus (1529–1597), Johann (d. 1598) and Jakob (d. 1598), all of whom left male issue. Marcus was the author of a book on horse-breeding, *Wie und wo man ein Gestiit von guten edeln Kriegsrossen aufrichten soll* (1578), and of a German translation of the *Historia ecclesiastica* of Nicephorus Callistus.

Johann Fugger had three sons, Christoph (d. 1615) and Marcus (d. 1614), who founded the families of Fugger-Glött and Fugger-Kirchheim respectively, and Jakob, bishop of Constance from 1604 until his death in 1626. The family of Kirchheim died out in 1672. That of Glott was divided into several branches by the sons of Otto Heinrich and of his brother Johann Ernst (d. 1628). These lines, however, have gradually become extinct except the eldest line, represented in 1909 by Karl Ernst, Count Fugger of Glott (b. 1859). Anton Fugger's third son Jakob, the founder of the family of Wellenburg, had two sons who left issue, but in 1777 the possessions of this branch of the family were again united by Anselm Joseph (d. 1793), Count Fugger of Babenhausen. In 1803 Anselm's son, Anselm Maria (d. 1821), was made a prince of the Holy Roman Empire, the title of Prince Fugger of Babenhausen being borne by his direct descendant Georg (b. 1889). On the fall of the empire in 1806 the lands of the Fuggers, which were held directly of the empire, were mediatized under Bavaria and Wiirttemberg. The heads of the three existing brariches of the Fuggers are all hereditary members of the Bavarian Upper House.

Augsburg has many interesting mementoes of the Fuggers, including the family burial-chapel in the church of St. Anna; the Fugger chapel in the church of St. Ulrich and St. Afra; the Fuggerhaus, still in the possession of one branch of the family; and a statue of Johann Jakob Fugger.

In 1593 a collection of portraits of the Fuggers, engraved by Dominique Custos of Antwerp, was issued at Augsburg. Editions with 127 portraits appeared in 1618 and 1620, the former accompanied by a genealogy in Latin, the latter by one in German. Another edition of this *Pinacotheca Fuggerorum,* published at Vienna in 1754, includes 139 portraits. See *Chronik der Familie Fugger vom Jahre 1599,* edited by C. Meyer (Munich, 1902); A. Geiger, *Jakob Fugger, 1459–1525* (Regensburg, 189j); A. Schulte, *Die Fugger in Rom, 1495–1523* (Leipzig, 1904); R. Ehrenberg, *Das Zeitalter der Fugger* (Jena, 1896); K. Habler, *Die Geschichte der Fuggerschen Handlung in Spanien* (Weimar, 1897); A. Stauber, *Das Haus Fugger* (Augsburg, 1900); and M. Jansen, *Die Anfänge der Fugger* (Leipzig, 1907); R. Ehrenberg, *Capital and Finance in the Age of the Renaissance: A Study of the Fuggers and their Connexions* (Eng. trans. by H. Lucas, 1928).

FUGITIVE SLAVE LAWS, a term applied in the United States to the statutes passed by Congress in 1793 and 1850 to provide for the return of negro slaves who escaped from one State into another or into a public territory.

The first specific legislation on the subject was enacted on F'eb. 1, 1793; by its provisions any Federal district or circuit judge or any State magistrate was authorized to decide finally and without a jury trial the status of an alleged fugitive. The measure soon met with strong opposition in the northern States, and Personal Liberty laws were passed to hamper officials in the execution of the law; Indiana in 1824 and Connecticut in 1828 providing jury trial for fugitives who appealed from an original decision against them. In 1840 New York and Vermont extended the right of trial by jury to fugitives and provided them with attorneys. As early as the first decade of the 19th century individual dissatisfaction with the law of 1793 had taken the form of systematic assistance rendered to negroes escaping from the South to Canada or New England — the so-called "Underground Railroad" (*q.v.*). The decision of the Supreme Court of the United States in 1842 that State authorities could not be forced to act in fugitive slave cases, but that national authorities must carry out the national law, was followed by legislation in Massachusetts (1843), Vermont (1843), Pennsylvania (1847) and Rhode Island (1848), forbidding State officials to help enforce the law and refusing the use of State gaols for fugitive slaves.

The demand from the South for more effective Federal legislation was voiced in the second Fugitive Slave Law, enacted on Sept. 18, 1850, as a part of the Compromise measures of that year. Special commissioners were to have concurrent jurisdiction with the U S. courts in enforcing the law; fugitives could not testify in their own behalf; no trial by jury was provided; penalties were imposed upon marshals who refused to enforce the law or from whom a fugitive should escape, and upon individuals who aided negroes to escape; the marshal might raise a *posse comitatus;* a fee of $10 was paid to the commissioner when his decision favoured the claimant and only $5 when it favoured the fugitive; and both the fact of the escape and the identity of the fugitive were to be determined on purely *ex parte* testimony. The severity of this measure led to gross abuses and defeated its purpose; the number of abolitionists increased, the operations of the Underground Railroad became more efficient, and new Personal Liberty laws were enacted in Vermont (1850), Connecticut (1854), Rhode Island (1854), Massachusetts (1855), Michigan (1855), Maine (1855 and 1857), Kansas (1858) and Wisconsin (1858). These Personal Liberty laws forbade justices and judges to take cognizance of claims, extended the *habeas corpus* act and the privilege of jury trial to fugitives, and punished false testimony severely. These State laws were one of the grievances officially referred to by South Carolina (in Dec. 1860) as justifying her secession from the Union Attempts to carry into effect the law of 1850 aroused much bitterness. The arrests of Sims and of Shadrach in Boston in 1851; of "Jerry" M'Henry, in Syracuse, N Y., in the same year; of Anthony Burns in 1854, in Boston; and of the two Garner families in 1856, in Cincinnati, with other cases arising under the Fugitive Slave Law of 1850, probably had as much to do with bringing on the Civil War as did the controversy over slavery in the Territories.

For some time after the beginning of the Civil War the Fugitive Slave Law was considered still to hold in the case of fugitives from masters in the border states who were loyal to the Union government, and it was not until June 28, 1864 that the Act of 1850 was repealed.

See J. F. Rhodes, *History of the United States from the Compromise of 1850,* vols. i. and ii. (1893) ; and M. G. M'Dougall, *Fugitive Slaves, 1619–1865* (Boston, 1891).

FUGUE, in music, the mutual "pursuit" of voices or parts. It was, up to the end of the 16th century, if not later, the name applied to two art-forms. (A) Fuga *ligata* was the exact reproduction by one or more voices of the statement of a leading part. The reproducing voice *(comes)* was seldom if ever written out, for all differences between it and the *dux* were rigidly systematic; *e.g.,* it was an exact inversion, or exactly twice as slow, or to be sung backwards, etc., etc. Hence, a rule or *canon* was given, often in enigmatic form, by which the *comes* was deduced from the *dux;* and so the term *canon* became the name for the form itself and is still retained (B) A composition in which the canonic style was cultivated without canonic restriction was, in the 16th century, called *fuga ricercata* or simply *ricercare,* a term which is still used by Bach as a title for the fugues in *Das musikalische Opfer.*

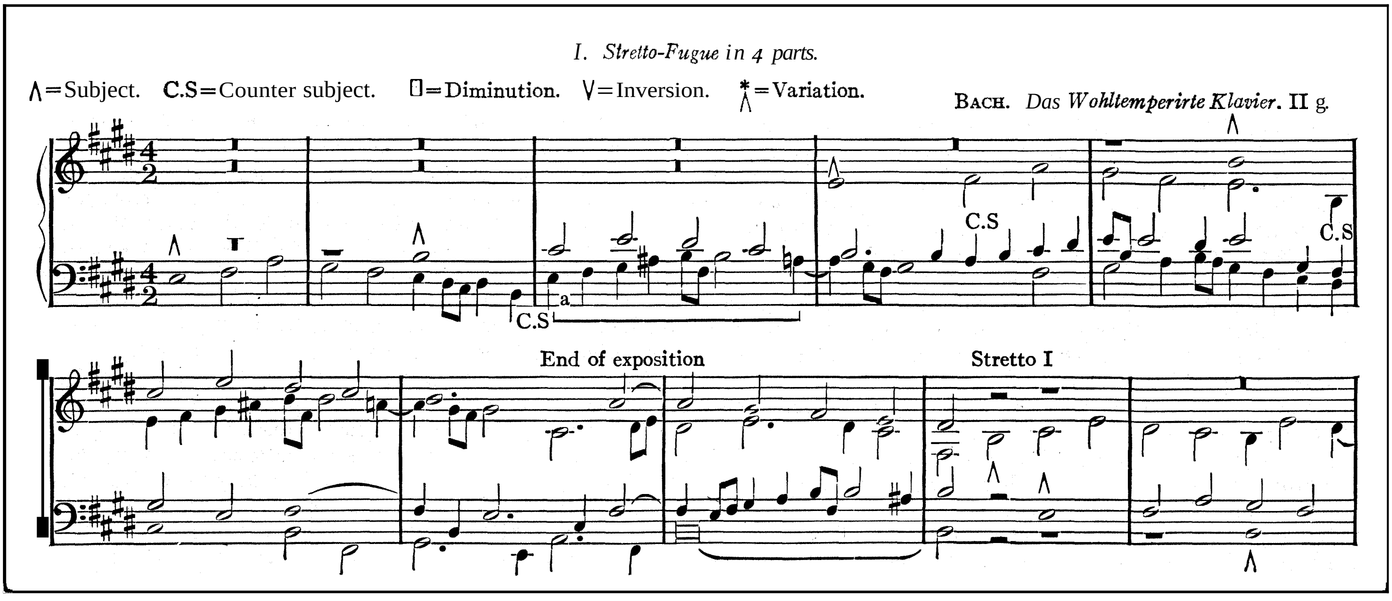
Fugue is a texture the rules of which do not suffice to determine the shape of the composition as a whole. Schemes such as that laid down in Cherubini's treatise, that legislate for the shape, are pedagogic fictions; and such classical tradition as they represent is too exclusively Italian to include Bach. Yet, strange to say, the Italian tradition in fugue style is represented by hardly any strict works at all. Under the general heading of COUNTERPOINT many facts concerning fugues are discussed; and only a few technical terms remain to be defined here.

(i.) If during the first entries or "exposition" of the fugue, the counterpoint with which the opening voice accompanies the answer is faithfully reproduced as the accompaniment to subsequent entries of the subject, it is called a *countersubject.* Obviously the first countersubject may continue with a second when the subject enters in the third part and so on. The term is also applied to new subjects appearing later in the fugue in combination (immediate or destined) with the original subject. Cherubini, holding the arbitrary dogma that a fugue cannot have more than one subject, applies the term to the less prominent of the subjects of what are commonly called double fugues, *i.e.,* fugues which begin with two parts and two subjects simultaneously, and so also with *triple* and *quadruple* fugues. It is remarkable that Bach (with only three known exceptions) never writes this kind of double fugue, but always introduces his new subjects later.

(ii.) *Episodes* are passages separating the entries of the subject. There is no reason for distinguishing episodes that occur during the exposition from later episodes. Episodes are usually developed from the material of the subject and countersubjects; they are, when independent, conspicuously so.

(iii.) *Stretto* is the overlapping of subject and answer. *A stretto maestrale* is one in which the subject survives the overlapping. The makers of musical terminology have no answer to the question of what a non-magistral stretto may be.

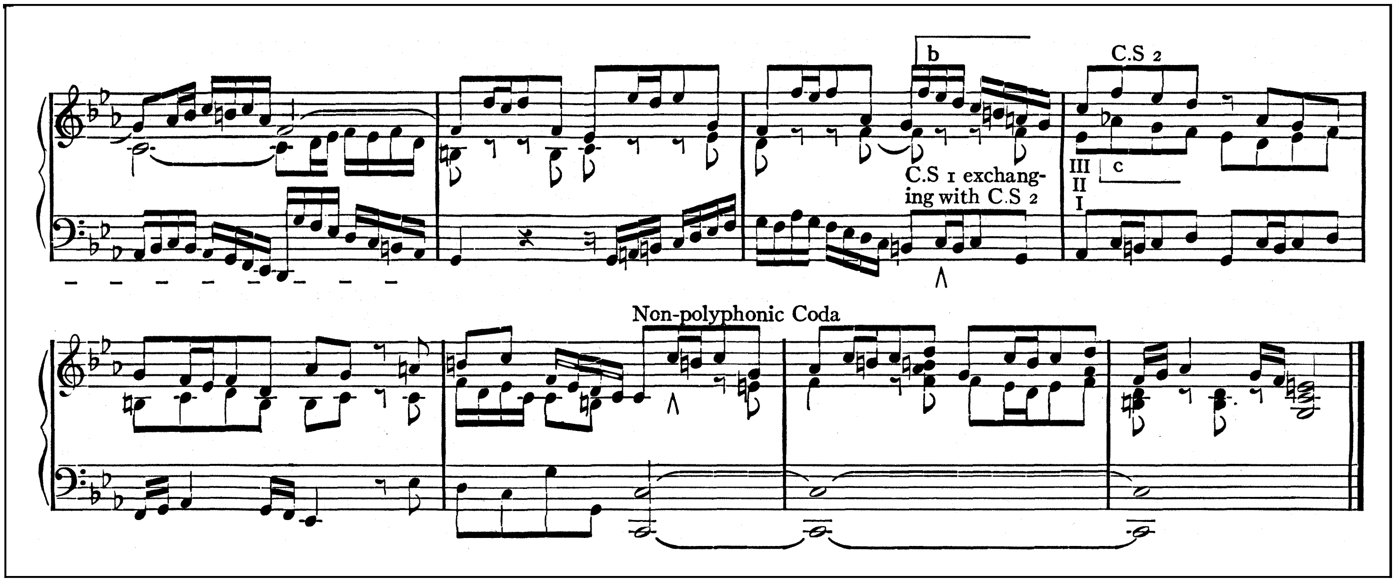
(iv.) The distinction between *real* and *tonal* fugue is a matter of detail concerning the answer. A fugal exposition is not intended to emphasise a key-contrast between tonic and dominant. Accordingly the answer is (especially in its first notes and in points that tend to shift the key) not so much a transposition



Canonic Episode suggested by C.S(a)
(a)
Stretto II: chromatic, with two new counter subjects
New C.S 1
New C.S 2
New C.S 1 (combined at different point)
New C.S 2(ditto)
New C.S 2
Stretto III on a variation of the subject
Stretto IV by diminution. (Note new position in scale, with first two entries)
Stretto V combining normal subject with Diminution freely inverted and direct.
Stretto VI, reviving C.S as a result of
C.S
**These two notes would have been an 8ve higher if 10ths could be stretched on Bach's instruments.

II. *Fugue in* 3 *parts, with* 2 *countersubjects and highly organized episodes.*

BACH. *Das Wohltemperirte Klavier* I 2.



of the subject to the key of the dominant as an adaptation of it from the tonic part to the dominant part of the scale or vice versa; in short, the answer is as far as possible on the dominant, not *in* the dominant. This is effected by a kind of melodic foreshortening on principles of great aesthetic interest but difficult to reduce to rules of thumb. The rules as often as not produce answers that are exact transpositions of the subject; and so the only kind of "real" fugue (*i.e.*, fugue with an exact answer) that could rightly be contrasted with the tonal fugue would be that in which the answer ought to be tonal but is not.

The term "answer" is usually reserved for those entries of the subject that are placed in what may be called the "complementary" position of the scale, whether they are tonal or not. Thus the order of entries in the exposition of the first fugue of Das Wohltemperirte *Klavier* is subject, answer, answer, subject, a departure from the usual rule, according to which subject and answer are regularly alternated in the exposition.

The nature of fugue and of polyphony as building harmony in "horizontal" melodic threads instead of in "vertical" chordal lumps is all summarized by Milton, during no classical period of polyphony, but in the chaotic time half-way between the death of Frescobaldi and the birth of Bach.

His volant touch,
Instinct through all proportions, low and high,
Fled and pursued transverse the resonant fugue.
Paradise Lost, book *XI.*

(D. F. T.)

FUHRICH, JOSEPH VON (1800–1876), Austrian painter celebrated for his portrayals of scriptural episodes, was born at Kratzau in Bohemia on Feb. 9, 1800. His sacred subjects were transferred in numberless repetitions to the roadside churches of the Austrian state. Fiihrich has been fairly described as a "Nazarene," a romantic religious artist whose pencil gave shape to countless incidents of the Gospel and scriptural legends. He composed with great skill, especially in outline. His mastery of distribution, form, movement and expression was considerable. He had, however, no feeling for colour; and when he produced monumental pictures he was not nearly so successful as when designing subjects for woodcuts. Fiihrich's illustrations to Tieck's Genofeva, the Lord's Prayer, the Triumph of Christ, the Road to Bethlehem, the Succession of Christ according to Thomas a Kempis, the Prodigal Son, and the verses of the Psalter, became well known. In 1834 he was made custos and in 1840 professor of composition in the academy of Vienna. After this he completed the monumental pictures of the Church of St. Nepomuk. In 1872 he was pensioned and made a knight of the order of Franz Joseph. He died on March 13, 1876.

FUJI SAN or FUJIYAMA, a celebrated quiescent volcano of Japan, standing 70 mi. W.S.W. of Tokyo. It rises to a height of 12,385 ft. and its southern slopes reach the shore of Suruga bay. It is a cone of beautifully simple form, the more striking to view because it stands isolated; but its summit is not conical, being broken by a crater about 2,000 ft. in diameter. *See* JAPAN.

FUJIWARA NO SADAIE (the characters for Sadaie can also be pronounced, in Sino-Japanese, as TEIKA, and he is commonly so called) (1162–1241), Japanese poet and critic, was probably responsible, more than any other person, for the formation of Japanese literary taste. The son of the celebrated poet Shunzei (1114–1204), Teika while still in his 20s gained renown both for his poetic genius and for his rare acumen in judging the poetry of others. His early works were in a clear, classical style, but gradually Teika's poems took on the symbolic and suggestive qualities of his mature work. One of his most famous *waka* (see JAPANESE LITERATURE), written when he was 37, is characteristic:

The floating bridge
Of the dream of a spring night
Had shattered;
In the sky a bank of clouds
Was drawing away from the peak.

In this poem Teika suggests that what he sees is not merely a cloud meaninglessly drifting in the sky, but an indication, a symbol, of some truth glimpsed perhaps in his dream.

Teika's poetry in this vein at first aroused opposition and even derision, but he acquired a powerful protector in the emperor Gotoba (1180–1239), himself a distinguished poet. The *Shinko*-kinshu (New Collection of Ancient and Modern Poetry), compiled in 1205 at Gotoba's command, was largely a product of Teika's style and taste. It is a superb collection and one that influenced later Japanese poets enormously, as indicated by the comment of a 15th-century critic: "Those who adversely criticise Teika's poetry will never know Heaven; their crime will surely be punished."

The compilation of *Hyakunin Isshu* (Hundred Poets, a Poem Each), a collection known by heart by almost every Japanese, is generally credited to Teika. His influence was not restricted to poetry: most of the important works of Heian prose that are still extant were edited by him, and our picture today of that glorious period is conditioned by his judgments.

See *Guide to the Composition of Poetry,* in De Bary, *Sources of the Japanese Tradition* (1958); *A Hundred Verses From Old Japan,* trans. by Porter (1909). (DD. K.)

FUKIEN, one of the three maritime provinces of south China between Chekiang on the north and Kwangtung on the south. Area 46,376 sq.mi. Its western boundary follows the crest of the high ranges which form the water parting between the Kan section of the Yangtze basin and streams flowing eastward to the China sea. These ranges effectively separate it from its western neighbour Kiangsi and form the boundary zone between Mandarin, spoken in that province, and the Fukien dialects, of which there are about seven main varieties. Topographically isolated on the landward side and with a distinct group of languages, Fukien has marked individuality. The province is mountainous and, apart from its border ranges, is crossed by several ridges with the southwest-northeast axis characteristic of the eastern portion of the south China highlands. A longitudinal system of drainage parallel to. these ridges has been tapped by coastal streams of which the most important is the Min, which drains two-thirds of the province. These streams are invaluable for floating timber. In the valleys, two crops of rice are harvested yearly, the first in June and the second in September. The forests are still of great importance and, as a source of timber, Fukien is only rivaled by Manchuria and Hunan in all China. The most important woods are fir, pine and rosewood. The camphor of Fukien was formerly of great importance.

Fukien became a great tea-growing province, a special feature being its production of flower-scented teas.

In addition to its agricultural and timber resources, Fukien has considerable and varied mineral wealth, including coal, iron, copper, gold, silver, graphite and good clay for porcelain. Mines are scattered widely over the province.

Foochow, on the navigable lower Min and the outlet for the northern and central interior, is the largest city. Amoy, where another system of valleys finds its contact with the sea, is the great regional centre for the south. There are several smaller intermediate ports and in the extreme north is Funing.

The great majority of the population of Fukien, (1953) 13,142,-721, lives in the coastal zone. A number of Chinese from Fukien and especially from Amoy emigrated to countries of southeast Asia, where they form the majority of the oversea Chinese.

After the outbreak of war, 1937, the Japanese occupied Amoy and, in 1941, temporarily Foochow. In 1949 the province fell to the Chinese Communists.

FUKUI, Japanese coastal prefecture on the Sea of Japan in central Honshū. Area 1,647 sq.mi.; pop. (1960) 752,696. The Wakasa bay coast west of Tsuruga, an important port, has many deep embayments and peninsulas, while the main inhabited lowland, Fukui plain, lies on the northern coast backed by high mountains. Wet-rice agriculture on the plains and forestry in the mountains are leading occupations, and Fukui is noted for its silk and rayon textile manufacturing. The capital, Fukui, and smaller towns of the Fukui plain are the main textile centres. Optical goods, cement and chemicals are also produced on a small scale. (J. D. EE.)

FUKUI, capital and largest city of Fukui prefecture, Japan, located in the central Fukui plain along the Asuwa river. Pop. (1960) 149.823. Famed as the rayon capital of Japan, Fukui traces its modern origins to the early 17th century. when it was a thriving castle town. Silk weaving developed rapidly after 1871, and between 1920 and 1935 rayon cloth became a specialty. The manufacture of machinery and the processing of foodstuffs are also important. About one-third of the city's labour force is employed in textiles, dyeing and other textile-supply industries. The city was burned badly in 1945 and was virtually destroyed by an earthquake in 1948, but has rebuilt. (J. D. EE.)

FUKUOKA, Japanese prefecture of northern Kyūshū, facing on the Inland sea (northwest), Shimonoseki strait (north), Tsushima strait (west): and the Ariake sea (south). Pop. (1960) 4,006,679; area 1.892 sq.mi. Rivers draining seaward have built up extensive habitable plains. The west coast is heavily indented. Fukuoka is important industrially especially in coal mining. The main coal fields, industria! and transportation centres, R'akamatsu, Yawata, Moji (*qq.v.*), Tobata and Kokura, are concentrated in northern Fukuoka. Fukuoka is the prefectural capital. Southern Fukuoka is mainly agricultural except for Kurume (silk textiles) and Omuta (coal and chemicals). (J. D. EE.)

FUKUOKA, capital city of Fukuoka prefecture, northwestern Kyūshū, Japan, and the largest and most important city of Kyūshū. Pop. 11960) 647.122. The city lies along the southern coast of Hakata bay on a river delta. Here developed the port city of Hakata, which in ancient times had many continental contacts; after 1600, the castle town of Fukuoka was established. Separated only by the Naka river, the two amalgamated in 1878. In the early 1940s incorporation of Hakozaki increased the city's area. Physically removed from the northern Kyūshū coal fields and industrial belt and poorly located for trade with the rest of Japan, Fukuoka has grown as a regional commercial, administrative and cultural centre. It has many large department stores and wholesale-retail establishments. In addition to prefectural offices, there are regional offices of a number of federal government agencies. Fukuoka is the seat of Kyūshū university (in Hakozaki) founded in 1910. The modernized port has a depth of about 30 ft. and is one of Japan's best equipped and most active fishing ports. Although the city's industries include shipbuilding and heavy chemicals, consumer goods are the main products. (J. D. EE.)

FUKUSHIMA (FUKUSHIMA-KEN) , Japanese prefecture of northeastern Honshū. Pop. (1960) 2,051.137; area 5.320 sq.mi. It is mostly mountainous and human activity is concentrated in small interior basins and along the Pacific coast. Essentially agricultural. it produces rice surpluses and such cash crops as tobacco, mulberry (silk), fruit (apples, pears and cherries) and vegetables. Forestry and fishing are important but modern industry has developed only in a few cities (Kōriyama the main centre)

FUKUSHIMA, the capital and largest (pop 1960, 138,961) city of Fukushima prefecture, is located on the Abukuma river in the Fukushima basin. Once a castle town, it is the prefectural administrative, commercial and educational hub. It serves as the silk mart of northern Honshii and has excellent railway facilities. (J. D. EE.)

FUKUZAWA YUKICHP (1834–1901), Japanese educator, author and publisher, one of the foremost 19th-century advocates of modernization in Japan, was born in Osaka of a low-ranking military family on Dec. 15, 1834, 20 years before Matthew Perry's arrival. He entered a school in Osaka to study the Dutch language and Dutch medicine, and this acquaintance with western civilization produced in him great enthusiasm for modernization. Fukuzawa went abroad three times, in 1860, 1861 and 1867, traveling in the U.S. and Europe. He returned to write in simple language and vigorous style the first of a large number of books exhorting the Japanese people to modernize their politics and society. In the course of his life he wrote over 100 volumes explaining and advocating parliamentary government, popular education, language reform, women's rights and a host of other causes. In 1871 he founded Keiō university, to provide the kind of education he advocated in a great university independent of government domination. His newspaper, the *Jiji Shimpō,* founded in 1882 and dedicated to enlightenment of the people, also was written in simple language and style and was for years one of Japan's most influential newspapers. To the end of his life Fukuzawa insisted on promoting his beliefs by private efforts, and he consistently refused to accept any government office. He died on Feb. 3, 1901.

See **Fukuzawa Yukichi,** *Autobiography.* (T. C. SH.)

FULANI, a long-headed white race of pastoralists of disputed origin with considerable intermixture of other blood, calling themselves *Fulbe* (sing. *Pullo*), distributed from the upper Nile to Senegal. They have regular features and narrow nose, wavy hair, light complexion; are long-limbed, highly strung. They live independently, or near cultivators whose cattle they herd, and in certain districts constitute the ruling class, as in the theocratic states of Fouta Djallon, Guinea. They conquered the Hausa states of Nigeria about 1804; and maintained precarious power up to the establishment of the British Protectorates (1904). Some have taken up cultivation. They are usually Moslems and observe the Koranic code; a small proportion are Animists (Senegal, Mali and on the Niger).

See Arcin, *La Guinée Française* (1907); Delafosse, *Haut Sénégal Niger* (1912); **Meek,** *The Northern Tribes of Nigeria* (1925).

FULBERT, SAINT, OF CHARTRES (c. 960–1028), bishop of Chartres and educator, whose pupils called him Socrates because of his encyclopaedic knowledge and determined pursuit of truth, was born in Picardy. During his education at Reims his teacher was Gerbert, later Pope Silvester II. Robert, later king of France, was a fellow student and good friend. In ggo Fulbert was appointed chancellor of the cathedral of Chartres, which under his direction, became one of the most vigorous schools in Europe. As bishop of Chartres from 1006, Fulbert used his friendship with the king of France and the duke of Aquataine to advantage. He was sent on diplomatic missions to Rome by both parties. In 1020 Fulbert began to rebuild the burned cathedral of Chartres, but he died on April 10, 1028, before its completion. His feast is April 10.

See Loren C. MacKinney, *Bishop Fulbert and Education at the School of Chartres* (1957); Hilda Johnstone, "Fulbert, Bishop of Chartres," *Church Quarterly Review,* 102:45–67 (1926). (E. G. RN.)

FULCMER OF CHARTRES (1059–*c.* 1130), French chronicler, was a priest who was present at the council of Clermont in 1095, and accompanied Robert II, duke of Normandy, on the first crusade in 1096. He became chaplain to Baldwin, king of Jerusalem. His *Historia Hierosolymitana* or *Gesta Francorum Jerusalem expugnantium,* one of the most trustworthy sources for the history of the first crusade, covers the period between the council of Clermont and 1127, and the author only details events which he himself had witnessed. It was used by William of Tyre. Fulcher died after 1127, probably at Jerusalem. He has been confused with Foucher of Mongervillier (d. 1171), abbot of St.-Père-en-Vallée at Chartres, and also with another person of the same name who distinguished himself at the siege of Antioch in 1098.

FULDA, a town and episcopal see of Germany, in the *Land* of Hesse, between the Rhon and the Vogel-Gebirge, 60 mi. N.E. from Frankfurt am Main by rail. Pop. (1950) 42,213.

Fulda owes its existence to its abbey, and became a town in 1208. In the middle ages there were many struggles between the abbots and the townsfolk. It came finally into the possession of Prussia in 1866. From 1734 to 1804 Fulda was the seat of a university, and latterly many assemblies of German bishops have been held in the town.

The great Benedictine abbey of Fulda was founded in 744 at the instigation of St. Boniface by his pupil Sturm, who was the first abbot, and became a missionary centre. It was liberally endowed with land and soon became one of the most wealthy establishments of its kind. About 968 the pope declared its abbot the primate of Germany and Gaul, and later he became a prince of the empire. The school at Fulda was the centre of theological learning in the early middle ages. Among its teachers were Alcuin. Hrabanus Maurus, who was abbot from 822 to 842, and Walafrid Strabo. Early in the 10th century the monastery was reformed by monks from Scotland, but had declined considerably before the Reformation. In 1752 the abbot was raised to the rank of a bishop, and Fulda ranked as a prince-bishopric. This mas secularized in 1802. In 1816 the greater part of the principality was ceded by Prussia to Hesse-Cassel, a smaller portion being united with Bavaria. Sharing the fate of Hesse-Cassel, this larger portion was annexed by Prussia in 1866. In 1829 a new bishopric was founded at Fulda.

The present cathedral was built early in the 18th century on the model of St. Peter's at Rome, but it has an ancient crypt, restored in 1892. Opposite the cathedral is the former monastery of St. Michael, now the episcopal palace. The Michaelskirche, attached to it, is a small round church built, in imitation of the Holy Sepulchre, in 822 and restored in 1853. The library, the palace, the former Benedictine nunnery (founded 162j, and now used as a seminary), and the Minorite friary (1238) now used as a warehouse, may be noted. Industries include weaving and dyeing, the manufacture of linen, felt and tapestry. There are also railway works in the town, and trade is in cattle.

FULGENTIUS, SAINT, OF RUSPE (*c.* 467–532/3) was born in Telepte, Byzacium, a province of Roman Africa, of a pious mother, Mariana. After a short career as fiscal procurator of the province, he became a monk residing successively in Africa, Sicily and Rome. He accepted the bishopric of the little African town of Ruspe about 507. The Arian Vandal king, Thrasimund, exiled the Catholic bishops, and 60 of them retired to Sardinia with Fulgentius as their leader and spokesman. Thrasimund recalled Fulgentius about 515, but because of Fulgentius' intransigent Catholicism, he was exiled again. Hilderich, successor of Thrasimund, was pro-Catholic and allowed the triumphal return of Fulgentius to Africa, where he died in 532/3. His liturgical feast day is Jan. 1.

The importance of Fulgentius lies in his theological work. The suggestion has been made (but not widely accepted) that he wrote the Athanasian creed. His writings are numerous but not original. He faithfully reproduces the thought of St. Augustine, whom he admired, and he has been called the "abbreviated Augustine." His writings were in large part polemical, against Arianism and Semipelagianism; his major work against the Semipelagians, a refutation of Faustus of Riez, has unfortunately been lost. *(See* FAUSTUS, SAINT.) Fulgentius' surviving writings are included in J. P. Migne (ed.), *Patrologia Latina,* vol. lxv, pp. 117–150, and vol. lxvii, pp. 887–962.

See G. Lapeyre, *L'ancienne église de Carthage,* 2 vol. (1932); G. Weigel, *Faustus of Riez* (1938). *(G. WL.)*

FULGENTIUS, FABIUS PLANCIADES (fl. *c.* late 5th and early 6th centuries A.D.), Christian Latin writer of African origin, who sought in two of his extant works to reconcile his Christian contemporaries with ancient legends. He is the author of the fantastic *Mitologiarum libri iii* containing allegorical interpretations of myths supported by absurd etymologies and of an astonishing *Expositio Vergilianae continentiae* (= contenta) *secundum philosophos moralis,* in which he makes Virgil himself appear in order to reveal the mystic meaning of the *Aeneid.* He also wrote an *Expositio sermonum antiquorum,* explanations of 62 rare Latin words supported by quotations, sometimes from authors and works that never existed, and a *Liber absque litteris de aetatibus mundi et hominis,* a strange, superficial and inaccurate work based chiefly on Bible history. As indicated by the title one letter of the alphabet is not used in each book. His youthful poems and a work entitled *Physiologus* are lost.

Fulgentius is a foolish and insipid writer. His style is luxuriant and he sometimes violates fundamental grammatical rules. Whether he is identical with Fulgentius bishop of Ruspe (467–532) is disputed.

BIBLIOGRAPHY.—Edition by R. Helm, Teubner series (1898). *See* also F. Skutsch in Pauly-Wissowa, *Real-Encyclopadie der Classischen Altertumswissenschaft,* vol. vii, 215–227 (1910); O. Friebel, *Fulgentius der Mythograph und Bischof* (1911). (G. B. A. F.)

FULGURITE is the name given to glassy tubes produced by the fusion of sand by lightning and to superficial coatings of glass formed on rocks by the same agency (from the Latin *fulgar,* "lightning"). These may be distinguished as sand fulgurites and rock fulgurites. The former are more common.

Sand fulgurites are cylindrical, more or less branching objects which usually vary in diameter from about half an inch to several inches. In length they are mostly less than a foot, but some extend ten feet or more. The central cavity is usually lined with glass and the exterior shows adhering sand grains. The temperature reached in the melting of sand to produce the fulgurite is about 1,800° C. since lightning discharges take place in less than 100 microseconds (a microsecond is a millionth of a second). The temperature is estimated from the melting point of quartz. The silica glass of sand fulgurites was called lechatelierite by Alfred Lacroix after Henry le Chbtelier. noted French chemist. Among sand fulgurites those collected along the shores of Lake Michigan and the Atlantic coast of the United States are prominent.

Rock fulgurites usually occur about mountain summits. They have been found at Toluca, Mex., by Alexander von Humboldt, in the Caucasus by Otto von Abich and on Mt. Thielsen, Oregon, by J. S. Diller of the U.S. geological survey. (4. F. R.)

FULHAM, a western metropolitan borough of London, bounded N. and N.W. by Hammersmith, N.E. by Kensington, E. by Chelsea and S.E., S. and W. by a loop of the river Thames. Pop. (1951) 122,064. Area 2.7 sq.mi. It includes what were once the four villages of Fulham, Parson's Green, Walham Green and North End. The intervening land was built over during the last half of the 19th century and is mainly residential. Fulham lies almost entirely on a low gravel terrace and before it was built over it was one of London's chief sources of fruit and vegetables. Its only outstanding industry is pottery, first made there when John Dwight set up his kilns in c. 1670. There are many wharves along the river front. The electric power station (1936) supplies electricity to a wide area. Gas was first made in Fulham in 1829 and its gasworks are therefore one of the oldest in the world. The manor house or palace of the bishops of London stands in beautifully planted grounds near the river west of Putney bridge. It was originally surrounded by a moat, believed to be Danish, but this was filled in in 1921 and part laid out as a public park. The oldest portion of the house is the picturesque western quadrangle built by Bishop Richard Fitzjames, bishbp of London from 1j06 to 1522. The borough includes several well-known sports enclosures: Hurlingham park, where there were two polo grounds until one was built over and the other turned into a public park; Queen's club, which has tennis, rackets and other courts; the association football grounds at Craven cottage and Stamford bridge; and the Empress hall of Earl's court. The annual Oxford and Cambridge university boat race starts at Putney bridge.

Fulham, or in its earliest form *Fullanham,* is believed to signify either "the place of fowls" or "the place of dirt." The manor was bought by Waldhere, bishop of London, from Tyrhtel, bishop of Hereford, in the 8th century. There is no record of the first erection of the parish church of All Saints, but the first known rector was appointed in 1242. The four-storied tower is 14th or early 15th century work greatly restored. At the Grange in North End road Samuel Richardson lived from 1739 and Sir Edward Burne-Jones from 1867 until his death.

FULK (1092–1143), king of Jerusalem, was the son of Fulk IV, count of Anjou, and his wife Bertrada (who ultimately deserted her husband and became the mistress of Philip I of France). He became count of Anjou in 1109. Within his county he was active in asserting and recovering his powers over his vassals; outside it he played a part in the conflicts between Henry I of England and Louis VI of France. supporting each side in turn. But his ties with Henry became closer when his son Geoffrey Plantagenet married Henry's daughter Matilda. Already in 1120 Fulk had visited the Holy Land and become a close friend of the Templars. On his return he assigned to the order of the Templars an annual subsidy, while he also maintained two knights in the Holy Land for a year. In 1128 he was preparing to return to the east. when he received an embassy from Baldwin II, king of Jerusalem, who had no male heir to succeed him, offering his daughter Melisinda in marriage with the right of eventual succession to the kingdom. Fulk accepted the offer; and in 1129 he was married to Melisinda, receiving the towns of Acre and Tyre as her dower. In 1131 he became king of Jerusalem.

His reign was not marked by any considerable events. The kingdom, which had reached its zenith under Baldwin II, was quietly prosperous under Fulk's rule. In the beginning of his reign he had to act as regent of Antioch and to provide a husband, Raymund of Poitou, for the infant heiress Constance. But the great problem with which he had to deal was the progress of the atabeg Zengi of Mosul. In 1137 he was beaten near Barin and, escaping into the fort, was surrounded and forced to capitulate. A little later, however, he greatly improved his position by strengthening his alliance with the vizier of Damascus, who also feared the progress of Zengi (1140); and in this way he was able to capture the fort of Banias, to the north of Lake Tiberias. Like his predecessors in Anjou, Fulk was a great builder of castles. In southern Palestine he constructed Ibelin, Blanche Garde and Gibelin as a means of checking the Mohammedan garrison of Askalon. Belvoir was founded to survey the Jordan valley south of the Sea of Galilee, while in Trans-Jordan, Kerak was fortified by a royal vassal. Twice in Fulk's reign the eastern emperor, John Comnenus, appeared in northern Syria (1137 and 1142); but his coming did not affect the king, who was able to decline politely a visit which the emperor proposed to make to Jerusalem.

Fulk died in 1143 leaving two sons who both became kings and reigned as Baldwin III and Amalric I.

Fulk continued the tradition of good statesmanship and sound churchmanship which Baldwin I and Baldwin II had begun. Unfortunately he was unable to head a combined resistance to the rising power of Zengi of Mosul.

See J. Chartrou, *L'Anjou de 1109 à 1151* (Paris, 1928); R. Grousset, *Histoire des croisades,* vol. ii (Paris, 1935). (E. B.; R. C. SMA.)

FULK (d. goo), archbishop of Reims and support of the Carolingian dynasty, succeeded Archbishop Hincmar in 883. He was soon preoccupied in defending his territories against the Norman invaders. Personal ambition led him to support the claim to the West Frankish crown of his kinsman Guy of Spoleto after the deposition of Charles the Fat (887), but he grudgingly rallied to the cause of the successful candidate, Odo, count of Paris. Odo's failure to defend France against the Normans soon allowed Fulk to become the leader of unrest among the disgruntled nobility of the northeast.

Their instrument and the hope of all legitimists was the young Carolingian, Charles the Simple, whom Fulk crowned at Reims in 893. From 898 (when Charles, after five years of civil war, became Odo's heir) to his death, Fulk was chancellor. His efforts to keep the wealthy abbeys and benefices of his church out of the hands of the nobles incurred the hatred of Baldwin II, count of Flanders, who secured his assassination on June 17, 900.

FULK NERRA (c. 970–1040), count of Anjou, eldest son of Count Geoffrey I. Grisegonelle ("Gray Tunic"), and Adela of Vermandois, was born about 970 and succeeded his father in the countship of Anjou on July 21, 987. He was successful in repelling the attacks of the count of Rennes and laying the foundations of the conquest of Touraine (see ANJOU). In this connection he built a great number of strong castles, which has led in modern times to his being called "the great builder." He also founded several religious houses, among them the abbeys of Beaulieu, near Loches (c. 1007), of St. Nicholas at Angers (1020) and of Ronceray at Angers (1028), and, in order to expiate his crimes of violence, made three pilgrimages to the Holy Land (in 1002–03, c. 1008 and in 1039).

On his return from the third of these journeys Fulk died at Metz in Lorraine on June 21, 1040. By his first marriage, with Elizabeth, daughter of Bouchard le Vénérable, count of Vendôme, he had a daughter, Adela, who married Boon of Nevers and transmitted to her children the countship of Vendôme. Elizabeth having died in 1000, Fulk married Hildegarde of Lorraine, by whom he had a son, Geoffrey Martel (*q.v.*), and a daughter, Ermengarde, who married Geoffrey, count of Gbtinais, and was the mother of Geoffrey le Barbu ("the Bearded") and of Fulk le Réchin (see ANJOU).

BIBLIOGRAPHY.—Louis Halphen, *Le Comté d'Anjou au XI" siècle* (1906). The biography by Alexandre de Salies, *Histoire de Foulques Nerra* (1874) is confused and uncritical. A very summary biography is given by Célestin Port, *Dictionnaire historique, géographique et biographique de Maine-et-Loire,* 3 vol, vol. ii, pp. 189–192 (1874–78); and there is also a sketch in Kate Norgate, *England Under the Angevin Kings,* 2 vol., vol. i, ch. iii (1887). (L. Ha.)

FULLER, GEORGE (1822–1884), U.S. painter, noted for his haunting, dreamlike figure paintings, was born at Deerfield, Mass., Jan. 17, 1822. At first an itinerant portraitist, he settled in New York city about 1847 and enjoyed moderate success there until 1860. Then, after a visit to Europe, he retired to Deerfield and for the next 1j years managed the family farm, painting only for his own pleasure. In 1876, however, pressed for money, he sent some paintings to Boston. They attracted much attention and he never thereafter lacked patrons. He died at Brookline, Mass., March 21, 1884. Fuller is remembered for his introspective later works, notably "The Quadroon" and "Romany Girl."

(D. H. W.)

FULLER, JOHN FREDERICK CHARLES (1878–), British soldier, military analyst and war historian, one of the earliest students of armoured warfare, was born on Sept. 1, 1878. During World War I, after holding staff appointments, he became chief genera1 staff officer of the tank corps in Dec. 1916. Armoured tactics had been given a setback by the premature use of tanks in the battle of the Somme, but Fuller introduced vigorous new concepts. He planned the surprise attack of 381 tanks at Cambrai on Nov. 20, 1917, which dates the coming of age of armoured warfare, and had a responsible share in planning the 1918 tank operations.

In 1922 Fuller became chief instructor at the Staff college and in 1926 was appointed military assistant to the new chief of the imperial general staff. Promoted major general in 1930, he retired in 1933 to devote his time to writing. His *Tanks in the Great War* (1920) was followed in 1923 by *The Reformation of War,* the first of a series of provocative books challenging many of the tenets of British military thought. Fuller's books had a devoted following of readers in Europe and the United States, though in conservative military circles he was regarded as an extremist and visionary. The lectures of his *Field Regulations* III (1932) were adopted for study by the general staffs of the German, Soviet and Czechoslovak armies. But his insistence on the potentialities of the armoured offensive for swiftly crushing an unready nation clashed with the defensive tactical doctrines of British staff officers of the 1930s, and he lost favour with Britain's allies by predicting that the Maginot line would become "the tombstone of France." Thus his controversial writings were influential chiefly in molding German and Russian tactical thought on the eve of World War II.

As correspondent for the *Daily Mail* (London), he reported the Italian invasion of Ethiopia and the Spanish civil war, and he was the only foreigner at Hitler's first maneuvers, in 1935. Fuller devoted the World War II period entirely to writing, and in 1948 he published one of the first histories of that conflict, *The Second World War, 1939–1945.* Eight postwar years were spent in the preparation of his most comprehensive work, the three-volume *Military History of the Western World* (1954–56), covering all ages of warfare from the earliest times down to the end of World War II.

Fuller's output of more than 30 books was based on a wide range of reading and research, and he was outstanding in his field for the emphasis he placed on political and economic factors shaping tactics. No other military analyst of the first half of the 20th century had such an influence on his own age, but he was criticized on the ground that his writings about World Wars I and II were coloured at times by personal prejudice. (Ln. Ms.)

FULLER, LOIE (1862–1928), U.S. dancer, achieved distinction for her innovations in theatrical lighting as well as for her invention of the "skirt dance" or "serpentine." Born Marie Louise Fuller, in Fullersburg, Ill., she made her debut as an actress at the age of four. After tours as a child prodigy, she acted in stock companies, burlesque, vaudeville and Buffalo Bill's Wild West show.

During rehearsals for a play, *Quack, M.D.,* in 1889, she received a gift of a voluminous skirt of transparent china silk. Twirling in its billowing folds, she made her first appearance as a dancer and attained instant success.

Next she experimented with "skirt dances" performed under lights of various colours, achieving spectacular effects. In her *Fire Dance* she danced on a pane of glass, illuminated from below.

Appearing at the Folies Bergère, Paris, in 1892, Fuller attracted the attention of such artists as Toulouse-Lautrec, Jules Cheret and Auguste Rodin. She had her own theatre at the Paris Universal exposition of 1900. In 1909 she toured the United States, and in 1923 staged an inferno scene for a Paris Opéra production of Berlioz' *La Damnation de Faust.* She made her last appearance in London, in 1927, in a "Shadow Ballet" employing new silhouette techniques.

A close friend of Queen Marie of Rumania, Loie Fuller accompanied her on her American tour in 1926.

See her autobiography, *Fifteen Years of a Dancer's Life* (1913), and *Chronicles of the American Dance,* ed. by Paul Magriel (1948). (Ln. Me.)

FULLER, (SARAH) MARGARET, Marchioness Ossoli (1810–1850), U.S. writer, was born in Cambridgeport, Mass., May 23, 1810. A brilliant and erudite woman, she has been remembered by later generations more for her personality than for her writing. Her father's rigorous supervision of her early intellectual training made her a "youthful prodigy." Although colleges were closed to women, she pursued her scholarly interests until she became both admired and feared for her learning.

Plagued by financial difficulties after her father's death in 1835, she taught in Bronson Alcott's Temple school in Boston, 1836–37, and in the Greene Street school in Providence, 1837–39. In 1839 she published a translation of *Eckermann's Conversations With Goethe* and in 1842 a translation of part of the correspondence of Fraulein Giinderode and Bettina von Arnim. Her most cherished project, never completed, was a biography of Goethe. In 1840 her friendship with Ralph Waldo Emerson and her critical essays in *The Western Messenger* won her the position of editor of the *Dial,* a magazine launched by the Transcendentalists. She wrote poetry, reviews and critiques for the quarterly; but in 1842 she had to relinquish the unprofitable editorship to Emerson.

For five winters, 1839–44, she conducted in Boston classes of "conversations" for women on literature, education, mythology and philosophy. This venture into adult education was apparently a great success; she was reputed to be a dazzling leader of discussion. Her professed purpose was "to systematize thought"; more generally, she attempted to enrich the lives of women and to dignify their place in society. The same purpose guided her in writing *Woman in the Nineteenth Century* (1845). This tract on feminism went far beyond the conventional demand for political equality in its ardent plea for the emotional. intellectual and spiritual fulfillment of women. It was published by Horace Greeley, who had admired her *Summer on the Lakes, in 1843* (1844), a perceptive study of frontier life in Illinois and Wisconsin.

In 1844, Margaret Fuller assumed the responsible position of literary critic on Greeley's newspaper, the *New York Tribune.* She warmly encouraged American writers and crusaded for social reforms but made her greatest contribution, she thought, as interpreter of modern European literature. Though many of her columns were hastily written, her critical principles and judgments have led to the 20th-century evaluation that she was "one of the best-equipped, most sympathetic and genuinely philosophical critics produced in America prior to 1850."

Before sailing for Europe in Aug. 1846, she selected some of her essays for publication as *Papers on Literature and Art.* This book assured her a cordial welcome to literary circles in England and France. As America's first woman foreign correspondent, she reported on her travels for the *Tribune;* the "letters" were later published in *At Home and Abroad* (1856). After settling in Italy in 1847, she was caught up in the cause of the Italian revolutionists, led by Mazzini, and was secretly married to the Marchese Giovanni Angelo Ossoli. During the siege of Rome (1849) she superintended a hospital while her husband fought. The suppression of the republic made her decide to return to America with her husband and child; they perished in a shipwreck off Fire Island on July 19, 1850, and with them was lost her manuscript history of the revolution.

Margaret Fuller's career was one of valiant endeavour to overcome obstacles of all kinds, a few of her own making. Emotional and impulsive. she was capable of the most intense attachments; her friends, however devoted, often found her too demanding in personal relationships. Hawthorne thought her a pretentious humbug. Because her books are diffuse in organization and undisciplined in style, she has not survived as a notable writer; but her earnest, idealistic efforts to civilize the taste and enrich the lives of her contemporaries make her significant in the history of American culture.

Bibliography.—The *Writings of Margaret Fuller,* selected and edited by Mason Wade (1941) has a "Bibliography of Published Writings of Margaret Fuller." Wade's *Margaret Fuller: Whetstone of Genius* (1940) lists the chief biographies to that date. Later studies are Madeleine B. Stern, *The Life of Margaret Fuller* (1942), and Faith Chipperfield, *In Quest of Love: the Life and Death of Margaret Fuller* (1957).
(W. R. Eb.)

FULLER, MELVILLE WESTON (1833–1910), chief justice of the United States, was born of a cultured New England family at Augusta, Me., Feb. 11, 1833. His grandfather, Nathan Weston, was chief justice of Maine. Graduated in 1853 with honours from Bowdoin college, Brunswick, Me., Fuller attended Harvard law school for six months, being admitted to the bar in 1855, and, after a short career on an Augusta newspaper, started, in 1856, to practise law in Chicago. He was elected as a Democrat to an Illinois constitutional convention in 1861 and to the state house of representatives in 1862, but his political career deteriorated when the people refused to adopt the constitution and the Republican governor prorogued the legislature for Civil War disloyalty. Unknown nationally, but eminent at the Chicago bar, Fuller was appointed chief justice in 1888 by Pres. Grover Cleveland. In 1897–99 he served as an arbitrator in the Venezuelan boundary controversy between Great Britain and Venezuela and from 1900 to 1910 as a member of the Hague court of arbitration. He served as chief justice until his death which occurred at Sorrento, Me., on July 4, 1910, a longer term than that of any other chief justice except John Marshall and Roger B. Taney.

As chief justice, Fuller's great success was as an administrator rather than as a jurist. A gentle, modest, moderate man, scholarly and able but not of transcendent brilliance, he won the affection of his associate justices. Justice Oliver Wendell Holmes and Justice Samuel F. Miller both declared that Fuller was the best presiding judge they had ever known. By his independence and courage, his impartiality and nonpartisanship, his human sympathy and sense of humour, his skill in suppressing acrimonious dissents and, most of all, his rare executive ability, he raised the court in professional and popular esteem. He left behind no outstanding opinions of his own except those declaring the Income Tax law of 1894 unconstitutional. (W. L. K.)

FULLER, THOMAS (1608–1661), English scholar, writer and preacher, was one of the wittiest and most prolific authors of the 17th century, but, because even his weightiest pronouncements contain amusing passages and his writings abound with epigrams, anecdotes, puns and other conceits, a name for quaintness has obscured his real merits. Fuller's fame as a popular preacher and writer never prevented him from careful attention to literary form. As a historian he made no claims to profound research, but he was a serious gatherer of facts from original sources, and his larger works are still highly regarded for the information they contain. *The Holy War* (1639), a history of the crusades, is of permanent value. *The Holy (and Profane) State* (1642), a collection of characters, now Fuller's most readable work, provides both instruction and entertainment and is important to the historian of the English essay and biography. His *Worthies,* also highly readable, is still an important work of reference for biographical details of Englishmen, arranged by counties.

Fuller was born in Aldwincle, Northamptonshire, where his father was rector, and was christened on June 19, 1608. His mother's brother, John Davenant, bishop of Salisbury, had been president of Queens' college, Cambridge, and he was entered at Queens' at 13 and at 20 became the youngest M.A. in the university. In 1630 he was appointed curate of St. Bene't's, Cambridge; in 1631 he was given a prebend's stall in Salisbury cathedral and was presented to the living of Broadwindsor, Dorset. He took his bachelor of divinity degree at Cambridge in 1635. In 1638 he married Ellen Grove; she bore him a son, John, in 1641, but died a few months later. In 1640 Fuller represented the diocese of Rristol at the first church convocation in London, and established his great reputation as a preacher in the pulpits of the city churches. In 1641 he was appointed preacher at the Chapel Royal, Savoy, London, where he officiated until Aug. 1643. An adherent of the Royalist cause, he yet preached peace: "The best and only way to purge errors out, is in a faire and peaceable way; for the sword cannot discerne betwixt truth and error; it may have two edges, but never hath an eye." Yet his moderate views did not save him from the attentions of the Parliamentarians, and he found it advisable to leave London for Oxford. From Dec. 1643 to July 1644 he acted as chaplain to the royalist army, spending several weeks with the forces besieged in Basing house, Hampshire. In May 1644 he returned to Oxford, where he preached a notable sermon entitled *Jacob's Vow*. He moved with the army to Exeter, where for nearly two years he was in attendance on the household of the infant Princess Henrietta, and there published his small book of meditations, *Good Thoughts in Bad Times* (1645), many times reprinted, sometimes with *Good Thoughts in Worse Times* (1647).

In June 1646 he returned to London and wrote *Andronicus, or the Unfortunate Politician* (1646), a satire against Cromwell. After a few months, however, he moved to Boughton house, Northamptonshire, the seat of an old friend, Lord Montagu, where he applied himself to his two great historical works, *The Church-History of Britain* (165j) and *The History of the Worthies of England* (1662); but he was soon again leading the life of a wandering scholar.

The execution of the king on Jan. 30, 1649, was to Fuller "the midnight of misery," and his *Church-History* gives a full and accurate account of the king's death and burial. In the same year he was presented to the living of Waltham abbey, Essex. He made many friends in the district, including Izaak Walton, and was given a library at Copt hall by the earl of Middlesex. Under these conditions he was able to complete a large historical work, *A Pisgah-Sight of Palestine* (1650).

In 1652 Fuller was again appointed to preach in a London pulpit at St. Clement's, Eastcheap. He married Mary Roper, who bore him two sons and a daughter, though only one, Thomas, survived infancy, and was at last able to complete his *Church-History,* to which he added a *History of the University of Cambridge* and a *History of Waltham Abbey*. *The History of the Worthies* was published posthumously by his elder son.

Probably in 1657 Fuller had to appear before Cromwell's "Tryers" to test his fitness for public preaching. He came successfully through the ordeal, but soon after resigned his living at Waltham abbey. In 1658 he was presented to the living of Cranford, near London. He continued to preach in London, and at the Restoration was again given his prebend's stall in Salisbury cathedral and became a doctor of divinity at Cambridge. He might have received a bishopric for his loyalty, but was taken ill while preaching a marriage sermon at the Savoy and died at his lodgings in Covent Garden on Aug. 16, 1661.

Fuller in his prime was described as a tall, burly man with a ruddy face and curly hair. He possessed a remarkable memory and needed little sleep, which helps to account for his great output, despite the harassed life he led. He confessed, indeed, that he had written too many books, but he loved all books for their own sake and took an interest in the physical appearance of those that he published. He has had no more sincere admirer than Charles Lamb, who made a selection of his works, for Leigh Hunt's quarterly *Reflector* (1812).

BIBLIOGRAPHY.—There is a full *Bibliography of Fuller,* ed. by S. Gibson for the Oxford Bibliographical society, with introduction by Geoffrey Keynes (1936). For his life *see* the short anonymous *Life* (1661); and J. E. Bailey, ***The Life*** of ***Thomas Fuller*** (1874). (G. L. K.)

FULLER'S EARTH, an important industrial clay used primarily as an absorbent, so named from its use by fullers, that is, textile workers who fulled or scoured, cleansed and thickened cloth, to remove grease from it. It was increasingly employed in the second half of the 20th century as a carrier for insecticides and fungicides and in drilling mud. As these uses increased, its former use as a colour remover in mineral oil and vegetable oil refining declined. The decolorizing action of the clay is not a filtering action but a selective adsorption by which the dark constituents of the oil are absorbed as a coating on the clay particles, leaving behind the colourless constituents. This selective property, which is mainly physical, has been explained as being connected with open bonds in the clay developed by the removal of hydrogen (H), hydroxyl (OH) or some of the cations from the component minerals. It is not limited to any one clay mineral, nor is it present to an equal degree in clays that are identical in mineralogical and chemical composition. Weathering improves the adsorptive capacity of some clays and the upper exposed portion of the deposit is superior to the lower part having the same mineralogical composition. Clays having a marked bleaching action on oils are termed adsorbent clays; these are divided into active clays (or fuller's earth) that are used without any other treatment except drying and grinding, and the activated clays that are prepared by partial bleaching with strong acids. Activated clay which includes many calcium bentonites *(see* BENTONITE), is expensive because of the added cost of the acid treatment, but it has a strong bleaching action on some oils so that a little ddes the same work as more of the cheaper naturally active clays. Other substitutes include activated bauxite, diatomite and synthetic magnesium silicate.

Two methods of treatment are used in industry: the contact method in which the ground adsorbent clay is stirred in the oil, heated and filtered; the percolation method, in which the oil percolates through a cylinder filled with dried clay ground to pass a 150-mesh screen. Some granular fuller's earth and bauxites that have been activated by heating. can be heated at a controlled temperature to drive off the colouring matter and can be reused.

The selective adsorption of fuller's earth and bleaching clay is connected mainly with the minerals of the montmorillonite group (see CLAY AND CLAY MINERALS), which are hydrous aluminum silicates containing calcium, magnesium and iron. These clay minerals have base exchange properties and are often the chief components of bentonite, a clay formed by the alteration of the glass that once constituted volcanic ash. The mineral smectite, a term used synonymously with fuller's earth in the textbooks of the 18th century. has an X-ray diffraction pattern and a chemical composition identical to montmorillonite, which is the preferred name. The smectite of Cilly, Styria, and of the Woburn sands. England, shown to be montmorillonite retaining the structure of volcanic ash, is bentonite as well as fuller's earth. Decolorizing effects on edible oils and lard have been connected with a few clays composed of kaolinite and halloysite (hydrous aluminum silicates) and hydrous micas (hydrous aluminum silicates containing potash). The fuller's earth of Attapulgas, Ga., composed of the clay mineral attapulgite, has a chain structure in place of the usual sheet structure of other clay minerals. Some glauconite (a hydrous potassium iron silicate) has natural bleaching qualities that can be further developed by acid treatment. The quality of fuller's earth can be determined only by a practical test.

Fuller's earth may occur at any geological horizon; in Surrey, Eng.. it is of Cretaceous age; near Bath it is of Jurassic Age; at Bala, north Wales, it occurs in Ordovician rocks; in Saxony it is said to be the decomposition product of a diabasic rock. In North America, Ordovician to Pliocene deposits are distributed from Mexico to Alberta, Can. In the United States the main production has been from the Eocene and Miocene of Georgia and Florida and the Eocene of Tennessee, and to a lesser extent from Mississippi, Texas, Colorado, Illinois and Utah. (V. T. A.; X.)

FULLERTON, a city of Orange county, Calif, U.S., 25 mi S.E. of Los Angeles (*q.v.*) and a part of the Los Angeles metropolitan area. Within the city limits are located one of the pioneer public junior colleges of California (established in 1913) and a state college (established in 1959). In keeping pace with the tremendous growth of Orange county during and after World War II, the industrial section of Fullerton underwent rapid but orderly development. Many of the nation's leading companies located branches there. The citrus and other agricultural industries and the production of crude oil, mainstays of the city's economy before its industrialization, continued to be important sources of revenue. Besides possessing excellent local recreational facilities, the city is conveniently located within easy driving distance of all of southern California's beach, mountain and desert recreational centres. The original townsite of Fullerton was laid out in 1887 and the city was incorporated in Jan. 1904. It was named for George Fullerton, an executive of the Santa Fe railroad, who in 1879 was allocated $50,000 to invest for the company. He purchased the land on which the city lies and incorporated the Pacific Land Improvement company to develop it. Fullerton has a council-manager form of government, in effect from 1953. Pop. (1960) 56,180. For comparative population figures see table in CALIFORNIA: Population. (WM. H. K.)

FULMAR, an arctic sea bird belonging to subfamily Fulmarinae, also containing the shearwaters (*q.v.*), in the order Procellariiformes. It is a large petrel (length 19 in.) resembling the herring gull (Larus *argentatus*) or European common gull (L. *canus*), but with primaries gray instead of black. It flies over cold northern oceans to 85° north, visiting land only to breed. It nests in vast numbers, like gulls, on rocky islets, laying one dull white egg on rocky ledges and cliffs. Its flight is slow, flapping, owllike, alternating with gliding when the wings are held out straight. It settles on the water to feed on fish, floating offal and animal debris. The Atlantic fulmar (*Fulmarus* g glacialis) breeds to Greenland, Scotland, Ireland, north into the Arctic ocean, west to Melville Island and east to Novaya Zemlya. It is replaced in the North Pacific by F. g. rodgersii, breeding from the Kuriles and Kamchatka north into the nearby Arctic ocean (Wrangel and Herald islands). Male and female in courtship simultaneously display the mauve lining of the mouth. Like many of the petrels, when handled the bird ejects oil from its mouth and tube-nostrils. Most of the fulmar's relatives live on subantarctic islands and range the southern seas. The largest near-relative is the giant fulmar (*Macronectes giganteus*) or bonebreaker, 3 ft. long and 7 ft. spread and dark sooty in colour. It lives in cold southern seas, wanders north to Peru and is very destructive to eggs and young of other sea birds on subantarctic islands. (G. F. Ss.)

FULMINIC ACID is an organic compound of formula CNOH. Its salts have been known for a long time and are of interest because they are sensitive explosives. The silver salt, fulminating silver, seems to have been obtained in the 17th century; and the mercuric salt, mercuric fulminate (*q.v.*), first prepared by E. Howard in 1799. It is obtained by the action of ethyl alcohol and nitric acid on mercuric nitrate. The salts vary in sensitivity and some are among the most sensitive explosives known, since explosions have been recorded when they have been rubbed under water with a glass spatula.

The free acid is unknown. A solution of it in ether can be obtained by acidifying an aqueous solution of the sodium salt and extracting with ether. The acid, however, is volatile with ether vapour and cannot be separated by fractional distillation. Further, it is unstable and polymerizes rapidly in both aqueous and ethereal solution to products which are mentioned below.

The constitution of fulminic acid was a matter of controversy for many years, and investigation of the problem was not made easier by the instability of the acid and the explosive nature of both the acid and its salts. The stumbling block to general acceptance of the formula CNOH for the acid was that it implies "bivalent" carbon. Wider knowledge of the modes of union of atoms removes this difficulty. It is now known that bivalent carbon in the isocyanides, RNC, is a misconception: the link which was written $-\mathrm{N}=\mathrm{C}$ shows the properties of a triple link in its length, its heat of rupture and the force constants of the oscillation of the carbon and nitrogen atoms. Bivalent carbon in these compounds is not bivalent in the sense that the atom has six valency electrons: the "lone pair" of electrons of the nitrogen atom is also involved in the linkage between the two atoms so that each has the normal number of eight valency electrons. The same is almost certainly true for fulminic acid. Its behaviour makes complete investigation difficult, but the resemblance of its chemistry to that of the isocyanides is strong evidence that its structure is correctly represented by the formula : C : : : N : OH in which the dots represent valency electrons. (T. W. J. T.; X.)

FULTON, ROBERT (1765–1815), U.S. engineer best known for his development of the steamboat, was born on a farm at Littfe Britain (now Fulton) 22 mi. S. of Lancaster, Pa. At an early age Fulton became a jeweler's apprentice in Philadelphia; in 1785 he began working independently as a "miniature painter and hair-worker." He went to England in 1786 to study under Pennsylvania-born Benjamin West (*q.v.*), the artist. He abandoned art for engineering in 1793, his principal interests being reflected in his Treatise on the *Improvement* of Canal *Navigation* (1796). Fulton tried, unsuccessfully, to interest the United States and, later, France in his canal proposals, moving to France in the spring of 1797. A few months later he submitted plans for a submarine, suggesting to the French that British warships could be destroyed by submarines attaching underwater bombs and then escaping undetected. His "Nautilus," having most of the features of David Bushnell's earlier (1775) submersible (see SUBMARINE), was launched in 1800 and performed creditably. The vessel was reconstructed with improvements in 1801, but nevertheless the project was rejected. Fulton turned now to steamboats. having formed a partnership with Robert R. Livingston (*q.v.*), then U.S. minister to France. Livingston had experimented with steamboats and held a monopoly for steam navigation on the Hudson river. The two men launched a steamboat of Fulton's design on the Seine in 1803. The British government, long having full knowledge of the submarine plans through Fulton's connivance, induced him to come to England in 1804; however, with the victory at Trafalgar in 1805, British interest in new naval weapons vanished. Fulton also tried unsuccessfully to interest President Jefferson in his submarine.

He returned to the U.S. in 1806. having been abroad for nearly 20 years. Livingston was also back in America, and a boat hull was ordered by the two. On Aug. 9, 1807, "The Steamboat" (as Fulton called it) made its trial runs powered by a 24-h.p. Boulton and Watt engine. Eight days later came the historic 150-mi. trip from New York to Albany. Commercizl schedules were established in the fall, the boat then being advertised as "The North River Steamboat." Substantially rebuilt and lengthened to 149 feet, the boat was registered as "The North River Steamboat of Clermont" (shortened to "Clermont" by the press) in 1808. Additional boats were built in the next few years. Fulton married Livingston's cousin Harriet, established an engine works in New Jersey, and developed steam ferries for the Hudson and East rivers. The first steam navigation of the central U.S. waterways was made by the Fulton-designed, Pittsburgh-built "New Orleans" on the Mississippi in 1811. Fulton's last triumph was the promotion and building of a mobile floating fort for the defense of New York harbour in the War of 1812. This ship, known both as the "Demologus" and "Fulton the First," mas launched shortly before the war ended in December 1814. Fulton died in New York on Feb. 24, 1815.

It is clear that Fulton—a clever mechanic with fertile imagination, a perennial opportunist and an astute businessman—was the leader in developing the steamboat to commercial status by the synthesis and extension of the most successful ideas of Europe and America. The steamboat patents he held were for improvements; they were not basic patents. His submarine plans were also based largely on the work cf others.

FUMARIC AND MALEIC ACIDS, a pair of stereoisomeric unsaturated organic dibasic acids. The chemical formula for both acids is $C_4H_4O_4$. Fumaric acid (trans-butenedioic acid) is found in fumitory (*Fumaria officinalis*), various fungi (*Agaricus piperatus*, etc.) and Iceland moss. It is obtained by heating malic acid alone to 150° C. or by heating it with hydrochloric acid or hydrobromic acid. It may also be obtained by boiling monobromosuccinic acid with pyridine in aqueous or alcoholic solution, and by heating maleic acid to 210° C. Commercially, the acid is prepared by the fermentation of sugar. It crystallizes in small prisms or needles and is practically insoluble in cold water. It sublimes to some extent at about 200° C.. being partially converted into maleic anhydride and water. the reaction becoming practically quantitative if dehydrating agents are used. Potassium permanganate oxidizes it to racemic acid (see TARTARIC ACID).

Maleic acid (cis-butenedioic acid) is obtained in the form of its anhydride by distilling malic or fumaric acids, or by heating fumaric acid nith acetyl chloride to 100° C. It crystallizes in monoclinic prisms, which are easily soluble in nater, and it inelts at 130° C. to a liquid which boils at 160° C. with decomposition into water and maleic anhydride. When heated with concentrated hydrobromic or hydriodic acid, it is converted into fumaric acid. Oxidation by potassium permanganate converts it into mesotartaric acid.

Maleic anhydride is obtained by distilling maleic or fumaric acid with phosphorus pentoxide. The anhydride forms triclinic crystals nhich melt at 60° C., and it boils at 196° C. On a manufacturing scale maleic anhydride is prepared by oxidation of benzene vapour with air over a vanadium pentoxide catalyst.

Both acids yield acetylene by the electrolysis of aqueous solutions of their alkali salts, and on reduction both yield succinic acid; while by the addition of hydrobromic acid they both yield monobromosuccinic acid. From this behaviour it follows that the tno acids are structurally identical, the isomerism being caused by differences in the spatial arrangement of their constituent atoms (see STEREOCHEMISTRY), thus:

$$\begin{array}{l} H\!-\!C\!-\!CO_2H \\ \quad\ \| \\ H\!-\!C\!-\!CO_2H \end{array} \quad \begin{array}{c}\text{Maleic acid}\\ (\textit{cis})\end{array} \qquad \begin{array}{r} H\!-\!C\!-\!CO_2H \\ \| \quad\ \ \\ HO_2C\!-\!C\!-\!H \end{array} \quad \begin{array}{c}\text{Fumaric acid}\\ (\textit{trans})\end{array}$$

The foregoing formulas account fur the reactions mentioned above and also for the fact that maleic acid readily yields an anhydride, whereas fumaric acid does not.

Uses.—Both acids are of considerable industrial value, particularly in the preparation of various resins, which find their greatest use in the manufacture of lacquers, enamels and laminating varnishes.

During World War II maleic and fumaric polyesters came to be used widely as binders for glass fibres. The resin formed by the condensation of glycols with maleic or fumaric acid was dissolved in a monomeric vinyl composition such as styrene; this procedure permitted the formation of a viscous liquid which could be cured without the loss of any volatile components.

Currently these resins, together with glass fibre, are employed for the fabrication of various structural assemblies for automobiles, tank cars, furniture, complex moldings, boats,' refrigerators, as well as other large structural assemblies.

See Sir T. E. Thorpe, *Dictionary of Applied Chemistry*, 4th ed. by J. F. Thorpe and M. A. Whiteley, vol. 1–10 (1937–50). (E. L. KA.)

FUMAROLE, a vent from which volcanic vapours issue, named indirectly from Lat. *fumariolum*, "a smoke hole." The vapours from fumaroles were studied first by R. W. Bunsen in Iceland, and afterward by H. Sainte-Claire Deville and other chemists and geologists in France, who examined the vapours from Santorin, Etna, etc. The hottest vapours issue from dry fumaroles, at temperatures of at least 500° C., and consist chiefly of anhydrous chlorides, notably sodium chloride. The acid fumaroles yield vapours of lower temperature (300° to 400° C.) containing much water vapour, with hydrogen chloride and sulfur dioxide. The alkaline fumaroles are still cooler, though above 100° C., and evolve ammonium chloride mith other vapours. Cold fumaroles, below 100°, discharge principally aqueous vapour, with carbon dioxide and perhaps hydrogen sulfide. See VOLCANO; VOLCANISM.

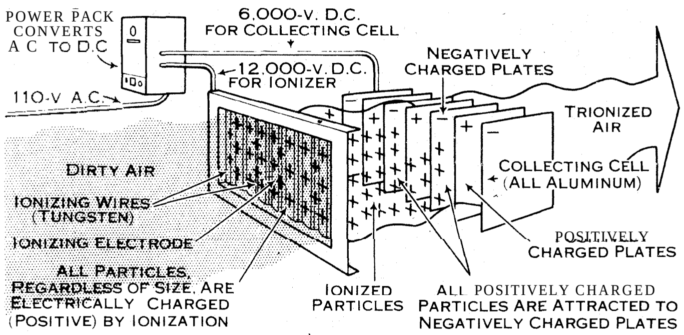
FUME PRECIPITATION, ELECTRICAL. The precipitation of smoke by electricity was described in 1824 by M. Hohlfeld. a teacher of mathematics in Leipzig, but only after it was independently rediscovered and critically studied by Sir Oliver Lodge about 1884 did it attract general attention and lead to attempts at industrial applications. At the time, however, these proved unsuccessful due to the lack of modern equipment. It was not until 1906, following experiments at the University of California, Berkeley, that the process was commercially successful.

The first installation was at the Selby Smelting works, near San Francisco, where it was used for the removal of sulfuric acid mist from about 5,000 cu.ft. of gases per minute. Although first applied purely to mitigate nuisances, the demand for the process is primarily based on a greater profit to be derived from the gases cleaned or the material removed.

Another circumstance aiding the development through friendly public interest was the creation in 1912, under the auspices of the Smithsonian institution, of the Research corporation in New York city?to hold and administer as an endowment for research most of the United States patent rights to the process.

The Process.—Technically the process consists in securing a uniform, copious but nondisruptive discharge of electricity from small electrode surfaces of one polarity into a stream of cloudy gas. The fine solid or liquid particles composing the dust, fume or smoke are immediately attracted to, and deposited on, large electrode surfaces of opposite polarity, the particles having become charged from the depletion of electrons from their surfaces; *i.e.*, ionization. The process is illustrated diagrammatically in the figure.

Dirty air is passed through a series of fine tungsten wires maintained at a positive potential of 12,000 v. This step is called the ionizing step. Immediately following this, the ionized particles flow past a set of plates spaced about ⅜ in. apart. Alternate plates are charged with a positive potential of about 6,000 v. Upon contact with the negative collecting plates the positively charged ions gain electrons. stick to the plates and fall into a bin or hopper for collection. The voltage on the wires in the ionizing chamber is regulated to secure as strong a glow as is possible without passing over into the disruptive discharge; *i.e.,* a spark or arc. The discharge electrodes are customarily nega-



BY COURTESY OF ASSOCIATION OF IRON AND STEEL ENGINEERS

THE **TRION** PRINCIPLE OF CLEANSING AIR BY COLLECTION OF **IONIZED** PARTICLES ON ELECTRICALLY CHARGED ALUMINUM PLATES

tive. because positively charged particles are easiest to produce in the ionizing chamber.

The gas treaters now in general use consist either of a multiple set of pipes, each containing an electrode. or of plates hung vertically in a flue. the wires being stretched parallel between them. The materials of construction, including the collecting electrodes, vary from iron and lead to reinforced concrete and vitrified earthenware: depending on the composition and temperature of the gas stream to be heated. The original Cottrell precipitator styles are used almost exclusively for liquid mists or fogs. Condensation of vapour to liquid occurs and the liquid drains along the walls of vertical tubes. For dry dusts or fumes the precipitator takes the form of plates similar to those shown in the figure. Gas flow is horizontal and dust collected on the plates falls to a hopper or other conveyor for easy removal. Mechanical agitation of the collecting plates often is necessary.

Factors in **Design.**—Most plants are designed with electrodes of opposite sign 2 to 6 in. apart and operating at 50,000 to 80,000 v. The size of installation is determined primarily by the volume of gas to be treated and the percentage of suspended matter to be removed; the amount, kind and size of particle of the iatter being of minor importance. If P is the ratio of outgoing to incoming suspended matter, t the average time in seconds that the gas remains between the electrodes and K a constant depending upon the apparatus, voltage. temperature and kind of raw gas, then $P=K^t$. In most commercial practice t averages about 2 sec. and K varies from 0.2 to 0.7, the gases travelling from 10 to 40 ft. through the electric field at linear rates of 3 to 15 ft. per second. Removal of 90% to 99% of the suspended matter is usually aimed it, and the energy required is 1 to 3 kw.hr. per 100,000 cu.ft. of gas treated.

Industrial Uses.—The earliest applications of the process were to the smelting and sulphuric acid industries. Equipments at cement mills were fewer in number but handled a large volume of gas and a large tonnage of precipitate. Other important applications are to the detarring of coke-oven gases, the cleaning of producer and iron blast-furnace gas, the cleaning of ventilating air in crushing, grinding and polishing mills (especially where cost of heating in minter makes recirculation of air important), the recovery of sludge acid fumes in petroleum refineries, the recovery of dust. from brown-coal dryers and the removal of ash from the stack gases of large power plants burning powdered coal. On a laboratory scale the process has also been applied successfully to sanitary atmospheric analysis and to gas masks, including the removal of bacteria from air.

FUMIGATION, the use of gases, vapours, smoke or fumes for the destruction of organisms; the practice is derived from the early use of fumes, perfumes, smoke or vapours for ceremonies of incantation and for the purification of air. The burning of incense or other aromatic substances was closely associated with primitive religious ceremonies; it counteracted the disagreeable odours generated by the sacrifice of animals and mystified and exerted a favourable psychological influence over the religious devotees. Later, fumigation was practised in churches to purify the air in time of public sickness and to dispel the reek of the populace and of the gases arising from burial vaults beneath church floors. In medicine, the term in early times meant the exposure of the body to fumes; for example. sulfur fumes once were recommended for the treatment of scabies.

The value of fumigant chemicals for destroying organisms was known to the early Greeks and Romans: Cato in about zoo B.C. described the use of fumes from a mixture of sulfur and asphalt to control tree-infesting insects.

Chemical warfare (*q.v.*), or the use of poisonous smoke or chemicals for the destruction of man, is a form of fumigation and is helieved to have been attempted first during the wars of the Athenians and Spartans (431–404 B.C.), when the Spartans saturated wood with pitch and sulfur and burned it under the walls of Plataea and Belium in an effort to drive the defenders from their posts. Perhaps the first poison gas successfully used in war was "Greek fire" (*q.v.*), which protected Constantinople against the invasion of the Arabs in A.D. 670. This mixture of chemicals when released upon the sea burst into flames, liberating clouds of poisonous gas and setting fire to ships.

The great modern development of fumigation for the control of noxious organisms began in 1854, when the use of carbon disulfide for insect control was reported.

Characteristics of Fumigants.—Fumigation is most commonly accomplished with toxic gases. Gases have the capacity to expand or diffuse indefinitely into any volume available. This capacity, coupled with the extremely small size of their individual particles (considerably less than 0.001 micron *[p]* in diameter), enables gases to reach the tissues of organisms readily via the respiratory tract. These same characteristics enable some fumigants to exert a significant toxic effect by direct penetration of exposed skin surfaces. However, this does not apply as extensively to insects and related organisms because of their protective exterior skeletal structure. Vapours (gaseous materials very near the condensation point) have a tendency to diffuse and are entirely satisfactory for use in fumigating. However, smokes and fumes do not diffuse, and with individual particle size ranges of 0.001–0.4 and 0.1–1.0 μ, respectively, are near the limit of effectiveness for fumigation. Even less effective are aerosols, which consist of airborne liquid droplets ranging from 0.1 to 30.0 p in diameter. An idea of the effect of particle size on the respiration of air-borne materials is gained from the knowledge that. in man, there is little effective penetration of the lungs by particles larger than three microns in diameter.

Methods of Fumigation. — Fumigation for the destruction of insects and rodents is acconiplished in a variety of ways. Dry-wood termites are commonly controlled by placing a plastic tent over the entire infested building and releasing methyl bromide within it. Mills, factories, warehouses and packing plants are freed of vermin by the introduction of hydrocyanic acid gas within the structure, after first ensuring that all openings are sealed. Stores of raw and manufactured items of organic origin are routinely fumigated to eliminate contained pests,

Fumigation of packaged items is normally accomplished under vacuum in specially constructed chambers in order to ensure thorough penetration. The application of fumigants heavier than air to soils infested with destructive nematodes and insects is common practice, as is also the destruction of undesirable rodents and animal predators by pumping calcium cyanide into their burrows. This chemical is a bluish-gray powder that combines with atmospheric water to release hydrocyanic acid gas. Under certain conditions, it is possible to remove pests from living organisms with fumigants. For example. control of scale insects on citrus trees is accomplished by placing a tent over each tree and releasing hydrocyanic acid gas therein.

Extensive efforts have been made to destroy air-borne micro-organisms by the release of disinfectant vapours—glycol, for example — but there are serious limitations to the practical use of this form of fumigation. (K. L. K.; X.)

FUMITORY, any plant of the genus *Fumaria,* family Fumariaceae, comprising small, branched, often climbing annual herbs with much-divided leaves. The flowers are small, tubular. with a spurred base, and in the British species pink to purplish in colour. These are weeds of cultivation growing in fields and waste places. F. capreolata climbs by means of twisting petioles. In past times fumitory was in esteem for its reputed medicinal properties; and in England, boiled in water, milk or whey, it was used as a cosmetic.

The root of the allied species (*Corydalis tuberosa*) was known as radix aristolochia, and has been used medicinally for various cutaneous and other disorders.

About 11 alkaloids have been isolated from it. The herbage of *Fumaria officinalis* and *F. racemosa* is used in China as an application for glandular swellings, carbuncles and abscesses, and was formerly valued in jaundice.

The climbing fumitory or Allegheny vine (*Adlumia fungosa*), native to moist woods in the northeastern United States, with delicate flowers and foliage, is cultivated as an ornamental vine. It is suited only to well-shaded places in the wild garden.

FUNCHAL, the administrative centre of the Portuguese archipelago of the Madeiras; on the south coast of Madeira, in 32° 37′ N. and 16° 54′ W. Pop. (1960) 100,476 (mun.). Its whitewashed houses, in their gardens full of tropical plants, are built along the curving shore of Funchal bay, and on the lower slopes of an amphitheatre of mountains which form a background 4,000 ft. high. Numerous country houses (*quintas*), with terraced gardens, vineyards and sugar-cane plantations occupy the surrounding heights. The chief buildings include the cathedral, Anglican and Presbyterian churches, hospitals, opera house, museum and casino. In the steep and narrow streets, which are lighted by electricity, wheeled traffic is impossible; sledges drawn by oxen and other primitive conveyances are used instead (see MADEIRA). In minter the fine climate and scenery attract numerous invalids and other visitors; many foreigners engaged in the coal and wine trades also reside there permanently. The British community was first established there in the 18th century. Funchal is the headquarters of Madeiran industry and commerce (see MADEIRA). Funchal is connected by cable with Carcavellos (for Lisbon), Porthcurnow (for Falmouth. Eng.) and St. Vincent in the Cape Verde Islands (for Pernambuco, Brazil).

FUNCTION, in mathematics, an expression, rule or law which makes correspond to each value taken by one variable, called the independent variable or argument of the function, one or more values of another variable, called the dependent variable. In its most general usage in mathematics the word "function" refers to any correspondence between two classes of objects. A simple example under this general definition would be afforded by a group of people seated in a room, with the independent variable standing for any person in the room, while the corresponding value of the dependent variable is the chair in which he sits. But for most functions occurring in mathematics, the variables range over classes of numbers. For example the formula d $=\pi r^2$ gives for each positive real number r the area of the circle with radius r. The formula $w=c/\nu$ gives the wave length of radio or light waves in terms of the frequency ν. Here c is the velocity of light. The expressions

$$a + bx + cx^2,$$
$$a, + a_1x + \dots + a,x^n$$

are polynomial functions of x when the coefficients $a, b, c,$ a,, $a_1,$ . . ., a_n are given. The short symbols $f(x)$, $g(x)$, $P(x)$, . . ., are often used to stand for functions of the independent variable x, either for the sake of abbreviation. or because the nature of the function is unknown or unspecified. The quotient of two polynomials $P(x)/Q(x)$ is called a rational function. A polynomial is regarded as a special case of a rational function. The trigonometric functions sin x, cos x, tan x and others, where x is the measure of an angle, are defined geometrically in elementary trigonometry (*q.v.*). However, for practical purposes their values are given in tables. Many functions of practical importance are defined only by means of tables, as in statistics. For example, the death rate in each year over a period of years is given in mortality tables used by life insurance companies.

Inverse functions are obtained from given functions by interchanging the roles of the independent and dependent variables. Thus, if the given function is written $y=x^2$, the inverse function would be written $x=\sqrt{y}$. The two functions determine the same correspondence between the two variables. But note that when y is real and positive in the example just cited. $\sqrt{y}$ is usually understood to stand for the positive square root only, so that the inverse function, which is two-valued, should then be written $x=\pm\sqrt{y}$. The exponential function $y=10^x$ gives a value of y for each real value of x. Except when x is an integer these values are not easily computed. In this case the inverse function is written $x=\log_{10}y$, and its values are given in tables of common logarithms.

Functions of two or more variables occur frequently in applications of mathematics. For example, the formula $A=\frac{1}{2}bh$ gives the area of a triangle in terms of its base b and altitude h. The formula $E=\frac{1}{2}mv^2$ gives the kinetic energy of a moving body in terms of its mass m and its velocity v.

Functions of a Complex Variable. — In the preceding examples the variables have been thought of as real variables. The practical applications of functions of a complex variable are not so easy to illustrate, but are nevertheless very extensive. They occur, for example, in electrical engineering, in aerodynamics and in the theory of the potential. In the case of a polynomial, or, more generally, of a rational function, the variables may obviously be taken to be complex variables if desired, since the operations of addition, subtraction, multiplication and division may be performed on complex numbers (*q.v.*), and satisfy the same formal laws as they do for real numbers. However, functions of a complex variable may easily be formed in more arbitrary ways. If we represent the complex variable in the form $x=u+iv$, where i is the imaginary unit, and u and v are real, we may set $f(x)=P(u,v)+iQ(u,v)$, where for example

$$P(u,v)=u^3+v^2,\ Q(u,v)=3uv^3-v, \text{ or} \tag{1}$$
$$P(u,v)=\sin u \cos v,\ Q(u,v)=2u+3v, \text{ or} \tag{2}$$
$$P(u,v)=u^2-v^2,\ Q(u,v)=2uv, \text{ or} \tag{3}$$
$$P(u,v)=e^u \cos v,\ Q(u,v)=e^u \sin v, \tag{4}$$

where $e=2.718$ . . . is the base of the natural system of logarithms. (See LOGARITHMS.) Other less obvious and less direct methods of defining functions will be described later.

Geometric Representation of Functions. — Real-valued functions $y=f(x)$ of one real variable may be given a geometric representation by means of the analytic geometry (*q.v.*) of René Descartes. The independent variable x is plotted along a number scale on a line called the x-axis, which is usually taken as horizontal, and the dependent variable y is plotted along a number scale on another line called the y-axis which is usually taken as vertical. The graph of the function consists of the points with co-ordinates (x, y) where $y=f(x)$. For example, the graph of a quadratic function $y=a+bx+cx^2$ is a parabola. if $c\neq 0$. Some functions are given only by their graphs. Examples are the temperature. air pressure and wind velocity as recorded by weather bureau instruments.

A complex number may be plotted in a complex plane. A function of a complex variable is represented geometrically by a correspondence between two planes. but this graphical representation is not so vivid as that described above for a function of a real variable. However. it has been found suggestive and helpful to use geometric terminology in the theory of functions in both cases.

History. — The development of the theory of functions goes back to Descartes' publication of his work on analytic geometry (1637). The abscissas x and ordinates y of a plane curve are variables; the curve pictures the dependence of the one on the other. The word "function" seems first to have been used in such a sense by Gottfried Wilhelm Leibnitz (1694), who thus denoted certain lengths such as abscissas, ordinates. tangents, normals and radii of curvature, associated with the position of a point on a curve. J. Bernoulli (1698) applied the term to mathematical expressions involving variables and constants. The notation $f(x)$ was used by Leonhard Euler in 1734. His *Introductio* in *Analysin Infinitorum* (1748) may be regarded as the first treatise on the theory of functions. although its point of view would now be described as elementary and formal, As in the definition of Bernoulli. a function is identified with its analytic expression and according to the form of this expression it is classified as explicit or implicit. algebraic or transcendental.

The 18th century was a constructive period in mathematics, an epoch of discovery, when scientific accuracy played a subordinate role. The first part of the 19th century ushered in the present era of criticism. The *Théorie* des *fonctions analytiques* of Joseph L. Lagrange (1797) was a precursor of this change. Better foundations were here sought by basing the processes of the calculus on the properties of series of powers of the independent variable. Analytic expressions were still of central interest. but soon a new point of view was forced upon mathematicians by the discovery of Jean B. J. Fourier (1807) that a single analytic expression, a trigonometric series. may represent, in different domains. what had been regarded as different functions. It was believed at first that an arbitrary function could be represented by a series of Fourier. When it appeared that there were necessary restrictions. the way mas open to a treatment of functions based on their intrinsic properties. In connection with his proof of the convergence of Fourier series (1829) Pierre G. Lejeune-Dirichlet gave a definition for the term function closely akin to that at the beginning of this article (*Werke,* vol. 1, p. 135).

Among the founders of the modern theory of functions. both real and complex, three are pre-eminent, Augustin L. Cauchy (1789–1857), Georg F. B. Riemann (1826–66), and Karl Weierstrass (1815–97). To the latter is especially due the arithmetization of the subject, n-hereby all definitions are based on equalities and inequalities concerning numbers. The theory of aggregates (see SET THEORY [THEORY OF AGGREGATES]). which furnishes a necessary foundation for ideas regarding domains. and which arose from the investigations of Georg Cantor (1845–1918), has become one of the most important adjuncts of the theory of functions. (See also POINT SETS.) Its development has been connected with recent generalizations of the notion of integration by Henri Lebesgue (1902) and others.

The Notion **of** a Limit. —This is a fundamental concept in the theory of functions. A function $f(x)$ is said to have the limit L as x approaches a value c in case for every positive number e there exists another positive number 6 such that if $|x-c|<\delta$ then $|f(x)-L|<\epsilon$. If phrased in more intuitive language, this requirement states that the value of $f(x)$ remains arbitrarily near L whenever the point x is sufficiently close to c. When the variable x is real, the inequality $|x-c|<\delta$ means the same thing as the double inequality $c-\delta<x<c+\delta$. When the variable x is complex, it means that the Euclidean distance between the points of the complex plane representing x and c, is less than 6. Corresponding statements apply to the inequality $|f(x)-L|$<e. In the definition of limit it is frequently required that the point x shall never coincide with c, so that if the function has a value $f(c)$ at c, that value has nothing to do with the existence or value of the limit L. But this requirement is not essential. The same logical form of the definition of limit applies to other cases than the ones mentioned above, but one or both of the restrictions on the values taken by the independent variable and by the function may need to be changed in form. The notation $\lim_{x\to c} f(x)=\text{L}$ is used as a shorthand for the statement defined above. This symbol is to be read, "The limit as x approaches c of $f(x)$ is L." Simple examples of limits are the following:

$$\lim_{x\to 2} (x^2+5x)=14. \tag{5}$$

$$\lim_{x\to 0} x \sin (1/x)=0, \text{ if X is a real variable.} \tag{6}$$

$$\lim_{x\to 0} 1/x^2=+\infty\text{, if } x \text{ is a real variable.} \tag{7}$$

$$\text{lirn}_{x\to 0} \frac{1}{10^{1/x}+1}=0\text{, if x is a positive real variable.} \tag{8}$$

$$\text{lirn}_{x\to 0} \frac{1}{10^{1/x}+1} - 1\text{, if x is a negative real variable.} \tag{9}$$

In example (5) the value of the limit may be found by substituting 2 for x in the given expression, but this is not true for the other cases. In example (7) the inequality $|f(x)-L|<$ in the definition of limit is to be replaced by the inequality $1/x^2>1/\epsilon$. The function $f(x)=\sin(1/x)$ is one which does not have a limit as x approaches zero, since sin $(1/x)$ oscillates infinitely often between the values $+1$ and -1.

Continuity.—This is another important concept in the theory of functions. A function $f(x)$ is said to be continuous at $x=c$ in case $f(x)$ has a limit as x approaches c, which equals the value $f(c)$ of the function when $x=c$. An intuitive conception of the nature of a continuous function may be given by saying that it is one whose graph has no break. However, the theory of functions must consider continuous functions whose graphs cannot be drawn, as well as functions which are continuous at some points and discontinuous at many others. This makes the abstract logical form of definition essential. Examples (1), (2), (3), (4) and (5) are cases when the function in question is continuous for every value which may be assigned to c. The function sin $(1/x)$ is not continuous at $x=0$ because it is not defined there, but if we arbitrarily give it the value zero when $x=0$, then it becomes continuous. Such a discontinuity is called *removable*. The discontinuities of the functions sin (=/%) and $\frac{1}{10^{1\ x}+1}$ at $x=0$ are not removable.

The *derivative* of a function, when it exists, is an important aid in the study of the function. A function $f(x)$ has a derivative $f'(x)$ in case

$$\lim_{h\to 0} \frac{f(x+h)-f(x)}{h}=f'(x). \tag{10}$$

(See CALCULUS, DIFFERENTIAL AND INTEGRAL for further discussion and examples.) The derivative $f'(x)$ need not exist for all values of x for which $f(x)$ is defined. This is illustrated by the example $f(x)=x\sin(1/x), f(0)=0$.

Mathematicians formerly assumed that every continuous function of a real variable has a derivative except at isolated points, as in the example just cited. Weierstrass was the first to give an example of a continuous function of a real variable which does not have a derivative anywhere. This example was defined by means of an infinite series of trigonometric functions. From such an example it is easy to construct a function which has a continuous first derivative but has nowhere a second derivative, and so on.

Analytic Functions of a Complex Variable.—Functions of a complex variable which do not have derivatives are much more common than those which do. The functions given by (1) and (2) do not have derivatives anywhere but the functions given by (3) and (4) have derivatives everywhere. A criterion to be used in verifying the last statement will be given in the next paragraph. In applying the definition (10) of derivative to functions of a complex variable it is essential to notice that the variable h is also complex. A function $f(x)$ of a complex variable x which has a derivative at every point x sufficiently near a point c of the complex plane (including c itself) is said to be analytic at c or regular at c, and c is said to be an ordinary point for $f(x)$. All other points of the complex plane are said to be singular points. A single-valued analytic function, sometimes also called a holomorphic function, is one which is regular at some points. Every polynomial in x is a single-valued analytic function.

A function $f(u+iv)=P(u, v)+iQ(u, v)$ specified by formulas like (1) to (4) is regular at a point $c=a+ib$ if, and only if, the functions P and Q have continuous partial derivatives near the point c which satisfy the Cauchy-Riemann partial differential equations

$$\frac{\partial P}{\partial u}=\frac{\partial Q}{\partial v},\quad \frac{\partial P}{\partial v}=-\frac{\partial Q}{\partial u}.$$

It may also be proved that such a function has derivatives of all orders at points where it is regular. This is in marked contrast to the situation for functions of a real variable. By differentiation of the Cauchy-Riemann equations and elimination alternately of the function Q and then of the function P, it may be shown that the two components $P(u, v)$ and $Q(u, v)$ of an analytic function satisfy Laplace's equation

$$\frac{\partial^2 P}{\partial u^2}+\frac{\partial^2 P}{\partial v^2}=0.$$

A solution $P(u, v)$ of Laplace's equation is called a harmonic function. Every harmonic function $P(u, v)$ has associated with it another harmonic function $Q(u, v)$, called its harmonic conjugate, such that $P(u, v)+iQ(u, v)$ is an analytic function. Harmonic functions of two variables may be used to describe the electromagnetic field around a long straight wire carrying a current. If the curves $P(u, v)=$constant in the uv-plane are the curves of equipotential, the curves $Q(u, v)=$constant are the lines of force, if Q is a harmonic conjugate of P. Harmonic functions also are used in the theory of the flow around a straight aeroplane wing. Laplace's equation in three dimensions

$$\frac{\partial^2 P}{\partial u^2}+\frac{\partial^2 P}{\partial v^2}+\frac{\partial^2 P}{\partial w^2}=0$$

is satisfied by gravitational and electric potentials at the points of free space. (See SPHERICAL HARMONICS.)

A mapping or correspondence between two planes is called conformal or isogonal in case corresponding pairs of intersecting curves always meet at the same angle in the two planes. When also the sense or direction of rotation is preserved under a conformal mapping, the correspondence is determined by an analytic function of a complex variable. Conversely, every analytic function determines a conformal mapping. The notion of conformal mapping may be applied in the case of curved surfaces as well as planes. For example, a map of the earth's surface may be conformal.

Functions of a complex variable also have applications in the theory of numbers. It seems surprising at first sight that properties involving only whole numbers should be provable by means of such functions.

Formula (4) may be used to define the exponential function e^{u+iv} for complex values of the argument. The definitions of the trigonometric functions for complex arguments may then be based on the formulas of Euler:

$$\sin x=\frac{e^{ix}-e^{-ix}}{2i},\quad \cos x=\frac{e^{ix}+e^{-ix}}{2}.$$

Other methods of defining these functions will be mentioned later.

Integral of a Function $f(x)$.—This may be defined as another function $g(x)$ whose derivative $g'(x)=f(x)$. Such an integral is also called an antiderivative, an indefinite integral, or a primitive function. The possibility of finding an antiderivative for a given function is a matter of luck. A large part of elementary integral calculus is taken up with devices for finding such antiderivatives in simple cases. In order to be sure of the existence of the entity searched for, and for other reasons, it is desirable to consider other definitions of the concept of an integral, of a constructive type.

For functions of a real variable, one of the simplest of these is the one which is used in elementary calculus, which was given by Riemann, and is known by his name. Let the function $f(x)$ be defined on the interval $a\leqq x\leqq b$, and let this interval be partitioned into a finite number of parts $\Delta_i x$, of which the longest has length L. Let a point x_i be selected arbitrarily in each part $\Delta_i x$, and multiply the functional value $f(x_i)$ by the length of the corresponding part $\Delta_i x$. We may denote the sum of all such products for a particular partition of the interval from a to b by the symbol

$$\Sigma f(x_i)\Delta_i x$$

where me have used the symbol $\Delta_i x$ to stand also for the length of the part $\Delta_i x$. If this sum $\Sigma f(x_i)\,\Delta_i x$ has a finite limit **I** as the length L of the longest part approaches zero (this limit **I** being the same for all methods of partitioning the interval and choosing the points x_i in the parts) then this limit **I** is called the Riemann integral or definite integral from a to b of the function $f(x)$ and is denoted by the symbol

$$\int_a^b f(x)\, dx.$$

When $f(x)$ is continuous, it is not difficult to prove the existence of its definite integral. It is easily seen intuitively that when in addition the values of $f(x)$ are all positive, $\int_a f(x)$ dx gives the area bounded by the x-axis, the ordinates $x=a$ and $x=b$, and the graph of $y=f(x)$. It is in fact convenient to define the area as equal to this integral.

For functions of a complex variable, the definite integral becomes a line integral and its value may depend on the path of integration. Let us suppose that $x=\phi(t)$ is a continuous complex-valued function of the real variable t on the interval $c\leqq t\leqq d$, and let this interval be partitioned into a finite number of parts $\Delta_i t$. Let $\Delta_i x$ be the increment of x corresponding to the increment $\Delta_i t$, and let $x_i=\phi(t_i)$ where t_i is chosen arbitrarily in the interval $\Delta_i t$. Then the points x_i lie on separate short arcs of the curve C whose equation is $x=\phi(t)$. In case $f(x)$ is defined for x on the curve C and the sum

$$\Sigma f(x_i)\Delta_i x$$

approaches a finite limit **I** when the length L of the longest interval $\Delta_i t$ approaches zero, this limit **I** is denoted by the symbol

$$\int_C f(x)\, dx$$

and called the *line integral* of $f(x)$ along the path C. In examples (1) and (2) its value depends on the path, but in examples (3) and (4) its value depends only on the ends of the path.

The Fundamental Theorem of Integral Calculus.—For functions of a real variable, this theorem states that if $f(x)$ has an antiderivative $g(x)$, and also a Riemann integral $\int^{b} f(x)\,dx$, then the latter equals $g(b)-g(a)$. For functions of a complex variable, it states that if $f(x)$ has an antiderivative $g(x)$ (which is understood to be single-valued) throughout a region R of the complex plane, then $f(x)$ has also a line integral along any curve C in the region R, and if C begins at the point a and ends at b, then the line integral equals $g(b)-g(a)$, and so is independent of the path.

Cauchy's Integral Theorem.— This states that if $f(x)$ is an analytic function of the complex variable x in a region R which is simply connected (that is, R is all in one piece and has no holes in it), then the line integral of $f(x)$ is independent of the path. From this we find that $f(x)$ must also have an antiderivative. This theorem of Cauchy is the basis for the larger part of the modern theory of functions of a complex variable. An immediate consequence is Cauchy's formula

$$f(b)=\frac{1}{2\pi i}\int_C \frac{f(x)dx}{x-b}$$

where C is a simple closed curve enclosing the point b and lying with its interior in a region where $f(x)$ is regular. The fact shown by this formula, that the values of f at points inside the curve C are determined by its values on C, is a remarkable property of analytic functions of a complex variable. The property that analytic functions have derivatives of all orders is proved by successive differentiation of Cauchy's formula. This formula may also be used to prove Taylor's theorem, which states that near an ordinary point b an analytic function may be expressed by means of an infinite series of powers of the form

$$f(x)=a_0+a_1(x-b)+a_2(x-b)^2+\ldots$$

where $a_0=f(b),\ a_1=f'(b),\ a_2=f''(b)/2!,\ \ldots$

Singularities of Analytic Functions.— These are of various kinds. A singular point is called removable in case it becomes an ordinary point when the function is properly defined at the point. A singular point b is a pole for $f(x)$ in case there is another function $g(x)$ which is regular and not zero at b, and a positive integer m such that near b we have $f(x)=g(x)/(x-b)^m$. For convenience we say that $f(x)$ becomes infinite at a pole. All other singularities of single-valued functions are called essential singularities. The behaviour of a function near an essential singularity may be very peculiar.

By the *analytic continuation* into a region R_2 of a function $f(x)$ which is regular in a region R_1 overlapping R_2 me mean a function $g(x)$ which is regular in R_2 and such that $g(x)=f(x)$ in the common part of R_1 and R_2. If the process of analytic continuation is repeated a number of times we sometimes obtain a continuation $h(x)$ regular in the original region R_1 but having different values from $f(x)$ there. This fact makes the consideration of multiple-valued functions necessary. A simple example of such a function is $\sqrt{x}$, which has tn-o values except at the origin. If we start with the value of $\sqrt{x}$ which is positive when x is positive, and continue analytically through a sequence of regions forming a single loop around the origin, me arrive at the value of $\sqrt{x}$ which is negative when x is positive. The origin is a branch point for the two-valued function $\sqrt{x}$. This type of singularity is not encountered with single-valued functions. For the geometric representation of multiple-valued functions it is found convenient to substitute a multiple-sheeted Riemann surface for the plane of the independent variable. This is especially useful in the theory of algebraic functions and their integrals.

Methods of Defining a **Function.**—A function may be defined by means of a power series. For example the series

$$\sin x=x-\frac{x^3}{3!}+\frac{x^5}{5!}\cdots,$$

$$\cos x=1-\frac{x^2}{2!}+\frac{x^4}{4!}\cdots$$

could be used to define these functions for all complex values of x. Other types of series than power series, and also infinite products, may be used when convenient. An important case is the series of Fourier, expressing a function in terms of sines and cosines,

$$f(x)=a_0+a_1\cos x+a_2\cos 2x+\ldots$$
$$+b_1\sin x+b_2\sin 2x+\ldots$$

Such representations are of great importance in physics, in the study of wave motion and other oscillatory phenomena.

A function may be defined by the values of y satisfying an equation involving x and y. For example $y=\sqrt{x}$ is defined by the polynomial equation $y^2-x=0$. Every function $y=f(x)$ defined by a polynomial equation between x and y, such as $x^2y^3-x^3y+x=1$, is called an algebraic function. Transcendental functions may be defined by other types of equations. For example, if the function sin x is known, the function $y=\cos x$ is defined by the equation $\sin^2 x+y^2=1$ if we take the solution y which has the value $+1$ when $x=0$. The solution of $x=e^y$ for y gives the inverse function $y=\log_e x$, which is a multiple-valued function having infinitely many values when x is complex. Sometimes functions are most convenientlq- defined by means of differential equations. For example $y=\sin x$ is the solution of the differential equation $d^2y/dx^2+y=0$ having $y=0$, $dy/dx=1$ when $x=0$, and $y=\cos x$ is the solution of the same equation having $y=1$, $dy/dx=0$ when $x=0$. In special cases the solution of a differential equation may be represented as a line integral. For example,

$\log_e x=\int_1^x \frac{dx}{x}$. The value for this integral may be shomn to depend on the number of times the path encircles the origin in the complex plane. Some functions are more conveniently defined by means of definite integrals. For example.

$$\Gamma(x)=\int_0^\infty e^{-t}\,t^{x-1}\,dt.$$

It may be shown that when n is a positive integer $\Gamma(n)=(n-1)!$ Integral equations may also be used to determine functions. Thus the function $f(x)=\sin x$ for x on the interval from 0 to π is a solution of the integral equation

$$f(x)=\int_0^\pi G(x,t)\,f(t)\,dt,$$

where the kernel $G(x,t)=(\pi-x)t/\pi$ for $t\leqq x$ and $G(x,t)=(\pi-t)x/\pi$ for $t>x$. Very frequently it turns out that the various properties of a function are most conveniently studied by using srveral methods of representing it.

Abstract Function Theory.— Many of the advances in the modern theory of functions have been made possible by proceeding from the basis outlined above to a more abstract and general point of view. The functions considered in the calculus of variations (*q.v.*) are integrals such as

$$\int y\sqrt{x'^2+y'^2}\,dt$$

whose values depend on the shape of a curve $x=\phi(t)$, $y=\psi(t)$. The calculus of variations mas one influence which led to the consideration of functions whose arguments and values range over domains defined only by descriptive properties. These abstract ideas have been found to have value in such fields as ballistics and quantum mechanics. Mention should also be made of the more general theories of integration known by the names of Lebesgue and T. J. Stieltjes. These theories have been very useful in modern mathematics and its applications.

FUNCTIONAL PSYCHOLOGY: see PSYCHOLOGY, HISTORY OF.

FUNCTIONS, ANALYTIC. A function $f(z)$ is said to be analytic in a two-dimensional region if, at each point of the region, the derivative $f'(z)$ exists. Analytic functions are also called holomorphic, monogenic, regular or regular-analytic functions.

HISTORICAL BACKGROUND

The theory of analytic functions was created by A. L. Cauchy, who, in 1814, began the task of integrating between complex limits. His results were first made known in 1825. Cauchy's theory applies to functions having a unique derivative, and complex integration is the tool which gives the results. Cauchy used his new ideas to lay the foundation for a theory of ordinary and partial differential equations, including applications to problems in mathematical physics.

The other two founders of the theory of analytic functions were Bernhard Riemann and Karl Weierstrass. In 1851 Riemann outlined a theory in which the analytic function is defined by a pair of harmonic functions joined by the so-called Cauchy-Riemann equations, and in which the values of the function form a geometric entity that later came to be known as a Riemann surface. In the same paper the problem of conformal mapping was formulated.

Weierstrass lectured in Berlin from 1864 on, and by 1876 his fame was well established. He replaced intuition by logic and introduced a careful study of real numbers and limiting processes. His basic point of view was that analytic functions are defined by power series which are linked by a method of analytic continuation. Both he and Riemann devoted considerable effort to the theory of Abelian functions and integrals. (*See* COMPLEX NUMBERS; FUNCTION; FUNCTIONS, SPECIAL.)

FOUNDATIONS

Complex Numbers and the Complex Plane.—The complex numbers form a field (see FIELDS). The elements of this field are ordered pairs of real numbers (a,b) for which equality, addition, multiplication and scalar multiplication are defined by

(i) $(a,b) = (c,d)$ if and only if $a = c$, $b = d$
(ii) $(a,b) + (c,d) = (a + c, b + d)$
(iii) $(a,b) \cdot (c,d) = (ac - bd, ad + bc)$
(iv) $c \cdot (a,b) = (ac,bc)$

The associative, commutative and distributive laws hold; (0,0) acts as zero, (1,0) as unity. From (iv) the result

$$(a,b) = a \cdot (1,0) + b \cdot (0,1) = a + bi \tag{1}$$

is obtained, using the classical notation. The numbers $(a,0)$ are identified with the real numbers a so that $(1,0) = 1$, and $(0,1) = i$ may be written.

The notation (a,b) suggests the geometric representation of the complex number $a + bi$ by the point (a,b) in an ordinary Euclidean plane. The x-axis is then called the real axis, and the y-axis the imaginary one. An alternate representation is by the vector joining (0,0) with (a,b). The length r of this vector is called the absolute value of the complex number $c = a + bi$ and is written $|c| = r$. The angle θ which the vector makes with the positive real axis is called the argument, $\theta = \arg c$. Thus

$$c = r(\cos\theta + i\sin\theta) = re^{i\theta} \tag{2}$$

The point $a - bi = \bar{c}$ is called the conjugate of c. In the geometric representation of complex numbers, addition becomes vector addition. The absolute value of a product is the product of the absolute values: and the argument is congruent to the sum of the arguments (mod. 2π).

The plane used for this representation is known as the complex plane. The complex variable is usually denoted by $z = x + iy$. There is an extensive geometry of the complex numbers based on this representation. For the following discussion it is important to realize that the equation $|z - c| = r$ represents a circle with centre at c and radius r and that the inequality $|z - c| < r$ defines the interior of the circle, often called a disk.

Functions.—The idea underlying the function concept is that of a correspondence, or of a mapping of one set of objects D, called the domain, upon another set of objects R, called the range. If there is a unique definite object Q of R corresponding to every object P of D, then Q is said to be a function of P and is written $Q = f(P)$. In the present case D and R are sets of complex numbers and D will be a domain in a narrower sense, namely, an open connected set (often called a region). This means that for every point of D there is a small neighbourhood which is also in D, and that any two points of D may be connected by a broken line in D.

A function $f(z)$ defined in D may be continuous there. This means that if z is near to z_0 in D, then $f(z)$ is near to $f(z_0)$ in R. The differentiable functions form a subclass of the continuous functions. In the present case $f(z)$ is said to be differentiable at a point z_0 in D if the ratio

$$\frac{f(z) - f(z_0)}{z - z_0} \tag{3}$$

approaches a finite limit when z approaches z_0, the limit being independent of how z approaches z_0. This limit is known as the derivative of $f(z)$ at $z = z_0$ and is denoted by $f'(z_0)$ (see CALCULUS, DIFFERENTIAL AND INTEGRAL). If $f'(z)$ exists everywhere in D, the function $f(z)$ is said to be holomorphic or analytic in D. The term analytic, however, will be used below in a more general sense.

The formal rules of the calculus apply to complex-valued functions. Thus, sums and products of functions holomorphic in D are also holomorphic in D, although in the case of a quotient the points where the denominator is zero must be excepted. If n is a positive integer, z^n is holomorphic in the finite plane; this implies that every polynomial is a holomorphic function and that rational functions are holomorphic except at the zeros of the denominators.

If $f(z) = U(x,y) + iV(x,y)$ is holomorphic in D, then the real-valued functions U and V have partial derivatives with respect to x and y which satisfy the Cauchy-Riemann equations

$$U_x = V_y,\ U_y = -V_x \tag{4}$$

where the subscripts indicate differentiation with respect to x and y. Conversely, if a pair of real-valued functions has continuous partials in D which satisfy (4), then $f = U + iV$ is holomorphic in D. The functions U and V are known as conjugate harmonic or logarithmic potential functions. They satisfy Laplace's equation

$$F_{xx} + F_{yy} = 0 \tag{5}$$

This is the two-dimensional analogue of the equation satisfied by the Newtonian potential.

Power Series.—The basic class of holomorphic functions is formed by the power series; *i.e.,* series of the form

$$\sum_{n=0}^{\infty} a_n(z - a)^n \tag{6}$$

Such a series converges for a given z if the sequence of partial sums converges to a finite limit (see SERIES). This may happen only for $z = a$ or, at the other extreme, for all values of z. In general there exists a positive number R, known as the radius of convergence of the series, such that (6) converges (even absolutely) for $|z - a| < R$ and diverges for every z outside the circle $|z - a| = R$, known as the circle of convergence. The value of R is given by

$$\frac{1}{R} = \limsup |a_n|^{\frac{1}{n}} \tag{7}$$

The sum of the series in $|z - a| < R$ is a holomorphic function $F(z)$, whose derivative can be obtained by termwise differentiation of (6). The resulting power series has the same radius of convergence and may be differentiated as often as desired. Thus $F(z)$ has derivatives of all orders. According to Weierstrass, the series defines an element of an analytic function. Further elements can be obtained by elementary rearrangements of (6).

If $|b - a| < R$, write $z - a = (z - b) + (b - a)$, expand the nth power of this expression by the binomial theorem, multiply by a_n and add. Collection of terms results in a Taylor's series

$$F(z) = \sum_{k=0}^{\infty} \frac{F^{(k)}(b)\,(z-b)^k}{k!} \tag{8}$$

which converges at least for $|z - b| < R - |a - b|$. If the radius of convergence of (8) exceeds this value, then the new series defines a holomorphic function in a disk which overlaps the old one. In the intersection of the two disks the functions coincide; outside, each function defines the analytic continuation of the other. The new element (8) can be rearranged in the same manner and gives rise to further new elements. The totality of such elements (with some adjunctions, see below) constitutes the analytic function defined by (6). In this process, it is possible to get back to the starting point with an element distinct from (6). The number of distinct elements having the same centre $z = a$ is at most countable.

It may happen that (6) is not continuous outside its circle of convergence, which in this case is said to be the natural boundary of the function $F(z)$. In a certain sense this is the rule rather than the exception; the phenomenon is apt to present itself if the coefficients exhibit recurrent nonperiodic irregularities, such as very long gaps between terms, or if the coefficients have only a finite number of distinct values which do not recur periodically.

THE CAUCHY THEORY

Cauchy's Integral Theorem.— A rectifiable curve C is given by $z = g(t)$, $0 \leqq t \leqq 1$, where $g(t)$ is continuous and of bounded variation. If $f(z)$ is continuous on C, then the Riemann-Stieltjes integral

$$\int_C f(z)dz = \int_0^1 f[g(t)]dg(t) \tag{9}$$

exists. If D is a simply connected domain with $f(z)$ holomorphic in D, and if C is a simple, closed, rectifiable curve in D, then

$$\int_C f(z)dz = 0 \tag{10}$$

This basic theorem, announced by Cauchy in 1825, is the source of most of the results in analytic-function theory. First, it gives a representation of $f(z)$ in terms of its boundary values on C. If z is interior to C, then

$$f(z) = \frac{1}{2\pi i}\int_C \frac{f(t)dt}{t-z} \tag{11}$$

The integral can be differentiated with respect to z under the sign of integration as often as desired, and

$$f^{(n)}(z) = \frac{n!}{2\pi i}\int_C \frac{f(t)dt}{(t-z)^{n+1}} \tag{12}$$

Thus the existence of a first derivative implies the existence of derivatives of all orders.

Representation Theorems.— Cauchy's formula (11) can also be used to obtain expansions of $f(z)$ in infinite series. The Cauchv kernel $(t - z)^{-1}$ is expanded in a series of the desired type; multiplication by $f(t)$ and termwise integration then gives the corresponding series for $f(z)$. In this manner, for instance, Taylor's series (formula [8] with F replaced by f), which converges in the largest circle with centre at b in which $f(z)$ is holomorphic, is obtained. Laurent's series is obtained in an analogous manner:

$$f(z) = \sum_{-\infty}^{\infty} a_n(z-b)^n,\ a_n = (2\pi i)^{-1}\int_C f(t)\,(t-b)^{-n-1}dt \tag{13}$$

it is valid in the largest annulus $0 \leqq R_1 < |z - b| < R_2 \leqq \infty$ in which $f(z)$ is holomorphic. Various expansions of holomorphic functions in so-called interpolation series are obtainable by the same method.

If in (13) $R_1 = 0$, the point $z = b$ is an isolated singularity of $f(z)$. This singularity is removable if $a_n = 0$ for $n < 0$. It is a pole of order m if $a_{-m} \neq 0$ but $a_{-k} \equiv 0$ for $k > m$; it is an essential singularity in the remaining case. The coefficient a-I is known as the residue of $f(z)$ at $z = b$. In the case of a pole, $|f(z)|$ is uniformly large in the neighbourhood of $z = b$. The function $f(z)$ is assigned the value ∞ at $z = b$ and the expansion (13) is adjoined to the elements which define the analytic function. At an essential singularity no value can be assigned to the function; in fact, $f(z)$ assumes every value infinitely often, with at most one exception, in every neighbourhood of $z = b$ (Émile Picard, 1880).

Residue Theorem.— Formula (10) must be modified if $f(z)$ is not holomorphic inside C. Suppose that the only singularities are isolated and that none are on C. Then

$$\int_C f(z)dz = 2\pi i \sum a_{-1,k} \tag{14}$$

where the summation extends over the residues of the integrand inside C. This residue theorem of Cauchy also has a large number of applications. Cauchy used it to evaluate definite integrals—a problem of considerable practical importance. For example, in electrical engineering the desired solution of a system of linear differential equations with constant coefficients occurring, for instance, in network analysis, may turn out to be an inverse Laplace transform

$$f(t) = (2\pi i)^{-1}\int_{a-i\infty}^{a+i\infty} e^{zt}F(z)dz$$

where $F(z)$ is a rational function. The value of the integral is the sum of the residues of the integrand in the domain to the left of the line of integration. Cauchy also used his residue theorem for the first rigorous discussion of series expansions arising in boundary-value problems of mathematical physics, and this is still a valuable method. The residue theorem also plays a central role in the theory of elliptic functions.

Another important application of the residue theorem is the principle of the argument. Suppose that inside C there are no singularities other than poles of $f(z)$ and that no pole or zero lies on C. If the residue theorem is applied to the logarithmic derivative of $f(z)$, it is found that the change in the argument of $f(z)$ as z describes C in the positive sense equals 2π times the difference in the number of zeros and poles of $f(z)$ inside C.

SELECTED APPLICATIONS

The following paragraphs outline a few other central topics in the theory of analytic functions. Many others could be added.

Principle of the Maximum.— Let $f(z)$ be holomorphic in a domain D and let $M < \infty$ be the supremum of $|f(z)|$ in D. Then either $|f(z)| < M$ everywhere in D or $f(z)$ is a constant C, with $|C| = M$. If $f(z) \neq 0$, the same alternatives hold for the infimum of $|f(z)|$. If $U(z)$ is harmonic in D, it can have neither a maximum nor a minimum in D. Let $M(r;f)$ be the maximum of $|f(z)|$ in $|z| \leqq r$. If $M(r;f)$ is bounded for all r, then $f(z)$ is a constant (J. Liouville). In 1908 the principle of the maximum was extended by E. Phragmén and E. Lindelof to give information on the boundedness and rate of growth of $f(z)$ near singular points.

Entire and Meromorphic Functions.— A function $f(z)$ is entire (integral in British terminology) if it is holomorphic in the finite plane. It is transcendental if it does not reduce to a polynomial. In 1876 Weierstrass showed how to construct an entire function of given zeros. An entire function without zeros is of the form exp $[g(z)]$, where $g(z)$ is also entire. Entire functions are classified according to their order

$$\rho(f) = \limsup_{r\to\infty} \frac{\log\log M(r;f)}{\log r} \tag{15}$$

where $0 \leqq \rho \leqq \infty$. The order is closely related to the asymptotic behaviour of the coefficients of the defining power series and imposes an upper bound on the frequency of the zeros.

An entire function takes on every value infinitely often, with at most one exception. This theorem, proved by Picard in 1879 by use of the elliptic modular function, has been in the centre of attention ever since. Elementary proofs have been found by E. Borel and by E. Landau, and the theorem also follows from a mapping theorem due to A. Bloch (1924). It is now a simple consequence of an elaborate theory of the distribution of the values assumed by an entire or meromorphic function developed by F. Nevanlinna and R. Nevanlinna starting in 1924.

A function having only polar singularities is said to be meromorphic. The representation of such a function by partial fractions was given by G. Mittag-Leffler in 1877.

Normal Families.—A uniformly convergent sequence of holomorphic functions converges to a holomorphic limit. It suffices that the uniform convergence holds on the (rectifiable) boundary of the region. A sequence of functions $\{f_k(z)\}$ holomorphic and uniformly bounded in a domain D which converges in a point set with a limit point in D also converges to a holomorphic limit everywhere in D (G. Vitali, M. B. Porter, 1903). A uniformly bounded family of holomorphic iunctions contains a uniformly convergent sequence. The study of such "normal families" is largely due to P. Montel.

Conformal Mapping.— Every simply connected domain D having at least two boundary points can be mapped conformally onto the unit disk. This is Riemann's mapping problem, formulated in 1851 and completely solved around 1913. Such a mapping is one-to-one and angle preserving. There are important applications to the theory of wing profiles and to other problems of fluid mechanics as well as to electric and magnetic fields. A multiply-connected domain can be mapped conformally on various canonical domains of the same connectivity. *See* also ANALYSIS; ANALYSIS, COMPLEX; GROUPS, CONTINUOUS.

FUNCTIONS, SPECIAL. In mathematics this term is commonly reserved for those functions frequently applied in various branches of mathematics, physics. chemistry and other sciences (see FUNCTION). It is customary to divide them into elementary and higher transcendental types; frequently they include only the latter. The most important elementary functions are the exponential. logarithmic and trigonometric, combinations of these, and others that are related to them (see EXPONENT; LOGARITHMS; TRIGONOMETRY).

In the past, some of the most illustrious mathematicians took a hand in the investigation of higher transcendental functions; in the 20th century, E. T. Whittaker (1873–1956) and those influenced by him developed special functions as a valuable means of attacking problems in applied mathematics. Special functions continue to be used as a valuable tool, although their importance has declined somewhat with the advent of high-speed electronic computers.

Higher transcendental functions vary greatly as to their origin. nature and applications and no adequate classification of them exists. The one large group sho ing some degree of unity consists of the hypergeometric functions and others that are related to them. These arise from ordinary linear differential equations of the second order, and their principal applications occur in connection with partial differential equations of mathematical physics.

In the following discussion some of the more important higher transcendental functions will be considered.

Elliptic and Abelian Functions.— The integral $\int R(x,y)\,dx$ can be evaluated in terms of elementary functions if R is a rational function of x and y, and y^2 is a polynomial of degree two or less in x. An evaluation in terms of elementary functions is impossible in general if y^2 is a more involved function of x.

If y^2 is a polynomial of degree three or four, the integral is known as an elliptic integral and the functions arising in the inversion of such integrals are elliptic functions (*q.v.*). These are doubly periodic and thus generalizations of the (simply periodic) trigonometric functions. If y^2 is a polynomial of degree higher than four. the integral is a hyperelliptic integral; and the integral $\int R(x,y)\,dx$ is an abelian integral if R is a rational function of x and y, while y is an algebraic function of x, *i.e.*, a root of an equation $P(x,y) = 0$ where P is a polynomial in x and y. The systematic study of such integrals was initiated by Niels Abel in 1826, Karl G. Jacobi solved (1832–34) the inversion problem for hyperelliptic integrals, and G. F. B. Riemann, Karl Weierstrass and others developed the theory of $2p$-fold periodic functions of p complex variables which are needed to solve the inversion problem for abelian integrals. The resulting functions are called abelian functions and were found to have many applications in algebraic geometry, topology, the algebraic theory of numbers and other fields of mathematics; they also influenced the development of the general theory of functions of complex variables.

The Gamma Function and Related Functions.— The gamma function originated in an attempt to generalize the factorial function (*see* COMBINATORIAL ANALYSIS) $n! = 1\cdot 2\ldots\ldots n$ to nonintegral values of n. Leonhard Euler defined (1729) the gamma function as the limit of a product from which Euler's integral of the second kind, $\Gamma(z) = \int_0^\infty e^{-t}\,t^{z-1}\,dt$ can readily be derived, $\Gamma(n+1) = n!$, $\Gamma(z+1) = z\,\Gamma(z)$. The gamma function is a meromorphic function with simple poles at $z = 0, -1, -2, \ldots$. Karl F. Gauss investigated the function $\pi(z) = \Gamma(z+1)$ (also denoted by $z!$). Weierstrass represented $1/\Gamma(z)$ by an infinite product (1856); this is an entire function with simple zeros at $z = 0, -1, \ldots$.

The gamma function is applied in combinatorial analysis. in the evaluation of infinite and improper integrals. in the solution of differential and difference equations and in many other branches of mathematics. It and related functions are ubiquitous in probability theory and statistics, and in mathematical physics and engineering mathematics.

Some of the functions related to the gamma function are (1) the beta function $\beta(p,q) = \int_0^1 t^{p-1}(1-t)^{q-1}\,dt$ (Euler's integral of the first kind) $= \Gamma(p)\,\Gamma(q)/\Gamma(p+q)$; (2) the logarithmic derivative $\psi(z) = d\log\Gamma(z)/dz$ of the gamma function; (3) the incomplete gamma functions

$$\gamma(z,x) = \int_0^x e^{-t}t^{z-1}dt, \qquad \Gamma(z,x) = \int_x^\infty e^{-t}t^{z-1}dt;$$

(4) the exponential integral, sine integral and cosine integral, which are related to $\Gamma(0,z)$; and (5) the error functions and Fresnel integrals. which are related to $\gamma(\frac{1}{2},z)$ and $\Gamma(\frac{1}{2},z)$.

Riemann's Zeta Function.— The zeta function was known to Euler (1737). The first great discoveries relating to it were made by Riemann (1859). Many results have been extended to A. Hurwitz' zeta function $\zeta(s,a) = \sum_{n=0}^{\infty} (a+n)^{-s}$, related to Riemann's zeta function $\zeta(s)$ by means of $\zeta(s) = \zeta(s,1)$.

$\zeta(s)$ has a simple pole at $s = 1$ and is regular at all other points. Euler's product. $\zeta(s) = \text{a}\,(1-p^{-s})^{-1}$ in which p runs through all primes and Re $s > 1$, shows that $\zeta(s)$ has no zeros when Re $s > 1$, and this in conjunction with Riemann's functional equation $2^{1-s}\,\Gamma(s)\,\zeta(s)\cos(s\pi/2) = \pi^s((1-s)$ shows that the only zeros of $\zeta(s)$ for Re $s < 0$ are the "trivial zeros," $s = -2, -4, -6, \ldots$. All nontrivial zeros of $\zeta(s)$ must lie in the strip $0 \leqq \text{Re } s \leqq 1$ of the complex plane, and Riemann conjectured (in 1859) that these zeros lie on the central line, Re $s = \frac{1}{2}$, of this strip. In investigating this problem mathematicians tremendously enriched mathematical analysis, discovered many important properties of $\zeta(s)$ and made some progress toward a solution; yet a full proof of Riemann's hypothesis about the zeros of the zeta function has not been given.

Arithmetical Functions, $f(n)$, are defined for all positive integers n. Examples of such functions include the number of distinct primes dividing n; the number of (positive) divisors of n; the number of nays in which n can be represented as a sum or a product of a given number of positive integers; the number of integers between 1 and n which are prime to n (Euler's function); $\mu(n) = 1$ for $n = 1$, $= (-1)^m$ if n is the product of m distinct primes, $= 0$ if n is divisible by the square of a prime (Moebius' function). Such functions have important applications in number theory, combinatorial analysis, and counting problems. Bernoulli numbers (*q.v.*), Euler numbers (*q.v.*), Stirling numbers (*q.v.*), and other numbers defined as coefficients in the expansion of generating functions are also arithmetic functions, with applications in mathematical analysis as well as in the fields mentioned above.

Hypergeometric Functions.— The hypergeometric series

$$1 + \frac{a\cdot b}{c\cdot 1}z + \frac{a(a+1)\,b(b+1)}{c\cdot(c+1)\cdot 1\cdot 2}z^2 + \frac{a(a+1)(a+2)\,b(b+1)(b+2)}{c(c+1)(c+2)\cdot 1\cdot 2\cdot 3}z^3 + \cdots$$

was known in 1769 to Euler, who discovered many of its properties; it was investigated by Gauss (in 1812, in the first adequate discussion of the convergence of any infinite series). by Riemann (in 1857), and by many other outstanding mathematicians. This series is of great historical importance since its investigation initiated far-reaching developments in the theory of convergence and the general theories of analytic functions and ordinary linear differential equations; and it is of great importance in modern mathematics since a large number of the most important special functions are related to the hypergeometric function $F(a,b;c;z)$, which is defined by the hypergeometric series.

The hypergeometric series satisfies the differential equation

$$z(1-z)y'' + [c-(a+b+1)z]\, y' - aby = 0$$

which is called the hypergeometric equation and is an important source of information for properties of the hypergeometric function. Twenty-four solutions of the hypergeometric equation can he expressed in terms of hypergeometric series, and the relations between these solutions lead to transformations of hypergeometric series. Two distinct hypergeometric series whose corresponding parameters a, b, c differ by 0, 1, or -1 are called contiguous. Any three contiguous hypergeometric series are connected by a linear relation. The derivative of the hypergeometric series is a multiple of a contiguous series and is linearly connected with the original series and a contiguous series. Of the numerous integral representations of the hypergeometric function the oldest and best known is Euler's,

$$F(a,b;c;z) = \frac{\Gamma(c)}{\Gamma(b)\Gamma(c-b)} \int_0^1 t^{b-1}(1-t)^{c-b-1}(1-zt)^{-a}dt \qquad (\mathrm{Re}\, c > \mathrm{Re}\, b > 0)$$

Generalized hypergeometric series,

$$\begin{aligned} {}_pF_q(a_1,\cdots,a_p;\, c_1,\cdots,c_q;\, z) \\ = 1 + \frac{a_1\cdots a_p}{c_1\cdots c_q\cdot 1}\, z + \frac{a_1(a_1+1)\cdots a_p(a_p+1)}{c_1(c_1+1)\cdots c_q(c_q+1)\cdot 2!}\, z^2 + \cdots \end{aligned}$$

and in particular the confluent hypergeometric series ${}_1F_1\ (a;c;z)$, have also been extensively investigated. ${}_pF_q$ satisfies the generalized hypergeometric differential equation

$$[\delta(\delta + c_1 - 1)\cdots(\delta + c_q - 1) - z(\delta + a_1)\cdots(\delta + a_p)]y = 0$$

in which $\delta = z\dfrac{d}{dz}$. Among other generalizations and related functions are the hypergeometric series of several variables and basic hypergeometric series; a sample of the latter is

$$\begin{aligned} \Phi(a,b;c;z) = 1 + \frac{(1-a)(1-b)}{(1-c)(1-q)}\, z + \frac{(1-a)(1-aq)(1-b)(1-bq)}{(1-c)(1-cq)(1-q)(1-q^2)}\, z^2 \\ + \frac{(1-a)(1-aq)(1-aq^2)(1-b)(1-bq)(1-bq^2)}{(1-c)(1-cq)(1-cq^2)(1-q)(1-q^2)(1-q^3)}\, z^3 + \cdots \cdot (|q| < 1) \end{aligned}$$

Among the tremendous number of higher transcendental functions related to the hypergeometric series we mention: Legendre functions (see SPHERICAL HARMONICS). Bessel functions and the classical orthogonal polynomials (cf. below), and among those functions arising out of differential equations related to the hypergeometric equation, Lamé, Mathieu and spheroidal functions (cf. below).

Bessel Functions. — These are solutions of the Bessel differential equation

$$z^2y'' + zy' + (z^2 - p^2)y = 0$$

and are sometimes called cylinder functions. They first appear in the investigations by Daniel Bernoulli (in 1732) and Euler (in 1764) on vibrations of a heavy chain and a stretched membrane; they are named after Friedrich W. Bessel, who used them in the theory of planetary motion. In modern times they frequently occur in connection with wave propagation problems in optics, electromagnetic theory. elasticity, fluid motion and many other fields; also in potential and diffusion problems. They are among the most useful higher transcendental functions, and many volumes of numerical tables are available for them.

One solution of Bessel's differential equation is the Bessel function of the first kind (sometimes called "Bessel function" shortly),

$$J_p(z) = \sum_{n=0}^{\infty} \frac{(-1)^n(z/2)^{p+2n}}{n!\,\Gamma(p+n+1)}$$

which can be expressed in terms of generalized hypergeometric series, either in terms of ${}_1F_1$ or in terms of ${}_0F_1$; it also can be expressed as a limit of Legendre functions or of hypergeometric series. A second solution is the Bessel function of the second kind, or Neumann function.

$$Y_p(z) = \frac{\cos(p\pi)J_p(z) - J_p(z)}{\sin p\pi}$$

and two further solutions are the two Bessel functions of the third kind or, Hankel functions, $H_p^{(1)} = J_p + \mathrm{i}\, Y_p$ and $H_p^{(2)} = J_p - i\, Y$,. If z is replaced by iz, the resulting differential equation is called the modified Bessel equation and its solutions are modified Bessel functions. These also have been extensively tabulated. If z is replaced by $i^{1/2}x$, the real and imaginary parts of the resulting functions are known as Kelvin functions.

When p is the half of an odd integer, the Bessel functions can be expressed as (finite) combinations of elementary functions, and this is the only case when such an expression is possible. When $p = \pm\frac{1}{3}$, the Bessel functions can be expressed in terms of Airy functions, $Ai(z)$ and $Bi(z)$, which were encountered, about 1838, by George B. Airy in his researches in optics.

Many functions can be expanded in series or integrals involving Bessel functions. Some of these expansions have a direct significance in physics, as in the representation of a plane wave by superposition of cylindrical waves.

Orthogonal Polynomials. — A system of polynomials $p_n(x)$, $n = 0, 1, 2, \ldots$, where p_n is a polynomial of degree n in x, is said to be orthogonal on the interval (a,b) with respect to the weight function $w(x)$ (which is assumed to be nonnegative) if

$$\int_a^b p_m(x)p_n(x)w(x)dx = 0, \text{ where } m \neq n$$

and the system is called an orthonormal system if it is orthogonal and so normalized that

$$\int_a^b [p_n(x)]^2 w(x)dx = 1$$

There is a well-developed general theory of orthogonal polynomials. Among the many special polynomials of great importance, the best knonn are the classical orthogonal polynomials, nhich are enumerated in the folloning table together with their intervals of orthogonality and weight function.

Classical orthogonal polynomials	Intervals of orthogonality		Weight function
	a	b	$w(x)$
Legendreor spherical	-1	1	1
Chebichev.	-1	1	$(1-x^2)^{\pm 1/2}$
Gegenbauer or ultraspherical.	-1	1	$(1-x^2)^{\lambda - 1/2}$
Jacobi or hypergeometric	-1	1	$(1-x)^{\alpha}(1+x)^{\beta}$
Hermite	$-\infty$	∞	$\exp(-x^2)$
(generalized) Laguerre 0		∞	$x^{\alpha}e^{-x}$

Of these, Chebichev polynomials can be expressed in terms of trigonometric functions, Jacobi polynomials (and their special cases including Legendre and Gegenbauer polynomials) in terms of hypergeometric series and Laguerre and Hermite polynomials as confluent hypergeometric series.

The importance of orthogonal polynomials is derived largely from the possibility of expanding "arbitrary" functions in series of orthogonal polynomials. Such expansions are frequently used both in pure mathematics and in problems of physics and engineering (see FOURIER SERIES).

Lamé, Mathieu, and Similar Functions occur mainly in connection with partial differential equations of mathematical physics (potential equation, wave equation, etc.) when the boundaries involved are elliptic cylinders (Mathieu functions), spheroids (spheroidal functions) or ellipsoids (Lamé functions, Lamé wave functions). They satisfy linear ordinary differential equations of the second order which may be considered generalizations of the hypergeometric equation. The theory of these functions is much less complete than that of the functions more directlv related to the hypergeometric series, and with the exception of Mathieu functions and spheroidal functions no extensive numerical tables exist.

FUNDAMENTALISM. The term Fundamentalism is used in two related but clearly distinguishable senses: (1) to designate what is more generally called a conservative type of Christian thought. as opposed to the liberal or modernist tendencies mhich became influential in the latter part of the 19th century and still more so in the first part of the 20th; and (2) as the name of a specific conservative movement with its own organizations and agencies devoted to the propagation of a definite doctrinal program (the Five Points of Fundamentalism) which, it was claimed! constitute the indispensable elements of the true Christian faith. In the first of these senses, the term is more often used by liberals to describe conservatives than by conservatives to describe themselves. In the second sense, it lost the wide currency that it had in the first three decades of the 20th century and. though what it stands for is by no means extinct, the movement which it describes changed its methods and less frequently used that name. These two aspects of Fundamentalism will be treated separately.

Classical **Orthodoxy.**—In Fundamentalism considered merely as a reaction against the liberalizing tendencies of modern thought. there was nothing new except that it was a reaction against something new. The content of its teaching was identical with that of classical Protestant orthodoxy. Its purpose was nothing more than to preserve unchanged the presuppositions and convictions of Reformation Protestantism and also of Roman Catholicism in regard to the nature of Christianity as a redemption religion, the place of the supernatural and the miraculous in Christianity and the nature of the Bible as being in every part an authoritative revelation of the mind and purposes of God. With rare exceptions. all Christian thinkers prior to the middle of the 19th century had been Fundamentalists in this sense. The exceptions are important in the total history of religious thought, but their immediate influence was not sufficiently widespread to invalidate this generalization, especially when applied chiefly to preaching and the life of the churches.

New and disturbing elements began to enter the religious situation with the critical study of the Bible by the methods of historical and literary analysis ("higher criticism"), the popularization of the concept of evolution and its application to the interpretation of the whole process of human culture including religion. and the delayed impact of Kantian and post-Mantian philosophy on theological thought. In addition to these, or including them all, was the enhanced prestige of the scientific spirit and scientific method. It was not simply the existence of these forces and tendencies but their infiltration into the religious thought of both clergy and laity that gave alarm to those who adhered to what was now coming to be called the "older view" of the Bible and Christianity. The actual divergence of views was most clearly marked with reference to views of the nature of the inspiration of the Bible and consequently of its authority. Liberal evangelical theologians did not deny the divinity of Christ (though most of them thought "deity" was too strong a term), nor did they doubt the reality of the supernatural or of God's redemptive purpose, but they rejected the presupposition that the entire Bible is the inerrant "word of God." and insisted that, as William Newton Clarke put it, the most reverent attitude toward the Bible is to take it for what the critical and scientific study of its text and its history indicates that it actually is.

Fundamentalism Proper.— The specifically Fundamentalist movement was foreshadowed by a series of conferences in which a strict view of biblical inerrancy and a literalistic interpretation of the Bible were applied to emphasize the premillennial second coming of Christ. A Bible conference at Swampscott, Mass., in 1876 was followed in 1877 by a Prophetic conference at New York city. The notable Niagara Bible conferences had Seen held annually for nearly 20 years before putting forth the Five Points which were to become the fundamentals of Fundamentalism. The Five Points, which were the hard core oi Fundamentalist doctrine as long as that term mas used in its strict sense, were: the plenary inspiration and inerrancy of Scripture; the deity of Jesus; the virgin birth of Jesus; substitutionary blood atonement; the bodily resurrection and premillennial second coming of Christ. This Bible conierence movement, with its strong "prophetic" coloration, was vigorously evangelistic and revivalistic. A volume entitled *Jesus Is Coming,* by %" E. B.," was given a subsidized circulation oi about 2,000,000 copies in the United States and 1,000,000 abroad. Beginning in 1909 a series oi 12 books under the general title *The Fundamentals* was published and widely circulated at the expense of two wealthy brothers, Lyman and Milton Stewart, who also established and endowed the Los Angeles (Calif.) Bible institute. Other Bible institutes, notably the efficient Moody Bible institute in Chicago, Ill., took up the task of training preachers, evangelists and Christian workers who would be untouched by the modern influences which, it was believed, were contaminating the standard theological seminaries. This phase of Fundamentalism was strictly undenominational. As liberal thought permeated the seminaries, the literature and the missionary agencies oi leading denominations, the conservative forces within these denominations organized themselves for resistance and a second phase oi fundamentalism began, while the first still continued.

Baptists.— -4. G. Strong, president emeritus of Rochester Theological seminary, visited Baptist foreign missionary stations and in *A Tour of the Missions* (Philadelphia, 1918) reported his alarm at lapses from orthodoxy, especially in regard to the inerrancy of the Bible. The weekly *Watchman-Examiner* followed with a demand for an investigation of the seminaries. Suspicion in regard to the divinity school of The University of Chicago had already led to the founding of the Northern Baptist Theological seminary in Chicago (1913), and the Rochester seminary also n-as reparded as suspect. In May 1930 a Pre-Convention conference on Fundamentals of Our Faith was called by 150 members of the Northern Baptist convention. At the immediately subsequent convention, the Fundamentalist group, with J. S. Massee as principal spokesman, continued to urge scrutiny of the seminaries and the adoption of a strict statement of iaith, which was substantially the Philadelphia and New Hampshire Confessions. The majority of the convention, however, following Cornelius Woelfkin, affirmed confidence in the seminaries and the sufficiency of the New Testament as a statement of Baptist faith. The Fundamentalists formally organized their iorces in the Baptist Bible Union of America (1923), which adopted 18 articles of faith. Its triple presidency was J. Frank Norris in the south, W. B. Riley in the north and T. T. Shields in Canada. John R. Straton led in the east with his Baptist Fundamentalist League of Greater New York and Vicinity. State chapters were formed. Attack was centred largely on the boards of missions. The union disavowed any intention to "disturb existing Baptist affiliations," but at the same time it recommended the undenominational "Bible Institutes and Bible Conierences conducted by Christian Fundamentalists." The Southern Baptist convention, more conservative than the northern, contained more Fundamentalists but had less conflict because the liberal forces on the other side were so few. The energies of the Baptist Bible union as an organization mere spent by 1929. In the north. however, the Fundamentalists, after several years of agitation and preconvention sessions, separated in 1947 from the Northern Baptist convention and organized the Conservative Baptist Association of America.

Presbyterians.— The strain of Fundamentalism which appeared in the Presbyterian Church was, for the most part, only a staunch adherence to classical Protestant orthodoxy. The tensions resulting from the infiltration of biblical criticism had already been ielt and the storm period passed before the campaign oi the Fundamentalists as such had begun to affect deeply the organized life of the great denominations. A long controversy over the revision of the Confession of Faith was ended (1903) by the adoption of 11 amendments. The conservatives were pleased that the revisions were so slight and the liberals, that there mas any revision at all; peace prevailed. though the basic issues remained. On May 21, 1922, Harry Emerson Fosdick, a liberal Baptist then preaching regularly for the First Presbyterian church, New York city, delivered a sermon entitled, "Shall the Fundamentalists Win?" This precipitated lively controversy. The general assembly of 1923 directed the New Tork presbytery to see to it that the pulpit should conform to the church's Coniession of Faith and reaffirmed its own "five points" of 1910. The same assembly defeated the candidacy of William Jennings Bryan ior the post of moderator. The 1927 general assembly adopted a report of a special commission which denied that the assembly had the constitutional right to set up such formulas as the "five points" as tests oi orthodoxy. This is regarded as a crucial action, since it left room for a considerable degree of liberalism in the church. Differences both theological and administrative in regard to the policies of Princeton Theological seminary led to the withdrawal of an ultra-conservative group headed by J. Gresham Machen and to the organization of Westminster seminary, Philadelphia (1929), an Independent Board for Presbyterian Foreign Missions (1933) and, in 1936, a separate denomination, the Presbyterian Church in America, which later (1939) took the name the Orthodox Presbyterian Church.

Methodists. — Having recently had unhappy experience with two heresy cases — H. G T. Mitchell, a professor at Boston university (1895), and Borden P. Bowne (1904–08) — the Methodists were generally indisposed to a resumption of hostilities when the Fundamentalist movement arose. There was a definite slant toward a more liberal view of the Bible and toward stress upon the "social gospel." This was seen in the church's publications and in the courses of study for ministers. An organized group of militant "essentialists" opposed but could not check this tendency. The New Jersey conference was the storm centre of this protest. The question of maintaining a strict ban on "sinful amusements" was an issue, as well as biblical criticism. A conservative Methodist League for Faith and Life (1925) functioned with diminishing effectiveness for a few years. A rather high degree of theological conservatism has gone along with the denomination's characteristic emphasis on evangelism, but the antagonisms of the Fundamentalist controversy did not leave deep scars.

Disciples of Christ. — The influence of new views of the Bible and of more liberal theology was scarcely felt in this communion before 1895 and produced no wide response until several years later There has been strong, but generally unorganized, resistance to the liberal movement. The conservatives never called themselves Fundamentalists, and the issues did not prove to be identical with the Five Points of Fundamentalism. The biblical question has been central In place of a specific doctrine of the atonement and a premillennial second coming — in neither of which they took much interest — conservative Disciples substituted renewed insistence on immersion and opposition to open membership; *i.e.*, the admission of the unimmersed.

In 1916 a Bible College league was organized to clear the new learning out of the College of the Bible, Lexington, Ky., and to instigate scrutiny of other institutions. This campaign failed. About 1920 there was the beginning of heated criticism of certain missionaries, especially in China, and of the missionary society which supported them, chiefly on the ground that open membership was being practised. A Christian Restoration association became the agency of this opposition; an annual North American Christian convention, the rival of the International Convention of Disciples of Christ; and a New Testament Tract society (later merged with the Restoration association), its publishing agency. Many conservative so-called Bible colleges and institutes have been organized to train ministers opposed to co-operation through the general missionary and benevolent agencies.

Protestant Episcopal Church. — Fundamentalism in its stricter meaning had little to do with such disharmonies as have arisen in this communion Planes of cleavage appeared between the Catholic and the Evangelical party, and between those who insist on rigid adherence to the Thirty-Nine Articles and those who do not. Bishop William Lawrence's plea (Oct. 1923) for theological freedom in the church was promptly answered by a pastoral letter from the house of bishops (Nov. 1923) insisting on strict conformity. The more conservative group has so little in common with the Fundamentalists that the term has no proper application in this connection. The Episcopal Church has schools of thought and there have been tensions between them, but in general it has been able to contain them without disastrous conflict.

Antievolution. — Interdenominational Fundamentalism reached its climax of intensity and publicity in the decade during and after World War I. A huge World Bible conference (1919) in Philadelphia, Pa., led to the organization of the World Christian Fundamentals association. A campaign of great intensity was directed toward drawing a sharp line between Fundamentalists on one side and all non-Fundamentalist Christians and non-Christians on the other. Stress on the literal inerrancy of the Bible in matters of science and history inevitably brought evolution (*q.v.*) under discussion. Antievolution had long been a position held by ultraconservatives generally. The Fundamentalists attacked the teaching of evolution in the schools. Tennessee made it a criminal offense. (*See* SCOPES TRIAL, THE).

Antievolution laws were passed by three other states — Mississippi (1926), Arkansas (1928) and Texas (1929). Although the Fundamentalist associations continued to exist for several years, interdenominational Fundamentalism of this type had lost its drive. What remains is a strong body of theological conservatism in most of the great denominations, an important "neo-orthodox" movement which many regard as providing a scholarly middle way between liberalism and Fundamentalism and a considerable number of independent Fundamentalist churches. Many of these last were loosely united in the Independent Fundamental Churches of America, organized at Cicero, Ill., in 1930. This association required its member churches to sever every connection with any denomination and to subscribe to 16 articles of faith which include the original Five Points of Fundamentalism.

FUNDY, BAY OF, an inlet of the North Atlantic, separating New Brunswick from Nova Scotia. It was first explored by the sieur de Monts in 1604 and named by him La Baye Français. It is 94 mi. long and 32 mi. wide at the mouth, but narrows toward the head, where it divides into Chignecto bay to the north (which subdivides into Shepody bay and Cumberland basinj and Minas basin to the south. The Bay of Fundy is remarkable for the great rise and fall of the tide. which at the head of the bay has been known to reach 70 ft. The incoming tide creates the well-known reversing falls at the mouth of the St. John river, and rushes up the Petitcodiac river to beyond Moncton in a bore from 3 to 6 ft. high. There is a 25-ft. rise and fall of the tide in Passamaquoddy bay, which forms part of the boundary between New Brunswick and the state of Maine. The large areas of tidal marshlands at the head of the Bay of Fundy attracted Acadian settlers before 1750. and have since been diked for agricultural use. The bay has numerous harbours. of which the chief are St. John and St. Andrews in New Brunswick and Digby (on an inlet known as Annapolis basin) and Hantsport in Nova Scotia. See also FUNDY NATIONAL PARK. (C. W. RD.)

FUNDY NATIONAL PARK, in New Brunswick. Canada, covers 80 sq.mi. on the Bay of Fundy, famous for its high and fast-running tides Along the shores of this historic bay began the earliest settlement in Canada with the arrival of Champlain and the sieur de Monts. Skirting the rugged coast for eight miles and extending nine miles inland, the park rises to an elevation of 1.000 ft. It is richly forested, and in autumn its maple-covered ridges and great expanses of rolling hills become a sea of crimson and gold. The park was established in 1950.

There are no natural bathing beaches, but a large heated saltwater swimming pool was built in the park. Other facilities include an open amphitheatre for plays, concerts and other activities, a golf course overlooking the bay, and a recreation and sports centre. Accommodations include cottages of French chalet design and a number of camp grounds and trailer parks. (J. G. P.)

FUNERARY RITES AND CUSTOMS. Rites and customs connected with the disposal of the dead are as universal as the phenomenon of death itself. Since the conscious realization of death as the inevitable end of every human life is one of the most distinctive and central features of human experience. it is only natural that every actual occurrence of death should be an occasion for the living to react to this fact by appropriate behaviour. Structures and mechanisms that may well derive from the ultimately biological instincts of self-preservation and fear of death acquire, on the human level, an "existential" significance: our very experience of life itself is determined by our awareness of its finality and its orientation toward death. The corpse, representing the human subject suddenly become a mere object, confronts every man with his own ultimate alienation from his subjective individuality. Man must deal with this threat to his existence on a psychological level; he must readjust and reaffirm himself by actualizing appropriate attitudes and by expressing them in corresponding behaviour. Not in vain has man been described by many writers as the "eternal protestant" against death, desperately and often pathetically refusing to accept its inexorable finality. On the sociological level, death represents the destruction of extant sets of intersubjective, social relationships, necessitating readjustments in various spheres. Roles of authority as well as positions of political and family status become vacant and have to be filled, "wives" become "widows," redistribution of property becomes necessary, etc. Against the elements of disruption and change introduced by death. society has to emphasize the permanence of its values, institutions and culture patterns (including the place accorded therein to the transitory and mortal individual).

Hence, death customs are susceptible of both psychological and sociological interpretations. It is the culture — often more particularly the religion — of any particular group that defines and institutionalizes the meaning of death, theoretically as well as behaviourally, by assigning specific roles to its various members and functionaries (priests, family, mourners) and by prescribing specific rites and practices. Death customs therefore generally form a complex involving a number of interrelated cultural traits which function together in a more or less consistent and meaningful way.

Whatever the rituals may do for the deceased, they certainly also perform a function for the living; *i.e.*, for the surviving potential diers. The attitude toward death and the dead reflects on the general life of the individual and the group.

It is not surprising, therefore, that funerary customs in most societies by far exceed the practical. rational minimum required for the mere disposal of the body. Not only is the actual disposal more or less ritualized, at times even very elaborately so, but it is also surrounded by a great variety of preburial and postburial rites. some of them extending over a long period after death and burial (*e.g.,* mourning, memorial customs, ancestor worship).

Variety of Customs.—The variety of death customs is immense. Even on one small Melanesian island 21 different manners of disposal of the dead have been counted. There are many descriptive and comparative accounts of funerary customs available. as well as many speculative interpretations. Only a brief and schematic survey can be attempted here. To venture beyond description to interpretation would require detailed analyses of particular groups and culture areas. That the basic problem is the same in prehistoric, illiterate, ancient, medieval and modem societies is borne out by the fact that in the 20th century death "is big business in the U.S., where more money is spent upon funerals and accessories each year than is spent on all hospitals and sanitaria" (W. M. Kephart, "Status After Death," *American* Sociological Review, vol. 15. p. 636 [1950]).

The immense variety of death customs is due to many factors and influences—geographical, cultural and historical. It is the particular combination of these factors that is distinctive and decisive. Thus mummification could originate only in areas with a dry climate (Egypt) and nith the necessary preservative materials (*e.g.,* Tibet with its salt lakes or New Mexico with its saltpetre caves). In northern areas where the ground is frozen most of the year, inhumation is obviously impossible. Prevailing notions regarding the origin of man ("dust to dust"; *cf.* Gen. iii, 19) or of the tribe or clan (hence, orientation of tomb in the appropriate direction), as well as beliefs concerning the individual's destiny and afterlife (reincarnation, judgment, reward and punishment, continued life in some faraway land or island), play an important part. Migrations, conquest and other forms of culture contact may lead to combinations of diverse or even conflicting patterns. Of course, the mythological or rational explanations offered by particular groups are not always or necessarily co rect as accounts of the past origins or present functions of their mortuary customs. But whereas general interpretations of funerary rites as such are a matter of sociological theory. the specific interpretation of details, especially uhen they are very widespread, is more often than not in the nature of unverifiable speculation.

Two Main Interpretations.— The two main types of over-all interpretation can conveniently be labeled as functionalist and structuralist, respectively. The former, deriving mainly from the anthropologist Bronislaw Malinowski, considers death customs as a social mechanism for readjustment and release of tension. Violent and conflicting emotions (*e.g.,* horror of death and love for the deceased, the desire to break the ties with the dead but also to maintain them) find normative expression in the obsequies and mourning rites "which endorse and duplicate the natural feelings of the survivors; they create a social event out of a natural fact." The rituals with their underlying religious notions counteract "the centrifugal forces of fear, dismay, demoralisation" and provide "the most powerful means of reintegration of the group's shaken solidarity, and of the re-establishment of its morale" (Malinowski). The ultimately psychological basis of this approach is rejected by the structuralists, who emphasize that ritual tends to build up tension and not merely to provide release. Émile Durkheim, the father of the structuralist approach, noted that socially prescribed demonstrations of grief (wailing, seif-laceration) might be out of all proportion to the actual strength of the individual emotions. The real function of ritual is not to release emotions but to create and manifest them and thereby to affirm the basic values of society. A widow's wailing provides no comfort, but it publicly reasserts the significance and value of the marital tie at the very moment of its suspension and dissolution by death. Even so, psychological factors no doubt also play their part, and depth psychology in particular has shown to what extent death customs may answer unconscious needs and attitudes arising out of feelings of guilt, desire for expiation. and fears (*e.g.,* due to death wishes or other repressed ambivalent relationships to the deceased, to oneself or to others).

Ambivalence Toward the Dead.—Almost all authorities have commented on the basic ambivalence underlying death customs, notably the horror of death and the dead on the one hand, and the desire to perpetuate the bond on the other. Defilement and pollution emanate from the corpse; yet a remarkable lack of dread and even positive familiarity are equally in evidence: mourners may lie down on the corpse, kiss it, or anoint themselves with the exuding fluid However. even rites intended to assist the deceased in his afterlife, to provide for his variously conceived needs (food offerings. rituals, prayers) and to speed him on his way to his ultimate destination (the land of the dead, paradise. nirvana) often imply the concurrent intention to get rid of him and to prevent his return either as body or as ghost. The treatment of the corpse (burial, cremation, breaking of bones, tying of hand and feet), the tabu on mentioning the name of the deceased, and many other customs have been interpreted in this sense. Some tribes even have a special ceremony of "burying the soul." The soul or ghost likes to linger by the body or near the living; hence it must be chased or lured away and its return prevented. Doors or windows may be opened for a moment after death but then immediately shut again; in China and Basutoland a hole is made in the roof. The corpse may have to be carried out through a specially made hole or entrance so that the ghost may not find the way back. For the same reason the mourners may return along a different route from the burial or even efface their footprints. Special precautions may be taken against haunting or "walking." The severance of the ties is, at times, effected slowly and by degrees: there may be carousing "with" (i e., in the presence of) the corpse during the preburial wake; the Koryaks (northeastern Siberia) even play cards on the corpse.

Rites of **Passage.**—Whatever specific ideas prevail regarding afterlife in the different cultures, death is generally regarded not as an absolute end but as the transition from one particular world or kind of existence to another. The attendant rituals are therefore passage rites (*q.v.*) consisting of rites of separation, rites of transition and, finally, rites of incorporation of the deceased in his new world. The burying of utensils and the destruction of property, in addition to simplifying problems of inheritance. also serve to finalize the separation of the deceased from the world of the living Yet although the purpose of mortuary rites often is to speed the ghost to the ghost-world and to implore him not to trouble the living, the opposite tendency is equally often at work. The bond, albeit on a different basis, between the quick and the dead is ceremonially re-established, the latter granting protection and blessings to the former (see ANCESTOR WORSHIP). Hence the deceased may also be preserved in whole (mummification of holy men in Tibet and their preservation in chortens as objects of veneration) or in part (*e.g.* relics, ancestor skulls kept in places of honour [Melanesia] or worn as amulets [Andaman Islands]). The dead may return and visit the living as recognized "supernaturals" or as ghosts; on such occasions they may be welcomed and entertained, either gladly or with fear accompanied by precautionary measures (Zuñi pueblo dances, Greek *anthesteria*, Trobriand *baloma* feasts). Many death customs represent a compromise between the conflicting tendencies. Hence it is often difficult to be sure of the exact significance of a rite; *e.g.,* to decide whether a particular funerary amulet was meant to protect the dead or the living. Coins placed on the corpse or in the grave may ensure that the deceased suffers no penury or can pay the boatman's fare nhen he is ferried over to the land of the dead, but they may also be meant to prevent him from returning and fetching his property.

PRE- AND POSTBURIAL RITES

It follows from the above that the actual disposal of the body is merely part of a larger sequence of actions, beginning with the onset or imminent expectation of death and ending with the final cessation of mourning (or even later). On the imminence of death. a strictly regulated procedure, varying in different cultures. is followed: family and friends are notified, and priests are called in to assist nith prayer, confession or other ministrations. In many parts of Europe it is customary to stop all clocks in the house at the moment of death. to cover all mirrors (or even windows), to extinguish the hearth fire and light a new one, etc. The corpse may be washed. shrouded, dressed up, dyed. or laid on the ground or in state; often lights and ritual objects (*e.g.*, a crucifix among Roman Catholics) are placed near it. The time that has to elapse between death and disposal is generally regulated by religion. social custom and (in some countries) law; it may be filled with nailing and other prescribed manifestations of grief. religious ceremonies, banquets and wakes (*q* v.). The manner of exit from the house and the procession to the place of disposal are similarly subject to detailed regulations. Religious obsequies may be celebrnted at the house, at the place of disposal or—between the two—at a place of religious worship. The actual disposal of the body map include the provision of the dead man's necessities, such as amulets, food and grave goods (weapons, tools, treasures). These may be given in actual fact. including the killing of a man's (usually a ruler's) wives and slaves to minister to his wants (in many ancient and some primitive civilizations) or merely symbolically (paintings or cheap imitations). Sometimes the objects or imitations are burned or destroyed so that the deceased may profit from their spiritual essence.

Disposal is followed by a more or less fixed time of mourning. varying for different mourners and relatives. and involving a number of prescribed actions and avoidances: a funerary banquet, mourning distinctive appearance and attire (disheveled hair, nearing of specific colours, such as the black crape in use until recently in Europe), prayers and offerings, food and speech tabus (among many primitive tribes), abstention from certain forms of amusement and social life, purification ceremonies and the like. Society participates with the immediate mourners: there may be obituary notices and speeches visits of condolence, attendance at the various ceremonies. The postburial rites formally end with secondary disposal, unveiling of the tombstone or similar ceremonies. though, in a sense. they may continue as long as there is anyone to perform memorial rites at the tomb or elsewhere.

Almost everywhere the proper performance of the funerary ritual or. at least, the proper disposal of the body, is held to be of the utmost importance — either to ensure the admittance of the soul to the land of the dead and to save the living from his vengeance. or simply as an act of piety. For example, where interment is the traditionally required mode of disposal, its neglect may be considered as a great misfortune for the deceased (cf. Jer. xvi, 4). preventing his soul from finding rest (Suetonius, Caligula 59) or from entering the Elysian fields (Tertullian. De *anima* Ivi). Sepulture was instituted by the gods as a sacred duty (Sophocles. *Antigone* 454 ff). and God himself buried Moses (Deut. xxxiv. 6). Burial must be given even to enemies (Euripides, *Supplices* 524–7; Pausanias. *Description* of Greece ix. 32, 9) and to unbelievers (Muslim *fiqh*), indeed to all from whom it has been withheld (II Sam xxi, 12–14). It is a particular act of charity to bury remains found in a desert or when traveling; according to Jewish law this duty even suspends the rigid rules of levitical purity applying to priests At least a symbolic gesture of burial should be made by throwing some earth on a corpse which one happens to find (Horace. Odes i. 28. 23–5). The Greeks used to give ceremonial burial "in empty clothes" to those who died at sea (Euripides. Helen 1241–43).

DISPOSAL OF THE DEAD

Different methods of disposal are practised not only by different cultures but, occasionally, also among a single people. Where this is so, the mode of disposal is usually determined by cultural and social differences: membership in a particular social group. totem or clan association; degree of initiation in a secret or ritual society; rank as commoner or chief: sex; achievements and ethico-social status (criminal, hero. saint); manner of death (suicides and women who died in childbed are given different treatment in most primitive societies. and special rules often also apply to those who died by an extraordinary "act of God." *e.g.*, being struck by lightning); special circumstances (*e.g*, twins, among the Nuer. are not buried but placed in the fork of a tree); religious persuasion (Muslims, orthodox Jews and Roman Catholics insist on inhumation; a pious Buddhist may forego cremation and prefer to feed his carcass to the animals and birds); and various other factors. Also, the details of any one particular method. the elaborateness of the funerary ritual as well as of the preburial and postburial rites. and the time taken over the ceremonies, vary according to the afore-mentioned differences. Those who do not "belong" to a recognized group or class (*e.g.*, unbaptized children or excommunicates) are treated differently from full members of the community. Among some tribes the social ascription determines even the classification "alive" and "dead": the very aged or those nho have been ill very long are considered as dead and may be buried even though still alive. The main methods of disposal are as follows:

Inhumation. — Interment is one of the oldest methods, practised at least from the Mousterian (Middle Paleolithic) onward. Usually in contracted or extended position. though at times even sitting or standing, the corpse may be placed in immediate contact with the earth or protected by matting, stone slabs, pottery jars or urns (*pithoi*), or a coffin (among seafaring people also in the form of a canoe). Alternatively the tomb may be lined with matting. bricks etc. Orientation varies according to religious and other social traditions; e g., views about the direction and location of the land of the dead, or traditions about the direction from which the ancestors (or totemic ancestor) of the clan of the deceased had come — the land of the ancestors and that of the dead being often identical. Muslims are laid on their right side, facing Mecca: Buddhists (where they bury) lie face upward with the head to the north, like the Buddha when he died; Christian tradition preferred the feet toward the east, ready to rise and to meet Christ when he appears on the Mount of Olives. Burial usually takes place singly, though in collective cemeteries near the settlements. more rarely in the settlement or even in the house, and occasionally in sites chosen for special reasons (crossroads, churches).

Similar to inhumation is cave burial. Natural or artificial caves (burial chambers and niches or shafts nith side vaults hewn into the rock) are knonn from prehistoric, present-day primitive and some ancient civilizations (*e.g.*, Knossos, Sicily. Fiji Islands, South American Pueblos). Mass graves are dug only in wartime or after major catastrophies. Memorials, varying from a simple stone or nooden board to sumptuous mausoleums. may be erected over the tombs. (See also CEMETERY; COFFIN; MONUMENTS AND MEMORIALS; SCULPTURE. SEPULCHRAL; TOMB.)

Cremation.—Destruction of the body by fire is world-wide in incidence Appearing in Europe with the late Neolithic banded-pottery culture, it began to displace inhumation toward the later Bronze Age. Since then the two alternative methods have coexisted. Ousted by Christianity in the late Roman empire, cremation experienced a revival in more recent times. In many societies cremation is associated with rank and status; it may be accorded to chiefs only or. conversely. to criminals It is the usual method of disposal among Hindus and frequent among Buddhists. In ancient Egypt, China and Israel, cremation was excluded by the respective beliefs; e.g, the view that immortality depended on the preservation of the body, veneration for the dead ancestors or belief in the resurrection of the body. Cremation may be partial only; the remains (bones, ashes) are then buried, scattered or preserved. Only rarely is it complete. in which case the bones are ground. mixed with combustible matter and burned again. The details of the procedure (place, time, kind of timber used) are generally regulated by tradition, in modern countries also by sanitary requirements. Explanations of the origins of cremation are speculative. to prevent magic being performed with the corpse. to prevent "walking," to liberate the spirit and speed it upward (India) etc

In the same way as tombs were originally conceived as "houses" for the dead (tomb chambers. house-shaped sarcophagi), urns too could be given the shape of a house (as among the Etruscans), thus indicating that the idea of a dwelling for the dead may have persisted even in cremation cultures (See also CREMATION)

Conservation. — The preservation of the whole body is generally regarded as the most extreme form of the denial of death. Known particularly from ancient Egypt (see MUMMY), it was also practised by many other groups, among them some of the most primitive (Australia, Torres strait), though usually reserved for high-ranking persons only (chiefs, priests, kings). The methods used vary from simple desiccation (*e.g* , smoke-drying) or treatment of the body with mineral or vegetable preservatives (usually after evisceration), to the most modern techniques of embalming (*q.v.*). The custom originated in countries with a suitably dry climate. Surprising similarities have been noted in the more highly developed techniques used in distant areas (*e.g.*, Egypt and Central and South America). Where only parts of the corpse are to be preserved (*e.g* , skulls for ancestor cults) or to be disposed of in some other way, decomposition may be artificially hastened.

Water Burial.--Next to exposure, the simplest way of disposing of a corpse is to fling it into the water. Hence this is often the method applied to slaves, foreigners and people considered to be of no account. In some islands, parts of the coast are reserved as "cemeteries"; corpses are wrapped up to protect them against fishes and weighted with stones. (In the Solomon Islands, however, they are laid on the reef to be eaten by sharks.) In the western world, nater burial is the usual practice for those who die on board ship.

The custom of placing the body in a canoe and pushing it into the sea cannot strictly be called water burial; it was practised by people who were probably the descendants of immigrant tribes and mas thus essentially a method of dispatching the deceased to the land of his ancestors. Disposal by launching on the water may be practised symbolically and combined with other methods: burial in boat-shaped tombs or coffins (*e.g.*, the boat-shaped Bronze Age stone arrangements in Bornholm, the Sutton Hoo boat or those found at Oseberg, Gokstad and Tune in Norway) or cremation on a blazing ship (as in the Germanic saga of Balder). The underlying idea seems to be that of a "voyage" to the land of the dead.

Exposure. — Exposing the corpse where it is left to decompose (on the ground, in trees, on rocks, on special platforms), to be devoured by animals or to await further treatment, is a method widely practised. In hot, dry climates exposure may result in desiccation and thus become a method of preservation The Vedda (Ceylon) and the ancient Chinese left the bodies in rock caves or in the jungle, protecting them slightly by a covering of leaves or brushwood. Some Buddhists prefer exposure as an act of charity toward the hungry animals and birds, and it is still the accepted manner of disposal among orthodox Parsees, who place their dead in their dakhmas ("towers of silence") to be devoured by vultures, lest they defile the earth or the fire. In the arctic region, where the ground is frozen. exposure is the nearest alternative to burial; some tribes (*e.g.*, the North American Naskapi) leave the body on a scaffold during winter until burial becomes possible. Actual platform burial (on artificial scaffolds or in trees) is frequent in Indonesia, Melanesia, Australia and America, but rare in Africa. According to one school of ethnology (W. Schmidt and W. Koppers). the method is related to totemistic ideas of immortality and is designed to facilitate the flight of the soul to the realm of the dead, but the explanation is doubtful.

Cannibalism. — Endocannibalism (*i.e.*, the devouring not of prisoners or strangers but of relatives) is a method ensuring that the deceased remains in the closest possible union with his tribe and does not fall prey to hostile demonic powers. Often the old and the sick are dispatched before death comes to snatch them The flesh is ceremonially eaten; in some tribes even the bones are pulverized and mixed with food or drink. (The same is done by some American Indian tribes with the ashes of cremation.) The method is held by some ethnologists to have originated among primitive matriarchal agriculturalists (*e.g.*, in Melanesia); it is found in Australia, South America and Africa.

Secondary **Disposal.**—With the exception of water burial, most methods of disposal leave room for subsequent secondary treatment of the remains; in the case of cremation it is a necessity. Even where interment is the rule, the bones may be exhumed for reasons of space economy (*cf.* the medieval charnel houses) or as part of a prescribed ritual (as in modern Greece). This secondary treatment may be accorded to parts (*e.g.*, the skull) or all of the remains. The interval between the two stages of the disposal varies from a few weeks (*e.g.*, the Trobriand Islands) to 10 or 12 years (e g , the North American Hurons). Secondary burial may be individual (as in eastern South America) or collective (as in the great Neolithic barrows). The ceremonies too may be related to the individual dead or to all the deceased of the tribe. In the former case they mark the close of the period of mourning and function as the passage rite whereby the soul is finally integrated in the community of the dead and the mourners are finally reintegrated into the community of the living.

HISTORICAL SURVEY

As mankind passed through the stages of culture marked by the discoveries of the crafts and techniques of stone polishing, copper- , bronze- and ironnorking, a variety of funerary customs developed. conditioned partly by natural and cultural resources and partly by beliefs about the kind of life after death and the relationship betneen the dead and the living. Whereas the death customs of historic cultures are known from their mortuary remains as well as from a nealth of literary testimonies. our knowledge of prehistoric culture as a whole is largely provided by funerary monuments. Prehistoric man made his arrangements for the dead nith permanency in view. The evidence yielded by the tombs (mode of disposal type of burial, objects deposited), in conjunction with related evidence (geological stratification, contemporary fauna), is our sole source of information concerning the nature and significance of the funerary remains. as well as the period and race to which they should be assigned.

Paleolithic. — Interment of the body together with ceremonial implements is attested at least from the Middle Paleolithic onward (in France. at Le Moustier, La Chapelle, La Ferrassie). The provision of food and implements suggests some kind of belief in continued life and a conception of the tomb (cave or rock shelter) as a dwelling Funerary equipment (personal ornaments of bone and shell, amulets. figurines) increases in the Upper Paleolithic period (Grimaldi, Barma Grande, Cro-Magnon, Brno. Solutré) and there is a striking and lavish use of red colour—possibly as a vitalizing agent. The body may be placed in ochreous earth.or smeared or sprinkled with red ochre (*e.g.*, the "Red Lady of Paviland," Wales) The "sleeping" position and the even more tightly flexed position ("contracted burial") mere most frequent in Upper Paleolithic Europe. as they still are with many primitive tribes Flexing and tying the body have been explained as a return to the fetal position (thus implying some kind of idea of rebirth). as a measure to prevent the dead from walking, and as economy of space. Upper Paleolithic tombs also yield remarkable indications of a cult of the skull Skulls would be severed from the body and prepared as "bowls," or buried separately. The Ofnet (Bavaria) deposits—two scooped-out "nests"—contained over 30 richly ornamented skulls. all facing west.

The Paleolithic practices continued into Mesolithic times as witnessed hy the Ofnet skull burials and the Téviec (Brittany) tombs a well as the Mas d'Azil and similar ossuaries Many of these show that the bones were deposited after the flesh had decayed or had been scraped off. In Denmark extended burial (as distinct from the contracted position) was practised, the tombs being surrounded sometimes by large stones (Erteholle). These again, could be covered with earth (mound burial) or with single capstones. The latter type known as dolrnens or (Danish) *dysser*, became a prominent feature of the megalithic culture that spread in Europe during the Neolithic period (see ARCHAEOLOGY: *Neolithic and* Bronze Ages in *Europe*).

Egypt. — The transition from food gathering to food production nhich is generally considered as one of the turning points in the history of human societies and their cultures, also had profound effects on mortuary ritual, which became increasingly elaborate. reaching a climax in the funerary cult of Egypt. Egyptian Neolithic cemeteries were situated nearly (only rarely in) the settlements. The bodies mere buried in flexed position, clothed, and provided with ornaments and various means of sustenance. Often they were turned toward the west—possibly the first sign of the subsequently very important notion of a western land of the dead. With the unification of Egypt soon after 3000 B.C., the early dynastic tombs underwent rapid elaboration: the pit was undercut on one side to allow for more tomb furniture; the sand mound over the tomb became a rectangular stone mastaba; doors, niches and steps were added; and finally the cult offerings were transferred from the tomb itself to a temple by it. The superimposition on each other of mastabas of decreasing size (stepped pyramid) finally produced the pyramid (*q.v.*) tomb.

Whereas burial in the dry sand of Egypt might result in the natural preservation of the body, this would not be the case in tombs. however elaborate. Permanence had to be assured by artificial mummification as well as by the use of effigies. The latter, placed in a temple, had the advantage of being more accessible for ritual purposes than the corpse which lay at the bottom of the funerary shaft. The effigy was "brought to life" by the ceremonial of the "Opening of the Mouth" (performed later on the actual mummy) and made the object of regular mortuary rituals. With the development of the worship of Osiris in the later dynastic period, the whole ritual became assimilated to the myth of the death, dismemberment and resurrection of Osiris: the dead man's body was reconstituted and his spiritual, *i.e.*, vital essences, the ba and the ka, restored to him. This rebirth to immortality or "Osirification" was, at first, the privilege of the king—himself divine. Later it became accessible to nobles and even to commoners.

To assist the deceased in his "resurrection," to protect him from demons and other dangers, and to ensure a favourable verdict at the judgment of the dead (presided over first by the sun god Ra, and since the 11th dynasty by Osiris), he was also provided with suitable texts and magical formulas. These texts, of different ages and varied contents, and known as the Book of the Dead, were inscribed on papyrus or on the walls or the coffins (Pyramid texts). In the New Kingdom the papyri were put into the coffin together with the mummy, so as to increase their efficacy. (See also EGYPT: History: Ancient Religion.)

Mesopotamia.—Unlike Egypt, Mesopotamia never had a highly developed mortuary cult. The outlook for the dead was gloomy: a kind of shadow existence in a House of Darkness, the "Land of No Return," similar to the underworld of the Hebrews (Sheol) and the Greeks (Hades). Grave goods, though meagre, nevertheless indicate some kind of belief in survival. The exception to the general rule are the sumptuous royal tombs at Ur (2900–2700 B.C. according to C. L. Woolley) with their wealth of funerary furniture. The Sumerian kings took to their graves not only priceless vessels and ornaments but also their retinue of wives, courtiers, attendants and guards. However, this royal funerary cult is not characteristic of subsequent development in Babylonia.

Eastern and Western Mediterranean.—Burial in stone structures of different shapes and kinds and various degrees of elaboration (vaults, passageways, etc.) spread throughout Europe during the Neolithic period. The earliest tholoi (circular stone structures) in Cyprus have been found similar to those discovered in Iraq near Nineveh (Tell Halaf period). Groups of tholoi came to be enclosed with dry-stone walls and roofed with corbeled vaults, thus producing the vaulted "beehive tombs." Some tholoi (Hagia Triada, tholos B at Koumasa) have yielded the remains of hundreds of interments; clearly, many generations were being "gathered to their fathers" in community tombs. The same applies to the stone-built or rock-cut tombs in Crete and the Aegean Islands (see AEGEAN CIVILIZATION). Megalithic and rock-cut tombs of similar layout and constructions have been found in Sardinia (the gallery tombs known locally as *tombe* di giganti), Malta, Spain, the Pyrenees and Atlantic Europe; *e.g.*, Brittany (the famous passage grave at Carnac [*q.v.*]) and the British Isles (barrows and cairns [*qq.v.*]). In northern Europe the megalithic tradition, deriving from the Mediterranean, met with other cultures coming in from other directions and practising different types of burial. However, the contents of all these tombs (ornaments, trinkets, animal bones—possibly remains of funerary sacrifices—female figurines perhaps representing some kind of mother goddess, designs) clearly suggest ceremonial treatment of the dead involving certain beliefs.

Bronze Age.—Although some Neolithic and Early Bronze Age tombs contain evidence of whole or partial cremation, this mode of disposal became general only from the Middle Bronze Age onward. Characteristic of the period is the appearance in Europe, from western Asia Minor to Ireland, of cremation cemeteries in the form of urn fields. Particularly well-known examples are the "terramara" and Villanova urn fields in Italy, and the great Hallstatt cemetery in the Austrian Alps. The precise reason for the correlation of cremation with Bronze Age culture is unknown. (See also VILLANOVANS; HALLSTATT.)

Greece.—From the earliest times in Greece, when inhumation still was the sole mode of disposal, different types of tombs are known: circular dome tombs, rectangular chamber tombs, shaft tombs and pit tombs. Burial often took place in the village or even under the house. There is evidence of human sacrifices having been offered as part of the funerary ritual, in addition to the regular tomb furnishings (treasures, vessels, etc.). Funeral games in honour of the dead were no longer held in later periods. Exposure of the corpse before burial, sometimes for ten days or more, was not unusual. Violent expressions of grief (wailing, self-laceration, beating the breast) were customary though disapproved by lawgivers and moralists (Solon, Plato).

Proper burial rites were essential for the soul's admission to the realm of the dead, and sacrifices were performed at the tomb at prescribed dates (the third and the ninth day after burial). Mourning included abstention from pleasures and wearing black. There were also annual commemorations of the dead and festivals at which the dead were supposed to return in order to be welcomed and entertained (*anthesteria* [*q.v.*]). These visits were occasions of considerable uneasiness: precautionary measures were taken, and there was great relief at the end of the festival.

By the time of Homer cremation had become fairly general, and his detailed account of the obsequies of Patroclus (Iliad xviii, xxiii) gives a good idea of the pomp and costliness of the elaborate ceremonial as performed for outstanding persons. For ordinary folk the rituals of cremation and (more generally) burial would, of course, be simpler.

Rome.—In ancient Rome, funerary ceremonial varied with the times as well as with the rank, wealth, occupation, place and religion of the dead person. Most of our evidence dates from the late republican and imperial periods. As a man breathed his last, his name mas called out (*conclamatio*)—a ceremony that is still performed at the death of a pope. When the deceased failed to respond and to return, conclamatum est and the corpse was bathed, washed, perhaps also embalmed, and arrayed in a toga. Formal announcement of the decease and the impending obsequies was made, and at the appointed time the funeral procession (which sometimes included actors and jesters) made its way to the Forum where the departed citizen was eulogized (laudatio), and thence, through the city gates. to the place of inhumation or cremation. This was not in a public cemetery but in family holdings which lined the roads. The best known of these is the line of tomb ruins along the Via Appia. Tombs were of various types: mausoleum, tumulus, columbarium (*q.v.*). The latter, which derives its name from the dovecot type of chambers with niches, is usually found in plots belonging not to families or gentes but to co-operative funeral associations '(collegia *funeraticia*). It was as such an association that the early Christians in Rome were organized (see CATACOMBS). The tomb would be marked by an epitaph giving biographical information about the deceased, and often also by a portrait bust. Incised in the stone there might also be a request for remembrance or a more general exhortation, couched in the form of an address to the passing stranger. Even when cremation had become fairly general, at least among the upper classes, the earlier form of disposal still survived symbolically in the burial of some minor part of the body (os *resectum*), usually the little finger. Lower-class funerals were, of course, much simpler, and slaves and the poor were buried in a general cemetery, the "potter's field" of Rome.

Mourning lasted for nine days, followed by offerings at the tomb (*sacrum* novendiale) and a banquet at the house. There was a further period of mourning—eight or ten months, according to the relation of kinship. The Roman rituals imply a general belief in some kind of survival and a wide solidarity between the quick and the dead. The latter exist and participate, albeit in a ghostly manner, in the affairs of the living. Hence scrupulous care had to be taken for the correct regulation of mutual contacts. Ancestors enjoyed a divine cult (di paternales, later the di *manes* generally). and the Parentalia were celebrated every year from Feb. 13–21, the last day of the festival having a public character (see MANES). During the feasts of the dead, no marriages could be concluded and all temples were closed. Spirits. if dissatisfied or unpropitiated, could become dangerous, bloodsucking, vampirelike ghosts (lemures); to propitiate them the Lemuria were held, during which the pater *familias* performed certain ceremonies and finally chased the ghosts away.

THE MAJOR *RELIGIONS*

Islam.—At the approach of death a Muslim (or those around him) pronounces the profession of faith. which may then be recited again, together with sura 36 of the Koran, over the dedd body. The body is laid on a stretcher in the direction of Mecca (kibla) and reverently and carefully washed (*ghusl*) according to very precise regulations. The nostrils and orifices are stuffed with cotton and the body sprinkled with camphor and rose nater. The eyes are closed and the feet tied. About the sort and number of shrouds (in any case an odd number), their colour, and other details there are rnany differences of opinion and custom. Next. the prayer for the dead (salat *al-djinaza*), the formula of which is minutely prescribed, is recited. Martyrs, however, are not washed and not prayed over. A watch by the corpse is customary, though not prescribed, and the Koran is recited by hired readers.

Details of the procession to the cemetery vary In Egypt the poor and the blind may precede the bier, chanting the *kalima,* followed by the relatives and someone who carries a reading desk with the Koran. The bier is borne by men only, even if the deceased is a woman. It is recommendable to follow a funeral procession (oil foot. because the angels of death go on foot). and it is considered a particular act of merit to help carry the bier. The grave is of ample size, to enable the deceased to sit up when interrogated about his orthodoxy by the angels Munkar and Nakir. The body is laid on its right side. propped by bricks, with the face toward Mecca There is no further service. A shawl is rent, three handfuls of earth are cast on the grave by the bystanders, and sura 112 of the Koran is recited (though not by the Wahhabis and some others) Before the tomb is closed, the correct answers for the angelic examination on the catechism ("Who is your God, Who is your prophet?" etc.) are prompted into the dead man's ear by two *fikis* (tutors); the Malikites, however, disapprove of this custom. The tomb is closed and the mourners depart reciting the *fatiha.*

A good many popular death customs are practised in spite of the disapproval of tradition; *e.g.,* wailing or declaring the praises of the dead man, burning a light near the bier, the ornamentation of graves and the placing of inscriptions on the tomb. On returning from the funeral to the house the *fikis* may hold a repast, recite *sura* 67 and perform the ritual of the *sabha* (the rosary of 1,000 heads), transferring the merit of the recitation to the deceased Visits of condolence to the mourners are prescribed by religious law Wailing is resumed by women every Thursday for three weeks; on the Fridays they visit the grave and perform various rituals. Visits to the graves take place also on other occasions

Judaism.—Many of the death customs mentioned in the Bible were ancient Semitic practices (rending of garments, self-mutilation walking barefoot. funeral meals; see Jer. xvi, 5–8; Ezek xxiv, 17), and some of them were prohibited because of their pagan associations (Lev. xix, 28; Deut. xiv, 1). Inhumation, if possible in one's country and "with one's fathers," was the generally practised mode of disposal. To be deprived of proper burial was considered a major disaster, and exposure was a disgrace which even convicted criminals must be spared (Deut. xxi, 22 ff.; Jer. vii, 33; Ezek. xxix, 5; Ps. lxxix, 3). To be properly lamented and mourned over was almost as important as burial, and the Old Testament contains many references to the ritual of wailing and keening.

Postbiblical Judaism has preserved many biblical funerary customs, modified by later developments. At the approach of death the confession of sins and the confession of faith are recited (the latter also by those present). The dead body is then laid on the ground, acd Psalms (particularly Ps. xci) are recited by the watchers. The corpse is washed with decency and reverence according to a prescribed ritual, arid wrapped in a simple white linen shroud. (Since the ordinance of Gamaliel II, 2nd century A.D., all Jewish burials have been of equal simplicity.) For climatic reasons the original custom required immediate burial. All ministrations connected with the washing and burying of the corpse are performed by voluntary or professional organizations known as "holy brotherhoods." These ministrations, as well as the attendance at a funeral and the comforting of the mourners are considered as meritorious acts of charity. The corpse is buried in extended position, either in a plain wooden coffin or immediately in the grave lined with stone slabs Usually a handful of dust or earth from the Holy Land is laid in the grave or coffin. The funeral service consists of Psalms, the "acknowledgment of the justice of God's decree," funeral speeches in praise of the deceased. prayers for the repose of his soul, and the Kaddish doxology Those present throw earth on the grave and then stand in two rows through which the next of kin walk out of the cemetery.

The ancient funeral banquet has fallen into desuetude, but on returning from the burial, mourners eat a simple meal served to them by friends and neighbours. The next of kin manifest mourning by rending their upper garment and staying indoors for seven days (cf Gen 1, 10 and I Sam. xxxi, 13), sitting on the floor or on low stools. Since the niourners cannot leave the house to attend synagogue, morning and evening services may be held at the house Mourning varies according to the degree of kinship (strictest for the death of parents) and is graded in stages: the first seven days after the funeral, the first month after the decease. the first year. These stages of the mourners' return to normal life correspond to the stages of the soul's progress in the hereafter (final separation from the body in the grave, purgatory, admission to celestial repose). During the latter part of the middle ages, the idea gained currency that prayers and merits accruing from good works might profit the departed souls. and some earlier customs (e g., the recital of the Kaddish) were reinterpreted in that sense. The development of more ideas and customs of this kind (e g, for protecting the soul from hostile demonic powers) was stimulated by the kabbalistic movement of the 16th century.

Christianity.—When discussing the funerary customs of Christian people, a distinction must be made between the essentially Christian elements, deriving from specifically Christian beliefs and liturgical traditions on the one hand, arid general, folkloristic elements on the other. The latter, which may combine in sundry ways with the Christian element, will not be considered in this section (but see Pre- and *Postburial* Rites, above).

The starting point of all Christian mortuary rites is the faith that by Christ's death on the cross and by his resurrection man has shed his old condition. spiritual death (ie., sin), as well as its outward expression, physical death (Rom. vi, 23). The individual incorporated in Christ, i e, in the church of which Christ is the head. has gained immortality by sharing in the resurrection-life of Christ. This immortality will become fully manifest at the general resurrection.

Mourning over death was not an original Christian custom, since the deceased had merely left this temporary abode in order to join his Lord in glory and to expect the final resurrection. In the 4th century, funerals were still occaiions of joy and those attending them wore white Also, the Christian form of the "cult of the dead." *i.e.*, the cult of the martyrs, was not a matter of mourning; there was in it an element of triumph. and altars, chapels and finally churches were constructed by preference above or near the tombs of martyrs By the 8th century, however, the realities and attitudes of the Christian world had changed. Funerals were now occasions of mourning (*i.e.*, the wearing of black), and prayers mere said for the purification and deliverance of the soul from hell.

By the end of the middle ages the following sequence of rites had developed: At the approach of death. a priest is called in to confess and absolve the dying person, to administer Holy Communion (viaticum: spiritual food for the last journey of the soul) and extreme unction (anointing with olive oil blessed by a bishop) and to pray (commendatio *animae* of the western rite). Burial is preceded by the office of the dead. consisting of the usual canonical hours (vespers, matins, lauds; the special antiphon *dirige* (has given rise to the "dirge") and, in the morning, the Requiem Mass (*q.v.*) with prayers for absolution of the dead, and the censing and aspersing of the body. Requiem Masses are also said on the 3rd. 9th. 30th and 366th day. The burial service of the Anglican Book of Common Prayer is a modified version (sentences. psalm, lesson) of the dirge. Some modern Protestant liturgies do not have prayers for the dead. though there is no doubt that from very early times the eucharistic liturgy was offered for the dead as well as the living. All the souls of the faithful are commemorated on Nov. 2, All Souls' day (*q.v.*).

The actual inhumation is accompanied by a short committal prayer, sometimes also by censing and sprinkling with holy water. Interment has always been the traditional Christian practice. The permissibility of cremation has given rise to discussion in recent times, and many churches have adapted their funeral service to cremation. But even the Roman Catholic prohibition of cremation is considered to be a matter of ecclesiastical discipline rather than of divine precept or natural law. Tombs are usually marked by a cross or by (at times very ornate) tombstones incised with a cross.

The Roman Catholic doctrine of purgatory (*q.v.*), rejected by both the Eastern and the Protestant churches, has given rise to practices intended to obtain remission of (temporal) punishment for poor souls. Of these. the practice of indulgences (*q.v.*) is the best known because of the abuses to which it gave rise and the misinterpretations to which it was subject. There are minor as well as major differences (*e.g.*, regarding liturgy, orientation of the corpse, vestments worn) in the burial rite. depending on whether the deceased is a priest, layman, infant, etc.

Hinduism.—The Hindu way of life. the Aryan *dharmá*, is permeated by ceremonials and sacramental rituals (*samskaras*)—most of them domestic rituals. Considering the particular Hindu doctrines regarding the soul and reincarnation (see HINDUISM). ceremonies connected with death and afterlife are clearly of outstanding importance. In fact, every Hindu desires a son mainly because only a son can properly perform the regular funeral rites (*antyeshti*) which ensure a happy rebirth in the hereafter. Hindu death ceremonial is long and complicated. There are many variations in points of detail, some local, others due to the caste of the deceased. the particular school or sect to which he belonged. and other factors.

At the approach of death. relatives and Brahmnns are summoned, *mantras* and sacred texts are recited and ceremonial gifts prepared. It is desirable that the dying person touch a cow (*vaitarani*) which is then given to a Brahman. The subsequent ceremonial is concerned partly with the deceased and partly with his relatives (particularly the chief mourner or *purohita*), who are all impure and consequently have to go through various purification rites. Since the time of the Rigveda, cremation has been the usual mode of disposal. It is performed, wherever possible, near a river, though some low castes usually bury their dead and the same is done occasionally with children and ascetics. The treatment of the corpse, the shrouding, the procession to the place of cremation with the attendant rituals (offerings. circumambulations, etc.), the location, size, orientation and arrangement of the pyre, the kind of timber used, the procedure of committing the body to the flames (sprinkling of the pyre, placing various utensils and offerings on the body), the postcommittal rites (lustrations, recitations. return to the home after sunset)—all these are strictly regulated. For ten days after the funeral the mourners are unclean and secluded from society. They are subject to certain tabus (*e.g.*, they must not study the Veda or cut their hair) and must perform daily ceremonies intended to provide the naked soul of the deceased with a new spiritual body with which it may pass on to the next life; otherwise the soul might become a ghost and haunt the living. Ceremonies include the setting out of milk and water, and the offering of rice balls (*pinda*). At a date fixed according to various rules, the secondary burial takes place. The bones are collected and placed in urns or barrels which may be either buried or thrown into the water; some schools enjoin a second cremation after pulverizing the bones and mixing them with combustible material. Further rites are performed to ward off evil and to mark the return of the mourners to ordinary life (*santikarma* and *smasana*), including the kindling of a new fire in the house and the construction of a ritual hut for the disposal of the urn; viz., the bones. Other regular memorial offerings (*shraddha*) continue to be made on fixed dates in order to nourish the souls of the ancestors in the afterlife.

Buddhism.—There is no fixed funerary ritual characteristic of all Buddhists. Customs vary according to geographical and ethnocultural factors (southeast Asia, Ceylon, Tibet, China. Japan). local pre-Buddhist traditions, and the particular school of Buddhism concerned. Even in a single relatively homogeneous Buddhist area, e g, Japan. there are considerable differences in the rituals of the different sects (Shingon, Tendai. Jodo, Shinsho, Nichiren. etc.). Buddhism has generally countenanced popular superstitions. Hence animistic and magical beliefs as well as other folkloristic elements are much in evidence in the death customs of many Buddhist countries. The most usual method of disposal among Buddhists is cremation, though burial. preservation and exposure also occur. Often the dead are kept—embalmed or buried—for a period of time before cremation (*e.g.*, in Thailand).

Death plays a central role in Buddhist theory and meditation. Death is painful and inevitable. and all men fear it. But its real sting is the fact that it is not an end but a new beginning: it is the birth of new existence. Hence meditation on death is necessary to enlightenment. For the truly enlightened man death is no longer the passing to another existence but the extinction of, and release from, existence: Nirvana. Buddhism rejects the notion of a substantial soul. Yet the notion of karmic rebirth presupposes that even after the dissolution of the combination of changing elements which constitute the empirical human organism. some kind of substratum or element remains which may become the point of crystallization for the emergence of a new set of mental states; i.e, a new existence. Hence one's last thoughts before death determine the nature of rebirth: at death the "fundamental thought" (*bhāvanga*) is transformed into "emigrating thought" (*chyntichitta*) which, in its turn. determines the "rebirth thought," the nucleus of the new existence. Proper preparation for death, by mēditation as well as by *puja* ceremonies. was therefore considered important and even provided for in the emperor Astoka's instruction regarding criminals awaiting execution. But whatever determines in theory the nature of the following rebirth. whether the last thought at death or whether the total quality of a whole life's endeavours, these considerations affect popular Buddhist practice only little The most conspicuous elements in popular funerary ritual are the fear of hell and the demons, efforts to reduce punishment by vicarious acts of merit and by magical formulas, and the assurance of bliss by invocation of the merciful beings. In some sects the corpse, after being washed. is shaved and "ordained" a monk: *i.e.*, a member of the *sangha.* Wakes and (at times very elaborate) temple rituals are held which may include burning of incense, chanting of the confession of faith, exhortation of the deceased, invocations of the Buddhas and the use of secret *mantras.* Great importance is attached to the recitation of sutras—before as well as after disposal—and to other works of merit. The idea underlying these vicarious acts of worship and charity is the accumulation of disposable merit which can be transferred to the deceased. As a matter of fact, many Mahayana rituals are simply "masses for the dead."

FUNG (DARFUNG), a mixed Negroid people occupying parts of Sennar (*q.v.*) and the hilly country to the south between the White and Blue Niles in the Republic of the Sudan. They traditionally come from west of the White Nile and are affiliated to the Negro Shilluks. The Fung became the dominant race in Sennar in the 15th century, assimilated the speech, religion and habits of the Arabs settled in that region, and until the 19th century were one of the most powerful of African peoples in the eastern Sudan. See AFRICA: Ethnography (Anthropology) : Northeast Africa.

FUNGI. This term, Latin for "mushrooms." is applied not only to mushrooms but to all of the large and diverse group of plantlike organisms, to which the mushroom family belongs. Fungi have no chlorophyll; they are not differentiated into roots, stems and leaves; and they reproduce by forming spores — reproductive cells that develop directly into new organisms. They range in size from microscopic single-celled forms to large and elaborate structures; in properties, from such useful organisms as yeasts and penicillin to destructive plant rusts. mildews and molds.

Because of their lack of chlorophyll and other physiological means of synthesizing carbohydrates from carbon dioxide and water. fungi are dependent on other organic matter, living or dead, for their food. Lack of chlorophyll is not, however, a characteristic that is unique with fungi. Certain algae (*q.v.*) are devoid of chlorophyll and are parasitic; and most bacteria (see BACTERIOLOGY) are unable to synthesize primary foods. Fungi cannot be defined with complete precision therefore; membership in the group is inferred from similarities to typical fungi.

The undifferentiated body of a fungus — lacking stem, leaf and root structures — is known as a thallus. In typical fungi the thallus consists of an extensive network of branching threads, the hyphae, collectively called the mycelium. However, many fungi are nonmycelial. In these the thallus may be an amoebalike structure, at first naked but later enclosed in a secreted membrane, or a simple cell with a permanent wall, or a more or less spherical structure with minute rootlike outgrowths.

From the earliest attempts at scientific classification all living things were held to belong to one of the two kingdoms, plant and animal. But at least since the early years of the 20th century it has been apparent that the plant kingdom consists of a number of independently evolving groups. The sorting of these groups into the two kingdoms is a matter of convenience rather than an indication of actual relationship. In this historical sense, and in everyday speech, fungi may be called plants,

DISTRIBUTION OF FUNGI

Fungi occur throughout the earth, wherever organic material occurs on which they can subsist. Like other forms of life, they are most abundant in temperate and tropical lands. But they form an important part of the small number of living things inhabiting Antarctica, they are found in considerable numbers in most fresh waters and in smaller numbers in the sea, and even at high altitudes and latitudes viable fungus spores occur in the air. It is estimated that about 100,000 species exist. More names have been published for fungi, but more than half of these are duplicates. In a small area of limited vegetation (such as the Marshall Islands) the species of fungi outnumber by several times the seed plants. while in a larger area (such as the state of Iowa) the numbers are about equal. Since fungi are nowhere thoroughly known, estimates of their numbers are quite tentative.

Because most fungal structures are unlikely to have been fossilized. their distribution in time is little known. The hyphae of fungi have been found within fossil plants of the Devonian period. Many fungus spores have been found mixed with fossil spores, pollen and other remains of higher plants. but although they have been given names suggesting their similarity to recent fungi, their correct classification, in the absence of the fruiting structures that produced them, is rarely possible.

STRUCTURE OF FUNGI

The visible mycelium of the simpler fungi forms a loose, cottony mass. Within the substratum (such as a parasitized leaf, decaying organic material, soil) it constitutes a similar loose, branching network of separate threads. In many of the more complex fungi there exist, in addition to assimilative mycelia of distinct fibres, massive structures in which the threads are felted together. In Sclerotium and Rhizoctonia lens-shaped or oval bodies the size of a small seed are formed by the branching, intertwining and compaction of the hyphae. When these are carried about they serve to disseminate the fungus. In various pore fungi (Poria *cocos*, Polyporus tuber-regium and others) hard oval bodies 20 cm. or more in diameter are formed in the soil, and serve as reservoirs of food from which fruiting bodies are developed. Whether small or large, these structures are sclerotia. Similar massive structures of sterile hyphae, often crustlike or nodular but frequently clublike or of various other shapes, may later produce conidia on their surface or inside spore-producing cavities within their substance. These are stromata. In other fungi many nearly parallel hyphae are united into long strands, resembling shoestrings (in the honey mushroom, *Armillaria* mellea) or flattened cottony cords (in the house fungus, Serpula [*Merulius*] lacrymans), two to ten millimetres in width. These strands. the rhizomorphs, have the central hyphae enlarged as conducting tubes. and serve to carry water and nutrients from the area in which they occur to a new area which the fungus may later penetrate. Thus they are organs for the spread of the fungus.

The fruiting body of the higher fungi is similarly composed of a felt of large numbers of branching hyphae. A mushroom, which is one type of fruiting structure, is composed of threads as truly as is a mold. Most of the threads in the stalk run lengthwise. Many of those in the cap run from the centre toward the margins, and the surfaces are composed of variously oriented hyphae. These may be of three sorts: structural hyphae, often thick walled, sparsely branched. with little protoplasm; generative hyphae, thin walled. with abundant protoplasm; and binding hyphae, short celled, much branched. irregular and contorted. which serve to tie the others into a mass. However compact the larger fungus structures may be, the structural unit is a branching thread and the whole is a felt rather than a true tissue.

Noncellular Fungi. — If spores of one of the common black molds (Mucor, *Rhizopus*) are placed on a suitable nutrient (cooked corn meal, blotting or filter paper soaked in fruit juice, or nutrient agar) they will soon germinate. The outer spore wall is ruptured and the inner, colourless wall protrudes, swelling and elongating to become the wall of a hypha (fig. 1[D]). The older, basal part of such a hypha soon becomes fixed and rigid, but the tip continues to push out, increasing the length of the hypha, and commonly branches. Soon there is formed a large and complex branched system (fig. 1[A]). Where growing tips come in contact with each other they often fuse and thereby produce a network. Each hypha consists of a tubular wall of secreted material, lined with a layer of fluid protoplasm in which are embedded numerous nuclei. and enclosing a central stream of sap, containing in solution various salts, food substances and other metabolic products. The protoplasm (including the nuclei) is mobile within its wall and continually migrates from the older parts of the mycelium toward the growing tips. In a mycelium several days old the protoplasm entirely evacuates the hyphae first formed, and the abandoned segments are separated from the living by secreted partitions formed successively behind the migrating protoplasm. In most black

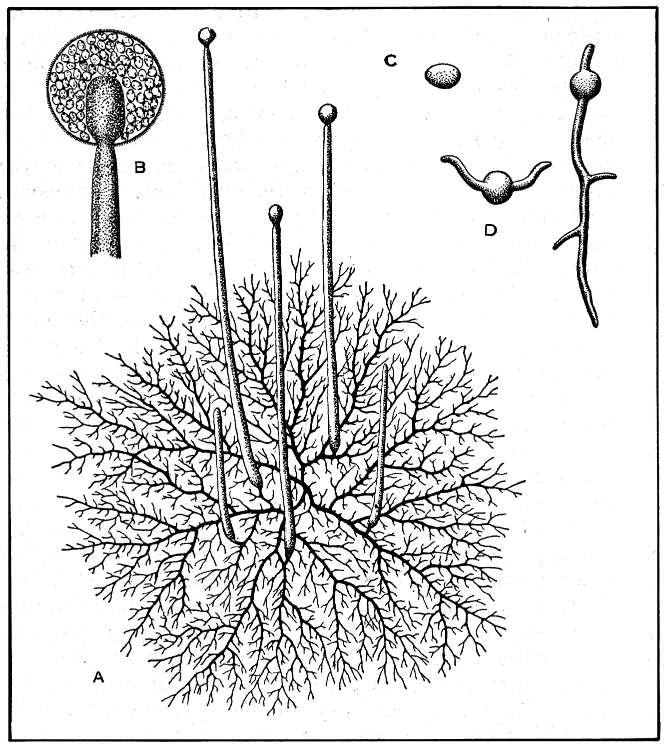

FIG. 1—MUCOR MUCEDO

(A) Diagram of mycelium with several upright sporangiophores; (B) sporangium; (C) spore; (D) germinating spores with germ tubes

molds true septa. which are partitions dividing one portion of the protoplasm from another, are not regularly formed except in the fruiting structures. Thus, except for injured areas or the oldest hyphae. the protoplasm and enclosed sap (the vacuole) are continuous throughout large masses of mycelium.

When a mycelium has attained sufficient size and sufficient reserve food it proceeds to reproduce. (See below for a fuller description of the reproductive process.) In the black molds the first step in this process is the formation of thicker and more rigid hyphae which grow not into the substratum but out into the air. Into these fruiting branches a large amount of protoplasm migrates, so that it is much denser there than in assimilative hyphae. After such a branch has reached its full length (from about 0.5 to 4 mm. in the genera under discussion, but up to 30 cm. in other black molds) the tip swells to form a more or less spherical vesicle (fig. 1[A]). into which most of the protoplasm flows, and which is then separated from the stalk by a septum. This septum does not lie straight across the summit of the stalk, hut arches into the vesicle so as to form a protrusion into it (fig 1[B]) The vesicle is the spore case or sporangium, the stalk is the sporangiophore, and the protrusion is the columella. Within the sporangium, the protoplasm is divided into many blocks each including one or more nuclei. These blocks then contract into a spherical or oval shape, secrete a dark-coloured external mall and become spores (fig. 1[C]) that are set free by the rupture of the sporangial wall On a suitable substratum they germinate to repeat the cycle. These black molds exemplify the structure of a coenocytic (noncellular or nonseptate) mycelial fungus.

Cellular Fungi.—One of the green molds *Aspergillus* or *Penicillium,* found on decaying fruits and vegetables illustrates a cellular or septate fungus. When its spores are sown on a suitable nutrient, such as one of those employed for the black molds, they germinate in similar fashion to form a short, branched hypha But before the hypha has attained any great length it becomes divided into segments—i e., cells—by septa. These are begun by the deposition of wall material in a ring on the inner surface of the hyphal wall The deposition continues toward the centre of the hypha until a circular partition is formed, complete except for a pore in the centre. Through these pores the protoplasm of each cell is continuous with that of the cells immediately above and below it in the hypha, so that even in a septate mycelium the cell contents form a continuous system. When the mycelium reaches the stage of fruiting it gives rise to stout aerial branches (fig. 11[A]) which are septate like the assimilative hyphae. In *Aspergillus* the apex of such a branch swells to form a vesicle which, rather than producing internal spores. pushes out from its surface a large number of fingerlike protrusions (fig. 11[A. c]). These may branch once or twice; ultimately the outer portions are constricted just back of the end, a septum is formed at the constriction and the cell so formed develops a thick wall and becomes a spore. By constriction and septation a second spore is cut off just below the first, and later a nhole series of spores is similarly formed, having to each other the relation of beads on a string. A single vesicle may bear scores or hundreds of these series. Such spores. formed from a specialized segment of a hypha, are conidia, and the stalk on which they are borne is a conidiophore. The other common green mold. *Penicillium,* is similar except that the branches of the conidiophore do not radiate from the surface of a conspicuous vesicle.

Composition of *the* Wall.—In a relatively small number of species of fungi the wall is composed of the carbohydrate cellulose, as in all young cells and most mature cells of green plants. In most fungi. however, the wall is chiefly chitin, a carbohydrate similar to that forming the integument (covering) of insects and many other animal structures. In some fungi (Tremella and other jelly fungi) the wall swells in the presence of water and becomes gelatinized. In others (Fomes) the wall is greatly thickened and hardened by the deposition of mineral compounds, resins and other metabolic by-products, becoming lignified as in the harder tissues of woody plants. Hyphal walls frequently are impregnated also by pigments. Nearly all the colours shonn by fungi—and these include the whole spectrum as well as black—result from pigmented hyphal walls.

NUTRITION AND FUNCTIONS

The nutrient requirements of fungi are similar to those of bacteria, of animals and, except that fungi cannot synthesize carbohydrates, of green plants. According as they are able to produce the appropriate digestive enzymes, various fungi are able to utilize sugars, starches. cellulose and lignin as carbohydrate foods. Fats are suitable as food for a number of fungi. It is not certain that any fungus can fix atmospheric nitrogen, as can some bacteria, to form proteins; therefore, some form of combined nitrogen is a necessary nutrient for fungi. Some species can use nitrates. others can use nitrogen in the form of ammonia, and many others require external supplies of organic nitrogenous substances such as proteins or amino acids. Apparently all fungi need phosphorus. potassium. sulfur, iron and magnesium, and at least some species must have zinc. manganese, copper, molybdenum and gallium, although in minute quantities. The required amounts of these trace elements are so small that it is difficult to prepare nutrient solutions sufficiently free from them for the fungus to show the effect of deprivation. It is probable that ultimately other mineral requirements will be demonstrated. Like other organisms, fungi also require in minute quantities certain vitamins. Thiamin (vitamin B_1) is probably needed by all fungi. but some are able to synthesize an adequate supply from simpler compounds. Many, however, can grow only if an external source of thiamin is provided. Other vitamins are similarly required by some fungi although none, apparently, need riboflavin (B_2). Like all living things, fungi need water, and all need at least a low concentration of atmospheric or dissolved oxygen,

The surface of the living mycelium absorbs water and water-soluble mineral and food substances. These diffuse through the hyphal wall into the protoplasm and may be passed on to the central vacuole. There they are moved to other portions of the mycelial network not only by the relatively slow process of diffusion. as in organisms divided into cells. but also by the flow of the sap through its enclosing protoplasmic tubes. The mycelium also secretes enzymes through the wall into the substance on which the fungus is growing. By their action a part of the nutrient substratum is digested outside the fungus, the soluble products of digestion then being absorbed.

With respect to their sources of food, fungi fall into three classes: (1) saprophytes feed on dead organic material; (2) parasites derive their food from living things, to the detriment of the host; and (3) symbionts live in association with other organisms with mutual benefit, each commonly contributing essential nutrients to the symbiotic partner and receiving nutrients from it.

Saprophytic Fungi. — Saprophytic fungi have an important place in nature. They reduce to a form usable by other organisms the dead bodies of plants and animals. freeing the carbon, nitrogen, hydrogen and minerals which otherwise would remain forever locked up in the corpses. This function they share with bacteria. Although there is no sharp dividing line, the fungi do most of the work of digesting complex carbohydrates and the bacteria digest mostly proteins. The black and green molds usually live as saprophytes. Another familiar saprophyte is the meadow mushroom, *Agaricus campestris,* which grows wild in meadows and pastures where the dung of grazing animals is added to the organic matter in the soil, and is also cultivated in prepared beds composed largely of partially decomposed manure. In either situation the mycelium, starting from spores or from commercially prepared masses of mycelium (spawn). spreads through considerable volumes of soil. breaking down, by enzymes which it secretes, the organic soil components to simple carbohydrate and nitrogenous compounds which can be absorbed by the mycelium and serve as its food. After a period of growth and food storage which may involve weeks (in mushroom beds) or years (in nature), the mycelium forms at the surface of the substrate (substance on which the enzyme sets) a crop of mushrooms, its fruiting structures, which immediately shed spores from which new mycelia may arise.

Other saprophytic fungi are those which produce bracket mushrooms or conks (*Fomes applanatus,* Polyporus sulphureus) on the surface of tree trunks. The tree may be standing or fallen, living or dead. Although any part of a dead tree may be attacked. the mycelium in living trees penetrates, digests and destroys only the dead heartwood. House fungi, especially *Serpula* (*Merulius*) lacrymans and Poria incrassata can reduce timbers to a weak, friable mass. The yeast fungi, minute single-celled forms, belong to the same biological class. They live in watery solutions, chiefly those containing sugar, such as fruit juices, ensilage, plant sap and the moist component of bread dough.

Parasitic Fungi. — These are numerous in species, partly because many of them are able to attack only a few kinds of host plants, or even only a single one. Many of them are facultative parasites; that is, they can live at the expense of a living host until it dies, and then continue to feed on the dead tissue. Often the mycelium on the living host reproduces by conidia, or asexual spores, and that on the dead host by other and more complex fruiting bodies. Corn smut grows parasitically within tissues of the ears, tassels and other organs of Indian corn (maize), stimulating the host to produce large, tumourlike swellings whose soft tissues finally are absorbed by the mycelium whose cells then round off and become spores. These spores germinate in soil and there produce large numbers of cells capable of reinfecting the host. Other fungi are obligate parasites, unable to live apart from living tissues of a suitable host. Such species have never been cultivated. An example of this class is stem rust of wheat, which produces two types of spores while growing on wheat and certain grasses, and two other types on the leaves of barberry. Many parasites form their mycelia between the cells of the host, absorbing nutrients through the cell walls of both host and fungus. Others, of which the downy mildews are examples, send out short specialized hyphae which penetrate the cell wall of the host and sometimes its outer protoplasm, coming to lie near the nucleus of the cell attacked. These hyphae may form coils or branches within the cell, thereby increasing their surface for absorption. Such intracellular absorptive hyphae are called haustoria.

A successful obligate parasite is necessarily one that does not kill, although it may cause dwarfing, enlargement, sterilization or distortion of the living plant or animal on which its own life depends.

Symbiotic Fungi. — Lichens provide the most conspicuous examples of symbiotic fungi. Lichens are often mistaken for mosses. as the common name, reindeer moss, of one of the most important lichens indicates. However. a lichen is an association of a fungus and an alga, with the fungus forming a leaflike, crustlike or branched matrix enveloping large numbers of algal cells (see LICHENS). A similar beneficial relationship exists between fungi and many seed plants and ferns, whose roots are symbiotic with the mycelium. The two organisms together form a compound structure known as a mycorhiza (*q.v.*). An especially complex symbiosis exists between various scale insects and fungi of the genus Septobasidium, which is widely distributed in the warm temperate and tropical regions of both hemispheres. These fungi grow only on living parts of higher plants, most commonly on the smooth bark of various trees. where they form feltlike or lichenlike crusts. They appear to be parasitic on the tree, but actually each fungus covers a colony of scale insects. The insects suck the juices of the plant and in turn are infected with haustorium-bearing hyphae that extend from their bodies into the fungus crust. Such insects are not killed by the *Septobasidium,* although they remain sterile. The fungus is an obligate parasite upon them, as they in turn are upon the plant. Other insects of the same colony, however. live within an elaborate system of tunnels or houses developed by the fungus, within which they feed upon the host plant protected from most of their normal enemies. At the season when the uninfected insects are producing young. the fungus is producing spores on its outer surface. The immature insects which crawl over this surface may carry off a spore and become infected by it. If they move to another area of bark they establish a new growth of the fungus, and if they remain close by they add to the size of the old. Those insects that do not crawl over the surface, or that otherwise escape infection. may settle down within the protection of the old Septobasidium. The fungus thus parasitizes a part of the insect colony and protects the rest.

REPRODUCTION

The spores of fungi serve the function of the seeds of higher plants but differ from them in their smaller size and simpler structure. Both sexual and asexual reproduction occur among fungi, and some species exhibit an alternation of generations. in which a sexual phase of the plant is followed by an asexual phase. In some fungi the mycelium can reproduce asexually of itself, but will reproduce sexually only when grown with certain other mycelia. This selective mechanism in sexual reproduction, known as heterothallism, functions to ensure the genetic heterogeneity of the offspring.

Asexual Reproduction. — Asexual reproductive spores, oïdia and conidia, are produced by the separation of cells from a mycelium. Oidia commonly occur among various species of mushrooms. Conidia, which are distinguished from oïdia by their shapes, may be spherical, cylindrical or of other distinctive form; they may be one or many celled; and they may be formed directly on assimilative hyphae or borne on conidiophores. The conidium-bearing hyphae may be isolated or, in the more highly developed species, aggregated into crusts, cushions or clusters resembling sheaves of wheat. In many species the conidiophores arise within more or less pear-shaped cavities of special spore-producing structures (pycnidia). Other fungi produce minute pellets (bulbils) formed of a knot of intertwined hyphae, which serve for reproduction. The black molds and the water molds and their relatives are dispersed by specialized cells formed within and from the protoplasm of larger cells (sporangia). In the black molds these sporangiospores are provided with a firm wall, are resistant to desiccation and are scattered abroad by the air. In many water molds (fig. 4[D, E]) the spores are naked particles of protoplasm provided with threadlike flagellums by which they swim through water (zoospores). All of these types of reproductive bodies are usually (but not always) endowed with the same hereditary potentialities as the mycelium from which they arise.

Sexual Reproduction. — Most fungi exhibit the process of fertilization. This consists in the fusion of two bodies of protoplasm to form one, the zygote. The interval between cell fusion and nuclear fusion may extend through most of the life cycle;

nuclear fusion is the final, critical event in fertilization. The gamete (fusing) nuclei have in any species a basic number of chromosomes, the haploid number; the zygote has the double (diploid) number; and nuclear fusion is the end of the haploid and beginning of the diploid phase. The reverse process is meiosis (see CYTOLOGY) by which the haploid condition is restored, marking the end of the diploid and beginning of the haploid phase. In many Ascomycetes and in Basidiomycetes there is a third phase, after the protoplasts have fused but before nuclear fusion has occurred, in which haploid nuclei from the two parents are associated in a common cytoplasm; if the nuclei are paired, this is called the dicaryotic phase. Few fungi have a diploid phase protracted beyond the zygote. In the black molds the fusing bodies are multinucleated branches (fig. 6); in the water molds (fig. 4[B]), they are an egg and one nucleus from a male hyphal branch (antheridium). In some Ascomycetes the gametangia are differentiated as males and females (fig. 8) but the fusing protoplasts are completely undifferentiated; in others the antheridium is missing and its function is assumed by an ordinary hyphal cell. In the Basidiomycetes, the most highly developed class of fungi, fertilization occurs between two hyphae, a hypha and a conidium, or even two conidia.

Heterothallism.—This phenomenon is best exemplified by the black mold *Rhizopus* nigricans. It had long been known that although any culture of this species produced sporangia, only rarely did one show gametangia and the zygospores (fig. 6[G]) resulting from their fusion. In 1904 the cause of this rarity became known when it was discovered that all mycelia of this species fall into two groups. such that any member of one fails to produce zygospores when grown together with any other member of the same group, but forms them when combined with any member of the other. The species is heterothallic. There are no constant differences between the members of the two groups other than their reciprocal behaviour when crossed, each stimulating the other to the formation of gametangia, and usually no differences are apparent in size of gametangia, rate of growth or biochemical properties. It is therefore impossible to designate one accurately as male and the other as female, and the complementary groups are called merely plus (+) and minus (−). A (+) mycelium produces only (+) sporangiospores, and a (−) only (−). The zygospore, upon germination, may produce either. Heterothallism has since been found in most other groups of fungi, as well as in algae. In many fungi, especially among Basidiomycetes, the mycelia fall into four rather than two groups in each of which the four will mate only with one other. Here the groups clearly are not sexually differentiated. Homothallic species, in which fusion of cells or nuclei from a single mycelium can occur, are frequent. Many of these are believed to have descended from heterothallic forms.

Types of Spores.—Fusion, whether of multicellular gametangia, of cells or of nuclei within a single cell, usually initiates the formation of distinctive spore types. In the Phycomycetes the typical spore is either the zygospore, usually thick walled. with a sculptured surface, and supported between the two similar gametangial branches, or the oospore, a fertilized egg with thickened wall.

The Ascomycetes are characterized by ascospores (fig.. 12), formed in limited numbers (usually eight) within a saclike cell in which fusion earlier occurred.

In the Basidiomycetes the typical basidiospore (fig. 14[C]) is formed on a slender stalk growing from the surface of the cell where fusion took place.

These four types of spores, formed directly after fusion, are known as perfect spores, and have been found to be the best indicators of relationships within the fungi. Classification accordingly is based on them. The fruiting structure which gives rise to perfect spores is called the perfect stage. Conidia, oïdia and the other types produced without change in the cytological or genetic state of the fungus are said to be imperfect, but the term must not be taken to indicate a failure in reproducing the parent. Fungi lacking perfect stages, or in which they are unknown, are called Fungi Imperfecti.

CLASSIFICATION

Most students of the fungi now regard them as derived from colourless flagellates. Along with the algae, they are placed within the phylum Thallophyta of the plant kingdom. Three classes of fungi are universally recognized: Phycomycetes, Ascomycetes and Basidiomycetes; and a fourth problematical class, Myxomycetes, once regarded as an offshoot of the amoeboid protozoa, usually is included. The bacteria or Schizomycetes, which are sometimes classified as a third subdivision of the Thallophyta and sometimes as an additional class within the fungi, are discussed elsewhere (see BACTERIOLOGY). The lichens, as associations of algae and fungi, are classified according to their components, the algal components among the algae and the fungal components among the Ascomycetes and Basidiomycetes.

The basis of classification of the fungi, as mentioned above, is the mode of spore formation. The Fungi Imperfecti include members of all four classes—but mostly Ascomycetes—that lack or rarely produce the perfect stage, that is, the fruiting body that forms spores by fusion.

SCHEME OF CLASSIFICATION

Class I. Myxomycetes (slime molds)
- Subclass I. Exosporeae
- Subclass II. Myxogastres

Class II. Phycomycetes (algaelike fungi)
- Subclass I. Archimycetes
- Subclass II. Oömycetes
- Subclass III. Zygomycetes

Class III. Ascomycetes (sac fungi)
- Subclass I. Protoascomycetes
  - Orders: Dipodascales; Saccharomycetales ; Taphrinales
- Subclass II. Euascomycetes

Class IV. Basidiomycetes (club fungi)
- Subclass I. Heterobasidiomycetes
  - Orders: A. Ustilaginales (smuts) ; Uredinales (rusts)
  - B. Auriculariales; Tremellales
- Subclass II. Homobasidiomycetes
  - Orders: Agaricales; Gasteromycetes

FIG. 3

(A) Three emptied sporangia and two spiny resting spores of *Olpidiopsis saprolegniae* in the end of a hypha of Saprolegnia; (B) sporangia of *Rhizidiomyces* apophysatus, in various stages of development, attached to the oögonium of *Saprolegnia* and sending delicate rhizoidal threads into it; (C) conjugation of thalluses of Polyphagus euglenae, showing female nucleus about to enter the copulation tube; (D) *Zygorhizidium willei;* the male thallus (at left) with developing copulation tube; the female thallus (centre) and the two in process of conjugation; (E) branching thallus of *Urophlyctis* alfalfae, the lower turbinate cell of which bears a single mature resting spore and three branches, each terminated by a turbinate cell in the early stages of resting-spore formation

Myxomycetes (Slime Molds)

All but perhaps two species of Myxomycetes belong to the subclass Myxogastres. The spores are surrounded by a firm, ornamented wall. and are sufficiently resistant to desiccation that in some species they germinate after 40 years' storage. In water the wall opens by rupture or by a pore to set free a single amoeboid body later transformed into one or two naked swarm cells that swim by two unequal flagellums. one directed forward and one trailing. These swarm cells may fuse directly, or increase in size and each divide to form two similar cells. Such division may be repeated, and the cells may pass through amoeboid or encysted phases. Ultimately, flagellated cells fuse in pairs, retract their flagellums and assume an amoeboid form, the first stage of the plasmodium, which is diploid. The plasmodium increases in size and becomes multinucleate by division of the original fusion nucleus. It may also join other plasmodia so completely that no evidence persists of its often compound nature.

In fruiting, the protoplasm forms a thick, enclosing membrane. and frequently a stalk and a tangle of threads running through the sporangium. All of these structures are secreted; *i.e.,* noncellular. The protoplasm then breaks up into uninucleate units, each of which forms its own wall and becomes a spore. The haploid condition is restored by meiotic reduction divisions immediately preceding spore formation.

Groups of sporangia of the Myxogastres are frequently seated on a common membrane, the hypothallus. The branching fructification of the subclass Exosporeae is only a more complex hypothallus. The cysts of the latter group are not spores, but rather are homologous with the sporangia of the former. They do not form firm-walled spores, but germinate directly by forming eight swarm cells. Otherwise the two subclasses are essentially alike. (See MYCETOZOA.)

Phycomycetes (Algaelike Fungi)

This large primitive group includes the fuzzy molds found on bread, jelly and preserved fruit, water molds, insect and fish parasites, the downy mildews parasitic on hops and other plants and destructive blights such as the potato blight that caused the Irish famine in 1846–47. Typically the mycelium is composed of nonseptate, branching hyphae, although cellular hyphae occur in some higher forms and in some lower forms hyphae are poorly developed or absent.

In asexual reproduction, which is the more common form for the Phycomycetes, spores are formed in cells called sporangia. In sexual reproduction either zygospores, resulting from the conjugation of two like cells, or oospores, resulting from fertilization of an egg cell by a sperm cell, may be formed. In lower forms the spores may be motile, animallike zoospores; in higher forms they usually are air-borne. Alternation of generations occurs in some members of this class.

Archimycetes.—In the separation of the Phycomycetes into the three major subclasses—Archimycetes, Oomycetes and Zygomycetes—a standard classification is used. The primitive Archimycetes are regarded by some students as degenerate Oomycetes and Zygomycetes. By others they are considered to be primitive forms such as those from which the Oomycetes and Zygomycetes are postulated to have arisen. In some modern classifications the Archimycetes and Oomycetes are merged, the former name being abandoned, and a primary division into two groups, Uniflagellatae

(A) Uniciiiate spermatozoids of *Monoblepharis macrandra* emerging from the basal antheridium and moving up over the surface of the oogonium. The single oosphere is fertilized by the entrance of one of these at the apex of the oogonlum. (B) Globose oogonium of *Saprolegnia* containing two oospheres each of which is being approached by a fertilization tube sent in from a laterally applied, clavate antheridium; (C) fertilization of the oöplasm of *Pythium* debaryanum by the entrance of a male nucleus from the antheridium; (D) sporangium of Achlya freeing swarm spores which encyst at the mouth before breaking out to swim away; (E) sporangia of Phytophthora *infestans,* the lower freeing swarm spores. Below these, encysted spores germinating by tube. (F) Branched sporangiophore of Peronospora schleideni emergent from the stomate of an onion leaf; the sporangia, often termed conidia, germinating by tube without forming swarm spores and Biflagellatae, based on the number of cilia on the zoospore, is adopted.

The mycelium is rudimentary or lacking; at maturity the thallus is transformed into a sporangium or differentiated to provide vegetative and sexual cells. In the simplest representatives of the Xrchimycetes, such as the genera of pond-scum parasites, *Olpidium* and *Synchytrium* (fig. 2), the thallus undergoes development in the cells of the host for a period as a naked protoplast. Later it assumes a wall and reproduces asexually as a sporangium or sorus of sporangia, freeing uniciliate zoospores. In sexual reproduction a pair of uniciliate, swarm-sporelike gametes fuse to form a motile zygote. The zygote after a period of vegetative growth encysts to form a resting spore. A similar morphology and mode of life are present in *Olpidiopsis* in which the zoospores are, however, biciliate. Here there are no motile gametes, a larger female and a smaller male thallus merely conjugating, with the passage of the content of one cell into the other. The receiving cell then forms a heavy wall and matures into a resting spore to which the emptied cell remains attached. In *Rhizophidium, Rhizidiontyces* (fig. 3[B]) and other related forms the parasite is enveloped in a visible membrane from an early stage and is attached to the outer surface of its host, into which it sends a short peglike haustorium or delicate branching mycelial threads. At maturity the whole thallus functions as a sporangium or acquires a thick wall and becomes a resting spore. A mode of sexual reproduction in which the conjugation of two individual thalluses creates a resting zygote is found in various genera; *e.g.*, in *Polyphagus* and *Zygorhizidium* (fig. 3[C,D]). In the former. which is parasitic on *Euglena*, the fungus possesses a highly developed system of haustorial threads, enabling it to attack a number of algal cells simultaneously. In certain other members of the group these threads are less delicate and resemble the hyphae of higher forms. In *Physodema* and *Urophlyctis* such hyphae develop large, swollen, intercalary, pluricellular vesicles, whose component cells not only serve as centres for fresh hyphal development. but also give rise to large, thick-walled resting spores (fig. 3[E]). In the case of species of these genera on alfalfa, beet and other plants, prominent warts or tumourlike swellings are formed on the host. The same is true of *Synchytrium* (*e.g.*, in black wart of potato).

FIG. 6—MUCOR HIEMALIS

(A, B) Progametangia formed as lateral branches of the hyphae; (C) each progametangium divided by a septum to form a gametangium and a suspensor; (D) fusion of the two gametangia; (E–G) successive stages in the maturation of the zygospore

Oömycetes.—These fungi have a well-developed mycelium of large coenocytic branching hyphae. The lower families (Monoblepharidaceae, Saprolegniaceae) are usually saprophytes, living in water on vegetable or animal remains, while the Peronosporaceae are chiefly highly specialized parasites on land plants. The group exhibits structural modifications of both its asexual and sexual organs which are related to the gradual change from an aquatic to a terrestrial existence.

In the lower orders propagation is by zoospores. uniciliate in the Monoblepharidales. biciliate in the Saprolegniales and Peronosporales or downy mildews. The sporangium in the Saprolegniales may be merely a slightly enlarged terminal portion of the hypha (fig. 4[D]). In *Pythium* and *Phytophthora* of the Peronosporales it is usually spherical or oval in form and under certain conditions, following dissemination, may put out a germ tube which develops directly into a hypha. In other genera of the order (*e.g., Peronospora)* this direct mode of germination is alone possible, zoospores are no longer produced and the sporangium is now capable of germinating in moist air or in dew and thus adapted for a parasitic life on land plants (fig. 4[F]).

During sexual reproduction the group exhibits the tendency for replacement of the union of motile gametes by conjugation of walled gametangia. In *Monoblepharis* the female organ, the oogonium, contains a single, nonmotile. uninucleate egg which is fertilized by a motile spermatozoid, which closely resembles the zoospore in structure. The fertilized egg then surrounds itself with a thick membrane and forms a resting oospore (fig. 4[A]). In the Saprolegniales the young oogonium contains many nuclei, potential gametes, only a few of which persist to function as the egg nuclei. There are usually several eggs (oospheres) in the mature oogonium but there are no spermatozoids. Though parthenogenesis occurs in some species the antheridium normally puts forth a fertilization tube which conveys the male nuclei to the eggs. Thus, even in members of this aquatic group, water is no longer the means by which the male nuclei reach the eggs. In

Albugo bliti of the Peronosporales the egg has many nuclei and numerous male nuclei pass from the antheridium and fuse nith them in pairs. There is thus multiple fertilization The odspore which results may be regarded as a coenozygote since it contains many zygote nuclei, each the result of a separate fertilization In most of the higher Oomycetes, however, the mature egg is uninucleate and only one male nucleus passes into it from the fertilization tube. The assumption of the function of the gametes by the gametangia results in a single fertilization, made so as to ensure the production of the zygote. Many of the Oomycetes are parasites of cultivated plants and the cause of destructive diseases; *e.g.*, "damping off" disease of seedlings *(Pythium)*, late blight of potato *(Phytophthora)*, downy mildew of grape *(Plasmopara)*.

Zygomycetes.—These fungi are largely saprophytic in habit and terrestrial. Reproduction by conjugation results in the production of zygospores. Zoospores are unknown; the characteristic sporangia contain thousands of walled spores. Certain higher genera, however, are reproduced by conidia *(e g., Chaetocladium, Cunninghamella)*, and there is a series of forms showing that in this family, as in the Oomycetes, transition of sporangium to conidium has taken place. In one series this has been brought about by the gradual reduction in the number of spores in the sporangium; *e.g., Thamnidium* has small few-spored sporangia (sporangiola) with sometimes only one spore while in *Chaetocladium* a small sporangiolum in one species is completely filled by a single spore and hence appears as a conidium except at germination (fig. 5[A, B, C]), and in another no indication whatever of an endogenous spore is given. In *Blakeslea* multispored sporangia are normally accompanied by spherical heads bearing many sporangiola, each with only three spores. Between these types occasionally a complete series of intergrading forms exists. In the closely related genus, *Choanephora*, sporangiola are lacking and large multispored sporangia are accompanied by conidia borne over spherical heads as are the sporangiola of *Blakeslea*.

Members of the order Mucorales are saprophytes on organic substances or parasites on other molds. Among them is the genus *Mucor*, or bread and jelly molds. In the complete life cycle of the Mucorales, conjugation of coenocytic gametangia occurs. The resulting structure, the zygospore, contains many zygote nuclei.

FROM "ZEITSCHRIFT FUR BOTANIK (GUSTAV FISCHER)

FIG. 8.— (A) ANTHERIDIUM (LEFT) AND ASCOGONIUM (RIGHT) IN PYRONEMA, (B) ASCOGENOUS HYPHAE GROWING FROM ASCOGONIUM

The gametangia are usually morphologically indistinguishable. They may both arise on the same mycelium or on a specialized erect hypha or zygophore, as in *Sporodinia*. Such species are termed homothallic. In other cases the gametangia arise on two separate mycelia, differing in kind but not corresponding to distinct sexes. an example of heterothallism.

The germination of the zygospore usually results in the production of a germ tube bearing a germ sporangium. and in *Phycomyces nitens* it is in this structure that the zygote nuclei undergo the reduction divisions. The resulting spores are of two kinds, (+) and (—); but in any one germ sporangium only one kind is formed, except for a few spores, presumably binucleate, which are homothallic. It is of interest to note that H. Burgeff experimentally produced similar mycelia by the admixture of the contents of hyphae from (+) and (—) mycelia and thus reached the conclusion that homothallic mycelia contain both (+) and (—) nuclei.

Insect Parasites.—The Entomophthoraceae are chiefly a family of insect parasites of which one, *Entomophthora muscae*, attacks the common housefly. They are reproduced asexually by conidia which are shot off from the conidiophores in such numbers as to form a halo around the dead fly.

The small family of the Endogonaceae molds with its chief genus *Endogone* may be included here. The species form mostly underground stromata in which the reproductive organs are embedded. In *Endogone lactiflua* two conjugation branches of unequal size grow in contact with each other. They are multinucleate at first and from each a terminal cell containing a single nucleus is cut off. These cells unite and from the larger there arises an outgrowth which rapidly enlarges; into this pass the two gamete nuclei. This outgrowth is the zygote, which not only develops a thick wall but becomes surrounded and embedded by a number of vegetative hyphae (fig. 7[A, B, C]). Its germination is unknown.

Endogone has been included in the Ascomycetes and is of considerable interest as indicating a possible relation between that class and the Zygomycetes.

Ascomycetes (Sac Fungi)

This large class of higher fungi includes yeasts, molds, mildews and edible truffles and morels. Spores are produced in asci or spore sacs. The mycelium is composed of hyphae regularly segmented into portions containing one or several nuclei. Asexual reproduction is common and this class provides a rich variety of conidial fructifications. Many species may show several different types of conidia on the same mycelium. There are many species in which the ascus fruit is rarely produced and there may consequently be many generations reproduced entirely by conidia. It is not, therefore, surprising to find a large assemblage of fungi (Fungi Imperfecti) which are only known to reproduce asexually and many of which are believed to be incomplete forms of Ascomycetes.

The sexual reproduction of the lower Ascomycetes (Protascineae) may be compared with that of certain Phycomycetes such as *Endogone*. In *Eremascus fertilis* the sexual branches arise from two ceighbouring cells of a hypha and grow up side by side. They each receive a nucleus from their parent cells and then fuse together. The two nuclei unite and the zygote enlarges and forms a spherical ascus. The fusion nucleus divides and eight ascospores are formed (fig. 7[D, E, F]). The main point in which *Eremascus* differs from *Endogone* is that the direct product of fertilization is in the latter a zygospore and in the former an ascus. This then is one of the essential differences that mark off the lower Ascomycetes from the Zygomycetes. The higher forms are distinguished by a further advance, in that every ascus in an ascocarp is a separate zygote. The ascogenous hyphae usually grow out from ascogenous cells and by proliferation form a number of crooks or crosiers and thus provide for large numbers of asci. In heterothallic species the cells of the ascogenous hyphae may contain only a single pair of nuclei each and so form a dicaryotic system or dicaryon. It is in the ascus that nuclear fusion is finally accomplished, to be succeeded immediately by the meiotic phase and the formation of spores.

The ascogenous hyphae, however! do not form an independent self-supporting mycelium. They are dependent on the haploid mycelium for their nutrition, and this is accomplished by the enclosure of the ascogenous hyphae in a simultaneous growth of vegetative hyphae from the parent mycelium. Thus there is formed the fruit body or ascophore, one of the characteristic structures of the higher ascomycetes, showing in the different families great variety in structure and organization.

In *Eremascus* the two sexual organs are alike, but in the related *Endomyces* they are differentiated into a large female gametangium, the ascogonium and a smaller male, the antheridium (fig. 7[G, H. 1 In the Euascomycetes this differentiation in sex is maintained and the ascogonium is usually characterized by the development of a receptive portion, the trichogyne. Both structures may be divided by cross walls into several cells, the whole ascogonial branch (archicarp) thus consisting of a hypha of many cells, which is sometimes spirally coiled.

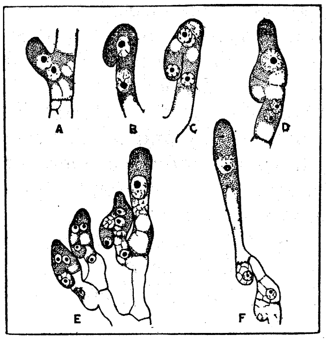
The antheridium shows no corresponding development, in fact it is possible to trace throughout the whole group the gradual dwindling in importance and final elimination of this organ.

It has been proved that macroconidia as well as microconidia (the so-called spermatia) may function in fertilization and that nuclei of opposite mating type may also be brought together as a result of nuclear migrations from one purely vegetative system to another. In *Neurospora* the microconidia also germinate readily to form perfectly normal mycelia. They are therefore asexual organs of dissemination. that may in addition function in place of gametes, rather than differentiated male cells.

In *Pyronema omphalodes* the large pear-shaped ascogonium bears at its upper end a tubular trichogyne, the tip of which fuses with the club-shaped antheridium. All these structures are multinucleate. The contents of the antheridium pass first into the trichogyne and then. by absorption of the intervening wall, into the ascogonium, where the male and female nuclei become associated (fig. 8[A, B]). In *Humaria granulata* the trichogyne has disappeared though the ascogonium still has the form of those described above and like them gives origin to the ascogenous hyphae. Finally in *Humaria rutilans* the ascogonium itself has disappeared and with it, all trace of autogamous fertilization.

A parallel series can be traced in a related genus, *Ascobolus*, in which the ascogonium is many celled. In *A. magnificus*, which is heterothallic, normal conjugation takes place between antheridium and trichogyne; in *A. furfuraceus* antheridia are absent. In one species, *Ascobolus carbonarius*, the long and often coiled trichogyne comes into contact with one of the oval, stalked conidia, borne on the mycelium, and fuses with it and thus, apparently. fertilization is effected.

This process finds an interesting parallel in one of the lichen fungi. *Collema pulposum*. Here the archicarp, as in many lichen fungi, is a coiled thread terminating in a long slender trichogyne; the latter comes into contact with a conidium and fusion results. In other species of *Collema* the trichogynes, projecting above the surface of the thallus, get attached to their surface one or more uninucleate bodies, the so-called spermatia, which are formed in flask-shaped bodies resembling pycnidia. As the name implies, these spermatia have been regarded sometimes as male gametes.

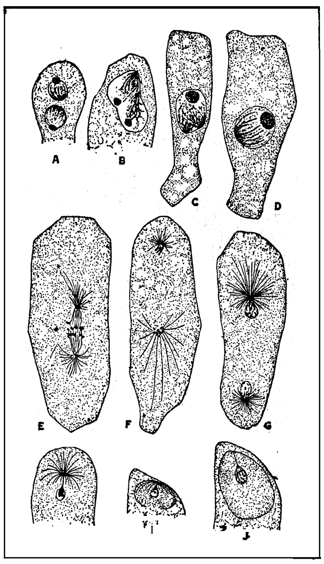


FROM "ZEITSCHRIFT FÜR BOTANIK" (GUSTAV FISCHER)

FIG. 9.—(A–F) CROSIERS IN ASCOGENOUS **HYPHAE** OF PYRONEMA

These processes of modification and disappearance of the sexual organs should not obscure the fact that the essential feature of fertilization is the fusion of two haploid nuclei, and it is immaterial whether these nuclei are derived from different sexual organs, antheridium and ascogonium, from the ascogonium alone, from an ascogonium and a vegetative cell or from two vegetative cells. In every case the process which brings them together, whether fusion immediately results or not, marks the starting point of a new development, viz., dicaryotic growth, represented by the ascogenous hyphae. These hyphae eventually give rise to the asci and in the majority of the Ascomycetes they are formed in a characteristic way. As already stated the ultimate segments of these hyphae are binucleate and any one of them may grow out to a short branch, into which the two nuclei pass. This cell now curves over at the tip to form a hook, and the nuclei moving up to the summit divide there conjugately. The spindles are so arranged that when the two cross walls are formed, the summit of the crook contains two nuclei, while one is in the tip and another in the stalk (fig. 9).

In most cases the tno nuclei at the summit fuse together and form the fusion nucleus of an ascus, which is the only truly diploid cell in the whole life cycle. The point of the crook and the stalk lie close together and either of them may now become binucleate by the migration into it of the nucleus from the other. The binucleate cell so formed may now originate a new crook and so the process may be repeated several times.



FROM E. GAUMANN VERGLEICHENDE MORPHOLOGIE DER PILZE (GUSTAV FISCHER)

FIG 10.—PHYLLACTINIA CORYLEA (A) Young ascus with dicaryon; (B–D) caryogamy; (E–G) steps in division of primary ascus nucleus (*Erysiphe cichoracearum*); (H–J) spore formation

The young ascus now enlarges, the nucleus also increasing in size, and finally the latter divides; this is followed by two further divisions and thus eight nuclei are formed uhich become the centres in forming eight ascospores (fig. 10). There is no doubt that the first division in the ascus is the heterotype or reducing division (*see* CYTOLOGY). The two following divisions have, for the most part, the characters of postmeiotic divisions.

There are a number of forms, however (*Sphaerotheca, Humaria, Lachnea, Ascobolus*), in which the nuclei in the ascogonium, however derived, have been described as fusing together. Obviously a double reduction would be necessary to produce haploid nuclei for inclusion in the ascospores, and the second reduction is said to take place during the second or third division Genetic uork on Ascomycetes disproves the whole theory of a double fertilization and a double reduction. Until one finds through hybridization experiments eight genetically different kinds of spores formed in certain asci of a cross, or that the spores alternate one and one for definite generic characters, the theory of double fertilization must be abandoned.

These genetic studies have shown also that heterothallic Ascomycetes can readily be hybridized, and it has been shown that genetic characters are inherited according to Mendelian principles. The Mendelian ratios. which are only approximated in experiments with higher animals and plants, occur precisely and regularly in breeding the mold *Neurospora,* which has the additional merit of permitting mating of cells of known genetic composition. Dominance, recessiveness, heterocaryotic vigour. lethal factors. which may be either dominant or recessive, as well as other genetic features nhich are so well knoun in connection with genetic work nith the common fruit fly, maize, datura and other diploid organisms. are not known in the fungi.

The mode of spore formation in the ascus is peculiar. The eight nuclei formed in the third division show delicate radiations, extending from a centrosome, nhich meet around the nucleus and thus delimit a portion of the protoplasm on which a wall is secreted to form a young spore (fig. 10[H, I. J]).

In the higher Ascomycetes, the developing ascogenous hyphae are enclosed by a development of the haploid mycelium, on nhich, in fact, they are parasitic. The whole structure which results is known as a fruit body or ascocarp. In the simpler orders (Plectascales and Perisporiales) the enclosure is complete, the sterile hyphae compacting together on the outside to form a completely closed investment. Such a fruit body is called a perithecium. In other orders (Hypocreales, Sphaeriales, Laboulbeniales) a perithecium is formed, often flask shaped and with a neck with a definite opening for the discharge of the spores (fig. 12).

The remaining orders have a fruit body known as an apothecium. Here the numerous asci are assembled, together with sterile hyphae or paraphyses, in a continuous layer known as the hymenium. This is freely exposed on the surface of the ripe fruit body which may be a flat disk or a cup (Pezizaceae) or a convex, often stalked, structure (Helvellaceae).

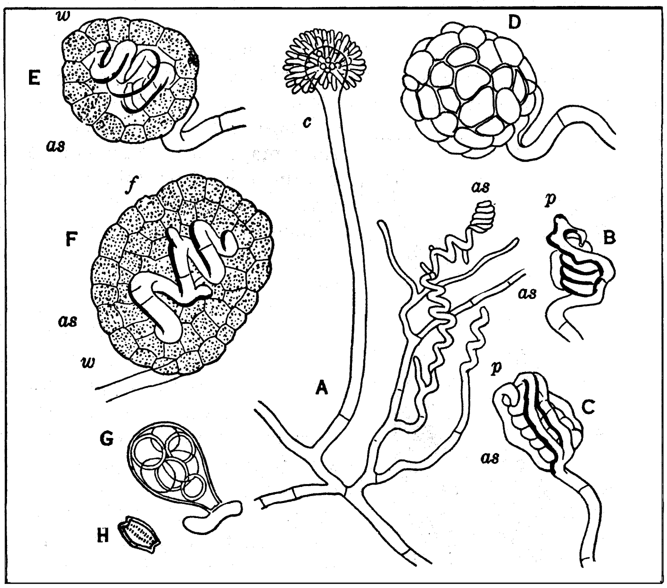


FIG. 11.—DEVELOPMENT OF EUROTIUM REPENS

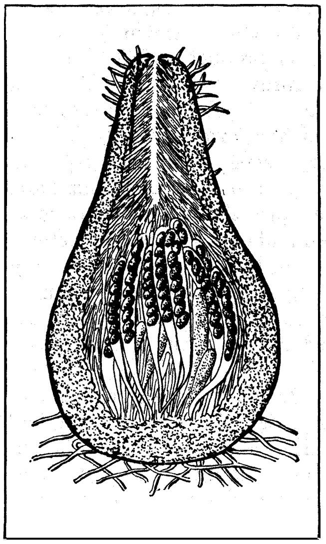
(A) Hypha with conidiophore (*c*) of the *Aspergillus* stage and young archicarp (as); (B) spiral archicarp (as) with the antheridium (*p*); (C) the same, beginning to be surrounded by hyphae forming perithecium wall; (D) perithecium; (E, F) sections of young perithecia: (*w*) parietal cells, (*f*) pseudoparenchyma, (as) ascogonium; (G) an ascus; (H) an ascospore

Yeasts.—The Endomycetales are a small family in which (Endomyces, *Eremascus*) the asci result directly from the conjugation of the gametangia and are thus borne directly on the mycelium (fig. 7). The important family of the yeasts, Saccharomycetaceae, is included in this order. These are fungi which, living normally in liquid media, have the form of oval or spherical cells which reproduce by budding. Some forms, when grown under certain conditions. can develop true hyphae and thus show their derivation from fungi of normal structure. Many genera have a sexual process represented by the conjugation of ordinary cells. The result is the formation of an ascus in which ascospores are formed (*Schizosaccharomyces, Zygosaccharomyces*). *Saccharomycodes* ludwigii forms the ascospores in the ordinary yeast cells and conjugation takes place between the germinating spores. The ordinary yeast cells so produced are thus diploid cells. Work on the yeasts has shown that the industrial yeasts may be, in fact, diploid in their nature. It has been proved that hybrids between various strains of the industrial yeasts may be obtained rather easily so that new and better races of yeasts can be developed.



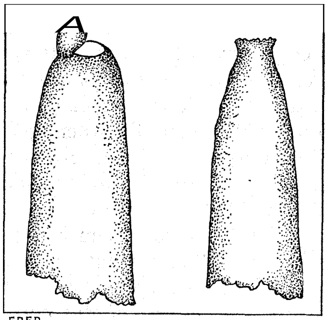
FROM STRASBURGER LEHRBUCH DER BOTANIK (GUSTAV FISCHER)

FIG 12 —PERITHECIUM OF PODOSPORA FIMISEDA IN LONGITUDINAL SECTION

The Exoascaceae is a family of parasitic fungi which grow on the higher plants, often producing malformation of the leaves, fruits, etc. The mycelium may develop in the deeper tissues, but eventually makes its way to the surface and the asci are produced between the epidermal cells, or more frequently they arise from hyphae which lie between the epidermis and the cuticle The cells of the mycelium are binucleate, and in the young ascus the two nuclei fuse and then undergo division, eight spores resulting in the usual manner. In some species (*Taphrina*) the original spores may bud in the ascus and give rise to hundreds of small conidia.

When spores are sown in suitable culture fluids they bud after the manner of yeast cells and produce conidia. In two species of *Taphrina* it has been shonn that these secondary conidia can conjugate in pairs by means of a short tubular process The nucleus from one-cell passes into the other and the binucleate cell so formed nos puts out a germ tube. Moreover. when the eight spores from one ascus are carefully isolated and germinated apart, it is found that they fall into two groups, the conidia of one group will not conjugate together but do so readily with any member of the other group. They are thus, like many of the Mucorini. heterothallic, and the separation into the two mating types must take place during the divisions in the ascus.

Blue and Green Molds.—The Plectascales include the genera *Eurotium* (fig 11) and *Carpenteles,* whose imperfect stages are the common saprobic molds *Aspergillus* and *Penicillium,* among the most ubiquitous and omnivorous of fungi. The ascocarps are closed and comparatively rare. Dissemination is chiefly by conidia, and for many of these molds perfect stages are unknown; these must be considered Fungi Imperfecti.



FRED J. SEAVER

FIG. 13.—LEFT, TIP OF OPERCULATE ASCUS; RIGHT, INOPERCULATE ASCUS

Powdery Mildews.—The Perisporiales include the Erysiphaceae or powdery mildews and the Perisporiaceae or sooty molds. The Erysiphaceae occur as parasites on leaves and tender parts of living plants, forming a white mycelium dotted over with black fruiting bodies (the cleistothecia). They give rise to diseases on numerous plants in temperate regions, among them the mildew of hop, gooseberry and rose and many other cultivated plants. The Erysiphaceae rarely fruit in the tropics; the one and only species reported in fruit from Puerto Rico (*Erysiphe malachrae*) was later found to be the cause of the commonest cotton disease in Peru. There it is known as

FIG. 14

(A) *Armillaria mellea:* young basidium with the two primary nuclei; (B) after fusion of the two nuclei (*Hypholoma appendiculatum*); (C) basidium before the four nuclei, derived from the secondary nucleus of the basidium, have passed into the four basidiospores; (D) passage of a nucleus through the sterigma into the basidiospore; (E) basidium and spores (*Auricularia auricula*); (F) basidium and spores (*Exidia glandulosa*); (G) *Uromyces*

manta blanca or "white blanket" because of the frosted appearance imparted to the leaves of cotton in autumn. The Perisporiaceae in contrast are predominantly tropical, produce a black mycelium on leaves and other parts of living plants but occur as epiphytes, feed on honeydew and other materials excreted by sucking insects, disfiguring the hosts on which they grow. The Microthyriaceae also included here differ from the Perisporiaceae in having shield-shaped perithecia with an ostiole instead of closed cleistocarp or cleistothecium.

The orders Hypocreales and Sphaeriales (sphere fungi) include most of the families which frequently have been grouped together under the name of Pyrenomycetes. They have perithecia which, when mature, have a well-defined mouth (fig. 12). In some genera the fruit bodies are borne directly on the mycelium *(Sordaria, Chaetomium)* or isolated in the host tissues (*Venturia*), but more often they are borne on a stroma *(Nectria, Cucurbitaria)* or embedded in it *(Epichloe, Claviceps, Valsa)*. The stroma may be flat or cushion shaped or immersed in the tissues of the host. In the more specialized forms the stroma may show a sterile basal stalk, the perithecia being limited to the upper part, where they may more efficiently distribute their spores *(Xylaria)*. The Pyrenomycetes is by far the largest group of the Ascomycetes, a conservative estimate of the number of species being 10,000. Though the majority are saprophytes some well-known diseases of plants are caused by members of this group; *e.g.,* canker in fruit trees (*Nectria*), ergot of cereals and other grasses *(Claviceps)*, apple and pear scab *(Venturia)*. Most species of *Cordyceps* are parasites on insects.

The Pezizales are divided into two sections, the operculates in which the asci open with a definite circular lid (the operculum), and the inoperculates in which the ascus opens with an irregular rupture (fig. 13). At maturity the spores are discharged from the asci like shot from a gun and in such numbers that they appear as a cloud of smoke. This phenomenon occurs in the operculates and inoperculates alike. The fungi of this order are called cup fungi because many of the species are disk or cup shaded.

The operculates include the larger and more conspicuous forms, the cups often reaching a diameter of several inches, although many are also minute. Two families are recognized—the Pezizaceae, in which the fruiting bodies are predominantly cup shaped, and the Helvellaceae, which comprise those with a stem and head of variable form. To this group belongs the May mushroom, *Morchella esculenta.* With few exceptions the operculates are saprophytic; and the conidial stage, while present in some forms, is inconspicuous and in most forms unknown. A few of these, such as *Pyronema* and *Ascobolus,* have definite sex organs, while in a large majority definite sex organs are obscure or absent, although heterothallism has been demonstrated in several.

The inoperculate cup fungi include some medium-sized forms, but a large majority are minute in size. While perhaps a large majority are saprophytic, a much larger percentage of this group is strictly parasitic and in these the asexual or conidial stage is much more highly developed and is doubtless an adaptation to their parasitic habits. This is especially true of *Sclerotinia* and its segregates. The conidial stages take a variety of forms, such as *Monilia* and *Botrytis*. The genus *Monilinia* was established for those species which have a *Monilia* as their conidial stages. *Monilinia fructicola* is the brown rot of peach and very destructive.

L. Tulasne in 186j observed minute bodies in certain Discomycetes which he called spermatia or conidiola, which he believed to be male sperms. In *1832* it was definitely proven by F. L. Drayton that microconidia which were found in many species of *Sclerotinia,* and which were probably morphologically identical with the spermatia of Tulasne, stimulated the production of apothecia when placed on certain structures which develop on another thallus of the same fungus. To this process is applied the term "spermatization," thus definitely proving heterothallism or the existence of (+) and (—) strains.

Truffles.—The Tuberales is a small group of fungi that includes the well-known delicacy truffles (*Tuber* sp.). They live underground in the neighbourhood of trees and may be concerned in the formation of mycorhizae. The hymenium lines internal chambers in the fruit bodies.

The Laboulbeniales is an order of peculiar fungi, whose manifold structure has been made known by the investigations of

R. Thaxter in the United States. They are minute fungi from one to ten millimetres in height which grow attached to the bodies of insects, especially beetles. They are dark brown in colour and consist of a basal receptacle which bears appendages, on which are the sexual organs. The female organ is fertilized by male cells or spermatia. The fertilized ascogenic cell (ascogonium) gives rise to asci which are enclosed in a perithecial wall that develops around the female organ. Some species are probably heterothallic (*Amorphomyces*). They have been aptly described as ornamental parasites, and seem not to harm their hosts.

Basidiomycetes (Club Fungi)

The mycelium, like that of the Ascomycetes, is fully segmented, but in the haploid mycelium the segments are uninucleate. They differ from the Ascomycetes in the absence of sexual organs, whose functions are performed by hyphal or conidial fusions. The dicaryotic (binucleate) mycelium which results is extensively developed, has an independent existence and in the higher forms, is, in fact, the only mycelium which can normally be distinguished.

Though gametangia are absent, the haploid mycelium is often differentiated for mating type. Heterothallism occurs in the Uredinales and Ustilaginales, and is widespread in the higher forms. In the latter, pseudogamous fusions presumably occur between hyphae of the mycelia of different kinds, though in only a few cases have these actually been observed. Asexual reproduction by conidia and oïdia occurs in both types of mycelia.

In the lower families the basidia are borne directly on the dicaryotic mycelium, but in the vast majority of forms they are borne on fruit bodies or sporophores. These are not formed, as in most Ascomycetes, as the immediate result of a sexual process (see above) but arise from dicaryotic mycelium at a time and stage in its development which are determined by physiological factors, such as .nutritive conditions, humidity, light, etc. The basidium, like the ascus, is the gonotocont. In it the reduction of the chromosomes is effected but the daughter cells (usually four) resulting are exogenous; *i.e.*, borne on short stalks (sterigmata) outside the mother cell (fig. 14[D]). Two kinds of basidia occur. Those characteristic of the subclass Homobasidiomycetes are, like asci. undivided (holobasidia). Most of those of the subclass Heterobasidiomycetes have the basidia divided by septa into four cells (phragmobasidia) (fig. 14[E]). The dividing walls may run transversely, *e.g.*, Auricularia, or longitudinally as in Tremella (fig. 14[F]). The fertilization which takes place in the young basidium is followed immediately by the reducing divisions and the development of spores. but in the Uredinales and Ustilaginales, after the nuclear fusion, a resting stage, often prolonged. may intervene. This may be accompanied by a thickening of the wall of the mother cell! which may even become set free from the mycelium as a spore (teleutospore, chlamydospore). These probasidia, as they are called, germinate by a short hyphal outgrowth (promycelium) which bears the four basidiospores (sometimes termed sporidia). The prohasidium and promycelium together constitute two successive developmental stages and two morphological divisions of the complete basidium. In these forms the probasidium is concerned with the distribution and perennation of the fungus as well as with the production of the basidiospores (fig. 14[G]).

The basidiospores may be thin walled and adapted for immediate germination, and this is the case in the Heterobasidiomycetes and in some of the lower families of the Homobasidiomycetes. These thin-walled spores when germinated in water or nutrient solutions may sprout like yeast cells and produce gemmae or secondary conidia. In the higher families many are thick walled and are resting spores. In the majority of Basidiomycetes the spores are discharged from the sterigmata, but only for a short distance (0.1–0.2 mm.). They are, for the most part, distributed by air currents.

Within the subclass Heterobasidiornycetes is the family Auriculariaceae of mostly parasitic forms of which the simpler representatives, *e.g., Helicobasidium,* bear the basidia scattered on a loosely woven mycelium, but in the more typical forms, *e.g.*, Auricularia, the hyphae, which have gelatinous walls, are compacted to form fruit bodies, often of considerable size. The basidia are borne on the lower surface of these fruit bodies and are the terminal portions of hyphae which do not reach the surface, become somewhat wider and divide transversely into four cells. From each of these arises a long filament which projects beyond'the surface of the thallus and develops a spore at its tip (fig. 14[E]). The spores can germinate at once and bud off small curved conidia. The fruit body is formed throughout of binucleate cells; the origin of this condition is unknown. The Jew's-ear (Auricularia *auricula*) is a well-known representative of this order.

Rusts.—The Uredinales is a large order of parasitic fungi, in the subclass Heterobasidiomycetes: known as the rusts, which are responsible for the diseases of many of the higher plants—ferns, conifers and flowering plants. There are two kinds of mycelium, haploid and dicaryotic. Both are parasitic and may be found on the same host (autoecious) or on different hosts (heteroecious), sometimes belonging to widely different families. They are intercellular, highly specialized parasites, producing haustoria which penetrate the living cells of the host, and often stimulate the tissues to increased growth and the formation of galls. They are often short-lived—attacking the leaves of the host and falling with

them; but when they extend to the stems of perennial plants. they are also perennial. Four kinds of spores may be produced in the life cycle of one species. viz., pycniospores (called also spermatia) on the haploid mycelium and aeciospores (aecidiospores), uredospores and teliospores (teleutospores) on the dicaryotic mycelium. The aeciospores are borne in fructifications (sori) known as aecia. which are frequently cup-shaped receptacles surrounded and enclosed by an investment (peridium), and containing chains of spores, which arise from a primordial layer of cells at the base of the aecidium. The spores are binucleate, and it has been shown that in the development of the aecium the basal cells are formed from uninucleate cells which either become binucleate by the migration of a nucleus from a neighbouring cell or, by uniting in pairs. give rise to a fusion cell with two nuclei (fig. 16). In either case there is a process. regarded by some workers as sexual in nature, by which the dicaryotic generation is initiated, whose first products are the aeciospores. The pycniospores are thin-walled cells of small size borne in sori known as pycnia (spermogonia). In many species these are flask-shaped structures with the base sunken in the host tissue and with protruding ostiolar filaments. Attempts to bring about infection of the host by means of pycniospores were unsuccessful and they long were regarded as functionless. It has been discovered that the pycniospores are functional. They are exuded from the pycnia in drops of sweet fluid (nectar) which is sought by flies and other insects. When drops of this nectar are transferred from the pycnia on one mycelium to those on another mycelium, pycniospores are thereby transferred and the formation of aecia follows. When such transfer of pycniospores is prevented by the exclusion of insects, which serve to transfer the nectar in nature, aecia do not form. It seems clear that the dicaryotization which is effected in the aecial primordium is initiated by the transfer of pycniospores by insects. The details of the mechanism by which the invading pycnial nuclei finally reach the deep-seated aecial primordium are less clear. Evidence indicates the ostiolar hyphae as the place of entry and that nuclear migration follows. These facts explain how new races of rust may arise through hybridization in the development of the aecial stage.

The aecidiospores germinate readily on the surface of the appropriate host, and the germ tubes enter the tissues by way of the stomata. They give rise to a binucleate mycelium and on this in due course appear the uredospores. These are so-called "summer" spores, *i.e.*, conidia of the diploid mycelium, and can infect fresh hosts and so spread the disease. Later in the year and on the same mycelium teliospores are formed. These are typically thick-walled and resting spores. The uredospores are binucleate and so are the young teliospores, but in the latter the two nuclei fuse before their development is completed. The teliospores are thus the probasidia. They germinate in due course and give rise to the promycelium; on the sterigmata of this organ after its division into four cells the four basidiospores. known as sporidia, are produced. These are uninucleate and can at once infect the proper host and develop the haploid mycelium. This is the life history of one of the most complicated forms, the so-called euforms. of which the black rust of wheat (*Puccinia graminis*) is an example. In this species the host of the haploid mycelium is the common barberry (fig. 15). In other species one or more of the spore types may be absent. The -opsis forms have no uredospores (*Gymnosporangium* sp.). In the brachy- forms the aecia are absent but the pycnia are accompanied by sori of uredospores, nhich in some cases arise as the result of a fertilization like that already described as taking place at the base of the aecium. These primary uredospores thus appear to be homologous with aeciospores. Other species have neither aecia (or primary uredospores) nor pycnia and are known as hemi- forms; there are micro- forms in which teliospores alone occur. In the latter the binucleate condition is established at an early stage— probably by the migration of a nucleus from one cell to another of the haploid mycelium. The most reasonable interpretation of these forms with a shortened life history is that they have been derived from the more complete forms. The teliospore is the spore form almost invariably present and the classification of the family is based largely on its structural peculiarities.

Smut and Bunt Parasites.—The Ustilaginales were regarded by O. Brefeld as shoving a halfway stage in the evolution of the class Basidiomycetes from the lower fungi and he placed them in a separate group, the Hemibasidiomycetes. The cytology of the group, however, leaves little doubt that they are true Basidiomycetes and form a parallel order to the Uredinales or rusts.

They are parasites on grain and fodder plants causing the well-known diseases smut and bunt The mycelium, nhich is usually binucleate, often develops slowly at first and then grows rapidly at a particular stage of development of the host and produces its spores; *e.g.*, the smut of wheat (*Ustilago tritici*) attacks the wheat in the flower. The grains already infected are sown, the plant develops without external sign of disease and not until the ears are formed does the fungus develop in the flowers and give rise to a black powdery mass of spores. These chlamydospores are formed from binucleate hyphae which divide into short cells which separate, round themselves off and form the thick-walled chlamydospores. The two nuclei fuse in the spore which is, like the teleutospore of the rust, uninucleate (fig. 17), but diploid.

On germination the spores give rise to a promycelium. In the Ustilaginaceae the nucleus undergoes two successive divisions as in the Uredinales, and the promycelium (basidium) is divided by transverse walls into four cells. These may not form sporidia but may pair by conjugation tubes between genetically unlike (+) and (−) cells (*Cintractia montagnei;* fig. 17), or they may bud off sporidia, which sprout like yeast cells and eventually conjugate in pairs (fig. 17). The binucleate cells, however formed, can sprout secondary cells or give rise to hyphae, either of which can infect a new host. In one species (*Ustilago zeae*), the mycelium in the host is at first uninucleate and conjugation takes place at the appropriate time between cells of the hyphae, which then round off and form spores.

In the Tilletiaceae, the promycelium remains undivided! eight or more daughter nuclei are formed by division and a whorl of long curved sporidia arise at the tip of the promycelium. These fuse together in pairs, and from the fusion cell secondary sporidia may arise (fig. 17[A]).

The Tremellaceae is a family of mostly saprophytic fungi with gelatinous fruit bodies. Their mycelium is binucleate and gives rise to nearly spherical basidia. In these the fusion nucleus undergoes the usual divisions and the cell becomes divided by four vertical walls into four daughters, from each of which a long filament grows up to the surface of the fruit body and develops a spore (fig. 14[F]).

The general characters of the subclass Homobasidiomycetes have already been outlined. Their basidia are undivided and they are typically collected together in a continuous layer, the hymenium, in which are associated with them sterile hyphae or paraphyses. In the lower families the hymenium is borne on the surface of the fruit body. This may be a flat crust of indeterminate form and extent or, in species growing on vertical trunks of trees, may be bracket shaped. In this case the hymenium is on the lower surface. A whole series of forms show that the bracket may narrow at its point of attachment and form a stalk and the fruit body is then differentiated into the stalk or stipe and the broad cap or pileus. More advanced forms show the central stalk and caplike pileus characteristic of the common mushroom and its relations, the toadstools. A further modification of the hymenium-bearing surface is the development of spines and wrinkles, folds, thin plates (gills) and of pits and tubes, all of which have the effect of increasing manyfold the surface of the hymenium, without correspondingly increasing the size of the sporophore (fig. *18).*

In the higher families the fruit body when young is a rounded spherical structure and the hymenial layers are differentiated from the inner tissues. In the Agaricales the fruit body ruptures before the basidia are matured and so exposes the hymenium, but in the Gasteromycetes the opening of the fruit body is delayed until the spores have been formed. In this last-named group the fungus fruit body is often elaborately constructed and may be formed of fibrous tissue, gelatinous tissue, plectenchyma, etc. At maturity a rapid expansion of pseudoparenchymatous tissue forming the so-called receptaculum may rupture the outer covering and expose the mass of spores, embedded in the mucilaginous remains of the fertile tissue clinging to its surface (Phallus impudicus, Clathrus cancellatus; fig. *19).*

FUNGUS GNAT, or mushroom fly, any member of the families Mycetophilidae and Sciaridae of the order Diptera (*q.v.*), small, mosquito-like flies almost all of which as maggots (larvae) feed on fungi. In the Sciaridae, or dark-winged fungus gnats, the eyes almost touch and the wings are usually dusky. The larvae are creamy white or grayish and sometimes occur in such large numbers that they migrate over the ground in snakelike lines which may be one-half inch deep, the migrations evidently occurring when the food in the leaf mould or humus is exhausted and a new Source must be found. *Sciara tritici* damages the roots of wheat. Species of *Sciara,* and certain mycetophylids, attack mushroom beds and sometimes completely destroy them. In the Mycetophilidae there are a few injurious forms, including *Pnyxia* scabiei which bores into potato tubers and causes unsightly scabs; severe infestations occur; the female is wingless. Larvae of several species are luminous. *Arachnocampa luminosa,* occurring in countless numbers in the caves of New Zealand, light the caves; they spin webs, and sticky strands hang down apparently to catch flying insects. Large numbers of tourists visit the caves.

In Europe and North America the larvae of *Ceroplatus* are luminous and build sticky webs on which they crawl with ease; some, if not all, are predaceous. Adults, mostly less than one-fourth inch long, abound in swampy areas. (C. H. CN.)

FUNGUS INFECTIONS. Fungus diseases of man, or mycoses, vary in severity from the relatively benign skin infections such as dermatophytosis (ringworm) to fatal systemic infections such as coccidioidomycosis. In the United States in the 1950s, 350 to 400 deaths per year were reported as caused by fungi (*q.v.*). Benign infections and superficial mycoses occur much oftener.

Local Infections.—Dermatophytosis is caused by about 20 species of dermatophytes, a group of related fungi able to utilize keratin. Ringworm is contagious and usually is acquired from other persons or from such animals as dogs, cats, cattle and horses. The epidemic form of ringworm of the scalp (*q.v.*), caused by Microsporum *audouini,* occurs in children. Athlete's foot, caused by species of Trichophyton and Epidermophyton, occurs over a wide age range. (See also SKIN DISEASES; TINEA VERSICOLOUR.)

Thrush (*q.v.*), caused by Candida albicans, is an infection of the mucous membranes which sometimes spreads to the skin and occasionally becomes systemic. Vaginal thrush during pregnancy and oral thrush in the newborn are common. The fungus is commonly present in the intestinal tract of normal persons and is often present in the sputum of persons suffering from any type of pulmonary disease.

Actinomycosis, which occurs in both cattle and man and is caused by *Actznomyces bovis,* may involve the skin, subcutaneous tissues of the jaw, including bone (the condition called "lumpy jaw") and many of the visceral organs; *e.g.,* the lung, appendix or liver. The disease is characterized by firm swelling with formation of sinus tracts that discharge pus containing small colonies of the fungus. The fungus is present in normal persons in the tonsils and on tooth surfaces, and infection sometimes follows dental neglect or injury. *(See* also RESPIRATORY SYSTEM. DISEASES OF.)

Systemic **Mycoses.**—The three preceding groups of infections are caused by fungi which are frequently present on body surfaces of man, in many instances without producing apparent disease. The fungi causing most of the more severe systemic mycoses, on the contrary. are not normal residents in or on man but grow and survive independently as saprophytes in soil and decaying organic debris. Some of these fungi can be recovered easily from such sources and, therefore. man must frequently be exposed to pathogenic fungi. The conditions under which such exposures are followed by infections are not fully known, but they include inhalation of air-borne spores. ingestion and implantation of the fungus under the skin as the result of an injury. In respiratory mycoses. severity of the disease appears to increase with the intensity of exposure. The factors of individual immunity and susceptibility are of prime importance. In coccidioidomycosis, for example, a person who recovers from an initial mild infection appears to be immune to reinfection. Most of the systemic mycoses respond poorly to treatment.

Coccidioidomycosis, caused by *Coccidioides immitis*, occurs either as an acute but benign respiratory infection known as valley fever or as a progressive, generalized granulomatous disease called coccidioidal granuloma. Granulomata are growths consisting primarily of granular tissue surrounding a centre of irritation. The respiratory infection is primary and is usually self-limited (*i.e.,* ceasing after a time as a result of its own processes). However, in some cases (and more often in dark-skinned peoples) it may involve almost all organs with the usual exception of the gastrointestinal tract. Coccidioidomycosis is endemic only in the southwestern section of the United States. in Argentina and in intervening arid areas. The fungus has been isolated from soil and found to produce disease in dogs, rodents and cattle as well as in man. *(See* RESPIRATORY SYSTEM, DISEASES OF.)

Histoplasmosis, caused by *Histoplasma capsulatum,* also has an acute respiratory form, usually self-limited, but occasionally it is a rapid fatal infection involving the spleen, liver, lymph nodes and other organs. Healed pulmonary lesions may calcify and then may be confused with those of tuberculosis. Histoplasmosis is endemic in many parts of the world. Cats, dogs and other animals are often infected. The fungus is present in soil and in organic debris, especially in the enriched soil around chicken houses.

North American blastomycosis, caused by *Blastomyces dermatitidis,* is a granulomatous disease involving the skin, the lungs and many other organs. The fungus is similar to *Histoplasma* in some respects, including its ability to incite the formation of similar antibodies in the blood of the infected person.

South American blastomycosis, caused by *Pavacoccidioides brasiliensis (Blastomyces brasiliensis),* is a granulomatous disease involving the skin. the mucous membranes, the lymph nodes and the gastrointestinal tract. It is an important fatal disease in South America. Infection is thought to follow ingestion of fungus spores.

Cryptococcosis (torulosis), caused by *Cryptococczis neoformans,* usually produces meningitis (*q.v.*), although the skin, bones and visceral organs are often involved. It is world-wide in distribution. Unlike most pathogenic fungi, *Cryptococcus* usually produces little cellular reaction in the host. It has been isolated from soil and pigeon droppings.

Sporotrichosis, caused by *Sporotrichum schenckii,* is seen as a persistent ulcer at the site of a penetrating thorn wound with secondary lesions in the regional lymph nodes. It is rarely systemic. Unlike most of the deep mycoses it responds promptly to treatment with iodides.

Chromoblastomycosis, caused by species of *Phialophora,* is a chronic, slowly progressive, granulomatous disease of the skin and subcutaneous tissues, usually of the lower legs. Its more frequent occurrence in the tropics is believed to be due to exposure of barefoot workers to thorn injuries, which permit implantation of fungus spores.

The mycetomas are a group of mycoses having multiple causes. They are characterized by swelling, usually on the feet, and the eventual death of the affected tissues, with a formation of sinus tracts containing pus in which the fungus causing the infection may be found in the form of dense colonies (granules), varying in consistency and colour according to the species of fungus. The mycetomas also are more commonly seen in the tropics, probably because of more frequent exposure.

FUNKIA, a genus of the lily family; the plants are tufted with broad several-ribbed radical leaves and scapes of ahite or blue ascending horizontal or drooping flowers, planted both for the ornamental clumps of foliage and the bloom. Other names for this group are *Hosta* and plantain lily. *See* HOSTA.

FUNSTON, FREDERICK (1865–1917), U.S. soldier, was born at New Carlisle, O., on Nov. 9. 1865. After three years' study at the University of Kansas, Lawrence. he worked as a railway conductor and as a newspaper reporter in Kansas City. In 1891 he was appointed botanist for the department of agriculture in the Death valley expedition and two years later was commissioned to report on the flora of Alaska, where he made extensive explorations. including a journey down the Yukon alone in an open boat. In 1896 he joined the Cuban insurgent army in which he became a lieutenant colonel. On the outbreak of the Spanish-American War in 1898, he returned to the U.S., was appointed colonel of the 20th Kansas volunteers and sent to the Philippine Islands. For his conduct at the battle of Calumpit in 1899, during the Filipino insurrection, he received the congressional medal of honour and was promoted to brigadier general of volunteers. For his capture in 1901 of Emilio Aguinaldo (*q.v.*), the leader of the revolt, he was made brigadier general in the regular army. In April 1914, when the naval forces turned the captured city of Veracruz, Mex., over to the army, Funston became military governor of the city. He was rewarded with the commission of major general. In 1916 he directed the army's pursuit of Francisco ("Pancho") Villa and died Feb. 19, 1917, at San Antonio, Tex.

FUR. Fur is the soft, downy, dense growth of fibres covering certain animals. The word is derived from the Old French *fuerre* and *forre,* meaning either "sheath" or "covering." Fur-bearing animals also have a covering of longer hairs above the fur undergrowth. This is called guard hair or overhair, protects the underlying fur from injury and prevents it from matting or felting. Both guard hair and fur protect the animal from cold and storm.

The use of fur as apparel probably dates from the early stages of human history. Primitive man's chief needs in the colder regions of the earth were food and warmth, and it is reasonable to suppose that the use of animal fur for warmth was not long separated from that of animal flesh for food. To the barbarian in his northern forests fur was a necessity and as such had its value; but it is important to note that in almost every civilization of which history is cognizant fur had its value from early times as an ornament or decoration. The Chinese are said to have esteemed it highly 3,500 years ago; the Greek legend of Jason and the Golden Fleece may well have had its origin in some more than usually perilous and fortunate fur trading voyage to the Euxine; and the use of furs was one of the luxuries Rome adopted from Greece. In the narrowing of this distinction between fur as a necessity and fur as the luxury of the few, desirable because of its rareness and beauty, may be found the clue to the subsequent development of the fur trade. In the civilization of mediaeval Europe fur was emphatically a luxury. As such its use was forbidden by the church to monks and to all but the highest ecclesiastics, while among the laity it was carefully regulated by frequent and severe sumptuary laws. None but those of royal blood were allowed to wear certain furs, and in general a man's social importance could be gauged by the amount and nature of the fur he wore. Fur, be it observed, was mainly connected uith male attire at that time; in certain instances, indeed, it became almost a badge of office, as witness the judge's ermine. The only form in which fur seems to have been permitted to all who could afford it in the middle ages was as headgear, and in the English language the words "beaver" and "hat" seem to have been used almost interchangeably from the time of Chaucer. The chief sources of European fur supply in the middle ages were northern and central Europe. and the Hanseatic league. with its chain of towns dotted round the Baltic was a great power in the trade.

The modern age may be said to have begun for the fur trade with the discovery of America. That event opened up vast fur resources to European enterprise. and this seems to have been an aspect of the neu continent uhich appealed to the early explorers most strongly In patents of discovery and charters to early settlements "trade in furs" is frequently mentioned, and much of the interior exploration of North America was the direct consequence of this trade. The French settlers in Canada uere especially ardent fur traders; the more adventurous among them had penetrated to the Mississippi, and probably to Lake Winnipeg, long before the English had crossed the Alleghenies The Hudson's Bay company entered the field in the latter half of the 17th century and from the time of its existence has spread its trading posts and interests from Vancouver to Prince Edward Island, and northward to the Arctic ocean. The fur trade of the 18th and early 19th centuries, nhen an Indian trapper would barter his winter's catch for a blanket and a bottle of cheap spirits, uas a highly profitable business; John Jacob Astor, among others, founded his fortune upon it. The supply of furs appeared inexhaustible and the demand steadily grew; for the industrial revolution in Britain and western Europe, creating vast new wealth, created also new desires and furs, from being a luxury, became by the middle of the 19th century a fashion. In the 20th century, the United States emerged as the uorld's major user of furs. After World War II, however, changes in the American way of living acted to the detriment of fur sales. The virtual universality of the automobile diminished the importance of fur coats as items of utility and uarmth. The shift to suburban and informal living by the upper middle class—the best fur customers—reduced the desire for formal fur apparel. Such small furs as capes, stoles and jackets became popular. The rapid economic growth of Canada made it an increasingly important consumer of furs Also, the economic recovery of post-World War II Europe brought indications that Britain and the continent in the 1950s were bigger users of furs than in the previous decade.

THE MODERN FUR TRADE

Sources of Wild **Furs.**—Wild furs come not only from cold climates, as is commonly believed, but from temperate and tropical zones as well. More than 80 countries on all six continents contribute to the world supply of pelts for commercial use. The fur trade reaches from the arctic areas of Siberia and Canada to the southernmost tip of Africa for almost 80 varieties of furs which can be made into apparel. Still, the most important sources of supply are the cold regions where the temperature ensures the growth of thick, luxuriant fur.

North America is the home of the greatest variety of fur bearers. The frozen wastelands, forests and marshes of this continent are inhabited by mink, beaver, muskrat, skunk, American opossum, marten, fisher, ermine, silver fox, blue fox, red fox, white fox, cross fox, raccoon, bear, wolf, weasel, wildcat, fitch, otter, sable, lynx and wolverine. The United States has 40 different types of indigenous furs. The most important are mink, muskrat, beaver, raccoon. skunk and opossum.

Northern and central Europe and Siberia supply badger, beaver, ermine, fitch, fox, hare, lynx, marmot, marten, mink, muskrat, nutria, otter, Persian lamb and karakul, sable, squirrel, wolf, fox, goat and moleskin. The latter fur is found in the British Isles and in the Netherlands, France and parts of Africa.

China delivers marmot, kolinsky, marten, kid. goat and lamb. Korea supplies kolinsky; central Asia Persian lamb and other lamb skins. India contributes leopard, ocelot, tiger and some stone marten. Ceylon provides leopard. From Japan come mink or weasel and flying squirrel. South America is the home of chinchilla, nutria, fox, skunk and chinchilla rats.

Tremendous quantities of rabbit skins are pelted in Australia, France, Belgium and Great Britain, and big quantities came from New Zealand until 1953 when exports were halted. In the 1950s, myxomatosis, a virus disease, reduced the supply from Australia, Tasmania, New Zealand and Great Britain.

The seal is the principal marine animal used commercially. The best type, known as Alaska fur seal, comes from the Pribilof Islands. 300 mi. west of the Alaska mainland. When the United States purchased Alaska in 1867, the seal herd was an estimated 3,000,000 animals. Uncontrolled slaughter of the seals cut the herd to 100,000 animals in 23 years. This indiscriminate slaughter or pelagic sealing came to an end in 1911 under an international conservation agreement, restoring the herd to 1,500,000 animals by 1954. The Pribilofs account for 80% of the world's seal population, and about 60,000 are killed annually. Other seals are to be found in the Komandorski Islands of the U.S.S.R. in the Bering sea, in Robben Island off the coast of the Union of South Africa, in the Kurile Islands of Japan and in the antarctic islands belonging to Uruguay and South Africa.

Ranched Furs.—The outstanding development in the world's fur supply in the 20th century has been the breeding of mink and fox on farms or ranches. Mink ranching began commercially in the United States in the 1930s. The scientific development of mutation mink, natural pelts bred in a variety of colours ranging from pale brown and platinum gray to pale blue and pure white was notable. (See below, under Fur Farming.)

Collection and Distribution.— Fur skins find their way into the world's markets through two main channels. A large number are delivered or sold to collecting agents, who sell them to skin merchants in various fur centres. Skin merchants maintain stocks of furs, selling them to manufacturers or retail furriers. Most raw fur skins, however, are shipped to auction houses and offered at public auction to skin merchants, manufacturers and commission brokers who buy for merchants and manufacturers. Fur auction houses act as marketing agents for shippers of fur skins and receive fees based on the value received for the furs at auction.

The major fur auction centres are London, New York city, Leningrad and Montreal. Regular auctions of secondary importance are held in St. Louis, where fur seal skins are sold semiannually, Seattle, Minneapolis, Winnipeg, Edmonton, Vancouver, Regina, Copenhagen, Oslo, Helsinki, Stockholm. Melbourne and Sydney are the main centres for rabbit-skin auctions, which are also held in London. The practice in fur auctions all over the world is to set aside several days prior to the sale as an inspection period, enabling buyers to examine the skins in the warehouse and to make judgments as to the quality and value of the pelts. The buyers work from catalogues in which are listed lot numbers, corresponding to the lots or bundles of skins in the warehouse.

Bidding at fur auctions is not free, strictly speaking, in that shippers often set minimum limits on the price they want for certain pelts. The auctioneers reserve the right to withdraw or "buy back" a bundle of pelts if the buyers' bids fall below the shipper's limit. In some auctions, however, bidding is not restricted in this manner. Furs from all over the globe are auctioned off in London, which is considered the capital of the international industry. In a typical month, for example, London auction firms offered more than 700,000 Persian lamb, and 25 other types of furs amounting to an additional 850,000 skins.

The Hudson's Bay company is the dominant fur collecting organization and marketing agent in the world, with auction houses in London, Montreal and New York city. The London Public Sales, comprised of Hudson's Bay company and two other firms,

FUR AND HAIR UNDER THE MICROSCOPE. SHOWING OUTSIDE VIEW AND LONGITUDINAL SECTION

The magnification is shown by the figure preceded by an x. The average diameter of the hairs in μ is shown under the name of the animal. (μ = 1/1000 mm) holds major auctions in the spring, summer, autumn and winter.

In New York city during the height of the season (December to March), few days pass without an auction sale at one of four firms, and occasional sales are held throughout the year. New York is the centre for American ranch and mutation mink and ranks second to London as a seller of Persian lamb. Monthly auctions are held in Montreal and other Canadian cities.

The important auctions in London, New York and Montreal draw an international audience and often last a week or longer. The annual Leningrad sale is usually held in July. It is conducted by Soyushpushnina, official Soviet agency, which buys the skins from state and collective farms and controls domestic and foreign marketing. The auction runs a full week. In 1954, for example, 30 types of furs totalling 3,000,000 skins were offered to 80 to 100 buyers representing 15 countries. Soyushpushnina also sells furs by contract to individual purchasers.

World Wars I and II eliminated Leipzig as a fur centre, its business being diverted to Leningrad, London and New York city.

Fur Dressing and Fur Dyeing.—Briefly, the function of the fur skin dresser is to make the skin suitable for use in the later stages of the trade, the objects aimed at being the creation of a soft, pliable leather; the removal of superfluous matter from the pelt; and the preservation and enhancement of the natural lustre of the fur. The details of the process vary widely with the nature and condition of the skin treated, but in every instance there are at least four distinct stages, some being comprised of several processes, in the operation. First of all there is the preliminary cleaning and softening of the pelt; then fleshing (removal of fleshy matter from the skin) and stretching; then leathering (the formation of a leather on the skin, actually a form of tanning); and then a final cleaning. After each stage and between many of the intermediate processes the fur is cleaned, a revolving wooden drum containing sawdust or other suitable material being generally used for this. Separate departments of the fur dresser's art are unhairing (the removal of guard hairs where necessary), shaving and seal-skin dressing which is a complicated business presenting features not found in the majority of furs. Though it doubtless originated in a primitive and haphazard manner, modern fur skin dressing is a highly developed scientific process requiring, incidentally, considerable mechanical equipment.

Fur dyeing is of great antiquity but may be said to date its modern development from the latter part of the 19th century. Before that period the dyeing of furs was mainly carried out with vegetable or mineral colouring matters. Since then, however, various chemical compounds known as fur bases have come into general use and have largely superseded the older materials by reason mainly of the ease with which they can be applied. The use of these synthetic compounds has also enabled fur dyers to produce many new colours on furs, and fresh ones are added every year. This again has led to the adoption by the fur trade of many skins which in their natural colours would be disdained by the public, but when well dressed and dyed make attractive furs.

The importance of fur dyeing increased in the 1950s as the fur trade began to catch up with the international trend toward colour in virtually every type of product from cloth coats and dresses to automobiles. New colours became an important selling point among fur retailers, marking the transition from the traditional browns and blacks of natural furs to such shades as blonde, beige, charcoal and platinum gray, blue, white and even pink and red. Typical of the innovations made possible by the fur processor's art was the case of raccoon. The long-haired, brown raccoon coat of the 1920s had become, three decades later, a sheared, lighter-weight fur available in blonde, beige or white as well as the natural colour. Great secrecy is maintained on the technical side of fur dyeing, each dyer jealously guarding his methods from competitors. France, Belgium and London are the chief dyeing centres of Europe. Leipzig was once supreme in this field but after World War II its experts relocated in Frankfurt, London and New York. The largest fur processing industry is in New York.

Fur Manufacturing.—Furriery, or the making up of furs into garments, has progressed from the primitive sewing together of skins to the position of a highly skilled and intricate occupation, and the modern manufacturing furrier often has a good claim to be recognized as an artist in the same sense in which a designer and creator of gowns is so recognized. Paris exerts great influence in originating fur fashions, and the ideas of Italian designers are also significant. New York city, the largest manufacturing centre, developed a highly respected corps of fur designers among its custom furriers, stylists who create for individual manufacturers and commercial designers who sell patterns to manufacturers and retailers.

Fur manufacturing remains, essentially, a handicraft industry. Highly skilled and well-paid labour in the United States accounts for 20% to 25% of the cost of manufacturing a garment. Cost of skins and other materials runs about 62%. Typical of the manual operations in furriery is that of fur cutting. The cutter, best-paid artisan in the trade, is charged with matching pelts according to colour and quality in order to make for uniformity of colour and texture in the finished garment. He also cuts the skins to conform to the designer's pattern with a minimum of wastage. Sewing is performed on power-driven machines and is a task requiring much painstaking and skill.

There are two main types of fur manufacture. One is the letting-out technique; the other, the skin-on-skin method. The first, usually applied to mink, involves slicing every skin into diagonal strips $\frac{1}{8}$ to $\frac{1}{4}$ in. in width and then sewing these strips together to make a longer and narrower skin that will run the full length of the garment without seams showing on the fur side. The skin-on-skin method is less costly. It consists of sewing one full skin adjacent to another in a uniform alignment. Some firms specialize in sewing the leftovers of full skins, such as paws, flanks and gills, into blanketlike "plates" which are then fashioned into garments.

Manufacturers distribute their products either by selling directly to retailers, or to wholesalers or jobbers who sell to retailers. New York city's manufacturing industry in the 1950s had about 2,000 firms. There were about 600 firms in Montreal and Toronto.

The Fur Retailer.—Retailers of fur garments are the direct contact of the industry with the consuming public. There are three main types: (1) custom furriers who design and manufacture their own garments and also carry stocks of ready-to-wear furs; (2) women's apparel specialty stores which carry furs as part of a general stock of apparel; and (3) department stores. All these stores usually maintain fur servicing departments, which remodel and repair garments for customers and also store furs in refrigerated vaults.

Retailers obtain merchandise directly from the manufacturer or from the wholesaler or jobbing house. In the United States, department stores first became important factors in fur retailing in the 1920s. Previously, custom and specialty retail furriers had been practically the only sellers of furs; the thousands of smaller fur retailers, however, continued to do more than 50% of U.S. fur sales dollar volume.

When aggressive (and often exaggerated) advertising practices were introduced in the retail fur trade, certain restrictions were imposed by the U.S. federal trade commission. These were made more stringent in 1952, when congress passed the Fur Products Labeling act, designed to protect the consumer from misleading advertising and selling practices. The law forbade a store to describe a fur in terms of another. For example. marmot dyed to resemble mink could no longer be described as mink-dyed marmot but only as dyed marmot. A fur products name guide was issued by the federal trade commission, listing the true and permissible fur names. In addition, retailers were required to note the country of origin of fur skins. Thus, a garment made of Canadian muskrat, which has been sheared and dyed black to resemble fur seal, could no longer be called Hudson seal but had to be labelled, "black-dyed sheared muskrat; country of origin, Canada." Government regulations in other countries vary but are generally less stringent than those of the United States.

FUR FARMING

The keeping and breeding of animals for their fur is one of the oldest occupations. The Chinese have farmed goats and dogs for an unknown number of centuries, using the flesh of the animals as food and their skins, fur or hair, according to species, for the purpose of trade; while, if one considers the sheep as a fur-bearing animal, the inception of fur farming is lost in the mists of antiquity. Though many of the animal-husbandry practices of livestock raising were adapted to the raising of fur animals, some of the fur-farm problems were peculiar to these wild species under confinement. This necessitated specific research. The Canadian government in co-operation with the Canadian National Silver Fox Breeders association established a research station at Summerside. P.E.I., in 1920, and the United States government started the United States Fur Animal experiment station at Saratoga Springs, N.Y., in 1923. These stations have published many scientific and popular articles. By 1940 the U.S. government was conducting research on fur animals co-operatively with colleges and universities in the states of Wisconsin, New York, Pennsylvania, Washington and Alaska. Several of the provinces in Canada were also doing fur-animal research in addition to that on Prince Edward Island, and Sweden, Norway and Denmark began similar research because of the increasing importance of fur farming in their economies.

Silver Fox Farming.—A silver fox is a mutation of a red fox in which the red colour is replaced by black. The white band on the guard hairs gives the silvery effect. The early captured foxes were nearly black, but by selective mating over a 20-year period the bright silver fox was produced in which the white bands were extremely wide and the black was free from the rusty brown so common in the early foxes. Since the black colour is dependent upon a single genetic recessive factor, black or silver foxes when mated together always produce silver-black foxes. Because of the rare chance-mating of two black foxes in the wild, however, only a very small percentage were of this colour.

On fur farms odd-coloured fox pups occasionally appeared in a litter. At first such animals were quickly discarded for fear that the purity of the herd would be questioned. Some enterprising fox farmers, however, mated them and eventually several profitable mutant colours were developed, such as white face, platinum, pearl and glacier blue. The breeding of silver foxes in captivity was accomplished on Prince Edward Island in 1894. At first it was carried on with much secrecy until an especially beautiful silver-fox skin brought £580 at auction in London. Charles Dalton, later knighted by the English crown for his contributions to fox farming, and R. T. Oulton (both Canadians) are considered to be the pioneers in fox farming. Such prices for skins made prices for breeding stock fabulous. The cost of a pair of foxes rose from $3,000 in 1910 to $35,000 in 1913, and extensive speculation took place even on options on newborn pups. World War I and better business judgment had reduced operations to a more practical basis by 1927.

Peak production in the United States of 350,000 silver-fox skins was reached in 1939. In that year Canada produced 230,000 and the Scandinavian countries somewhat fewer. By the mid-1950s fewer than 10,000 silver fox pelts were being produced annually in the Gnited States, and production in other countries was also drastically reduced.

Long furs were not wanted in the late 1940s, and the average price of $12 to $16 for fox pelts that cost more than $30 to produce then put many fox farmers out of business and caused others to reduce their operations. The highly desirable U.S. market affected fox farmers in other countries, especially Canada.

Though pair mating was at first deemed necessary, polygamous mating finally became the common practice. The one litter per year is whelped after a gestation period of 52 days. An average of four young per litter is considered satisfactory, and these are weaned when about eight weeks old.

Silver foxes after about seven months old weigh from 10 to 15 lb. The pups are pelted in November and December of the first year. Those pups selected for the herd are bred during late winter and early spring of the following year.

The early large ground-floored pens were replaced with smaller ones with raised wire floors to avoid parasite infestation and for better sanitation. A guard fence with an overhang to prevent foxes that break out of their pens from escaping is essential. This also provides seclusion and prevents stray dogs and other animals from giving the foxes distemper. Distemper ravages caused enormous losses until a satisfactory vaccine was developed.

A desirable fox ration is composed of 25% to 50% of horse meat or various packing-house by-products. The rest of the ration is composed of dry concentrates, vegetables and water. Continuous feeding of certain fish may cause losses in foxes. A fox ordinarily eats about one pound of food per day. The feed companies finally developed a satisfactory cubed feed for summer and fall feeding of foxes. This reduced materially the necessary refrigeration.

Blue Fox Farming.—Though some blue foxes are raised in pens—principally in Norway—the most interesting early development was in Alaska, where entire islands were leased and the foxes ran wild. The natural foods were supplemented during certain parts of the year. Parasitism and lack of controlled breeding, together with lower prices for pelts, finally put these operations out of business by the late 1940s. Litters of blue foxes often had ten young.

Mink Ranching.—Though minks were raised in captivity for their fur as early as 1866, it was not until about 1930 that they were produced in quantity. Undoubtedly, the impetus was due in great part to the development and fostering of new and striking mutant colours. After mid-20th century there were three times as many mutation mink skins produced as the dark natural-coloured mink, and the Mutation Mink Breeders association rigidly controlled the market. Most skins were sold dressed.

In minks the underfur should be about $\frac{5}{8}$ in. long and the guard hair about one-half again as long. Mink skins lend themselves admirably to a manufacturing process known as letting-out in which the skins are cut into narrow strips diagonally from the centre and then resewn in such a manner as to make the skin two or three times its original length. The darker centre strip is retained, and the flow of the garment is enhanced.

A mature female mink weighs about $1\frac{1}{2}$ to 2 lb. and the males about 4 lb. The sexes are kept separately, and polygamous mating is the common practice—usually in March. There is a varying time of delayed implantation of the embryos, and consequently the gestation period varies from 40 to 76 days. A litter average of four is satisfactory. Weaning takes place at eight weeks and the pelting about the last of November of the same year. Mink will breed when about 11 months old.

Minks are kept in individual pens having 10 to 20 sq.ft. of raised wire floor space. Small detachable nest boxes facilitate care of the animals. The mink ration requires a higher percentage of raw meat than that for foxes, and fish may replace most of this without harm to the animals. The daily feed allowance is about $\frac{1}{4}$ lb. per day though animals to be pelted should be fed all they will eat.

Chinchilla Raising.—The chinchilla is a native of South America, and during the early 1900s many chinchilla furs from animals trapped in the wild were marketed. Overtrapping produced such a scarcity that an American, M. F. Chapman, was induced to start raising them in captivity. By the mid-1950s more than 500,000 chinchillas were being kept in captivity in the U.S., one-fourth as many in Canada and only a small number in the rest of the world. Until 1954 operations were largely in selling breeding stock for several hundred dollars per pair, but in June of that year the first auction ever held of a large quantity of chinchilla pelts from ranch-raised animals resulted in an average price for selected skins of $37. This put chinchilla raising on the more stable basis of producing skins for use in the fur trade.

Chinchillas are small, squirrel-like land rodents weighing about $1\frac{1}{2}$ lb. at maturity. Their fur is extremely fine and silky, blue-gray in colour, with characteristic white bands on the guard hair.

Martens.—This attractive and interesting forest fur animal is closely related to the sable and weighs from 1½ to 3 lb. at maturity. Many attempts to raise martens in captivity have failed because only about 15% to 20% of the females produce young.

Martens breed in July and August and, after several months delayed implantation, whelp in April. Experimentally, this implantation period was shortened by artificial lighting, simulating early spring conditions, so that the martens were caused to whelp in December instead of April. Twenty litters obtained over several years at the United States Fur experiment station averaged 2.6 young per litter. Martens thrive on about the same kind of feed as the foxes and minks. They consume from six to eight ounces daily and particularly relish small fruit and berries.

Other Fur Animals. — Karakul sheep and somewhat similar breeds of sheep have been raised in Russia and the near eastern countries for hundreds of years. These produce the very desirable black Persian lamb skins and other similar types. By the 1950s South-West Africa was producing several million Persian lamb skins after many years of selective mating of karakul rams to progeny of white sheep. Selected skins from white lambs are sheared, plasticized and usually dyed to be sold as mouton.

The raising in captivity of several other fur animals was initiated and developed to a promotional basis for selling, but by the mid-1950s had not materialized commercially because of availability of the furs from the wild supply. Among these can be listed beavers, nutrias (a South American rodent), fishers, muskrats, fitches, raccoons and skunks.

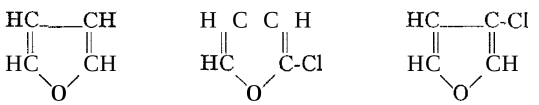
Possibilities of raising these animals in captivity for their fur depended upon fashion and the finding of new striking colours. It is true that even with the natural-coloured animals improvement can be made by selective mating for clearer colour, greater density and the other characteristics that give them greater fashion appeal. The scarcity of the wild types will be a contributing factor toward successful farming of these animals.

Rabbit skins from animals raised in hutches primarily for their meat have been used extensively in the fur trade from time to time. Selected skins from the older animals of Europe have proved very satisfactory in the natural state or sheared and dyed, but only a small percentage of the skins from the eight-week-old "fryer" rabbits in the United States are suitable for fur garments. Very few rabbits are raised primarily for their fur.

Soc.*, vol. 96, no. 6 (1952); Artur Hansson, *The Physiology of Reproduction in the Mink* (Stockholm, 1947), in English and Swedish with an extensive bibliography. (C. E. K.)

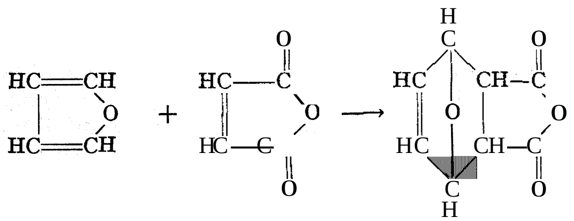
FURAN CHEMISTRY is that branch of organic chemistry that deals with the family of organic compounds known as the furans (see also FURFURAL). Furan itself (boiling point 31.3° C.; specific gravity 0.937) is a colourless liquid of strong ethereal odour which is relatively insoluble in water, but completely soluble in alcohol, ether and acetone. It has been found to occur in various wood oils, and it may be prepared conveniently in the laboratory by the decomposition by heat of furoic acid. Large-scale production is carried out by passing the vapours of furfural and steam over a suitable catalyst.

The constitution of furan (C_4H_4O) is generally represented as indicated below, and while the other members of the family retain the characteristic five-membered ring or nucleus, one or more of the hydrogen atoms is replaced or substituted by other atoms or groups of atoms—*e.g.*, C_4H_3O-Br, bromofuran; C_4H_2O-$(COOH)_2$, furandicarboxylic acid. Because of the asymmetry of the ring, however, these substitution products can exist in more than one form, and to distinguish these forms, or isomers, it is convenient to denote the location of the substituent(s) by numbering the five-ring atoms counterclockwise beginning with the oxygen atom as number one. Since it has been experimentally established that positions 2 and 5 and positions 3 and 4 are equivalent, two and only two monosubstitution isomers (C_4H_3O-X) of furan are possible, depending upon whether the new substituent (X) replaces a hydrogen atom on a carbon adjacent to, or once removed from, the oxygen atom. This is illustrated below by the case of chlorofuran (C_4H_3O-Cl). There are four possible isomeric disubstitution derivatives if the substituents are alike; if unlike, the number of isomerides is greater. For polysubstituted furans the number of isomers can be deduced readily from the structure.



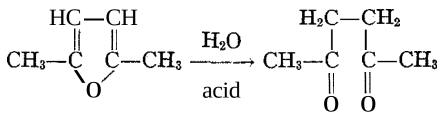
furan 2-chlorofuran 3-chlorofuran

The chemical behaviour of the furans is quite complex as a consequence of the combination, in one-ring system, of characteristics associated with dienes, with vinyl ethers and with benzene types. A great many addition reactions attest to the dienic behaviour of this class, including Diels-Alder syntheses involving the simple furans (*e.g.*, reaction of furan with maleic anhydride).



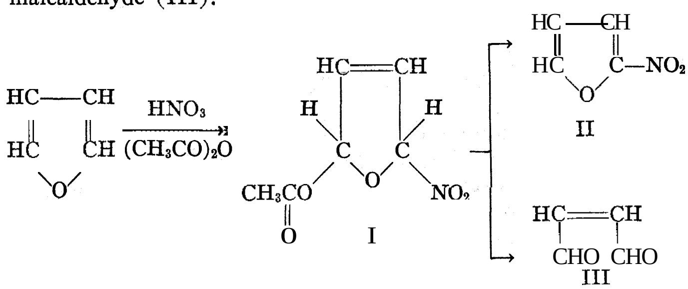
This dienic activity is suppressed in derivatives possessing electron-withdrawing substituents (CO, NO_2, etc.), so that furans such as furfural and nitrofuran fail to react in like manner.

Acid hydrolysis reveals the kinship of the furan ring to a vinyl ether. Furan and its alkyl-substituted derivatives are readily cleaved by aqueous acids to open-chain dicarbonyl compounds, as illustrated by the formation of acetonylacetone from 2,5-dimethylfuran.



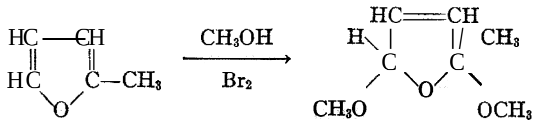
Again, however, the nature of substituent groups can affect the ease of reaction, and furfural, furoic acid and particularly the nitrofurans are resistant to acid hydrolysis.

In general, furan types are more reactive and less in the sense of nuclear integrity than their benzene counterparts, and the usual substitution reactions have been applied with varying success. The reagents employed are acidic in nature and it is important, in most instances, to avoid moisture, and to control experimental conditions carefully in order to minimize resinification and cleavage of the ring. By appropriate modification the Friedel-Crafts reaction (*q.v.*) can be applied for the synthesis of alkylated and acylated derivatives. The related Gattermann aldehyde synthesis has also been carried out in a number of instances. Sulfonation, while not usually feasible with fuming sulfuric and chlorosulfonic acids, has been accomplished by use of the milder pyridiniumsulfonic acid. Halogenation may be carried out to obtain either addition or substitution products. Nitration is usually effected with nitric acid in acetic anhydride as the reagent. With furan itself, this gives rise to an intermediate nitro-acetoxy-dihydrofuran (I) which, by the action of pyridine, loses the elements of acetic acid to form 2-nitrofuran (II). If water is present, however, I may decompose with formation of malealdehyde (III).



That the furan ring is less stable as a unit than the benzene ring is further reflected by the fact that the extensive chemistry of the phenols and aromatic amines has no complement in the furan series. The furanols and furylamines exhibit much more kinship to the aliphatic keto-enol and ketimine-enamine systems, respectively, than to the analogous benzene derivatives.

Furan compounds are very susceptible to nuclear oxidation, particularly in acidic medium. Under such conditions, it is difficult to find reagents that permit selective oxidation of a substituent group. In admixture with air, over a suitable catalyst (vanadium pentoxide) at elevated temperature, furan or furfural give rise to maleic anhydride in excellent yield. Carefully controlled alkoxylation, electrolytically or with chlorine or bromine, permits the isolation of unsaturated acetals which are useful intermediates in organic syntheses. This is illustrated by the alkoxylation of 2-methylfuran to a cyclic acetal of acetylacrolein.



When furan compounds are subjected to the action of hydrogen in the presence of a nickel catalyst, the ring is reduced, and saturated cyclic ethers, the tetrahydrofurans, are obtained. In this way, furan gives rise to tetrahydrofuran itself (IV), and this represents another step in the industrially important synthesis of nylon from furfural. The further steps involve cleavage of IV to 1,4-dichlorobutane (V), treatment with sodium cyanide to obtain adiponitrile (VI), and reduction to hexamethylenediamine (VII). Nylon is made by reaction of VII with adipic acid.

FURETIÈRE, ANTOINE (1619–1688), French scholar and miscellaneous writer, was born in Paris and became abbé of Chalivoy in the diocese of Bourges. His satires—Nouvelle *Allégorique, ou histoire* des derniers troubles arrive's au royaume *d'éloquence* (1658); Voyage de Mercure (1653)—won him admission to the French Academy in 1662. When the academicians heard that Furetikre was on the point of issuing a dictionary of the French language, they interfered, alleging that he had used their information, and that they possessed the exclusive privilege of publishing such a book. After much bitter recrimination on both sides the offender was expelled in 1685; but he took his revenge in his satire, *Couches de l'académie* (Amsterdam, 1687). Furetière is best known as the author of Le Roman bourgeois (1666; ed. by Fournier and Asselineau, 1854), which ridiculed the fashionable romances of Madeleine de Scudéry and of La Calprenkde. His *Dictionnaire universel* was posthumously published in 1690. Le Roman bourgeois was newly edited in 1921 with notes by François Tulou. *Poésies* diverses was partially reprinted, after its 1664 edition, in 1908 in Baltimore, Md.

FURFOOZ, a village 10 mi. from Dinant in the Ardennes, Belg. Pop. (1955 est.) 139. Three caves with prehistoric remains were excavated there in 1872. Of these the Trou du Frontal is the most famous. In it were found human skeletons with brachycephalic skulls, associated with animal bones, those of the reindeer being particularly plentiful. People with anthropological characters, similar to the skulls found at Furfooz, seem to have arrived in central Europe soon after the Ice Age. They spread along the Alpine region and adopted the culture of Azilian-Tardenasian folk.

FURFURAL (2-furaldehyde, fural, furfurol) is the best-known member of the furan family and the source of the other technically important furans (*see* FURAN CHEMISTRY). It is a colourless liquid (boiling point 161.7° C.; specific gravity 1.1598) subject to darkening on exposure to air. It dissolves in water to the extent of 8.3% at 20° C., and is completely miscible with alcohol and ether. The chemical formula is C_4H_3O-CHO.

A span of about 100 years marked the period from discovery of furfural in the laboratory to the first commercial production in 1922. The subsequent industrial development provides an excellent example of the industrial utilization of agricultural residues. Corncobs, oat hulls, cottonseed hulls, rice hulls and bagasse are the major raw material sources, the annual replenishment of which ensures a continuing supply. In the manufacturing process, ten-ton lots of the raw material and dilute sulfuric acid are steamed under pressure in large rotary digesters. The furfural formed is removed continuously with steam, and concentrated by distillation: the distillate, on condensation, separates into two layers. The bottom layer, comprising wet furfural, is dried by vacuum distillation to obtain furfural of minimum 99% purity.

Furfural is used as a selective solvent for refining lubricating oils and rosin, and to improve the characteristics of diesel fuel and catalytic cracker recycle stocks. It is employed extensively in the manufacture of resin-bonded abrasive wheels, and for the purification of butadiene needed for the production of synthetic rubber. The manufacture of nylon requires hexamethylenediamine, of which furfural is an important source. Condensation with phenol provides furfural-phenolic resins for a variety of uses. Nitration gives 5-nitrofurfural, which, in the form of its semicarbazone, is the pharmaceutical Furacin, a bactericide with numerous applications in human and veterinary medicine.

When vapours of furfural and hydrogen are passed over a copper catalyst at elevated temperature, furfuryl alcohol is formed. This important derivative is used in the plastics industry for the production of corrosion-resistant cements and cast-molded items. The similar hydrogenation of furfuryl alcohol over a nickel catalyst gives tetrahydrofurfuryl alcohol, from which are derived various esters and dihydropyran.

In its reactions as an aldehyde, furfural bears a strong resemblance to benzaldehyde (*q.v.*). Thus, it undergoes the Cannizzaro reaction in strong aqueous alkali; it dimerizes to furoin, C_4H_3O-CO-CHOH-C_4H_3O, under the influence of potassium cyanide; it is converted to hydrofuramide, $(C_4H_3O\text{-}CH)_3N_2$, by the action of ammonia. It participates in the Perkin and Claisen condensations and related syntheses; with acetone, furfural gives rise to furfurylideneacetone, C_4H_3O-CH=CH-CO-CH_3; with acetaldehyde, it reacts to form furylacrolein, C_4H_3O-CH=CH-CHO. However, furfural differs markedly from benzaldehyde in a number of ways, of which autoxidation will serve as an example. On exposure to air at room temperature, furfural is degraded and cleaved to formic acid and formylacrylic acid. Behaviour similar to that of benzaldehyde would have given rise to furoic acid as the major product under these conditions. To obtain the latter in good yield, it is the practice to oxidize furfural in alkaline medium, the acid being subsequently liberated from the resulting salt. Furoic acid (formerly called pyromucic acid as a consequence of its formation by heating mucic acid) is a white, crystalline solid which is useful as a bactericide and preservative. Its esters are fragrant liquids which are used as ingredients in perfumes and flavourings.

FURIES, from the Latin *furiae,* by which name the Greek Erinyes (q *v.*) were known in Roman literature. The resemblance of name caused occasional confusion with the very ancient, but obscure, Roman goddess Furrina, whose functions and the derivation of whose name are unknown.

FURLONG, a measure of length, originally the length of a furrow in the "common field" system (from the O.E. *furlang, i.e.,* "furrow-long") (*see* LAND TENURE: ECONOMIC AND AGRARIAN ASPECTS). As the field in this system was generally taken to be a square, ten acres in extent. and as the acre varied in different districts and at different times, the furlong also varied. The side of a square containing ten statute acres is 220 yd. or 40 poles, which was the usually accepted length of the furlong. This is also the length of one-eighth of the statute mile. Furlong was as early as the 9th century used to translate the Latin *stadium,* one-eighth of the Roman mile.

FURNACE, ELECTRIC, a device used for heating material to change its state (*e.g.,* to melt it) or its physical, chemical and mechanical properties. In such furnaces electrical energy is converted into heat energy; the heat thus generated is proportional to the resistance encountered by the electric current and to the square of the current passed.

Electric furnaces are commonly classified as resistance, arc and induction types. The resistance medium for the resistance furnace is usually a solid wire. ribbon or rod or sometimes a liquid electrolyte; the resistance medium for the arc furnace is a gas, and for the induction furnace the medium is generally a solid or liquid.

Electric current usually 'does not flow through the material to be heated (*i.e.,* the charge) in resistance furnaces, although in certain electrolytic processes. such as those used in the production of aluminum. the current does flow through the electrolyte. Electric current may flow through the charge in certain arc furnaces, or the current flow may be confined to the gas phase above the charge. Finally, in induction heating electric current generally passes through the charge, except in the case of some melting furnaces in which current flows through the crucible and the charge is heated indirectly.

It is important to note in the study of furnaces that heating usually takes place by a subtle interplay of the three modes of heat transfer — convection, conduction and radiation.

Resistance Furnaces. — Most resistance furnaces are the indirect type—the current does not flow through the charge. Instead, separate resistors, which serve as heating elements, are provided. In furnaces for laboratory use, nichrome, graphite or molybdenum are the most commonly used resistors. Graphite and molybdenum oxidize readily in air and therefore can be used only in a protective nonoxidizing atmosphere, such as helium or oxygen-free nitrogen. Platinum resistors can be used in air but are. of course, expensive. For temperatures up to 1,200' C. (2,200° F.) iron-chromium-aluminum resistors are used; for temperatures up to 1.000° C. (1,832" F.) nickel-chromium is satisfactory. In industrial furnaces, and to a limited extent also in laboratory furnaces. rods and tubes of silicon carbide form satisfactory heating elements for temperatures up to 1,300° C. (2,650° F.), yielding resistor life of several hundred to several thousand hours, according to temperature and kind of service.

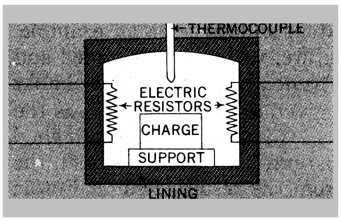

FIG. 1. — RESISTOR FURNACE

Laboratory furnaces usually consist of a refractory tube (*e.g.,* alumina), around which the resistor is wound. Tube and resistor are then embedded in appropriate insulating material, which in turn is held in an outside casing.

Resistor furnaces for industrial use are built in a large variety of shapes and forms. However, all consist essentially of resistors (heating elements) which usually, although not always, are located in the working chamber, electric insulators to support the heating elements, an inside wall, heat insulation and an outside shell. In some instances the electric insulators form part of the inside wall; on the other hand, frequently the inside wall and heat insulation coincide. Fig. 1 is fairly representative of a batch-type unit. However, many indirect heat resistor-type furnaces are provided with conveying means to carry the charge through the furnace; the variety of designs does not permit detailed description here. The majority of furnaces of this type are equipped with automatic temperature control, maintaining the furnace temperature constant within narrow limits.

In the listing of resistor materials one group of materials, fused salts, was not mentioned because it involves a totally different furnace design. In this type of furnace the electric current passes through a molten salt resistance, and heating of the salt bath occurs. In some cases technically pure salts such as barium chloride and potassium chloride are placed in metallic or nonmetallic containers; electrodes are placed in the salt, and the current passing from one electrode to the other provides enough energy to melt the salt. The charge can be placed in the liquid salt bath and heated to the desired temperature. Because of the intimate contact between the molten salt and the charge, heating of the latter is very rapid; moreover, the salt may prevent oxidation of the charge.

A type of direct-heating salt bath is characterized by the electrolytic furnaces used in the production of lithium, sodium, potassium, calcium. magnesium, aluminum, etc. In these furnaces the electrolyte is a fused salt heated directly by the passage of current through it. For example, in the production of aluminum, the fused salt is a mixture of aluminum oxide and sodium aluminum fluoride. During electrolysis of the fused salt aluminum metal collects at the bottom of the furnace on a graphite cathode and oxygen is set free at graphite anodes. Heating of the furnace is accomplished entirely by the passage of current through the resistance of the electrolyte.

Another direct-heating resistance furnace is employed in the production of silicon carbide. The raw materials are placed on a refractory base within a furnace and at each end the charge is connected to one or several electrodes which, in turn, are connected to the power supply. Current flows lengthwise through the charge, which may be several yards in length.

Resistance heating has been in use since the early 1900s and has undergone various developments. Infrared heating, for example, is carried out by exposing the surfaces to be heated to high-temperature sources. Banks of incandescent lamps, preferably with carbon filaments, are frequently used as heat sources; or common resistors (nickel-chromium type) may be designed to reach high temperatures. Infrared heating is useful mainly for rapid heating of surfaces. For example, in order to dry paint (a major field of application) at a temperature of 400° F., heat sources at 2,000° F, or even higher are used, but exposure times are short (from a few seconds to a few minutes).

Arc **Furnaces.**—Arc furnaces are used for melting or refining ferrous (and, occasionally, nonferrous) metals and for the production of refractories and ferroalloys. One important type of arc furnace is the direct arc or open arc, characterized by the Heroult

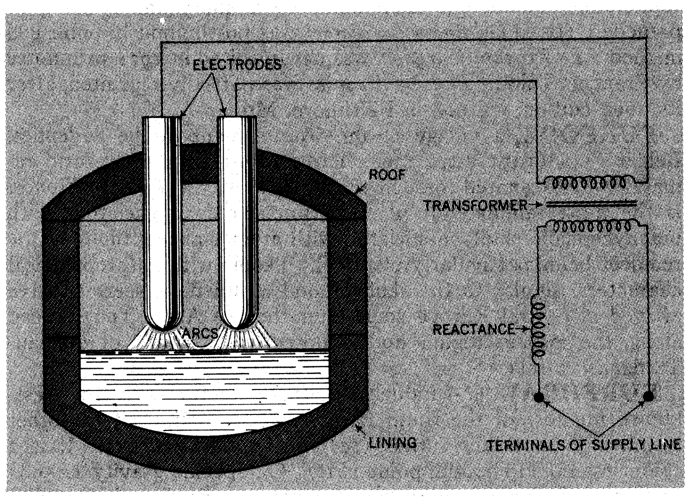

FIG. 2. — ARC FURNACE

furnace in fig. 2. A direct arc furnace consists of a transformer, often a reactance, buses and the furnace proper. In the transformer, voltage is reduced from the supply system to that required by the furnace. The buses, consisting of heavy copper or aluminum bars, connect the transformer to the electrodes. The latter bring the current into the furnace chamber. Electric arcs extend from the tips of the electrodes into the bath.

In the United States electrodes are made exclusively of carbon or graphite rods or bars; in other countries such electrodes find competition with Soderberg, or self-burning, electrodes, consisting of steel sleeves filled with a carbonaceous mass, that are fed continuously into the furnace. The furnace proper consists of a steel shell, lined with a refractory (generally basic magnesite) and covered by a roof. Tapholes permit withdrawal of the molten product as well as the slag and the furnaces can usually be tilted. Charging of the furnace is done either through doors or from the top, after removing the roof.

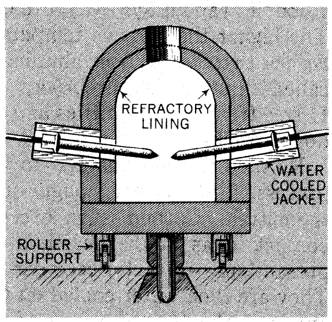

FIG. 3.—STASSANO ROTATING FURNACE

Over the years the size of furnaces as well as the power rating increased, both contributing to a decrease of energy consumption per ton of output. The maximum voltage used in open-arc furnaces for steel production increased gradually to about 300. High voltages make possible high production rates but present a safety problem for the operator and (since high voltage results in long arcs) reduce the life of the furnace roof.

Another type of arc furnace is the Stassano rotating furnace, essentially a cylindrical enclosure with two or three electrodes placed on a horizontal axis and facing each other. The arc is maintained between the electrodes and burns in the centre of the furnace, radiating toward the lining above and the charge below. This type of furnace is illustrated in fig. 3, which shows a vertical section through two of the electrodes. The electrodes are surrounded by water-cooled jackets. Gases from the reactions pass out through a vent in the top and the furnace is provided with a charging hopper and tapping spout (not shown). Slow oscillation of the furnace provides mixing of the charge. This type of furnace originally was used for the smelting of magnetite and hematite but is now built in small units for nonferrous alloys and gray iron foundry work.

Submerged arc furnaces are used for the production of ferroalloys. This type of furnace is illustrated in fig. 4. Transformer and buses are essentially the same as those in open arc furnaces. but the electrodes extend well into the charge, with short arcs playing from the electrode to the nearest parts of the charge and between various particles of the charge. In addition to the types of electrodes mentioned for open arc furnaces. European industry also uses composite electrodes, built of a number of discrete carbon or graphite blocks arranged in rows or cylindrically. The intense concentration of heat creates an odd-shaped reaction zone (see fig. 4). Some furnaces have no lining, the cold, nonmolten material protecting the side walls of the shell. Furnaces frequently do not have covers: and, since gases develop in the reactions involved, flames often may be seen burning around the upper end of the electrodes.

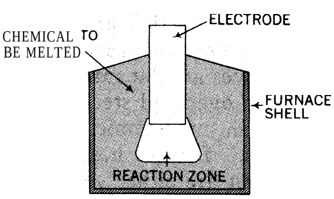

FIG. 4.—SUBMERGED ARC FURNACE

Induction Furnaces.— Furnaces of the induction type depend for their operation upon resistance heating. Although in induction furnaces there is no electrical connection between the electrical supply and the metal in the bath: there is an indirect connection by electrical induction similar to that prevailing in transformers between primary and secondary windings; in fact, induction furnaces may be understood as transformers with the coil as primary and the bath or crucible as a one-turn secondary winding. On the other hand, since heat generation occurs in the charge or in the crucible, induction furnaces are of the direct-heat type. The charge is generally the hottest point in the furnace.

Induction furnaces may be classed broadly into two groups, the core type and the coreless induction furnace. Induction furnaces are used for melting and induction heating appliances for heat-treating. brazing and soldering. Use of induction heating (or melting) is limited to good conduction materials, essentially metals.

Core-type melting furnaces are used almost exclusively in the nonferrous field. Fig. 5 shows a typical cross section. A V-shaped channel penetrates a coil. which is connected to the power supply; both legs of the V issue into a receptacle containing the batch of metal. This type of furnace must operate continuously; when pouring. the furnace is never emptied completely, enough metal being left to form a closed loop. The electromagnetic forces in the melt result in an energetic stirring; the forces are so strong that the same principle—of a liquid conductor surrounded by a coil—has been used successfully to pump hot liquid metals.

Core-type induction furnaces are rarely used for melting steel. For this purpose they have been replaced by coreless furnaces. Mechanically, coreless furnaces are very simple. They consist of a crucible surrounded by a water-cooled coil. the space between crucible and coil being filled with heat insulation. The coil is connected to a high-frequency power source. Up to 10.000-cycles-per-second rotating machinery can be used; beyond that value vacuum-tube generators or spark generators are used. The former make use of vacuum tubes of the same principle as, though larger than, those used in radio. Spark generators use the high-frequency oscillations occurring when a spark discharge across an air gap occurs. In view of the magnetic stray fields, any metal used in the construction of the furnacemould heat up. Hence the outside shells are made of wood, plastic or similar materials. Coreless induction furnaces for melting have been built in sizes up to several tons. When melting a nonconducting material. a conducting crucible (*e.g.,* graphite) which transfers heat to the charge may be used. Theoretically there is no limit to the temperature which can be reached in a coreless induction furnace. Practically, temperatures beyond 1,500° C. are hard to achieve.

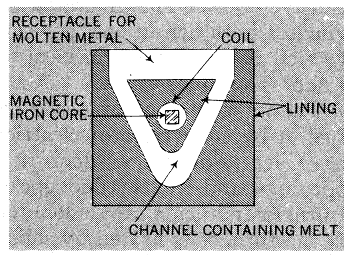

FIG. 5.—CORE INDUCTION FURNACE

As noted above, induction heating is used not only for melting purposes but also for heat-treating and brazing. The very rapid temperature rise, taking only seconds and occasionally only fractions of a second, and the possibility of localizing the points of heat generation are two of the main reasons for the rapid development of this technique. The arrangement is simple: a high-frequency power generator? of the same general type but normally of smaller rating than the generators used in melting furnaces. is connected to a water-cooled copper coil. The shape of the coil matches that of the piece to be heated. In view of the rapid temperature increase, control is frequently by time: power is disconnected after a preset length of time.

Because of the nature of energy transfer by induction (from the coil to the heated object). only a thin layer next to the surface is heated, the thickness of the layer decreasing with increasing frequency. From this shallow layer of heat generation heat is conducted to the inside of the piece. Basically in the same manner, but in technical execution quite different, induction heating at supply line frequency (50 to 60 cycles per second) can be used for raising the temperature of chemicals in pipes, bottles or other containers.

As stated, induction heating is applicable only to good conductors of electricity. Frequently confused with this method is one applicable only to very poor conductors, called dielectric heating. Fig. 6 shows schematically the arrangement for such heating. The piece to be heated is placed between two metal pieces, the electrodes. The latter must not touch the material. The electrodes are connected to a high-frequency (*e.g.,* 500.000 cycles per second) power supply. operating usually at more than 1,000 v. Under the influence of the high-frequency field, ,small (technically called "displacement") currents flow in the material, heating the latter, the heat being proportional to the electric resistivity of the material. This method of heating is used widely in the manufacture of plastic objects and finds increasing use in the curing of rubber and the drying and glueing of wood. See also HIGH-FREQUENCY HEATING.

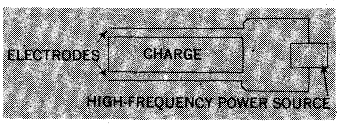

FIG. 6.—SCHEMATIC ARRANGEMENT FOR DIELECTRIC HEATING

FURNACE, METALLURGICAL. A metallurgical furnace is a structure in which a temperature in excess of 1,000° F. (about 540° C.) can be maintained without serious damage to the walls and in which one of the following operations can be performed: (1) the heating of solid pieces of metal to various temperatures in different atmospheres; (2) the melting of metals for making castings; (3) the extraction or reduction of metals from their ores; (4) the refining of metals; (5) the distillation of metals; (6) the roasting of metallic ores; (7) the carburization of steel; and (8) the brazing of metals.

In metallurgical practice, a structure that is designed for a temperature between 600° F. (about 300° C.) and 1,000° F. is called an oven. A furnace or an oven is called a kiln if a gas or vapour is driven off the solid material being heated. The term coke oven violates both definitions, however, because in the making of coke (which is not a metallurgical process) the temperature rises to 1,800° F. (almost 1,000° C.) and gases and vapours are released.

The interior of a furnace is heated either by the combustion of fuel or by conversion of electrical energy into heat. All furnaces have access-openings (doors). A fuel-fired furnace has burner openings and vents (flue openings), usually in the side walls. Burners and vents are seldom located in the hearth or in the roof. If the furnace is heated by solid fuel that burns on a grate, a firebox is provided, which is separated from the hearth by a bridge wall.

If the charge remains in the same spot during the metallurgical operation, the furnace is called a batch furnace. If the charge moves progressively, the furnace is continuous. If solid pieces of metal are heated, the hearth is plane, horizontal or slightly inclined. If metals are smelted or refined on a hearth, the hearth is concave and is equipped with a taphole and a spout. The taphole is poked open at regular intervals or at the end of the operation. Furnaces with concave hearths are usually flame heated and are called open-hearth furnaces, reverberatory furnaces and (rather inaccurately) air furnaces. The term reverberatory arose from the fact that products of combustion transmit a large portion of their heat to the vaulted roof of the furnace, whence the heat is reflected (reverberated) to the hearth. Metals also are refined in externally heated pots, or crucibles, and in shaft furnaces that are charged at the top, the processed material being withdrawn at the bottom.

A furnace in which air or oxygen is blown into and through molten metal is called a converter. Underground furnaces in which long pieces are heated in a vertical position are called pit furnaces.

If the charge is in contact with the products of combustion, the furnace is said to be direct fired. In a muffle furnace, a separating nall lies between charge and products of combustion. Either the charge or the flame can be inside the muffle. If the flame is inside, the muffle is called a radiating tube.

Materials and Elements of **Construction.**—Furnaces are built of refractory material. of heat resisting metals and of metals cooled by air or water. The great majority of the refractories are oxides, such as silica, alumina, magnesite, dolomite, chromite and zirconia. Fire clay is a mixture of silica and alumina, with impurities that soften the bricks at high temperatures. Silicon carbide (which is not an oxide) has a high strength at elevated temperatures, but both silicon and carbon burn in oxidizing atmospheres if the protective skin of silica flakes off. The ideal refractory material has a high compressive strength at furnace temperature, a low thermal conductivity and a low coefficient of expansion. Refractory insulating bricks approach this ideal. These bricks, which are often called lightweight firebricks, are used up to 2,400° F. (about 1,300° C.). They resist temperature, but are destroyed by slags. Lightweight bricks have a lower compressive strength than dense bricks. Difficulties with refractories increase with temperature, with superimposed load and with chemical attack by liquids and gases. For heating solid metal up to 1,600° F. (about 870° C.), fire clay of medium quality is adequate. The higher the furnace temperature, the purer the clay must be. Bricks that are rich in alumina and low in impurities, formerly called "first quality firebrick," are known as "high-duty" bricks. If free from any impurities and very dense, they are called "superduty" bricks.

Refractories are adapted to the chemistry of the metallurgical process. Silica is acid; magnesite and dolomite are basic; chromite is neutral. Carbon is an excellent refractory if no oxygen can contact it, as in the hearth of a blast furnace. In spite of all precautions, refractories wear away under extreme conditions. They are then water-cooled on the outside of the furnace. An example is the blast furnace of the steel industry. Its hearth is built of bricks that are water-cooled. When the furnace is shut down for relining, no trace of the bricks remains; they have been worn away and replaced by frozen slag. In the upper part of the blast furnace (for making pig iron), the walls are subjected to abrasion by ore and coke and to infiltration of carbon monoxide, which breaks up ($2\,CO = CO_2 + C$) at decreasing temperatures. Pressure by solid carbon disintegrates the brick. For both reasons. a hard and dense special brick is used.

Refractory bricks are available in many standard sizes and shapes. Special shapes, especially large tiles, are expensive and liable to crack during the burning process. (See also FIREBRICK.)

Depending upon furnace temperature, muffles are made of alloy steel, fireclay or silicon carbide. Whenever conditions permit, furnaces are insulated by insulating bricks, powder or cement.

In furnace walls, expansion and contraction are not reversible. Unless bound together, a furnace will become leaky and finally collapse. For that reason, furnaces are bound by structural material. The vertical members are called buckstays; the horizontal members are called tie rods. If a furnace is to be gastight, it is enclosed in heavy steel sheets.

Most furnace roofs are arches that are built up from arch bricks and straight (constant thickness) bricks. Roofs that are arched in two directions (turtleback arches) are rare except over electric-arc furnaces. Roofs on large heating furnaces are flat rather than arched. The roof tiles are suspended from overhead steel beams. The suspension members are either metallic or ceramic.

Because concrete is disintegrated by heat, furnace hearths are not set directly on concrete foundations, but are either ventilated by air passages (between hearth and foundation) or set on thick slag fills.

Furnace Stacks.—Metallurgical furnaces for roasting or smelting develop dust and gases. In densely populated sections, nonpoisonous dust is removed by filters or electric precipitation. Poisonous gases, such as sulphur dioxide, can be converted at high cost into commercial products. As a rule, these gases are discharged at the tops of stacks several hundred feet tall, where wind velocity is many times greater than it is near the ground. When the gases reach the ground, miles away from the stack, they have diffused and are so diluted that they are not injurious.

Fuels.—Coal and coke are the usual solid fuels. In shaft furnaces for reduction of metal and in cupolas, solid fuel is a necessity. For metallurgical operations performed on hearths, solid fuels burning on a grate have been replaced by powdered coal and by gaseous or liquid fuels, where available. Flame control with solid fuels burning on a grate is poor and the labour cost is high, even if mechanical stoking is employed. Finely powdered coal

(95% through a sieve of 200 meshes per inch) is burned in large furnaces if the ash causes little trouble. Ash does no harm if it drops on a slag bath or an ash-cover in the furnace, but fly ash clogs ducts and wears nearby machines.

Early in the 20th century. coal was extensively gasified in gas producers; it is still so gasified to producer gas where more convenient fuels are not generally available. Producer gas has a low heating value; it contains soot. tar and dust. Its composition varies, and the gas ducts between producer and furnace must be burned out each week end. (See GAS INDUSTRY.)

In integrated steel works, blast furnace gas, coke-oven gas, tar and pitch are the principal fuels. In most other furnaces, powdered coal, natural gas, fuel oils and city (manufactured) gas are burned.

Fuel consumption per unit weight of processed metal varies within wide limits. If a component of the charge is burned in the process, the so-called fuel consumption may be zero. In some other processes, it is very great. In the blast furnace (for making pig iron) from 0.8 to 1.0 lb. of coke is required to make a pound of iron.

Electrical energy is utilized for metallurgical furnaces in three ways. In one method, electric heating elements (resistors) are fastened to the walls and the roof of the furnace. Metallic resistors are useful up to 1,900° F. (about 1,040° C.) furnace temperature. Resistors of silicon carbide are useful up to 2,500° F. (about 1,370° C.). In a second method, electric current passes through the charge, which then becomes a resistor and is heated by the current. This method is applied to both solid and liquid metals. In a third method. alternating current flowing in a coil induces eddy currents in the metal that is encircled by the coil or closely surrounds the coil. The eddy currents heat the metal. Metallic objects of less than 1¼-in. thickness are induction heated without being enclosed in a furnace.

See also FUELS; FURNACE, ELECTRIC.

Furnaces for Heating Solids on Hearths. — If metallic solids are heated on a hearth or on a support immediately above the hearth, the furnaces are used for annealing or heating for carburizing, quenching, drawing (tempering), rolling or forging. Most of these are tube furnaces and are continuous (see ANNEALING). The charge is pushed through the furnace, either directly or while resting on trays, or is carried through the furnace on a rotating hearth. In other furnaces, the charge rests on live (driven) rollers, or on traveling chains, or on belts of woven wire. Shaking hearths and vibrating hearths also transport the charge through the furnaces. Metallic objects are also heated while suspended in furnaces. At temperatures approaching 2,300° F. (1,260° C.), strength of the means of suspension is of concern. If the furnace is continuous, tightness of the strips that cover the slot in the roof is very important.

Bright sheet strip and machined parts are heated in protective atmospheres to prevent discolouration and oxidation. Most protective atmospheres are prepared by partial combustion of a hydrocarbon. such as natural gas, in separate furnaces, and by removing water vapour and carbon dioxide from the products of combustion. Furnaces with protective atmospheres are heated either by electric resistors or by radiant tubes. Infiltration of air is prevented by furnace pressure and by vestibules at entrance and exit doors. "Atmosphere" furnaces, including vacuum furnaces, are enclosed in airtight steel shells.

Metal heating furnaces are precision heating machines with automatic transportation of the charge and automatic control of furnace pressure, temperature and atmosphere.

Shaft Furnaces. — In these furnaces air rises in the shaft and burns the fuel, which is either coke or sulphur, or both. As a rule. air is blown into the shaft near its bottom. The required air pressure depends upon the height of the shaft, fineness of charge and rate of air flow desired per unit of cross-sectional area of shaft. Most shaft furnaces, such as the cupola which remelts iron in foundries, are cylindrical; but if the charge tends to hang to the walls and to vault, the shaft is conical, wide end down. Despite this precaution, "hanging" occurs occasionally in a blast furnace for smelting iron. The blast pressure then rises up to 30 lb. per square inch gauge. The air that is blown into cupolas or roasting furnaces is usually cold, but fuel economy requires that the air for iron blast furnaces be preheated. Beginning about 1945, the blast pressure was increased in some furnaces by throttling (restricting) the outflow of gases at the top. The throughput of blast furnaces is increased by this measure. Blast furnaces for smelting iron are about 100 ft. tall and have hearth diameters up to 28 ft. They produce up to 1,200 tons of pig iron in 24 hours. Furnace height, blast pressure and blast temperature can be reduced if the blast is enriched with oxygen.

hlultideck (or multihearth) furnaces also are shaft furnaces. They consist of from 8 to 12 circular hearths (up to 25 ft. in diameter) on top of one another. Alternately, the hearths have drop holes at the rim and near the center. A vertical shaft moves rabble arms which are so shaped that they move the ore alternately in and out. The size of the drop holes is critical: if too small, dust fuses on the underside of the hearth above; if too large, the roaster runs cold.

Some hood furnaces resemble shaft furnaces. Coils of strip sheets that are to be bright annealed are stacked on top of one another and are covered by a metallic hood, through which a protective gas is circulated. The hood is surrounded by a cylindrical furnace.

Flame Furnaces. — This term includes all those furnaces in which a flame passes horizontally over the charge that is melted on a dished hearth. Flame furnaces are called open-hearth furnaces when used for the production of steel, reverberatory furnaces when used for the production of copper and nickel, and air furnaces nhen used to melt scrap cast iron. The dished hearth is made so dense and impervious by fusion that the heavy molten metal cannot penetrate into and through it. At the slag line, the walls are built of a material that resists chemical attack by the slag (silica for acid slags or chrome-magnesite and dolomite for basic slags).

Silica bricks are strong at high temperatures. For that reason, silica roofs are common even in furnaces with basic slags, although the silica is gradually worn away by vapours and spittings from the bath. Chrome-magnesite bricks last longer in basic processes, but (in most industrial districts) are more expensive.

Open-hearth furnaces are of the batch type. Reverberatory furnaces are continuous. The ore concentrate is fettled (charged) through lateral openings in the roof. Slag overflows continuously at one end, and metal is tapped at intervals at the deepest part of the bath.

With a few exceptions, the reaction heat released by the process does not suffice to maintain reaction temperature. In furnaces of this type, fuel is burned above the charge. Depending upon the required furnace temperature, the fuel is burned either in cold air or in preheated air. Air temperatures up to 1,300° F. (about 6j0° C.) are obtained in metallic recuperators, which are heat exchangers with a metallic wall between outgoing products of combustion and incoming air. Higher air temperatures up to 1,800° F. (about 980° C.) preferably are attained in regenerators, which are brick-filled chambers through which air and hot gases flow alternately in opposite directions. The result is that flame also flows through the furnace alternately in opposite directions. Direction of flow is controlled by reversing valves.

Since 1942, oxygen has been blown, through lances, into the bath of open-hearth furnaces. This is done in the latter part of the refining period. when the slag reactions are slow.

The first open-hearth furnace for steel (c. 1870) held five tons of metal. In the second half of the 20th century the standard size in steelworks was a50 tons, and furnaces of up to 600 tons capacity were in operation.

In flame furnaces for the reduction and refining of metals, wear by chemical action at high temperatures is so rapid that the furnaces must be rebuilt at regular intervals.

Crucible Furnaces. — For many years, steel of high quality was produced in crucibles, mhich are pots of refractory material. Crucibles of graphite or of high grade fire clay were heated by the products of combustion of preheated producer gas and preheated air. Since about 1932, steel of highest quality and other metals have been refined in evacuated crucibles heated by induction. Crucible and ingot mold are then integral. The alloy is both melted and poured (by tilting) in vacuo. Metals such as titanium, which must be free from bases, are melted and annealed in hermetically sealed pots or crucibles.

Crucible furnaces for remelting nonferrous metals are of simple design. The crucible rests upon a support in a cylindrical furnace into which a flame is projected tangentially. (See also CRUCIBLE STEEL.)

Converters. — Converters are refractory-lined vessels into which a molten metal is poured for the purpose of changing the composition of the metal by burning undesirable elements and removing them in gaseous form. This aim is reached by blowing either air or oxygen into and through the metal. Converters are bottom-blown, side-blown or top-blown. In steel works practice, the air enters from the windbox (under the hearth or bottom), and flows upward through many small openings (tuyères), the total area of which is less than 1% of the hearth area. In the blouing of steel, the air pressure ranges between 20 and 26 lb. per square inch gauge. If the pressure is too low, the air rises in bubbles, containing improperly utilized oxygen. If the air pressure is too high, too much of the metal is thrown out, in the shape of pellets, through the mouth of the converter. The reactions are most intense immediately above the bottom, which wears away quickly. Converters rest in two trunions; they are tilted for receiving and for discharging metal. Bottom-blown converters must have, on one side, a pouch that holds the charge in the inclined vessel, without the metal's spilling out of the mouth or flowing into the tuyères. Blowing begins before the vessel is righted. In converters constructed since 1950, oxygen is blown into the bath from above, through a central pipe. Converters in steel works range from 1j to 50 tons holding capacity. Small steel converters are usually side-blown.

Converters in the metallurgy of copper and nickel are side-blown cylindrical vessels, with an average size of 13 ft. in diameter and 30 ft. in length, having from 46 to 52 tuyères of $1\frac{1}{2}$ inch diameter. The air pressure is 14 lb. per square inch (gauge).

Depending upon the nature of the charge, converters are lined with acid (silicious) material, or with basic (dolomite) material. (See also CONVERTER STEEL.)

Electric Arc Furnaces. — Electric furnaces for making alloy steels are round or elliptical boxes, through the roofs of which carbon electrodes reach down to the charge. Electric arcs, combustion of the electrodes and heat generated by the current in the charge bring the charge up to reaction temperature and supply reaction heat. When the process has been finished, the furnace, including electrodes, is tilted. The electrodes are moved in and out automatically to maintain the current near a predetermined value. A transformer located close to the furnace is connected to the electrodes by heavy flexible cables. In steel making, electric furnaces have taken the place of crucible furnaces and of small open-hearth furnaces. Because heat is generated directly in the charge under the slag cover, the roof is protected so that higher temperatures can be obtained in the bath than in crucible or open-hearth furnaces.

Electric furnaces using direct current serve in the production of aluminum. Carbon electrodes reach down into a bath of molten salts (cryolite), which lies in a carbon-lined tank. Liquid aluminum collects on the carbon lining and is withdrawn at regular intervals through a taphole. Such furnaces are electrolytic cells operated at high temperature.

Salt Bath Furnaces. — Salt bath furnaces are containers filled with molten salts, the composition of which is such that the salt is liquid at the desired temperature. These furnaces heat fine tools uniformly and, in many cases, saturate the surface of the charged pieces with carbon and nitrogen, for imparting hardness after quenching. Low-temperature salt baths lie in suspended iron pots that are externally heated. High-temperature salt baths are contained in refractory pits, which are usually heated electrically through electrodes that dip into the bath. Some salt baths are flame heated from above.

Retort Furnaces. — Easily volatilized metals such as mercury, magnesium and zinc are produced in slightly inclined retorts that project outside the furnace at one end. The vapourized metals condense in the cold zone. Burners must be so arranged that all retorts reach the same required reaction temperature. Too low a temperature reduces the yield of metal; too high a temperature shortens the life of the retorts.

Recirculating Furnaces. — If metallic objects are to be heated to a uniform specific temperature below 1,500° F. (about 800° C.), fuel is burned in a separate combustion chamber. When leaving this chamber, the products of combustion mingle with other products that have already passed through the heating chamber. Circulation is obtained by mechanical means. The charge is safe from local overheating. For temperatures below 1,000° F. (about 540° C.), these furnaces are really ovens. They are often called air furnaces.

Tower Furnaces. — Strips of steel sheet and tin plate are delivered from the cold mill at speeds that exceed one mile per minute. Continuous bright annealing at a corresponding rate of speed requires a long time in the furnace, for heating, holding at temperature, and cooling, all in a protective atmosphere. The long time period is obtained in special furnaces by passing the strip up and down several times over graphite rollers, between heaters and, finally, between coolers. These furnaces are as tall as 40 ft.— hence the name "tower furnace."

Other Furnace Types.--Furnaces that do not fit into any classification appear from time to time. An example is the electric-arc crucible furnace with inert atmosphere (including vacuum). The walls are water-cooled copper; an induction coil is provided for stirring the molten metal and the bottom of the crucible is removable for dropping the ingot after solidification.

Laboratory and Portable Furnaces. — Most laboratory furnaces use gas, oil or electricity as the heating medium. The furnaces are small copies of the muffle, tube and crucible types. Small portable assay furnaces, using coke or coal and arranged so that they can be used either as muffle or crucible furnaces, are frequently used in situations where other methods of heating are not available, as in prospecting.

FURNABIIDAE: see OVENBIRD.

FURNEAUX, TOBIAS (1735–1781), English navigator who introduced domestic animals and potatoes into the South sea islands, and who made the earliest British chart of the south and east coasts of Tasmania. He was born at Swilly, near Plymouth, on Aug. 21, 1735.

Furneaux entered the Royal Navy, and was employed on the French and African coasts and in the West Icdies during the latter part of the Seven Years' War (1760–63). He served as second lieutenant of the "Dolphin" on her voyage around the globe (Aug. 1766–May 1768), and commanded the "Adventure" which accompanied Captain James Cook on his second voyage. On this expedition Furneaux was twice separated from his leader; the first time he explored a great part of the south and east coasts of Tasmania. Most of the names which he gave to the features observed survive, and Cook, on his third voyage, named after Furneaux the islands in Banks strait, the opening into Bass strait, and some islands of the group now known as the Low islets. After the "Adventure's" final separation from the "Resolution" off New Zealand in Oct. 1773, Furneaux returned home alone, bringing with him the first South sea islander seen in the British Isles, Omai of Ulaietea, who returned to his home with Cook in 1776–77. Furneaux was made a captain in 1775, and commanded the "Syren" in the British attack of June 28, 1776, upon Charleston, S.C. He died at Swilly on Sept. 19, 1781.

See J. Hawkesworth, *An Account of the Voyages undertaken . . . by Captain Wallis,* etc., 3 vol. (1773).

FURNES (Flem. VEURNE), an old-fashioned little town amid the dunes near the coast in West Flanders, Belgium, about 26 mi. S.W. of Bruges. Pop. (1955 est.) 7,297. It is the centre of a considerable area extending to the French frontier, and its market is an important one for the disposal of corn, stock, hops and dairy produce. During the Norman raids Furnes was destroyed, and the present town was built by Baldwin Bras de Fer, first count of Flanders, about the year 870. In the 14th century the barony of Furnes owned 52 rich villages; but these have all disappeared, partly because of French invasions down to the end of the 18th century, but chiefly through encroachment of the sea followed by accumulation of sand. Furnes contains a market place with many curious old houses and the church of St. Walburga, which is a fine survival of the 13th century with some older portions.

Near Furnes on the seashore is the fashionable bathing place called De Panne. On the last Sunday in July the *fête* of Calvary and the Crucifixion is celebrated. Of all popular festivities in Belgium this is the nearest approach to the old Passion play.

FURNESS, HORACE HOWARD (1833–1912), U.S. Shakespearean scholar, was born in Philadelphia, Pa., Nov. 2, 1833, the son of William Henry Furness (1802–96), minister of the First Unitarian church in that city. He graduated from Harvard in 1854 and was admitted to the bar in 1859 but soon devoted himself to the study of Shakespeare. He accumulated a collection of illustrative material of great richness and extent and brought out in 1871 the first volume of a new variorum edition, designed to represent and summarize the conclusions of the best authorities in all languages — textual, critical and annotative. The volumes appeared as follows: *Romeo and Juliet* (1871); *Macbeth* (1873; revised by his son, 1903); *Hamlet* (2 vol., 1877); *King Lear* (1880); *Othello* (1886); *The Merchant of Venice* (1888): *As You Like It* (1890); *The Tempest* (1892) ; *A Midsummer Night's Dream* (1895); *The Winter's Tale* (1898); *Much Ado About Nothing* (1899); *Twelfth Night* (1901); *Love's Labour's Lost* (1904); *Antony and Cleopatra* (1907); and *Cymbeline* (1913). For his first volumes he made an independent text, but beginning with *Othello* he used the first folio.

Few U.S. scholars have shown such single-hearted devotion to a formidable task, and few have so brightened erudition with gentleness, sanity and humour. Furness was conservative in his methods but sound in his judgments. He died at Wallingford, Pa., on Aug. 13, 1912. His wife, Helen Kate Furness (1837–83), compiled *A Concordance to the Poems of Shakespeare* (1874); and his son and namesake (1865–1930) was a partner in and successor to his father's work.

Furness' *Letters* were edited by his son in 1922.

FURNESS, a district of Lancashire, Eng., separated from the major portion of the county by Morecambe bay, though once easily accessible over the sands at low tide. It is bounded by Morecambe bay, the Irish sea, the Duddon estuary, Cumberland and Westmorland. Its area is about 230 sq.mi. It forms part of the Morecambe and Lonsdale parliamentary division of Lancashire and contains the county borough of Barrow-in-Furness (*q.v.*). Except for a coastal strip the surface is almost entirely hilly and contains such eminences as the Old Man of Coniston and Wetherlam.

Apart from the Duddon, the principal rivers are the Leven (which drains Windermere) and the Crake (which drains Lake Coniston). They flow into a common estuary in Morecambe bay. Furness is nearly all included in the Lake District National park. Roudsea Wood Nature reserve was the first one to be declared within an English national park. It covers 287 ac. about 10 mi. W. of Grange over Sands. Several of the place names are suffixed with that of the district, as Barrow-in-Furness, Dalton-in-Furness, Broughton-in-Furness. Between the Duddon estuary and Morecambe bay lies Walney Island, 8 mi. long and 1 mi. wide, connected by a bridge to the mainland. The southwestern part of Furness is rich in iron ore, which has been worked from early times. Production reached its peak in the 1880s after which it declined. It was because of the existence of this ore that Barrow grew in the 19th century, at first as a port from which the ore was exported to south Wales, while later furnaces were established on the spot, but now they depend upon ore imported from abroad.

Furness has an especial interest because of its famous abbey, the ruins of which, beautifully situated in a wooded valley to the north of Barrow, are extensive and mainly of fine transitional Norman and Early English date. The abbey of Furness, dedicated to St. Mary, was founded and built of fine red sandstone in 1127 by monks of the Benedictine order of Savigny in France. In 1124 they had settled at Tulketh, near Preston, but migrated in 1127 to Furness.

In 1148 the brotherhood joined the Cistercian order. Stephen granted to the monks the lordship of Furness, and his charter was confirmed by Henry II and subsequent kings. The abbot's power throughout the lordship was almost absolute. He had a market and fair at Dalton. The abbey became one of the richest in England and was the largest Cistercian foundation in the kingdom. At the dissolution of the monasteries its revenues alone amounted to between £750 and £800 a year. The abbot was one of the 20 Cistercian abbots summoned to the parliament of 1264 but was not cited after 1330. The abbey founded offshoot houses, the most important being Rushen abbey on the Isle of Man. In 1535 the royal commissioners reported four of its inmates, including the abbot, for incontinence; in 1536 the abbot was charged with complicity in the Pilgrimage of Grace and on April 7, 1537, surrendered the abbey to the king.

In 1540 the estates and revenues were annexed to the duchy of Lancaster. About James I's reign the site and territories were alienated to the Prestons, from whom they descended to the dukes of Devonshire.

Conishead priory, near Ulverston, an Augustinian foundation of the reign of Henry II, has left no remains, but of the priory of Cartmel (1188), 6 mi. E., the fine church is still in use. It is a cruciform structure of transitional Norman and later dates, the design of the tower being unique in England. The chancel contains some superb Jacobean carved oak screens.

FURNISS, HARRY (1854–1925), British caricaturist and illustrator, best known for his political and social lampoons, was born at Wexford, Ire., March 26. 1854. Mainly self-taught, he settled in London in 1873 and, before turning wholly to free-lance work in 1894, became very popular as a staff artist on the *Illustrated London News* (1876–84) and *Punch*. In his parliamentary cartoons he never used the distortions of the Rowlandson-Gillray tradition, but drew in the less savage tone of a Richard Doyle or a "Phiz," rather emphasizing idiosyncrasies of face and dress: an amusing example is the strip cartoon "Getting Gladstone's Collar Up." He also designed a famous commercial "tramp" poster for a brand of soap ("I used your soap two years ago since when I have used *no other!"*). Strongly critical of the Royal Academy, he held in 1887 an exhibition of parodies of the work of leading Burlington House exhibitors. and in 1890 published *Royal Academy Antics*. He illustrated many books. including Lewis Carroll's *Sylvie and Bruno* (1889) and complete editions of Dickens (1910) and Thackeray (1911). In 1912–13 he worked as a film writer, actor and producer for Thomas Edison in New York and London; *Our Lady Cinema* (1914) outlined his hopes for that art. He also appeared as a novelist, essayist and writer of art instructional manuals. He died at Hastings, Sussex, on Jan. 14, 1925.

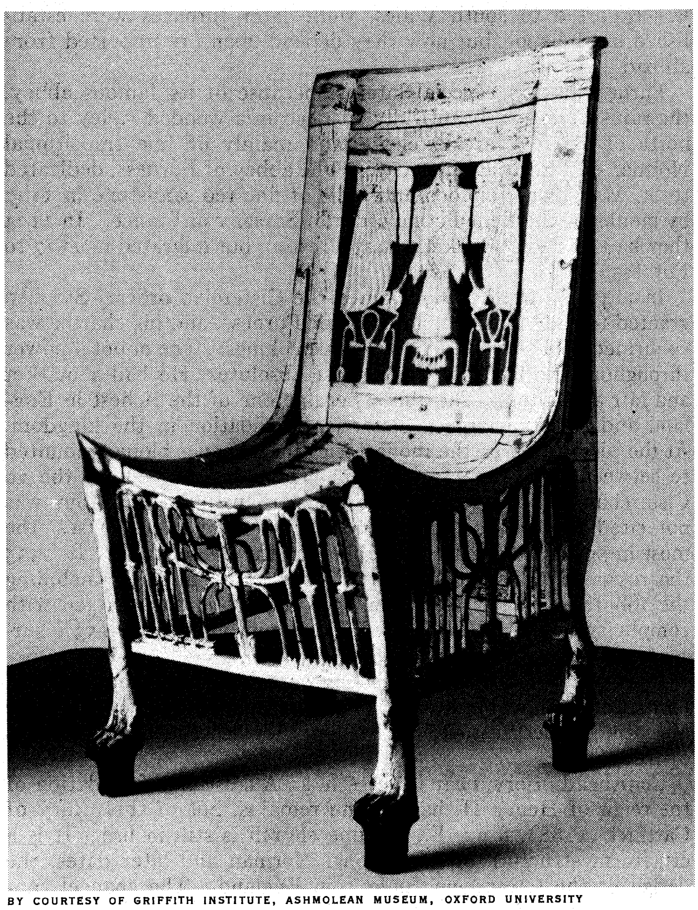
See H. Furniss, *Confessions of a Caricaturist,* 2 vol. (1901).

FURNITURE. In this article the furniture of Egypt, Greece and Rome, China, India, Europe and America is described in its development through the ages.

The article INTERIOR DECORATION is similarly treated to complete the picture of the interiors of houses in different parts of the world from the earliest times.

ANCIENT CIVILIZATIONS

Egypt. — The bed was perhaps the earliest piece of furniture. It consisted of a wooden framework raised on four legs which were often carved; soft flax cord, plaited, was lashed to the four sides of the framework and formed a springy surface for the sleeper to



BY COURTESY OF GRIFFITH INSTITUTE, ASHMOLEAN MUSEUM, OXFORD UNIVERSITY

EGYPTIAN CARVED WOODEN CHAIR FROM THE TOMB OF TUTENKHAMON (14TH CENTURY B.C.), THEBES

lie on. In the 18th dynasty (c. 1587–1375 B.C.) beds sloped up toward the head, a painted or carved wooden footboard preventing the sleeper from slipping down. The great beds found in the tomb of Tutenkhamon were put together with bronze hooks and staples so that they could be taken to pieces for convenience of carriage. In the same tomb was a folding wooden bed with bronze hinges which was probably for the use of the Pharaoh on his tours of inspection. Pillows were not used; in their stead were wooden or ivory headrests. These were so essentially individual, being made to the measure of the owner, that they are often found in tombs to be used by the dead man on his arrival at the land of eternity. A folding headrest was evidently for the use of a traveller.

Early stools were merely squared blocks of stone, probably required only for ceremonial purposes by a people accustomed to squatting on the ground. When made in wood the stool had a flat seat covered with a soft cushion. In time the stool developed into the chair by the addition of a back and arms; the legs were held in position by crossbars, but in the 18th dynasty angle pieces of acacia wood also fastened the seat to the legs; such angle pieces had been artificially forced to grow at right angles and were therefore exceptionally strong. Footstools were of wood. The royal footstool was painted with the figures of the two traditional enemies of Egypt so that the Pharaoh might symbolically tread down his enemies under his feet.

For keeping clothes or other objects, boxes or baskets were used, the boxes being often elaborately painted. Tables were almost unknown, a pottery or wooden stand supporting a flat basketwork tray held the dishes for a meal, and the stands which held the great pottery jars which contained the drinks—water, wine or beer—were also of wood. Wooden furniture was usually put together by dovetailing or with dowels of acacia wood.

Ewers and basins of pottery or metal were probably in use in every household. for where meals are eaten with the fingers hand-washing is essential before and after a meal. Of the 22nd dynasty (*c.* 952–749 B.C.) is a silver "antisplash" basin, evidently part of the travelling equipment of a Pharaoh. (M. A. M.)

Greece and Rome.—Knowledge of the furniture of the Greeks and Romans is obtained from various sources including literary descriptions. representations of chairs, tables, etc.. on sculptured reliefs, vase paintings and other works of art, and from the few actual pieces of furniture which still survive.

In ancient homes the couch, used for reclining on by day and as a bed at night. held an important place, and the earliest couches probably consisted of a mattress on a simple framework on four legs nith a solid seat or with the latticework of cords or leather thongs which persisted into Roman times. The legs occasionally imitate those of animals with claw feet or hooves, but usually they are either turned on the lathe and ornamented with mouldings, or they are rectangular and decorated in various ways, either with incised designs or with volutes, rosettes and other patterns in high relief. From about the 6th century B.C. onward the legs project above the couch frame and these projections become the head-boards and footboards, the latter being lower than the headboards and developing at a later date. In Hellenistic times headrests and footrests are curved and decorated with bronze medallions carrying busts of children or satyrs or heads of birds and animals in high relief. Turned legs now largely replace rectangular ones. While a bronze bed of 2nd-century B.C. date has been found at Priene (Samsun) and marble couches sometimes occur in tombs, wood was the usual material, the legs being sometimes encased in bronze mouldings and having metal feet and the rails covered with bronze sheathing. Couches of the same type were used in the early Roman empire, and remains of several examples with these bronze fittings have been found at Pompeii. Gold. silver, tortoise shell. bone and ivory were also used for decoration, with veneers of rare woods. Late couches found in Italy and in many parts of the empire are characterized by the high back and sides which replaced the earlier headrests and footrests.

From the Greek archaic period onward many varieties of individual seat are known, the most imposing, perhaps, being the high-backed thrones of wood or marble. elaborately adorned. Like the couches, they are supported on rectangular or turned legs or legs with animal feet, and they frequently have arm rails. Another type of throne, with or without back and with a boxlike seat and no feet, is also found. and in the Roman period this develops into a small armchair with solid rounded back made in one piece with the sides. set on a rectangular or semicircular base. This armchair was often of wickerwork, as well as of wood or stone. There was also the popular Greek *klismos*, a lighter chair with slightly curved back and plain curved legs, which turned into the more substantial Roman *cathedra.* The *diphros,* a stool standing on four turned legs, was another long-lived favourite, and from works of art it is known that the Romans developed a yet more decorative type of stool, probably made of bronze, with curved legs ornamented with scrolls. The convenience of the folding stool was also realized at an early date and the crossed legs are sometimes connected by stretcher bars, while in another form of this stool they terminate in hooves or claw feet. The variety with straight legs became the *sella curulis* of the Roman magistrate, but it also continued in domestic use and remains of actual folding stools are known from such sites as Ostia. It., and the British barrow burials at Bartlow, on the Essex-Cambridgeshire border, and Holborough, Kent. The stool with animal feet developed more solid legs with a double curve. and examples of it have come to light at Pompeii. An iron stool of this type with bronze decorations found at Nijmegen, Neth., belongs to a still more substantial form of this cross-legged stool which may not have always folded up

Greek tables were usually small and easily portable and included an interesting type with an oblong top supported by three legs, two at one end and one at the other. These legs usually tapered from the top and ended in claw feet, and the bronze and stone examples, which are occasionally found. show carved flutings on the front of the legs and scroll ornament at the side below the table top. Rectangular tables with four legs were also used and in the Roman period largely replaced the three-legged variety.

Round-topped tables with three legs of animal form became increasingly popular from the 4th century B.C. onward. A nearly complete wooden table, found in Egypt and now in the Musée du Cinquantenaire. Brussels, is decorated with swans' heads with graceful necks rising out of a band of acanthus foliage, below which are very realistic antelope legs with hooves instead of claw feet. This type of table seems to have been popular all over the Roman empire, as it often appears on tombstones depicting funerary banquet scenes. Actual fragments of table legs and tops are sometimes discovered; and Britain produced a remarkable series of them made of Kimmeridge shale. From references in Pliny and other authors it is known that citrus wood was another favourite material. Several complete tables found at Pompeii and Herculaneum are made of marble and decorated with beautifully carved heads of lions and panthers. Another type of smaller table is round or rectangular with only one central leg. and there are pairs of table supports consisting of solid slabs, ornamented in high relief, which carried tops of mood or marble.

Pompeian wall paintings show that plain undecorated wooden tables and benches were used in kitchens and workshops, and some household possessions were kept in cupboards with panelled doors. Rectangular footstools, sometimes with claw feet, were used with the high chairs and couches. Small bronze tripods and stands are further items of Roman furniture. Clothes and money were stored in large wooden chests with panelled sides standing on square or claw feet. Chests used as coffins in the Crimea in the 4th century B.C. are still in existence and give a good idea of the skill of the Greek carpenters. They have arched or gabled lids and are decorated with marquetry work and with applied stucco or terra-cotta ornament, gaily painted. Roman treasure chests were covered with bronze plates or bound with iron and provided with strong locks. Jewellery and personal belongings were kept in caskets, in small round or square boxes or even in baskets.

THE ORIENT

China.—Although examples of Chinese furniture are familiar to most westerners, remarkably little systematic study has been made of it. Its origins remain comparatively obscure, its workshops mostly unrecorded, its designers unknown and accordingly its dating extremely difficult. The Chinese almost entirely ignore it as an art form. G. Ecke in his *Chinese Domestic Furniture* (Peking, 1944) says, "Chinese furniture has retained its architectural character and the imprint of pristine dignity throughout changes of taste, into the days of a dying tradition." Certainly most of the forms of Chinese furniture such as the low table and the covered bed are found on the oldest Chinese paintings in existence and can even be recognized in the early forms of the Chinese characters dating back to before 1000 B.C. The designs have been remarkably conservative throughout the ages—a factor which greatly hinders the historian in his attempts to date pieces.

Chinese furniture can be divided into two main types: (1) lacquered wood pieces either inlaid with mother-of-pearl or elaborately carved; and (2) plain hardwood pieces.

Of the first almost nothing is known and dating of such pieces as tables or stools is possible only from the designs of such decorative motifs as dragons, peonies, etc., and by their background motifs. The most important historically in this class are the black lacquer pieces inlaid with mother-of-pearl which have been preserved in the imperial repository (Shōsō-in), Japan, from the 8th century. In the red lacquers, such as seats and tables, the earliest pieces date back to the Ming dynasty (1368–1644), their workmanship being characterized by softer contours and freer, more spirited designs than the later (Ch'ing, 1644–1911) pieces. These lacquered objects influenced the European cabinetmakers.

The plain hardwood furniture is frequently encountered. Its deserved popularity both in China and the west has been gained by its classical simplicity, reserved ornament and lack of pretence. In these products of the finest workmanship, purity of line, plastic strength and a flawless polish combine to produce a harmonious, solid effect.

A Chinese house requires less furniture than a western house. Correspondingly, the types of furniture are fewer—nardrobes, chests, tables both high and low of all types and shapes, altar tables, stools, beds sometimes testered with curtains, screens and stools for use by the bed, chairs and couch-tables.

Although the fundamentals of Chinese joinery must have been formed a millennium before the modern era. the great development in Chinese furniture took place with the introduction of Buddhism from India into China during the first centuries A.D. Hitherto the Chinese had sat cross-legged, or knelt on the floor or on stools. Buddhism made popular the western style of sitting on higher chairs with back rests and with or without side arms. The fusing of the Indo-Asian back-and-arm chair to the Chinese architectural style involved the fusing of the existing stool forms into a chair formed of frame and panel, post and rail or bamboo construction. None can be called comfortable. Unlike the chair, which is not a successful piece of furniture, the chests and armoires are superb examples of careful joinery and often have finely worked metal mounts which greatly enhance the beauty of their solid design. These mounts, which often adorn wardrobes, cabinets and chests, can sometimes provide a clue to their dating.

A number of hardwoods were used for the plain furniture. Their names and equivalents are difficult to render in English and no agreement has been found for them—purple sandalwood (the most distinguished), rosewood of many varieties, mostly imported from Indochina and called "old," "new" and "yellow," rednood, burl (especially for inlay) and a kind called "chicken-wing" wood. Rosewood in its many varieties is perhaps the most frequently encountered and the most popular for its seeming translucence and satin-soft finish. It is above all the faultless workmanship, so typically Chinese, and the fine polish of Chinese furniture which attracts the westerner. It was the Chinese respect for the spirit of wood, their command of line, curve and cubic proportions which became the ideal of the 18th-century *ébéniste*.

According to the Chinese, the best period for furniture was the early Ming period, but examples from the 15th century are extremely rare though modern reproductions of excellent workmanship continue to be made in China. (P. C. S.)

India.—India's place in the history of furniture is that of an adapter or transformer of imported western styles rather than a creator of independent styles of its own. Domestic furniture in the sense in which it is known in Europe was not traditional in India before the 16th century, and even such familiar objects as tables and chairs were rarely used until the spread of Portuguese, Dutch and English furniture.

It was precisely the difficulty of obtaining suitable furniture locally for their settlements which encouraged the European traders to export western prototypes for copying. It was soon found, however, that the Indian craftsman, although a poor copyist, was a skilled and imaginative adapter of foreign styles. This led to the emergence of an independent Indo-European style of furniture which was much admired for its own sake and subsequently exerted fresh influences in the west.

The Indian craftsman's poor copying is reflected not only in distortions of shape but also in his misunderstanding of European joinery techniques. For instance, in most 17th-century Indian furniture, dovetailing is imitated without recognition of its true structural function, with the result that such joints often had to be reinforced with glue or pegs. In decorative treatment, on the other hand, the Indian was more at home, and much of his inlay and veneering is equal to the best contemporary western work.

Early Indo-European furniture can be divided into two distinct groups, according to whether the influence was primarily Portuguese or Dutch (the English, although participants in the furniture trade, did not exert a national influence on styles until the late 18th century).

The Indo-Portuguese group includes a northern Indian or provincial Mogul style and a southern or so-called Goanese style. The former is artistically the more interesting and includes a variety of furniture decorated with inlaid bone or ivory on ebony and other dark woods. The most important historical piece in this group is a credence table made for the Jesuit chapel at Lahore in 1610, now preserved at the Victoria and Albert museum. London. This table provides a firm dating point. With it can be identified a large number of portable writing cabinets (Portuguese *escritorio*), Italian in form but purely Mogul in decoration. Italian influence is explained by the fact that in the late 16th century Renaissance styles were dominant in Portugal itself. When the English reached India in the early 17th century, examples of this northern. Indo-Portuguese furniture were shipped to London, there to be coveted as something entirely exotic.

The second Indo-Portuguese style) sometimes called Goanese (though in fact more probably made on the Malabar coast, south of Goa), is more stereotyped in form and in decoration. It is distinguished by large and rather cumbersome cabinets of a type known in Portugal as *contador*, the inlay ornament being either geometrical or semi-abstract. The Indian contribution to this style is more inhibited and lacks altogether the charm and fancifulness of northern Indo-Portuguese furniture.

Indo-Dutch furniture is easily distinguishable from Indo-Portuguese, since the former reflects contemporary Dutch taste as clearly as the latter reflects Portuguese. There were two types of Indo-Dutch furniture. The first, which was made on the Coromandel coast, was mainly in light-coloured woods, the decoration being in inlaid bone. incised and lacquered. The second is a style of carved ebony furniture which, although commonly found in India and often thought to be Indian in origin. was in fact made at Batavia (modern Djakarta) in Java, the Dutch administrative headquarters in the east. The carved relief decoration of the ebony furniture is floral in character and closely related to the flowering-tree style of contemporary Indo-Dutch embroidered bedspreads and hangings, in which the tulip is prominent.

With the growth of British power in India in the 18th century, all Indo-European furniture styles came increasingly under English influence. Whole suites were made in ivory in the manner of Chippendale and Sheraton, not only for European buyers but also for Indian native rulers who increasingly favoured European styles of furniture. Some of the best surviving pieces of ivory furniture of this kind were seized from the palace of Tipu Sahib at the fall of Seringapatam in 1799 and are now preserved at the Victoria and Albert museum.

In the 19th century Indian artistic standards degenerated and furniture of the period reflects this clearly. The emphasis was on decorative elaboration for its own sake and although much 19th-century Indian wood carving shows great technical skill: this rarely compensates for formlessness and stereotyped ornament. It would be unfair to associate the tastelessness of this style with Indian furniture as a whole.

See R. Edwards and K. de B. Codrington, "The Indian Period of European Furniture," *Apollo Magazine,* vol. xxi–xxii (London, 1934–35) ; V. I. van de Wall, Het *Hollandsche Kolonial* **Barokmeubel** (Antwerp, 1939). (J. C. I.)

EUROPE

Early Middle Ages.—Comparatively little furniture of the mediaeval period in Europe has survived, and only a handful of these pieces date from before the end of the 13th century. One reason for this is the perishable nature of wood, but more important is the fact that furniture was made in such small quantities up to the time of the Renaissance. Therefore much of the earlier history of furniture has to be drawn from other sources, from contemporary literature. illuminated manuscripts, from Romanesque and Gothic sculpture and later from inventory descriptions.

During the early mediaeval period little furniture was used, and what there was was limited to the most basic types of a single design. After the collapse of the Roman empire during the 4th century and its withdrawal to Byzantium. western Europe lost the many sophistications of Roman domestic life and among them furniture. It was to take the Teutonic peoples several centuries before they evolved furniture that approached the standard of domestic equipment familiar to the Roman empire. But there is evidence that certain ancient traditions of furniture making, and particularly that of turnery, were known to and influenced the early Teutonic craftsmen. Turnery was used in making chairs, stools and couches in Byzantium. and it seems that this technique was known across Europe as far north as Scandinavia. Few types of furniture were made during these early centuries, but there were chairs, stools, benches and the most primitive forms of chest. *Beowulf,* which gives some glimpses of the domestic economy of western Europe in about the 7th century, mentions no other furniture than benches and some kind of seat or throne for the overlord.

Later Middle Ages.—The 14th and 15th centuries produced many developments both in construction and design of furniture throughout Europe, and a range of new types, among them cupboards, ambries and various sorts of desks, were slowly evolved. One of the main reasons why so little furniture was made during mediaeval times was the constant insecurity of life. No man could possess more than he could defend, and therefore he was forced to keep his possessions limited to the barest necessities that he could carry away with him in times of emergency. Both the French word for furniture, *meuble*, and the German, *Mobel*, have the sense of movables, and during the whole of the middle ages this was exactly what they were. Any nobleman who owned more than one dwelling place did not have furniture for each of his establishments but instead had one set of furnishings that he carried with him from house to house. Anything that could be moved, and this frequently included the locks on the doors and the window fittings, was carried away and used to furnish the next house en route. Furniture was so scarce that it was quite usual for a visitor to bring his own bed and other necessities with him. These conditions had a double effect on mediaeval furniture, for not only did it make it difficult for men to possess more than the basic types of furniture, but it also affected the design of the furniture itself. Folding chairs and stools, trestle tables with removable tops and beds with collapsible frameworks were usual.

The religious houses were an exception to this. They enjoyed a certain security denied to the outside world. Much of the best furniture of this period was therefore made for use in churches and monasteries, and many of the ideas and developments that were later to add to the domestic comfort of Europe originated in the cloister. An example of this can be seen in the early development for ecclesiastical use of the various types of reading and writing furniture, such as lecterns and desks, which show an ingenuity in construction lacking in that of more domestic pieces such as chairs and tables. It must be remembered that throughout the middle ages and well on into the 16th and 17th centuries all types of furniture remained scarce, and what furniture there was belonged to the nobility and the wealthy merchants. The household equipment of the peasantry throughout Europe, even as late as the 18th century. was frequently so crude in design and roughly constructed that it was hardly worthy of the name of furniture.

The introduction of framed panelling in the Burgundian Netherlands at the beginning of the 15th century, an innovation that soon spread throughout western Europe, was one of the most important constructional developments in the whole history of furniture. Panelled construction solved the problem of building large surface areas, as on the front of a chest or cupboard, which before this time had been limited by the size of individual planks. These, usually hewn by an adze, were heavy and liable to warp and split. Panels could be cut thinner. the main strain being taken by the framework, thus making furniture lighter; and, by not fitting the panels too tightly in their stiles, if the wood warped it was less likely to split. Now that it was possible to construct larger surface areas a new range of case furniture. in particular cupboards and improved chests, was developed. while panelled construction was also used for chairs. Other constructional improvements of the 15th century included the introduction of drawers into cupboards and similar case furniture, and neater and more efficient joints such as the mitre and the mortise and tenon. Panelling was frequently decorated with a flat form of ornament called linen fold or parchment, since it resembled folded sheets of these materials laid on the surface of the wood. Linen fold was widely used in the north of France. Flanders, Low Germany north to the Baltic. Scandinavia and England. It is noticeable that the linen fold of France, the Low Countries and Germany is carved with a sharper definition and greater delicacy than was usual in England and elsewhere. Both panelled furniture and room panelling were decorated with linen fold. Other forms of ,carved decoration on furniture became commoner during the 15th century and surfaces were carved with tracery and other Gothic motifs. During the middle ages a great many pieces of furniture, including those with carved decoration, were painted and sometimes gilded: a practice that continued well on into the Renaissance. The present state of existing pieces, with their plain wooden surfaces, is misleading. Pieces such as chairs, tables and various types of cupboards were also frequently draped with bright fabrics while chairs. settles and other seat furniture were provided with cushions.

The chest was the basic type of mediaeval furniture; acting as cupboard, trunk, seat and, if necessary. as a simple form of table and desk. Apart from its versatility, it was from the chest that several other types of furniture, such as the cupboard and the box chair; were evolved. The most primitive form of chest was made from a hollowed-out log, a single plank! roughly hinged to it, forming the lid. Later, chests were made of six planks. crudely pegged or nailed together and frequently strengthened with iron banding. Chests of this sort, dating from the 13th century, in many cases found in churches. are among the earliest pieces of European furniture that exist. The chest remained one of the most important pieces of furniture until the end of the 1jth century when on the continent the cupboard began to compete with it in usefulness.

Chairs remained scarce throughout the middle ages. Occupation of a chair long symbolized authority or a mark of honour, and even a large house might possess only chairs for the lord and his wife and perhaps another for a distinguished visitor. The use of the word "chairman" is a reflection in modern times of this mediaeval custom. All chairs were made with arms and sets of chairs mere unknown. Early chairs constructed of turned spindles, seen in Romanesque sculpture, have already been mentioned. Later, there were two main types. One was a variety of folding chair, with X-shaped frame: made both of wood and metal, the seat and back consisting of rectangular strips of some strong fabric or leather. As the need for moving furniture about lessened, a heavier type of chair was made. This was basically a development of the chest and in many cases the seat was hinged, allowing the base to be used for storage, with panelled back, arms and base. The panelling was often carved with linen fold, and sometimes with other Gothic motifs. Many of these chairs had exaggeratedly high backs terminating in elaborately carved canopies; some were freestanding while others had their backs fixed to the wall in the manner of a church stall. Settles were also used for seating during the 1jth century. An innovation on the continent nas the settle mith a pivoted bar forming the back rest. which could be snung over to allow a person to sit on either side—evidence of the weight and immovability of the furniture of this period.

Tables were mainly of trestle construction with long rectangular tops that could be dismantled. During the 1jth century smaller tables nere made on the continent which could be more conveniently moved and. especially. drawn up to the fire. Various forms of cupboard, ambry and *dressoir* were developed at this time, panelled and decorated with linen fold or Gothic carved ornament. Basically all these types were a chest nith doors, raised on legs of simple rectangular form; elaborations of construction and decoration soon followed as did the specialization of their functions. Cupboards. *dressoirs* and credence tables were used for the storing of plate and for serving at banquets. the plate being displayed on the top and on shelves above and below the cupboard. Other cupboards were made to hold food and day-to-day provisions; in the case of food or dole cupboards, as they were called, the front and sides were pierced for ventilation.

Little English furniture survives from mediaeval times and, as on the continent, information must be sought in contemporary references and from the pictures of domestic interiors in illustrated manuscripts. Most of these manuscripts are of foreign, particularly French or Flemish, origin but they are reliable evidence because the governing classes, who were practically the sole possessors of proper furniture, copied the domestic habits of the continent. English oak was the chief material, but softer woods were also used. A certain amount of furniture was imported from abroad, providing new ideas for the English carpenter and joiner. The furniture usually found in important houses consisted of beds, chests, cupboards, tables, benches and stools. Wills and inventories prove that draped bedsteads were treasured possessions of mediaeval householders, both in England and on the continent, prized not for the rough framework but for the magnificent woven and embroidered hangings. These hangings consisted of a celure (back), tester (canopy), curtains and valances. Humbler beds of the truckle type were also used.

RENAISSANCE

Italy. — The Renaissance, which originated in Italy in the early years of the 1jth century, gradually brought about a complete change in the domestic furniture of that country and of Europe. The classical tradition had never been entirely lost in Italy and when a deliberate return to old models was made, furniture gained an importance that it had not known hitherto. Social and economic changes also affected the history of furniture at this time. The growth of a wealthy and powerful middle class throughout Europe caused the building of more substantial houses and the demand for good furniture. Italian Renaissance furniture shows a strong architectural bias and the purpose of the piece, as in Roman furniture. was subordinated to its form. The furniture of the early Italian Renaissance is often restrained, with beautiful, simple designs carved in walnut. For more elaborate work, sculpture in low relief and stucco modelled in intricate patterns were much used. The stucco was usually gilded all over and picked out in bright colours.

There was no class of furniture on which rhe wood carver's and stucco modeller's skill was more exercised than on the *cassone* (see **Cabinet Furniture**) or marriage coffer, frequently made in pairs and provided and filled for the bride. In addition to elaborate relief work and gilding, these coffers were often painted on the front and sides, and occasionally inside the lid as well, with appropriate biblical or mythological scenes. Motifs popular with the Italian carver included cupids, amorini, grotesque masks, scrolled foliage and strapwork. The fixed writing desk is the forerunner of the writing bureau, which became an indispensable article of furniture as writing became more general.

A type of chair or back stool, called a *sgabello*, was much favoured at this time in Italy. Often richly carved and gilded, it was evolved out of a simple joiner's contrivance of the middle ages. The seat mas a small wooden slab, generally octagonal, supported at front and back by two solid boards cut into an ornamental shape. A piece of wood in the shape of a half-opened fan formed the back. Another chair of the period also drew upon mediaeval inspiration, the folding X-shaped chair, sometimes called a Dante chair. Tables were generally oblong, supported by columns, consoles or terminal figures, with a long central stretcher running from end to end. The influence of Italian furniture of the Renaissance was paramount and soon spread abroad, revolutionizing the furniture of Europe. Some countries borroned freely, others, particularly in the north, selected ideas and motifs and adapted them to a more individual style.

France. — The furniture of France was among the first to be influenced by the Italian Renaissance. Louis XII and many of his court visited Italy. and soon imported Italian artists and craftsmen and works of art into France. The French Renaissance of furniture can roughly be divided into two stages. First there was a period of transition and adaptation, during the reign of Louis XII and the first part of Francis I's reign. when the pieces were basically Gothic in form and Gothic ornament was mixed with the *putti*, medallion heads and grotesque decoration of the incoming Renaissance style. During the second phase. from the end of the reign of Francis I, the new style displaced the Gothic. But the more exuberant arabesque shapes of Renaissance decoration gave way to increasingly architectural design and oak was almost entirely superseded by walnut. Centres of furniture making were established at Fontainebleau, where Francis I employed several Italian artists and craftsmen; in the Île-de-France, headed by the work of J. du Cerceau; and in Burgundy, where, led by the craftsman and designer Hugues Sambin. design was influenced by the Renaissance style evolved in the Netherlands.

Much of the carved walnut furniture of France in the 16th century is remarkable for gracefulness and delicacy. Sometimes it is enriched with inlay of small plaques of figured marble and semi-precious stones, sometimes with inlay or marquetry of ivory, mother-of-pearl and different coloured woods. Many of the pieces of carved walnut, especially the buffets produced at this time under the influence of Du Cerceau and Sambin. are heavy and the whole surface is covered in elaborate carving. a particular feature being the wide variety of muscular and satyr-faced caryatids which adorn the front or are set at the corners.

Chairs began to be lighter in design. the back became narrower and the panelled sides and base were replaced by carved and turned arms and supports. and legs were joined by stretchers at their base. A particular chair of this pattern was known as a *caquetoire* or conversation chair, supposedly designed for ladies to sit and gossip in. A further feminine influence on chair design of this period. not limited to France, was the introduction of the chair without arms, or the single chair. which is said to have been designed to accommodate the wide skirts of the period.

Elaborately carved oblong tables were supported by consoles or fluted columns connected by a stretcher surmounted by an arched colonnade. Again they were lighter than their mediaeval equivalents and by now the tops were permanently joined to their bases. Chests. decorated in the new style, were still widely used. though they were frequently replaced by the armoire (see CABINET FURNITURE), which was now sometimes made in two stages, the upper compartment containing numerous small drawers.

Austria and Germany. — Italian models were followed in the northern Austrian provinces. The cabinetmakers of Augsburg and southern Germany evolved an elaborate type of work based on the example of Italy. Cabinets had doors in front, which revealed an arrangement of drawers and compartments inside. Inlay and marquetry decoration mere popular, particularly for architectural scenes. The inlaid writing desk of Christoff Müller of Augsburg, made in 1555 and later placed in the Berlin museum, is shaped at the end like the façade of a Renaissance mansion.

Spain. — In Spain foreign influence came at a far earlier time and from remoter parts. namely the Islamic world. With the invasion and occupation of the south by Arabs and Moors in the 8th century. the greater part of the peninsula became virtually an oriental country, After the expulsion of the last Arab ruler, at the end of the 15th century. many Moriscos still remained in the country. and the intelligent and industrious craftsmen among them still worked for the Christian rulers of the land in their own traditional styles. Thus a style. half eastern and half western, called Mudejar, was created in Spain.

A type of cabinet known as a *vargueño* is typically Spanish—a medley of European and oriental elements. The upper part is a chest with a fall front. often elaborately mounted in wrought iron and backed with velvet, and with a massive iron lock. Inside is an intricate arrangement of drawers and recesses. The cabinets were richly carved, painted and gilded and inlaid with ivory. A *vargueño* in the Victoria and Albert museum. London, is decorated on the front with a representation in inlaid woods and ivory of the animals entering the ark. There is a tendency for Italian models to be followed in the furniture of the 16th and 17th centuries. In a country so renowned for its ironworkers it is not surprising to see that bracing irons of fanciful workmanship were often attached for strengthening to tables and benches.

Low Countries. — In the 16th century Italian Renaissance ornament was adopted and transformed by the artists and designers of northern Europe, particularly in northern Germany and the Low Countries. who created an independent style of decoration. Strapwork, cartouches and grotesque masks are characteristic features of this northern Renaissance style, and are found repeatedly in the pattern books of such German and Flemish artists as W. Dietterlein and V. de Vries — books of ornament which circulated among and influenced metalworkers, carvers, plasterers and furniture makers throughout the north.

Mediaeval furniture of the Low Countries was strong and solid, and these characteristics remained in the time of the Renaissance, combining with the new style of ornament. Heavy oak tables, sometimes draw tables. had massive legs and solid stretchers. The beds in the corners of the living room were heavily draped. Folding wooden chairs and low stools. with more or less elaborate turnery, were still used, besides a new type with baluster-formed or twisted legs and arms, and straight backs heightening as the 17th century went forward.

Scandinavia. — In Scandinavian countries furniture for the most part remained simple and primitive. Houses of the well-to-do contained furniture from northern Germany or from the Low Countries, and these provided models which the native craftsmen copied.

England. — The Italian Renaissance did not affect the design or ornament of furniture in England until about 1520. As in France, evolution from the Gothic style was a gradual process, influence coming first from Italy and in the second half of the 16th century from the Low Countries. In the early stages furniture remained Gothic in form, though slowly Italian motifs replaced the older Gothic ornament. Many pieces of early Renaissance English furniture combine linen fold panelling with medallion heads and Italianate cupids, but by the middle of the century both new ornament and new forms had replaced the mediaeval style. About the middle of the century the direct influence of Italy weakened and its place was taken by that of the Low Countries. The northern style of Renaissance ornament already mentioned was propagated in England by the pattern books, immigrant workmen and the example of imported Flemish and German furniture, and before long it was adapted by English craftsmen into an individual and peculiarly English style. Characteristic of this style is the enrichment of every surface with flamboyant carved, turned, inlaid and painted decoration. an exuberance which strongly reflects the spirit of the English Renaissance. During Elizabeth I's reign there was a considerable and fairly widespread increase in domestic comfort, to be seen in improved construction! a multiplication of types and the tentative beginnings of upholstered furniture. The celebrated inventory of Lord Lumley, made in 1590, indicates that large houses of the late 16th century were equipped with considerably more and better made furniture than previously, though many of the most highly regarded pieces in the greater Elizabethan households were imported from abroad. These pieces, however. were quickly copied by the English craftsmen, and new decorative techniques were applied to other suitable pieces. A series of inlaid chests with perspective architectural scenes, often called nonsuch chests, were either imported from Germany or made by German workmen in England. They were strongly influential in propagating the technique of inlaid decoration, which by the end of the century was being applied to every type of furniture. The majority of the population was still using furniture as rough and makeshift as it had been a century before.

At this time there were important changes in the constitution of the furniture-making trade in England. Individual woodworking crafts became more specialized and the differences between the carpenter's, the joiner's. the turner's, the coffer maker's and other craftsmen's work became more clearly defined. The carpenters possessed a charter as early as 1477. The Joiners' company of London was granted one in 1570 and the turners theirs in 1604. In the provinces two crafts were frequently united under the protection of one company; for example, the Carpenters' and Joiners' company of Worcester and the Turners' and Joiners' company of Chester. In country districts. where skilled labour was scarce arid the discipline of the companies could not be enforced, the local carpenter practised all the crafts as best he could. The companies performed two main offices, first the protection of their members' rights under their charter and second the maintenance of a high standard of craftsmanship in the products of their members. In both they did much to imprbve the design and construction of English furniture in the 16th and 17th centuries.

Apart from the gradual change from Gothic to Renaissance ornament, the 16th century produced several changes in the design and construction of individual types. Chairs became slightly more common, though even in Elizabeth's own palaces stools were the usual form of seating. Evolving from the box chair came a type where the arms and legs were no longer filled in with panelling, but had plain or turned legs. with shaped arms resting on carved or turned supports. The backs of chairs were still panelled and decorated with carving and inlay or surmounted with a wide and richly carved cresting. X-shaped folding chairs of varying construction were also used. In the early 17th century chairs without arms were introduced, called farthingale chairs, made to accommodate the wide skirts of the ladies. They had upholstered seats and a low rectangular upholstered back raised on short supports a little above the seat. Armchairs of similar design were made. Turkey work and velvet were usually employed for upholstery.

Early in the 16th century the mediaeval practice of concealing all the wooden frame of a bed beneath its hangings gave way to the new style of leaving the greater part of the frame exposed and enriching it with carving and other decoration, making the frame itself an important part of the general design. Later examples, notably the celebrated Great Bed of Ware. are lavished with elaborate turnery. carving, inlay and painted decoration. Favourite carvers' motifs, for beds and other types, included strapwork, grotesque masks and caryatids. bulbous turned pillars and supports, arcading and patterns of scrolled foliage. The heavily turned cup and cover motif is frequently found on bedposts in the later 16th century. The cumbersome Gothic trestle tables were replaced by "joyned tables" with their tops fixed to their frames. Draw tables which could be conveniently lengthened by pulling out the two leaves concealed under the top were also introduced. A few smaller tables were made in the second half of the 16th century. sometimes for cards or gaming. Table legs and the friezes of the frames were decorated with carving and inlay. and the cup and cover motif is often found on the legs. Various types of cupboard were made, usually in two stages. With court cupboards both stages were left open, but with other types either the top or both stages were enclosed. A simple form of chest of draners was introduced about 1620.

The progress of English furniture was greatly retarded in the first half of the 17th century by the Great Rebellion. A certain amount of austere furniture produced in the middle of the century can be called Cromwellian. though the influence of the puritan regime was largely negative. and it was not until 1660 and the return of Charles II that the baroque style came to England and with it a revolutionary progress in English cabinetmaking.

BAROQUE

During the 17th century the baroque style (*see* BAROQUE) had a drastic effect upon furniture design throughout western Europe. Large wardrobes. cupboards and cabinets had twisted columns. broken pediments and heavy mouldings But the main characteristic of baroque furniture is not the application of more and richer surface ornament; few pieces of furniture can have had more lavish surface decoration than those made in the late Renaissance. In baroque furniture the details are related to the whole, and instead of making the piece into a framework of unrelated surfaces, each detail contributes to the harmonious movement of the over-all design. A change to the baroque style of furnishing was not made in all countries at the same time, but the evolution was spread over a period starting with its adoption in the Low Countries in about the 1620s and going on late into the 17th century when Germany and England began to develop it.

The baroque style owed much to the oriental influence that snept over Europe in the 17th century. when several of the European maritime countries, particularly Portugal. Holland and England, established regular trading relations with India and the far east. Lacquered furniture and domestic goods were imported from the east and, also, the oriental craftsmen worked in a pseudo-European style from designs supplied by the traders. Before the end of the 17th century oriental decorative techniques were being widely imitated in Europe and the roots of the "Chinese taste" were firmly entrenched. Heavy tropical woods were also brought to Europe, and from these furniture was made which borrowed much from the prevailing taste for oriental elaboration. Ebony cabinets with eaved mouldings, intricate carvings in low relief and marquetry in tinted ivory and coloured woods were made in Italy, Germany, the Low Countries and elsewhere. It was at this time that the *ébéniste* acquired his name.

Flanders and Holland.—The early Flemish baroque furniture, dating from the second quarter of the 17th century. was but a slight adaptation of the late Renaissance style. Typical are the oak cupboards with four doors and the chairs with seats and backs of velvet or leather held in place by nails.

In Holland the baroque style did not encroach on late Renaissance furniture until nearly 1640. Dutch furniture of this period can be distinguished by its simpler design and a preference for moulded panels over carved ornament. Later, marquetry decoration and walnut veneer surfaces became the commonest decorative treatments. At the end of the century lacquered furniture, particularly cabinets with small drawers, became popular.

Italy.—Though it was in Italian architecture. painting and sculpture that the baroque style was evolved, Italy was not the first to apply this style to furniture. But by the mid-17th century it was producing flamboyantly carved, painted and gilded furniture, decorated with such typical motifs as *amorini*, acanthus, shells and boldly drawn scrolls, and was further enriching chairs and stools with fine-cut velvets and table tops with marble, *pietra dura* and scagliola. Chairs and stools with exaggerated scrolled arms and legs, exemplified by the work of A. Brustolone in Venice, and handsome walnut and ebony cabinets and cupboards with carved decoration on the pediments, friezes and corners and sometimes inlaid with marble or *pietra dura* set in moulded panels typify the Italian furniture of the later baroque phase.

France.—In France the Italian influence of the 16th century was gradually assimilated and a national style of furniture was evolved which soon spread its influence into neighbouring countries. The reign of Louis XIII, covering most of the first half of the 17th century. was a time of transition. The Gobelins factory. which still remains a national establishment, was founded by Louis XIV for the production of *meubles de luxe* and furnishings for the royal palaces and the national buildings. Charles le Brun was appointed the first director. Furniture was veneered with tortoise shell or foreign woods, inlaid with brass and ivory or heavily gilded all over. At times it was even completely overlaid with silver. The name of André Charles Boulle (*q.v.*) is particularly associated with this style of decoration. His cabinets and tables were completely covered by sheets of tortoise shell and brass cut into intricate patterns so as to fit into one another, the tortoise shell alternately forming the pattern and the ground; hence the two types, *boulle* and *contreboulle*. The light fanciful grotesques of J. Berain were much used for this work. Heavy gilt brcnze mounts protected the corners and other parts from friction and rough handling and provided further. ornament. Many other craftsmen, both in France and other countries, copied Boulle's method and its influence lingered on until the 19th century.

England.—After the Restoration, from 1660 onward. there was almost revolutionary progress in English cabinetmaking, as it came to be called at about this time. The exiled court on its return introduced French and Dutch fashions and the English craftsmen were considerably helped in supplying the tastes of the nobility by a large influx of foreign workmen. Furniture became lighter, more highly finished and better adapted to varying needs. The general increase in technical skill of the cabinetmaker between 1660 and about 1690 is astonishing. Walnut was the favourite wood, though the use of oak continued in country districts for many generations. New processes appeared. notably veneering wide surfaces with thin sheets of wood, into which, in many cases, floral patterns in marquetry were inserted. In the earlier period of the Restoration these patterns were large, but toward the end of the century they grew smaller and more intricate. leading eventually to the type of marquetry made up of numerous small scrolls and called seaweed marquetry.

The passion for colour found an even better outlet in lacquer decoration. The importation of works of art from the east had begun in Tudor times, but was of little account until after the Restoration. Then the taste became widespread. John Evelyn and others reported their friends' houses to be furnished with Indian screens or panelled in the finest japan — descriptions implying oriental lacquer. Such things came from China and mere soon imitated in England, the native version of lacquering being called japanning. Toward the end of the century two men called John Stalker and George Parker published an elaborate treatise outlining in detail the various techniques of this craft.

New forms of decoration coincided with a multiplication of types. Day beds. a form of couch with an adjustable end. and winged armchairs served for repose. The upholstered armchair had its origin at this time, and a pair of chairs at Ham house, Surrey, called in the 17th century "sleeping chairs," are among the earliest of this type. A little later, toward the end of the century: sofas with backs and arms carried comfort a stage further. Velvet. silks and needlework were usual materials for upholstery. Various kinds of writing furniture were rapidly developed, including the bureau with enclosed desk and interior fittings of small drawers and pigeonholes which was made toward the end of the century. Chests-of-drawers came into more general use. Mirrors were no longer rarities! though glass remained expensive for some time after the duke of Buckinghain established his famous glass-works at Vauxhall. The frames n-ere carved, lacquered or decorated with marquetry. Fashions succeeded each other with great rapidity. Chairs show these changes most clearly, developing in a brief period from mere seats into movable decorations. Scrolled legs were common under Charles II, while later straight tapering baluster iorms mere used. In the grander beds of this period the tester, back and posts are covered with material and match the hangings. These state beds were strongly influenced by the designs of the Frenchman Daniel Marot, who came over to England to work for William and Mary. They were of enormous height with elaborately moulded cornices, and had ostrich plumes or vase-shaped finials at the corners of the tester.

During the late 17th century and on into the first half of the 18th century, besides the plain walnut furniture and the marquetry and lacquered pieces, a certain amount of elaborately carved and gilded iurniture, much influenced by the style of Louis XIV, was produced in England. Foremost among the makers of this de luxe furniture were three cabinetmakers, J. Pelletier, G. Jensen, and James Moore. Toward the end of the 17th century, during the reign of William and Mary, baroque furniture tended to become simpler and the use of ornament mas somewhat restrained. At the beginning of the 18th century, during the reign of Queen Anne, a new and entirely simple style arose, much influenced by the contemporary furniture of Holland. Carving and applied ornament were reduced to a minimum, the beauty of a piece relying on carefully designed curved lines and the colour of fine walnut veneers. The cabriole leg, originally devised in classical times and based on the curve of an animal's leg, mas introduced into England from the continent about 1700. Terminating in a clan-and-ball or paw foot and soon discarding the stretcher, it was widely used on chairs and tables and for every kind of support. Chairs had hooped uprights and fiddle-shaped splats curved to support the back. Tallboys, or double chests-of-drawers, cabinets fitted mith shelves and bureaus in two stages met the demand for greater convenience, as did a new range oi dining, card and other sorts of table.

By the second quarter oi the 18th century the English cabinetmaker had become well established and the progress of design and construction was no longer hampered by lack of skill. The system oi specialization practised under the companies had broken down and the different crafts were now practised under one roof, the cabinetmaker's shop. There, by the middle of the 18th century, it appears from cabinetmakers' bills that no side of interior decoration was too large or too small for attention.

ROCOCO AND NEOCLASSIC

The influence of French furniture was predominant in Europe during the 18th century, an influence that stretched from Russia to Sweden In the second half of the century England played a leading role in establishing the neoclassic style, and ior supreme craftsmanship provided an inspiration to workshops in several countries, but in the diffusion of the two styles of that century, the rococo and the neoclassic, French designs were imitated, with varying degrees of success, in every sophisticated household in Europe.

France. — The transitional phase in French furniture from baroque to rococo (*q.v.*) is called *régence,* though in fact this phase started just before the regency of Philip oi Orléans (1715): Strongly under the influence of oriental art, the heavy, monumental style of the earlier part of Louis's reign was gradually replaced by a lighter and more fluent curvilinear style. The leading exponent of the *régence* style was Charles Cressent (1685–1768), *ébéniste* to the regent. In his work the ormolu mounts, so important a part of the design of French furniture in the 18th century-, become equally if not more important than the marquetry decoration of the carcass. The curvilinear form was introduced. not only to externals such as legs and supports but, in the *bombé* commodes which first appeared during this period, to the case itself. High-qualitj- marquetry in coloured woods replaced ebony.

The rococo style, a development oi the *régence,* affected French furniture design from about 1735 to 1765, when it pave way to the incoming neoclassic style. The word rococo is derived from *rocaille;* the shell mas one of the basic forms of rococo ornament. Rococo is based on asymmetrical design, light and iull of movement. The iurniture oi this period is designed on sinuous and complicated lines. If any style can be attributed to one man. it was the designs of J. Meissonier, a goldsmith, sculptor and architect, that originated rococo. The repertory of ornament was large, hut it centred around subtle arrangement of the C-scroll with ragged edges, combining mith scrolled foliage, floral motifs, ribbon and, on occasion, trophies iormed oi musical instruments or gardening implements. The rococo Chinese taste had a convention of its own, pagodas, exotic birds, Chinese figures. icicles and dripping water. Chairs with flowing lines, delicately carved and gilded, were upholstered with silk, needlework or tapestry. The graceful *bombé* commode, often with marble top and with two or three drawers. the surface enriched with finely modelled ormolu mounts, was popular. Under Cressent's influence the importance of the mounts predominated, though later in the century the marquetry decoration gained first importance. Commodes and other pieces were decorated mith marquetry of floral or geometrical patterns, or sometimes with lacquer decoration, again combined with ormolu mounts. The most celebrated makers of mounts during Louis XV's reign were Jacques Caffieri and his son Philippe. J. Oehen was made *ébéniste du roi* in 1754. *A* pupil of Boulle, he mas the most celebrated *ébéniste* of the period, famed for the writing table made for Louis XV and now in the Louvre, Paris. which was finished by his brilliant pupil, J. Riesener.

The neoclassic style, sometimes called Louis Seize, began in the 1750s. Tiring of the rococo style! the restless spirit of the 18th century turned for inspiration to classical art. The movement was stimulated by recent archaeological discoveries, travel in Italy. Greece and the near east and the publication, all over Europe, of works on the classical monuments. The neoclassic style, based on straight lines and rectilinear iorms and using a selection of classical ornaments, mas first applied to French furniture during the 1760s. To begin with, the classical motifs were sparingly applied to furniture of unchanged form. but slowly the curved line of rococo was replaced by a simpler and more severe rectilinear design; chair legs were straight, tapered and fluted, and the commodes and other case furniture were no longer of *bombé* form. Marquetry was still widely used ior decoration, while some cabinets mere made of ebony inset with panels of Japanese lacquer. *Boulle,* which had not been employed in Louis XV's reign, returned to fashion. A greater number of pieces were signed during this period (signing had been made compulsory in Paris) and Riesener. M. Carlin and J. Saunier were a few of the leading *ébénistes.* Several German craftsmen also worked in France, among them Abraham and David Rontgen. A. Weisweiller and G. Beneman. Of the workers in bronze mounts Pierre Gouthière was supreme.

England. — .%bout 1720 mahogany mas imported into England and slowly it superseded walnut as the fashionable wood for making furniture; its consumption increased mith the repeal of the heavy import duties and its use was widespread by about 1735. The Palladian interiors demanded furniture more striking and larger in scale than the restrained walnut-veneered pieces of the early 18th century. Inspired by the contents oi French and Italian palaces. iurniture began to be designed by architects. William Kent, the most celebrated, having lived in Italy before starting practice. The design was classical, in keeping with the traditions of Andrea Palladio and Inigo Jones, the ornament baroque. At Holkham in Norfolk, Rousham in Oxfordshire and elsewhere Kent's iurniture may be seen in its proper environment, gilt mirrors and side tables mith sets of chairs and settees covered with patterned velvets matching the grandeur of elaborate architectural Palladian interior decoration.

During the 1740s, despite the resistance of the Palladian classicists who deplored its asymmetrical principles, the rococo style crept into English decoration and furniture design. During this decade pattern books of ornament in the full rococo style by M. Lock and H. Copeland were published in London, and in 1754 Thomas Chippendale published his *Gentleman and Cabinet-Maker's Director* which provided patterns ior a wide range of English iurniture in the rococo style and its two ofishoots, the Chinese and Gothic tastes. During the following years several similar works were published by such craftsmen and designers as W. Ince and J. Mayhew, T. Johnson and R. Manwaring. The

Bottom right: The finished chair, assembled and upholstered

rococo style was firmly established in England throughout the 1750s and into the 1760s. Chippendale and other cabinetmakers borrowed not only ornament from the French *rocaille* but designs ior individual types as well. The fame of Chippendale as the chiei exponent of the rococo in English iurniture rests largely on his publication, though in fact it has now been more or less conclusively proved that he was not himself responsible for the designs, but employed two "ghost" designers, the pioneers of the rococo style in England, Lock and Copeland. Two important things should be rrmembered. First, there were several other cabinetmakers, for example William Vile and John Cobb, whose work irequently excelled that irom Chippendale's workshop, but whose only memorial is a small quantity of attributed furniture. Second, though it has become the practice to talk of a Chippendale chair or a Vile commode, this does not imply that the pieces were actually made by these craftsmen, but that they were made in their workshops.

Pattern books such as the *Director* admirably illustrate the wide range and diverse types of furniture in use in the mid-18th century. By this time every act of the day that necessitated the use of iurniture was catered for by some specialized piece, while the basic furniture such as chairs, cupboards, beds and tables mere designed and decorated in innumerable different iorms. The number of variants on the rococo chair splat must run into several hundreds. The ingenuity of the cabinetmaker and carver knew few limitations. During the rococo period marquetry decoration mas not used, though it was revived again and practised by Chippendale on some oi his finest pieces early in the neoclassic period. For bedroom iurniture japanning was popular.

The Gothic taste was an offshoot of the rococo style peculiar to England. Starting early in the century as a literary device, in the 1740s it began to take more solid shape in architecture, interior decoration and iurniture. As with furniture in the Chinese taste, Gothic furniture bore no relation to its mediaeval equivalents, but borrowed Gothic ornament, such as tracery and cusped arches, and applied them to furniture. The Gothic taste mas much publicized by Horace Walpole's celebrated villa, strawberry Hill, Twickenham, Surrey. Chippendale included designs for iurniture in the Gothic taste in all three editions of his *Director*.

The classical reaction, which set in shortly after 1760, swept away tortuous iorms and reimposed a classical discipline on design, though of lighter and more delicate touch than that of the previous classicists, the Palladians. Robert Adam, whose name is inseparably associated with this movement, had, like earlier architects, studied in Italy. There he sought inspiration both in the monuments oi classical times and the Renaissance, particularly the styles of decoration that the Romans had used ior their own domestic interiors. When he was given a free hand he included interior decoration and furniture in his architectural schemes, one of the best examples being his alterations and redecorations at Osterley, Middlesex, where he even provided harmonious designs for the lock plates and chimney furniture. His iurniture makes a restrained use of classical ornament, but paterae, husks, ram's heads and urns are less eloquent of the change than the symmetrical structural lines. At this time commodes and other objects were of satinwood, with delicate marquetry and ormolu mounts. Soon painted decoration was also used on furniture. Adam's furniture was copied and modified by contemporary cabinetmakers and may be seen translated into popular terms in George Hepplewhite's *Cabinet-Maker and Upholsterer's Guide* (1788).

In the last 20 years of the 18th century there mas a tendency toward greater and greater refinement. lightness and delicacy in furniture design. Furniture design retained, for the most part, symmetry of iorm and excellence of proportion. Heart- and shield-shaped backs on chairs and settees! tables and other pieces with tapered and fluted supports are characteristic, while feathers, wheat ears and shells are prominent in the painted or inlaid decoration. This refinement, strongly ieminine in character, is found represented in Thomas Sheraton's *Cabinet-Maker and Upholsterer's Drawing Book* (1791).

EMPIRE STYLE

The empire style, which quickly spread throughout Europe, each country adapting it to its own national taste, began in Paris after the Revolution. In England it is commonly called the regency style. The two French architects, C. Percier and P. Fontaine, who designed the furnishings for the state rooms of the first consul, contributed in great measure to the creation of the style and their work was assiduously copied at all the courts of Europe. Their ideas were incorporated and propagated in their *Recueil de décorations intérieures* (1801 and 1812).

Basically the new style was a continuation of the neoclassic style, with a much stronger archaeological bias. leading to direct copying of classical types of furniture, added to which mas the new repertory oi Egyptian ornament, stimulated by Napoleon's campaigns in Egypt. Mahogany-veneered furniture with ormolu mounts assumed the shapes of Roman, Greek and Egyptian chairs and tables. with winged-lion supports, pilasters headed with sphinxes' busts or palm leaves, while where no classical prototypes existed contemporary designs were enlivened with classical ornament.

In England the regency style is seen in the books of furniture designs by Thomas Hope (1807) and George Smith. Thomas Hope was the chief exponent, an amateur designer with some antiquarian knowledge who entirely decorated his own house, Deepdene, Surrey, in the style. When the fashion mas tàken up by cabinetmakers the results were often woefully incongruous. Mahogany and rosewood were used with bronzed or gilt ornament, and metal inlay, a cheaper technique, replaced inlay and marquetry. Along with this style there came a renewed enthusiasm ior the Chinese taste, as best exemplified in the iurniture and decoration of the Brighton pavilion. Between the 1820s and 1830s, in the final stages oi the regency style, both the design and construction of iurniture in England and on the continent showed signs of heaviness and overelaboration which heralded the general decline throughout Europe in the 19th century.

19th AND 20th CENTURIES

The Biedermeier style, strongly associated with Germany and Austria where its most salient features were developed, flourished in the prosperous middle-class homes of Europe irom about 1815 to 1848. This style is characterized by chairs with curved legs and sofas with rolled arms and generous upholstery. Mahogany veneers and light birch. grained ash, pear and cherry were used. The design and much of the ornament were influenced by the empire style, in particular the Grecian element.

In the 1820s there mas a revival of the Gothic style in England, which n-as partly stimulated by such romantic literature as the novels of Sir Walter Scott. Losing all the lightness and humour of the mid-18th-century Gothic revival, heavy mediaeval motifs were profusely and indiscriminately applied to every type of iurniture irom xi-ashstands to pianos. From the 1840s onward the furniture manufacturers, who had by this time replaced the cabinetmakers, began to borrow irom the styles of the past, Renaissance, baroque and rococo, lavishing misinterpreted decoration of these styles on pieces oi exaggerated and distorted iorm. The late Biedermeier was claborated mith a neorococo style, and in the middle of the century this iurniture was further encumbered with the sombre plush and velvet upholstery and bobbin-fringed covers so characteristic of the mid-Victorian period. e

While the widespread use of machinery lowered the standard of individual workmanship, and meaningless imitations of past styles suppressed originality in iurniture design, throughout Europe during the 19th century creative and experimental designers and cabinetmakers, working with such new materials as bentwood and metal, produced new types of iurniture which, though they mere exhibited at the Great exhibition in 1851 and at similar displays on the continent, mere largely ignored by the manufacturers. It was these neglected experimental pieces that were eventually to prove the prototypes of contemporary furniture.

William Morris has irequently been called the "father oi the modern movement." Sickened bv the shoddiness of the machine-produced goods of his own day, h turned for inspiration to the hand-craitsmanship of the middle ages and, basing his own work on their designs and methods, attempted to revive a respect for fine craftsmanship and to stir the aesthetic sense oi his contemporaries. His influence, though important, would have been greater if, instead of turning away irom the machine, he had applied his high ideals to discovering a way in which machines might be used to the best advantage. Morris' followers in the field of cabinetmaking included such designer-craftsmen as Ernest Gimson and the Barnsley family, who, working with a few assistants, produced small quantities of high-quality handmade furniture, the craitsmanship oi which has never been rivalled at any time. In Europe the example of Morris and his followers was so widely copied that many people believe modern iurniture design originated exclusively on the continent.

The *art nouveau* style mith its elongated forms flourished irom 1895 to about 1910, being well represented at the Paris exhibition in 1900. In England *art nouveau* mas not so popular as on the continent, and was entirely ignored by the Gimson school, though it is found in the work of the Scottish architect and designer, C. Mackintosh. Early in the 20th century, under the influence of Morris and Gimson, modern furniture design received a powerful stimulus in Germany with the creation of the *Werkbund* in 1907. Here at last the teachings oi Morris were used in conjunction with machinery. In 1914 the *Werkbund* held an exhibition at Cologne which inspired the creation in England of the Design and Industries association mhich aimed to bring about the collaboration of the artist and the manufacturer and to produce machine-made goods compatible mith the highest standards of design and workmanship. The results of this synthesis can be seen in the work of Ambrose Heal, who, at the beginning of the 20th century, began to produce large quantities of reasonably priced contemporary iurniture of simple line, decorated solely by the natural beauty oi the colour and graining of the timber. With commercial production of this kind a new public was slowly created and educated to appreciate not only English contemporary furniture but also that of Scandinavia. France and Italy.

Modern furniture continued to remain in an experimental period, and makers worked in a wide range of new materials. metal, plywood and laminated board, plastic and glass. Some designs were partly traditional, others completely original, the simplicity of modern furniture being relieved by beautiful moods from all over the world and by the use of bright contemporary textiles ior upholstery. Influenced by contemporary conditions, where a great percentage of city dwellers live in flats, ingeniously constructed built-in furniture began to replace the ireestanding furniture of the past, and the design of furniture was once again passing into the hands of the architect. *(See* also INLAYING; JAPANNING; MARQUETRY; ORMOLU; and BED; CABINET FURNITURE; CHAIR AND SOFA; TABLE; etc.)

UNITED STATES

The story of North American furniture gains true significance when seen against its European background, mainly English Its successive variations irom this background reflect those geographic, economic and spiritual iorces which were shaping a total national individuality.

Early Settlers' Furniture.— From ancient wills and inventories and irom surviving pieces it is known that the first settlers in Massachusetts Bay and Virginia brought few comforts across the Atlantic. But by the second generation, about 1650, they had triumphed over enormous difficulties to create for themselves a fair facsimile of domestic equipment in the homeland. The simple furniture oi the early one-, two- or three-room irame cabin consisted of chests, cupboards, tables, benches, stools, an occasional chair and simple bedframes made by the community carpenter from memory rather than models. The heavy squared members and plane surfaces of oak were relieved by simple turning and scratch or two-plane carving, recalling the late mediaeval tradition of Elizabethan times. Toward the end of the century pine, maple and other woods came into use, sometimes in combinations. Surfaces formerly left in the wood were enlivened with coats or touches of black and earth reds and yellows, corresponding to the soitly dyed homespun wools and linens used in curtains and cushions and needed to relieve the starkness of wood and plaster.

From 1650 to 1700 there was probably little differentiation in the domestic furnishings of the English settlements. Dutch and Scandinavian forms came with Dutch and Swedish settlement on the Hudson and the Delaware, but these remained local in their influence.

Examples that have survived irom this early period show differences from the European prototypes that came not merely from lack of means or skill. The need to adapt and combine shows up in the different size, character and emphasis of parts, reflecting a changed environment and outlook.

Colonial Styles.— By 1700 the effect of French and Dutch fashions on late Stuart furniture in England had become evident in the American colonies. Fashion consciousness appeared, though for decades to come the furniture of the average colonial home kept to the earlier tradition evolved from mediaeval joining. The box chest was succeeded by the chest of drawers, often placed on a stand with turned legs. Chairs began to replace stools and the early heavy turned and wainscot type gave may to simplified versions of the high-backed scrolled forms of the English Restoration fashion. The day bed or chaise longue appeared with its upholstered pad. Small folding tables, cabinets and the tiered dresser to store and display tableware can testify to the rapidly increasing standard of comfort among the more prosperous. Carved suriace decoration was largely replaced by colour, through the use of paint or veneers or inlays of contrasting wood.

These innovations accompanied the use of the cabriole or reverse curve, which by about 1725 became the favoured form for legs oi chairs, tables, cabinets and stands of all sorts. At first. when it had little or no carving and a simple pad foot, this cabriole leg became the principal feature of the so-called Queen Anne style which dominated colonial iurniture designs until the Revolution.

Early in the 18th century the craft of the cabinetmaker became distinct from that of the joiner. The increasing complexity and lightness of construction and the use of veneers demanded special skills. The decorative effect of drawer and case pieces was enhanced with brass drawer pulls and escutcheons. Walnut became the principal cabinet wood and mas used over a structural carcass of pine.

Development of U.S. Styles.— Shortly after 1750 the earlier cabriole style was transformed by two factors. One was the rapidly increasing popularity of mahogany. The other was the influence of the English version of free rococo ornament, as reflected in the publication of Thomas Chippendale (*Gentleman and Cabinet Maker's Director,* 1754). Increased prosperity made it possible for a new generation of highly skilled artisans to take full advantage of the qualities of the new wood and the rich new ornamental vocabulary.

While the southern planter still depended largely upon London for his fine iurnishings, the merchants of Philadelphia, New York, Newport and Boston were well rewarded by their patronage of local craitsmen. In Philadelphia a local version of the so-called Chippendale style was brought to the highest mastery by such craftsmen as Thomas Affleck, Jonathan Gostelowe, Benjamin Randolph and William Savery. In Newport, R.I., the genius of the Goddard and Townsend iamilies evolved an equally distinctive style by developing the block front, decorated by the patterns of the wood grains instead of the carving of their contemporaries in Philadelphia. In spite of the Philadelphians' evident desire to match the works of the best London shops, they actually created their own style as distinct from that of England as the innovations of their Newport colleagues. Though less strikingly characterized, the cabinetmakers oi Boston, New York and the Connecticut valley also produced work of high quality and a definitely local flavour. Maintaining its hold on popular taste until well after the Revolution, this colonial "Chippendale" retained more of the sturdy elegance oi the earlier cabriole style than did its English equivalent.

The tendency of English design to massiveness and surface decoration contrasts with an apparent preference for the vertical and linear tension in colonial design.

Classic Influences.— The new classicism introduced into England by Robert and James Adam in the 1760s and later popularized in the furniture designs of George Hepplewhite (1788) and Thomas Sheraton (1791) came into vogue in the United States during the last years of the century. The shipowners and merchants of Salem, Boston and New York equipped their mansions with the work of Samuel McIntire, James Seymour and Duncan Phyfe, each of whom produced individual interpretations of the Hepplewhite-Sheraton mode. This early iederal style, which also shows some influence of the French *Directoire,* is characterized by small-scale rectangular design relieved by curved forms in plan only, and by a preference for light-toned wood finishes. Surfaces are generally unbroken, but decorated with bandings and inlays of contrasting woods, or in Phyfe's case with low relief carvings in the Adam manner. The most typical pieces are the sideboard and the small secretary desk, both of which developed a peculiarly American form.

Victorian Styles.— The early phase of the classic revival was followed about 1820 by the heavy iorms and archaeological detail preferred by devotees oi the Napoleonic empire style and the Greek revival. Refinement of proportion was sacrificed to effects of richness and mass. Carved accents became coarser in size and were often heightened by gilding or gilt bronze mounts. Veneers of crotch mahogany stained to a dark ruddy finish became the principal surface decoration.

A rapid degeneration of quality followed the introduction of machine processes after 1830. Factory production and popular demand encouraged the welter of ornament and a restless search for eclectic novelty which characterized all design irom 1850 until the contemporary functional movement. In terms of decorative design in general, the Victorian era is well described as "the battle of the styles," though most of the theory behind the modern movement was evolved during the last hali of the 19th century.

Later Styles.— While the revolt against the past began with the *art nouveau* of the 1890s, it was brought to a head in the 1920s by the Bauhaus movement in Germany which was based upon modern technology and was inspired largely by fresh insight into the traditional Japanese attitude toward design. In spite of widespread reluctance irom producers and consumers to follow this lead it largely prevailed, undergoing considerable modification in the process.

In furniture the movement was marked by a drive toward lightness and mobility. A tendency to carry simplicity to the point of desiccation, however, generated its own reaction. There was an accompanying development of modular design, involving the economy of interchangeable parts, and also of the storage wall as a space-saving substitute for case pieces and cupboards. Technological developments gave scope to a new range of wood finishes. principally in light tones, and to attenuated forms made possible by extruded metal parts and new methods of upholstery. Improved processes of mood lamination made it possible for plywood to play a vastly greater part in furniture construction and even to inspire new iorms such as the Eames chair. While advanced mechanical techniques made construction improvements possible, output was largely influenced by the prevailing industrial philosophy of obsolescence. After 1945 the contemporary mode became international in scope.

MATERIALS

Wood.—Species generally used for the exposed parts of furniture are: walnut, birch, maple, cherry, mahogany and gum (which is coloured to mahogany or walnut finish). For the covered parts of upholstered furniture such woods as ash, oak, maple and beech are used as irames because of their stability, straightness and ability to hold nails or tacks. The most widely used imported wood is mahogany and for solid furniture Honduras is preferred. Other kinds of red-coloured woods that are called mahogany come from the upper Amazon, Africa and the Philippines. Both the light and dark mahogany from the Philippines are widely used for plywood and case goods. Other foreign moods such as teak are used in smaller quantities for special custom-made pieces. Solid woods are used for soia and chair construction while veneer panels or plywood are favoured in cases and chests.

At the sawmill, where the trees are cut into boards of various thicknesses, the lumber is piled with strips between layers. This permits free circulation of air to dry the lumber. It takes two or three years to air-dry one-inch lumber outdoors. depending on the species and atmospheric conditions. To dry lumber more rapidly these stripped piles are placed in kilns. A kiln is a heated room where the temperature and humidity are very closely controlled and the air is forced through stripped piles of lumber by large fans which periodically change the direction of air flow. By kiln-drying, the moisture content of some species of one-inch lumber can be reduced to 6% or 10% in a matter of days.

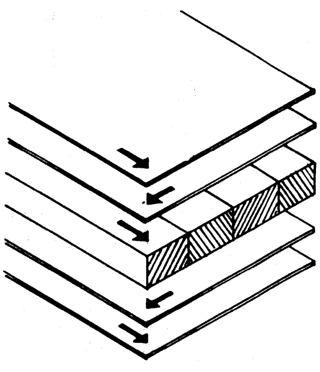

FIG. 1.— TYPICAL VENEERED LUMBER CORE PLYWOOD PANEL CONSTRUCTION

Plywood.— Panels with solid lumber cores in ¾-in. or 13/16-in. thicknesses are used for case goods construction because of the greater stability and interesting, uniform grain pattern of the face veneer. These panels consist of a ⅝-in. solid mood core sandwiched between two sheets of thin veneer, each 1/28-in. thick. These are set at right angles and glued and bonded under pressure. Beautifully grained veneers are cut irom select logs which are too costly to be used as solid wood. Cherry, white maple, birch, mahogany, oak, walnut. primavera. rosewood and other rare woods and plastics are used as veneers. Following World War II a resin-impregnated chip core is gradually replacing the solid poplar or other softwood core. The wood chips used in making this core were once a waste product of lumber mills.

In the thinner sizes plywood is made up of more uniform thicknesses oi glue-bonded pieces of wood set at right angles to each other. This type of plywood is used ior case backs, dust bottoms, drawer bottoms. It is also moulded to shape ior parts such as chair seats, chair backs, table and chair legs.

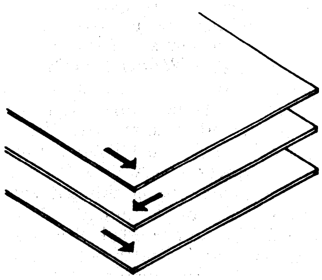

FIG. 2.— TYPICAL THIN PLYWOOD CONSTRUCTION

Hard Board.— Masonite is an example of hard board used instead of the thinner plywood in some inexpensive furniture

Glue.— Glue derived from animal hides has been used for centuries in the manufacture of furniture During. World War II there was a shortage of hide glue and synthetic glues were introduced. Of these the polyvinyl resin-base glues proved most satisfactory because they are easy to use and set quickly. Electrically heated resin glues will produce strong bonds in a matter of seconds.

Metal.— Steel in the form of sheets, rods and tubes is widely used for iurniture in institutions, hospitals, offices, homes and the transportation industry. In contemporary furniture steel is often combined with wood as a decorative feature. Following World War II aluminum almost completely replaced steel in outdoor furniture and invaded the institutional-furniture field because it neighs little and resists rust.

Brass, aluminum, silver, chromium and magnesium also became popular for decorating upholstered furniture and case goods.

Plastics.— Plastics appear in furniture in many forms. There are substitutes for metal hardware such as knobs and handles. Plastic veneers are laminated to wooden surfaces of table tops. They are used as ingredients in adhesives which bond together the parts of a piece of furniture. Some finishing materials are plastics, and plastics are moulded into chair seats.

Upholstery.—Upholstery is still mainly a handcraft. Modern machines cut multiple layers of fabrics, and staples replace tacking on inexpensive pieces, but well-made furniture is still produced by the skilled upholsterer, armed with needle, thread, hammer and a mouthful of tacks.

Upholstered furniture consists oi three main parts: the supporting unit, padding and cover. Spring-supported upholstery, which came into use during the 18th century, consists either of coil springs resting on burlap webbing and tied to the irame or the more modern non-sagging springs clipped to the frame. Other supporting units are plywood panels, webbed seat frames or steel bands held to the frame by helical springs. Padding is applied to the unit to provide comfort as well as styling. Padding is usually a layer of cotton placed over foam rubber, rubberized hair, Spanish moss or palm fibre held in place with burlap. The cover, of muslin and fabric or iabric alone, conceals this and is held in place by tacks or staples. Loose cushions are filled with special spring units, foam rubber or down, covered with layers oi cotton and encased in fabric.

Foam rubber, first introduced in furniture production in 1930, replaced many of the older padding materials. This spongelike rubber is made in sheets of various thicknesses which are easily cut to fit the furniture irame.

In upholstery work very few tools are necessary and only secondary experience is required on production-line operations. But highly skilled craftsmen are needed to make fine furniture.

Other Materials.— Glass is used to make doors and table tops or to protect table and chest tops. Ceramics, marble and tile are used to some degree in iurniture construction.

FURNITURE PRODUCTION

The Cabinet Shop.—A cabinet shop is usually a very small organization where the skilled headman develops or lays out the design and, with a few assistants, produces a finished piece of furniture. This type of shop specializes in custom and repair work so many hand tools are used, and the power-driven machines are oi the kind which can be easily adjusted to a wide variety of operations. In the C.S. only a small percentage of furniture is still made in cabinet shops.

A Typical Furniture Factory.— The average furniture plant usually has fewer than 100 employees. They operate many semi-automatic machines but such a factory is not conveyorized so completely as the mass-production plant. It is in these iactories that most of the fine iurniture is manufactured. This type of furniture requires considerable handwork to add refinements not found in inexpensive mass-produced iurniture.

The design for a piece of furniture is sketched and aiter the sketch is approved by the manufacturer a full-size drawing is made. Then a sample is made to check the design and production problems. After revising, the dran-ings are corrected and patterns and detailed cutting orders are sent to the production department. There the proper species of well-seasoned lumber is brought in. The lumber is usually planed on two sides so defects such as knots, cracks, and colour variations can be detected.

Straight rails are cut irom the boards by straight-line ripsaws and cutoff saws. The stock ior parts, which must be flat and straight, is usually faced or jointed aiter being cut to rough size. Curved parts are traced on boards, following patterns, and are cut out by a band saw. When curved parts are too large to be cut from boards received irom the lumber mill, the board defects are ripped out and the resulting narrow pieces are glued together into large panels from which the parts will be cut. Covered back legs are often made this way to save lumber. If the piece is a table or chest the panels which iorm the top or sides may also be glued in a similar manner, when solid wood is used for their construction.

In most rase goods such as chests and tables veneered lumber core plywood is used ior the large panels. If 100 or more pieces of the same kind are to he made. panels are purchased cut to exact size from plywood manufacturing companies. Then all that is necessary is to edge-band and cut the joints.

When parts must all be cut exactly alike, they are clamped in iorms having the proper contour and are then brought in contact with high-speed rotating knives which shape the part to proper size as the form rides against a guide on hand or automatic shapers and routers. Intricately carved pieces such as legs are roughly carved on multiple-spindle carving machines. These duplicate a master leg. by means of a follower point which is guided along the model surface and imparts the same motions to as many as 32 high-speed rotating

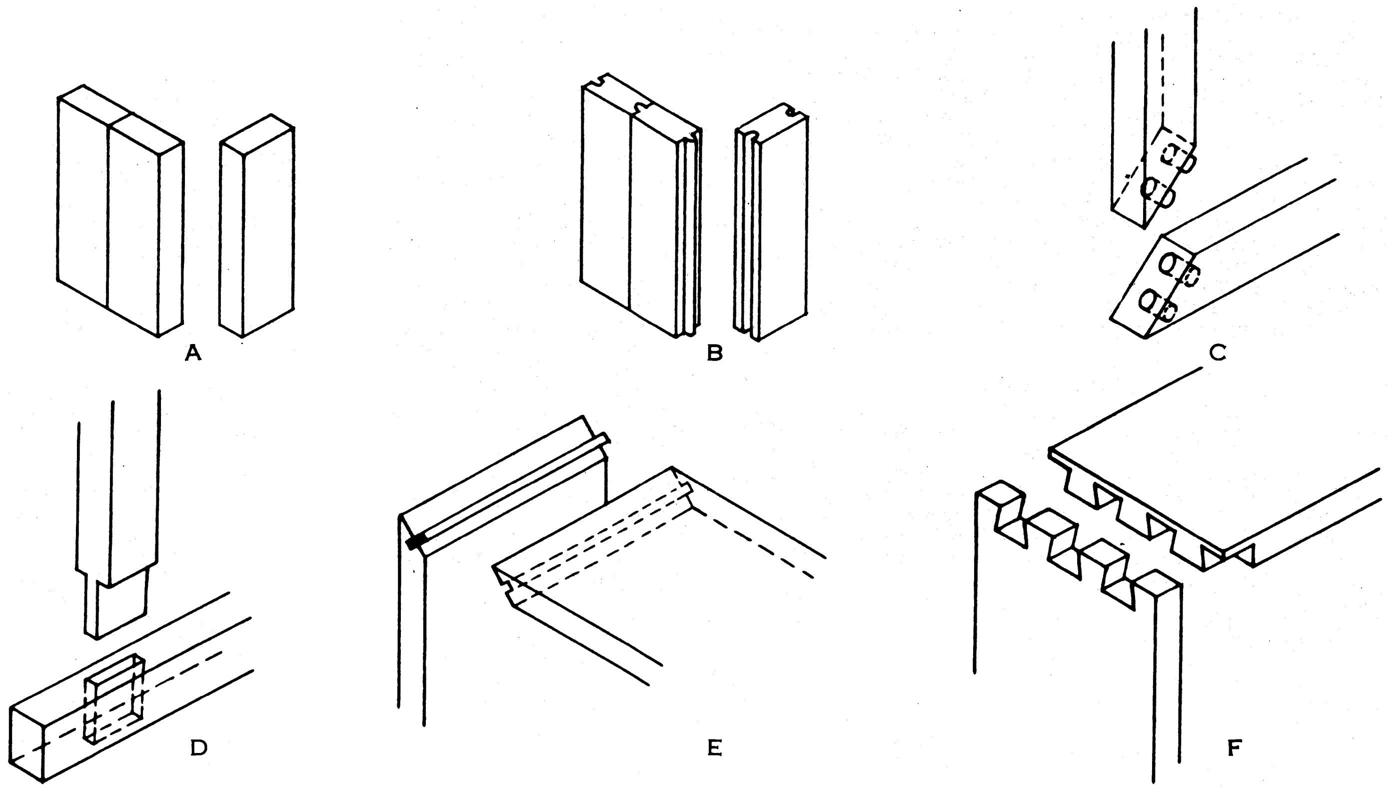

FIG. 3.— TYPICAL JOINTS USED IN FURNITURE MANUFACTURE: (A) PLAIN BUTT. AND (B) TONGUE AND GROOVE ARE USED CHIEFLY IN GLUED UP PANELS: (C) DOUBLE DOWEL IS THE MOST WIDELY USED JOINT IN UPHOLSTERED FURNITURE; (D) MORTISE AND TENON; (E) MITRE AND SPLINE. AND (F) DOVETAIL ARE USED PRIMARILY IN CASE GOODS CONSTRUCTION

knives as they whittle the leg blanks. After rough carving the legs are machine-sanded, and fine detail is added by the hand-carver. The next operation is periormed in the fitting department where the ends are cut to the desired angle, bored ior dowels or tenoned. Automatic modern machines often combine these operations. Exposed parts are sanded on edge belt sanders, three-drum travelling-bed sanders or belt sanders. Rounded parts are sanded on soft pneumatic drums and carved parts are sanded on a buffer, a machine ,which has shredded sandpaper supported by brushes on a revolving wheel. The parts are then glued and assembled. Often the side or back of a piece is assembled in air-driven clamps.

After the glue has set the parts may be returned to the machine department for additional machining that could not be performed before assembling, such as sanding joints even and shaping the edges. Then it goes back to the assembly department for final assembly. Air-driven clamps are used where the design permits. In other cases the piece can only be pressed together by hand clamps. Unless electronically cured glues are used, clamps must be applied long enough to ensure a good glue bond. The completed article is then cleaned to remove excess glue, inspected and hand-sanded to provide a smooth surface lor the finish. Application of the finish as well as upholstering is sometimes done in another iactory.

The **Mass-Production** Factory.— Mass-production factories are found in Grand Rapids, Mich., Jamestown, N.Y., and High Point, N.C. In the mass-production plants built after World War II it is possible to produce a small dinette chair in 35 minutes. The lumber is brought from the kiln to the rough mill department by motorized lumber carriers. There it is often lightly surfaced on both sides. Then power-fed cutoff saws remove deiects and cut the boards to length. Conveyors carry the hoards to hiah-speed ripsaws which remove remaining defects and trim the board to widths ready for gluing. These narrow boards are glued up into large panels, using resin glue in high-frequency quick-drying machines. The panels then go to a double surface planer. Such parts as chair back posts are rough-cut on a band saw in multiples and then shaped to exact size on an automatic shaper. The ends are trimmed and all holes bored in one operation by a front and back post-boring machine. Such parts as seat rails have both ends cut off, on plain or compound angles, and chucked or bored in one cycle of a double-end sawing, boring and chucking machine. Glue is shot into the dowel holes and the dowel driven in on a gluer and dowel driver. The exposed parts such as legs are then sanded on various types of automatic sanding machines before the chair is assembled and clamped in air-driven presses. The chair is now cleaned and sanded with 6/0 or 7/0 sandpaper to provide a smooth base for the finish.

FURNITURE CONSTRUCTION'

Wood Case Goods.— In most high-quality case goods the sides and tops usually are made of panels ⅝ in. or more in thickness. Panels may be made of solid woods or veneered lumber core. Back panels, dust panels and drawer bottoms usually are ¼-in. plywood. Drawers are separated by dust panels and slide on guide rails. The corner joints oi the drawers are oi a locking type such as the dovetail. If the design permits, there are numerous glue blocks reinforcing the corners of the case. On well-constructed furniture the joints are neatly made, well glued and tightly fitted.

Wood Chairs.— Good chair construction requires that the main rails be made oi well-seasoned hardwoods having sufficient width and thickness to provide rigid members. Joints should be well machined to provide complete wood contact for the glue whether they are double-dowelled or mortised and tenoned. Corners should be reinforced by fitted corner blocks glued and grooved or screwed in place. Cross members are added so that the tension of the springs and upholstery will not bend the long rails. Long legs of chairs are glued and dowelled between the rails or notched out, glued and double-dowelled to the rails, reinforced by screws, bolts or glue blocks. Short legs are usually double-dowelled to the bottom of the rails. On some modern iurniture the legs are pegged and glued into fitted corner blocks which are glued and screwed in place. A well-constructed piece of furniture is a rigid structure; arms should not be loose nor should the frame creak when someone sits on it. Cabinetmakers used to test the frame of an upholstered sofa by lifting the right front leg and watching the leit iront leg, which should lift when the right leg is about two-inches off the floor.

Finishing Wood **Furniture.**—The purpose of finish is to stabilize and preserve wood as well as to enhance-the beauty of the wood texture. A typical operation necessary to produce a quality finish of walnut wood is this: after the final machine sanding with 4/0 sandpaper just prior to finishing, the piece is hand-sanded with j/o paper. Light sapwood is stained to match the darker heartwood. Next a wash coat of lacquer thinned with three parts,of thinner is sprayed on and after drying is sanded with 8/0 paper. A filler is then sprayed or brushed on and padded into the pores of the wood. A coat of sealer is applied and sanded with 8/0 paper and followed by one or two coats of lacquer which are allowed to dry overnight or are quickly dried in heated chambers. It is then rubbed using ,360-grit wet-or-dry sandpaper and naphtha as a lubricant. Fine steel wool or special rubbing compounds are also used.

On tight-grained wood such as maple, a good quality finish can be obtained by using nongrain-raising stain and lacquer sealer. This is well sanded and followed by two coats of lacquer, each one rubbed down after application. On much inexpensive furniture the finish consists of a coat of coloured sealer followed by only one coat of lacquer which produces a less durable finish.

Some fine modern iurniture is finished by applying several coats of boiled linseed oil. This gives a mellow satin appearance.

After World War II a scratch-resistant group of synthetic lacquers was introduced to the furniture industry.

In the United States lacquers have almost completely replaced the so-called French finish and varnishes and shellacs in furniture production, which are used only in repairs or restorations of antiques.

Metal Furniture.—A great step was taken in metal furniture design when a chair of tubular steel was designed by Marcel Breuer in 1925 at the Bauhaus school in Germany. From his basic idea came large-scale production of low-priced steel and aluminum furniture designed for use in factories, hospitals, outdoors and in offices. Rod, wire and tubular metal shapes came to be used also in making complete furniture pieces or as supporting members of wood and upholstered furniture. Tubular steel is well adapted to furniture manufacture because it is lightweight, strong, flexible and more easily shaped than solid metal.

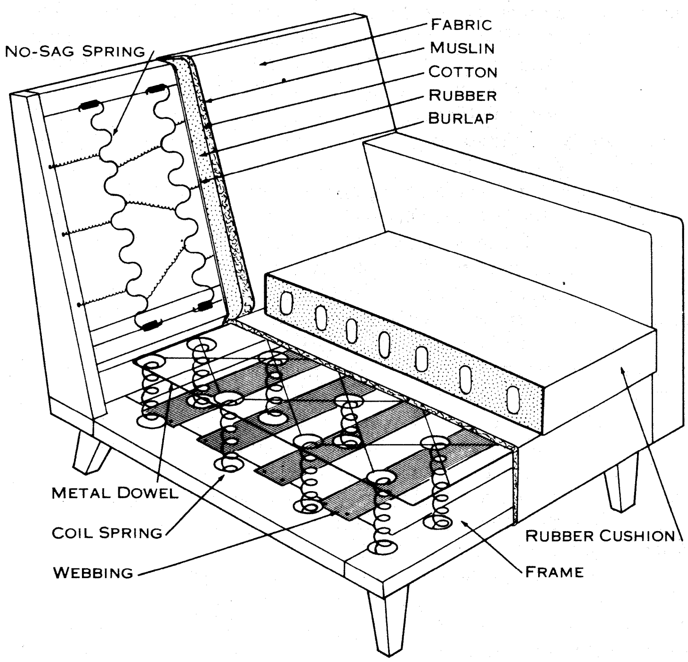

FIG. 4.—CONSTRUCTION FEATURES OF A MODERN UPHOLSTERED CHAIR

Metal furniture can be finished in several different manners. It can be painted with various coloured enamels applied over specially adapted primers. Steel can be chemically treated to produce a black or green rust-resistant finish or it can be chrome-plated.

Plastic Furniture.—Moulded plastics opened a great field for new design in sculptured forms.

The largest use of plastic is in the form of laminated sheets such as Formica and Micarta, which are easily bonded to plywood panels by special adhesives. These sheets are made with durable finishes in various colours and wood imitations. They are used extensively for table tops, kitchen-counter tops and bathroom furniture. Other plastics such as Koroseal, Naugahyde, Fabrilite and Duran, woven or in sheet form, are used in place of cloth fabric and replaced conventional upholstery webbing.

"Do-It-Yourself."—The "do-it-yourself" movement grew rapidly after World War II. This hobby, for which more than $6,000,000,000 a year are spent in the U.S., is a source of relaxation for millions of people who enjoy making things with their own hands. And what they make saves them money—they have only the cost of materials and tools.

The expansion of the "do-it-yourself" movement boosted the market for new tools, simple machinery, easily applied varnishes and paints, wood and plywood and simplified drawings which enabled amateur craftsmen to manufacture their own furniture.

The easiest "do-it-yourself" projects are outdoor furniture, magazine racks, tables, bookcases, cabinets, wardrobes, beds, chests and built-in units. The hard ones are chairs, armchairs and sofas.

(*See* also INTERIOR DECORATION.)

BIBLIOGRAPHY.—Mario Dal Fabbro, *How to Build Modern Furniture,* 2 vol. (New York, 1951–52); Herbert Bast, *Making Upholstered Furniture* (Milwaukee, Wis., 1951). (PL. R. B.; L. J. G. B.; M. D. F.)

FURNITURE POLISH. The two varieties in commonest use are furniture creams and furniture wax polishes, the quality of the polish differing with the ingredients used in its preparation.

Furniture creams are thick, milky white liquids, and are made by dissolving beeswax in turpentine by means of steam heat in a double-jacketed pan. Steam heat is used because of the dangerous inflammability of turpentine vapour in the presence of a naked light. After the beeswax has thoroughly melted, the steam is shut off and a solution of soft soap in hot water is added. The whole mass is then well beaten up to a thick, milky emulsion and packed in bottles ready for use. The beeswax may also be replaced, or partially replaced, by other waxes such as carnauba wax, Japan wax, ceresine wax, etc. The proportions of 9 oz. of pure beeswax (finely shredded) to $1\frac{1}{2}$ pt. of American spirits of turpentine, with the after addition of $1\frac{3}{4}$ pt. of hot water containing 2 oz. of soft soap dissolved in it, is considered to make a good mixture.

Furniture wax polishes are made by similarly dissolving beeswax and other waxes in turpentine with the aid of heat, about 1 lb. of wax to 1 qt. of turpentine being used. The clear melted liquid is then poured into tins, and on cooling sets hard and is ready for use. The addition of a little wax-soluble aniline dyestuff to the polish when in the liquid state is made in order to give it a more pleasing appearance.

An easily made polish, particularly suitable for cleaning old and dirty furniture, is obtained by shaking together 1 part of raw linseed oil, 1 part of turpentine and 1 part of vinegar.

FURNITURE WOODS: *see* HARDWOODS; TIMBER.

FURNIVALL, FREDERICK JAMES (1825–1910), English philologist and editor, was born at Egham, Surrey, Feb. 4, 1825. He assisted Frederick Denison Maurice in the Christian Socialist movement and was one of the founders of the Working Men's college, London. He promoted the study of early English literature, partly by his own work as editor and partly by the foundation of learned societies, especially the Early English Text society (1864), the Chaucer, Ballad, New Shakespeare and Wyclif societies and, at a later period, societies for the special study of Browning and Shelley.

His most important work was his "Six-Text" edition of the *Canterbury Tales.* He was honorary secretary of the Philological society and one of the original promoters of the *Oxford New English Dictionary.* He cooperated with its first editor, Herbert Coleridge, and after his death was for some time principal editor during the preliminary period of the collection of material.

Furnivall was always an enthusiastic oarsman, and throughout his life kept up his interest in rowing; with John Beesley in 1845 he introduced a new type of narrow sculling boat, and in 1886 started races on the Thames for sculling fours and sculling eights. He died July 2, 1910.

FURPHY, JOSEPH (pseudonym, TOM COLLINS) (1843–1912), Australian novelist, whose works proclaim nationalist social equality and were written with typical Australian raciness and broad humour. He was born at Yering, near Yarra Glen, Victoria, on Sept. 26, 1843, the son of an Irish immigrant. Educated by his mother, he worked at Kyneton, the Riverina and Shepparton, Victoria, where in 1884 he accepted a position in a foundry. There he began to write *Such Is Life,* which he finished in 1897 and published in three parts: *Such Is Life* (1903); *Rigby's Romance* (1921), which was serialized in *The Barrier Truth* in 1905; and *The Buln Buln and the Brolga* (1948). His *Poems* were published in 1916. A lean, shrewd, kindly man, Furphy was interested in schemes of social regeneration. He died at Claremont, Western Australia, on Sept. 13, 1912.

See K. Baker and M. Franklin, *Joseph Furphy* (1944).

(C. M. H. C.)

FURSE, CHARLES WELLINGTON (1868–1904), English romantic painter, was born at Staines, Middlesex, on Jan. 13, 1868. He entered the Slade school in 1884, winning the Slade scholarship the following year, and completed his education at Julian's academy in Paris. "Cain" was the first painting he exhibited at the Royal Academy (1888). He regularly showed work at the New English Art club. Among his pictures are: "Diana of the Uplands," "Lord Roberts" and "The Return from the Ride" (London). Elected an associate of the Royal Academy in 1904, Furse died in London on Oct. 16, 1904. (D. L. FR.)

FUR SEALS, a little group of marine carnivorous mammals forming the genera *Arctocephalus* and *Callorhinus.* The fur seals resort, or once resorted, in vast numbers to crowded "rookeries."

All the islands of the Southern ocean were densely peopled by fur seals when first discovered; so were Juan Fernandez, the neighbouring Mas-a-Fuero, the Kuriles and the islands in Bering sea. On the other side of America, in the Plate estuary, the Lobos Islands also have their seal herd. The history of nearly all these rookeries is one of wanton waste and rapid extermination. The South Shetlands were discovered in 1819; within two years the rookeries were already exterminated. The only herds to escape destruction are those of the Lobos Islands (Uruguay), of the Pribilof Islands (United States), and of the Russian Commander Islands.

The fur seal is polygamous as well as gregarious. The bulls or sikatchi, live to a great age and grow to a great size, far beyond that of the females. They arrive on their breeding-places in spring, choose their quarters on the rocky beach, and are joined a few weeks later by the cows (or matkas), who come in heavy with young. The pups (or kotik) are born soon after, and the comparative quiet of the rookery becomes a babel of angry noise. The bulls fight for possession of the cows, each striving to gather and keep a "harem" round him. The cows go out to sea to feed, but the bulls never leave their posts and fast throughout the season; they come in fat and vigorous in May, and leave in autumn gaunt, lean and battle-scarred. The young males or bachelors (holloschickie) keep to themselves, "hauling out" behind the breeding herd. Males and females are born in equal numbers; and the economic management of a rookery consists in protecting all females, in leaving the harems undisturbed, and in taking such toll of the young bachelors as to leave enough to take the places of the breeding bulls.

The Pribilof Islands, discovered in 1786, passed into the hands of the United States with the Territory of Alaska in 1867; their great rookeries had been wastefully used and ruinously depleted to begin with, but the Russian government had nursed them back into prosperity for 30 years, till at the time of the purchase they yielded 100,000 skins a year. But about 1880, pelagic sealing grew up, wherein young and old, males and females were killed without discrimination. This soon showed its effects upon the herd. After the U.S. government in 1911 took the fishery into their own hands, pelagic sealing was finally abolished, on terms of equitable compensation. The Commander Islands on the Russian side have a different tale to tell. The war and then the revolution led to neglect ashore and to piratical raids from the sea; and an expert who had visited these islands in 1897 and came again in 1922 was "dismayed" at the shrunken rookeries. See SEAL FISHERIES, CARNIVORA. (D. W. T.)

FURSEY (FURSEUS), **SAINT** (d. before 652), Irish monk and visionary. Of his early years nothing certain is known. After 630 he left Ireland for England and founded the monastery of Cnoberesburgh in the dominions of King Sigebert of East Anglia. After the king's death he crossed to France (before 644) and founded a monastery at Lagny on the Marne. When Fursey died (perhaps in 649) Erchinoald, mayor of the palace in Neustria, took possession of his body and 30 days later had him buried in his newly founded church at Péronne in Picardy. The earliest life of Fursey, written shortly after his death, has considerable historical value. His feast day is Jan. 16.

Fursey was said to have had visions of the other world, which became widely known through the account in Bede's Ecclesiastical History; they had considerable influence on the vision literature of the later middle ages. The shrine of Fursey at Péronne attracted many pilgrims, especially from Ireland, and the monastery of Péronne retained its Irish character until (and possibly beyond) the end of the 8th century. Fursey's brothers, St. Foillan (who had succeeded him at Cnoberesburgh) and St. Ultán, stayed at Péronne for some time, then went to Brabant and established themselves at Fosses. Later Ultán seems to have been abbot of Péronne.

See J. F. Kenney, *Sources for the Early History of Ireland,* pp. 500–505 (1929); L. Gougaud, *Christianity in Celtic Lands,* pp. 146–148 (1932). (L. BR.)

FÜRSTENBERG, the name of two noble houses of Germany. 1. The more important ruled in a mediatized principality in the district of the Black Forest and the Upper Danube, which comprises the countship of Heiligenberg, about 7 m. N. of the Lake of Constance, the landgraviates of Stuhlinger and Baar, and the lordships of Jungnau, Trochtelfingen, Hauser and Moskirch or Messkirch. The territory is discontinuous; and lies partly in Baden, partly in Wurttemberg, and partly in the Prussian province of Sigmaringen. The relations of the principality with Baden are defined by the treaty of May 1825, and its relations with Wurttemberg by the royal declaration of 1839. The *Stammort* or ancestral seat of the family is Furstenberg in the Black Forest, but the principal residence of the Furstenbergs is at Donaueschingen.

The family of Furstenberg claims descent from a certain Count Unruoch, a contemporary of Charlemagne, but their authentic pedigree is only traceable to Egino II., count of Urach, who died before 1136. In 1218 his successors built the town and castle of Furstenberg. Of the two sons of Egino V. of Urach, Conrad, the elder, inherited the Breisgau and founded the line of the counts of Freiburg, while the younger, Heinrich (1215–1284), received the territories lying in the Kinzigthal and Baar, and from 1250 onward styled himself first lord, then count, of Furstenberg. His territories were subsequently divided, though temporarily reunited under Count Friedrich III., whose wife, Anna, heiress of the last count of Wardenberg, brought him the countship of Heiligenberg and lordships of Jungnau and Trochtelfingen in 1534. On Friedrich's death (1559) his territories were divided between his two sons, Joachim and Christof I. Of these the former founded the line of Heiligenberg, the latter that of Kinzigthal.

In 1909 there were two branches of the princely house of Fiirstenberg: (1) the main branch, that of Fürstenberg-Donaueschingen, the head of which was Prince Maximilian Egon (b. 1863), who succeeded his cousin Karl Egon III. in 1896; (2) that of Fiirstenberg-Konigshof, in Bohemia, the head of which was Prince Emil Egon (b. 1876), chamberlain and secretary of legation to the Austro-Hungarian embassy in London (1907). The cadet line of the landgraves of Furstenberg is now extinct, its last representative having been the landgrave Joseph Friedrich Ernst of Fürstenberg-Weitra (1860–1896), son of the landgrave Ernst (1816–1889) by a morganatic marriage. He was not recognized as *ebenbürtig* by the family. The landgraves of Furstenberg were in 1909 represented only by the landgravines Theresa (b. 1839) and Gabrielle (b. 1844), daughters of the landgrave Johann Egon (1802–1879).

From the days of Heinrich of Urach, a relative and notable supporter of Rudolph of Habsburg, the Furstenbergs have played a stirring part in Germany history as statesmen, ecclesiastics and notably soldiers. There was a popular saying that "the emperor fights no great battle but a Furstenberg falls." In the Heiligenberg line the following may be more particularly noticed.

FRANZ EGON (1625–1682), bishop of Strasbourg, was the elder son of Egon VII., count of Furstenberg (1588–1635), who served with distinction as a Bavarian general in the Thirty Years' War. He began life as a soldier in the imperial service, but on the elevation of his friend Maximilian Henry of Bavaria to the electorate of Cologne in 1650, he went to his court and embraced the ecclesiastical career. He soon gained a complete ascendancy over the weak-minded elector, whose Francophile policy he instigated. Ecclesiastical preferments were heaped upon' him, and in 1663 he became bishop of Strasbourg. On the conclusion of a treaty between the emperor and the elector of Cologne, on May 11, 1674, Franz was deprived of all his preferments in Germany, and was compelled to take refuge in France. He was, however, amnestied with his brother William by a special article of the Treaty of Nijmwegen (1679), whereupon he returned to Cologne. He died on April 1, 1682 at Strasbourg.

His brother WILLIAM EGON (1629–1704), bishop of Strasbourg, began his career as a soldier in the French service. He went to the court of the elector of Cologne at the same time as Franz Egon, whose policy he shared. In 1672 William was seized by imperial soldiers in the monastery of St. Pantaleon at Cologne, hurried off to Vienna and there tried for his life. He was saved by the intervention of the papal nuncio, but was kept in prison till the signature of the Treaty of Nijmwegen (1679). As a reward for his services Louis XIV. appointed him bishop of Strasbourg in succession to his brother in 1682, in 1686 obtained for him from Pope Innocent XI. the cardinal's hat, and in 1688 succeeded in obtaining his election as coadjutor-archbishop of Cologne and successor to the elector Maximilian Henry. At the instance of the emperor, however, the pope interposed his veto; the canons followed the papal lead, and, the progress of the Allies against Louis XIV. depriving him of all prospect of success, William Egon retired to France. He died on April 10, 1704 near Paris.

In the Stühlingen line the most notable was KARL EGON (1796–1854), prince of Fürstenberg, the son of Prince Karl Alois of Furstenberg, a general in the Austrian service, who was killed at the battle of Loptingen on March 25, 1799. In 1804 he inherited the Swabian principality of Furstenberg and all the possessions of the family except the Moravian estates. By the mediatization of his principality in 1806 the greater part of his vast estates fell under the sovereignty of the grand-duke of Baden. In politics he distinguished himself by a liberalism rare in a great German noble, carrying through by his personal influence with his peers the abolition of tithes and feudal dues and stanchly advocating the freedom of the press. His palace of Donaueschingen, with its collections of paintings, engravings and coins, was a centre of culture, where poets, painters and musicians met with princely entertainment. He died on Sept. 14, 1854, and was succeeded by his son Karl Egon II. (1820–1892), with the death of whose son, Karl Egon III., in 1896, the title and estates passed to Prince Maximilian Egon, head of the cadet line of Fürstenberg-Pürglitz.

2. The second Fiirstenberg family has its possessions in Westphalia and the country of the Rhine, and takes its name from the castle of Furstenberg on the Ruhr. The two most remarkable men whom it has produced are Franz Friedrich Wilhelm, freiherr von Fiirstenberg, and Franz Egon, count von Fürstenberg-Stammheim. The former (1728–1810) became ultimately vicar-general of the prince-bishop of Munster, and effected a great number of important reforms in the administration of the country, besides doing much for its educational and industrial development. The latter (1797–1859) was an enthusiastic patron of art, who assisted the completion of the Cologne cathedral, and erected the beautiful church of St. Apollinaris near Remagen on the Rhine. He was a member of the Prussian Upper House in 1849, collaborated in founding the *Preussisches Wochenblatt,* and was an ardent defender of Catholic interests.

FURSTENWALDE, a town of eastern Germany, on the Spree river and the Oder-Spree canal. 28 mi. E. of Berlin on the railway to Frankfurt an der Oder. Pop. (1950) 30,388. Fürstenwalde is one of the oldest towns in the district of Frankfurt. From 1385 it was the seat of the bishop of Lebus. whose bishopric was incorporated with the electorate of Brunswick in 1595. The industries include. besides brewing and malting. manufactures of chemicals. boots, organs. stoves, etc.. iron founding and wool weaving. It was bombed in World War II.

FURTH, a manufacturing town of Germany, in the *Land* of Bavaria. at the confluence of the Pegnitz with the Regnitz. 5 mi. N.W. of Nurnberg by rail, at the junction of lines to Hof and Würzburg. Pop. (1950) 99,943. Fürth was founded, according to tradition, by Charlemagne, and was for a time under the burgraves of Nürnberg, but about 1314 it was bequeathed to the see of Bamberg. In 1806 it came into the possession of Bavaria. The old St. Michaeliskirche is a handsome structure; but the town's chief edifice is the new town hall, with a tower 175 ft. high. Furth owed its prosperity to the tolerance it meted out to the Jews, who found here an asylum from the oppression under which they suffered in Nurnberg, and who had a synagogue and a high school and were prosperous until Hitler's rise to power. Industries include production of chromolithographs and picture-books, manufacture of mirrors and mirror-frames, bronze and gold-leaf wares, pencils, toys, haberdashery, optical instruments, silver work, turnery, machinery and fancy boxes, and a trade in hops, metals, wool and coal. An annual fair is held at Michaelmas. The earliest railway in Germany was that between Nurnberg and Furth (opened Dec. 7, 1835).

FURTWÄNGLER, ADOLF (1853–1907), German archaeologist, was born on June 30, 1853, at Freiburg-im-Breisgau, and died at Athens on Oct. 10, 1907. From 1878 to 1879 he was engaged in work on the excavations at Olympia, and in 1884 became professor of archaeology in Berlin, exchanging his chair in 1894 for one at Munich. He conducted the excavations at Aegina and Orchornenos in 1901–03, and was the author of many important works on archaeology, notably *Die antiken Gemmen* (1900), and *Griechische Vasenmalerei,* begun in 1900 with Reichold, and continued by other scholars.

FURTWÄNGLER, WILHELM (1886–1954), German conductor, was born in Berlin Jan. 25, 1886, the son of the archaeologist Adolf Furtwängler (1853–1907). He received his musical education in Munich from Beer-Walbrunn, Rheinberger and Schillings, and then acted as conductor at Zürich. Later he occupied similar positions at Strasbourg, Lübeck, Mannheim, Vienna and Frankfurt-on-Main. In 1922, on the death of Arthur Nikisch, he became director of the Berlin Philharmonic and of the *Gewandhaus* concerts at Leipzig; he also gave annual concerts in New York. He conducted the Wiener Philharmonische Konzerte from 1927 to 1944 and again after 1948, became first conductor of the Berlin State Opera in 1933 and led the Bayreuth festivals. 1931, 1936 and 1937. He died near Baden-Baden, Ger., Nov. 30, 1954.

FURZE, GORSE or WHIN, botanical name *Ulex,* a genus of thorny papilionaceous shrubs of the family Leguminosae (*q.v.*), comprising 20 species, confined to west and central Europe and northwest Africa. Common furze, *U. europaeus,* is found on heaths and commons in western Europe from Denmark to Italy and Greece and in the Canaries and Azores, and is abundant in the British Isles. It grows to a height of two to six feet; it has hairy stems, and the smaller branches end each in a spine; the leaves, sometimes lanceolate on the lowermost branches. are mostly represented by spines from two to six lines long, and branching at their base; and the flowers, about three-quarters of an inch in length, have a shaggy, yellowish-olive calyx with two small ovate bracts at its base, and appear in early spring and late autumn. They are yellow and sweet scented and visited by bees. The pods are few seeded; their crackling as they burst may often be heard in hot weather. This species comprises *U. europaeus* proper, which has spreading branches and strong, many-ridged spines. and U. *strictus* (Irish furze), with erect branches and slender four-edged spines. Another British species of furze is *U. nanus,* dwarf furze, also a native of Belgium. Spain and the west of France; it is a procumbent plant. less hairy than *U. europaeus,* with smaller and more orange-coloured flowers, which spring from the primary spines and have a nearly smooth calyx with minute basal bracts. Furze or gorse is sometimes employed for fences.

Notwithstanding its formidable spines, the young shoots yield a palatable and nutritious winter forage for horses and cattle. To fit it for this purpose it must be chopped and bruised to destroy the spines. There are a variety of machines by which this is done rapidly and efficiently, and which are in use where this kind of forage is used to any extent. The agricultural value of this plant has often been overrated by writers. In the case of poor, dry soils it does, however, yield much valuable food at a season when green forage is not otherwise to be had. It is given to horses and cows in combination with chopped hay or straw.

This plant is invaluable in mountain sheepwalks. The rounded form of the furze bushes in such situations shows how diligently the annual growth, as far as it is accessible, is nibbled by the sheep. The food and shelter afforded to them in snowstorms by clusters of such bushes is also of much importance. Young plants of whin are so kept down by the sheep that they can seldom attain to a profitable size unless protected by a fence for a few years. In various parts of England whin is cut for fuel. The ashes contain a large proportion of alkali and are a good manure, especially for peaty land.

FUSARO, a lake of Campania, Italy, ½ mi. W. of Baiae and 1 mi. S. of the acropolis of Cumae. It is the ancient Acherusia *palus,* separated from the sea on the west by a line of sand hills It may have been the harbour of Cumae in early antiquity. In the 1st century AD. an artificial outlet was dug for it at its south end, with a tunnel, under the hill of Torregaveta. This hill is covered with the remains of a large villa, which is almost certainly that of Servilius Vatia, described by Seneca. There are remains of other villas on the shores of the lake. Oyster cultivation is carried on there and there is a hydrobiological station in the former royal casino on an island in the lake.

FUSE. Japanese city in Osaka prefecture, east of Osaka city of which it is essentially an industrial and residential satellite. Pop. (1955) 176,052. Cotton textiles and metal casting were locally important during the feudal period and provided the foundation for modern industrialization after rail lines were built to Osaka in 1914 and 1924. In addition to metals and machinery manufacturing, Fuse specializes in such consumer goods as textiles, celluloid toys, leather and rubber goods, medicinals and chemicals. (J. D. EE.)

FUSE (FUZE), an appliance for firing explosives in military shells, missiles, mines and bombs, in blasting operations, in fireworks and, in an entirely different form, to protect electrical circuits from the effects of overloads. *(See* BLASTING; AMMUNITION, ARTILLERY; FIREWORKS.)

The word is one of the forms in which the Latin *fusus* ("spindle") has been adapted into English, early forms of the military shell fuze having taken the form, ordinarily, of a spindlelike tube. Spelling of the word for detonation of explosives was originally with an "s." United States military forces found it desirable to adopt the "z" spelling to avoid confusion with the verb fuse, to melt by heat, or with the electrical fuse derived from the verb, or the fuse of blasting operations and fireworks.

In ammunition and other ordnance-type munitions, fuze denotes a device that causes the munitions to function under desired conditions. It regulates the final functioning of the munition, and should not be confused with either the primer or the firing pin which initiate launching of a rocket or artillery shell, nor with such items as a detonator or striker which are initiating components of a fuze.

Normally, a fuze has elements to set off the munition, to prevent its premature functioning and to cause it to perform only under predetermined conditions. These conditions determine the general type to which a fuze belongs, there being, broadly, five types: (1) impact fuze, which functions as it hits the target; (2) time fuze, which delays functioning for a certain period from a starting time; (3) command fuze, which acts upon some form of signal from a remote-control point; (4) proximity fuze, which functions when the munition carrying it approaches to within a given distance of the target; and (5) inferential fuze, which recognizes conditions leading to the inference that a target is nearby.

In blasting operations and in fireworks, the term fuse denotes a device employed to fire explosives from a distance or after a delay. Safety fuse is a hollow cord filled with a cpmposition resembling black powder and designed to propagate burning at a slow and steady rate. The far end of the fuse is usually crimped into a detonator *(q.v.)* embedded in the explosive charge. Instantaneous fuse, also called Cordeau and Primacord, is a hollow cord filled with powdered PETN (pentaerythritoltetranitrate). Fired by a detonator, it propagates detonation at a speed in excess of 6,000 m. per second and is capable of initiating the detonation of certain explosives.

In electrical engineering a fuse (always so spelled) is a safety device, commonly consisting of a strip or wire of easily fusible metal, which melts and thus interrupts the circuit of which it forms a part, whenever that circuit, through some accident or derangement, is caused to carry a current larger than that for which it is intended. In this sense the word derives from *fusus,* the past participle of Lat. *fundere* ("to pour") from which comes the verb fuse, to melt by heat. (F. D. McH.)

FUSELAGE, the central structure of an airplane (*q.v.*), connecting the wings with the tail surfaces, and containing the crew, passengers and sometimes the power plant and fuel. "Body" is in general use in a similar sense but includes also both the shorter nacelle of the airplane with "pusher" air screw, and the engine nacelle of the multiengine airplane.

There are two chief forms of fuselage construction. In one an underlying braced framework is used (formerly of wood and steel, now generally of metal throughout) with a covering of fabric, the latter kept in a "fair" shape by light supporting ribs. The other is on the lines of a boat, comprising a thin continuous skin with strengthening ribs, of wood or of metal throughout.

Such a scheme has the advantage that cross bulkheads are not essential, and is therefore convenient when large cabin space is required. In practice, however, the construction of the former can be made sufficiently free from obstructions, and is generally preferred on account of lightness. (W. S. F.)

FUSELI, HENRY (JOHANN HEINRICH FÜSSLI or FUESSLI) (1741–1825), Anglo-Swiss historical painter and author, one of the most exotic, original and sensual of painters, though not one of the greatest, was born at Zurich, Switz., on Feb. 7, 1741, the son of Johann Caspar Fussli, a court painter and town clerk. Educated at the Collegium Carolinum in Zurich he was influenced by J. J. Bodmer, but later as a theological student he fled together with his friend Johann Caspar Lavater as the result of a political publication. He traveled to Berlin and, on the recommendation of the British ambassador, to London in 1764. In 1765 he translated J. J. Winckelmann's *Reflections on the Painting and Sculpture of the Greeks* into English. He was encouraged by Sir Joshua Reynolds to become a painter and went to Italy, arriving in Rome in 1770. In Venice in 1772 fever affected his right hand. He sent his first work, "The Death of Cardinal Beaufort" (Liverpool), to the Royal Academy in 1774. During his stay in Rome he studied Michelangelo and the antique, and visited Naples in 1775. He left for Zurich in 1778, where he painted "The Oath on the Rutli," returned to London in 1779 and painted "The Nightmare" in 1781. In 1788 he was elected associate of the Royal Academy. becoming a member two years later. He contributed nine pictures for John Boydell's Shakespeare gallery. His own Milton gallery of 40 large paintings, opened in 1799, was only moderately successful. During 1799–1805 he was professor of painting at the Royal Academy. In 1801 the first of his *Lectures on Painting* were published, showing his continued admiration for the heroic and for Michelangelo. He was elected keeper of the Royal Academy in 1804 and edited Matthew Pilkington's *A Dictionary of Painters* in 1805, and wrote the introduction for William Blake's edition of R. Blair's *The Crave*. Although he said, "Blake is damned good to steal from," he introduced the younger artist to Joseph Johnson, his only commercial publisher. In 1810 he was re-elected professor at the Royal Academy. His pupils included Sir Thomas Lawrence, Sir David Wilkie, William Etty, W. Mulready, B. R. Haydon, Sir Charles Eastlake and Sir Edwin Landseer, his "little dog-boy." He died on April 16, 1825, at Putney Hill, and is buried in St. Paul's cathedral.

His diminutive size and bitter wit made him one of the best-known figures in London artistic life. His mannered drawings of elongated women and dreamlike paintings had and still have an influence on European imaginative painting.

BIBLIOGRAPHY.—Life by John Knowles, prefixed to the collected *Works* (1831); Eudo C. Mason (ed.), *The Mind of Henry Fuseli* (1951); Nicolas Powell, *The Drawings of Henry Fuseli* (1951); Frederick Antal, *Fuseli Studies* (1956). (C. N. P. P.)

FUSEL OIL, the term applied to the mixture of volatile, oily liquids of characteristic odour and taste produced during alcoholic fermentation processes.

The fusel oil alcohols and their esters find wide use as specialty solvents and plasticizers in the lacquer, plastic coating and pharmaceutical industries.

In industrial alcohol plants, fusel oil alcohols and ethyl alcohol are recovered from the fermented liquors and separated from each other by complicated distillation processes. Very little fusel oil is recovered by the beverage industry. In small doses fusel oil alcohols cause thirst and headache. In larger doses they are convulsive poisons.

The amount produced is comparatively small and is dependent on the raw materials used and the conditions of fermentation. The gallons of fusel oil produced per 1,000 gal. of ethyl alcohol for the principal fermentation raw materials are: blackstrap molasses 4–5; evaporated cane juice 1–2; corn 4–5; degerminated corn 2.5–3.0; wheat 2–3; rye 2–4; potatoes 5–11; sulfite liquor 2–3.

Fusel oil is a mixture of n-amyl, active amyl, isoamyl, isopropyl, *n*-propyl, *n*-butyl and isobutyl alcohols with traces of various esters. As indicated by the table the percentage composition varies with the raw materials used.

A typical fusel oil will contain 60%–70% of amyl alcohols, the remainder being lower alcohols, primarily *n*-propyl and isobutyl alcohol. Distribution of the amyl alcohols present is approximately 80%–85% isoamyl alcohol, 10%–15% active amyl alcohol, with

Constituent	Corn	Molasses	Potatoes	Rye
Isopropyl alcohol	—	0.6	—	—
n-Propyl alcohol	20.4—11.7	24.3	6.85	—
Isobutyl alcohol	23.9—12.2	7.4	24.35	15.7
n-Butyl alcohol	—	8.1	—	—
d-Amyl alcohol	14.6—23.4	55.3	68.76	77.8
Isoamyl akohol	36.3—59.7	—	—	—
n-Amyl alcohol	—	4.3	—	—
Undetermined	4.8— 3.0	—	0.04	6.5

perhaps a trace of n-amyl alcohol.

Unlike ethyl alcohol the fusel oil alcohols do not seem to be produced by the action of the yeast enzyme zymase on glucose, but rather by its action on the protein impurities and protein decomposition products (amino acids) present in the fermentation liquors. (D. G. Z.)

FUSIBLE ALLOYS, which generally are composed of bismuth, lead and tin, possess the property of melting at comparatively low temperatures, below the melting point of tin. They are used as soft solders and for safety plugs in boilers, oxygen tanks, sprinkler systems, etc. Newton's fusible alloy (named after Sir Isaac Newton) contains 50 parts of bismuth, 31.25 of lead and 18.75 of tin; that of Jean Darcet (1725–1801), 50 parts of bismuth with 25 each of lead and tin; and that of Valentin Rose the elder (1736–71), 50 of bismuth with 28.1 of lead and 24.1 of tin. These melt between 91° and 95° C. Mercury also is sometimes used as an ingredient. The addition of cadmium gives still greater fusibility; in Wood's metal, for instance, which is Darcet's alloy with half the tin replaced by cadmium, the melting point is lowered to 66°–71° C.; while another alloy containing 15 parts of bismuth, 8 of lead, 4 of tin and 3 of cadmium softens at about 55° and is completely liquid a little above 60°. By the addition of mercury to Darcet's alloy the melting point may be reduced as low as 45°.

These fusible alloys have the peculiarity of expanding as they cool; Rose's alloy, for instance, remains pasty for a considerable range of temperature below its fusing point, contracts somewhat rapidly from 80° to 55°, expands from 55° to 35°, and contracts again from 35° to 0°. For this reason they may be used for taking casts of anatomical specimens, making impressions of woodcuts, etc., the expansion on cooling securing sharp impressions.

By suitable modification in the proportions of the components, a series of alloys can be made which melt at various temperatures above the boiling point of water; for example, with eight parts of bismuth, eight of lead and three of tin the melting point is 123°, and with eight of bismuth, 30 of lead and 24 of tin it is 172°. With tin and lead only in equal proportions it is 241°. Such alloys are used for making the fusible plugs inserted in the furnace crowns of steam boilers, as a safeguard in the event of the water level being allowed to fall too low. When this happens the plug, being no longer covered with water, is heated to such a temperature that it melts and allows the contents of the boiler to escape into the furnace. In automatic fire sprinklers the orifices of the pipes are closed with fusible alloys which melt and liberate the water when an outbreak of fire in the room raises the temperature above a predetermined limit.

FUSION. In business and finance, fusion is a term signifying a complete combination of several concerns into one. Fusion is accomplished by two methods, by merger and by consolidation. When the fusion of two or more business organizations takes place by merger one of them absorbs the other or others, maintaining its own corporate existence under its own charter (amended if necessary), and taking either its own name or that of one of the concerns absorbed. All of the concerns to a merger which are absorbed into the remaining one give up their charters and corporate existence.

When fusion by consolidation takes place two or more companies organize a new company, transfer to it all of their assets, and then dissolve their own respective organizations. In popular usage the terms fusion, merger, consolidation, and several others are often confused and used incorrectly. Fusion is the general term embracing both mergers and consolidations. If companies *A*, *B* and *C* fuse by merger, two of them, let us say B and C, will go out of existence and all of their assets will go to build up the enlarged company *A*. If, however, companies X, Y and *Z* are to be consolidated, all of them will go out of existence and their assets will go to form the new company under a new charter.

For Fusion in Physics see HEAT.

FUST, JOHANN (c. 1400–1466), early German printer, belonged to a rich and respectable burgher family of Mainz, which is known to have flourished from 1423, and to have held many civil and religious offices. Johann Fust appears to have been a money-lender or banker. He advanced money to Gutenberg (apparently 800 guilders in 1450, and another 800 in 1452) for carrying on his experiments in printing, and, in 1455, brought a suit against Gutenberg to recover the money he had lent, claiming 2,020 (more correctly 2,026) guilders for principal and interest. It appears that he had not paid in the 300 guilders a year which he had undertaken to furnish for expenses, wages, etc., and, according to Gutenberg, had said that he had no intention of claiming interest. The suit was apparently decided in Fust's favour, Nov. 6, 1455, in the refectory of the Barefooted Friars of Mainz, when Fust made oath that he himself had borrowed 1,550 guilders and given them to Gutenberg. The 42-line Bible known as Gutenberg's, of which the Mazarin library copy bears the date of 1456, is thought by a preponderance of bibliographers to have been printed by Fust and Peter Schöffer, of Gernsheim, who is known to have been a scriptor at Paris in 1449. To him, probably about 1455, Fust gave his only daughter, Dyna or Christina, in marriage. Their first certain publication was the Psalter, Aug. 14, 1457, a folio of 350 pages, the first printed book with a complete date, and remarkable for the beauty of the large initials printed each in two colours, red and blue, from types made in two pieces. The Psalter was reprinted with the same types, 1549 (Aug. 29), 1490, 1502 (Schoffer's last publication) and 1516. In addition to the works already mentioned Fust and Schöffer printed: Durandus, *Rationale divinorum officiorum* (1459), folio, 160 leaves; the *Clementine* Constitutions, with the gloss of Johannes Andreae (1460), 51 leaves; *Biblia* Sacra *Latina* (1462), folio, 2 vols., 242 and 239 leaves, 48 lines to a full page; the Sixth Book of Decretals, with Andreae's gloss, Dec. 17, 1465, folio, 141 leaves; Cicero, *De officiis* (1465), 4to, 88 leaves, the first edition of a Latin classic and the first book containing Greek characters, while in the colophon Fust for the first time calls Schoffer "puerum suum"; the same, Feb. 4, 1466; *Grammatica rhytmica* (1466), folio, 11 leaves. They also printed in 1461–62 several papal bulls, proclamations of Adolf of Nassau, etc.

Fust is said to have gone to Paris in 1466 and to have died of the plague which raged there in August and September. He was formerly often confused with the famous magician Dr. Johann Faust, who, though an historical figure, had nothing to do with him (*see* FAUST).

See the articles GUTENBERG, JOHANN and TYPOGRAPHY.

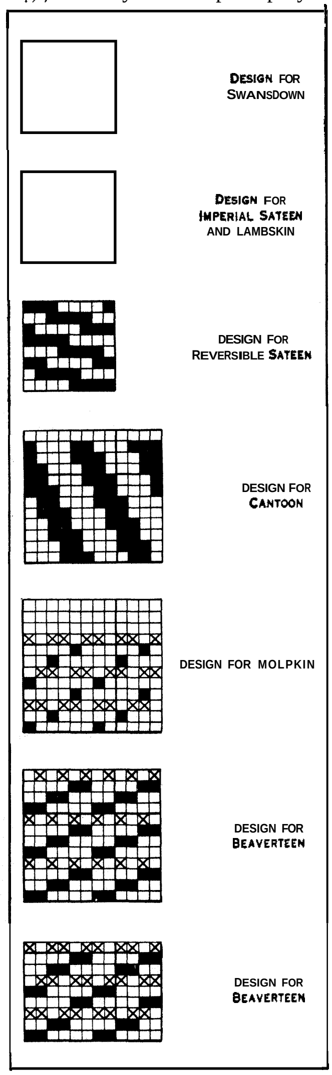
FUSTEL DE COULANGES, NUMA DENIS (1830–1889), French historian, was the originator of the scientific approach to the study of history in France. He was born in Paris on March 18, 1830, of Breton descent. After studying at the

École Normale Supérieure he was sent to the French school at Athens in 1853, directed some excavations at Chios and wrote a historical account of the island. From 1860 to 1870 he was professor of history at the faculty of letters at Strasbourg, where he had a brilliant career as a teacher. Subsequent appointments included a lectureship at the École Normale Supérieure in Feb. 1870. a professorship at the Paris faculty of letters in 1875, the chair of medieval history at the Sorbonne in 1878 and the directorship of the École Normale in 1880. He died at Massy, Seine-et-Oise, on Sept. 12, 1889.

Fustel's historical thought had two main tenets: the importance of complete objectivity and the unreliability of secondary sources. By his teaching and example he thus established the modern idea of historical impartiality at a time when most French historians wrote like Chateaubriand and when few had any qualms about combining the careers of historian and politician, and his insistence on the use of contemporary documents led to the very full use of the French national archives in the 19th century. Fustel. however, was no paleographer and his fondness for manuscript sources was occasionally responsible for major errors of judgment. His work has long been superseded, but his influence on the development of historical studies in France will endure.

Apart from *La Cite' antique* (1864), a study of the part played by religion in the political and social evolution of Greece and Rome, most of Fustel's work was related to the study of the political institutions of ancient France and of the Germanic invasions under the Roman empire. The first volume of the *Histoire des institutions politiques de l'ancienne France* appeared in 1875; it was subsequently recast and published in three volumes: *La Gaule romaine* (1891); *L'Invasion Germanique et la fin de l'empire* (1891); and *La Monarchie franque* (1888), to which were added *L'Alleu et le domaine rural pendant l'e'poque mérovingienne* (1889); *Les Origines du système fe'odal: le bénéfice et le patronat* (1890); and *Les Transformations de la royauté pendant l'époque carolingienne* (1892).

See J. M. Tourneur-Aumont, *Fustel de Coulanges, 1830–1889* (1931); J. Herrick, *The Historical Thought of Fustel de Coulanges* (1954). (B. J. R.)



FIGS. 1 TO 7.—FUSTIAN DESIGNS

FUSTIAN, a technical term descriptive of an important class of cotton fabrics comprising several distinctive types and varieties of which moleskin, corduroy, and velveteen are the three principal types. Each of these types also comprises various modifications in respect of the minor details of their construction, such as beaverteen, cantoon or diagonal. imperial sateen or swansdown, lambskin and other varieties. Fustian fabrics, with the exception of swansdown and velveteen, are firm and compact textures of great strength and durability, adapted for hard wear and chiefly employed in the production of clothing for both sexes. These characteristics are obtained by employing warp threads usually of folded yarn and of great strength, in combination with a relatively high rate of picks per inch, of soft-spun single weft.

The simplest varieties of fustian fabrics are those known as imperials, comprising swansdown, lambskin and reversible sateen, of which the designs showing the weave structures are given in figs. 1, 2 and 3 respectively.

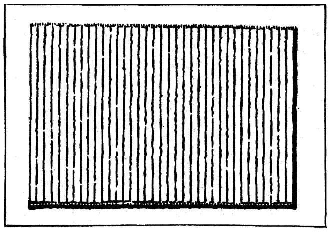


FIG. 8.—FINE-RIBBED THICKSET CORDUROY FABRIC WOVEN FROM DESIGN IN FIG. 9

Swansdown.—Swansdown is based on the five-end weft face satin weave, but with two contiguous warp threads raised together, instead of singly, as indicated in tne design, fig. 1. After weaving, these fabrics are submitted to an operation of perching or raising, in order to develop on the face side of the fabric a soft furry nap or down which characterizes a swansdown fabric and gives it additional warming properties suitable for underclothing and night attire. One quality of swansdown contains 60 warp threads per inch, of 18s T., and 120 picks per inch, of 20s soft weft of good quality to develop a good nap.

Imperial Sateen.—Imperial sateen is virtually swansdown of stronger and heavier texture and based on the eight-end weft face satin weave structure, but with two contiguous warp threads raised together, as indicated in the design, fig. 2. This weave produces relatively longer weft floats and permits of a greater density of picks being inserted in the fabric. When perched on the face side, imperial sateen is sold as lambskin, from the long, soft and woolly nap. It is also sometimes dyed and finished to imitate a light texture of moleskin. A good quality of lambskin contains 46 warp ends of 2/20s, and 450 picks of 20s weft, per inch; while a medium quality of dyed imperial sateen contains 68 warp ends of 16s T. and 150 picks of 16s weft, per inch.

Reversible imperial is a variation of imperial sateen simply by floating the weft equally on both sides of the fabric, as indicated in the design, fig. 3, showing the weave structure of this variety of which a good quality contains 62 warp ends of 14s T. and 330 picks of 30s weft, per inch.

Cantoon.—cantoon or diagonal is a strong and compact texture produced with fine diagonal cords or ribs of twill running at a low angle of about 18°, and based on the twill weave structure indicated in fig. 4. It is usually dyed a fawn or a drab hue, perched on the back, and largely employed for men's and ladies' riding and sporting habits. A good quality of cantoon contains 54 warp ends of 2/20s, and 400 picks of zos weft, per inch.

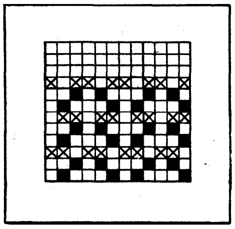

FIG. 9—DESIGN FOR FINE-RIBBED CORDUROY FABRIC

Shown in Fig. 8, containing two pile picks to one back pick

Moleskin.—Moleskin is a thicker, stronger, and heavier texture than other varieties of fustian and is more suitable for men's clothing requiring very hard wear and durable qualities, and especially for rough occupations as iron and brass moulding, navvying, and similar work. Moleskin is a semicompound texture consisting of one series of warp threads and two series of weft, viz., face picks and back picks (of the same kind of weft) inserted in the ratio of two face picks to one back pick, uniformly, as indicated in fig. 5, showing a design tor a moleskin fabric which is virtually a stronger and heavier texture of uncut velveteen (*q.v.*), as described in a separate article. A moleskin of good quality contains 38 warp ends of 3/34s and 400 picks of 14s weft, per inch.

Beaverteen is virtually a light texture of moleskin which, after weaving, is dyed, printed, and perched on the back to produce a short nap. Two designs for beaverteen are given in figs. 6 and 7. The design fig. 6 will produce what is practically a tabby back beaverteen, with three face picks to one back pick; while the design fig. 7, will produce a fabric with two face picks to one back pick, and a three-end weft twill back which is better for perching. A good quality of beaverteen contains 32 warp ends of 2/18s, and 280 picks of 18s weft, per inch.

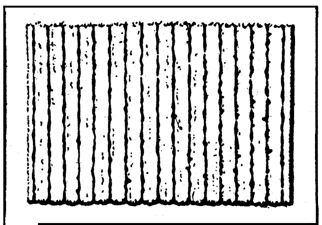

FIG. 10.—CORDUROY FABRIC WITH WIDE RIBS, WOVEN FROM THE DESIGN IN FIG. 11

Corduroy and Velveteen.—Unlike other varieties of fustian fabrics, corduroy and velveteen are characterized by having a short plush or velvet weft pile formed on the face of the fabric. In corduroy, the pile is formed in a series of more or less crowned ribs or cords of uniform width extending lengthwise of the fabric, in the direction of warp threads; while in velveteen, the pile forms an even and level surface. In both of these types of fabric the pile surface is developed subsequent to weaving, by submitting the cloth to an operation of fustian cutting in which the face or pile picks of weft are severed, either manually or mechanically, by means of special knife blades or circular discs, thereby causing the severed weft threads to assume a vertical position and thus constitute the tufts of pile which characterize these fabrics.

Corduroy fabrics consist of a foundation texture based on the three-end or four-end twill or other simple weave structure that will ensure sufficient stability in the fabric. The cords are usually of uniform width, and sometimes of different width, in the same fabric. When the cords are of uniform width, they are formed at regular intervals ranging from three to 16 or 20 warp threads, uniformly, chiefly according to the width of cords required and the style of clothing for which the fabric is intended, as, for example, suits for artisans, or for sporting and riding suits for both men and women.

Corduroy fabrics are produced in a variety of different textures, styles and qualities, according to the special purpose for which they are intended. The simplest variety, and one of the neatest styles employed for boys' and men's clothing is commonly termed thickset corduroy of which an example is illustrated in fig. 8. This fabric is constructed with two pile picks to one back pick, uniformly, in accordance with the design shown in fig. 9, which is for a corduroy fabric formed with a three-end twill back, though it may be formed with a tabby back. The cords in this example recur on the smallest possible number of warp threads, viz., three, with two cords constituting one repeat of the design which, therefore, repeats on six warp threads, as indicated. A corduroy fabric constructed with much wider and bolder cords is illustrated in fig. 10, of which the design is given in fig. 11. This example is based on the four-end 2 x 2 twill foundation texture. with two pile nicks to one hack pick, and with the cords recurring at regular intervals of eight warp threads, uniformly, as indicated in the design. Corduroy fabrics comprise many other modifications of structure both in respect of their foundation textures and also in the particular manner of intersecting the pile picks with the stitching or binding warp threads that form the cuttings or furrows between the cords: hut the two examples here given will serve to indicate the general principle of their construction. See also the article VELVETEEN.

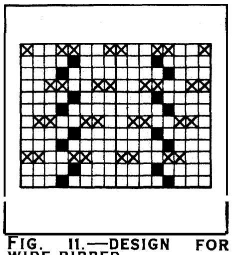

FIG. 11.—DESIGN FOR WIDE-RIBBED CORDUROY FABRIC, SHOWN IN FIG. 10, CONTAINING TWO PILE PICKS TO ONE BACK PICK

See H. Nisbet, *Grammar of* Textile *Design* (1927). (H. N.)

FUSTIC, YELLOWWOOD or **OLD FUSTIC,** is the wood of a large tree (*Chlorophora tinctoria*) of the mulberry family (Moraceae, *q.v.*) growing in the West Indies and tropical America. The best quality comes from Cuba and the poorer from Jamaica and Brazil. It is still employed in the form of extract for wool dyeing. mainly in conjunction with other dyewoods, for the production of browns, olives and compound colours, and for deadening the shade of blacks. The mordant mainly in use is bichromate of potash, and the olive yellow thus obtained is fairly fast to light. In other respects, the dyeing properties of this wood closely resemble those of quercitron bark. It contains two colouring matters, morin and maclurin, of which the former is the more important. The dyestuff termed young fustic, or zante fustic and Venetian sumach, is the wood of the smoke tree (*Rhus Cotinus*), a southern European and Asiatic shrub of the Cashew family (Xnacardiaceae). (A. G. P.)

FUTURE FARMERS OF AMERICA is the national organization of boys studying vocational agriculture in the public secondary schools under provisions of the national vocational education (Smith-Hughes) acts. Organized in 1928, it serves to motivate and vitalize the systematic instruction offered to students of vocational agriculture, and to provide further training in farmer-citizenship. It is a nonprofit, nonpolitical, farm youth organization of voluntary membership with dues of ten cents per member per year. The motto of the organization is:

"Learning to do
Doing to learn
Earning to live
Living to serve"

There are four grades 'or degrees of active membership: "Green Hand," "Chapter Farmer," "State Farmer" and "American Farmer." The first two of these grades or degrees are under the control of the local chapters. The state FFA organizations specify the requirements for "State Farmer" membership and the national FFA determines the requirements for the "American Farmer" title. In addition to the youthful officers of the local, state and national FFA organizations, teachers of vocational agriculture serve as local chapter advisers. and state and national supervisors of agricultural education serve as state and national advisers. The executive secretary and the treasurer of the FFA are adults, officials in national vocational agricultural education. The national adviser is the chief of the agricultural education service of the U.S. office of education.

Programs of work participated in by all members are set up annually by most chapters, each state association and the national organization. All FFA activities are boy-initiated and boy-directed. Local chapters often engage in crop and animal husbandry projects to supplement their class work. In many cases the crops and animals raised are sold at community auctions with financial benefits both to the individual members and to the treasury of the local group. In some cases FFA products are exhibited at local fairs.

An official statement of specific aims and purposes of the FFA lists twelve specific purposes as follows:

"1. To develop competent, aggressive, rural and agricultural leadership.
2. To create and nurture a love of country life.
3. To strengthen the confidence of farm boys and young men in themselves and their work.
4. To create more interest in the intelligent choice of farming occupations.
5. To encourage members in the development of individual farming programs and establishment in farming.
6. To encourage members to improve the farm home and its surroundings.
7. To participate in wotthy undertakings for the improvement of agriculture.
8. To develop character, train for useful citizenship and foster patriotism.
9. To participate in cooperative effort.
10. To encourage and practice thrift.
11. To encourage improvement in scholarship.
12. To provide and encourage the development of organized rural recreational activities."

National headquarters of the Future Farmers of America is located in the agricultural education service; United States office of education. National conventions are held annually in Kansas City, Mo., at the time of the American Royal Livestock show.

See also RCRAL EDUCATION. (W. W. Wx.)

FUTURES, contracts which consist of a promise to deliver specified quantities of some commodity. foreign exchange, etc., at a specified future time. The obligation is usually for a single quantity in a given month; *e.g.,* 10,000 bu. of, wheat in May. Futures are thus a form of security, analogous to a bond or promissory note. They are traded like any other security. and may be bought and sold many times before the date of maturity. In a competitive market their price is determined. like any other, at the level where the quantity demanded is equal to the quantity supplied. If a contract to deliver 10,000 bu. of wheat in May is sold for $9,000, the price of "May wheat" is said to be 90 cents per bushel. The price of futures depends mainly on the expected future course of their prices. and on the expected "spot" price (*i.e.,* the price of the commodity in current transactions) at the date of maturity of the contract. Thus if the price of "May wheat" in December is high, this indicates a general expectation that wheat will be scarce and its spot price high in May. There is no necessary limit to the extent by which the spot price can exceed the futures price. There is, however, a limit on the extent to which the futures price can exceed the spot price. as commodities can be held for sale at a future date. Thus if it costs 5 cents per bushel to carry wheat from December to May, and if in December the spot price is 90 cents and the futures price $1.05 per bushel, an operator by buying spot wheat and selling May futures in December, and fulfilling his futures contract by delivering in May the wheat bought in December, would make a profit of 10 cents per bushel. The prospect of these profits would bring a rush of buyers into the December spot market, raising the price there, and a rush of sellers into the May futures market, lowering the price there. and the difference between the two prices would soon fall to 5 cents or less.

The main justification of the futures contract is that it permits specialization between two elements of the economic process—the function of holding commodities (or other assets) and the function of bearing the risk of price changes. Without the futures contract anyone who held stocks of goods in the course of business would have to take the risk of changes in the price of these goods. By selling futures that mature in the month when he expects to sell his stock, the holder removes from his calculations any uncertainty about the future price of the goods at the time when he expects to sell them. Thus if a grain dealer has in October a stock of 5,000 bu. of wheat that he expects to sell in December, he can sell 5,000 bu. of "December futures"—*i e.,* he enters into a contract to deliver 5,000 bu. in December at a price fixed in October. This is the simplest form of the operation known as "hedging." It may be used by anyone who in the regular course of his business finds himself obliged to hold stocks of-goods, and who wishes to avoid speculation as to changes in the price of this stock. On the other hand the speculator who buys futures, in the hope of selling them later at a profit, or of buying spot at a lower price when the contract matures, is enabled to speculate on price changes without the burden oi holding title to the commodity.

Although hedging makes the future price certain, it is not necessarily advantageous. If the "hedger" thinks that the spot price in December mill be so much higher than the current price of December futures, that the risk of this expectation not being fulfilled is worth taking, he will not hedge but will simply hold his stock for sale at the spot price. The lower the futures price relative to the anticipated spot price, the greater is the premium paid for insurance against price changes, and the less advantageous it is to hedge.

With the abandonment of the international gold standard in 1931, and the subsequent wide fluctuations in foreign exchange rates, the futures, or "forward market" in ioreign exchange became an important part of the mechanism of international trade. As before, it resulted in a specialization between "traders" and "speculators," with possible advantage to both. (K. E. B.)

FUTURISM: *see* PAINTING; POST-IMPRESSIONISM.

FUX, JOHANN JOSEPH (1660–1741), Austrian musician, was born at Hirtenfeld. Styria. In 1696 he was organist at one of the principal churches of Vienna, and in 1698 was appointed by the emperor Leopold I as his "imperial court-composer," with a salary of about £6 a month. At the court of Leopold and of his successors Joseph I and Charles VI, Fux remained for the rest of his life. To his various court dignities that of organist at St. Stephen's cathedral was added in 1704. Fux died at Vienna on Feb. 14, 1741. The 18 operas which Fux wrote do not differ essentially from the style of the Italian *opera seria* of the time. Oi greater importance are his sacred compositions, psalms, motets, oratorios and masses, among the latter the celebrated *Missa canonica* which is written in canon throughout. As a contrapuntist and musical scholar generally, Fux was unsurpassed by any of his contemporaries, and his great theoretical work, the *Gradus ad Parnassum* (Vienna. 1725), written in Latin, long remained by far the most thorough treatment of counterpoint and its various developments.

FUZULI (d. 1556), Turkish poet, is the outstanding figure in the classical school of Turkish literature. Very little is known of his life. His real name was Mohammed bin Suleyman and, probably born at Hilla, he never left Iraq. When in 1534 Suleiman the Magnificent conquered Baghdad, Fuzuli presented a *kaside* (congratulatory poem) to him. He received little favour, however, and he never seems to have achieved the status of the court poets of Istanbul. His famous *Shikeyetname* ("Complaint") sarcastically comments upon his failure to receive even the small pension granted to him. Victim of a plague, he is buried at Kerbela. Although born in an Azeri Turkish-speaking area and himself writing in this dialect, he studied also early Ottoman poets, particularly the great Chagatai poet Nevai, and achieved a synthesis of all these influences and the Persian classics, soon becoming recognized as the great poet of the Turkish world. There is a pervading strain of melancholy in his work. This is very evident in his romance of the unhappy love of *Leyla and Mecnun,* a story well known in Moslem literature, which is imbued with mystic passion and contains some of his best poetry. His *Divan* (book of collected poems) contains most of his other works. Fuzuli's intense sincerity overcomes the restrictive clichés of conventional literary forms and communicates to the reader the poet's own emotion.

BIBLIOGRAPHY.—A. N. Tarlan (ed.), *Fuzuli Divani,* in Roman script (1950). The *Divan* are also to be found in *Kulliyat-i Fuzuli* (1924). For the *Leyla and Mecnun* see edition by N. H. Onan (1956) and, with Eng. trans. by Sofi Huri, in *Fuzuli Memorial Volume* (1958). (F. I.)

FYN or FÜNEN, one of the larger Danish islands, second in size to Zealand (Själland) lying between that island and south Jutland. Area, 1,151 sq.mi. Its physical features are similar to those of eastern Jutland. Pop. (1955) 366,323. *(See* DENMARK.)

FYRD, the name given to the English militia during the Anglo-Saxon period *(see* MILITIA). In early times the ealdorman of the shire was probably charged with the duty of calling out and leading the fyrd, which appears always to have retained a local character, as during the time of the Danish invasions we read of the fyrd of Kent, of Somerset and of Devon. It is probable that originally all free landholders were required to attend the fyrd. and exemption from this duty was only very sparingly granted. The fyrd was gradually superseded by the gathering of the thegns and their retainers. but it was occasionally called out for defensive purposes even after the Norman Conquest.

FYT, JAN (1611?–1661), Flemish painter of animals, was horn at Antwerp. He was registered apprentice to Hans van den Berghe in 1621. At 20, young Fyt entered the gild of St. Luke as a master, and from that time until his death in 1661 he produced a vast number of pictures in which the bold facility of Snyders is united to the powerful effects of Rembrandt. There never was such a master of technical processes as Fyt in the rendering of animal life in its most varied forms. He was not clever at figures. and he sometimes trusted for these to the co-operation of Cornelius Schut or Willeborts, while his architectural backgrounds were sometimes executed by Quellyn. "Silenus amongst Fruit and Flowers," "Diana and her Nymphs with the Produce of the Chase." and "Dead Game and Fruit in front of a Triumphal Arch" are specimens of the co-operation respectively of Schut, Willeborts and Quellyn. These pictures are also Eyt's masterpieces. The earliest dated work of the master is a cat grabbing at a piece of dead poultry near a hare and birds, and executed in 1644. The latest dated work of Fyt is a "Dead Snipe with Ducks," of 1660. Great power is shown in hunting scenes.

FYZABAD, properly FAIZABAD. a city, the headquarters of a tehsil. a district and division of Uttar Pradesh, India. The city, comprising the municipal area of Faizabad-cum-Ajodhya and cantonment. stands on the left bank of the Gogra river, 78 mi. by rail east of Lucknow. Pop. (1951) of city 76,582; of tehsil (355 sq.mi.) 366,577. To the east of Faizabad is the ancient site of Ajodhya (*q.v.*).

Faizabad was founded about 1730 by Sa'adat Ali Khan. It received its present name in the reign of his successor, and Shuja ud-Daulah. the third nawab, laid out a large town and fortified it. It was afterward the residence of the begums of Oudh. On the outbreak of the mutiny the officers of the Indian garrison were almost all murdered by their own troops.

Faizabad is the headquarters of a military subarea. There is a government college, the Shri Saket Mahavidyalaya college affiliated to Agra university. Sugar refining and trade in agricultural produce are important.

FAIZABAD DISTRICT, lying between the two great rivers Gogra and Gumti, has an area of 1,710 sq.mi. It is entirely alluvial and well wooded, and has a good climate. Pop. (1951) 1,481,796. Tanda, with a population in 1951 of 29,288, has the largest production of cotton goods in Oudh.

FAIZABAD DIVISION has an area of 12,069 sq.mi., and comprises the six districts of Faizabad, Gonda, Bahraich, Sultanpur, Partabgarh and Bara Banki. Pop. (1951) 8,362,713.

G THE history of this letter began with the Latin alphabet. The Greek alphabet from which, through Etruscan, the Latin was derived, represented the voiced velar stop by its third letter gamma Γ, < or C. This passed into Latin and was used in its rounded form C, to represent the same sound in early times, *e.g.,* in the word RECEI (probably an early dative form of rex, "king"), occurring in an early Latin inscription. The letter, however, came to represent the unvoiced velar stop, thus ousting K. This was probably due to Etruscan influence. To avoid confusion a new letter G was differentiated from C and used to represent the voiced velar, while C henceforward stood for the unvoiced velar only. The new letter was placed in the alphabet in the place of Greek Z (zeta) which was not required in the Latin alphabet. (See ALPHABET.)

The uncial form of the letter in the 6th and 7th centuries was ς or ς. The form with rounded head g, from which our minuscule g is derived, appears first in Latin cursive writing about the beginning of the 7th century taking the place of such earlier forms as ʃ. It was Standardized in Carolingian as g. The minuscule flat-headed form was adopted by Irish writing of the 6th and 7th centuries, *e.g.,* ʒ or ʒ. Such a form had been in use in Latin cursive, *e.g.,* ʒ (5th cent.), ʒ (late 7th cent.), ʒ (7th or 8th cent.). A form ʒ appears in Merovingian (pre-Carolingian French) writing in the 8th century, and a descendant of this was adopted into the Carolingian hand, not being entirely ousted by the round-headed form till the 11th century.

The flat-headed form was adopted by the early English hand from the Irish and remained the only form of the letter in use in England until introduction of Carolingian writing by Norman scribes in the 12th century. Meanwhile certain changes had taken place in the sound represented by the letter. The voiced velar had become palatalized before the front vowels e and i. Thus the flat-headed form of the letter, the only form in use in pre-Norman England, represented the velar before back vowels, the palatal before front vowels. It also stood for the sound now represented by y initially before front vowels. In Middle English the palatal stop developed into the sound now represented by j, a similar change having taken place in the development of the Latin velar on the continent. This sound was therefore introduced to English ears by the Normans, and in the Middle English period we find the two forms of the minuscule letter in use to represent different sounds. g represented the voiced velar (modern "hard" g) and the sound of *j*, ʒ represented the palatal stop (y) and the sound of y. As the palatal stop (in such words as might, high, enough, etc.) disappeared from the language, the use of the flat-headed form was discontinued. It survived in remote parts, and by its similarity to the form of *z* produced confusion with the latter.

In modem English the letter represents two sounds: (1) the voiced velar; (2) the sound of j (dž) before the vowels e, *i* and y

THE DEVELOPMENT OF THE LETTER "G" FROM THE PHOENICIAN. THROUGH THE LATIN DOWN TO MODERN FORM

in words of Romance origin—gesture, ginger, gymnastics (contrast give, gilt). The combination gh often has the sound of f (as in cough, rough, laugh), yet not consistently, for in some words it is silent (ought, though, through). (B. F. C. A.; J. W. P.)

In music, G is the name of the seventh note of the musical alphabet or otherwise the fifth note of the scale of C. It gives its name also to the treble (or violin) clef, the distinguishing sign of which denotes the G line. To which it may be added that the said sign itself was originally nothing but a capital G which in the course of time has come to assume, as the result of various changes of shape, the conventionalized form with which we are now familiar.

GA'ALIIN, see ARABS.

GABARDINE, the term applied in the cloth trade originally to a particular type of waterproofed fabric employed for the manufacture of raincoats, but later as a general description of several varieties of worsted, cotton, silk and union or mixture fabrics, embodying certain features in common and chiefly made into suits and overcoat's. It is a relatively strong and firm cloth somewhat resembling whipcord, but of lighter texture.

Covert coating fabrics are virtually gabardines of a lighter texture suitable for summer wear and for use in hot climates.

Because of the predominance of warp over weft threads in gabardine fabrics, the weft lies entirely at the back and is therefore not visible from the front, a circumstance which allows the use of weft of inferior quality without loss of durability, for only the warp surface is exposed to wear.

Although all varieties of gabardine fabrics have the same general textural appearance; they vary considerably in respect to the particular twill weave and in the character. quality and counts of material employed in their construction, as well as in the number of warp threads and picks of weft per inch in the fabric.

Some gabardine fabrics are produced entirely from cotton yarn. The better qualities of these are made from super-grades of combed twofold warp and weft, while those of coarser texture and inferior quality are made from single yarn both for warp and weft.

A so-called "voile gabardine" fabric of a more open and much lighter texture is produced entirely of silk. (H. N.; X.)

GABBRO, in petrology, is a group name for medium- or coarse-grained rocks consisting primarily of calcic plagioclase feldspar and pyroxene (*qq.v.*); essentially gabbro is the plutonic equivalent of basalt. The word is of Florentine origin but unknown etymology. Xlthough basalt is often remarkably homogeneous in mineralogy and composition over vast areas, the gabbros are exceedingly variable. Gabbroic complexes may include sizable masses consisting almost entirely of plagioclase (anorthosite); of pyroxene and olivine (peridotite); of pyroxene alone (pyroxenite, hyperite); of pyroxene and plagioclase (norite). Banded or layered complexes in which these and other mono- or bimineral varieties (dunite, troctolite, etc.) are well developed have been described from Montana, the Bushveld in South Africa and the island of Skye. There are also gabbro complexes which, while locally streaky and inhomogenous, are not regularly layered. Among these may be cited the great Sudbury, Ont., basinlike intrusion or lopolith and some of the larger diabase sills, like those of Beaver Bay, Minn., the Palisades, N.J., and many of the Karoo diabases in South Africa. (For a brief description of lopoliths, sills and other forms *see* the article SILLS.)

Prominent among the unlayered gabbro complexes are the so-called "massive" anorthosites, rocks consisting largely or entirely of plagioclase, exemplified by the famous Adirondack anorthosite, the Laramie, Wyo., complex and the anorthosites of eastern Quebec.

Gabbros and anorthosites are considerably less abundant than either basalt or granite, but the complexes in which they occur are nevertheless often of immense size. About 60,000 sq.mi. of eastern Canada is underlain by anorthosite, for instance, the Saguenay mass alone accounting for a tenth of this. The Morin anorthosite in the same area occupies 1,000 sq.mi. and the nearby Adirondack anorthosite is exposed over an area of about 1,500 sq.mi. The Bushveld complex underlies an area of about 20.000 sq.mi. and the Great Dyke of Rhodesia, another layered complex, has been traced for more than 300 mi.

Although these large masses are generally supposed to provide the best sample of the deep lithosphere, they often appear to be floored over most of their outcrop area; they are usually laccoliths, lopoliths or sills. The Canadian anorthosites are thought to be laccolithic, the Adirondack anorthosite a floored sheet. The thickness of the Sudbury lopolith is estimated at two miles, that of the Bushveld at three miles.

Gabbros are sometimes quarried for dimension stone (the "black granite" of commerce) and the San Marcos gabbro of southern California is used for gauge blocks, but the direct economic value of gabbro is slight. Far more important are the primary mineralizations of nickel, chromium and platinum, which occur almost exclusively in association with gabbroic or related ultrabasic rocks. Primary magnetite (iron) and ilmenite (titanium) mineralizations are often intimately associated with gabbroic complexes.

Origin and Composition. — In the layered gabbroic complexes it is rather generally assumed that segregation is attributable to some form of rhythmic or oscillatory crystal fractionation of basaltic magma under gravity control. Xlthough there is much incidental laboratory support for the notion that any one of these varieties could crystallize from a magma of approximately basaltic composition, the notion that they in fact do so is substantially an *ad hoc* hypothesis, and the details of the process, particularly as regards the rhythmic or oscillatory nature of the fractionation, are vague. In the gabbro complexes that are not regularly layered, the passage between different members of a complex tends to be gradational rather than discontinuous, as in the layered variety. Interstitial micropegmatite, practically unknown in the sharply layered complexes, is common in these, in which it is not infrequently concentrated in rather irregularly bounded zones: seams or pods. Sometimes considered to be of hydrothermal origin, it is more often regarded as an end-stage derivative of crystal fractionation. At Pigeon point (Minn.), Beaver Bay, Sudbury and Duluth (Minn.) the micropegmatite occurs in masses large enough to collect and, sometimes, large enough to map. Field associations of this kind, together with much laboratory evidence based on phase equilibria, led to N. Bowen's hypothesis of the origin of granitic magma by crystal fractionation of basaltic magma. *(See* GEOCHEMISTRY: *Geochemistry of the Lithosphere: The Reaction Series).*

The plagioclase of the anorthosite members of layered complexes is ordinarily labradorite or bytownite but, in the absence of layering, plagioclase more basic than calcic andesine is uncommon. Anorthosite dikes are very rare, and effusive equivalents of anorthosite are unknown. The massive anorthosites, like the layered ones, are probably crystal accumulates: as suggested by Bowen, though the scale at which the process takes place must be staggering.

The Duluth lopolith is a notable exception to the rather arbitrary dichotomy between layered and unlayered gabbro complexes. The lower part of this mass has the average composition of an olivine gabbro but is strongly banded, individual bands varying in composition from anorthosite to peridotite. The upper portion is a comparatively homogeneous feldspathic gabbro, locally patchy and streaky but not sharply banded. Between the two major divisions, and again at the top of the feldspathic gabbro, is a zone of so-called "red rock," granophyre or micropegmatitic granite.

What is actually visible of most gabbro complexes is conveniently summarized by supposing that they are in general either of the sharply banded type, with ultrabasic derivatives: or of the unbanded type, with associated granitic or granophyric derivatives. The geology of the Duluth mass suggests that this distinction reflects observational limitations rather than any fundamental petrological distinction. (In this connection it may be noted that a granophyre facies occurs in the Bushveld complex, though there is much controversy about its relation to the gabbro.)

(F. Cs.)

GABELENTZ, HANS CONON VON DER (1807–1874), German linguist and ethnologist, born at Altenburg on Oct. 13, 1807, was the only son of Leopold von der Gabelentz, chancellor and privy-councillor of the duchy of Altenburg. He studied at Leipzig and Gottingen and after 1830 held various public offices. He died at Lemnitz, in Saxe-Weimar, on Sept. 3, 1874.

Gabelentz is said to have learned no fewer than 80 languages, 30 of which he spoke fluently. Immediately after quitting the university, he followed up his Chinese researches by a study of the Finno-Ugrian languages, which resulted in the publication of his *Eléments de la grammaire mandchoue* in 1832. In 1837 he became one of the promoters, and a joint-editor, of the *Zeitschrift für die Kunde des Morgenlandes.* His works include: *Grundziige der syrjänischen Grammatik* (1841); a complete edition (with J. Lobe), with translation, glossary and grammar, of Ulfilas's Gothic version of the Bible (1843–46); articles on the languages of the Swahilis, the Samoyedes, the Hazaras, the Aimaks, the Formosans and other widely-separated tribes in the *Zeitschr. d. deut. morgenland. Gesell.; Beiträge zur Sprachenkunde* (1852) containing Dyak, Dakota, and Kiriri grammars; a *Gramnzatik* u. *Wörterbuch der Kassiasprache* (1857); an edition of the Manchu translations of the Chinese Sse-shu, Shu-king and

Shi-king, with a dictionary (1864); and *Die melanesischen Sprachen nach ihrem grammatischen Bau und ihrer Verwandschaft unter sich und mit den malaiisch-polynesischen Sprachen untersucht* (1860–73). The last-named work treats of the language of the Fiji islands, New Hebrides, Loyalty islands, New Caledonia, etc., and shows their radical affinity with the Polynesian class.

GABELLE, a term which, in France, was originally applied to taxes on all commodities, but was gradually limited to the tax on salt. In process of time it became one of the most hated and most grossly unequal taxes in the country, but, though condemned by all supporters of reform, it was not abolished until 1790. First imposed in 1286, in the reign of Philip IV., as a temporary expedient, it was made a permanent tax by Charles V. Repressive as a state monopoly, it was made doubly so from the fact that the government obliged every individual above the age of eight years to purchase weekly a minimum amount of salt at a fixed price. When first instituted, it was levied uniformly on all the provinces in France, but for the greater part of its history the price varied in different provinces. There were five distinct groups of provinces, classified as follows: *(a)* the *Pays de grandes gabelles,* in which the tax was heaviest, *(b)* the *Pays de petites gabelles,* which paid a tax of about half the rate of the former; *(c)* the *Pays de salines,* in which the tax was levied on the salt extracted from the salt marshes; *(d)* the *Pays rédimés,* which had purchased redemption in 1549; and *(e)* the *Pays exempts,* which had stipulated for exemption on entering into union with the kingdom of France. *Greniers à sel* (dating from 1342) were established in each province, and to these all salt had to be taken by the producer on penalty of confiscation. The *grenier* fixed the price which it paid for the salt and then sold it to retail dealers at a higher rate.

See Necker, *Compte rendu* (1781); J. J. Clamagéran, *Histoire de l'impôt en France* (1876); A. Gasquet, *Précis des institutions politiques de l'ancienne France* (1885).

GABELSBERGER, FRANZ XAVER (1789–1849), inventor of the German system of stenography, was born on Feb. 9, 1789, at Munich. His system was tested at the first session of the Bavarian estates in 1819, and he was placed in charge of the stenographic reports of the Bavarian Chamber. His system is explained in his *Anleitung zur deutschen Redezeichenkunst oder Stenographie* (1834; new ed. 1900), and *Neuen Vervollkommungen der deutschen Redezeichenkunst* (1843; new ed. 1904) (*see* SHORTHAND). Gabelsberger also invented a calculating machine.

See A. K. Stubenrauch, *Gabelsberger und der deutsche Geist* (1924), and J. G. Schwaebl, *Erinnerungen an Gabelsberger* (1925).

GABERDINE or GABARDINE, any long, loose overgarment, reaching to the feet and girt round the waist. It was commonly worn in the middle ages by pilgrims, beggars and almsmen.

GABES, a town of Tunisia, at the head of the gulf of the same name. and 70 mi. by sea S.W. of Sfax, with which it is connected by rail. It occupies the site of the Tacape of the Romans and consists of an open port and European quarter and several small Arab towns built in an oasis copiously watered by the Wad Gades.

The European quarter is situated on the right bank of the Wad near its mouth. Adjacent are the Arab towns of Jara and Menzel. The houses of the native towns are built largely from the ruins of Tacape.

The population of the municipality (1956) was 24,420. There is a considerable export trade in dates. The port was used by the axis for reinforcements from Dec. 1942. It was recaptured by the British 8th army. March 28, 1943.

GABII, an ancient city of Latium, 12 mi. E. of Rome, on the Via Praenestina, which was in early times known as the Via Gabina. Its early history is obscure, though its importance was considerable; but we only hear of it again in the 1st century B.C. as a small and insignificant place, though its desolation is no doubt exaggerated by the poets. Its baths were well known, and Hadrian, who was responsible for much of the renewed prosperity of the small towns of Latium, appears to have been a very liberal patron, building a senate-house and an aqueduct. Its bishops continue to be mentioned in ecclesiastical documents till the end of the 9th century. The primitive city was on the eastern bank of the lake, the citadel being now marked by the ruins of the mediaeval fortress of Castiglione, while the Roman town extended farther to the south. The most conspicuous relic of the latter is a ruined temple, generally attributed to Juno, probably belonging to 250–200 B.C. To the east of the temple lay the Forum, where excavations were made by Gavin Hamilton in 1792. All the objects found were placed in the Villa Borghese, but many of them were carried off to Paris by Napoleon after his conquest of Italy in 1797, and are in the Louvre.

See E. Q. Visconti, *Monumenti Gabini della Villa Pinciana* (Rome, 1797, and Milan, 1835); T. Ashby in *Papers of the British School at Rome,* i. 180 *seq.;* G. Pinza in *Bull. Com.* (1903), 321 seq. for archaeological information. (T. A.)

GABINIUS, AULUS, Roman statesman and general, and supporter of Pompey. In 67 B.C., when tribune of the people, he brought forward the *Lex Gabinia,* conferring upon Pompey the command in the war against the Mediterranean pirates, with absolute control over that sea and the coasts for 50m. inland. By other measures of Gabinius loans of money to foreign ambassadors in Rome were made non-actionable (as a check on the corruption of the senate) and the senate was ordered to give audience to foreign envoys on certain fixed days (1st of Feb.–1st of March). In 58 he was elected consul, not without suspicion of bribery. During his term of office he helped Clodius to send Cicero into exile. In 57 Gabinius went as proconsul to Syria. On his arrival he reinstated Hyrcanus in the high-priesthood at Jerusalem, suppressed revolts, introduced important changes in the government of Judaea, and rebuilt several towns. During his absence in Egypt, whither he had been sent by Pompey, without the consent of the senate, to restore Ptolemy Auletes to his kingdom, Syria was devastated by robbers. and an insurrection had arisen against Hyrcanus. With some difficulty Gabinius restored order, and in 54 handed over the province to his successor, M. Licinius Crassus. The tax-farming interests, which had suffered from the disorders, had him impeached on his return. Gabinius went into exile, and his property was confiscated. After the outbreak of the civil war, he was recalled by Caesar in 49, and entered his service, but took no active part against Pompey. He died on service in Dalmatia against M. Octavius in 48 or early 47.

Civ.* ii. 24. 59; Cicero, *ad Att.* vi. 2, *ad* Q. *Fratrem,* ii. 13, *Post reditum in senatu,* 4-8, *Pro lege Manilia,* 17, 18, 19; exhaustive article by Bähr in Ersch and Gruber's *Allgemeine Encyclopädie;* and monograph by G. Stocchi, *Aulo Gabinio e i suoi processi* (1892)

GABLE, the upper part of the end walls of a building covered by a roof that slopes down from the centre to each side; hence the gable is always pointed in general form and usually triangular. In cases like the gambrel roof (*q.v.*) where the roof is in two slopes on each side, the gable becomes pentagonal. In classic work, where the slopes are low and where a cornice is continued across the end walls connecting the eaves, the gable is called a pediment (*q.v.*). The architectural treatment of the gable results from the effort to find a beautiful solution to the problem of keeping water out of the intersection of walls and roof. This was done either by carrying the roof out over the top of the end walls and finishing it with a molding, sloping cornices or a projecting, bracketed board known as a bargeboard (*q.v.*); or by carrying up the end ualls above the roof level and capping them with a waterproof coping or cap. The former method is general in wooden buildings, and in those of small size or little architectural formality; the latter in larger and more monumental masonry structures, particularly in the Gothic and early Renaissance styles.

In north and west areas of Europe, where roofs of steep pitch are general, gables are often richly decorated and finished at the top with a series of steps or fantastic breaks often curved, and in the Renaissance period further ornamented with obelisks, urns, statues and scrolls, as in the town hall of Bremen (1609), the Friedrichsbau at Heidelberg castle (*c.* 1590) or the town hall of Xntwerp (1561). In England, stepped and curved sided gables

were common during the Elizabethan and Jacobean periods, as in many of the colleges of Oxford and Cambridge; more complicated forms rich with scrolls and strap work were used as decorations for wall coverings, as in Wollaton hall, Nottingham (last quarter of the 16th century).

During the Gothic period gables were decorated with crockets (*q.v.*) and finials (*q.v.*), and sometimes, especially from the 14th century on, with tracery. Gables were also used purely as decoration, without roofs behind; the French flamboyant churches are unusually rich with examples of pierced and traceried gables, very similar to those of the porch of St. Maclou at Rouen (begun 1432).

Gables are important features in the architecture of China and Japan. In north China and Japan, gables follow the roof slope and are ornamented with rich projecting roof tiles, grotesque animals at the ridge and eaves. and occasionally with surface patterns. In south China stepped gables are more common.

See also ROOF.

GABLONZ: see JABLONEC NAD NISOU.

GABORIAU, EMILE (1835–1873), French novelist, was born at Saujon (Charente Inferieure). He became secretary to Paul Féval, and, after publishing some novels and miscellaneous writings. found his real gift in *L'Affaire* Lerouge (1866), a detective novel which was published in the Pays and at once made his reputation. The story was produced on the stage in 1872 A long series of detective novels, which are classics in their kind, followed. Among them are: Le Crime *d'Orcival* (1867), *Monsieur* Lecoq (1869), *La* Vie *infernale* (1870), Les *Esclaves* de Paris (1869), *L'Argent* des autres (1874). Gaboriau died in Paris on Sept. 28, 1873.

GABRIEL, in the Bible, the heavenly messenger (see ANGEL) sent to Daniel to explain the vision of the ram and the he-goat, and to communicate the prediction of the Seventy Weeks (Dan. viii. 16, ix. 21). He was also employed to announce the birth of John the Baptist to Zacharias, and that of the Messiah to the Virgin Mary (Luke i. 19, 26). Because he stood in the divine presence (see Luke i. 19; Rev. viii. 2; and cf. Tobit xii. 15), both Jewish and Christian writers generally speak of him as an archangel. In the Book of Enoch "the four great archangels" are Michael, Uriel, Suriel (Raphael). and Gabriel.

GABRIEL, JACQUES ANGE (or ANGE JACQUES) (1698–1782), French architect, creator of the Petit Trianon at Versailles. was born and died in Paris. Most celebrated of a family of accomplished architects, he was the son of Jacques V (1667–1742), whom he succeeded as premier architect of Louis XV and director of the Academy of Architecture in 1742. Among his royal commissions were the enlargements of Fontainebleau (1749) and the Louvre (1755), the chdteaux at Compiègne (1751) and Choisy (1752), the grand project for Versailles (1763), and the École Militaire (1752). The magnificent Place Louis XV (now Place de la Concorde) in Paris (1755) shows him to have been an accomplished urban planner. His best-known work. believed to be one of the most beautiful buildings ever built, is the gracefully precise Petit Trianon at Versailles (1762). The simple, highly refined architecture of Gabriel was esteemed for its elegance in an age that regarded elegance as commonplace.

(H. MN.)

GABRIELI, a family of great Italian musicians of the 16th century, of whom ANDREA and his nephew and pupil GIOVANNI were the most important.

ANDREA GABRIELI (*c.* 1510–1586), Venetian composer and teacher, was born in Venice, in the quarter called Canareggio, about 1510. He became a pupil of the Flemish master Willaert, maestro di cappella at St. Mark's. In 1566 he succeeded Merulo as second organist of St. Mark's and was later appointed first organist, a post which he held until his death in 1586. Willaert, who had settled in Venice in 1527, was the virtual founder of the new Venetian school, for it was under his pupils Andrea Gabrieli and Joseffo Zarlino that Italian music began to free itself from the supremacy of the Netherland masters, which had been unshaken for nearly a century. The rambling "Ricercar" for organ was given form and meaning by the two Gabrielis, in whose hands it finally became the "canzone alle francese," the first canzoni for organ being those written by Andrea in 1571. The canzone form was also adopted for combinations of strings or other instruments. Another form associated with Andrea is the Toccata, which was the earliest form of virtuoso composition for organ. Andrea enjoyed great fame as a teacher. His most celebrated pupils were his nephew Giovanni and Leo Hassler.

His works include: *Psalmi* Davidici, qui *poenitentiales nuncupantur, tum omnis* generis *instrumentorum, tum* ad *vocis modulationum* accomodati sex vocum (Venice 1583); Sacrae cantiones *quinque vocum, liber primus* (1565); *Madrigali,* lib. 1 a 5 (1566), lib. 2 a 5, 6 *&* 8 (1570); *Missarum* sex *vocum,* lib. *primus* (1572), *Canzoni* alla francese per *l'organo* (1571); *Madrigali* a 6 v (1574); a 3 v. (1575); *Cantiones ecclesiasticae* (1576); *Canti* concerti a 6, 7, *8, 10* e 16 v. (incl. 10 pieces by Giovanni) 1587; Choruses for Oedipus *tyrannus* (printed 1588); *Mascherate* (1601); a *Missa brevis* and motets in Proske's *Musica divina;* 6 vocal pieces in Torchi's *Arte musicale* in *Italia* vol. ii, and 4 organ pieces in vol. iii; and organ compositions, printed with Giovanni's, in 3 vols. of *Ricercari* (1593–96). A Ricercar in 8 parts has been published by Dr. Riemann (Augener). *See* Eitner: *Quellenlexikon;* Spemann: *Goldenes Buch der Musik.*

GIOVANNI GABRICLI (1557–1612?), nephew and pupil of Andrea, was born in Venice in 1557. He became first organist of St. Mark's in 1585. His monument in San Stefano gives the date of his death as Aug. 12, 1613, but this may be a mistake for 1612 as his post was filled on Aug. 12 of that year. He was a brilliant contrapuntist and, like his uncle, became a celebrated teacher. Heinrich Schütz, Alois Grani and Michael Praetorius were the most famous of his pupils. He experimented boldly with new combinations of instruments, new forms and new harmonies. New editions of some of his organ works appear in Ritter's *Zur Geschichte des Orgelspieles* (1884) and J. v. Wassilievski's *Gesch. d. Instrumentalmusik im 16 Jahrhundert* (1878).

See Karl v. Winterfeld: *Johannes Gabrieli und sein Zeitalter* in 3 vols. (1834) of which one vol. contains mus. examples.

GABRIELINO. This extinct Shoshonean group of California Indians inhabited Santa Catalina island; named from the Franciscan mission of San Gabriel. They numbered about 5,000. They shared their arts with the adjoining Chumash of Santa Barbara channel and had developed a religion with named gods. A form of this, referring to the supreme deity Chungichnish, and making use of *Datura* as a vision-producing narcotic, continued to spread to neighbouring tribes until after 1850.

GABRILOWITSCH, OSSIP (1878–1936), pianist and conductor, was born in St. Petersburg (now Leningrad), on Feb. 7, 1878. He studied music at the Imperial Conservatoire in that city in the class of Tolstov and under the personal supervision of Anton Rubinstein, winning the Rubinstein prize in 1894. Later he continued his studies under Leschetizky in Vienna. At 18 he toured in Germany, Austria and England. In 1900 he toured the United States, and again in 1902, 1907–08. He married Mark Twain's daughter, Clara Clemens, the singer, in 1909. After having conducted in Munich and Vienna he became conductor of the Detroit symphony orchestra in 1918.

GABROVO, a town of Bulgaria, situated on the upper Yantra, in the northern foothills of the Balkan mountains, on a branch of the Transbalkan railway from Stara Zagora to Trnovo. Pop. (1956) 37.919. It is the centre of the textile and tannery industry. The old gabled wooden houses along the Yantra are particularly fine specimens of Balkan architecture, and the Turkish bridge is also famous. The first Bulgarian national school was opened in 1835 at Gabrovo, which thus became to some extent the cradle of the national resurrection. About 10 miles away is the Sokol monastery.

GABUN (or GABON), former territory of French Equatorial Africa. became an autonomous republic within the French Community in Nov. 1958 and an independent republic on Aug. 17. 1960. It derives its name from the Gabun estuary or Rio de Gahao, so named by the Portuguese navigators who discovered it in 1485 because of its imagined likeness to the *gabão* or cabin. In 1839 the French founded their first settlement on the left bank of the Gabun. and in 1849 on the right bank they established Libreville. the capital of the territory. When during the second half of the 19th century the French gradually occupied the hinterland, the name Gabun was applied to the whole region.

Gabun covers 102,317 sq.mi. and had in 1950 a population of 408.778 The dense rain forests with hard woods, oil palms and rubber-bearing plants represent the territory's chief economic assets. (H. A. WF.)

GACE BRULÉ (d. *c.* 1220), French *trouvère,* was a native of Champagne. It has generally been asserted that he taught Thibaut of Champagne the art of verse, an assumption which is based on a statement in the *Chroniques de Saint-Denis:* "Si fist entre lui [Thibaut] et Gace Brulé les plus belles chançons et les plus délitables et melodieuses qui onques fussent oïes." This has been taken as evidence of collaboration between the two poets. The passage will bear the interpretation that with those of Gace the songs of Thibaut were the best hitherto known. Paulin Paris, in the *Histoire littéraire de la France* (vol. xxiii.), quotes a number of facts that fix an earlier date for Gace's songs. Gace is the author of the earliest known *jeu parti.* The interlocutors are Gace and a count of Brittany who is identified with Geoffrey of Brittany, son of Henry II. of England. Gace appears to have been banished from Champagne and to have found refuge in Brittany. A deed dated 1212 attests a contract between Gatho Bruslé (Gace Brulé) and the Templars for a piece of land in Dreux. It seems most probable that Gace died before 1220, at the latest in 1225.

See Gédéon Busken Huet, *Chansons de Gace Brulé,* edited for the Société des Anciens Textes Français (1902), with an exhaustive introduction. Dante quotes a song by Gace, *Ire d'amor qui en mon cuer repaire,* which he attributes erroneously to Thibaut of Navarre (*De vulgari eloquentia,* p. 151, ed. P. Rajna, Florence, 1896).

GACHARD, LOUIS PROSPER (1800–1885), Belgian man of letters, was born in Paris on March 12, 1800. He entered the administration of the royal archives in 1826, and was appointed director general, a post which he held for 55 years. Gachard died at Brussels on Dec. 24, 1885. Among his best known works are: *Don Carlos et Philippe II.* (1863), *Etudes et noticss historiques concernant l'histoire des Pays-Bas* (1863), *Histoire de la Belgique au commencement du XVIII^e siècle* (1880), *Histoire politique et diplomatique de P. P. Rubens* (1877), all published at Brussels.

GAD, a Semitic name. 1. A god of fortune, originally, perhaps, Aramaean, whose name occurs not infrequently in compound place names. The god himself is mentioned in Is. lxv. 11 (R.V.).

2. The name of a seer at the court of David, 1 Sam. xxii. 5, xxiv., 1 Chron. xxix. 25, 2 Chron. xxix. 25.

3. An Israelite tribe claiming descent from Jacob and Zilpah, Leah's maid.

The name is now generally supposed to be that of the god (1), but the traditional derivation is that which connects it with a word meaning "a raiding troop" (*cf.* Gen. xlix. 19). The territory of Gad lay to the east of Jordan, between Manasseh (Machir) and Reuben, and the more usual term for this district is Gilead. From Jud. v. 17, where Gilead is condemned for not following Barak, we gather that this name might be used for the tribe as well as for its territory. Gad is mentioned in the inscription of Mesha, and it is noteworthy that by this time Reuben has entirely disappeared, having been absorbed, apparently, partly by Gad and partly by Moab. Gad belonged nominally to the northern kingdom of Israel, but was liable to be raided from the desert, while it was also exposed to attack from the Syrians of Damascus in the north and from Moab in the south; hence the control exercised by the court of Samaria was uncertain and irregular.

GADAG (GARAG), a tonn and taluka in Dharwar district. Mysore state. India. 43 mi. E. of Dharwar town. Pop. (1951) 65.509; taluka (413 sq.mi.) 144,260. It is an important junction on the Central railway, with trade in cotton and silk and cotton stuffs, factories for ginning and pressing cotton and a spinning and neaving mill. Its temples exhibit fine carving, with inscriptions from as early as the 10th century A.D.

GADARA, an ancient city of Trans-Jordan, a member of the Decapolis, capital of Peraea (so at least Josephus), and political centre of the district of Gadaris It is now represented by the group of ruins, Umm Kēs. which are spread over the summit of a hill 1,193 ft high and about 6 m. S E. of the southern end of the Sea of Galilee "There could hardly be found a second point in this part of ʿAjlūn which combines so perfectly the advantages due to a magnificent soil and a commanding position"

Although the Mishna asserts that it was fortified by Joshua, Gadara was probably of Greek origin and it certainly maintained a religious interest in Zeus. It first appears in history as a place which fell to Antiochus the Great after his victory over Scopas at Paneas (Bāniās). Alexander Jannaeus took it after 10 months siege (*c.* 100 B.C.). Pompey restored it (64–63 B.C.) and Augustus gifted it to Herod the Great (30 B.C.). During the Jewish revolt Vespasian took possession of the city, the inhabitants pulling down the walls as an earnest of peace. Josephus knew it as a "place of strength with many rich citizens" and during the time of the Antonines it was adorned with buildings of some magnificence.

There exist to-day the remains of three large theatres, a basilica, a temple, a colonnaded street, a reservoir, the city wall, and an aqueduct which brought water from the Hauran. On the eastern side of the site there is a large necropolis with rock-hewn tomb-chambers (many with stone doors), which some of the modem inhabitants use as dwellings, together with numerous carved sarcophagi.

About 3 mi. to the north beside the river Yarmuk (Hieromax) are the celebrated hot springs and baths of Amatha described by Eusebius and Strabo. "To Gadara the pleasure-loving Romans, after having enjoyed the restorative effects of the hot springs, retired for refreshment, enjoying the cooler heights of the city and solacing their leisure with the plays performed in the theatres." From its leisured populace it produced many fine littérateurs; Philodemus, the Epicurean and epigrammatist; Meleager the anthologist; Menippus the satirist; Theodorus the rhetorician, and others.

The healing of the demoniac in the Gospel narrative has nothing to do with Gadara, but is rather to be associated with Kersa on the eastern shore of the Sea of Galilee.

GADDI, the name of a celebrated family of 14th-century Italian painters, active in Florence, 1318–96, comprising Gaddo di Zanobi (documented 1318/19, still alive in 1327), by whom no works are known, his son Taddeo, and his grandsons Agnolo and Giovanni. Two of these painters, Taddeo and Agnolo, were among the most important Florentine artists of their time.

Taddeo Gaddi *(c.* 1300–1366), a pupil of Giotto, is sometimes assumed to have participated in Giotto's altarpiece of the Coronation of the Virgin in the Baroncelli chapel in Sta. Croce, and to have been responsible, while in close association with Giotto, for a panel of St. Stephen (Horne museum. Florence). His earliest authenticated work is a small triptych in the Kaiser Friedrich museum, Berlin, signed and dated 1334. In 1341–42 he seems to have been employed in S. Miniato al Monte outside Florence and in S. Francesco at Pisa. His most extensive works, the frescoed scenes from the life of the Virgin in the Baroncelli chapel in Sta. Croce, were probably completed in 1338. In these the figure style stems from Giotto, but is modified by a new concern with light. Between 1347 and 1353 Taddeo Gaddi painted a polyptych for S. Giovanni Fuorvicitas at Pistoia, while a "Virgin and Child" in the Uffizi gallery, Florence, from S. Lucchese at Poggibonsi. is signed and dated 1355. The latter work maintains much of the dignity and weight of Giotto's figure style. Possibly about 1338, Taddeo Gaddi decorated the sacristy cupboards in Sta. Croce with panels representing scenes from the lives of Christ and of St. Francis; with one exception (in Berlin) these panels are in the Accademia in Florence. Enclosed in decorative frames, these are perhaps the most distinguished narrative panels of the generation after Giotto's. In 1363 Taddeo painted a fresco (lost) in the Mercanzia Vecchia and in 1366 is mentioned in documents for the last time. G. Villani and F. Sacchetti supply evidence of Taddeo Gaddi's considerable reputation,-and his work is highly praised in the *Commentari* of the sculptor Lorenzo Ghiberti.

Agnolo Gaddi *(c.* 1350–1396), son of Taddeo, was employed in Rome in 1369, as an assistant of his brother Giovanni (d. 1383) on frescoes for Pope Urban V. Between 1383 and 1386 he designed medallions of the Virtues for the Loggia dei Lanzi in Florence, which were carved by Jacopo di Piero Guidi. and between 1387 and 1395 his name appears as the designer or gilder of sculptures carved for the façade of the Duomo. His death in 1396 left unfinished the Altar of the Crucifixion in S. Miniato al Monte outside Florence. His most ambitious works are the frescoes in the choir of Sta. Croce in Florence, probably painted in the mid-1380s and certainly completed before 1395. They illustrate the Legend of the Cross, and in their figure style, their loose, flat compositions and their light palette are redolent of late Gothic mannerism. Between 1394 and 1396 Agnolo painted a cycle of scenes from the life of the Virgin and the legend of the Holy Girdle in the Cappella della Cintola in the cathedral at Prato, and subsequently (with G. Starnina) decorated the Castellani chapel in Sta. Croce in Florence. A facile and prolific painter, Agnolo Gaddi commanded neither the gravity of his father nor the decorative charm of his follower, Lorenzo Monaco.

GADE, NIELS VILHELM (1817–1890), Danish composer, was born at Copenhagen, on Feb. 22, 1817, his father being a musical instrument maker. Though he studied the violin under Wexschall, and theory under Weyse and Berggreen, he was largely self-taught. In 1840 his *Aladdin* and his overture of *Ossian* attracted attention, and in 1841 his *Nachklänge aus Ossian* overture gained the local musical society's prize, the judges being Spohr and Schneider. A further stipend from the king enabled him to go to Leipzig and Italy. In 1844 Gade conducted the Gewandhaus concerts in Leipzig during Mendelssohn's absence, and on the latter's death became chief conductor. In 1848, on the outbreak of the Holstein War, he returned to Copenhagen, where he was appointed organist and conductor of the Musik-Verein. In 1852 he married a daughter of the composer J. P. E. Hartmann. He became court conductor in 1861, and was pensioned in 1876—the year in which he visited Birmingham to conduct his *Crusaders.* This work, and the *Frühlingsfantasie,* the *Erlkönigs Tochter, Frühlingsbotschaft* and *Psyche* (written for Birmingham in 1882) enjoyed great popularity. Of his eight symphonies the best are the first and fourth. A friend of Mendelssohn and of Schubert, Gade was a romanticist. whose music owes much to Scandinavian folk-song. He died at Copenhagen on Dec. 21, 1890.

GADIDAE, a family of fishes including the cod, whiting, haddock, etc., inhabiting the waters of the northern hemisphere. *See* Cod; Fishes; Whiting.

GADOLINIUM [symbol Gd; atomic number 64; atomic weight 157.26; stable isotopes Gd^{152} (0.21%), Gd^{154} (2.14%), Gd^{155} (14.86%), Gd^{156} (20.61%), Gd^{157} (15.66%), Gd^{158} (24.75%), Gd^{160} (21.71%)] is a metallic element belonging to the rare-earth group. The early history of this element is in a rather confused state. J. C. G. Marignac in 1880 obtained a new rare earth in an impure condition and termed it Yα; in 1886 he gave it the name gadolinium in honour of the Finnish chemist J. Gadolin.

Fairly pure gadolinium salts were secured by E. A. Demarcay in 1900. It occurs in many minerals, some varieties of Norwegian ytterspar being quite rich sources; other common sources are gadolinite, samarskite and monazite. Gadolinium was formerly concentrated from other members of the rare-earth group by the fractional crystallization of the double magnesium nitrates. The more soluble fractions of these nitrates were then converted to the bromates and further purified by fractional crystallization. From 1945 it was separated fairly rapidly by means of ion exchange columns. This separation can be more readily carried out if advantage is taken of the fact that the two close neighbours to gadolinium — samarium and europium — exist in the divalent state. Usually these elements are removed from the rare earth mixtures by means of a sodium amalgam separation from aqueous solution before the rare-earth chloride mixtures are adsorbed on the ion exchange columns. Small amounts of samarium can also be removed from gadolinium by reducing the chloride to the gadolinium metal, using calcium as a reductant. Under these conditions samarium does not reduce to the metal but remains in the slag. Gadolinium oxide (Gd_2O_3) is white. Solutions of the salts are colourless and give absorption bands in the ultraviolet region of the spectrum; they are strongly paramagnetic. The metal has been produced by thermoreduction of $GdCl_3$ with calcium. It possesses a hexagonal close-packed structure ($a=3.622$ A, $c=5.748$ A) and has a calculated density of 7.948 g. per cubic centimetre. The metal is a silver white and is strongly ferromagnetic below room temperatures. Gadolinium salts are of particular interest because they were the first salts used in obtaining temperatures below 1° K. (below $-272°$ C.) by means of magnetic cooling. Gadolinium is of particular interest in atomic fission because two of its isotopes, 155 and 157, have large capture cross sections for thermal neutrons and can act as powerful poisons in destroying chain reactions. See RARE EARTHS. (F. H. SP.)

GADSDEN, JAMES (1788–1858), U.S. soldier, diplomat and railroad president, was born in Charleston, S.C.. May 15, 1788. He graduated from Yale college in 1806 and engaged in business in his native city until 1812, when he was appointed a lieutenant of engineers in the U.S. army. In 1820 he was made responsible for the establishment of military posts in Florida and supervised the removal of the Seminole Indians to southern Florida in 1823. Gadsden negotiated the treaty for the removal of the Seminoles to the west in 1832 and served in the war which followed the refusal of some Seminoles to leave Florida. (See also FLORIDA: History.) In 1840 he became president of a railroad in South Carolina.

Gadsden's most important public service followed his appointment as U.S. minister to Mexico in 1853. He was instructed to negotiate a treaty for the purchase of territory south of the Gila river through which ran the most desirable route for a railroad from the southern states to the Pacific. He succeeded in adjusting certain minor issues and in gaining a cession of territory in what is now southern New Mexico and Arizona. This added territory, which included the route of the proposed southern railroad, is generally known as the Gadsden Purchase (*q.v.*). Gadsden died at Charleston, Dec. 26, 1858. (H. W. BY.)

GADSDEN, a city of northeastern Alabama, U.S., the seat of Etowah county, is on the Coosa river, 65 mi. N.E. of Birmingham, in the foothills of the Appalachian mountain system. Pop. (1960) city 58,088; standard metropolitan statistical area (the entire county, including the town of Attalla) 96,980. (For comparative population figures see table in ALABAMA: Population.) Alabama City was annexed by Gadsden in 1932.

Gadsden is in the iron and coal region of Alabama and has abundant hydroelectric power from the Coosa river. Among its manufactured products are iron and steel, textiles, automobile tires and metal fabricated products. It is also in a rich agricultural region. The principal products are cotton, produce, grain and livestock.

The city was founded in 1840 and named for James Gadsden, southern railroad promoter, who later, in 1853, while serving as minister to Mexico, negotiated the Gadsden Purchase. Emma Sansom, Confederate heroine, lived near Gadsden. In 1863 she guided Gen. Nathan Bedford Forrest across flood-swollen Black creek, enabling him to capture Col. Abel D. Streight and his command. Gadsden was incorporated as a city in 1871. (B. CR.)

GADSDEN PURCHASE. While it ended the bitter Mexican War, the treaty of Guadalupe Hidalgo (Feb. 1848) did not resolve all difficulties between the United States and the republic of Mexico. Article xi made the U.S. government responsible for preventing Indian raids into northern Mexico, but Apache depredations were heaviest in the years immediately following the treaty. The dominating problem, however, concerned the international boundary. The 1848 treaty established the natural boundary of the Rio Grande as the international line from El Paso eastward to the Gulf of Mexico, but it failed to provide a positive demarcation west of El Paso to the Pacific. Stipulating no longitude or latitude, the 1848 treaty merely declared that the boundary from El Paso westward should coincide with the line shown on Disturnell's map (1847).

When a joint Mexican-American survey party met in 1851 to locate landmarks on Disturnell's line, the map was found to be seriously inaccurate in that El Paso mas placed 34 mi. N. of its actual site. This gave Mexico an unexpected advantage, which its commissioner, P. G. Condé, was determined to maintain. Condé's eventual compromise with the U.S. commissioner, J. R. Bartlett, was acceptable to the Whig administration of President Fillmore; but it was repudiated immediately by the Democratic expansionists who returned to office under Franklin Pierce in 1853. The Bartlett-Condé agreement was particularly noxious to the new secretary of war, Jefferson Davis of Mississippi, because it would mean the loss of about 3,000,000 ac. in the Mesilla valley, just west of El Paso. Davis strongly advocated a southern route in the construction of any transcontinental railroad; he argued, and with good reason, that the most practical route to California was across the Mesilla valley and then through the Gila river valley, which was altogether on the Mexican side of the 1848 line.

On the urgent recommendation of Davis, the South Carolinian railroad president James Gadsden (*q.v*) was sent to Mexico as US. minister in May 1853. The major object of Gadsden's mission was to acquire all the territory needed for a transcontinental railway route—and as much additional land as President Santa Anna might be willing to sell. Gadsden was instructed to propose five alternative cessions to Santa Anna, the largest to include all of Lower California, and he was authorized to offer as much as $50,000,000. On Dec. 30, 1853, Gadsden concluded a treaty nith Santa Anna, by which Mexico would relinquish the Mesilla valley and would cede 19,000,000 ac. south of the Gila river. Other adjustments were also incorporated: article xi of the 1848 treaty was abrogated; Mexico agreed to drop all claims for Indian depredations; and the United States assumed the Tehuantepec claims of the New York speculators P. A. Hargous and A. G. Sloo. The payment to Santa Anna's government was to be $15,000,000.

Gadsden had struck an admirable bargain, but his treaty became the subject of violent sectional debate when it reached the U.S. senate. Northern spokesmen, fearing as always the possible extension of slavocracy into the new lands of the southwest and still hoping to see a transcontinental railroad built elsewhere, argued that the territory was worthless. But protreaty lobbying by the New York speculators was vigorous, and southern senators finally achieved ratification by drastically amending the whole document.

The revised version was approved by a close vote on April 25, 1854, but not until the payment to Mexico had been cut to $10,000,000 and the total area of the cession reduced proportionately. Santa Anna placidly accepted these alterations, and the treaty was proclaimed on June 30, 1854. In Mexico the transaction was loudly denounced by Santa Anna's many rivals, and that veteran politician's career ended with banishment on a charge of high treason in 1855.

The Gadsden Purchase, as the cession came to be called, was the last addition to the continental domain of the United States. It should be viewed as the final step in the Democratic program of "Manifest Destiny" that dominated the decade of the 1840s. As finally defined by the senate, the cession was bounded on the east by the Rio Grande, on the north by the Gila and on the west by the Colorado. Its area has often been given as 45,535 sq.mi., but this figure is much too large. In his Report on the United States and Mexican Boundary Survey (1857–59), Maj. William H. Emory set the total at 26,185 sq.mi. A more exact modern approximation is 29,640 sq.mi., of which 27,305 are within the present limits of Arizona and comprise 24% of the area of that state.

Garber, *The Gadsden Treaty* (1923), but *see* also the extended comments in Hunter Miller (ed), *Treaties and Other International Acts of the United States*, vol. vi, pp. 293–437 (1942). Summaries are in J. Fred Rippy, *The United States and Mexico,* rev. ed. (1931) and James M. Callahan, *American Foreign Policy in Mexican Relatzons* (1932). A convenient review is Frank C. Lockwood's article, "The Gadsden Purchase," in *Arizona Quarterly,* vol. 2, pp. 5–16, (1946). (Jo. A. C.)

GADWALL, the common name of the duck *Chaulelasmus streperus.* Its habits and distribution are very similar to those of the common wild duck (see DUCK). It breeds in Iceland, southeast England, across northern and eastern Europe and northern Asia to Kamchatka and in North America from southern British Columbia and Saskatchewan south to southern California, Colorado, Nebraska and Wisconsin. It usually. occurs in twos and threes, or in mixed flocks with other ducks. It is also known as gray duck or canvas belly. Its small head, flat back, elongated form and elevated stern render it easily recognizable. In coloration the two sexes are almost equally sombre, but the drake exhibits chestnut upper-wing coverts. Both resemble the female of the mallard in colour, but the white secondary quills form one of the most readily perceived characteristics of the species. The gadwall is increasing as a breeding species in Britain. It has been always esteemed for the table (G F. Ss.)

GAELIC LANGUAGE. The term Gaelic is used for the surviving Celtic languages other than Welsh, Cornish and Breton. *i.e.*, for Erse, Manx and Scottish Gaelic. In these languages the qu sound is often used nhere the *p* sound would be used in the other group. Gaelic spread from Ireland to Scotland with the Dalriadic Scots. Scottish Gaelic has given up the nasal mutation (or eclipse). e g , Scottish or *bò*, "our cow," Irish ar m-bd; Scottish *mantêr* "of the countries." Irish *na* d-tir. See also CELTIC LAYGUAGES: IRISH LANGUAGE.

GAELIC LITERATURE: see IRISH LITERATURE : Gaelic; SCOTTISH LITERATURE: Gaelic.

GAETA, a town in Latina province, Lazio (Latium). Italy, a seaport and naval station and the seat of an archbishopric, lies 72 km (45 mi) N W. of Naples. on the Via Flacca which links it with Rome and Naples Pop. (1957 est) 19.188 (commune). Outside the walls the town has a modern appearance, but within them the character of a fortified square is preserved. The cathedral (1106. restored 1892) suffered considerable damage in World War II; it has a romanesque-Moorish campanile (12th–13th centuries), a banner of the victor of Lepanto and contains a nunnery. The castle, of Norman origin, the lower part of which dates from c. 1289. dominates the old town from the south Monte d'Orlando (a public park) is supposedly the site of the grave of Caieta, the nurse of Aeneas. after whom the town was named. The tombs of the consuls L. Munatius Plancus (d. after 22 B C.), the founder of Lyons, and L S Atratinus are also located there. West of this eminence. near the sanctuary of the Trinity, is the "cleft mountain." a vertical fissure running down to sea level. There is an oil refinery and a glassworks. Fishing. other maritime activities and agriculture are additional occupations. The principal import is raw petroleum; chief exports are petroleum products, bottles, fresh and preserved fish, vegetables. wine and fruit. Gaeta first came into contact with the Romans after the first Samnite War (see ROME: The Republic). A road was built *c.* 184 B.C. connecting the town with the port and the place became a holiday resort After the fall of the western empire Gaeta remained loyal to Byzantium and preserved its freedom throughout the Gothic and Saracen invasions. In the 8th century it was a marine republic and after 915 an autonomous duchy. It capitulated to the Normans in 1140 and under them achieved importance. In the 15th century it was the centre of struggles for succession to the throne of Naples. The town was occupied by the Austrians from 1707–34. In 1806. after a heroic defense, it fell to the French (see NAPLES, KINGDOM OF).

The capitulation of Gaeta in 1861 marked the unification of Italy. (P. Co)

GAETULIA, a district in the north of Africa, which in the usage of Roman writers comprised the wandering tribes of the southern slopes of Mt. Aures and the Atlas, as far as the Atlantic ocean, and the oases in the northern part of the Sahara. They were distinguished from the Negro people to the south, and belonged to the Berber race which formed the population of Numidia (*q* v).

The tribes to be found there at the present day are probably of the same race, and retain the same wandering habits. They were noted for the rearing of horses, were clad in skins, lived on flesh and milk. and the only manufacture connected with their name is that of purple dye.

GAGARIN, YURI ALEKSEYEVICH (1934–), who made the first manned space flight, was born near Gzhatsk in the oblast of Smolensk, U.S.S.R., on March 9, 1934. The announcement of the flight revealed that Gagarin, a major in the Soviet air force. was launched at 9:07 A.M. MOSCOW time on April 12, 1961, in the $4\frac{3}{4}$-ton spaceship "Vostok." He circled the earth in 1 hr. 48 min at a maximum speed of 18.000 m.p.h. and at a maximum height of 187 mi., landing at a predetermined spot in the Soviet Union without ill effects. During the flight he maintained radio contact with earth and was able to operate controls and make notes while in the state of weightlessness

The son of a carpenter on a collective farm, Gagarin's early education was interrupted by World War II In 1951 he graduated with distinction as a molder at a vocational school near Moscow. He later studied at the industrial college at Saratov and concurrently took a course in flying. On completing this course in 1955 he entered the military aviation school at Orenburg.

Gagarin, hailed throughout the world as "the Columbus of Interplanetary Space," was awarded the Order of Lenin, and given the titles of Hero of the Soviet Cnion and Pilot Cosmonaut of the Soviet Union. (W. J. BP.)

GAGE, THOMAS (1721–1787), British general and governor of Rlassachusetts. The second son of the first Viscount Gage, he entered the army in 1741 and saw service in Flanders and in the battle of Culloden. In 1754 he sailed with his regiment (the 44th) to America and took part in Gen. Edward Braddock's disastrous expedition. In 1758 he organized and became colonel of a regiment of light infantry (the 80th) and served in Jeffery Amherst's operations against Montreal. He was made governor of Montreal, promoted major general in 1761 and lieutenant general in 1770. In 1763 he succeeded Amherst as commander in chief of the British forces in North America, the most important and influential British post in the colonies, which he continued to hold until 1775. In 1774 he was appointed governor of Massachusetts and in that capacity was entrusted with carrying into effect the Boston Port act. The difficulties which surrounded him in the execution of his office at this time of the gravest unrest culminated in 1775. and the action of April 19 at Lexington initiated the American Revolution (*q.v.*). After the battle of Bunker Hill, Gage was superseded as commander in chief by Howe and returned to England. He became general in 1782 and died on April 2, 1787.

See John *R.* Alden, *General Gage in America (1948)*; Clarence E. Carter (ed.), *The Correspondence of General Thomas Gage, 2* vol. *(1931–33).* (B. KN.)

GAGERN, HANS CHRISTOPH ERNST, BARON VON (1766–1852), German statesman and political writer, was born at Kleinniedesheim, near Worms, on Jan. 25, 1766. After studying law at the universities of Leipzig and Gottingen, he entered the service of the prince of Nassau-Weilburg. He was the prince's envoy at Paris until 1811, and in 1812 he took part in the abortive attempt to excite a second insurrection against Napoleon in Tirol. He joined the headquarters of the Prussian army (1813), and became a member of the board of administration for north Germany. In 1814 he was appointed administrator of the Orange principalities; and, when the prince of Orange became king of the Netherlands, Baron Gagern became his prime minister. In 1815 he represented him at the congress of Vienna, and obtained for the Netherlands a considerable augmentation of territory. From 1816 to 1818 he was Luxemburg envoy at the German diet, but was recalled, at the instance of Metternich, owing to his too independent advocacy of state constitutions. In 1820 he retired with a pension to his estate at Homau, near Hochst, in Hesse-Darmstadt, where he died on Oct. 22, 1852. Baron von Gagern wrote some historical works, but the best known is his autobiography, *Mein* Anteil **an** der *Politik,* 5 vols. (Stuttgart and Leipzig, 1823–1845).

Of Hans Christoph von Gagern's sons three attained considerable eminence:—

FRIEDRICH BALDUIN, Freiherr von Gagern (1794–1848), the eldest, took service in the Austrian army, fought in the Russian campaign of 1812, and at Dresden, Kulm and Leipzig. He then entered the Dutch service, took part in the campaigns of 1815, and, after studying another year at Heidelberg, was member for Luxemburg of the military commission of the German federal diet (1824, 1825). In 1830 and 1831 he took part in the Dutch campaign in Belgium, and in 1844, was sent on a military mission to the Dutch East Indies. In 1847 he was appointed governor at the Hague, and commandant in South Holland. In the spring of 1848 he commanded the Baden forces against the insurgent "free companies" (Freischaaren). At Kandern, on April 20, he was mortally wounded. His Life, in 3 vols. (Heidelberg and Leipzig, 1856–1857), was written by his brother Heinrich von Gagern.

HEINRICH, Freiherr von Gagern (1799–1880), the third son, fought at Waterloo in the Nassau contingent. After the war, he studied law at Heidelberg, Gottingen, Jena and Geneva. As a student he had been a member of the *Burschenschaft,* and he now threw himself into open opposition to the unconstitutional spirit of the Hessian government, and was dismissed from the state service in 1833. Henceforth he lived in retirement at Monsheim until the February revolution of 1848 and its echoes in Germany recalled him to active political life. At the Heidelberg meeting and the preliminary convention (*Vorparlament*) of Frankfort he deeply impressed the assemblies; and when the German national parliament met (May 18), he was elected its first president. He was mainly instrumental in imposing the principle of a united empire aith a common parliament. and in carrying the election of the Archduke John as regent. On Dec. 15, when Schmerling and the Austrian members had left the cabinet, Gagern became head of the imperial ministry. and on the 18th he introduced a programme (known as the Gagernsche *Programm*) according to which Austria was to be excluded from the new federal state, but bound to it by a treaty of union. After a severe struggle this proposal was accepted; but on May 20 Gagern and his friends resigned. He died at Darmstadt on May 22, 1880.

MAXIMILIAN, Freiherr von Gagern (1810–1889), the youngest son, nas a member of the German national parliament in 1848. Throughout the revolutionary years he supported his brother's policy, and. after the collapse of the national movement, returned to the service of the duchy of Nassau. In 1855 he entered the Austrian service in the department of foreign affairs. In 1871 he retired and in 1881 was nominated a life member of the upper chamber (*Herrenhaus*). He died at Vienna on Oct. 17, 1889.

See Allgemeine *deutsche Biographie,* Band viii, p. 301, etc. (1878) and Band xlix, p. 654 (1904).

GAG LAWS, a series of resolutions passed in the U.S. house of representatives, between 1836 and 1840, providing that all petitions relating to the subject of slavery would be tabled without being printed, referred to committee or discussed. There was no similar action taken by the senate. These petitions flooded congress after the foundation of the American Anti-Slavery society (1833), reaching a total of 412,006 in 1838–1839, signed by more than 2,000,000 persons. The first gag rule was the Pinckney resolution of 1836. It was followed by the Hawes and Patton resolutions (1837), the Atherton resolution (1838) and the Johnson resolution (1840), which was adopted as standing rule 21 on Jan. 28, 1840. Abolitionists were greatly disturbed by these infringements on the constitutional right of petition and gained increased support nationally. They supplied expert advisers, such as Theodore Dwight Weld, to a house group, led by former Pres. John Quincy Adams (*q.v.*) and Joshua R. Giddings (*q.v.*), which attempted to get rule 21 repealed at the start of each session, finally succeeding on Dec. 2, 1844.

GAILLARDIA, a genus of showy North American herbs of the Compositae (*q.v.*) family, consisting of about 20 species. mostly from the far west and commonly known as gaillardia or blanketflower. All have yellow or yellow and red sterile ray flowers and fertile purple disk flowers. Two annual species. G. *amblyodon* and G. *pulchella,* are popular and widely grown in gardens and borders, and the perennial species, G aristata, one of the last plants in the garden to die in autumn, for the large handsome heads. All are easily grown in most garden soils and preferably in full sun. (J. M. BL.)

GAINESVILLE, a city in north-central Florida. U.S.. is situated approximately 70 mi. S.W. of Jacksonville and 140 mi. N. of Tampa. Founded in 1854 as the seat of Alachua county and named for Gen. Edmund Pendleton Gaines (1777–1849), U.S. army officer. it was incorporated as a town in 1869 and as a city in 1907. (For comparative population figures see table in FLORIDA: *Population.*)

During the 19th century. Gainesville mas an agricultural trading centre, first for cotton farmers and later for citrus and vegetable producers Freezes in the 1890s destroyed orange groves, and both citrus culture and truck gardening were moved to more southerly regions of the state. The East Florida State seminary, established in Ocala in 1853, was relocated in Gainesville in 1866 and was the cultural centre of the tonn. which contained less than 4,000 people at the turn of the century.

In the 20th century the city's growth paralleled that of the University of Florida. In 1905 Florida reduced the number of state-supported colleges from eight to three, and led by merchant William N. Wilson and Mayor William R. Thomas, Gainesville offered land, money and free water in perpetuity to win the University of Florida (so named in 1903) from Lake City, where it was located. The university and East Florida seminary were then consolidated as the new state university. The few hundred students of the first years in Gainesville increased in number to more than 13,000 by the middle of the 20th century. A medical centre, with a medical school and a teaching hospital, was added to the university in 1956; the hospital serves an area with a population of more than 1,000,000. The Florida State museum, with a large collection of Indian artifacts and wildlife specimens, and the Sunland Training centre for exceptional children who are unable to care for themselves are located in Gainesville.

Agriculture and industry also contributed to the city's growth. Watermelons, cucumbers, squash, tomatoes and other truck-garden crops are shipped from Gainesville in late spring and early summer. Electronics, wood products, meat packing, building materials, moss processing and other light industries provide employment.

Gainesville has a council-manager type of government, in effect since 1920. Broad avenues divide the city into quadrants. but within them are many narrow streets and few parks. Oak, pine, magnolia, dogwood, redbud, azaleas and camellias shade and beautify streets and yards. Near the city are Newnan's lake; the Devil's Millhopper, a picturesque sinkhole; and Payne's prairie, a wildlife preserve. The latter perpetuates the name of a Seminole Indian chief whose people once inhabited the area, and who in 1812 led his warriors in battle against the forces of Col. Daniel Newnan. (R. W. PA.)

GAINSBOROUGH, THOMAS (1727–1788), one of the foremost English painters of portraits and landscapes, was born at Sudbury, in Suffolk, the youngest son of John Gainsborough, a maker of woolen goods. About 1740 he was sent to London to study and worked in the studio of Hubert Gravelot, the French painter and engraver. Gainsborough must have met Francis Hayman, who undoubtedly influenced his work. but there is no evidence that he was his pupil, as is suggested in most of the early biographies. In 1746 he married, in London, Margaret Burr, the illegitimate daughter of the duke of Beaufort. Soon after this he returned to Suffolk and about 1752 settled in Ipswich, where he made the acquaintance of his first biographer, Philip Thicknesse, and of Joshua Kirby, the first president of the Society of Artists. Gainsborough early acquired some reputation both as a portraitist and landscape painter and had no difficulty in making a living. In 1759 he moved to Bath, where his studio was soon thronged with visitors. He moved in musical and theatrical circles, and among his friends were members of the Linley family, whose portraits (now in the Dulnich gallery, London) he painted. It was also at Bath that he met David Garrick, nho became a lifelong friend. His devotion to the work of Van Dyck was fostered by a visit to Wilton, where he made a free copy of the famous portrait of the Pembroke family. In spite of the demands for portraits, however, he continued to paint landscapes.

In 1761 he sent a portrait — the "Earl Nugent" — to the exhibition at the Society of Artists, and in the following year the first notice of his work appeared in the London press. Throughout the 1760s he exhibited regularly in London and in 1768 was elected a foundation member of the Royal Academy. In 1774 he moved to London and settled in part of Schomberg house in Pall Mall In the early part of 1781 Gainsborough was commissioned to paint King George III and Queen Charlotte, whose portraits appeared in the Royal Academy exhibition of that year, and after this he was in constant demand at court. In 1784 he quarreled with the academy about the hanging of his portrait "Three Elder Princesses," and removed all the pictures intended for showing that year. He never again showed at the Royal Academy but held private exhibitions at Schomberg house. In the 1780s Gainsborough painted some of his best-known landscapes and a series of "fancy pictures." portraits of pretty country children. He died on Aug. 2, 1788, and was buried at Kew, Surrey.

Unlike most of his contemporaries Gainsborough did not go abroad to study, and was contemptuous of the fashion for history painting. He knew, however, that the language of his art must be learned somewhere and he turned his attention to the Dutch and Flemish painters. His early landscapes show the influence of J. Wynants and J. van Ruisdael in the detailed treatment of the foliage and plants and in the general design, notably the "Cornard Wood" (National gallery, London) finished in 1748. The "View of Dedham" (National gallery of Ireland) is more original in its feeling for the gray light of England. and in the background to "Mr. and Mrs. Andrews" (collection of G. W. Andrews) he approached

"THE MORNING WALK" BY THOMAS GAINSBOROUGH. IN THE NATIONAL GALLERY. LONDON

the realism of Constable. But this soon gave place to a more generalized and poetic view of landscape, reflecting the French pastoral tradition and also the landscapes of Gaspar Poussin, then so popular in England. Gainsborough relied on memory rather than direct study of nature and often worked from model landscapes set up in his studio. "The Harvest Wagon" (Barber institute, Birmingham) painted in the 1760s is one of his loveliest landscapes, a perfect blend of the ideal and the real. Among the best-known of his later landscapes are "The Watering Place" (1775, Tate gallery, London) and "The Market Cart" (1786, National gallery, London). During the years in London he painted a number of pictures of idealized country scenes including "The Cottage Door" (Huntington collection, San Marino, Calif.). He also painted some sea pieces somewhat in the Dutch manner. Some of the "fancy pictures" of country children painted in these years, *e.g.*, the "Cottage Girl with a Pitcher," show a quasi-Wordsworthian approach to nature and are experimental not only in subject matter but also in technique, very thin oil paint being used almost as water colour.

Gainsborough was the only one of the great English portrait painters of the 18th century who also composed landscape drawings in great numbers and in a variety of techniques, including chalk, wash and water colours, some of them varnished. He made in addition a number of soft-ground etchings and constructed his own magic lantern with a number of glass slides painted by himself (now in the Victoria and Albert museum. London).

Gainsborough said landscapes were his real love but he was continually distracted by the demands of portrait painting. The portrait heads painted in Suffolk, if sometimes a little stiff, are penetrating character studies and are delicately penciled. Among the most distinguished are the "Self Portrait" (collection of Lady Cholmondeley) and "Mr. and Mrs. Kirby" (Fitzwilliam museum, Cambridge). While in Suffolk he painted a number of delightfully spontaneous portrait groups—small figures in landscapes, closely related to conversation pieces—that included "Mr. and Mrs. Brown" (collection of Lady Cholmondeley) and the more sophisticated "Heneage Lloyd and his Sister" (Fitzwilliam museum, Cambridge). The "Painter's Daughters Chasing a Butterfly" (National gallery), composed in the last years at Ipswich, is, in its easy naturalism and sympathetic understanding, one of the best of English portraits of children.

After he moved to Bath, Gainsborough had to satisfy a more worldly clientèle, and although he tried to preserve the simple unconventional character of his early work, he had to combine it with a more formal and elegant style which he based on that of Van Dyck. "Miss Ford" (1760, Cincinnati Art museum) is an essay in the grand manner. but "Mrs. William Henry Portman" (c. 1768, collection of Viscount Portman) is a fine character study, full of humanity, and distinguished by rhythmical drawing and delicate gray tones. Some of his best portraits of men date from this time, notably "Sir Benjamin Truman" (collection of Messrs. Truman, Hanbury and Co.).

When he went to Iive in London his portraits of women became more ethereal, and their flickering ribbons and laces seem to melt into the landscape background. "Mrs. Sheridan" (c. 1785, Washington, D.C., National gallery) and "Mrs. Robinson" (1781, Wallace collection, London) are insubstantial characters, but exquisitely painted. Unlike his great rival Sir Joshua Reynolds, he was less successful with men at this time, particularly public figures, but "Johann Christian Fischer" the hautboy player (1780, Buckingham palace. London) is one of his most inspired works of this period. "The Morning Walk" (1785, National gallery, London), a picture of Squire Hallet and his wife, sums up both the elegance and the informality of the 18th century. Gainsborough's many other works include "The Blue Boy" (Master Jonathan Buttall; Huntington collection, California) and "Mrs. Siddons" (National gallery. London).

Of all the English 18th-century painters, Gainsborough was the most versatile and original, always prepared to experiment with new ideas and techniques. He was not, like Reynolds, a master of formal composition, but was devoted to his craft and always sensible of the poetry of paint. His letters reveal a lively character with a pretty wit and a genius for friendship.

GAINSBOROUGH, a market town and urban district in the Parts of Lindsey and in the Gainsborough parliamentary division of Lincolnshire, Eng., on the right bank of the Trent, 18 mi. N.W. of Lincoln by road. Pop. (1951) 17,513. Area 3.7 sq.mi. A tidal bore or eagre of the Trent reaches the town. Gainsborough (Gegnesburh in 1013) was probably inhabited by the Saxons on account of the fishing in the Trent. The Anglo-Saxon Chronicle states that in 1013 the Danish king Sweyn landed there and subjugated the inhabitants. Gainsborough was probably a borough by prescription, for mention is made of burghal tenure in 1280. Mention is made in 1204 of a Wednesday market and in 1258 Henry III granted a Tuesday market to William de Valence, earl of Pembroke who also obtained from Edward I in 1291 licence for an annual fair on All Saints' day, and the seven preceding and eight following days. A fair was granted to John Talbot by Henry III in 1243, and two fairs were granted to Thomas, Lord Burgh, by Elizabeth I in 1592. The Tuesday market is still held, and the fair days are Tuesday and Wednesday in Easter week and the Tuesday and Wednesday after Oct. 20. The parish church of All Saints is classic of the 18th century, excepting the Perpendicular tower. The Old hall, of the 15th century, improved in the 16th, forms three sides of a quadrangle, partially timber framed, but having a beautiful stone bay window. Gainsborough possesses a grammar school founded in 1589 by a charter of Elizabeth I. There is carrying trade on the Trent and neighbouring canals. There are iron foundries and malt kilns and extensive agricultural and general engineering works. Shipbuilding is also carried on. Flour and cattle provender mills are established and corsetry, hosiery and woollen wear industries have been introduced. Gainsborough is the St. Ogg's of George Eliot's *Mill on the Floss.*

GAIRLOCH, a village and civil parish of Ross and Cromarty, Scot.. on the sea loch of Gairloch, 74 mi. W.N.W. of Inverness by road. Pop. (1951) 1,991. The parish includes Loch Maree, the Ben Eighe nature reserve and Invereme garden (owned by the Scottish National trust) with subtropical plants. Gairloch, with its sandy beaches, is a holiday place; it also has extensive herring, cod and salmon fisheries. Of the islands round the coast, only Isle Ewe in Loch Ewe is still inhabited.

GAISERIC or **GENSERIC (c. 390–477),** king of the Vandals. son of King Godegisel (d. 406) and king on the death of his brother Gonderic in 428. In 428 or 429 he led a host of Vandals from Spain into Roman Africa, and took Mauretania, and later Hippo. Having pillaged and conquered almost the whole of Roman Africa, the Vandal king concluded a treaty with the emperor Valentinian III. in 435, by which he retained his conquests. This peace was broken, and in Oct. 439 he captured Carthage, which he made the capital of his kingdom. In 455 he plundered Rome and returned to Africa laden with spoil. Among his captives was the empress Eudoxia, who is said to have invited the Vandals into Italy. The Romans made two unsuccessful attempts to avenge themselves, one by the Western emperor, Majorianus, in 460, and the other by the Eastern emperor, Leo I., eight years later. Gaiseric brought Sicily, Sardinia, Corsica and the Balearic Islands under his rule, and even extended his conquests into Thrace, Egypt and Asia Minor. Having made peace with the Eastern emperor Zeno (476), Gaiseric died Jan. 25, 477.

Gaiseric was a cruel and cunning man, possessing great military talents and superior mental gifts. Though the effect of his victories was afterward neutralized by the successes of Belisarius his name long remained the glory of the Vandals. *See* VANDALS.

GAITÁN, JORGE ELIÉCER (1902–1948), Colombian statesman and penologist, was born in Bogota on Jan. 26, 1902. He studied law at the National university, Bogotá, and continued his studies in Rome, nhere he was a student of Enrico Ferri and followed closely the early development of fascism.

In Colombia he became known as a champion of the people and founded a short-lived party called Union Nacional Izquierdista Revolucionaria or UNIR (Left Revolutionary National union). His maiden speech as a congressman was a polemic argument on the Santa Marta banana plantations owned by the United Fruit company (1928). He served as mayor of Bogotá (1936) and minister of education (1940).

In 1945, as the leader of the more radical factions of Liberals, he ran for the office of president in opposition to the officialLiberal party candidate. Gabriel Turbay. As a result of this split in the ranks of the Liberals the victory went to the Conservative party candidate, Mariano Ospina Pérez. Gaitán's growing popularity, which was scarcely surpassed by that of his contemporaries, seemed to indicate that his eventual election to the presidency was assured, but he was assassinated in Bogotá on April 9, 1948, while the ninth International Conference of American States was meeting. The infuriated populace rioted and set fire to the central part of the city. (G. As.)

GAIUS (CAIUS), **SAINT,** pope from 283 to 296, is said to have been a Dalmatian and even a relative of the emperor Diocletian. His epitaph was found in the cemetery of Callistus. His feast day is April 22. (J. V. HN.)

GAIUS, a celebrated Roman jurist of the 2nd century A.D. Of his personal history very little is known. It is impossible to discover even his full name. Gaius or Caius being merely the personal name (*prae-nomen*) so common in Rome. His works were composed between the years 130 and 180, at the time when the Roman empire was most prosperous and its government the best. Most probably Gaius lived in some provincial town, and hence we find no contemporary notices of his life or works. After his death, however, his nritings were recognized as authoritative; and the emperor Valentinian III named him, along with Papinian, Ulpian, Modestinus and Paulus, as one of the five jurists whose opinions were to be followed by judicial officers in deciding cases. The works of these jurists accordingly became most important sources of Roman law.

Besides the *Institutes,* which are a complete exposition of the elements of Roman law, Gaius was the author of a treatise on the *Edicts of the Magistrates,* of *Commentaries on the Twelve Tables,* of a treatise on the important *Lex Papia Poppaea* and of several other morks. His interest in the antiquities of Roman law makes his work valuable to the historian of early institutions. In the disputes between the two schools of Roman jurists he generally attached himself to that of the Sabinians, who were said to be folloners of Xteius Capito. Many quotations from the works of Gaius occur in the *Digest* of Justinian, and so acquired a permanent place in the system of Roman lam; while a comparison of the *Institutes* of Justinian with those of Gaius shows that the whole method and arrangement of the later work were copied from that of the earlier, and numerous passages are word for word the same.

Unfortunately the work was lost to modern scholars until, in 1816. a manuscript, probably of the 5th century, was discovered by B. G. Niebuhr in the chapter library of Verona, in which certain of the works of St. Jerome were written over some earlier writings, ahich proved to be the lost work of Gaius. The greater part of the palimpsest was painstakingly deciphered, and comparison with other sources enabled some missing passages to be filled in. Two other important additions were made by the Oxyrhynchus papyri of about 250 and the important Antinoite or Egyptian fragments of the 4th or early 5th century.

The *Institutes* of Gaius are divided into four books—the first treating of persons and the differences of the status they may occupy in the eye of the law; the second of things and the modes in which rights over them may be acquired, including the law relating to wills; the third of intestate succession and of obligations; the fourth of actions and their forms.

For editions of the *Institutes,* see P. Kriiger and W. Studemund, 7th ed (1923); B. Kübler, 8th ed. (1939); and F. de Zulueta. 2 vol. (1946–53), which contains an English translation and full commentary.

GAIUS CAESAR: *see* CALIGULA

GAJO (GAYO). According to tradition the Gajo and Alas peoples of northern Sumatra came from Batak lands to the highlands neighbouring the Achinese (*q.v.*). There they lived in relative isolation, yet not without modifying contacts. Indian influence introduced the idea of a hereditary chieftain and a graded society. However, this did not result in a powerful court of elaborate ceremonial life. During a period of Menangkabau supremacy they accepted Islam but its precepts were not fully understood. Mosques were feu in number and even in the 1960s only a minority performed the full religious rites. In the 17th century the Achinese imposed district rulers and strengthened the whole governmental structure. In later years these innovations tended to wane, and the *adat* or customary law became all-powerful.

A village consists of large community houses, each occupied by several families related in the male line. These structures are raised above the ground and consist of a men's gallery, a women's section and a common area which is divided into family compartments. A Gajo family consists of parents, children and married sons and their families. Theoretically all male members are related but adoption and other practices may modify this. A price is paid for the bride; then she and her offspring belong to the husband's clan. Polygyny is allowed but is rare.

In physical type the Gajo-Alas are proto-Malays but they show some intermixture with the Negrito and Malay. They probably do not exceed 100,000 in number. See also SUMATRA: *Population.*

See E. M. Loeb, *Sumatra (1935).* (F.-C. CE.)

GALAGO (**BUSH** BABY), the name of the long-tailed African lemurlike primates (*q.v.*); classed with the lorises and pottos in the family Lorisidae. They are extremely agile tree dwellers, characterized by the great elongation of the upper portion of the feet (tarsus) and the power of folding the large ears. They pass the day in sleep but are active at night. feeding on fruits, insects and small birds. When they descend to the ground they sit upright, and move about by jumping with their hind legs like jerboas. They are pretty little animals, varying from the size of a small cat to less than that of a rat, with large eyes and ears, soft woolly fur and long tails

There are several species, of which G. *crassicaudatus* from central Africa is the largest

GALAPAGOS ISLANDS (ARCHIPIÉLAGO DE COLÓN), a group of 14 main islands and numerous smaller islands scattered over 23,000 sq.mi. of equatorial Pacific ocean, between 500 and 700 mi. W. of Ecuador. Total land area is 3,028 sq.mi., about half of which is contained in the largest (1,754 sq.mi.) and highest (5,500 ft.) island, Albemarle (Isla Isabela).

There has been much speculation concerning the origin of the islands in the absence of conclusive evidence. Geological and bathymetric data indicate that they probably were never connected with the American mainland. The islands are comprised largely of lava piles dotted with volcanoes, mostly extinct. One on Albemarle erupted in 1948, 1953 and 1957.

The climate is characterized by such tropical anomalies as a markedly low rainfall along the coast (annual average 3–4 in.). low air temperatures (70°–85° F.) and low ocean temperatures at the surface (63°–86° F.). Largely responsible for this climatic regime are the chilling waters of the Humboldt or Peru current which upwells around Galápagos. Thundershowers may occur from January to April, and a mist (*garúa*) periodically blankets the area from May to December.

Treelike cactus, spiny shrubs and dwarf deciduous trees dominate the coastal regions. Native guava and unique sunflower trees flourish on the volcanic uplands.

Homever. the Galápagos are best known for their unusual animals. the most dramatic being the large spiny marine and land iguanas. The archipelago is named after the enormous land tortoises (*galápago,* old Spanish name for "tortoise"), considered among the oldest living creatures on earth, which may weigh 500 lb. or more. Other zoological curiosities include a four-eyed fish, distinct species of penguin, flightless cormorant and albatross, as well as a group of 13 species of very tame finches, one of which employs a stick as a tool to obtain food. Charles Darwin, who visited Galapagos in 1835 as naturalist of the "Beagle," was so impressed with the interisland variations in shape of the tortoise shells (some saddlelike, others domelike) and the finch bills (some like a warbler, others like a grosbeak) that they inspired many of his views on natural selection.

The Galápagos Islands were discovered by Tomás de Berlanga. bishop of Panamá, while en route to Peru in 1535, and named Las Encantadas ("the bewitched"). Sites on several of the islands have yielded Inca pottery fragments providing evidence of pre-Spanish occupation. Numerous Spanish voyagers stopped at the islands during the 16th century, and in the late 17th century pirates used the islands as a hideout. About 1800 freebooting gave way to whaling. The buccaneers and whalers named many of the islands after English personalities of the period. At the beginning of the war of 1812, American gunboats executed sea raids around Galapagos designed to harass British shipping. In 1841 the novelist Herman Melville visited the islands, which became the locale for his charming essay, Las Encantadas. Kineteenth-century sealers slaughtered untold thousands of fur seal and nearly exterminated this species. Since the earliest visits to the islands by man, domestic animals have escaped or have been put ashore, so that now cattle, horses. donkeys. goats, pigs, dogs and cats are running wild. The tortoises suffered the most from predation by pigs and dogs and from human exploitation for their meat and fat, and several forms have become extinct. The government of Ecuador made the Galipagos (in part) a wildlife sanctuary in 1935 and again in 1959.

The islands had been unclaimed for almost 300 years before colonization began on Charles Island (Isla Santa Maria) in 1832, when Ecuador took official possession of the archipelago and assigned Spanish names to the islands. Other colonies were started subsequently on Chatham Island or Isla San Cristóbal (the territorial capital), at Wreck bay (Bahia de Naufragio) and at Villamil on Albemarle Island. From about 1920 to 1940 a few European emigrants reached the islands, but most of them left because of food and water shortages. A few, however, settled on Indefatigable Island (Isla Santa Cruz) around Academy bay (Bahia de la Academia). In 1942 the United States constructed an air base (defunct since 1946) on South Seymour Island (Isla Baltra). Since then, Ecuadorians have been gradually settling on the arable islands. The population in 1960 was 1,900. Phenomenal yields of coffee, potatoes and lemons in the highlands and a plentiful supply of fish (tuna and groupers) along the coasts form the basis of the economy. There are small deposits of sulfur. The territory of Archipiélago de Colón is administered through Guayas province.

GALASHIELS, a small burgh of Selkirkshire, Scot. Pop. (1961) 12,374. It is on Gala Water within a short distance of its junction with the Tweed, 33 mi. S.S.E. of Edinburgh by road. The town stretches for more than 2 mi. along both banks of the river. the mills and factories occupying the valley by the stream. The municipal buildings were enlarged as a World War I memorial.

The Scottish Woollen Technical college (1909) is devoted to instruction in woolen manufacture. which dates there from the close of the 16th century. It is now mainly confined to the weaving of tweeds and the making of knitwear. Galashiels was originally a village built for accommodation of pilgrims to Melrose abbey (4 mi. S.E.). and was created into a burgh of barony in 1599. The Catrail or Picts' Work begins near the town and passes immediately to the west. Clovenfords, 33 mi. W., is noted for the large Tweed vineries.

Two miles farther southwest is Ashiestiel, where Sir Walter Scott resided from 1804 to 1812. Abbotsford (*q.v.*), his later house. lies to the south of the town, across the Tweed.

GALATIA. I. In the strict sense this is the name applied to a large inland district of Asia Minor occupied by Gaulish tribes in the 3rd century B.C. It was bounded on the north by Bithynia and Paphlagonia, west by Phrygia, south by Lycaonia and Cappadocia, east by Pontus.

Galatia is part of the great central plateau of Asia Minor, there ranging from 2,000 to 3,000 ft. above sea level: and falls geographically into two parts separated by the Halys (*Kizil* Irmak), a small eastern district lying chiefly in the basin of the Delije Irmak. the principal affluent of the Halys, and a large western region drained by the Sangarius (Sakaria) and its tributaries. On the north side Galatia consists of a series of plains with fairly fertile soil, lying between bare hills. But the greater part is a stretch of barren, undulating uplands, intersected by tiny streams and passing gradually into the vast level waste of treeless plain that runs south to Lycaonia; these uplands are little cultivated but afford pasturage for large flocks of sheep and goats.

The Gaulish invaders appeared in Asia Minor in 278–277 B.C. They numbered 20,000 of which only one-half were fighting men; not long after their arrival we find them divided into three tribes, Trocmi, Tolistoboii and Tectosages. They had split off from the army which invaded Greece under Brennus in 279 B.C., and crossed over to Asia at the invitation of Nicomedes I. of Bithynia, who required help in his struggle against his brother. For about 46 years they were the scourge of the western half of Asia Minor, ravaging the country without any serious check, until Attalus I., king of Pergamum, inflicted several severe defeats upon them, and about 232 B.C. forced them to settle permanently in the region to which they gave their name. In the settlement of 64 B.C. Galatia became a client-state of the Roman empire, and three chiefs were appointed, one for each tribe. But this arrangement soon gave way before the ambition of the chief Deiotarus (*q.v.*), the contemporary of Cicero and Caesar, who was recognized by the Romans as king of Galatia. On the death of the third king, Amyntas, in 25 B.C., Galatia was incorporated by Augustus in the Roman empire, and few of the provinces were more enthusiastically loyal.

The population of Galatia was not entirely Gallic. Before the arrival of the Gauls, western Galatia up to the Halys was inhabited by Phrygians, and eastern Galatia by Cappadocians and other native races. This native population remained, and constituted the majority of the inhabitants of the rural parts and almost the sole inhabitants of the towns. They were left in possession of two-thirds of the land (Caesar, *B.G.* i. 31) on condition of paying part of the produce to their new lords, and agriculture and commerce with all the arts and crafts remained in their hands. They ranked as "Galatians" equally with their overlords, and it was from their numbers that the "Galatian" slaves were drawn. The conquerors, who were few in number, formed a small military aristocracy, living not in the towns, but in fortified villages, where the chiefs in their castles kept up a barbaric state, surrounded by their tribesmen. With the decline of their warlike vigour they began gradually to mix with the natives and to adopt their religion: the amalgamation was accelerated under Roman influence and ultimately became complete; but they gave to the mixed race a distinctive tone and spirit, and long retained their national characteristics and social customs, as well as their language (which continued in use, side by side with Greek, in the 4th century A.D.). In the 1st century, when St. Paul made his missionary journeys, even the towns Ancyra (mod. Angora), Pessinus and Tavium (where Gauls were few) were not hellenized; while the rural population was unaffected by Greek civilization. Hellenic ways and modes of thought begin to appear in the towns only in the later 2nd century. In the rustic parts a knowledge of Greek begins to spread in the 3rd century; but only in the 4th and 5th centuries, after the transference of the centre of government to Constantinople placed Galatia on the highway of imperial communication, was Hellenism in its Christian form gradually diffused over the country. (See also ANCYRA; PESSINUS; GORDIUM.)

II. The Roman province of Galatia, constituted 25 B.C., included the greater part of the country ruled by Amyntas, viz., Galatia Proper, part of Phrygia towards Pisidia (Apollonia, Antioch and Iconium), Pisidia, part of Lycaonia (including Lystra and Derbe) and Isauria. For nearly 100 years it was the frontier province, and the changes in its boundaries are an epitome of the Roman advance to the Euphrates. Under Diocletian's reorganization Galatia was divided, about 295, into two parts, and the name retained for the northern. After suffering from Persian and Arabic raids, Galatia was conquered by the Seljuk Turks in the 11th century and passed to the Ottoman Turks in the middle of the 14th.

GALATIANS, EPISTLE TO THE, a letter of Paul usually printed as the ninth book in the New Testament. The authenticity of this letter has never been questioned save by occasional critics who have refused to admit the genuineness of any of the Pauline letters. The excitement under which it was written, the sweeping (and at times reckless) statements, the omission of a complimentary paragraph of thanksgiving at the beginning and of a group of salutations at the end, regular parts of a Pauline letter—all these indicate the free hand of one who felt under no obligation to make his composition resemble the work of another. Nor is there any reason to question the integrity of the letter. At times the Greek is awkward, with frequent breaks in construction (anacoloutha) and daring ellipses of thought, but these simply indicate the emotional strain under which the writer was labouring.

Content.—The temper of the letter and, in part, the situation which evoked it are evident in the opening words. Although Paul regularly styled himself an apostle, he here insists that his apostleship is not from men, but from God. His authority has been challenged. At once he proceeds to the attack, with no time or thought for any complimentary paragraph of thanksgiving; obviously at the moment he has little to thank God for as he views the attitude of these "foolish Galatians." Instead his word is: "I marvel that ye are so quickly removing from him that called you in the grace of Christ unto a different gospel." This "different gospel" is actually no gospel at all; it is simply the work of men nullifying the saving work of God. The gospel which Paul had preached had been divinely revealed to him; hence, any deviation from it is false and its champions are accursed (i, 1–9). This he attempts to justify by a brief recital of his own experiences. God had called him at a time when he was attempting to persecute the church, had made him an apostle and had revealed to him his message. Thus, his message was literally from God, not from men. He had had only the slightest contacts with those whom he styles "apostles before me." They had taught him nothing during his two brief visits to Jerusalem; on the latter occasion they had had to admit that he had been divinely commissioned as an apostle to the gentiles. Later when Peter was at Antioch, he (Paul) maintained his independence and had even publicly rebuked him, although to do so had meant to stand alone. Since his gospel is thus completely from God, he can speak as he does. Actually, since he has been "crucified with Christ," when he speaks, it is Christ who speaks in him (i, 10–ii, 21). Then follows an attack upon his opponents' contentions. The new freedom which they had received through his earlier preaching to them was the result of their faith in Christ, not of their adherence to the works of the law. It is folly then to slip back into the bondage from which they had been freed by God's grace (iii, 1–iv, 11). Then with a swift change of tone he reminds them of their former love for him and urges them to hearken to him, not to their false friends who are seeking to lead them astray (iv, 12–20). Once again the tone changes, and with a clumsy allegory about Ishmael and Isaac he seeks to undercut his opponents' contention (iv, 21–31). Frequently it has been asserted that at v, 2 a new main section begins. It is perhaps less artificial to regard v, 1–10 as a summary of the whole preceding section (iii, 1–v, 10), with the last main section, beginning at v, 11, a blistering attack upon his critics and concluding with the insistence that liberty (freedom) is far from being licence but demands the strictest sort of moral purity, not because of any demand in the Mosaic law but because one who is "in Christ" can do no other. The whole requirement is summed up in the one command: "Thou shalt love thy neighbour as thyself" (v, 11–25). Following a brief but detailed application of this command (vi, 1–10), he quickly concludes the letter with the briefest of benedictions and without the customary personal greetings or requests. This concluding section (vi, 11–18) was apparently written by Paul personally, the rest of the letter dictated to an amanuensis (*cf.* Rom. xvi, 22).

Occasion and Purpose. — While such critical problems as the date of the letter, the place from which Paul is writing and the exact location of the "churches of Galatia," have always been recognized as obscure, the occasion and purpose have seemed self-evident. From beginning to end the letter has seemed to have been directed against a group who mere insisting that gentile Christians must be circumcised and observe the Jewish law. Following Paul's departure after establishing these churches, Judaizers (Jewish Christians), perhaps from Jerusalem, had arrived and as at Antioch (Acts xv, 1 ff.) had insisted that full adherence to the Jewish law (including circumcision) was mandatory upon all Christians, Jewish and gentile alike. Far from being an apostle as were the Twelve, Paul was a dangerous latitudinarian. Not only had he preached an emasculated gospel, but his insistence upon freedom from the Jewish law could not fail to result in a moral breakdown. It was against this attempt to discredit him and his gospel that Paul directed his stinging reply.

That a group which may be styled Judaizers are attacked in this letter by Paul is obvious; that they are his only opponents is far less certain. The query, "But I, brethren, if I still preach circumcision, why am I still persecuted?" (v, 11), has always caused difficulty for the interpreter who saw only Judaizers as Paul's opponents. Why should they so charge Paul? Rather it sounds like an indignant denial of the charge that he was still so preaching. Again the ringing and detailed insistence upon moral probity, that liberty must not degenerate into licence, is not easily understood if directed to Judaizers. Finally, the nature of the autobiographical section, with its denial of contact with Jerusalem, is not easily explained if directed against a group who were insisting that he had proved false to the gospel which he had received (from them). On this assumption, the only possible explanation of this opening section would be: You claim that I have proved false to the gospel I received. Your contention is absurd. I have not "proved false" to it, for I never received it from you at all.

Aside from these obvious difficulties is the fact that there seem to be direct references in the body of the letter to a quite different sort of opposition. The stinging jibe, "ye who are spiritual" (vi, 1), would seem to be directed against a group which had arrogated to themselves that title, much as had a group in Corinth. To meet these obvious difficulties W. Liitgert (Gesetz *und* Geist [1919]) and J. H. Ropes (The Singular Problem of the Epistle to the Galatians [1929]) argued that there were two factions against whom Paul was contending and that both were resident in the region, not strangers who had followed him in. Some of the Galatian converts, although themselves gentiles, had become enamoured oi Jewish practices. They may well have felt that they were proving faithiul to the spirit of Paul's teaching, for to gentiles Paul undoubtedly seemed far closer to Judaism than he himself fancied that he was. Perhaps encouraged by local Jews these new and inexperienced "sons of Abraham" attempted to introduce Jewish practices, including circumcision, into the churches.

This ill-advised action provoked a crisis, for to many of the converts the one attractive note in Paul's preaching had been his insistence upon freedom. Their mystic union with Christ ("in Christ") seemed to them to remove all restraints. They were in Christ and hence were guided by the spirit, even as was Paul himself. The contention of their fellow Christians accordingly proved most unwelcome. If, as is far irom unlikely, these latter claimed Paul's support for their innovations, it would not be surprising that this had heightened the growing dissatisiaction of the "spirituals" for Paul and his inconsistent and galling moral restraints.

Word came to the absent Paul of the difficulty. Not being able to come personally, he wrote this letter. Both groups are before his eyes and both receive his indignant protest: the Judaizers for ignorantly nullifying his gospel of freedom from enslavement to the law and for provoking a crisis, the consequences of which no one could foresee; the spirituals for blatantly charging him with precisely those qualities which he was sure were not his. He had not suffered ostracism from his own race for his denial of precisely that with which his converts were now charging him? Furthermore, they were denying the validity of his one great confidence: that his gospel had come from God, not from men. And finally, in their arrogance they were so distorting his teaching of freedom as to endanger the good name of all Christians and even to make Christ himself a reproach. Caught between these two fires, it is not surprising that he wrote in passionate and at times extravagant and bitter words.

Readers. — The location of the "churches of Galatia" to which the letter is directed is far from certain. During the 4th and 3rd centuries B.C. Gauls had pushed south into the Italian and Grecian peninsulas. About 279 they had made their way into central Asia Minor and had set up a small kingdom. Following some years of independence, they had come under the sway of Cappadocia and Pontus and eventually (A.D. 25) together with Pisidia and parts of Lycaonia had become a Roman province. During the following years this newly constituted province had been increased by Paphlagonia and Pontus Galaticus. Thus, at the time of Paul's ministry the Roman province was iar larger than the old kingdom, and many of the provincials were not Gauls (Celts) but Phrygians and Lycaonians. Had we only the letter itself, probably no one would have thought of denying that the old kingdom of Galatia, centring about Ancyra, was indicated. To be sure, "churches of Galatia" might conceivably have been found in such southern cities as Pisidian Antioch, Iconium, Lystra and Derbe, but the address, "O foolish Galatians" (iii, 1), would certainly have seemed to indicate those who were such by race, not Phrygians, Lycaonians or Pisidians who chanced to be resident in the larger political unit.

But according to Acts, Paul is represented as working in these southern cities on his so-called first missionary journey (Acts xiii, 1–xiv, 28) and as passing through several of them on his second journey (Acts xvi, 1–5). There is no mention in Acts that he established any churches in northern Galatia or, in the judgment of some scholars, that he even visited this region. Thus, some concluded that the letter was addressed to churches in these four southern cities. This is the South Galatian hypothesis.

Two passages in Acts, however, provide distinct difficulties for this hypothesis — xvi, 6 ff. and xviii, 23. The most natural interpretation of the former is that Paul did not go through "Phrygia and Galatia" until after he had been prevented from entering the province of Asia. Unable to go to Ephesus, he had turned north, had skirted the east frontier of Mysia and had finally reached Troas. According to Acts xviii, 23 he left Syrian Antioch and "went through the region of Galatia and Phrygia, in order, establishing all the disciples." While this passage can be interpreted to mean that he retraced his steps, and is so interpreted by those who hold the South Galatian hypothesis, the change of order from "Phrygia and Galatia" to "Galatia and Phrygia" would seem to be intentional and to suggest that on this trip he did not go through Cilicia but instead entered Galatia via Cappadocia, and having left Galatia passed through Phrygia and so into Asia and eventually to Ephesus. The chiei objection to the North Galatian hypothesis is not the remoteness of the region — there is no occasion to assume with J. B. Lightfoot and his predecessors that he traversed the whole region, but only the western edge of it, in consequence of his inability at that time to enter Asia or Mysia — or the phrase "Galatic region," which most interpreters who hold the rival hypothesis insist is a deliberate substitute for "Galatia" to indicate territory subsequently added to Galatia proper, but the fact that Acts thus passes by in silence his activity in Galatia but recounts work in the southern cities to which, if the North Galatian view be adopted, no letter of Paul is extant. This objection is by no means fatal — to many it does not appear particularly serious — in view of the iact that the account in Acts is by no means complete even for the portion of the story outlined. Furthermore, that we have no letter to these cities in the south is no more surprising than the fact that we have no letter to Eeroea, Laodicaea or to the churches in the "region of Syria and Cilicia."

Date. — The date and place of composition are also obscure, and most divergent answers have been given, ranging all the way from Antioch, prior to the visit to Jerusslem recounted in Acts xv, to Rome, at the end of Paul's career. It has been frequently maintained that prior to writing this letter Paul had twice visited the region, once when he established the churches and once subsequently. In support of this contention two lines of argument have been advanced (1) "But ye know that because of an infirmity of the flesh I preached the gospel unto you the first time" (iv, 13). That the words τὸ πρότερον must be rendered "the first time" or "on the former oi two occasions" is by no means certain although often asserted. It may be remarked in passing that this verse does suggest that Paul had not intended a conquest of Galatia but had been taken ill while passing through the region after having been denied entrance into Asia. Paul was never a man to let an opportunity escape. (2) There are several statements in the letter which have been understood of a second visit, viz., i, 9; iv, 16, 20; v, 3. Neither argument appears decisive to the present writer.

The possibilities of dating the letter are thus seen to be many. For those who hold the Iiorth Galatian view it must have been subsequent to Acts xvi, 6 and thus scarcely before his arrival at Corinth on the second journey, for some time must be allowed for the rise oi the schism and for its report to reach Paul. If two visits be postulated— and most of those who hold the North Galatian view so maintain — the earliest and most likely time would be during his three years in Ephesus. For those who hold the South Galatian view a still wider latitude is possible. If but one visit is postulated, any time after returning to Antioch at the end of the first journey; if two visits seem demanded, any time after reaching Corinth in the course of the second journey.

Any adequate discussion of these several possibilities would require a detailed examination of a complicated and thorny problem: Paul's contact with Jerusalem (prior to his final visit which ended in his arrest) in the light of the fact that Paul would seem to recount but two such visits(Gal. i, 18 f.; ii, 1–10), while Acts mentions three (Acts ix, 26–30; xi, 27–30; xv, 1–35). A brief discussion of the problem and of what is involved may be found in M. S. Enslin's *Christian Beginnings*, pp. 226–32.

Perhaps the most likely situation for the composition of the letter was during the latter part of Paul's stay in Ephesus, that is, A.D. 54. The principal advantage of this hypothesis is that it would account for the similarity in tone. often remarked, between this blistering letter whose pages are "blotted by tears" and the so-called severe letter to Corinth (II Cor. x–xiii) and also for the marked similarity in content but the vastly more cautious and dispassionate tone and form of statement in Romans, written perhaps six months later from Corinth, which in many ways seems almost a revision or restatement of the diatribe to the churches of Galatia, perhaps at a time when both the rebellious Corinthians and the foolish Galatians had yielded to Paul's demands.

(M S EN.)

GALATZ (Rum. GALAŢI), a city of Rumania, in the region of the same name; on the left bank of the Danube river, 90 mi. W. by N. of its mouth at Sulina. Pop. (1956) 95,646. The Danube is joined by the Seret 3 mi. S.W. of Galatz, and by the Pruth 10 mi. E. Galatz is built on a slight eminence among the marshes which line the intervening shore and form, beside the western bank of the Pruth, the wide but shallow mere called Lake Bratych (Bratesul). It is the seat of the Rumanian 3rd army corps, the Rumanian naval school, the bishopric of the lower Danube, a prefecture, the main Danubian shipping companies and chambers of commerce. Galatz contains a cathedral and many other churches; St. Mary's church contains the tomb of Mazeppa.

Galatz is the chief Rumanian port of entry for imports, and the chief port of export for timber, while in grain it comes second to Braila

GALAX, an evergreen herb of the Diapensiaceae family containing a single species, the beetleweed (G. *aphylla*), which has a thick matted tuft of creeping rhizomes beset with fibrous red roots, and sending up stiff, shiny, veiny heart-shaped or rounded leaves, 3–16 cm. across, and a slender spikelike flower stalk bearing small white flowers. It is native in open woods from West Virginia to Georgia and Alabama in the U.S., and is cultivated and escaped northward to Massachusetts. The leaves are collected in quantities in the mountains of Worth Carolina and Virginia, especially in autumn when they show a beautiful bronze colour, and are much used by florists in wreaths and other decorative pieces.

(J. M. BL.)

GALAXY, the system of stars, appearing projected on the sky as the Milky U'ay (Greek, *galaxias* kyklos, the milky way), in which the solar system and all stars visible to the naked eye are located. The derived term "galaxies" refers to external systems similar to the Galaxy and is normally equivalent to extragalactic nebulae. The present article is limited to our own galaxy.

Nature of the Galaxy and Position of Solar System Within It.—Inspection of the Milky Way with a small telescope shows it to be resolved into myriads of faint stars. In fact, most classes of stars are concentrated to the Milky Way belt, the degree of concentration increasing as the stars studied become fainter, as was shown by the prolonged star counts (or gauges) carried out by Sir William Herschel at the end of the 18th century and extended to the southern hemisphere by his son, Sir John Herschel, in 1834–38. These counts were continued in selected areas, with the aid of photography and astrographic telescopes, by J. C. Kapteyn and his colleagues at Groningen in 1900–20. They found that the number of stars per unit volume of space decreased uniformly with distance in all directions in the Milky Way belt and concluded that our solar system is near the centre of a highly flattened discoidal system of stars with a radius of the order of 2.000 parsecs (1 parsec = 3.26 light years = 3.1×10^{13} km.). The conclusions as to the size of the system and our central position were quite mistaken because the obscuring effect of interstellar dust clouds (also concentrated in the Milky Way) was not realized at the time.

A more accurate picture was derived by Harlow Shapley from a study of the globular clusters, highly concentrated spheroidal systems, each with an average content of 1,000,000 stars. The 100 or so known globular clusters are equally numerous on either side of the galactic plane (the plane running centrally through the

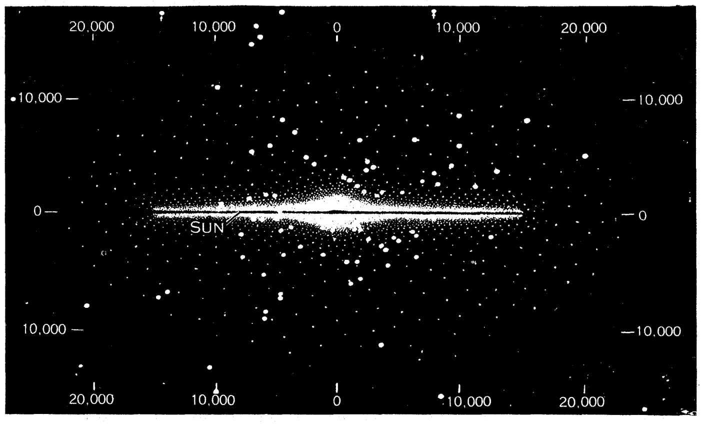

FIG. 1.—MODEL OF THE GALAXY
Numbers denote distances in oarsecs

Milky Way belt) and undoubtedly describe orbits about the centre of the galaxy, but most of them are situated in or near the direction of Sagittarius mhile the rest are almost all in that half of the sky. The globular clusters are rich in variable stars, pulsating with periods of a few hours. known as RR Lyrae stars or cluster-type variables; by fitting the period-luminosity relation for Cepheid variables (first discovered from observations of Cepheids in the extragalactic Magellanic Clouds and calibrated by Shapley himself from observations of galactic Cepheids) to these RR Lyrae stars, Shapley estimated the distances of several globular clusters and concluded in 1918 that the centre of the system of globular clusters (and thus the centre of the galaxy) is situated in the Milky Way at a distance of 30,000 parsecs toward a point in Sagittarius.

This conclusion as to the solar system's peripheral position in the galaxy remains valid today. but the distance of the centre turns out to be only about 8,200 parsecs when the effect of interstellar absorption (which makes the cluster stars look fainter than they would in a transparent medium) is allowed for.

Fig. 1 (after J. H. Oort) gives an idealized picture of the galaxy as seen edge-on from an external point in the plane of the Milky Way. The brighter region, containing the hottest, brightest stars and clouds of interstellar gas and dust, forms a highly flattened disk with the solar system about halfway out from the centre. The thickness of the disk is very small at the edges and perhaps about 5,000 parsecs in the central bulge. Surrounding this disk is a halo or corona of much lower mean density; the globular clusters (shown as large dots) are the most striking members of this nearly spherical subsystem. W. Baade's photographs of the Andromeda Nebula, which is probably very close to being a twin of our own galaxy, suggest that the spherical subsystem has a larger radius than the disk and may contain over 90% of the mass of the whole system.

Galactic Co-ordinates.—It is convenient to define a system of angular celestial co-ordinates based on the central plane of the Milky Way, also known as the galactic plane or galactic equator, which is inclined at about 63° to the celestial equator. Galactic latitude (b) is the angular distance from a point of the sky to the nearest point of the galactic equator, while galactic longitude (l) is the angular distance of this latter point (measured in the direction of increasing right ascension) from the intersection of the galactic and celestial equators in Aquila. The co-ordinates of the galactic centre are $b = -1°$, $l = 328°$, so that the sun is slightly north of the galactic plane. In 1959 a new system of galactic co-ordinates was adopted with $l = 0°$ in the direction of the galactic centre.

Rotation of the Galaxy.—Like other spiral nebulae, the galactic system rotates in its own plane. As might be expected from dynamics, the rotational speed is greatest in the highly flattened disk and least in the nearly spherical system of the globular clusters, which latter accordingly show a systematic drift velocity of about 250 km. per second toward Carina. B. Lindblad (1925) was the first to show how the phenomena of star streaming, and the drift velocities and spatial distributions of stars of various classes,

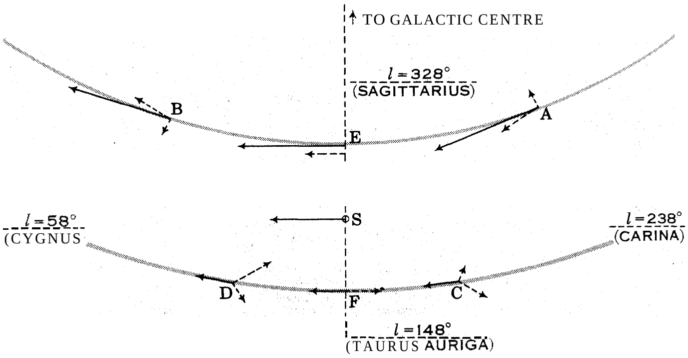

FIG. 2—DIFFERENTIAL ROTATION OF THE GALAXY

S represents the solar system. A and B represent two stars closer to the galactic centre and thus traveling around faster than the sun; C and D are two stars farther away from the galactic centre and traveling more slowly. The arrows with full lines represent velocities relative to the galactic centre; arrows with broken lines represent velocities along and perpendicular to the line of sight

could be understood in terms of a series of concentric spheroidal subsystems with the rotational speed and degree of flattening increasing from one subsystem to the next. In the inner portion of the galaxy. in which most of its mass is concentrated, it rotates more or less like a rigid body. but. in the outer parts of the disk, containing the sun and majority of observable stars, the angular velocity diminishes outward from the centre as with planets in the solar system. Thus, if a group of stars surrounding the solar system is taken, those between us (the solar system) and the centre will be gaining on us and those farther away will be lagging behind. Hence stars nearer the centre and ahead of us, and stars farther away and behind us (see B and C in fig. 2) will both show a systematic velocity of recession when their velocity in the line of sight is measured; while those nearer the centre and behind us, or farther out and ahead of us (A and D) will show a systematic velocity of approach.

For distances up to about 2,500 parsecs, this effect of differential galactic rotation (first definitely established by Oort in 1927) increases uniformly with distance at a rate of about 18 km. per second per 1,000 parsecs in those directions where the effect is at its maximum (positive or recession 1 = 13° and 193°, negative or approach 1 = 103° and 283°), a result based on extensive measurements in the spectra of hot stars by J. S. Plaskett and J. A. Pearce (1934). The efiect is thus most readily observed from the spectra of distant stars; for the nearer stars it is obscured by the presence of random velocities (such as the solar velocity of 20 km. per second toward Hercules) due to the fact that galactic orbits are not exactly circular.

A further effect of differential rotation appears in stellar proper motions, with a maximum effect in the directions toward and away from the galactic centre (see E and F in fig. 2). This is independent of distance and corresponds to a maximum proper motion of 0.15 sec. of arc per century, corresponding to a velocity of 8 km. per second per 1,000 parsecs. From the magnitudes of the effects in proper motion and radial velocity, it follows that the sun completes its orbit about the galactic centre in about 200.000.000 years; its velocity is less easy to estimate, since it depends on the distance of the galactic centre, but it is probably between 200 and 300 km. per second. From the speed of rotation it is possible to estimate the approximate mass of the galaxy, which is of the order of 3×10^{44} g. or 160,000,000,000 times that of the sun. From velocities perpendicular to the galactic plane, assuming that a condition of statistical equilibrium has been set up. it is possible to estimate the density of material in the solar neighbourhood. Oort (1930) found this to be 7×10^{-24} g. per cubic centimetre (or 0.1 of the mass of the sun per cubic parsec), slightly more than half of which is probably due to stars while the rest represents interstellar matter.

Relative to the "local standard of rest," a hypothetical point moving in a truly circular galactic orbit, the peculiar motions of most of the nearby stars (up to ±30 km. per second) tend to be toward or away from a vertex in the galactic plane about 22" away from the galactic centre. This phenomenon of star streaming nas discovered by J. Kapteyn (1904) and reinterpreted by K. Schwarzschild in terms of spatial distribution of the peculiar velocities over the surface of an ellipsoid with its long axis pointing toward the vertex. H. H. Turner and Lindblad explained this effect as a consequence of slight eccentricities in galactic orbits; the deviation of the vertex (which in the simple theory should be toward the galactic centre) may be due either to the gravitational effect of local concentrations of stars and interstellar matter or to the significant influence of a few rich, moving clusters on the statistics

High-Velocity Stars.—Many stars exist in the solar neighbourhood which do not share in this pattern of motion in and perpendicular to the galactic plane; they are known as high-velocity stars and belong either to the spherical population associated with the globular clusters or to an intermediate population with a lower degree of concentration ton ard the galactic plane than is possessed by the hot bright stars and clouds of interstellar matter. Although the high-velocity stars have a much greater spread of velocities (±100 km per second) than the low-velocity stars (±30 km per second), corresponding to very elongated galactic orbits. their motions relative to the sun are all toward the half of the sky centred on $b = 0°$. $1 = 238°$, *i* e., they are actually all lagging behind the solar system in galactic rotation. This is probably because stars overtaking the sun nith a high enough speed to be identified as having high velocity would be moving so fast as to escape from the galaxy altogether

Spiral Structure of the Galaxy.——Analogy with other galaxies having stellar populations similar to that in our own neighbourhood suggests that our own galaxy should be a spiral nebula. The spiral arms of external galaxies are rich in hot, bright stars and interstellar clouds of gas (mainly hydrogen) and dust; these same features serve as indicators of the spiral structure in our own system. The first evidence of spiral arms was obtained in 1951 by W. W. Morgan and various collaborators. From the spatial distribution of hot, bright stars (studied in collaboration with J. J. Nassau. A. E. Whitford and A. D. Code) and of regions of ionized hydrogen emitting the red H-a line (photographed in conjunction with S. Sharpless and D. E. Osterbrock). Morgan was able to identify portions of three spiral arms (see fig. 3): the Orion arm, stretching from Cygnus through Cepheus, Perseus, Orion and Monoceros and including the dust lane which causes the Great Rift in the Milky Way; the Perseus arm, farther off and with its nearest portion in roughly the same direction; and the Sagittarius

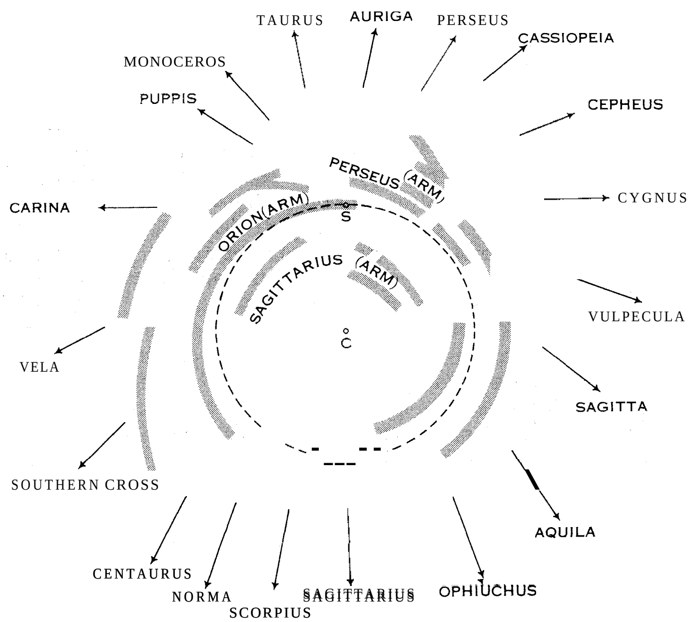

FIG. 3.— SPIRAL STRUCTURE OF THE GALAXY IN RELATION TO CONSTELLATIONS OF THE MILKY WAY FROM OPTICAL AND RADIO OBSERVATIONS

S represents the solar system and C the centre of the galaxy. The sense of galactic rotation is clockwise

arm toward the galactic centre.

The solar system appears to be situated toward the inner edge of the Orion arm: which is about 400 parsecs wide, while the Perseus arm is about 2,000 parsecs away in the direction away from the centre. These conclusions were confirmed and extended shortly afterward by observations of the 21-cm., radio-frequency emission of neutral hydrogen by H. C. van de Hulst, C. A. Muller and Oort. and by F. J. Kerr and J. V. Hindman in the southern hemisphere. Using Oort's theory of galactic rotation, the distances of the neutral hydrogen clouds were obtained from their motions in the line of sight, derived from the Doppler shift in the frequency at which emission is a maximum.

The radio method penetrates to far greater distances than the optical methods and has led to the fairly extensive picture of spiral structure shown in fig. 3. G. Münch has shown that the interstellar absorption lines in the spectra of hot stars in the Perseus arm split into two groups with velocity shifts corresponding to the differential galactic rotation effects in the Orion and Perseus arms, respectively. Furthermore, the profiles of the interstellar lines closely resemble those of the 21-cm. line observed in the same direction.

The results of these and other investigations suggest that our galaxy is a spiral nebula of E. P. Hubble's type Sb, with both spiral arms and nucleus well developed, closely resembling the Andromeda Nebula.

Stellar Populations and Evolution of the Galaxy.—In 1941, Baade succeeded in resolving the nucleus of the Andromeda Nebula into stars by using red-sensitive plates, in contrast to the more usual blue-sensitive plates with which the brightest stars in the spiral arms had been picked out long before. His success resulted from recognition of the fundamental difference between the stellar population in the disk and especially the spiral arms (Population I) in which the brightest stars are hot and therefore blue, and that distributed spherically with a concentration toward the galactic nucleus (Population II) in which the brightest stars are cool red giants. Population I includes most stars in our neighbourhood, Cepheids. galactic open clusters and interstellar clouds. while Population II includes globular clusters. RR Lyrae stars, novae. planetary nebulae and some of the high-velocity stars. The physical differences between the two populations arise from the fact that Population I includes many young stars which have recently condensed from the interstellar medium, while star formation virtually ceased nearly 10,000,000,000 years ago in Population II; there the most massive stars, which run through their supplies of nuclear fuel the most rapidly, have become cool giants or have disappeared from view, *e.g.*, as white dwarfs.

Elliptical galaxies, which show no spiral arms and are free from interstellar dust clouds, consist entirely of Population II; in spirals, Population II probably accounts for most of the mass, but the hot, bright stars and ionized hydrogen clouds are the most conspicuous feature. Probably the Population II stars were the first to be formed from the contracting cloud of gas and dust from which the galaxy and its companions in the "local group" of galaxies are believed to have been formed; the remaining interstellar material could then have continued contracting and been spread out into a disk by the resulting increase in its speed of rotation.

Spiral structure might arise from the differential rotation of long filaments held together by an interstellar magnetic field. Population I stars have presumably been formed continuously in the spiral arms, but some older members have undoubtedly drifted into the inter-arm region since their formation. There is also evidence that the older Population I stars in our neighbourhood have galactic orbits of higher eccentricity than the young stars and clouds of interstellar matter. It has not been possible to say whether the heterogeneous structure of the galaxy, with numerous individual star clusters and larger groups showing common streaming motion, is a permanent feature or an initial stage mhich will ultimately be reduced to a more uniform distribution by stellar encounters, and by disruption through the tidal effect of galactic gravitation. However, it is to be expected that the interstellar material required for star formation will ultimately be used up, so that hot. bright stars and the associated spiral structure must ultimately disappear, leaving a stellar population in mhich the brightest stars are cool red giants as in the present Population II.

GALBA, SERVIUS SULPICIUS, Roman emperor (June A.D. 68 to Jan. 69). born near Terracina, Dec. 24, 5 B.C. He came of a noble family and was a man of great wealth, but unconnected either by birth or by adoption with the first six Caesars. In his early years it is said that both Augustus and Tiberius prophesied his future eminence (Tacitus, *Annals*, vi, 20; Suetonius. *Galba*, 4). Praetor in 20, and consul in 33, he acquired a well-merited reputation in the provinces of Gaul. Germany, Africa and Spain. On the death of Caligula, he refused the invitation of his friends to make a bid for empire, and loyally served Claudius. For the first half of Nero's reign he lived in retirement until, in 61, the emperor gave him the province of Hispania Tarraconensis. In the spring of 68 Galba was informed of Nero's intention to put him to death, and of the insurrection of Iulius Vindex in Gaul. He was at first inclined to follow the example of Vindex, but the defeat and suicide of the latter renewed his hesitation. When news came that Nero had been killed and the praetorians had declared for him, he marched to Rome. At first he was welcomed by the senate and the party of order, but he was never popular with the soldiers or the people. He incurred the hatred of the praetorians by scornfully refusing to pay them the reward promised in his name, and disgusted the mob by his meanness and dislike of display. Otho's successful conspiracy followed. Galba was murdered by some cavalry near the Lacus Curtius. Tacitus rightly says that all would have pronounced him worthy of empire if he had never been emperor (*"omnium consensu capax imperii nisi imperasset"*).

GALBANUM, a gum resin, the product of *Fcrula galbaniflua*, indigenous to Iran. It occurs usually in irregular, more or less translucent and shining lumps, or occasionally in separate tears, of a light-brown, yellowish or greenish-yellow colour. and has a bitter taste and musky odour. It contains about 8% terpene, 65% of a resin that contains sulfur. 20% gum and a small quantity of the colourless crystalline substance umbelliferone. Galbanum is one of the oldest drugs. In Ex. xxx, 34 it is mentioned as a sweet spice. Hippocrates employed it in medicine, and Pliny ascribed to it extraordinary curative powers. Its use in medicine is obsolescent.

GALBULIDAE, a family (order Piciformes) of small to medium-sized tropical American birds comprising several species popularly called jacamar (*q.v.*).

GALE, ZONA (1874–1938), U.S. author whose *Miss Lulu Bett* established her as a promising novelist of the rising realistic school, was born at Portage, Wis.. on Aug. 26, 1874. She graduated from the University of Wisconsin in 1895 and received her M.A. there in 1899. For two years she worked for various Milwaukee newspapers then, in 1901, became a reporter for the *New York World*. After the publication of her first short story, in 1904, she gave her full time to writing.

Her books include *Romance Island* (1906); *The Loves of Pelleas and Etarre* (1907); *Friendship Village* (1908); *When I Was a Little Girl* (1913); *Heart's Kindred* (1915); *A Daughter of Tomorrow* (1917); *Birth* (1918); *Miss Lulu Rett* (1920); *Faint Perfume* (1923); and *Preface to a Life* (1926). Her early writings were in the sentimental, local colour tradition.

The dramatization of *Miss Lulu Bett* won her the Pulitzer prize in 1920. Other plays were Mr. *Pitt* (1924), a dramatization of *Birth*, and *Evening Clothes* (1932). She died in Chicago on Dec. 27, 1938.

See August Derleth, *Still Small Voice* (1940).

GALE. A wind of considerable force, specifically, in nautical and meteorological terminology, a wind classified on the Beaufort scale (*q.v.*) as force 8, g or 10 and, in some definitions, also force 7. This represents a range of wind speeds of from 32 to 63 m.p.h., or, including force 7, beginning at 25 m.p.h. The terms fresh gale, strong gale, etc., are used without standardization among the various countries, but a wind of force 10, or 55 to 63 m.p.h., is universally designated as a whole gale. (H. R. B.)

GALEN (*c.* A.D. 130-*c.* zoo), Greek physician, founder of experimental physiology and, after Hippocrates, the most distinguished physician of antiquity, was born in Pergamum, the capital of Mysia in Asia Minor, a city renowned for its magnificent library, the creation of Attalid kings. Galen is sometimes wrongly spoken of as Claudius Galen, but the cognomen Claudius has no authenticity and is a result of a misunderstanding on the part of Renaissance scholars. From his earliest years Galen was familiar with the Platonic, Peripatetic, Stoic and Epicurean schools of thought. He began the study of medicine in 146, and two years later went to Smyrna to attend the lectures of Pelops, a celebrated physician. In search of knowledge he roamed through Greece, Cilicia, Phoenicia, Palestine, Crete,' Cyprus and finally visited the famous medical school at Alexandria.

Settling at Rome in 164, Galen became acquainted with some of the highest officers of the state, among them the consul Boethius and the future emperor Lucius Septimius Severus. Many of these eminent persons attended his lecturesand demonstrations. Galen used an unsparing pen against medical sects, the methodists, dogmatists, pneumatists and empirics then flourishing in Rome, and thus provoked the hostility of his professional brethren. He belonged to no particular school, though in philosophy he favoured Aristotelianism. Later he left Rome for Pergamum, but was recalled by the emperor Marcus Xurelius for service in the Germanic wars. This he managed to evade, returning to Rome to look after the health of the youthful Commodus, heir of Marcus Aurelius. Little is known of the rest of his life. Apparently he was in Rome during the fire of 191, when many of his works mere burned, and he was still lecturing in the reign of Pertinax. He probably died in Sicily in A.D. 200.

Galen mas the author of about 400 treatises, written in clear Attic Greek. In his *De Libris propiis* he mentions 124 purely philosophical treatises, which include commentaries on the *Categories* and *Analytics* of Aristotle, and on the *Timaeus* and *Philebus* of Plato. He wrote five treatises on ancient comedy which are lost. Only an insignificant fraction remains of his nonmedical works. Of the surviving medical works 98 are held to be genuine, 19 doubtful. 45 spurious and 19 are merely fragments.

Researches in Anatomy. — Galen's anatomical investigations were unrivaled in antiquity for their fullness and accuracy. He was an indefatigable dissector, describing mainly what he actually saw. He dissected apes and lower animals, though much that is relevant to the human body is incorporated in his works. As a specimen of his accuracy it may be mentioned that he recognized the lacteal vessels, and described the ducts of the lingual and submaxillary glands, though he was unaware of their function.

Many structures to which names of 16th- and 17th-century anatomists are attached were observed by Galen; *e.g.*, the aqueduct of Sylvius and the *foramen ovale* known as *le trou Botal*. The mode of closure of the *foramen ovale,* Galen describes in language hardly since excelled.

Researches in Physiology. — Galen's physiological investigations were revolutionary. He knew of insensible perspiration, he ligatured the recurrent laryngeal nerve, he performed section of the spinal cord at various levels and observed the resulting sensory and motor disturbances and incontinence. He correctly interpreted the effect of cutting above the origin of the phrenic nerve. He described the heart with its three layers of fibres, which he hesitated to call muscle. The reasons for his reluctance are greatly to his credit: first, he noted that the cardiac substance presented characteristics different from those of ordinary muscle, as, for instance, in that its action was independent of volition; second, he recorded that section of its nerve supply was not followed by cessation of its activities. The valves of the heart are accurately described by him, and it is probable that he knew of the anastomosis of the vessels. One of his greatest contributions was the demonstration that the arteries contain blood and not air as the Alexandrian school had taught for over 400 years. He partially grasped the principle of the lesser circulation, as William Harvey (*q.v.*) pointed out.

Galen described aneurism, differentiating the traumatic from the dilated variety, and he was also familiar with the use of the catheter. His facile teleology led him. however, to some strange errors. Among them was the elaborate hypothesis which he formulated concerning the *pneumata* or spirits, to the influence of which he attributes many vital processes. He is also the author, or at least the propagator. of the fateful theory that the septum of the heart was pierced by imperceptible foramina, through which some of the blood was supposed to exude from the right into the left ventricle.

Monotheistic Views. — Apart from his medical work, Calen occupies a position of considerable interest in the history of both religion and philosophy. He was a firm believer in a supreme creator of the universe in all its parts. He had set himself to prove that the bodily organs are in such perfect relation to the functions to which they minister that it is impossible to imagine any better arrangement. Thus, following the Aristotelian principle that nature makes naught in vain, he develops the problem of final causes along definite lines. These lines amount to determinism with God as determiner.

The peculiar feature of Galen's doctrine, however, is neither his determinism nor his monotheism (both of which were familiar to the thinkers of the day), but his extraordinary claim that God's purposes could be elicited in great detail from the examination of his works. This comes out most strikingly, perhaps, in his famous description of the hand, contained in his treatise *On the* Uses *of the Parts of the Body of Man.*

In several places in his works Galen mentions both Judaism and Christianity, though without much respect. In the great anatomical work under discussion he explains that in his belief God always works by law, and that it is just for this reason that natural law reveals him. and he adds that "in this matter our view . . . differs from that of Moses." It seems probable that he had read some books of the Bible. His position can thus be summed up as intermediate between Stoicism and Christianity. On the one hand he accepted the natural law of the Stoic philosophy, but rejected its astrological corollary. On the other, he accepted the divine guide and architect of the universe which corresponded to the Christian scheme, but rejected all idea of miracle.

Influence on Logic. — Galen is held to have had a certain influence on the development of logic. He was, however, simply purveying the ordinary Peripatetic doctrines of his day. Nevertheless he is of some importance as the carrier or transmitter of these doctrines by reason of the avidity with which his medical works were read during the middle ages. He is thus in some sense responsible for both scholastic methods and scholastic philosophy. His chief philosophical influence, however, is to be traced in the medieval doctrine of *pneuma* and the resulting conception of the nature of life. His monotheism no doubt contributed to his popularity in the ages that followed him.

Though nearly all writings were lost to western Europe after the break-up of the Roman empire, they were translated into Arabic and about the 11th century the *Methodus Medendi* and the *Ars Parva* or so-called *Microtegni* were recovered in Latin versions. The 15th and 16th centuries saw the effective completion of the Galenic canon in Greek by humanist scholars such as Thomas Linacre and Guinter von Andernach. Latin translations were studied in the medical schools until the 19th century.

Editions. — The standard edition of Galen is still that of C. G. Kühn in 20 (22) vol. (1821–33). A critical edition was produced in the *Corpus Medicorum Graecorunz.* A French translation of the important anatomical and physiological writings is that of C. Daremberg, 2 vol. (1854). A section of the *De anatomicis administrandis,* of which the Greek original is lost, is edited with German translation by M. Simon in *Sieben Bucker der Anatomie des Galen,* 2 vol. (1906). *On the Natural Faculties* is available in English translation by A. Brock (1916).

Walzer (ed. and trans.), *Galen: on Medical Experience* (1944). A list of the manuscripts of Galen was prepared by H. Diels, *Die Handschriften der antiken Aerzte* (1905). (J. S. P.; X.)

GALEN, CLEMENS AUGUST, GRAF VON (1878–1946), German Roman Catholic prelate, the most effective opponent of Nazism among the German Catholic bishops, was born at Dinklage. Oldenburg. March 16. 1878. A descendant of one of the oldest noble families of Germany, he studied theology and philosophy and was ordained priest in 1904. He became bishop of Münster in 1933.

The Nazis mere willing to accept him in view of his general conservative views; these, however, were the very reasons why he felt it necessary to oppose them.

Galen's fight against the Nazis began with his first pastoral letter, issued for Easter 1934, and continued relentlessly afterward, culminating in three major incidents: In Oct. 1934 he took under his protection a hook severely criticizing Alfred Rosenberg's *Myth of the Twentieth Century*, which no one had dared publish, adding a vigorous preface; the Gestapo interfered but was unable to prevent 200,000 copies reaching the public. When in Nov. 1936 the Nazi administration of Oldenburg had all crucifixes removed from the schools. Galen protested so vigorously that a public demonstration, unparalleled under the Third Reich. occurred; the order was rescinded. Finally. in July and Aug. 1941 Galen, stung hy the seizure of religious houses and the killing of "unproductive" sick and old people. preached three sermons which. in the strongest, terms: scored these specific acts. as well as the general lawlessness of the Gestapo; as a result, the "mercy killings" were temporarily halted. Documents discovered later showed that the Nazis were close to a decision to hang him when Josef Göbbels interfered with the argument that such a step should he postponed until "after final victory." These incidents seem to confirm Galen's view that the risk of a more daring opposition to the Nazis than his fellow-bishops held possible was worth taking.

Galen was created a cardinal on Feb. 18, 1946, and died in the same year. at Münster on March 22.

GALENA, a city of Illinois. U.S.. seat of Jo Daviess county, is situated on the Galena river. 4 mi. from the Mississippi river in the far northwest corner of the state. The population is about 5.000. A quaint and picturesque town. Galena takes its name from the rich sulfite of lead deposits in the area.

Indians mined lead by 1700 and in the 1320s hopeful miners swarmed into the country. The town was laid out in 1826 and incorporated in 1835. For a time it prospered as a midpoint for Mississippi river traffic between Ft. Armstrong (Rock Island) and Ft. Snelling (St. Paul'). As the mining industry and river commerce declined. so did the town. By the 1960s Galena became a tourist centre. It also manufactures foundry products, mining machinery and dairy products. The restored home of Pres. Ulysses S. Grant. given to him by the people of Galena, is open to the public. (C. C. W.)

GALENA, lead sulfide (PbS), is the chief ore of lead. This mineral was mentioned by Pliny under the name black lead (*plumbum nigrum*) and it is sometimes known as lead glance (German *Bleiglanz*). It crystallizes in the cubic system; well-developed crystals are of common occurrence. The usual form of the crystals is that of the cube, cubo-octahedron or (less often) the octahedron. The mineral is most easily recognized by its perfect cubic cleavage and the brilliant metallic lustre of its freshly fractured surfaces. Galena also occurs in massive aggregates, sometimes with a fine or granular structure and occasionally fibrous or plumose. The colour of the mineral and of its streak is lead gray; it is opaque; the hardness is 2.5 and the specific gravity is 7.5.

Galena is one of the most widely distributed sulfide minerals and often occurs in metalliferous veins (Freiberg, Saxony: Broken Hill, Xustr.; Coeur d'Alene. Ida.; Clausthal. Ger.; Cornwall. Eng.) associated with sphalerite, pyrite. marcasite. chalcopyrite. cerussite, anglesite, dolomite, calcite, quartz, barite and fluorite. Large deposits are also found as replacements of limestones or dolomites (Santa Eulalia, Mex.). In deposits of contact metamorphic origin galena is associated with lime silicates and fluorite (Darwin, Calif.). The mineral has occasionally been observed as a recent formation replacing organic matter such as wood, and it is sometimes found in beds of coal. In many occurrences galena contains small amounts of silver, rarely exceeding 0.1%, presumably due to included silver minerals such as argentite or tetrahedrite. Often the galena is mined as a source of silver as well as lead.

In the upper oxidized part of a deposit the galena alters to produce secondary lead minerals such as cerussite, anglesite, pyromorphite, mimetite, phosgenite and cotunnite. Banded nodules of anglesite and cerussite nith galena cores are often found.

The electrical properties of galena have made it of considerable importance in the electronics industry. The point contact between a conducting metal and the cleavage surface of a crystal of galena is an efficient rectifier for small currents of radio frequency. This property made galena one of the most commonly used crystals in the early crystal radio sets. Its capability, when properly treated. of acting as either a P-(positive) type or N-(negative) type semiconductor (see TRANSISTOR) greatly enhances its use as an electronic circuit element. See also LEAD. (A. J. F.)

GALENA PARK, Texas: see HOUSTON.

GALERIUS (GALERIUS VALERIUS MAXIMIANUS), Roman emperor from A.D 305 to 311. was born near Sardica in Thrace. He served nith distinction as a soldier under Aurelian and Probus, and in 293 was designated Caesar along with Constantius Chlorus. In 305 on the abdication of Diocletian and Maximianus, he at once assumed the title of Augustus with Constantius his former colleague and having procured the promotion to the rank of Caesar of Flavius Valerius Severus, a faithful servant and Daia (Maximinus), his nephen, he hoped on the death of Constantius to become sole master of the Roman world. This scheme, however, nas defeated by the sudden elevation of Constantine at Eboracum (York) on the death of his father, and by the action of Maximianus and Maxentius in Italy.

In 307 he elevated his friend Licinius to the rank of Augustus, and devoted the remaining years of his life "to the enjoyment of pleasure and to the execution of some works of public utility." It was at his instance that the first of the celebrated edicts of persecution against the Christians was published, on Feb. 24. 303, and this policy of repression was maintained by him until the appearance of the general edict of toleration (311), issued in his own name and in those of Licinius and Constantine.

Galerius died in May 311.

GALESBURG, a city of western Illinois. U.S., about 170 mi. S.W. of Chicago, the seat of Knox county. Rev. George Washington Gale (1789–1862) of Whitesboro, N.Y., a Presbyterian minister for whom the city was named, selected the site for a colonization society to establish a college-centred community. In 1836 the first settlers arrived, and in 18.37 a charter was granted to the Knox Manual Labour college. The city was incorporated in 1857 and the institution was renamed Knox college. City and college played an important role in the abolition movement. and in 1858 one of the historic Lincoln-Douglas debates on the slavery issue was held on the Knox campus. Knox is now a private, nondenominational. coeducational. liberal arts college; in 1930 it absorbed Lombard college, founded by the Universalists in 1851.

Galesburg is the commercial centre of an agricultural and coal mining area. It is a division headquarters of the Burlington railroad which. with its freight yards, shops and tie plant, is one of the city's largest employers. Other industries produce a wide variety of goods ranging from refrigeration equipment to building supplies. from farm gates to outboard motors. A 30-mi. pipeline brings Mississippi river water to the city.

Galesburg is the birthplace of Carl Sandburg, the poet and Lincoln biographer. The Galesburg State Research hospital is a mental institution. Lake Storey. a beautiful artificial lake, once a railroad-owned water reservoir, has been transformed into a popular city-owned recreational park.

For comparative population figures see table in ILLINOIS: *Population*. (E. HG.)

GALGACUS, or perhaps rather CALGĀCUS, a Caledonian chief who led the tribes of North Britain against the invading Roman army under Iulius Agricola about A.D. 85 and was defeated at the battle of Mons Graupius.

GALIANI, FERDINANDO (1728–1787), Italian writer and economist was born at Chieti on Dec. 2, 1728, and was educated for the church. He went to Paris as secretary to the Neapolitan ambassador and remained from 1759 to 1769, lionized as a wit in the salons and befriended by the Encyclopaedists. Abbé Galiani enjoys a reputation in both French and Italian literature.

As an economist, he published a treatise on money, *Della moneta* (1750), and one on the grain trade. *Dialogues sur le commerce des blés* (1770), both remarkable for their clarity and methodical presentation. In the first, he evolves a theory of value based on utility and scarcity. which has been greatly praised for its originality but which follows scholastic tradition. In the second. Galiani stresses the necessity of regulation, opposing the Physiocrats who advocated complete freedom. After his return to Naples, he carried on a spirited correspondence with Madame d'Epinay and other Parisian friends. His letters are of interest for literary history and shed light on Galiani's debate with Abbé Morellet, the spokesman of the Physiocrats. Galiani died in Naples! Oct. 30. 1787.

See Fausto Nicolini, *Il pensiero dell'abate Galiani* (1909); Joseph Rossi, *The Abbe' Galiani in France* (1930). (R. DE R.)

GALIB DEDE (SHEYH GALIB), pseudonyms of MEHMED ESAD (c. 1758–1798), was the last of the five great classical Turkish poets. Born in Istanbul, the son of a Mevlevi dervish, he became the sheik of the Galata monastery. He had as his patrons Sultan Selim III, himself a poet and musician, and rnany princesses who admired his work. The monastery became a centre for poetry and music in Istanbul where leading men of letters and musicians gathered. In his divan (collected poems) and his allegorical romance *Hüsn ü Ashk* ("Beauty and Love") he happily combines the mystic enthusiasm of Jalal-ud-din Rumi (*q.v.*), the complex imagery of the Persian "Indian school" and the warm, flowing language of Nedim (*q.v.*). Classical poetry's strict forms did not hamper his originality—his power of imagination, colourful similes and descriptions infused fresh breath into Turkish literature.

See E. Gibb, *A History of Ottoman Poetry,* iv (1905). (F. I.)

GALICIA was the name formerly applied to that portion of Poland lying on the northern slopes of the Carpathians, which constituted an Austrian *Kronland* between 1772 and 1918. It is now called Halica and is part of the Ukraine. U.S.S.R. The area before World War I was 30.299 sq.mi., population 7,980,477.

'The early history of west Galicia is that of Poland (*q.v.*). In the east. an independent Ruthenian principality of Halicz appears in the 11th century. It grew in importance with the decay of Kiev, whence many refugees emigrated to Galicia. In the 12th century Galicia. under its prince Osmomysl. was one of the chief principalities of Russia. Many towns were founded, and much trade passed through Lemberg (Lwow), from Asia and the Black sea to Europe. Galicia failed, however. to achieve stability. largely owing to the character of its own nobles. who are described as rebellious to their king and tyrannical to their serfs. It was alternately allied and at war with the neighbouring principality of Lodomeria; and Poland, Hungary and Novgorod intrigued for possession of both districts. Hungary became master for short periods in 1190 and 1215; but the powerful native dynasty founded by Roman of Lodomeria (d. 1205) retained its independence. Roman's son, Daniel (1205–64), was one of the strongest princes of eastern Europe, and was even crowned by a Papal Legate. temporarily deserting the Orthodox Church. In 1223. however. he lost his eastern provinces to the Mongols, who overran and ruined all Galicia in 1241. In 1324 the Romanov line died out, and Casimir of Poland occupied Galicia in 1340. Lodomeria in 1366. On his death both provinces again came under Hungary. but reverted to Poland in 1372. Under the Jagellion kings prosperity revived, to sink again when the world trade routes changed.

At the partitions of Poland, Galicia (including Lodomeriai was assigned to, Austria, for the first time in 1772, definitively. with a slightly altered frontier in 1814, Cracow becoming an independent republic. Austrian rule introduced improvements. but progress mas slow. The Polish patriotic uprising of 1830 affected Galicia little, but Austria allowed legions to be formed here, and sheltered refugees from Russian Poland. In 1846, however, widespread and almost unconcealed preparations for revolution, to break out in mid-February, were made by the Polish nobles. The danger for Austria was averted by a rising of the Polish (not Ruthenian) peasants, whom disastrous floods had reduced to great misery. The peasants massacred a number of nobles in the Tarnów district. The revolt soon broke down, but as it had been largely directed from Cracow, Metternich took this pretext of incorporating the city in Galicia, as from Nov. 11, 1846.

In 1848 the Austrian Government countered the revolutionary movement among the Polish nobles by winning the peasants through land reforms, and the Governor of Galicia, Count Stadion, also for the first time encouraged the Rutheninns and won their support against the Poles. A period of centralized bureaucratic rule followed, during which Galicia was divided, on roughly ethnographical lines; into first three, and later two administrative districts; but the Polish nobles supported the Hungarian in their demand for decentralization, and after the Hungarian "Ausgleich" of 1867, Galicia, thanks to the efforts of Count Goluchowski, obtained more liberty than any other Austrian province. Under a special minister for Galicia, the Poles enjoyed *de facto* home rule and a free hand against the Ruthenians, Galicia being reunited into a single province with Polish as the official language. In return, the Poles formed the chief support of the successive Austrian Governments, and took a large part in directing Austrian policy, the Polish irridenta in Galicia never being serious. Besides being the largest Austrian province, Galicia was now acquiring great importance owing to the discovery and exploitation of its oil fields, although these were mainly in Jewish hands and the provincial budget to the last was subsidized from the Austrian treasury; the strategic importance was also great, and was probably the main reason why the Austrian Government never yielded to the wish of the German nationalists to give Galicia an independent status within the monarchy. The Ruthenian national movement made slow progress, discouraged by Poles and Austrians alike. while Russia pave it no support. for fear of awaking a national movement in the Ukraine.

The Neo-Slav movement had by 1910 laid the foundations for a reconciliation between Poles and Russians. The Galician Poles ceased to be safe supporters of the Austrian Government, which in return reverted to the idea of encouraging the "loyal" Ruthenians; but this new development was cut short by the war of 1914. The Central Powers were obliged to grant the Poles wider independence, and to promise them still more; and by 1918 Galicia was virtually independent of Austria. The Poles renounced allegiance to Austria in Oct. 1918, claiming all Galicia for the new Polish state. The Ruthenians, however, who had also been promised greater liberty after the I'eace of Brest-Litovsk, also claimed the right to self-determination, and in November formed a Government under Dr. Petrushievicz in Lwow, this being recognized by the liquidating Austrian Government. The Poles occupied Lwow (Nov. j), and the Ruthenian Government retired finally to Vienna. The Ruthenian troops joined the Ukrainian army of Petlura; the latter marched against the Poles and claimed East Galicia for the Ukrainian Republic—a claim first recognized, but later disallowed by Petrushievicz. Fighting continued throughout 1919. On May 8, 1919, the supreme council assigned West Galicia to Poland, and on June 25 allowed East Galicia the right of self-determination, while authorizing the continued Polish occupation. In December it announced that East Galicia should be granted autonomy under a Polish protectorate for 25 years, after which the League of Nations was to decide on its future. Petlura had meanwhile abandoned his claim to Galicia in return for recognition by Poland in the Ukraine; but he was overthrown by the Soviet troops, who continued the struggle with Poland until the treaties of Riga (Oct. 12, 1920, and March 18, 1921) finally reaffirmed the old Galician frontier. The Ruthenian Governments, of which there were many, were quite helpless, from lack of funds and internal dissension. Finding their repented appeals ignored. some of them made terms with Soviet Russia, which carried on a lively agitation in East Galicia. some were reconciled to Poland, a few abandoned politics. Poland continued to treat East Galicia as an integral part of herself. and it was recognized as such by the Council of Ambassadors on March 15. 1923. Under her minority legislation, Poland subsequently accorded her Ruthenian population a limited degree of self-government. All of Polish Galicia fell to Germany in the first stages of World War II. (C. A. M.; X.)

GALICIA (the ancient *Gallaecia* or *Callaecia,* Καλλαικία or Καλαικία), a captaincy-general, and formerly a kingdom. countship and province. in the north-western angle of Spain: bounded on the north by the Bay of Biscay, east by León and Asturias, south by Portugal and west by the Atlantic ocean. Pop. (1960 est.) 2,714,163; area 11.365 sq.mi. In 1833 Galicia was divided for administrative purposes into the provinces of La Coruña (*q.v.*), Lugo, Orense and Pontevedra. The high land north of the headwaters of the Miño forms the sole connecting link between the Cantabrians properly so-called and the mountains of central and western Galicia. The average elevation of the province is considerable. and the maximum height (6,706 ft.) is reached in the Peña Trevinca on the eastern border of Orense.

The principal river is the Miño (Portuguese *Minho;* Lat. *Minius;* so named. it is said. from the *minium* or vermilion found in its bed). Rising near Mondoñedo, within 25 mi. of the northern coast, the Miño enters the Atlantic near the port of Guardia, after a course of 14i mi. south and south-west. Of its numerous affluents the most important is the Sil. Among other rivers having a westerly direction may be mentioned the Tambre. the Ulla and the Lerez or Ler. which falls into the Atlantic by estuaries or *rias* called respectively Ria de Muros y Noya, Ria de Arosa and Ría de Pontevedra.

Gallaecia, the country of the Galacci, *Callaici* or *Gallaici,* seems to have been very imperfectly known to the earlier geographers. According to Eratosthenes (276–196 B.C.) the entire population of the peninsula were at one time called *Galatae.* The region properly called by their name, bounded on the south by the Douro and on the east by the Navia. was first entered by the Roman legions under Decius Junius Brutus in 137–136 B.C. (Livy lv., lvi., *Epit.*); hut the final subjugation cannot be placed earlier than the time of Augustus (31 B.C.–A.D. 14).

The coast line of Galicia. extending to about 240 m., is everywhere bold and deeply indented. presenting a large number of secure harbours. and in this respect forming a marked contrast to the neighbouring province. The Eo. which bounds Galicia on the east, has a deep estuary, the Rivadeo or Ribadeo, which is a good harbour. Vivero bay and the Ria del Rarquero y Vares are of a similar character: while the harbour of Ferrol is an important naval station. On the opposite side of Retanzos bay (the μέγας λιμήν or *Portus Magnus* of the ancients) is the great port of La Coruña (Corunna). The principal port on the western coast is that formed by the deep and sheltered bay of Vigo, but there are also some good roadsteads at Corcubión, at Marín and at Carril.

The rainfall is exceptionally heavy, and snow lies on some of the high ground for a considerable portion of the year. Much timber is grown on the high lands, and the rich valley pastures support large herds of cattle, while the abundance of oaks and chestnuts favours the rearing of swine. In the lowland districts good crops of maize, wheat, barley, oats and rye, as well as of turnips and potatoes, are obtained. The *dehesas* or moorlands abound in game, and fish are plentiful in all the streams. The mineral resources of the province, which are considerable, were known to some extent to the ancients. Strabo (*c.* 63 B.C.–A.D. 21) speaks of its gold and tin, and Pliny (A.D. 23–79) mentions the *gemma Gallnica,* a precious stone. Galicia is also remarkable for the number of its sulphur and other warm springs, the most important of which are those at Lugo and Orense.

The largest town in Galicia is La Coruña; Santiago de Compostela is the ancient capital and an archiepiscopal see; Lugo, Tuy, Mondofiedo and Orense are bishoprics.

GALILEE, a Roman province of Palestine, bounded on the south by Samaria and Carmel, on the east by Jordan, on the north by the river Leontes (Lītānī), and on the west by the Mediterranean. It has a maximum length of 60 mi. and a breadth of 30. Galilee represents a relatively low, but detached, continuation of the Lebanon ranges. The basic formation of its hills is limestone, and on this the vulcanism of a later geological age has superimposed extensively a layer of lava whose crumbling has produced a soil remarkable for its fertility. The province was divided into two districts, Upper and Lower, reflecting a change in the configuration of the land distinct enough in nature, but not easy to recognize on the map. The dividing line is a ridge running east and west, reaching the Jordan valley at a point midway between Lake Huleh and the Sea of Galilee.

Upper Galilee is the northern district and is in substance a broad mountain range up-tilted towards the Sea of Galilee. The eastern slopes dominating the Jordan valley are abrupt and rise to a height of 2,800 feet. On the west, the descent towards the sea and the plain of Acre is more gradual. In the southern part of the district the rocky range of Jebel Meyron reaches a height of 3,963 feet. The whole region is well watered. The height of the mountains causes a relatively heavy rainfall, and springs abound. Hence the valleys are full of vegetation and the mountain slopes are clothed on the west with small oaks, and on the east with scrub. The occasional level stretches and gentler slopes are covered with fertile grain fields. Upper Galilee was proverbially famous for its fine olives and vines. "It is easier," says the Talmud, "to raise a legion of olives in Galilee than to bring up a child in Palestine." Safad, the chief town, has a population of 10,586 of whom one half are Jews. It suffered severely in the earthquake of 1837, when 4,000 of its inhabitants perished.

Lower Galilee is the southern district of the province. Its highest hills are not more than 1,800 ft. Across the province, at its southern end, stretches the plain of Esdraelon (also called Jezreel). Triangular in shape it is drained by the river Kishon which, springing from the Gilboa hills, winds through the plain. For the most part a dry torrent bed in the height of summer, it becomes almost impassable at times during the rains, as when the hosts of Sisera were discomfited on its banks and "the River Kishon swept them away, that ancient river, the River Kishon." The eastern end of the plain forms the chief gateway to Palestine from regions beyond Jordan. The whole of Lower Galilee is well supplied with water. Springs abound in eastern Esdraelon, Wady-el-Melek and in the plain El-Buttauf. The great plains of Galilee, Esdraelon, El-Buttauf and the plateau of Sahel el-Ahma, are exceedingly fertile, producing wheat, cotton, maize, sesame, tobacco, millet and a variety of vegetables. The principal towns are Nazareth (*q.v.*); Tiberias (*q.v.*); Seffuriyeh (Sepphoris), a rival to Tiberias as capital and for a short period the abode of the Sanhedrin when it first transferred to Galilee; Jenin (En-Gannim), on the southern edge of the plain of Esdraelon; Jezreel (*q.v.*), now a poor village (Zer 'in) but once a royal residence, situated on Mt. Gilboa; Endūr (Endor, *q.v.*); Nein (Nain, the scene of one of Christ's miracles); Lejjūn (the Legio of the Romans), now identified with ancient Megiddo, on the west side of the plain, where the mighty empires of Egypt and Hattiland met in a famous conflict in the 15th century B.C.; Jefāt, a town amongst the hills north of El-Buttauf, the Jotapata which Josephus so vigorously defended against Vespasian; Kefr Renna probably Cana (*q.v.*) of Galilee, and Kānā, 6 m. north of it, another suggested identification with Cana.

Galilee of old was a highly prosperous land peopled by bold and hardy hillmen, who knew how to defend their homes, as, indeed, they had often occasion to do, since "they were encompassed with so many nations of foreigners." Josephus (*Bell. Jud.* iii. 3, 2), who in his capacity of military governor of the Galilees, knew the country well, gives an interesting account of the people and the land of his time. "The Galileans are inured to war from their infancy, and have been always very numerous; nor hath the country ever been destitute of men of courage, nor wanted a numerous set of them; for their soil is universally rich and fruitful and full of the plantations of trees of all sorts . . . and no part of it lies idle. Moreover, the cities lie here very thick, and the very many villages are full of people." The Galilee of to-day is not so prosperous nor so populous as in the days of Josephus, but faith in its future is not wanting. Within recent years 16 Jewish colonies have been established by Jewish organizations within its borders.

History. — The name (in origin, a "circle" or "circuit") was in early times loosely applied. In Isaiah (ix. 1) the full name of the district is given as "Galilee of the Gentiles," viz., the Phoenicians, Syrians and Aramaeans, who hemmed it in. In 1 Kings (xv. 29) it is the name of a district whose population was deported by Tiglath Pileser. The fortunes of the tribe, with its loose and varying territorial connections, interested the Hebrew more than the political history of a rigidly delimited district. Hence Galilee can hardly be said to have, as a whole, a history. The return of the Jews from captivity concentrated re-awakened national interest and prestige at Jerusalem, and Galilee was frowned upon and left to the hybrid race evolved from the mingling of the Jewish residue and fresh Assyrian colonization. The date of Galilee's reconquest for the Israelites is uncertain, but it is generally ascribed to John Hyrcanus; and the sturdy race which peopled its hills and valleys soon developed a fervid patriotism and nationalistic spirit. The contempt of the metropolitan for the Galilean provincial was probably intensified by the latter's uncouth speech, emphasized by his inability to pronounce some of the Hebrew consonants. The jibe "Out of Galilee cometh no prophet" (although Deborah, Jonah, Elisha and perhaps Hosea were Galileans) is not so much a reflection on the religious and cultural interest of the Galilean as a reflection of the biased and prejudiced mind of the metropolitan. We cannot forget that it was amongst the hills of Galilee and by its sea that Christianity was shaped and developed. In the Persian period too, the Mandaean religion took final shape in lone Galilee.

Galilee was moulded into a province by the Romans and became a tetrarchate governed by members of the Herod family. Galilee was the land of Christ's childhood and the chief centre of his ministry. In the neighbourhood of its great lake some of his chief discourses were uttered, and the scenes and incidents of its landscape inspired his parables. When the destruction of Jerusalem left the Rabbinic Schools homeless they sought refuge in despised Galilee, and Safad and Tiberias (*q.v.*) became their chief centres. It is in Galilee that the remains of ancient synagogues are found, and within its confines lie buried many Jewish doctors and philosophers whose tombs are still venerated.

Archaeology. — In Galilee there are relics of the Stone Age in dolmens and menhirs. Rock-cut tombs and wine presses, remains of Byzantine monasteries, the churches and fortresses of Crusading times bring archaeological interest down to a more recent time. **A** discovery of particular interest, furnishing a link with Palaeolithic man, was that made in a Galilean cave in 1925. In a cave in the Wady el 'Amūd, a valley abutting on the plain of Gennesareth, were unearthed portions of a human skull of the Neanderthal species. The fragments consist of nearly the whole of the frontal bone, the right zygomatic bone, and the right half of the sphenoid bone.

In 1927 Professor Garstang announced the discovery in the Huleh basin of a large permanent camp, about 1,000 metres in length and 400 across, at a point about $3\frac{1}{2}$ m. west of the point where the Jordan leaves the lake. Occupation throughout the three phases of the Bronze Age is indicated, and an identification with Hazor, Jabin's royal city, has been suggested.

The great Galilean field of excavation, however, is the Plain of Esdraelon. At Tell-Husn (Beisān, *q.v.*) extensive excavations are being carried out with important results. At Ta'annak (the Taanach of Judges v. 19), the walls were laid bare, traces of child sacrifice discovered, and several cuneiform tablets of the Amarna period unearthed. Excavations are proceeding at Megiddo, on the western border of the plain, and the soundings made at Tell Harbaj in the plain of Acre, near to its junction with the plain of Esdraelon make it reasonably certain that it, rather than Hārithīyeh, is the site of Harosheth of the Gentiles. Of great interest are the ancient synagogues,, of which about a dozen have been discovered at ancient sites, such as Capernaum (*q.v.*), Kerāzeh, Kefr Bir'im, Irbid, Meirūn, and elsewhere. The architecture is generally held to be a peculiar and debased imitation of the classical style associated with the and century A.D.

Crusading fortresses were spread over the land in the 12th century as outposts of the kingdom of Jerusalem. Torou (Tibnin) on the summit of the mountains of Upper Galilee, Bēauvoir (Iiaukab el-Haw), south-west of the Sea of Galilee. Chateau Neuf (Hunin), above Huleh lake, Belfort (Esh-Shakif). on the north bank of the Lītāni, Montfort (Kala'at el-Kurn), north-east of Acre, and the castle at Bāniās formed a strong chain of frontier fortresses.

GALILEE, SEA OF, a lake in Israel through which flows the river Jordan. It is 13 mi. long. 7 mi. broad. has a superficial area of 64 sq.mi. and lies 696 ft. below the level oi the Mediterranean sea. Its maximum depth is 157 ft. The excessive depth which Lortet believed he had discovered at the northern end of the lake has been disproved. The shape of the lake has been likened to a harp or a pear. In the Old Testament it is known as the Sea of Chinnereth or Chinneroth. In the books of the Maccabees and Josephus it is named Gennesar; in the Gospels it is usually the Sea of Galilee. Once it is called the Lake of Gennesaret (Luke v. 1), and twice the Sea of Tiberias (John vi. 1, xxi. 1), a name which has survived in the modern *Bahr Tabarīyeh.*

The sea of Galilee lies in the great Jordan valley trough-fault. During the Pluvial period almost the whole of this depression was occupied by a great inland sea extending from Huleh to a point 40 m. beyond the present southern limit of the Dead sea. Late in geological time the lava which flowed from the volcanoes amongst the southern Galilean hills into the depression combined with lava which flowed down the Tarmuk valley to the east, as well as with the silt washed down later to cause a blockage behind which the waters of the Jordan were pent to form a lake.

The hills which close in upon the sea on the south-west side recede from the shore towards the north to form a great natural amphitheatre with the Plain of Gennesareth as arena. On the east the plateau of Jaulan presents its steep and heavily-scored side towards the lake. Yet, unlike the Dead sea, there is between the water's edge and the foot of the hills a clear passage all round the lake. The Jordan enters it on the north, emerging from a narrow gorge and having on its left bank the marshy plain of El-Batihah. On the north-western shore is the plain of El-Ghuweir, generally supposed to be the plain of Gennesareth whose wonderful fertility is so glowingly described by Josephus. It is a land which "supplies men with the principal fruits, with grapes and figs continually, during ten months of the year, and the rest of the fruits as they become ripe together through the whole year." *(Bell. Jud.* iii. 10. 8.) The plain, which is to-day covered with rank grass and bushes, has been purchased by the Jews and may be expected to recover some of its former glory. North of El-Ghuweir are several warm springs of moderate temperature. At Hamath (Emmaus), a short distance south of Tiberias, are seven hot springs the largest of which has a temperature of 137° F. The lake is well stocked with fish of the genera *Chromis, Barbus, Capoeta, Discognathus, Nemachilus, Blennius* and *Clarias.* There is a close affinity between the fish of Galilee and those of the East African lakes and streams. The *Chromis Simonis,* according to popular belief. is the fish from which Peter took the piece of money (Matt. xvii. 27). Bird life is abundant. Grebes of all kinds. gulls and pelicans frequent the lake. On its shores are to be found tortoises and mud turtles, crayfish and sandhoppers.

The hills surrounding the sea are brown and bare in the summertime but in the spring are clothed with vegetation. Oleander brakes flourished round the lake and the tall papyrus plant is found on the north shore. The lake is set deep among hills and consequently subject to sudden squalls and violent storms, which develop rapidly; sailing is not unattended with risk.

Archaeology. — The principal sites of archaeological interest in the area of the lake are (1) *Kerāzeh* (Chorazin), 2 mi. from the north shore in a wady of the same name. Its ruins include a notable synagogue built with black basalt. (2) Tell-Hzlm (Capernaum, *q.v.*), on the lake shore south of Kerāzeh, with the remains of an early synagogue and possibly a church. (3) *Khān Minyeh,* with extensive ruins at the north end of the plain of Gennesareth. Its identification with Bethsaida is suggested. (4) Tell *'Ureimeh,* between Khān Minyeh and Tell-Hum, the site of an Amorite city whose name has been forgotten. (5) *Mejdel* (Magdala), south of the plain of Gennesareth, with rock-cut tombs. (6) *Tabariyeh* (Tiberias), with remains of the medieval period. (7) Khirbet Kerak, at the south-west corner of the lake, with a ruined citadel and traces of a large and important town. It has been generally identified with Taricheae but more recently an identification with the Beth-Yerah of the Talmud, called by the Greeks Philoteria, has been advocated. (8) *Sinn en-Nabreh* (Sennabris), near to Kerak, where Vespasian fixed his camp in his advance from the south on Taricheae and Tiberias. (9) Khirbet *Susieh,* on the eastern shore, identified with Hippos one of the cities of the Decapolis. (10) Kal 'at *el-Husn*, opposite Tiberias, exhibiting ruins of a city that was walled. broken sarcophagi and rock-cut tombs; suggested identification with the Gamala of Josephus. (11) Fik, about 2 mi. E. of Kal 'at el-Husn, a large village with ruins of ancient buildings, identified by Eusebius with hphek. (12) Khirbet Kersa, opposite Mejdel, the Gerasa or Gergesa of the 4th century. The *Wady el-'Amūd,* where the "Galilee skull" was found: opens onto the plain of Gennesareth. (See GALILEE.) (E. Ro.)

GALILEO GALILEI (1564–1642), Italian mathematician, astronomer and physicist, who made three significant contributions to the founding of modern scientific thought. (1) As the first man to use the telescope to study the skies, Galileo amassed evidence that proved the earth revolves around the sun and is not the centre of the universe as had been believed. His system was such a radical departure from accepted thought that Galileo was tried by the Inquisition in Rome, ordered to recant and forced to spend the last eight years of his life under house arrest. (2) Galileo informally stated the principles later embodied in Newton's first tmo laws. Because of his pioneer work in gravitation and motion and in the combining of mathematical analysis with experimentation, Galileo often is referred to as the father of modern mechanics and experimental physics. (3) Perhaps the most far-reaching of Galileo's achievements was his re-establishment of mathematical rationalism against Aristotle's logico-verbal approach, and his insistence that the "Book of Nature is written in mathematical characters." Through this he was able to found the modern experimental method. (See RATIONALISM: *Epistemological Rationalism.*)

Legend of the Lamp. — Galileo was born at Pisa on Feb. 15, 1564. the son of Vincenzo Galilei, a musician. He received his early education at the monastery of Vallombrosa near Florence, where his family had moved in 1574, and in 1581 entered the University of Pisa to study medicine. While in the Pisa cathedral during his first year at the university, Galileo supposedly observed a lamp swinging and found that the lamp always required the same amount of time to complete an oscillation, no matter how large the range of the swing. Later in life Galileo verified this observation experimentally and suggested that the principle of the pendulum might be applied to the regulation of clocks.

Until he supposedly observed the swinging lamp in the cathedral, Galileo had received no instruction in mathematics. Then a geometry lesson he overheard by chance awakened his interest, and he began to study mathematics and science with Ostilio Ricci. But in 1585, before he had received a degree, he was withdrawn from the university because of lack of funds. He returned to Florence, lectured at the Florentine academy and in 1586 published an essay describing the hydrostatic balance, the invention of which made his name known throughout Italy. In 1588 a treatise on the centre of gravity in solids won for Galileo the honourable but not lucrative post of mathematics lecturer at the University of Pisa.

Galileo then began his resenrch into the theory of motion, first disproving the Aristotelian contention that bodies of different weights fall at different speeds. Because of financial difficulties, Galileo in 1592. applied for and was awarded the chair of mathematics at Padua, where he was to remain for 18 years and perform the bulk of his most outstanding work. At Padua he continued his research on motion and proved theoretically about 1604 that falling bodies obey nhat came to be known as the law of uniformly accelerated motion. He also gave the law of parabolic fall nith its inertial component. The legend of his dropping neights from the leaning tower of Pisa apparently has no basis in fact.

Research With the **Telescope.**—Galileo became convinced early in life of the truth of the Copernican theory but was deterred from avowing his opinions — as shown in his letter of April 4, 1597, to Kepler — because of fear of ridicule. While in Venice in the spring of 1609, Gaiileo learned of the recent invention of the telescope. After returnmg to Padua he built a telescope of threefold magnifying power and quickly improved it to a power of 32. Because of the method Galileo devised for checking the curvature of the lenses, his telescopes were the first that could be used for astronomical observation, and they soon were in demand in all parts of Europe.

As the first person to apply the telescope to a study of the skies, Galileo in late 1609 and early 1610 announced a series of astronomical discoveries. He found the surface of the moon was irregular and not smooth as had been supposed; he observed that the Milky Way was composed of a collection of distant stars; he discovered the satellites of Jupiter and named them Sidera Medicea in honour of his former pupil and future employer, Cosimo II, grand duke of Tuscany. Galileo also observed spots on the sun, the phases of Venus and nhat appeared to him as the three forms of Saturn. His first decisive astronomical observations nere published in 1610 in *Sidereus Nuncius* (see TELESCOPE: *Early* History).

Although the Venetian senate had granted Galileo a lifetime appointment as professor at Padua because of his findings with the telescope, he left in the summer of 1610 to become "first philosopher and mathematician" to the grand duke of Tuscany, an appointment that enabled him to devote more time to research.

Conflict With Rome. — In 1611 Galileo visited Rome and demonstrated his telescope to the most eminent personages at the pontifical court. Encouraged by the flattering reception accorded to him, he ventured in his Letters on the *Sunspots,* printed at Rome in 1613, to take up a more definite position on the Copernican theory. Movement of the spots across the face of the sun, Galileo maintained, proved Copernicus was right and Ptolemy wrong.

The great expository gifts of Galileo and his choice of Italian, in which he was an acknowledged master of style, made his thoughts popular beyond the confines of the universities and created a powerful movement of opinion. The Aristotelian professors, seeing their vested interests threatened; united against him. They strove to cast suspicion upon him in the eyes of ecclesiastical authorities because of contradictions between the Copernican theory and the Scriptures. They obtained the cooperation of the Dominican preachers, who fulminated from the pulpit against the new impiety of "mathematicians" and secretly denounced Galileo to the Inquisition for blasphemous utterances which had been freely invented. Galileo, gravely alarmed, agreed with one of his pupils: B. Castelli, a Benedictine monk, that something should be done to forestall a crisis. He accordingly wrote letters meant for the grand duke and for the Roman authorities (letters to Castelli. to the grand duchess dowager, to Monsignor Dini) in which he pointed out the danger, reminding the church of its standing practice of interpreting scripture allegoricallp whenever it came into conflict with scientific truth. quoting patristic authorities and warning that it would be "a terrible detriment for the souls if people found themselves convinced by proof of something that it was made then a sin to believe." He even went to Rome in person to beg the authorities to leave the way open for a change. X number of ecclesiastical experts were on his side. Unfortunately, Cardinal Bellarmine. the chief theologian of the church, was unable to appreciate the importance of the new theories. He clung to the time-honoured belief that "mathematical hypotheses" have nothing to do with physical reality. He only saw the danger of a "scandal" which might undermine Catholicity in its fight with Protestantism. He accordingly decided that the best thing would be to check the whole issue by having Copernicanism declared "false and erroneous" and the book of Copernicus suspended by the congregation of the Index. The decree came out on March 5, 1616. On the previous Feb. 26, however, as an act of personal consideration. Cardinal Bellarmine had granted an audience to Galileo and informed him of the forthcoming decree, warning him that he must henceforth neither "hold nor defend" the doctrine, although it could still be discussed as a mere "mathematical supposition."

For the next seven years Galileo led a life of studious retirement in his house in Bellosguardo near Florence. At the end of that time (1623). he replied to a pamphlet by Orazio Grassi, S.J., about the nature of comets; the pamphlet clearly had been aimed at Galileo. The reply, titled *Saggiatore* . . . ("Assayer . . ."), was a brilliant polemic on physical reality and an exposition of the new scientific method. Galileo distinguished in it between the primary (*i.e.,* mathematical) properties of matter and the others. and wrote the famous pronouncement that the "Book of Nature is written in mathematical characters." The book was dedicated to the new pope. Urban VIII. who as Maffeo Barberini had been a longtime friend and protector of Galileo. Pope Urban received the dedication enthusiastically.

In 1624. Galileo again went to Rome, hoping to obtain a revocation of the decree of 1616. This he did not get, but he obtained permission from the pope to write about "the systems of the world" both Ptolemaic and Copernican, so long as he discussed them noncommittally and came to the conclusion dictated to him in advance by the pontiff, that is, that we cannot presume to know how the world is really made because God could have brought about the same effects in ways unimagined by us, and we must not restrict His omnipotence. These instructions were confirmed in writing by the head censor. Monsignor Riccardi.

Galileo returned to Florence and spent the next several years working on his great *Dialogo dei Massimi Sistemi* "Dialogue of the Two Chief World Systems"). As soon as it came out in 1632, with the full imprimatur of the censors, it was greeted with a tumult of applause from every part of Europe as a literary and philosophical masterpiece.

On the crisis which followed we have only inferences. It was pointed out to the pope that despite its noncommittal title, the work was a compelling and unabashed plea for the Copernican system. The strength of the argument made the prescribed conclusion at the end look anticlimatic and pointless. The Jesuits insisted that it could have worse consequences on the established system of teaching "than Luther and Calvin put together." The pope in anger ordered a prosecution. The author being covered by license, the only legal measures would be to disavow the licensers and prohibit the book. But at that point a document was "discovered" in the file, to the effect that during his audience with Bellarmine on February 26, 1616, Galileo had been specifically enjoined from .'teaching or discussing Copernicanism in any way," under the penalties of the Holy Office. His license, it was concluded. had therefore been "extorted" under false pretences. (The consensus of historians, based on evidence made available when the file was published in 1877, has been that the document was a plant and that Galileo was never so enjoined.) The church authorities, on the strength of the "new" document. were able to prosecute him for "vehement suspicion of heresy." Notwithstanding his pleas of illness and old age. Galileo was compelled to journey to Rome in Feb. 1633 and stand trial. He was treated with special indulgence and not jailed. In a rigorous interrogation on April 12, he steadfastly denied any memory of the 1616 injunction. The commissary general of the Inquisition, obviously sympathizing with him, discreetly outlined for the authorities a way in which he might be let off with a reprimand, but on June 16 the congregation decreed that he must be sentenced. The sentence was read to him on June 21: he was guilty of having "held and taught" the Copernican doctrine and was ordered to recant. Galileo recited a formula in which he "abjured, cursed and detested" his past errors. The sentence carried imprisonment but this portion of the penalty was immediately commuted by the pope into house arrest and seclusion on his little estate at Xrcetri near Florence. where he returned in Dec. 1633. The house arrest remained in effect throughout the last eight years of his life.

Although confined to his estate, Galileo's prodigious mental activity continued undiminished to the last. In 1634 he completed his *Discorsi e Dimostrazioni Matematiche intorno a due nuove scienze* . . . ("Dialogue on Two New Sciences . . ."), in which he recapitulated the results of his early experiments and his mature meditations on the principles of mechanics. This, in many respects his most valuable work. was printed by the Elzevirs at Leiden in 1638. His last telescopic discovery—that of the moon's diurnal and monthly librations—was made in 1637, only a few months before he became blind. But the fire of his genius was not even yet extinct. He continued his scientific correspondence with unbroken interest and undiminished acumen: he thought out the application of the pendulum to the regulation of clockwork, which Christiaan Huygens put into practice in 1656; he was engaged in dictating to his disciples, Viviani and Torricelli, his latest ideas on the theory of impact when he was seized with the slow fever which resulted in his death at Xrcetri on Jan. 8, 1642.

Value of His Work.—The direct services of permanent value a-hich Galileo rendered to astronomy are virtually summed up in his telescopic discoveries. A puzzling circumstance is his neglect of Kepler's laws, which were discovered during his lifetime. But, then he believed strongly that orbits should be circular in order to keep the fabric of the cosmos in its perfect order. This preconception prevented him from giving the full formulation of the inertial law. which he himself discovered although it usually is attributed to Descartes. Galileo believed that the inertial path of a body around the earth must be circular. Lacking Newtonian gravitation, he hoped this would allow him to explain the path of the planets as circular inertial orbits around the sun. His name is nevertheless justly associated with a vast extension of the bounds of the visible universe, and his telescopic observations are a standing monument to his ability. Within two years after their discovery, he had constructed approximately accurate tables of the revolutions of Jupiter's satellites; and he proposed their frequent eclipses as a means of determining longitudes on land and at sea. The idea. though ingenious, has been found of little use at sea. His observations on sunspots are noteworthy for their accuracy and for the deductions he drew from them with regard to the rotation of sun and the revolution of the earth.

The idea of a universal force of gravitation seems to have hovered on the borders of this great man's mind. but he refused to entertain it because, like Descartes, he considered it an "occult" quality. More valid instances of the anticipation of modern discoveries may be found in his prevision that a small annual parallax would eventually be found for some of the fixed stars, and that extra-Saturnian planets would at some future time be ascertained to exist, and in his conviction that light travels with a measurable although extremely great velocity. Although Galileo discovered, in 1610, a means of adapting his telescope to the examination of minute objects, he did not become acquainted with the compound microscope until 1624. when he saw one of Cornelis Drebbel's instruments in Rome and, with characteristic ingenuity, immediately introduced several improvements into its construction.

A most substantial part of his work consisted undoubtedly of his contributions toward the establishment of mechanics as a science. Some valuable but isolated facts and theorems had previously been discovered and proved, but it was Galileo who first clearly grasped the idea of force as a mechanical agent. Although he did not formulate the interdependence of motion and force into laws, his writings on dynamics are everywhere suggestive of those laws, and his solutions of dynamical problems involve their recognition. In this branch of science he paved the way for Newton. The extraordinary advances made by him were due to his happy method of applying mathematical analysis to physical problems.

Galileo was the first man who perceived that mathematics and physics, previously kept in separate compartments, were going to join forces. He was thus able to unify celestial and terrestrial phenomena into one theory, destroying the traditional division between the world above and the world below the moon. The method which was peculiarly his consisted in the combination of experiment with calculation — in the transformation of the concrete into the abstract and the assiduous comparison of results. He created the modern idea of experiment, which he called *cimento* or "ordeal." This method was applied to check theoretical deductions in the investigation of the laws of falling bodies, of equilibrium and motion on an inclined plane and of the motion of a projectile. The latter, together with his definition of momentum and other parts of his work, implied a knowledge of the laws of motion as later stated by Newton. In his *Discorso intorno alle cose che stanno in su l'acqua* ("Discourse on Things That Float"), published in 1612, he used the principle of virtual velocities to demonstrate the more elementary theorems of hydrostatics, deducing from it the equilibrium of fluid in a siphon, and worked out the conditions for the flotation of solid bodies in a liquid. He also constructed in 1607 an elementary form of air thermometer.

See ASTRONOMY: *The Founding of Modern Astronomy;* CAUSALITY (CAUSATION): *Historical Development;* GRAVITATION; MOTION. PRINCIPLES AND LAWS OF; *see* also references under "Galileo Galilei" in the Index volume.

BIBLIOGRAPHY.—The first complete edition of Galileo's works mas that of Eugenio Albèri (1842–56). It is now superseded by the final *Edizione Nazionale delle Opere di G. G.,* 20 vol., by the Galileo scholar Antonio Favaro (1890–1909), reprinted in 1929–39. It contains every single obtainable document and scrap of correspondence. The documents of the trial are in vol. xix.

The original documents from the archives of the Inquisition, relating to the events of 1616 and 1633, were first published in their entirety by H. di L'Epinois, *Les pièces du procès de Galilée* (1877). The earliest authoritative discussions are by Karl von Gebler, *Galilei und die römische Curie* (1876), and Emil Wohlwill, *Galilei,* 2 vol. (1875–1907). More recent is G. de Santillana, *The Crime of Galileo* (1955). On the Roman Catholic side are F. R. Wegg-Prosser, *Galileo and His Judges* (1889); Adolf Müller, S.J., *Galilei und die Katholische Kirche* (1910); Filippo Soccorsi, S.J., *Il Processo di Galileo* (1947).

The most important collections of monographs and scholarly sources are Antonio Favaro, *G. G. e lo studio di Padova* (1883) and *Scampoli Galileiani* (1891); Stillman Drake, "Galileo Gleanings," *Isis,* in six parts, vol. xlvii, pp. 393–397, vol. xlix, pp. 26–33, 155–165, 409–413, vol. 1, pp. 245–254 (19.57–59) and *Osiris,* vol. xiii, pp. 262–290 (1958). The *Bibliogvafia Galileiana,* (1896) by *A.* Carli and A. Favaro lists more than 2,000 publications. Its continuation by A. Boffito (1943) lists another 2,000.

The first English translation of Galileo's writings was T. Salusbury, *Mathematical Collections and Translations* (1661–62). Other English translations include *Dialogue on Two New Sciences,* trans. by *H.* Crewe and A. di Salvio (1939); *Dialogue of the Two Chief World Systems,* trans. *by* Stillman Drake (1953); *Dialogue of the Great World Systems* in the Salusbury translation, cd. by G. de Santillana (1953); *Saggiatore, Lettevs on the Sunspots, . . . ,* (abridged) in Stillman Drake. *Discoveries and Opinions of Galileo* (1055); *On Motion and On Mechanics,* trans. by I. E. Drabkin and Stillman Drake (1960). (G. D. DE S.)

GALIUM, a genus of plants of the madder family (Rubiaceae), comprising 250 species of world-wide distribution, mostly slender herbs. Of these. about 60 species are found in North America and 10 in Great Britain. *See* CLEAVERS; RUBIACEAE.

GALL, SAINT (fl. c. 600). Irish monk from Bangor, County Down, accompanied St. Columban (*q.v.*) to France and Burgundy. When Columban proceeded to Italy. Gall stayed behind among the Alamanni. He lived as a hermit on the banlrs of the Steinach river, preaching to the people of the district. which was still semipagan, and died there at an unknown date during the 7th century. His feast day is Oct. 16.

Little is known about. Gall from authentic sources. The biographer of Columban, Jonas of Bobbio, who knew Gall personally, relates merely that he once disobeyed Columban in a trifling matter. The earliest life of St. Gall, of which only a fragment survives, dates from the 8th century; most popular during the middle ages was the life by Walafrid Strabo of Reichenau, written about 833. Some incidents in these and other lives of Gall might be substantially historical.

The abbey of St. Gall, founded about 720 on the site of Gall's hermitage, had close links with Ireland especially during the 9th century and acted then as a channel for Irish influences on the continent, but there is no evidence of a continuous Irish tradition from the death of Gall to the abbey's golden age.

Kenney, *Sources for the Early History of Ireland,* pp. 206–208, mainly bibliographical (1929); H. J. Duft (ed.), *Sankt Gallus Gedenkbuch* (1952); J. M. Clark, *The Abbey of Saint Gall* (1926). (L. BR.)

GALL, FRANZ JOSEPH (1758–1828), anatomist. physiologist and founder of phrenology. was born at Tiefenbronn, Baden, Ger., on March 9, 1758, and studied at Baden. Strashourg and Vienna. Gall gradually reached the conviction that the talents and dispositions of men are dependent upon the functions of the brain. and that they may be inferred with precision from the external appearances of the skull. His phrenological lectures in Vienna met with increasing success until in 1802 they were interdicted by the government as dangerous to reiipion. Gall left Vienna in 1805 and eventually settled in Paris, where he practised medicine, lectured and wrote a number of books setting forth his theories. He died in Paris on Aug. 22. 1828. *See* PHRENOLOGY.

GALL, a digestive fluid secreted by the liver and known also as bile. The term is sometimes used also for the gall bladder, the pear-shaped diverticulum of the bile duct that forms a reservoir for the bile. From the extreme bitterness of the secretion, "gall," like the Latin *fel,* is ured for anything extremely bitter, whether actually or metaphorically.

"Gall," meaning a sore or painful swelling, especially on a horse, may be derived from an early use of the word as meaning "poison." But in Romance languages. the French *galle,* Spanish *agalla,* a wind gall or puffy distention of the synovial bursa on the fetlock joint of a horse, is derived from the Latin *galla,* "oak apple," from which comes the English "gall," meaning an excrescence on trees caused by certain insects. *See* DIGESTION; GALL BLADDER: GALLS; LIVER.

GALLA, a Cushitic-speaking people of eastern Africa, scattered over central parts of Ethiopia to the neighbourhood of the Sabaki river in Kenya. They appear to have occupied the southern part of their present territory since the 16th century. They are ethnically mixed, with high foreheads, brown skins and wavy hair.

The Galla include both cultivators and nomadic pastoralists. Each tribe has its chief, who in all public concerns must take advice of the fathers of families in council. Most Galla tribes of highland Ethiopia are either Christian or Moslem, but the pastoral Galla to the south are predominantly pagan. Among the more important groups are the Arusi, Xararetta. Boran, Ittu, Macha, Rendile. Tulama. Wallaga and Wollo.

GALLAIT, LOUIS (1810–1887), Belgian painter of historical scenes. was born at Tournay, Hainaut. on May 9, 1810. He studied at Tournay under Hennequin. and at Antwerp under Van Brée. He then settled in Paris, sending from there to the Belgian salons a series of important historical pictures. He was then urged to return to Brussels, where the latter half of his life was spent, and where he died on Nov. 20, 1887.

Among his most famous works are: "The Abdication of Charles V" (1841), "The Last Honours Paid to Counts Egmont and Horn by the Corporations of the Town of Brussels" and "The Death of Egmont." His art was that of a skilled painter. but superficial. As an artist employed by the state, he exercised considerable influence and was a leader of public taste in Brussels.

GALLAND, ANTOINE (1646–1715), French orientalist, archaeologist and numismatist whose translation of the *Arabian Nights* introduced the tales to Europe and remains the standard French translation. was born at Rollot (Somme), April 4, 1646. After walking to Paris at 14 to learn Greek and Hebrew, he studied at the Collège de France and accompanied the French ambassador to Coustantinople (1670), returning twice to the Levant for further studies. He was admitted to the Académie des Inscriptions (1710), was made "antiquary to the King" and was offered the chair of Arabic at the Collège de France (1709). He died in Paris, Feb. 17, 1715.

In addition to *Les Mille et une nuits*, 12 vol. (1704–17), Galland's works include *Paroles remarquables, bons mots et maximes des orientaux* (1694; Eng. trans. 1795); *De l'Origine et du progrès du cafe'* (1699); and many archaeological and numismatic treatises. A translation of the Koran and a history of the Turkish sultans remain unpublished. *Contes et fables indiennes de Bidpaï et de Lokman* were published posthumously in 1724. His *Journal pendant son séjour à Constantinople, 1672–73*, was edited by C. Schefer (1881); the *Journal parisien, 1708–1715*, with his *Autobiographie, 1646–1715*, was edited by H. Omont (1919). *See* also the article THOUSAND AND ONE NIGHTS.

GALLARATE, a town of Lombardy, Italy, in the province of Varese, 25 mi. N.W. of Milan by rail. Pop. (1951) 25,849. The town is of medieval origin. It is remarkable for its textile factories. Many Italian looms were established in and around the town to produce annually thousands of metres of cotton cloth. It is also the centre of the machine embroidery trade.

GALLAS, MATTHIAS, COUNT OF CAMPO, DUKE OF LUCERA (1584–1647), Austrian soldier, first saw service in Flanders, and in Savoy with the Spaniards, and subsequently joined the forces of the Catholic League as captain. On the general outbreak of hostilities in Germany, he distinguished himself, at Stadtlohn (1623) and elsewhere. In 1630 he was serving as General-Feldwachtntezster under Collalto in Italy, and was mainly instrumental in the capture of Mantua. Made count of the Empire for this service, he returned to Germany for the campaign against Gustavus Adolphus, covered Bohemia against the Swedes in 1631–1632, and served at the Alte Veste and also at Lützen sgainst Bernhard of Saxe-Weimar, rising to be lieutenant-general in the Emperor's own army. He was one of the chief conspirators against Wallenstein, and after the tragedy of Eger was appointed to the command of the army which Wallenstein had formed and led. At Nordlingen (Aug. 23, 1634) in which the army of Sweden was almost annihilated, Gallas commanded the victorious Imperialists. In northern Germany, where he commanded against the Swedish general Banér in 1637 and 1638, and in later crises he was unsuccessful. He resigned his command, and died in 1647 at Vienna.

His army had earned a reputation as the most cruel and rapacious force even in the Thirty Years' War, and his *Merode Brüder* have survived in the word marauder.

GALLATIN, ALBERT (1761–1849), American statesman, was born in Geneva, Switzerland, on Jan. 29, 1761, of an old and noble family. His father died in 1765, his mother five years later, and he was cared for by his grandparents and by a Mlle. Pictet, an intimate friend of his mother. In 1779 he graduated with honour from the college in Geneva, and, giving up iortune and social position, slipped away from home and embarked for America despite the wishes of his relatives. In July 1780 Gallatin and his friend Henri Serre (d 1784) landed in Massachusetts and entered business; but, conditions in the country being unsettled, they failed. For a time Gallatin taught French in Harvard college, then removed to the backwoods of Pennsylvania and Virginia, where he engaged in land speculation.

Beginning his service in Congress in Dec. 1795, Gallatin immediately made himself a conspicuous figure and before his first term was over became the Federalists' most dangerous opponent in Congress, and they attacked him not only politically but personally. for at this time they were opposed to the French Revolution and so resented Gallatin's ancestry. Gallatin became the financier of his party and succeeded in inaugurating the committee on finance, which is now the ways and means committee, and fought for his cardinal doctrines of simplicity and economy in government. In debate (1796) over the Jay Treaty he defended the constitutional right of the House to consider treaties, admitting that the President and Senate had the right to make treaties, but maintaining that the House could refuse to pass the finances to carry them out. When in May 1797 President Adams asked for appropriations for war because of France's refusal to receive American ambassadors, Gallatin struggled successfully to keep down appropriations and to prevent the three United States frigates from being equipped for sea. He continued his opposition to a strong navy, the mainspring of Washington's foreign policy, and in the following year helped to defeat a resolution for the preparation of 16 armed vessels and a declaration of war against France. He also opposed (Jan. 1798) commercial treaties and diplomatic intercourse, maintaining that all political intercourse should be gradually given up, and commercial intercourse protected by the consular system.

The greatest period of Gallatin's career in Congress was in 1798, when, after the publication of the famous X.Y.Z. despatches had inflamed the people against France and given the Federalists control of the Government, he was attacked as a French agent, and Jefferson believed that the Sedition bill was intended to drive him from office. However, the strong measures of the Federalists shocked the country, and the Republicans carried the elections of 1800. Gallatin led his party in the contest in the House of Representatives, which elected Jefferson over Burr.

When Jefferson became President (1801) he made James Madison secretary of State and Gallatin secretary of the Treasury. Gallatin made few changes in Hamilton's arrangements, but he did seek for simplicity of Government and the extinction of the public debt. He preferred to bribe the Barbary pirates to spending the money to subdue them, wished to avoid commercial warfare at all costs, and thought that (1803) the government should seize east Louisiana and west Florida. Despite the fact that he could not reduce naval expenditures as he wished, he achieved his goal and, despite the Louisiana Purchase (1803), reduced the public debt by $14,260,000 within six years and acquired a surplus. However, relations with Europe became strained and in Dec. 1807 Jefferson put into execution the embargo, though Gallatin. recognizing the consequences, declared, "I prefer war to a permanent embargo," and reported that a continuous embargo would necessitate a loan while war would not. The embargo proved futile and was repealed (1809) in favour of the nonintercourse act, after causing a deficiency in the treasury, and Jefferson retired to be succeeded by Madison. Madison had regarded Gallatin as his successor as secretary of state; but a cabal in the senate opposed him and Gallatin was left as secretary of the treasury.

In June 1812 war was declared against England. This shattered Gallatin's cherished schemes, for he believed war was fatal to prosperity and progress. However, he put the finances in the best order he could, and set himself to attain an early peace. With this end in view he grasped at the proffered mediation of Russia, and with Madison's permission sailed with James A. Bayard for Europe in May 1813 without resigning as secretary of the treasury. Great Britain refused to negotiate through Russia, and in addition Gallatin heard that the senate had refused to confirm his appointment because he was still secretary of the treasury. He sent in his resignation and worked unofficially until his second appointment was confirmed. In the meantime Great Britain had expressed its willingness to proceed with direct negotiations. The English and U.S. commissioners finally met at Ghent, Gallatin, Bayard and John Quincy Adams, who was minister to Russia, being supplemented by Jonathan Russel and Henry Clay. In the tedious discussions which followed, Gallaiin played the leading part. preserving peace among his colleagues and establishing a reputation as a diplomatist. He refused to push the U.S. claim to Florida, but stood firmly on other points with his colleagues. Peace rewarded them; the treaty was signed on Dec. 24, 1814.

While still in Europe he had been asked by Madison to become minister to France; this appointment he accepted in Jan. 1816, and adhered to his acceptance in spite of his being asked in April 1816 to serve once more as secretary of the treasury. He remained in France for the next seven years, and in 1818 assisted Richard Rush, then United States minister in London, in negotiating a commercial convention.

In June 1823 he returned to the United States, where he found himself in the bitter struggle then in progress for the presidency. His favourite candidate was his personal friend, William H. Crawford, with whom he consented in May 1824 to stand for the vice-presidency. The contest was bitter and full of intrigue. Martin Van Buren, then in the Crawford interest, came to the conclusion that Gallatin, by his foreign origin, weakened the ticket, and in October Gallatin retired from the contest. The election was thrown into the house, and resulted in the choice of John Quincy Adams, who in 1826 drew Gallatin from his retirement and sent him as minister to England. In Nov. 1827 he once more returned to the United States and bade farewell to public life.

Taking up his residence in New York, he was in 1832–39 president of the National Bank (afterwards the Gallatin bank) of New York. By writing his *Synopsis of the Indian Tribes Within the United States East of the Rocky Mountains and in the British and Russian Possessions in North America* (1836), and by founding the American Ethnological Society of New York in 1842, he earned the title of "Father of American Ethnology." He died in Astoria, L.I., on Aug. 12, 1849.

BIBLIOGRAPHY — *The Writings of Albert Gallatin*, edited by Henry Adams, as published at Philadelphia in 1879. With this was published an excellent biography. *The Life of Albert Gallatin*, also by Henry Adams; another good biography is John Austin Stevens' "Albert Gallatin" in the *American Statesmen Series* (1884). *See* also *The Diary of James Gallatin* (1915); Samuel F. Bemis (ed.), *The American Secretaries of State*, vol. iii (1927); L. M. Sears, *Jefferson and the Embargo* (1927); H. W. Temperley, *The Foreign Policy of Canning* (1925). For general information *see* A. W. Ward and G. P. Gooch (eds.), *The Cambridge History of British Foreign Policy*, vol. iii.

GALLAUDET, THOMAS HOPKINS (1787–1851), U.S. educator of the deaf-mute, was born in Philadelphia, Pa., of French Huguenot ancestry, on Dec. 10, 1787. He graduated at Yale in 1805 and studied theology at Andover. Eventually he determined to devote his life to the education of deaf-mutes. He visited Europe and studied the methods of the abbé Sicard in Paris, and of Thomas Braidwood and his successor Joseph Watson in Great Britain. Returning to the United States in 1816, he established at Hartford, Conn., a school for deaf-mutes, in support of which congress made a land grant. Gallaudet presided over the school with great success until ill-health compelled him to retire in 1830. He died at Hartford on Sept. 10, 1851.

GALL BLADDER. The gall bladder in man is a pear-shaped, hollow organ situated on the undersurface of the liver; it acts as a storage place for bile, the digestive fluid secreted by the liver. The base of the gall bladder is called the fundus; the main portion, the body; and the narrow end, the neck. The latter terminates in the cystic duct, which joins the common bile duct. The wall of the gall-bladder consists of three layers: (1) an inner mucous layer of surface epithelium, (2) a middle fibromuscular layer consisting of smooth muscle and connective tissue and (3) a serosa that covers that portion of the organ not in contact with the liver. The walls of the gall bladder are distensible, and its capacity varies considerably. The gall bladder receives its blood supply from the cystic artery, a branch of the hepatic artery, and from vessels reaching it from the liver. The veins of the gall bladder empty into the portal vein. It has a dual nerve supply, sympathetic and parasympathetic. It is generously supplied with lymphatics.

Although a gall bladder is present in most of the higher species of animals, there are several that do not possess it. It can be removed surgically nithout causing untoward effects. The gall bladder serves as a reservoir for bile. The liver secretes bile continuously, but bile is not required during the interdigestion periods. When there is no food in the intestine, a sphincteric mechanism closes the terminal end of the common bile duct and the bile passes into the gall bladder. Water is absorbed from the bile by the wall of the gall bladder until the bile is concentrated eight to ten times. In this manner it is possible for a relatively small organ to function as an important reservoir. This organ is emptied by contraction of the smooth muscle contained in its malls. The gall bladder may be caused to empty by ingestion of a meal of fat, such as egg yolk and cream, and specifically by a hormone, cholecystokinin, which is found in the mucosa of the upper portion of the intestine. The gall bladder is subject to many diseases such as inflammation and formation of calculi (gall stones) within it. *See* also DIGESTION; LIVER.

BIBLIOGRAPHY.—S. S. Lichtman, *Diseases of the Liver, Gallbladder and Bile Ducts* (1942); F. C. Mann, "The Functions of the Gall Bladder," *Physiol. Rev.*, 4:251–273 (April 1924); A. C. Ivy, "The Physiology of the Gall Bladder," *Physiol. Rev.*, 14:102 (Jan. 1934). (F. C. MN.)

GALL BLADDER, BILIARY TRACT AND LIVER, DISEASES OF, include a large number of disorders of the liver, the gall bladder and the bile ducts that link them with each other and with the small intestine. The anatomy and function of these organs are described in the articles GALL BLADDER and LIVER.

LIVER

The liver is the largest and functionally the most complex organ in the body. Its many vital activities concern the removal of bilirubin (bile pigment) from the blood, excretion of bile into the intestine, metabolism of proteins, carbohydrates and fats, utilization of vitamins, storage of materials essential to the formation of blood and protection against infections and poisons. The symptoms and consequences of liver disease depend upon the degree to which these functions are disturbed. Fortunately, the reserve capacity of the liver is tremendous, and it may function adequately until approximately 90% of its substance is destroyed.

Infectious Hepatitis — This disease (also called catarrhal jaundice) is an inflammation of the liver cells caused by a virus. It exists in sporadic or endemic form throughout the world, but increases in frequency under conditions of crowding and poor sanitation. Persons of all races and all ages are susceptible. The infection is transmitted usually from person to person and by water or food contaminated with infected fecal material; ordinary methods of purifying the water supply do not eradicate the resistant virus. Fifteen to thirty days usually elapse between exposure and the appearance of symptoms.

The illness is characterized by loss of appetite, nausea, a curious distaste for tobacco, weakness, headache, fever, chills, respiratory complaints, diarrhea and discomfort or pain in the upper abdomen. Jaundice (*q.v.*) develops gradually and increases in intensity; it may be absent in mild forms of hepatitis. The liver is large and tender; the spleen may increase in size. Laboratory tests show impaired liver function. The disease ordinarily is self-limited, with complete recovery in four to six weeks; however, it may persist for several months In a small percentage of cases, because of poor nutrition, insufficient rest, intercurrent infection or the use of alcohol, infectious hepatitis becomes chronic. The mortality rate is low. Treatment includes a substantial intake of carbohydrate and protein and a moderate amount of fat in the diet, vitamins and adequate rest; glucose solutions intravenously may be required. The return to full activity should be very gradual. Administration of immune serum globulin intramuscularly to persons in close contact with the patient generally is recommended as a prophylactic measure.

Homologous Serum Jaundice. — This is a similar viral infection, transmitted by the injection of human blood or its products; by plasma convalescent serum or vaccines, and by any type of hypodermic injection with a poorly sterilized syringe. The incubation period extends from 40 to 190 days. One attack probably confers substantial but not absolute immunity against reinfection. There is no cross-immunity between the two types of hepatitis. The mortality rate varies, perhaps approximating 35%. Treatment is the same as for infectious hepatitis. The control of serum jaundice is aided by the detection of carriers among prospective blood donors and upon the use of plasma stored at room temperature instead of under refrigeration.

In severe viral hepatitis, with extensive destruction of the liver, there may be temporary obstruction to the flow of bile from the small bile ducts to the small intestine, so-called medical obstructive jaundice. A similar situation may complicate bacterial inflammation of the liver, excessive accumulations of fat in the liver cells (as in severe malnutrition) and certain defects in enzyme systems within liver cells; the latter category includes deficiency of the enzyme glucuronyl transferase. In the Dubin-Johnson syndrome, the liver cells, though seemingly normal, apparently are unable to excrete properly the normally formed bilirubin-glucuronide.

Toxic Hepatitis. — Toxic hepatitis is an acute disease caused by a variety of poisons: commercial solvents containing carbon tetrachloride or chloroform. phosphorus. mercury, gold, snake venom and poisonous mashrooiris. The disease also may follow certain infections. Thz central portions of the liver lobules usually are destroyed; oiher changes include large accumulations of fat and shrinkage of the liver. Tne extent of liver injury and the outcome depend upon the injurious agent, the quantity of the toxic dose, the duration and frequency of contact and the nutritional state of tne iiver. Symptoms resemble those of infectious hepatitis but are more severe; the mortality rate is high. Treatment is limited to rest, diet vitamins and glucose intravenously. British antilewisite (BAL) may be effective when arsenic or mercury is the cause.

The liver also may be injured occasionally by medicinally prescribed drugs, including chlorpromazine, methyltestosterone, marsilid, thiouracil, methimazole, arsenicals, phenylbutazone, para-amino sulfonic acid, sulfanilamide, trinitrotoluene and cinchophen, among many others. The microscopic changes in the liver include bile stasis. inflammation around the portal tracts, mild degeneration of cells and proliferation of bile ducts. Symptoms may develop within four days to five weeks of the onset of the treatment, and include nausea, vomiting, anorexia, malaise, jaundice, itching and abdominal pain. The symptoms and laboratory findings suggest interference with the normal flow of bile. The liver and spleen may increase in size. Since this problem occurs only in a small percentage of patients receiving medication, hypersensitivity to the drug and individual susceptibility have been suggested as causative factors. Treatment consists in discontinuance of the medication, the general measures for liver disease and, occasionally, ACTH and the adrenal steroids. Recovery usually is complete; in a small number of cases, the illness may terminate fatally.

Primary Cholangiolitic Hepatitis. — This uncommon inflammatory disease of the liver occurs predominantly in young women. The cause is not known; the metabolism of lipids in the liver appears to be disturbed. The symptoms include, in addition to jaundice, itching and variable ahdorninal distress. There may be increased pigmentation of the skin and deposition of lipid around the eyes. the creases of the palms and on the elbows, producing striking lesions (xanthomata). The liver is enlarged, and the spleen may be normal or large. The urine is dark in colour. The laboratory findings are compatible with an obstruction to the flow of bile; namely. an increase in the serum bilirubin, cholesterol, alkaline phosphatase and bile acids; the pattern of the plasma proteins also is normal. Gallstones (cholelithiasis) develop occasionally. There is no completely satisfactory treatment. Therapy includes the usual measures for liver disease; adrenal steroids may provide symptomatic improvement, though the underlying disease is not improved. Linoleic acid, as ethyl linoleate, and as a modified milk in which all the butter fat is replaced by safflower oil, has been recommended.

Portal Cirrhosis.—Portal cirrhosis is the result of chronic diffuse liver injury, characterized by destruction of cells, deposition of fat, excessive scarring and distortion of the liver. The flow of blood within the liver is disturbed, causing enlargement of the spieen and the development of accessory venous channels (varices). especially around the esophagus. The liver becomes large, hard arid irregular. Chronic alcoholism and malnutrition are the most important causes; however, cirrhosis may develop after any injury to the liver cells associated with cell destruction and the accumulation of fat. Symptoms may be absent, but loss of appetite, nausea, jaundice and fever are common. Spiderlike dilatations of small blood vessels may appear on the face and upper portion of the body. Bleeding may occur into the skin or after the rupture of varices. Fluid inay accumulate within the abdomen (ascites, or dropsy) or in the tissues (edema). The accumulation of fluid within the abdominal cavity is attributable to several factors: interference with the outflow of blood from the liver; increased communications between the major blcod vessels of the liver; excessive production of hormones. such as aldosterone, from the adrenal gland; retention of salt in the body; decreased protein in the circulating blood; increased output of antidiuretic hormone; and excessive production of lymph from the liver.

Treatment is directed to resroration of normal nutrition and the control of complications. It includes the avoidance of alcohol, a diet rich in carbohydrate and protein, and vitamins, especially the B complex. Ascites and edema are treated by a low-salt diet. drugs facilitating the elimination of salt and the replenishment of body proteins with diet, blood transfusions and albumin: drainage of the excess fluid may be necessary. Various "shunting" operations, redirecting the flow of blood, may be required for recurrent bleeding. The liver cells may be so diseased as to result in serious metabolic and chemical disturbances.

Hepatic Coma. — Patients with severe liver disease may pass into a coma, continuing for days to weeks and often ending fatally. The onset is very gradual and is characterized by vague, almost imperceptible changes in emotion, including untidiness, inappropriate behaviour and nocturnal wakefulness. These symptoms are followed by mental confusion, a characteristic flapping tremor of the outstretched hands and fingers, and then by coma, accompanied by typical changes in the brain wave pattern of the electroencephalogram. The cause of this complication often is not apparent. Precipitating factors may include gastrointestinal bleeding from esophageal varices or peptic ulcer, removal of fluid from the abdominal cavity, excessive intakes of protein, infection, administration of drugs containing ammonium, diuretics, opiates, sedatives and other drugs. The laboratory findings frequently indicate severely impaired liver function and its associated metabolic disturbances, and often but not invariably an increased amount of ammonia in the blood. Important factors in the development of liver coma include abnormal bacterial action upon the proteins within the bowel, inability of the diseased liver to remove adequately the excessive ammonia from the portal blood stream draining the digestive tract, and rapid transfer of the excessive ammonia and other toxic substances into the general circulation. Other disturbances in protein metabolism and defective carbohydrate and vitamin metabolism also may be implicated.

The management of liver coma is difficult. Avoidance of those factors known to precipitate the complication is important. Treatment usually requires skilled nursing care; adequate fluids; glucose and vitamins intravenously; limitation of the protein intake, at least temporarily; saline enemas to eliminate excessive protein from the alimentary tract; antibiotics such as neomycin, chlortetracycline or oxytetracycline to decrease the bacterial content of the bowel and thereby reduce the production of ammonia and other toxic materials. Glutamic acid and I-arginine or arginine glutamate have been administered to decrease the ammonia content of the blood and the brain. In the most severely ill patients. corticotropin (ACTH) and adrenal steroids have been administered in very large quantities, with occasionally spectacular, though usually temporary, improvement. The outlook for patients with liver coma, though not necessarily hopeless, is grave, since the complication denotes very serious, often irreversible disease.

Biliary Cirrhosis. — This is characterized by excessive scar tissue formation, an increase in the number of small bile ducts within the liver, and inflammation of the bile channels (cholangitis). In the primary (cholangiolitic) type, the larger bile passages and the gall bladder are normal, and the process is confined to the smaller bile ducts within the liver. The cause is not known, although infectious hepatitis may be implicated. Biliary cirrhosis often is the result of persistent, incomplete obstruction of the common bile duct by impacted gallstones, adhesions or scar tissue developing after operations on the gall bladder, or by new growths.

Symptoms include jaundice, itching of the skin and attacks of chills, fever, sweats and abdominal pain. The urine is dark and the stools are light in colour. The liver and the spleen are large. The inadequate flow of bile into the intestine interferes with the metabolism of fats and with the absorption of fat-soluble vitamins. Treatment consists in rernoval of the obstruction, whenever possible. rest. diet, vitamins and control of infection with sulfonamides and antibiotics.

Abscess of the Liver. — Liver abscess most often is of the pyogenic type, with many small abscesses caused by bacteria brought to the liver via the blood stream from infected areas (as the appendix) within the abdomen. The characteristic symptoms are intermittent fever. chills, sweats, jaundice and toxemia. The liver becomes large and tender. Treatment consists of sulfonamides, penicillin or other antibiotics, and drainage of the abscess. "Tropical" abscess of the liver usually is single and large and almost always the result of infection with *Endamoeba histolytica* (the cause of amoebic dysentery). The administration of antiamoebic drugs and aspiration of the abscess usually are effective. Other less frequent causes of liver abscess are injury, the penetration of a foreign body or infection of an echinococcus cyst.

Weil's Disease.—This is an acute infection of the liver caused by the spirochete *Leptospira icterohaemorrhagiae.* It is transmitted via food or water contaminated with the urine of infected rats. The organisms may enter the body through the skin. eyes, mouth or intestine. Men coming in contact with rats—miners, fishermen, farmers and workers in sewers, railroad yards and rice or sugar-cane fields—often are affected. The illness begins suddenly nith fever, aching in the muscles and joints, headache. prostration and jaundice The liver and spleen become enlarged, hemorrhages occur in the skin, and the kidneys and central nervous system become involved. There is no specific treatment: penicillin and other antibiotics appear to be of value.

Syphilis of the Liver.—This is no longer common. The left lobe is especially involved, either by diffuse scarring or large masses called gummata. The liver is large, hard and very nodular Treatment consists in the administration of antisyphilitic drugs (see VENEREAL DISEASES).

Hemochromatosis.—Hemochromatosis of the liver is a metabolic disorder of unknown cause, characterized by the deposition of two pigments, hemosiderin (an iron-containing pigment) and hemofuscin. in the liver and pancreas and sometimes in the skin, The disease affects chiefly men during the ages of 50 or 60; it occurs in conjunction with chronic malnutrition and pellagra among the Bantu of South Africa. The symptoms are related to those of diabetes and cirrhosis. The skin occasionally assumes a rusty or bronze pigmentation, and there may be loss of body hair and atrophy of the testes. Treatment is directed to the diabetes, utilizing proper diet and insulin, if necessary. The management of the cirrhosis is similar to that outlined above.

Malignant Disease.—Primary cancer (*q.v.*) of the liver generally is uncommon, though the incidence is high in the far east and South Africa. where parasitic infestations and malnutrition are common. The tumour may arise in the liver cells or the bile ducts, in association with cirrhosis. Secondary involvement of the liver by cancer occurs in approximately 50% of patients with tumours originating elsewhere in the body, especially the stomach, colon, pancreas, lungs and breast. Symptoms include pain in the upper abdomen. loss of appetite and weight, fever and weakness. Jaundice results from invasion and obstruction of the larger bile ducts; ascites from obstruction of the portal vein; and hemorrhages from rupture of the esophageal varices. Treatment is limited to the relief of pain.

GALL BLADDER

The gall bladder is a thin, pear-shaped structure, with the capacity of one to two ounces, situated on the undersurface of the right lobe of the liver. Its principal activities are to store the bile excreted by the liver for digestive purposes, and to regulate the pressure in the biliary system, preventing back-pressure on the liver in its continuous production of bile. The gall bladder is not an essential organ, and its removal by operation does not deprive the body of any vital function; nor does removal of the gall bladder decrease the quantity of bile entering the digestive tract. Bile is of value in aiding the digestion of fat, and as a means of excreting certain toxins and poisons removed from the body by the liver.

Acute **Cholecystitis.**—This is an inflammation of the gall bladder caused usually by the following sequence of events: obstruction of the cystic duct (leading from the gall bladder to the common bile duct) by gallstones, stasis of bile and chemical inflammation, induced by constituents of bile. Bacterial infection may or may not be present.

There is a sudden onset of pain in the upper quadrant of the abdomen. often radiating to the back or shoulder, fever, nausea, vomiting and occasionally jaundice. Symptoms may continue for several hours to several weeks, depending upon the severity of the attack. The disease may be complicated by softening or gangrene of the gall bladder, nith rupture and peritonitis, or by inflammation of adjacent portions of the liver. Treatment comprises bed rest, relief of pain, avoidance of liquid and food by mouth, glucose and salt solutions intravenously, and the use of sulfonamides and antibiotics. In cholecystitis without jaundice, the flow of bile into the intestine is unimpeded; hence there is no need for bile salts or laxatives. Surgical removal of the gall bladder may be performed promptly or deferred until the inflammation subsides.

Cholelithiasis.—This term designates stones in the gall bladder; *i.e.*, gallstones (see CALCULUS). Several factors are involved: stasis of bile with concentration and precipitation of cholesterol (as in the latter months of pregnancy); infection of the gall bladder (typhoid fever); precipitation of calcium carbonate in obstruction of the cystic duct; and increased concentration of bilirubin, as in hemolytic anemia with destruction of red blood cells and excessive formation of bilirubin. Gallstones may develop at all ages and in both sexes, but they occur more often in obese women. after pregnancy. They may be present for a lifetime without producing symptoms. The complaints of belching. flatulence and intolerance for fatty or fried foods, commonly attributed to gall bladder disease. frequently develop in the presence of a normal gall bladder and are related to gastrointestinal irritability. The passage of, stones into the cystic or common bile channels causes stretching and spasm of these ducts and sudden, severe, cramping pain in the right upper abdomen, radiating to the back and right shoulder. Chills and fever reflect an accompanying cholecystitis; jaundice indicates an obstruction to the flow of bile. Biliary colic often occurs during the night, several hours after a heavy meal and the attack usually subsides within several hours. There may be an associated inflammation of the pancreas (acute pancreatitis), diagnosis of nhich is facilitated by measurement of one of the enzymes produced by the pancreas (serum amylase). X-rays may reveal calcium-containing gallstones; or the gall bladder may fail to visualize, indicating nonfunction. Opiates often are required to relieve the pain. Gallstones cannot be dissolved, nor can stones be evacuated from the gall bladder via the intestine. Surgical removal of the gall bladder is the only curative procedure. Recurrent or continuing symptoms after surgery may be caused by a remnant of the cystic duct overlooked at the time of operation. A more serious problem is that of injury to the main bile duct at surgery, producing partial or complete interference with the normal flow of bile into the intestine; infection of the bile ducts within the liver and extensive disease of the liver usually ensue.

New Growths.—Tumours and cancer of the gall bladder are uncommon, benign tumours being found in approximately 5% of gall bladders removed surgically. These conditions include papilloma, adenoma, fibroma and lipoma. Cholesterol stones imbedded in the wall of the gall bladder may simulate benign tumours. The diagnosis is made only at X-ray examination or operation. Cancer of the gall bladder usually occurs in association with gallstones. Symptoms are caused by the stones or by an accompanying cholecystitis. The principal physical findings are jaundice and a hard, irregular mass in the region of the gall bladder. Cancer of the bile ducts also is rare. Symptoms consist of progressively increasing jaundice, itching of the skin, fever, loss of appetite and weight, and bleeding. These diseases usually are fatal; early surgical removal offers the only hope of cure.

GALLE or Point de Galle, a town and port of Ceylon on the southwest coast. Galle is hardly noticed in the native chronicles before 1267, and Ibn Batuta, in the middle of the 14th century. distinctly states that Kali—that is. Galle—was a *small* town. It was not until the period of Portuguese occupation that it rose to importance. The opening of the Suez canal in 1869, and the construction of a breakwater at Colombo, leading to the transfer of the mail and most of the comimercial steamers to the capital of the island. seriously diminished the prosperity of Galle. The export trade is chiefly represented by coconut oil, rubber, coir yarn, fibre, rope and tea. The town is administered by a municipal council. Pop. (1953) 55,848 (mun.).

GALLEGOS, RÓMULO, (1884–) eminent Spanish-American novelist, educator and former president of Venezuela, was born Aug. 2, 1884, in Caracas, Venez. He began his literary career in 1909 as coeditor of *La alborada,* a periodical in which he published his first works, political and social essays.

His first short stories were published in El *cojo ilustrado* in 1910. After a brief attempt at the drama in 1915, Gallegos continued writing short stories until 1920, when his first novel. *El último Solar,* appeared., In 1925, a second novel, *La trepadora,* prepared the way for *Doña Bárbara* in 1929 (Eng. trans. by Robert Malloy; 1931, 1948). With *Doña Bárbara* he became an internationally known literary figure and one of the leading novelists of Spanish America. Two more major novels, *Cantaclaro,* 1934, and *Canaima,* 1935, followed. In 1936, Gallegos began an active political career that led to the ministry of education and finally to the presidency in 1947. His government was overthrown by a military coup in Nov. 1948, and he was sent into exile in December.

A historical novel, *Pobre negro,* 1937, was followed by three other novels: El *forastero* (1942), *Sobre la misma tierra* (1943) and *La brizna dc paja en el viento* (1952).

GALLEN-KALLELA, AKSELI VALDEMAR (186;–1931). Finnish painter, was born on April 26, 1865, at Pori. He established himself in 1884 in Paris. He is best known for his symbolic scenes from the *Kalevala* epic, for his landscapes, especially snow scenes, and for some admirable portraits, notably one of Maxim Gorky. He also executed work in black and white. His illustrations for *Seitsemän Veljestä,* by Aleksis Kivi (1906–07), are well composed and imaginative. He died at Stockholm, March 7, 1931.

GALLEY, a long single or half-decked vessel of war; with low freeboard, propelled primarily by oars or sweeps, but also having masts for sails. The word is used generally to refer to the ancient war vessels of Greece and Rome of various types, whose chief propelling power was the oar or sweep, but its more specific application is to the medieval war vessel which survived in the navies of the Mediterranean sea powers after the general adoption of the larger many-decked ship of war, propelled solely by sail power. Lepanto (1571) was the last great naval battle in which the galley played the principal part. It became the custom among the Mediterranean powers to sentence condemned criminals to row in the war galleys of the state. Traces of this in France can be found as early as 1532, but the first legislative enactment is in the *Ordonnance d'Orléans* of 1561. In 1564 Charles IX forbade the sentencing of prisoners to the galleys for less than ten years. The galley slaves were branded with the letters Gal. At the end of the reign of Louis XIV the use of the galley for war purposes had practically ceased, but the corps of the galleys was not incorporated with the navy until 1748. The name *galérien* was still given to all convicts, though the galleys had been abandoned. and it was not till the French Revolution that the name was changed to *forçat.* In modern nautical use, the galley is a ship's kitchen. *See* also Ship; Shipping, History of: *Developments in Ship Design and Navigation.*

GALLFLY, a name applied to a number of different kinds of insects that cause the production of galls in plants. In Diptera (*q.v.*), any gall-making fly belonging to the families Cecidomyidae or gall midges (*q.v.*), or to the family Trupaneidae or Trypetidae (*see* Fruit Fly). In Hymenoptera (*q.v.*), any member of the family Cynipidae, usually called gall wasps.

The name may also be applied to gall makers of the family Aphididae of the order Homoptera (formerly a suborder under Hemiptera). The galls are usually diagnostic for the species making them. (C. H. Cn.; X.)

GALLIA CISALPINA, that portion of northern Italy north of Liguria and Umbria and south of the Alps which was inhabited by various Celtic and other peoples, of whom the Celts were in continual hostility to Rome and rendered assistance to Hannibal. In early times it was bounded on the south by Liguria and the Aesis; Sulla readjusted the boundaries and in Caesar's time the southeast boundary was the Rubicon. For the early Celtic and other peoples and the later history of the district *see* Italy: *History;* Rome: *History, Ancient.*

GALLIARD (Fr. *Gaillard,* meaning "lively"; It. *Gagliarda),* is a gay dance of the 15th century. Coupled with the pavane, it became the earliest of court dances. Although the music was in $\frac{3}{4}$ time, the dance was performed, often without holding hands, to counts of six (2 measures), with various kicking and jumping steps (*petit saut*) on 1, 2, 3. 4, a *saut majeur* ("high jump") or *saut moyen* ("medium jump") on 5, with a cadence posture on 6. Hence it acquired the name of *cinque-pas* (the English cincopace). Musicians usually wrote pavanes and galliards in pairs, the galliard tune becoming a rhythmic adaptation of that of the pavane which it followed. It retained its vogue as a court dance from c. 1530 to 1620. (L. Ht.)

GALLIC ACID occurs in many plants either in the free state or combined as gallotannin *(see* Tannin). It is present to the extent of 40%–60% combined as gallotannic acid in tara, and in Aleppo or Chinese galls *(see* Galls) from which it is obtained commercially by the action of acids or alkalies.

Gallic acid is 3,4,5-trihydroxybenzoic acid and has the formula $(HO)_3C_6H_2.CO_2H$. When heated to 200°–250° C. it splits into carbon dioxide and pyrogallol (pyrogallic acid), the photographic developer. With iron salts it gives a deep blue-black colour, the basis of writing ink *(see* Ink). It is used in the manufacture of a few dyes and as bismuth subgallate it has been employed in medicine as a mild skin antiseptic and astringent. Esters of gallic acid, principally propyl gallate, are important antioxidants for the prevention of rancidity in edible oil and fats. (V. H. W.)

GALLICANISM, a name for various theories maintaining that both the church and the state in France had ecclesiastical rights of their own, independent and exclusive of the jurisdiction of the pope. These theories were developed in opposition to ultramontanism (*q.v.*). As regards the church, it was held that infallible authority was committed to pope and bishops jointly; the pope decided in the first instance, but his judgments must be tacitly or expressly confirmed by the bishops before they had the force of law. And as regards the state, Gallicanism goes back to the protests raised against the theocratic pretensions of the mediaeval popes. They claimed that they, as vicars of Christ, had the right to interfere in the temporal concerns of princes, and even to depose sovereigns of whom they disapproved. Gallicanism answered that kings held their power directly of God; hence their temporal concerns lay altogether outside the jurisdiction of the pope. During the troubles of the Reformation era, when the papal deposing power threatened to become a reality, the Gallican theory became of great importance. It was incorporated by Bossuet in a solemn declaration of the French clergy, made in 1682. This document lays down: (1) that the temporal sovereignty of kings is independent of the pope; (2) that a general council is above the pope; (3) that the ancient liberties of the Gallican church are sacred; (4) that the infallible teaching authority of the church belongs to pope and bishops jointly. This declaration led to a violent quarrel with Rome, and was officially withdrawn in 1693, though its doctrines continued to be largely held. In 1802 Napoleon contented himself by embodying Bossuet's declaration textually in a statute. Long before his time, however, the issue had been narrowed down to determining exactly how far the pope should be allowed to interfere in French ecclesiastical affairs. Down to the repeal of the Concordat in 1905 all French governments continued to uphold two of the ancient "Gallican Liberties." The secular courts took cognizance of ecclesiastical affairs whenever the law of the land was alleged to have been broken; and papal bulls were not allowed to be published without the leave of the state. *See* FEBRONIANISM; ULTRAMONTANISM.

GALLI-CURCI, AMELITA (1889-), Italian-American coloratura soprano, was born at Milan, Italy, on Nov. 18, 1889, of Italian and Spanish parentage. After a general education in the schools of Milan she entered the Royal Conservatory in the same city and studied piano and harmony. As a vocalist, however, she was self-taught. Her operatic début was at Rome in 1909 as Gilda in Verdi's *Rigoletto*. She later toured the smaller cities in Italy, appeared at Barcelona and Madrid in Spain, and had several successful seasons in South America, Cuba and Mexico. Her fame in these countries was immediate, but she was almost unknown in the United States when in 1916 she was engaged by the Chicago Opera association. Her Chicago début on Nov. 18, 1916, was again as Gilda in *Rigoletto*. She was re-engaged for nine seasons. On Jan. 27, 1918, she appeared for the first time in New York city in the title role of Meyerbeer's *Dinorah* at the Lexington opera house She joined the Metropolitan Opera company in 1920, opening the season that year as Violetta in La *Traviata*. Besides the roles mentioned, her favourite repertory included the roles of Juliette in *Romeo et Juliette,* Lucia in *Lucia de Lammermoor,* Mimi in *La Bohème* and Leila in Bizet's *Pearl Fishers*. Her voice reached astonishing heights with tone smooth, warm and well rounded. It had great fluency, enabling its owner to sing many intricate roles with simplicity and naturalness. Ill health brought about her retirement in 1930, except for a brief reappearance in 1936.

GALLIENI, JOSEPH SIMON (1849–1916), French general and statesman, is immortalized by his share in the strategically decisive victory of the Marne (*q.v.*). He was born at St. Béat, Haute-Garonne, on April 24, 1849. He left the military academy of St. Cyr in July 1870 as second lieutenant in the marines, becoming lieutenant in 1873 and captain in 1878. He saw service in the Franco-German War, and from 1877 to 1881 took an important part in the explorations and military expeditions which extended the French dominion in the basin of the upper Niger. In March 1881 he obtained a treaty from Ahmadu, almany of Segu, giving the French exclusive rights of commerce on the upper Niger, for ahich he received the gold medal of the Société de Géographie. From 1883 to 1886 Gallieni was stationed at Martinique. On June 24, 1886, he became lieutenant colonel and on Dec. 20 governor of Upper Senegal. He obtained several successes against Ahmadu in 1887, and compelled Samory to agree to a treaty abandoning the left bank of the Niger. *(See* SENEGAL: *History)*. In 1891 he was promoted colonel, and from 1893 to 189; he commanded the second military division of Tongking.

In 1896 Madagascar was made a French colony and Gallieni was appointed resident general (afterward governor general) and commander in chief. He completed the subjugation of the island, which was in revolt against the French. He also destroyed the political supremacy of the Hovas and restored the autonomy of the other tribes. The application of the French customs and other similar measures disastrous to British and U.S. trade were matters for which Gallieni was not wholly responsible. His policy was directed to the development of the economic resources of the island and was conciliatory toward the non-French European population. He also secured religious liberty for the Protestants. In 1905, when he resigned the governorship, Madagascar enjoyed peace and cocsiderable prosperity. In 1906 Gallieni was appointed to command the 14th army corps at Lyons.

Gallieni had reached the age for retirement in April 1914 but was retained on the active list without duty, and on mobilization in 1914 he was notified that in case of need he would be the successor of the commander in chief, Gen. J. J. Joffre, who had been appointed on his recommendation. On Aug. 26, in face of the imminent approach of the invading German armies, he was appointed military governor of Paris. He took energetic steps for the defense of the capital, abandoned by the government, and in addition to the garrison Gen. M. J. Maunoury's 6th army was placed under his control. Visualizing his role as one not merely of passive defense, his close watch on the German armies and his military intuition led him to see and seize the opportunity for a counterstroke. From air information received during Sept. 3, Gallieni concluded that the German forces marching on Paris had inclined to the southeast, thus offeringhim an exposed flank. He convinced Joffre first of the opportunity, and ultimately that the attack ought to be made on the line of the Ourcq north of the Marne. On the night of Sept. 4 Joffre issued orders for a general counteroffensive on Sept. 6. The outcome was the retreat of the right wing and with it the turning of the tide of World War I. Controversy has raged over the distribution of credit for this achievement, but it is at least indisputable that the first perception of the opportunity and the initiative to seize it were Gallieni's. With the German retreat the operations passed out of the zone over which Gallieni held command.

Joffre showed no haste to offer Gallieni a more active command, but on Oct. 29, 1915, the latter became minister of war in Aristide Briand's cabinet. In this office he sought to bring about reforms in the administration and higher command, while defending Joffre against the growing storm of criticism. The German attack on Verdun (*q.v.*), however, revealed a serious failure of foresight on the part of the higher command. Gallieni then proposed an extensive scheme of reorganization for the better co-ordination of the whole war effort of France. In the military sphere this involved a clearer separation between the strategical direction and the administration of resources, and to implement it Joffre was to be brought back to Paris as the commander in chief of all the French armies, while Gen. Edouard de Castelnau was placed in executive command of the field armies on the western front. Finding that his colleagues in the cabinet shrank from the risk of causing a political crisis, Gallieni resigned, ostensibly for reasons of ill health, on March 16, 1916. The pretext was, in part, justified for in order to fit himself for active service he underwent an operation without taking the preliminary rest that had been prescribed. The first operation was not successful and after a second he died at Versailles on May 27, 1916. His body was given a state funeral and lay for a time under the dome of the Invalides. He was buried at St. Raphael. On April 21, 1921, the dignity of marshal of France was conferred on him posthumously.

He published *Mission d'exploration du Haut-Niger, 1879–1881* (1885); *Deux campagnes au Soudnn français* (1891); *Trois colonnes au Tonkin* (1899), *Rapport d'ensemble sur la situation générale* de *Madagascar* (1899); and *Neuf ans à Madagascar* (1908).

See also *Les Carnets* de *Gallieni, publiés par son fils,* *Gaetan Gallieni, notes de P B Gheusi* (Paris, 1932).

GALLIENUS, PUBLIUG LICINIUS EGNATIUS, Roman emperor from A.D. 260 to 268, son of the emperor Valerian, was born about 218. From 253 to 260 he reigned conjointly uith his father, during which time he gave proof of military ability. But when his father was taken prisoner by Shapur I of Persia, in 260, Gallienus made no effort to obtain his release or to withstand the incursions of the invaders who threatened the empire from all sides. He deprived the senators of their military and provincial commands, which were transferred to equites. During his reign the empire was ravaged by a pestilence, and the chief cities of Greece were sacked by the Goths. His generals rebelled against him in almost every province of the empire, and this period of Roman history came to be called the reign of the Thirty Tyrants. Gallienus was killed at Mediolanum by his soldiers while besieging Aureoius, who was proclaimed emperor by the Illyrian legions. His sons Valerianus and Saloninus predeceased him.

Life by Trebellius Pollio in *Script. Hist. Aug.;* on coins *see* articles in *Numism. Zeit.* (1908) and *Riv. ital. d. num.* (1908).

GALLIFFET, GASTON ALEXANDRE AUGUSTE, MARQUIS DE, Prince de Martignes (1830–1909), French army officer. was born at Paris on Jan. 23, 1830. He entered the army in 1848, and served with distinction at the siege of Sevastopol in 1855. Under Napoleon III he served in several campaigns in Algeria, Italy and Mexico, and by 1867 became colonel of the 3rd Chasseurs d'Afrique. He commanded this regiment in the Franco-German War of 1870 and on Aug. 30 became general of brigade. At the battle of Sedan he led his brigade in the heroic charge of Gen. J. A. Margueritte's cavalry division (see SEDAN). He was taken prisoner at the capitulation, but returned to France and in the suppression of the Commune his severity earned him the bitter enmity of the Left. His military career continued until 1895; he suppressed an Algerian rebellion in 1872. was promoted general of division in 1875, and became a member of the Conseil Supérieur de la Guerre in 1885. In later life he became a politically controversial figure, being sponsored by L. Gambetta, who respected his military talents, and in 1899 became minister of war in the René Waldeck-Rousseau cabinet after the turmoil of the Dreyfus case. Although regarded by the moderates as a good "republican," he remained the object of great animosity on the Left. He died on July 8, 1909.

See L. Thomas, *Le général* de *Galliffet,* new ed (1941). (D. TN.)

GAELIFORMES, an order of birds, comprising the game birds (see CURASSOW; FOWL; FRANCOLIN; GAME BIRDS; GROUSE; MEGAPODE; BIRD (for classification); PHEASANT; PTARMIGAN; QUAIL: TURKEY).

GALLINULE, the name for about 10 genera and 23 species of fresh-water birds of the family Rallidae, about the size of a bantam hen but compressed like the rails and the coots (*qq.v.*). The common European gallinule (*Gallinula chloropus*), blackish with a scarlet forehead plate, is known as moor hen (*q.v.*), its North American race (G. c. cachinnans) as the Florida gallinule. They are noisy birds. They lay 7 to 11 brown-spotted creamy eggs in a bulky nest of rushes on or near the ground.

The larger purple gallinule or swamp hen of Mediterranean shores is Porphyrio *porphyrio,* with related species over Africa, Madagascar, southern Asia to Australia, the Philippines and southwest Pacific islands. The purple gallinule. water hen or sultana of America is *Porphyrula martinica,* with bright olive-green and purplish-blue plumage, light-blue forehead plate, red and yellow bill, yellow legs and feet. It is found from South Carolina and Texas to northern Argentina; an allied species, P. *parva,* occurs from central Brazil and Paraguay to the Guianas, and P. alleni is seen over Africa and Madagascar.

Many peculiar flightless island forms are found throughout South America. Africa, southern Asia, Australia and islands of western and southwestern Pacific: among those extinct or nearly so are the island hen of Tristan da Cunha (*Porphyriornis* nesiotis); the mountain cock of Gough Island (P. *comeri*); the white swamp hen of Lord Home Island (*Porphyrio albus*); the huge moho of New Zealand (*Notornis mantelli*); and *Pareudiastes pacificus* of Samoa. (G. F. Ss.; X.)

GALLIO, IUNIUS ANNAEUS (originally LUCIUS ANNAEUS NOVATUS), son of the rhetorician L. Annaeus Seneca and the elder brother of L. Annaeus Seneca the philosopher, was born at Corduba (Córdova) about the beginning of the Christian era. At Rome he was adopted by L. Iunius Gallio, a rhetorician. Both Seneca and Statius speak of his charm of disposition. It is probable that he was banished to Corsica with his brother and that both returned to Rome when Agrippina selected Seneca to be tutor to Nero. For a few years Gallio was proconsul of the newly constituted senatorial province of Achaea. During his tenure of office (in A.D. 53) he dismissed the charge brought by the Jews against the apostle Paul (Acts xviii). His behaviour on this occasion ("But Gallio cared for none of these things") shows the impartial attitude of the Roman officials toward Christianity in its early days. He survived his brother Seneca but was put to death by order of Nero (in 6j) or committed suicide.

GALLIPOLI (Turk. GELIBOLU), a seaport and city of European Turkey, in the province of Canakkale; at the northwestern extremity of the Dardanelles, on a narrow peninsula 132 mi. W.S.W. of Istanbul and 90 mi. S. of Adrianople. Pop. (1960) 12,956. Nearly opposite is Lapsaki on the Asian side of the channel, which is there about 2 mi. wide. There are several mosques, none of them remarkable, and many interesting Roman and Byzantine remains, especially a magazine of the emperor Justinian (483–565), a square castle and tower attributed to Bayezid I (1389–1403) and some iumuli on the south, popularly called the tombs of the Thracian kings. It has two good harbours. From its position as the key of the Dardanelles, it was occupied by the allied French and British armies in 1854. Then the isthmus a few miles north of the town, between it and Bulair, was fortified with strong earthworks by English and French engineers, mainly on tne lines of the old works constructed in 1357. These fortifications were enlarged in Jan. 1878. on the Russians' threatening to take possession of Constantinople. The peninsula thus isolated by the fortified positions has the Gulf of Saros on the northwest and extends about 50 mi. S.W.

The district (sanjak) of Gallipoli is exceedingly fertile and well adapted for agricuiture. It comprises four *kazas* (cantons), namely (1) Maidos: (2) Keshan, lying inland north of Gallipoli, near which are lignite mines; (3) Myriofyto; and (4) Sharkeui (Peristeri) on the coast of the Sea of Marmora. Copper ore and petroleum are worked at Sharkeui, and the neighbourhood formerly produced wine. For an account of the Gallipoli campaign in World War I, see DARDANELLES CAMPAIGN.

GALLIPOLIS, a city of southern Ohio. U.S., on the Ohio river, 100 mi. S.E. of Columbus. the seat of Gallia county. It mas founded in 1790 by the Ohio company as a town of 80 cabins for stranded French immigrants who had been beguiled by agents of the Scioto company to purchase land certificates which were .worthless (see OHIO COMPANY): the name Gallipolis means "city of the Gauls." It was incorporated as a village in 1842 and as a city in 1865. Its municipal government is by the council-manager plan in effect since 1918.

The city has a small number of manufacturing industries and is the shipping centre for a farming and coal mining region. Rio Grande college. a private college founded in 1876, is 12 mi. distant. The Gallipolis State institute for epileptics and mentally defective children was established in 1890. Hospital and medical services are provided by the Holzer I-Iospital foundation, consisting of a clinic, a hospital and a school of nursing, and the Gallipolis clinic.

Gallipolis, the third settlement on the Ohio river within the limits of the state of Ohio; has several points of historical interest. Our House, built as a tavern in 1819, is now a museum of the Ohio Historical society.

For comparative population figures see table in OHIO: *Population.* (G. J. BL.)

GALLITZIN, DEMETRIUS AUGUSTINE (1770–1840), U.S. Roman Catholic priest, known as the "Apostle of the Alleghenies," was born at The Hague. Neth., on Dec. 22, 1770, during the tour of duty there of his father: Prince Dmitri Aleksevich Golitsyn, as Russian ambassador to Holland. Both his parents were fiiled with the spirit of the Enlightenment, but at the age of 17 Demetrius joined the Roman Catholic Church. Traveling to America, he began studying for the priesthood and was ordained in Baltimore, Md., in 1795 Bishop John Carroll (*q.v.*), sent him to Carnbria county, Pa., where immigrant Catholics mere settling in the foothills of the Alleghenies. He was one of the first priest missionaries during the colourful immigrant period of American history, and was soon, like so many of his 19th-century counterparts, deeply engrossed in land and colony projects to attract Catholic immigrants into the west and onto the land. Known as "Mr. Smith" in the United States, Gallitzin was a benevolent and eccentric despot who at the same time exercised a great power for good among his parishioners. At the time of his death, on May 6, 1840, there were around 10,000 Roman Catholics living in his district. where 40 years earlier he had found a scant 12.

Gallitzin wrote controversial religious tracts and pamphlets in defense of the Catholic religion against attacks by frontier Protestant sects. Most typical of these polemics is his A *Defense of Catholic* Principles (1816). A collection of his letters was published in 1940.

BIBLIOGRAPHY.—A contemporary biography in German by his assistant, Peter H. Lemcke, *Life and Work of Prince Demetrius Augustine Gallitzin,* tr. by Joseph Plumpe (1940); several popular biographies typical of which is Daniel Sargent's *Mitri* (1945). (C. J. By.)

GALLIUM, a chemical element that is a bluish-white metallic solid. which becomes a liquid at slightly above room temperature. Gallium is a member of Group III of the periodic table and is generally associated with aluminum and boron in the main group, but in some forms of the table gallium, indium and thallium are placed in the subgroup. The symbol for Gallium is Ga; the atomic number is 31 and the atomic weight is 69.72.

Gallium was discovered in 1875 by Paul Émile Lecoq de Boisbaudran, who observed its principal spectral lines (λ 4172.2 Å and 4033 2 Å [sic]) while examining material isolated from zinc blende of Pierrefitte, Hautes-Pyrénées, France. He recovered a sample of the metal and studied its properties. A few years previously D I. Mendeleyev had predicted the existence of a number of elements, not yet discovered, each corresponding to a blank space in his periodic table. He gave the provisional name eka-aluminum to the missing element lying between aluminum and indium and predicted its principal physical and chemical properties. His predictions relative to eka-aluminum were verified by the discovery of gallium, whose properties were found to coincide almost exactly with those predicted.

Applications. — Gallium has not been extensively used, although its unique properties indicate some interesting possibilities. Because of its low vapour pressure and long liquid range, it would be a suitable material, enclosed in clear quartz, for a high-temperature thermometer. Its uses as a coating for optical mirrors, as a liquid seal in strongly heated apparatus and as a substitute for mercury in ultraviolet lamps have been suggested. Gallium has been considered as a possible heat-exchange medium in nuclear reactors, although it has a high neutron cross section. Gallium attacks a great many metals such as titanium, iron, nickel and copper, forming compounds or solid solutions; it must therefore be enclosed in a resistant material. Radioactive Ga^{72} shows some promise in the study of bone cancer; a compound of this isotope is absorbed by the cancerous portion of the bone, which may thus be more accurately identified.

Gallium may be quantitatively separated by extraction from an acid solution with a chloroform solution of 8-hydroxyquinoline and determined by the use of the spectrophotometer. It is also determined by spectrographic methods.

Occurrence and Production. — It has been estimated that gallium constitutes about 0.0015% of the earth's crust, although it is widely distributed and has not been found in concentrated deposits. It is a constituent of many coals and some of the ores of zinc, aluminum, iron, copper, germanium and chromium. The zinc blendes of the Missouri-Oklahoma-Kansas district contain up to 0.02% of gallium; aluminum-bearing minerals, particularly bauxite, contain up to 0.01%; germanite, a complex sulfide mineral found in the lead copper ores of the Tsumeb district of South-West Africa, contains up to 0.8%.

Gallium is extracted as a by-product from zinc and aluminum ores or from flue dust by processes which involve the separation of small quantities of its compounds from those of other metals and a subsequent electrolytic reduction. In an older method for the recovery of zinc the roasted ore is smelted in retorts and the gallium accumulates in the retort residues when the zinc is distilled. The metals in the residue are converted to chlorides and the more volatile gallium trichloride is separated by distillation. The more recent process involves leaching of the roasted zinc ore with sulfuric acid and neutralization of the excess acid to precipitate such impurities as gallium, aluminum and iron. The precipitate is treated with sodium hydroxide, which dissolves the aluminum and gallium compounds, and these are reprecipitated by neutralizing the solution with acid. The precipitate is then dehydrated to make insoluble any silicon dioxide which may be present, and treated with hydrochloric acid. The gallium trichloride is extracted from the concentrated acid solution by ether, the aluminum salt and some of the other impurities remaining in the hydrochloric acid solution. Gallium metal is obtained by the electrolysis of a sodium hydroxide solution of the gallium sait. The metal is purified by washing alternately with water, hydrochloric acid and nitric acid and by successive crystallizations from the supercooled liquid.

Gallium is recovered from the alkaline solutions of bauxite, which are prepared by treating the aluminum ore with hot sodium hydroxide. The concentrated solution, containing mostly sodium aluminate, is seeded with aluminum hydroxide and cooled. The hydrated aluminum oxide crystallizes and is separated from the waste liquor, which contains the gallium and considerable aluminum hydroxide. More of the aluminum compound is removed and the gallium compound is precipitated, redissolved in sodium hydroxide and electrolyzed.

In England gallium is commercially recovered from flue dusts which contain also iron and germanium. The dust is smelted with sodium carbonate, lime, carbon and copper oxide. A button or mass of metal containing most of the germanium and gallium thus formed beneath the slag is treated with chlorine under ferric chloride solution. The germanium tetrachloride is removed from the solution by distillation. The residue liquid containing the gallium is further purified by precipitation of the copper salts and other precipitable metals while the iron is reduced to the ferrous state. The gallium chloride is then extracted by ether. After removal of the ether by distillation, the gallium chloride is treated with sodium hydroxide and the gallium metal recovered by electrolysis.

Properties. — Gallium is a bluish-white metal with an unusually low melting point (29.78" C.). It expands upon solidification and supercools readily, remaining in the liquid phase at temperatures as low as 0° C. Gallium remains in the liquid phase over a temperature range of more than 2.000° C. with a very low vapour pressure up to about 1,500° C., the longest useful liquid range of any element. It has a hardness of 2–3 on Mohs' scale and at fairly low temperatures is brittle. Two stable isotopes with mass numbers 69 (60.1%) and 71 (39.9%) are known, and a number of radioactive isotopes have been prepared. The crystal structure of the metal is orthorhombic, with each atom surrounded by seven others, one at 2.44, two each at 2.70, 2.73 and 2.79 Å. The structure probably contains Ga_2 molecules. Gallium is diamagnetic. Additional physical and atomic properties are listed in the table.

Numerical Properties d [sic] Gallium

Outer electron configuration	$4s^2,4p^1$	Melting point, ° C.	29.780
Mass number and half life, radioactive isotopes	64 (2.5 min.)	Boiling point, ° C.	2,070

Atomic volume of solid c.c.	11.76		

The chemical properties of gallium resemble in some respects those of aluminum. It oxidizes slowly in moist air to form a thin surface film of oxide, but the oxidation does not proceed much further even under mere favourable conditions. The wetting of glass and similar surfaces by the metal is attributed to the presence of traces of the oxides. Gallium does not react with water at temperatures up to roo° C. but reacts slowly with hydrochloric and other mineral acids. The action of nitric acid is slow at room temperatures for, like aluminum, gallium becomes passive. The passivity is probably attributable to the formation of a protective film of the oxide, which on the liquid metal is tenacious and somewhat elastic. Hot nitric acid and aqua regia react on the metal more rapidly. Gallium is amphoteric and reacts with sodium or potassium hydroxide solutions, forming a gallate and liberating hydrogen. The halogen elements attack vigorously.

Compounds. — In most of its compounds gallium is trivalent; a few divalent salts, in particular the halogens, are known. There is no evidence of a monovalent gallium except in the sulfide, Ga_2S, and possibly the selenide, Ga_2Se.

All four of the trihalides of gallium are known. The hydrated fluoride, $GaF_3.3H_2O$, is prepared from gallic hydroxide and hydrofluoric acid; the anhydrous gallic fluoride is made by heating the complex salt. ammonium fluorogallate, $(NH_4)_3GaF_6$, in a stream of fluorine. The chloride, $GaCl_3$, the bromide, $GaBr_3$, and the iodide, GaI_3, are prepared by treatment of the metal with the respective halogen elements. The latter three gallic halides volatilize at relatively low temperatures and may be purified by distillation in *vacuo*. They dissolve in water but are extensively hydrolyzed. In the vapour phase the chloride, the bromide and to a lesser degree the iodide are dimeric and probably have bridge structures. Gallic chloride has been found to be more effective than aluminum chloride as an acid catalyst in the Friedel-Crafts synthesis of benzophenone and similar reactions. The anhydrous gallic fluoride. GaF_3, sublimes at temperatures above 800° C. and is only slightly soluble in water. The trihalide molecules are electron pair acceptors and thus classified as Lewis acids.

Gallium hydroxide. $Ga(OH)_3$, is amphoteric but slightly more acid than its aluminum analogue and when heated decomposes to the oxide. Ga_2O_3. Other trivalent gallium salts are: the sulfate, $Ga_2(SO_4)_3$, which forms alums with the sulfates of ammonium or the alkali metals; the nitrate. $Ga(NO_3)_3$; the perchlorate, $Ga(ClO_4)_3$; the sulfide, Ga_2S_3; and the nitride, GaN.

On the basis of electronic configuration) the existence of divalent gallium compounds seems improbable, yet several halides, the sulfide and probably the oxide have been prepared. Gallous chloride, $GaCl_2$, originally prepared by Lecoq de Boisbaudran, decomposes into the trichloride and the metal when heated above 200" C. Vapour density studies indicate the presence oi a considerable number of molecules of $GaCl_2$ with some polymers. Since the solid dichloride is diamagnetic. it is inferred that the polymers have Ga-Ga linkages. The fused salt is a conductor of electricity, dissolves in benzene but reacts with water, liberating hydrogen. Gallium dibromide and diiodide have also been prepared.

A hydride. Ga_2H_6, a methyl hydride, $Ga_2(CH_3)_4H_2$ and a methyl borohydride, $(CH_3)_2GaBH_4$, of gallium have been reported. Gallium forms a number of compounds with organic groups; *e.g.*, gallium trimethyl, $Ga(CH_3)_3$; triethyl, $Ga(C_2H_5)_3$; triphenyl, $Ga(C_6H_5)_3$; gallium acetylacetonate, $Ga(C_7H_5O_2)_3$; and a number of chelated oxy-compounds.

GALL MIDGE, any member of the family Cecidomyiidae of the order Diptera (*q.v.*); minute. delicate flies with beaded antennae and few veins in the very short-haired wings. The larvae are frequently orange in colour and live in flowers, axils of leaves and in the leaves themselves, usually causing the formation of galls, some of which are inconspicuous; pupation takes place in the gall or in the soil; the winter is passed in the immature stages. A few are beneficial, the orange-coloured larvae of *Aphidoletes* being predaceous on plant lice or aphids, hiding in axils of leaves or under the aphid colonies during the hot part of the day. A great many kinds are injurious to crops and ornamentals. The Hessian fly (*q.v.*) is the most serious pest. The chrysanthemum midge, *Diarthronomyia hypogaea*, attacks these plants in Europe and North America, making small galls in the leaves; in northern latitudes they occur chiefly in greenhouses. Nicotine spray is used to control them. The rose midge, *Dasyneura rhodophaga*, infests the young buds and shoots of roses in greenhouses and is a serious pest, occurring but rarely outside. Some other serious pests are the wheat midge, sorghum midge, rice midge, clover midge, pear midge. Tobacco fumigation and use of dust on soil controls them. The pine cone gall on willow results from the bunching of the terminal growth. The beneficial ones are predaceous on mites, scale insects and bark beetle larvae, in addition to aphids.

For classification *see* E. P. Felt, *Key to American Gall Insects*, New York State Museum, Bull. No. zoo (1918). (C. H. CN.)

GALLON, an English measure of capacity, usually of liquids, but also used as a dry measure for grain. A gallon contains four quarts. The word was adapted from an O.h'or.Fr. *galon*, Central Fr. *jalon* and was Latinized as *galo* and *galona*. It appears to be connected with the modem French *jale*, a bowl, but the ultimate origin is unknown; it has been referred without much plausibility to Gr. γαυλός, "milk pail." The British imperial gallon of iour quarts contains 277.274 cu.in. The old English wine gallon of 231 cu.in. capacity is the standard. gallon of the United States.

GALLOWAY, JOSEPH (*c.* 1731–1803), American colonial statesman and Loyalist, who introduced "A plan of a proposed Union between Great Britain and the Colonies" at the first Continental Congress in Philadelphia, Pa., in 1774, was born at West River, Anne Arundel county. Md., the son of Peter B. Galloway and Elizabeth Rigbie. Galloway studied law in Philadelphia. Beginning practice in 1747, he distinguished himself by pleading cases before the supreme court of Pennsylvania before he was 20 years of age. He married Grace Growdon. daughter of a wealthy provincial councillor in 17j3. In his practice Galloway became an authority on disputed land claims which often involved questions of provincial administration. His prominence was recognized by his election to the Pennsylvania assembly in 1756 where he occupied the powerful post of speaker from 1766 to 177j Probably his interest in colonial governmental theory began with his association with Benjamin Franklin's antiproprietary or Popular party, which endeavoured to tax the large proprietary estates. His writings exhibit a lawyer's concern for precedent and property rights. Galloway's plan of 1774 provided for a president general, appointed by the king, and a colonial legislature, the grand council, which had "like Rights Liberties and privileges as are held and exercised by and in the House of Commons." Members of the legislature were to be selected triennially by the colonial assemblies, and bills could be initiated either in parliament or in the colonial legislature but had to have the assent of both to become law. Galloway's plan was rejected by only one vote after a day's debate. The radicals opposed him because he believed differences between the American colonies and Britain could be solved by a written constitution for the empire rather than by rebellion. Because he thought the Revolution unreasonable and unjust he left Philadelphia and joined Gen. William Howe's army. He returned to the city as a civil administrator during the British occupation, but with the re-entry of the Patriots in 1778 he fled to England where he .remained until his death on Aug. 29, 1803. Although Galloway was a Tory, he was liberal in his views. He has been unjustly criticized by historians who attributed to him a conservative plan of union which was probably written in 1785 by Jonathan Sewell, the New England Loyalist. Galloway drew up several plans of union aiter the Declaration of Independence with the hope that they might be used when the rebels were defeated. These plans consistently demonstrate his respect for representative government. His appeal was addressed to men's judgment and reason, not to their emotions. Galloway was, perhaps, the greatest of the colonial Loyalists, a man who was exiled from his wife. his estates and the country of his birth because of his convictions.

Boyd, *Anglo-American Union* (Philadelphia, 1941) ; Oliver C. Kuntzleman, *Joseph Galloway, Loyalist* (Philadelphia,1941). (W. R. J.)

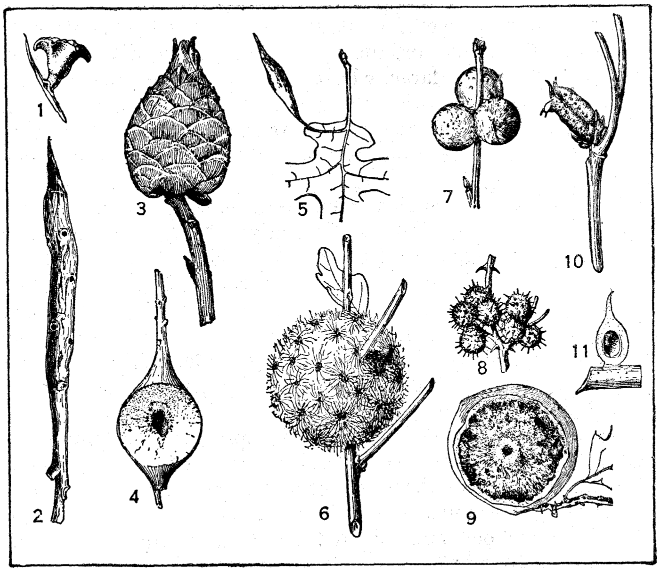
GALLOWAY, a district in southwest Scotland, comprising the counties of Kirkcudbright (East Galloway), Wigtown (West Galloway) and, until the end of the 12th century, Carrick (now part of Ayrshire). The name is derived from the Gallgaidhel or Gallwyddel, who were the Celtic Gauls of this region and the Novantae of the Romans. The last "king" of Galloway died in 1234, and during the 14th century the Baliols and Comyns were the chief families! succeeded about 1369 by the Douglases (until 1458) and in 1623 by the Stewarts. The polled black Galloway cattle are indigenous.

GALLOWS: *see* CAPITAL PUNISHMENT; *HANGING*.

GALLS. Galls are enlargements or hypertrophies of plant parts or organs caused by insects, mites. bacteria, fungi and possibly other organisms. The work of leaf and other miners and distortions of plant parts are not included except where there are enlargements or thickenings of tissue.

How Galls Are Produced.—Galls may be produced by either mechanical or chemical stimulus. An excellent example of the former is seen in stem swellings on roses caused by the closely placed spiral galleries of the rose stem girdler, *Agrilus viridis.*

Chemical stimulation is important, probably most important in the production of galls, although it may be supplemented by directive feeding or stimulation. The irritant fluid may be in the egg, as in sawflies, since the galls are full size before the eggs hatch. The ash midrib gall produced by *Contarinia canadensis* is evidently caused by larval or maggot fluids since there is no eroding, and size is proportional to the number of larvae.



FROM FELT, "PLANT GALLS AND GALL MAKERS" (COMSTOCK PUB. CO.)

TYPICAL GALLS CAUSED BY INSECTS

1. Flower-like gall on cypress. 2. Willow-twig gall. 3. Willow pine-cone gall. 4. Goldenrod ball gall. 5. Stemmed oak gall. 6. Wool-sower gall on oak. 7. Oak bullet gall. 8. Spiny rose gall. 9. Oak apple. 10. Blasted oak bud gall. 11. Hackberry flask gall

The eggs of the chrysanthemum midge, *Diarthonomyia hypogaea,* and of hickory leaf gall midges, *Caromyia* species, are deposited on leaf surfaces, rhe larva irritating the tissues and eventually becoming enclosed in a gall. Plant lice galls grow up around and enclose their producers.

Location and Form of Galls.—Insect galls occur upon all parts of plants including the flowers, even stamens in some cases, the fruit or leaf buds, branches, trunks and roots. They develop in or from the meristematic or softer growing tissues, such tender parts as buds and developing leaves. Twig, branch and root galls mostly originate in the cambium or meristem.

The structure of highly developed galls is suggestive of a seed. The gall maker occupies the place of the seed. The nutritive layers surrounding the gall maker are aaalogous to those of the embryo seed. The outer layers in both are protective. They may bear abundant plant hairs or spines. The development is somewhat comparable to that of buds.

There is a possible significance in the lobed splitting of the hickory leaf stem gall with its suggestion of the divided shuck of the nut. Some galls ripen and droplike seeds, namely, the hickory tube gall and the jumping, occasionally abundant "flea seeds" of western oaks.

The pear midge, *Contarinia pyrivora,* and the birch seed midge, *Oligotrophus betulae,* are fruit or seed infesting insects. The many species of gall wasps belonging to the genus *Neuroterus* produce a large variety of leaf galls on both European and hmerican oaks. The grape phylloxera, *Phylloxera* or *Peritymbia vitifoliae,* develops in leaf and root galls, the latter most injurious to European grapes.

The size and shape of galls are extremely variable. The largest, *Andricus championi,* has a diameter of more than 4 in. Globular galls vary in internal structure. The interior may be mostly hard tissue as in bullet galls, *Disholcaspis* species. The oak apples, *Amphibolips* species, have a thin outer shell and a spongy interior. The central cell may be supported by threads or, as in *Andricus palustris,* free-rolling.

The stemmed spindle shape in *Andricus pedicellatus* on oak and *Rhopalomyia pedicellata* on goldenrod are suggestive of modified leaves. Conical, cylindrical, disk-shaped or saucer-shaped galls, "oak spangles," are relatively common on oak and hickory leaves. Fig-shaped galls may originate from a common center and form a segmented sphere. The gall of the wool-sower, *Callirhytis seminator,* is a mass of stemmed hairy cells, the pink and white filaments interlacing to form a daintily tinted sphere nearly 2 In. in diameter and encircling cak twigs.

The determinate galls are produced mostly by the more highly developed insects such as gall wasps or Cynipidae.

Deiormations of growing tips of galls vary from plainly aborted buds to large swellings of the terminal parts, as in the cone flower gall, *Asphondylia conspicua.*

The willow wheat ear gall, *Rhabdophaga triticoides,* dwarfs sterns normally several feet in length to irregular swellings 3-4 in. long.

The open-mouthed galls, mostly globular or conical in shape, are pioduced by aphids or gall mites, the latter with the entrance guarded by plant hairs.

The indeterminate galls are mostly irregular swellings, the shape being modified largely by the vigour of the plant and the degree of infestation.

The hairy or pilelike growths, *erineums,* upon leaf surfaces are produced by plant mites or Eriophyids. They may be identified by the usually yellowish microscopic mites.

Geographical Distribution of **Galls.**—Plant galls occur in most places where plant life exists. They are more abundant in areas where there is a large and varied flora. A series of general works on galls appearing between 1911 and 1933 permits general comparisons. The total number of galls listed in these works from the various areas approximates 1400–1500 each for the Netherlands Indies, southern Europe, North America and South and Central America, with 1100 listed for Europe.

Gall Maker Preferences.—The general works cited below indicate gall maker preferences and the close relation between producers and plants. In southern Europe 569 galls are listed on willows and only 115 and 117 in North America and Moravia respectively. On the beeches and oaks of Asia there were 304, in southern Europe, 993, in North America, 419 and in Moravia, 143 galls. The data for rose galls were 109, 499, 130 and 113 and for the composites, 181, 660, 182 and 41, respectively.

The 419 Cynipid galls in the oak family in North America in 1918 was raised to 740 in E. P. Felt's *Plant Galls and Gall Makers* (1940). Many unknown galls await discovery.

Marked food preferences are indicated in *Plant Galls and Gall Makers.* In the beech family there are 740 Cynipid galls, all but 9 on oak and 39 midge galls; for the rose there are 41 and j6 respectively, while in the composites there are 17 gall wasps and 172 gall midges. The records show species of *Rhabdophaga* limited mostly to willow, *Cincticornia* to oak, *Caryomyia* and *Phylloxera* to hickory.

Gall Makers.—Gall wasps are highiy specialized, small four-winged insects with a strongly compressed abdomen. The maggots are usually white and without a distinct head. Gall wasps attack plants referable to only 6 botanical families and assignable to less than 20 plant genera. In America nearly 750 produce galls on oak, 34 on acorns or the acorn cup, 21 in flowers, 275 in leafy structures, 175 in woody galls, 45 in buds and 41 on roots.

The gall wasps, *Diplolepis* or *Rhodites,* produce 65 galls on plants of the rose family, 50 being on rose.

Gall midges, delicate two-winged flies usually yellowish or reddish, sometimes darker and with marked structural variations, are represented by a long series which produce mostly closed galls upon a great variety of plants. They occur in 69 of the 78 plant families attacked by gall insects. The larvae are mostly yellowish, with a distinct head and usually with a breastbone or anchor process. Many midge larvae winter in the galls. A few desert them in the spring and enter the soil prior to transforming.

Most of those in the softer leaf and fruit tissues drop and winter in the ground. Food preferences are indicated by the 37 species on willow, 37 on oak, j6 on the rose family, 25 on the pulse family, 21 on the vine family and 172 on various composites.

The beetles, Coleoptera, and moths, Lepidoptera, produce only a few plant galls, mostly the result of mechanical injury.

Plant lice, winged or wingless. with a proboscis and honeytubes, produce relatively few galls. The 29 species of *Phylloxera* on hickory, 7 *Adelges* on spruce and 5 *Pemphigus* on poplar represent better-known forms.

The 9 species of jumping plant lice, *Pachypsylla,* are limited to hackberry.

Plant mites are microscopic in size, pale yellowish or orange coloured. pear shaped and with but four legs. They produce relatively simple, mostly open galls in buds and on leaves and occur upon a large variety of plants; 158 galls are recorded from 38 of the 78 plant families.

A number of deformities such as the black knot, *Plowrightia morbosa,* on plum, and the cedar apple, *Gymnosporangium virginianiae,* and witches'-brooms on various trees are produced by fungi.

Diverse appearing blister-like thickenings on the leaves of aster and Solidago are produced largely by gall midges, *Asteromyia,* and not by fungi.

Crown gall, *Pseudomonas tumifasciens,* causes the very prevalent clown gall, mostly root infections.

The large woody swellings on the trunks of such trees as spruce, fir, poplar, oak and hickory are believed to be bacterial in origin.

Alternation of Generations. — This exists in many gall wasps or Cynipidae. The relationship was suspected by H. F. Bassett, an American, in 1873 and demonstrated in 1875 by Dr. H. Adler. The oak potato gall, *Neuroterus batatas,* and the noxious oak gall, *Neuroterus noxiosus,* develop in similar deformities, the perfect generation appearing in the summer and that represented only by females in early spring. A marked difference in the galls produced by the two generations of *Plagiotvochus punctatus,* occurs in the irregular twig swellings of oak and the blister-like leaf galls on or near leaf veins.

A relatively large number of both U.S. and European oak gall wasps have alternating generations. The relation between the tuo generations has been established for comparatively few. The series of galls on roses produced by Cynipids, *Diplolepis* or *Rhodites* have no alternate generation.

There is an approach to an alternation of generations among certain gall producing aphids except that it is an alternation of a series of generations. In the spiny witch hazel gall, *Hamamelistes spinosus,* the alternate series cause irregular corrugations on birch leaves.

The spruce gall aphid, *Adelges abietis,* is well-known in the U.S. because of the abundant pineapplelike gall on Norway spruce. The woolly aphids, *Adelges cooleyi,* on the needles of Douglas fir, produce the long cone gall on the Colorado blue spruce. The aphids from the globular, lipped leaf-stem gall of poplars, *Pemphigus populitransversus,* migrate in summer to the roots of cruciferous plants, cabbage, rape and turnip.

Honeydew Producing Galls.—A considerable series of galls produce honeydew. The sweetness of the ribbed bud gall of *Callirhytis gemmaria* draws swarms of insects in early sutnmer. The pip galls of the fall form of *Callirhytis operator* are also attractive. Several hickory leaf galls, *Caryomyia* species, are sticky with a sweet secretion. L. H. Weld states that the galls of *Disholcaspis eldoradensis* on *Quercus lobata* produce so much honeydew that bees in California may store 30-40 lb. of honey per hive from this source.

Galls Commercially Valuable.—The Eurasian *Cynips gallae-tinctoriae* produces the well-known gall nut of commerce containing 65% tannic acid. An eastern acorn gall contains 50% tannic acid. A Chinese sumac gall contains over 60% tannic acid and is produced by a species of *Pemphigus* related to the American *Pemphigus rhois.*

Some insect galls are used in medicine because of their astringent properties and a few serve as food, such as the catmint gall of *Aylax glechomae.*

A black oak gall, *Dryoscosmus deciduus,* is so abundant some years in Missouri and Arkansas as to constitute an important food for chickens, turkeys, cattle, hogs and sheep.

Injurious Gall Insects. — These are mostly introduced, prolific and relatively free from natural enemies. The Hessian fly *Phytophaga destructor,* and the wheat midge, *Thecodiplosis mosellana,* have destroyed large wheat areas. The clover-head seed midge, *Dasyneura leguminicola,* prevents the growing of clover seed in sections. Fruit trees are injured by the pear blister mite, *Eriophyes pyri,* the pear midge. *Dasyneura pyri,* and the closely related apple midge, *Dasyneura mali*

Severe losses to greenhouse men are caused by the rose midge, *Dasyneura rhodophaga,* the violet midge. *Phytophaga violicola,* and the chrysanthemum midge, *Diarthronomyia hypogea.*

Horticulturists are troubled by the spruce gall aphid, *Adelges abietis,* on the Norway spruce and a similar gall, *Adelges cooleyi,* on the Colorado blue spruce. The branch galls on oak caused by species of the *Plagiotrochus* are unsightly though usually not seriously injurious The killing of buds by gall wasps, notably *Neuroterus minutus,* may be serious.

Natural Enemies.—Gall insects in spite of their protecting shelters are attacked by considerable series of small parasites and in the gall midges there are slender predaceous larvae which prey on the gall producers Birds eat galls, notably the oak pill gall The large oak apple is fed on by gray squirrels. Mice gnaw into the goldenrod stem galls produced by *Gnorimoschema.* Woodpeckers drill the globular stem galls of *Eurosta solidaginis.*

Collecting and Rearing Gall Insects. — The collection and study of plant galls is easy and fascinating. Those with woody tissues require no special preparation. Many noody galls and herbaceous bud galls produce insects in the early spring. Keep the galls in containers at room temperatures, fairly moist and out of the sun. The rearing of species which winter in the earth is more difficult since it is difficult to provide normal conditions and not include other species in the soil or debris of the rearing jar. A good microscope is necessary as well as a collection and articles on the group studied Comprehensive, well illustrated guides are the most helpful for beginners.

GALLUP, a city of northwest New Mexico, U.S., at an altitude of 6.514 ft., on the Puerco river, about 20 mi. from the Arizona line and 140 mi. W.N.W. of Albuquerque; the seat of McKinley county. The city was established in 1882 and named for David L. Gallup, paymaster for the Atlantic and Pacific railroad. Prior to that time it served as a Westward Overland stagecoach stop. It was incorporated in 1891.

Gallup's economy is primarily mercantile; it serves as a trading centre for the Navaho and Zuñi Indians in a trade area exceeding 15,000 sq.mi. The city's leadership in the field of Indian arts and crafts and its proximity to Indian reservations and national parks and monuments have also established it as a tourist centre. At the Intertribal Indian ceremonials, held each year in August, southwestern Indians from as many as 40 different tribes present their ceremonial dances and display their native arts and crafts. For comparative population figures *see* table in New Mexico: *Population.*
(J. G. O'C.)

GALLUPPI, PASQUALE (1770–1846), Italian philosopher, was born at Tropea, in Calabria. He was professor of logic and metaphysics at Naples. Galluppi's works, which have importance in the history of Italian philosophy, include: *Sull' analisi e sulla sintesi* (1807); *Letters filosofiche* (1827); *Saggio filosofico sulla critica della conoscenza* (1819–32); *Filosofia della volontà* (1832–42, incomplete); *Considerazioni filosofiche sull' idealismo trascendentale* (1841), a memoir on the system of Fichte; *Storia della filosofia* (i. 1842).

GALLUS, GAIUS CORNELIUS (*c.* 70–26 B.C.), Roman soldier and poet, is famous for his four books of poems to his mistress "Lycoris" (the actress Volumnia; stage name, Cytheris). He also translated works of the Greek poet Euphorion. Born at Forum Julii (Fréjus on the French riviera coast). he was a friend of Augustus and Vergil and, having distinguished himself in the war against Mark Antony. was made governor of Egypt. There, however, his imprudent conduct led to his disgrace and suicide. The lass of his works is regrettable, for Quintilian ranks him with Tibullus Propertius and Ovid as one of the great Roman elegists. Vergil celebrated him in the tenth *Eclogue,* which contains many echoes of his poetry, and Parthenius dedicated to Gallus his book on unhappy love affairs. (E. J. KY.)

GALLUS, G. VIBIUS TREBONIANUS, Roman emperor A.D 251–253 or 254, held a command in the army that opposed the first invasion of the Goths in 251, and, according to a possibly inaccurate tradition, contributed by his treachery to the disaster that followed, in which Decius and Herennius were killed. Gallus uas then elected emperor and made peace with the invaders, who kept their plunder and were offered a tribute to bribe them not to return; it is the disgrace with which this treaty covered his name that makes the tradition of his earlier conduct suspect. In 252 fresh hordes arrived but were routed by Aemilianus whom his troops proclaimed emperor. Gallus went to meet him, but was defeated and killed at Interamna.

GALOIS, ÉVARISTE (1811–1832), French mathematician famous for his contributions to higher algebra, gave his name to the Galois theory of groups. He was born Oct. 25, 1811, at Bourg-la-Reine, where his father was mayor, and entered the Lycée Louis-le-Grand in Paris in 1823. Despite his genius for mathematics he was evidently a difficult student. He failed twice in the entrance examinations to École Polytechnique; he was accepted at the École Normale in 1830 but expelled the same year for a newspaper letter about the actions of the director during the July Revolution. In 1831 he was arrested for a threatening speech against King Louis Philippe, but acquitted; then shortly afterward he mas sentenced to six months in jail for illegally wearing a uniform and carrying weapons. He died May 31, 1832, when only 20 years old, from wounds received in a duel, possibly with an *agent provocateur* of the police.

Galois published onlv a few small papers; three larger works on the theory of equations were refused by the French Academy. Knowledge of his mathematical achievements stems mainly from a letter to his friend Auguste Chevalier written on the eve of his fatal duel and from posthumous manuscripts. Nevertheless, the Galois theory of groups has become one of the most penetrating concepts of modern mathematics. In the letter to Chevalier, published in the *Revue Encyclopédique,* Sept. 1832, Galois outlines the content of three mathematical treatises. One concerns elliptic integrals and the integrals of aigebraic functions. The other two, one of which was completed ("Mémoire sur les conditions de résolubilité des equations par radicaux"), deal with the theory of equations. Galois emphasizes the use of domains of rationality to which ail roots of the given equation have been adjomed, now called Galois fields Next he introduces the fundamental concept of the (Galois) group of an equation, consisting of all the permutations of the roots which may be applied to any existing rational relations between them. In modern form this leads to the one-to-one correspondence between the subfields of the Galois field and the subgroups of the Galois group. Galois applies the theory to express a general condition for the solvability of equations by radical expressions. Among other concepts associated with Galois's name are the Galois imaginaries, now usually considered as the elements of finite fields.

GALOP, a spirited dance of German origin in 2–4 time. It was introduced into Paris in 1829 and subsequently became a favourite dance of the Victorian era.

GALSWORTHY, JOHN (1867–1933), British playwright and novelist and Nobel prize winner in literature, was born at Coombe. Surrey, on Aug 14, 1867. Educated at Harrow and New college, Oxford, he was called to the bar in 1890, but devoted himself to literature. His first novel, *Jocelyn,* appeared in 1898, but he attracted wider attention in 1904 with *The Island Pharisees,* and *The Man of Property* (1906). The latter uas the first novel of the sequence to be known as *The Forsyte Saga,* the others being *The Indian Summer of a Forsyte* (1918), *In Chancery* (1920), *Awakening* (1920), and *To Let* (1921). As a detailed picture of upper middle-class society during the later Victorian and Edwardian eras. the sequence is a remarkable achievement. That picture was supplemented by the greater number of Galsworthy's other novels. of uhich it is the characteristic social setting. among them *The Country House* (1907), *Fraternity* (1909), *The Patrician* (1911). *The Freelands* (191j).

In 1924 Galsworthy published *The White Monkey,* the first volume of a new trilogy which endeavoured to do for London after World War I uhat *The Forsyte Saga* had accomplished for a generation uith more certain standards. Soames Forsyte appears in all three of the new series—The *Silver Spoon* (1926) and *Swan Song* (1928) being the other two. The new trilogy, together with two interludes, was collected in 1929 under the title of *A Modern Comedy.* The whole work is rather erratic in form. Galsworthy's sympathy with youth and beauty is tenderly displayed in *The Silver Spoon;* but the new world was too much for him. and much of all three books betrays passing reactions of an observer in a changing world rather than deeper reflections on human nature. Galsworthy's later novels were *On Forsyte 'change* (1930); *Maid in Waiting* (1931) and its sequel *Flowering Wilderness* (1932); and the posthumous *Over the River* (1933). He also wrote *The Dark Flower* (1913) and short stories, collected as *Caravan* (1925); essays; and a wartime commentary, *The Burning Spear.*

As a dramatist also, Galsworthy enjoyed a deserved fame. His plays, for the most part, are based on ethical or social problems and are marked by a scrupulously judicial effort to display the opposing points of view typified by his characters. Some have partaken too much of this scrupulousness to be counted as having an essentially dramatic quality, but at their best Galsworthy's plays reflect a keen sense of dramatic values.

Galsworthy was the first English dramatist of importance to adopt a strictly natural style of dialogue, in strong contrast to the laboured, rather stagey style favoured by A. W. Pinero and the dialectically charged manner of G. B. Shaw. In consequence his plays do not read so well, and unless acted by players of exceptional gifts, they are too easily infected by the commonplace, prosaic quality which is so characteristic of the spoken English of his day, especially the spoken English of the inarticulate upper and upper middle class which figure largely in his theatre. In *Escape* (1926) Galsworthy experimented in a technique suggested by the cinematography. Among his plays are *The Silver Box* (1906), *Joy* (1907), *Strife* (1909), *Justice* (1910), *The Pigeon* (1912), *The Eldest Son* (1912), *The Fugitive* (1913), *The Skin Game* (1920), *Loyalties* (1922), *The Forest* (1924). He was awarded the Order of Merit. June 3, 1929.

See S Kaye-Smith, *John Galsworthy* (1916); André Chevrillon, *Trois Études Anglaises* (1924); L. Schalit, *John Galsworthy* (1928).

GALT, SIR ALEXANDER TILLOCH (1817–1893), Canadian statesman, was the youngest son of John Galt (*q.v.*), author. Born in London on Sept. 6. 1817, he emigrated to Sherbrooke in Canada in 1835, where he entered the service of the British American Land company, of which he rose to be chief commissioner. Later he was one of the contractors for extending the Grand Trunk railway westward from Tordnto. In 1849 he became Liberal member for the county of Sherbrooke, but opposed the chief measure of his party, the Rebellion Losses bill, and signed a manifesto in favour of union with the United States, believing that in no other way could Protestant and Anglo-Saxon ascendancy over the Roman Catholic French majority in his native province be maintained. The same year he retired from parliament but re-entered it as chief representative of the English-speaking Protestants of Quebec province (1853–72).

On the fall of the Brown-Dorion administration in 1858 he was called on to form a ministry. but declined and became finance minister under Sir John Macdonald and Sir George Cartier on condition that the federation of the British North American provinces should become a part of their program. He was finance minister, 1858–62 and again in 1864–67; he introduced the decimal system of currency and adopted a policy of protection to Canadian manufactures. To his diplomacy was attributed the coalition in 1864 between Macdonald, Brown and Cartier, which carried the federation of the British North American provinces, and throughout the three years of negotiation which followed his was one of the chief influences.

He became finance minister in the first Dominion ministry, but resigned on Nov. 4, 1867. After his retirement he gave intermittent support to the administration of Sir John Macdonald, but advocated independence as the final destiny of Canada. In 1877 he was the Canadian nominee on the Anglo-American fisheries commission at Halifax. In 1880–83 he was Canadian high commissioner to Great Britain. During this period he advocated imperial federation. He was Canadian delegate at the Paris Monetary Conference of 1881, and to the International Exhibition of Fisheries in 1883. From this date until his death on Sept. 19, 1893. he lived in retirement. (W. L. G.; X.)

GALT, JOHN (1779–1839), Scottish novelist, was born at Irvine, Ayrshire, and educated in his native town and at Greenock. In 1804 he settled in London. Charged with a commission from a merchant firm to find methods of evading the Berlin and Milan decrees, he was traveling in the Mediterranean when he met Byron and Hobhouse at Gibraltar. He traveled with Byron to Malta, and met him again at Athens. In 1814 he visited France and Holland on similar business for a Glasgow firm. In 1826 he went to America as secretary of the Canada Land company. Galt opened up a road between Lakes Huron and Erie through the forest country, and founded Guelph in Upper Canada. The town of Galt was named after him. But, though his work was successful, he returned home practically a ruined man. All his life he had been a voluminous writer, and he now devoted himself entirely to literature. The last years of his life were spent at Greenock, where he died on April 11, 1839.

His masterpieces are *The Ayrshire Legatees* (1820), *The Annals of the Parzsh* (1821). *Sir Andrew Wylze* (1822), *The Provost* (1822), *The Entail* (1823) and *Lawrie Todd* (1830). *The Ayrshire Legatees* gives. in the form of letters. the adventures of the Rev. Pringle and his family in London. The letters are made the excuse for endless tea parties and meetings of kirk session in the rural parish of Garnock. *The Annals of the Parish* are told by the Rev. Micah Balwhidder, Galt's finest character. This work (which existed in manuscript before *Waverley* was published) is a humorous and truthful picture of the old-fashioned Scottish pastor and the life of a country parish. In *Lawrze Todd* the life of a Canadian settler is depicted with imaginative power.

GALTON, SIR FRANCIS (1822–1911), English scientist, explorer and anthropometrist, best known as the initiator of the study of eugenics, was born of Quaker ancestry on Feb. 16, 1822, near Sparkbrook, Birmingham. A cousin of Charles Darwin, he was educated at Birmingham General hospital, King's college, London, Trinity college, Cambridge. and St. George's hospital, London. After traveling in the Balkans, Egypt, the Sudan and the Levant, he undertook a 1,700-mi. journey in southwest Africa (1850–51), later visiting Spain. He received the Royal Geographical society's annual gold medal for his African explorations in 1853 and was elected a fellow of the Royal society in 1856. The following year he settled in London to devote himself to science, the latter part of his life being chiefly concerned with eugenics (*q.v.*), or improving the biological make-up of the human species by selective parenthood. In his analysis of men of famous families, given in his classic *Hereditary Genius* (1869), he tended to underestimate the role of social environment in the development of the individual.

In 1863 Galton indicated the significance in meteorology of anticyclones. a term coined by him. He was a pioneer in the development of composite photographs and in the use of fingerprints for personal identification. To interpret his numerous "family records" and the data obtained for more than 9,000 subjects examined in the anthropometric laboratory he established at the International Health exhibition in London, 1884–85, he devised new statistical methods, culminating in the correlational calculus, perhaps his greatest scientific achievement. The family records provided him with material for the quantitative assessment of heredity through correlating the physical and mental attributes of kinsmen, and his recognition that two characters measured on an organism are not independent but associated arose from his interest in anthropometry. His investigations of identical twins and of sterility arising from marriage with heiresses (who as sole issue of unprolific parents might tend themselves to be infertile) are of particular importance. He was knighted in 1909. He died at Haslemere on Jan. 17, 1911, leaving an endowment for a chair in eugenics at the University of London.

Galton's other principal works are *English Men of Science* (1874); *Inquiries Into Human Faculty* (1883); *Noteworthy Families* (1906); *Essays in Eugenics* (1909).

See his *Memories of My Life* (1908); Karl Pearson's *Life of Francis Galton,* 4 vol. (1914–30); C. P. Blacker's *Eugenics: Galton and After* (1952). (*J. C* TR.)

GALUPPI, BALDASSARE (1706–1785), Italian composer, was born on Oct. 18, 1706, on the island of Burano near Venice, and was named I1 Buranello His father, a barber, and violinist at the local theatre, was his first teacher. He studied at the Conservatorio degli Incurabili at Venice, under Antonio Lotti. After producing two operas in collaboration with G. B. Pescetti, in 1728 and 1729, he began to compose operas for the Venetian theatres, writing sometimes as many as five in a year. He visited London in 1741, and arranged a *pasticcio, Alexander in Persia,* for the Haymarket. Burney considered his influence on English music to have been very powerful In 1740 he became *vice-maestro di cappella* at St. Mark's and *maestro* in 1762. In 1749 he began writing comic operas to libretti by Goldoni, which enjoyed an enormous popularity. He was invited by Catherine II. in 1766 to Russia where he composed his opera *Ifigenia in Tauride* (1768). He returned to Venice in 1768, where he had held the post of director of the Conservatorio degli Incurabili since 1762. He died on Jan 3, 178j.

Galuppi's best works are his comic operas, of which *Il Filosofo di Campagna* (1754), known in England as *The Guardian Trick'd* (Dublin, 1762) was the most popular. His melody is attractive rather than original, but his workmanship in harmony and orchestration is generally superior to that of his contemporaries. He was one of the first to extend the concerted finales of Leo and Logroscino into a chain of several separate movements, working up to a climax.

GALVANI, LUIGI (ALOISIO) (1737–1798), Italian physiologist, an early experimenter in electricity, was born at Bologna on Sept. 9, 1737. He was appointed lecturer in anatomy at Bologna in 1762, and gained repute as a comparative anatomist from his researches on the organs of hearing and genitourinary tract of birds. He enunciated his theory of animal electricity in 1791. In the course of some experiments on frogs he had noticed what appeared to be a correlation between muscle twitching and simultaneous contact with both iron and copper. He proceeded to construct a device of two different metals; one metal he placed in contact with a frog's nerve, the other with a muscle; contraction of the muscle occurred. In Galvani's view the contraction was the result of the union, by means of the metallic "arc," of the arc's (exterior) negative electrical charge with positive electricity traveling along the nerve from the inner nerve substance (a process named galvanism). He had, of course, produced an electric current. Galvani died at Bologna on Dec. 4, 1798.

GALVANIZED IRON AND STEEL. A zinc coating applied to iron or steel protects it against rusting by sealing it from the atmosphere and is commonly known as galvanizing.

When porosity develops in the coating with age. if discontinuities of the coating occur, galvanic (electrolytic) action ensues and then protection of the steel is by sacrificial corrosion action, the zinc being the anode and the steel the cathode. (See ZINC: *Applications.*) When a galvanized coating has been properly applied protection from atmospheric corrosion may last for 1j to 30 years or more.

Zinc is applied by two general methods: hot dipping and electrolytic deposition, the former representing the bulk of the application. This article deals with the industrial processes used in galvanizing.

For production and uses of galvanized iron and steel see SHEETS, IRON AND STEEL; WIRE.

HOT-DIP PROCESSES

There are three general hot-dip processes: (1) hand dip for small steel articles; (2) mechanized operations for continuous sheet coating; (3) continuous-wire galvanizing. Other specific methods are sherardizing and metal spraying.

Before galvanizing, the object must be cleaned to remove oil or grease lubricants by immersion in weak alkali solutions or by vapour degreasing. After cleaning, the object is descaled (pickled) and then passed into the molten zinc.

Pickling. — Sulfuric acid solution (60° C.) is generally used at a concentration of 5% to 20%. This acid acts galvanically and to some extent chemically, and mechanically causes dislodgment of the scale, which after its separation is insoluble.

Hydrochloric acid (5% to 10%) acts chemically on both the scale and the underlying metal. Hence a greater loss of steel is sustained when this acid is used.

Inhibitors are used to avoid excessive acid attack of the steel without unduly restricting descaling. These compounds may be

A B

FIG. 1. — DRAWING OF ZINC-IRON ALLOY LAYERS SHOWING (A) SERRATED BOUNDARY BETWEEN ALLOY LAYERS AND OUTER ZINC AND (B) SMOOTH BOUNDARY OBTAINED BY CLEANING

inorganic, such as arsenic, or organic, such as oils, molasses, bran, etc.

Fundamentals. — The cross section of a hot-dip coating (fig. 1) shows the alloy-layer structure between the steel and the zinc, brittle when thick and causing the coating to crack when the sheet is bent. The portion of this multiple layer next to the steel is usually termed $FeZn_3$ or low-zinc alloy. It is frequently invisible or extremely thin. Next is the iron-zinc alloy, $FeZn_7$, high in zinc and forming an irregular boundary with the outer zinc layer which approximates the composition of the zinc bath.

The relation of the iron in the structure to the ductility of the coating lies largely in the smoothness of the boundary between this alloy layer and the outer zinc coating. The smoother and cleaner the steel surface the less rapidly and less irregularly the alloy grows.

If a clean descaled steel sheet is passed through a strong solution of zinc chloride (25%) or zinc ammonium chloride before entering the zinc bath, a thinner alloy layer and more ductile coating is obtained. When the steel surface is not cleaned from sulfates, chlorides or pickling products, the salts are reduced to sponge iron by the action of the molten zinc (a prime source of iron for dross in the zinc bath) and cover the steel surface with irregular jagged points of alloy.

Spangles.—Hot-dip coatings have characteristic crystalline surface patterns known as spangles. The size and shape of these metal crystals are influenced by several factors! principally the surface condition of the steel, the kind and amount of impurities present in the bath, metal additions to the bath and the rate of cooling (see fig. 2). Large spangles may be produced by the addition of metals such as tin and by slow-cooling of the freshly coated sheet.

FIG. 2. — SPANGLES ON SURFACE OF GALVANIZED SHEET STEEL

Effect of Metal Impurities and **Additions.**—Metals commonly present in the zinc bath, other than iron, are cadmium and lead in small fractions of 1%; these impurities come from the ore used in the production of the zinc. Metals commonly added to the bath for specific effect are tin and aluminum and sometimes antimony.

Tin promotes fluidity of the bath and imparts brightness to the coated sheet. Aluminum also promotes fluidity. The formation of thick viscous zinc oxide on the surface of the bath is retarded by a thin layer of aluminum oxide. Aluminum has a further beneficial effect in retarding the reaction between iron and zinc, thereby reducing the thickness of the iron-zinc alloy layer and making the coating more ductile.

Galvanizing Practice. — For actual galvanizing, a welded steel kettle is used to hold the molten zinc and is kept at approximately 8j0° F. by applying heat to the kettle sides (see fig. 3). The cleaned sheet is passed through a box containing a mixture (or compound) of zinc-ammonium chloride flux having a variable composition. This flux, floating in a confined area on the molten zinc bath, serves to evaporate the surface water on the sheet prior to its entrance into the zinc. and also to remove residual oxides. A system of multiple rolls receives and guides the sheet and partly controls the thickness of the zinc deposit. The amount of zinc taken up on the surface of the sheet may vary from one-half to two ounces per superficial square foot, depending upon the kind of process used, the quality of operation and the service intended.

The Effect of Steel Composition.——Great difficulty is experienced in securing a ductile heavy zinc coat on pure iron wire and steel of low carbon content when conventional practice is followed. A continuous process for galvanizing iron and low-carbon steel has been developed and is known as the Sendzimir Zincgrip process ("Armco," American Rolling Mill Co., Middletown, O.). Its aim is to obtain a surface, prior to galvanizing. which is absolutely free from oxides. This is accomplished by forming a thin layer of iron oxide integral with the steel. reducing it in an atmosphere of hydrogen at 1,100° F. and passing the hot strip, in the absence of air, into a relatively small kettle of molten zinc, the temperature of which is maintained by the aforesaid hot strip (see fig. 4).

Wire Galvanizing.—Wire galvanizing is also a continuous process. The wire is drawn through successive pickling, annealing and washing operations. It is frequently dried before passing into the galvanizing pan and is drawn out through wipers of charcoal,

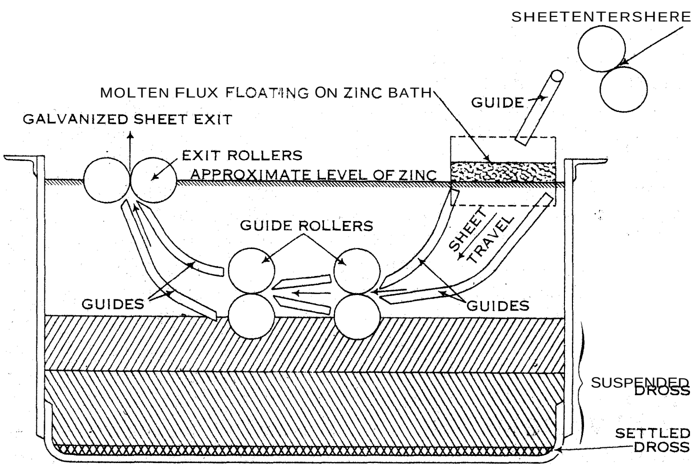

FIG. 3. — SCHEMATIC DRAWING OF SHEET GALVANIZING BATH, HOT-DIP PROCESS

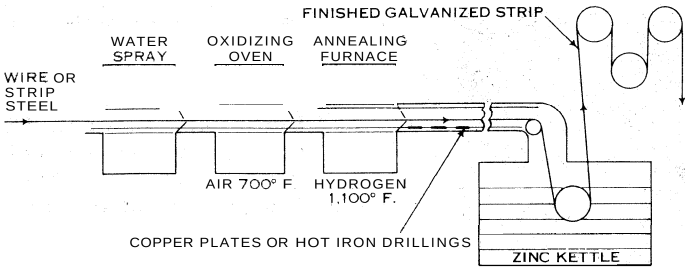

FIG. 4.—SCHEMATIC DRAWING OF ZINCGRIP PROCESS

saturated carbon. coke. sand or asbestos A 20% hydrochloric acid solution at 135° to 150° F is used for pickling, which must be rapid because of the high speed of the wire.

Low-Temperature **Processes.**—*Sherardizing* Process.—This is a process of forming intermetallic compounds of iron and zinc on the surface of a steel article by heating it in the presence of finely divided zinc below the melting point of the zinc.

Metallic Spraying (*Schoop* Process).—This is a process which consists of applying a fine spray of molten zinc to the surface of steel which has been cleaned, roughened, as by sandblasting, and narmed In this process the zinc, in the form of a wire, strip or powder, is fed at a uniform rate through an oxygen-hydrogen or other flame or through an electric arc, and then projected onto the surface to be coated. There are no chemical reactions to form compounds. the zinc adhering directly to the surface.

ELECTROGALVANIZING PROCESSES

The cold or electrogalvanizing process is used for certain classes of work. Its advantages over hot-galvanizing are: (1) greater economy in the use of zinc and somewhat healthier conditions; (2) complete control over thickness of coating; (3) deposition of a coat of pure zinc (no alloy of iron-zinc as found in the hot-dip process); (4) suitability for articles that would be adversely affected by the temperature of molten zinc if coated by the hot-dip process; and (5) no distortion of the coating of flat surfaces as with the hot process.

Its disadvantages are that greater care is required and greater difficulties are encountered in obtaining a correct coat than with hot-galvanizing; for articles that have to be made watertight the electrolytic process does not have the same "soldering" effect as the hot process.

There are two general processes of electrogalvanizing or electroplating (*q.v.*) with zinc, distinguished by (1) soluble anodes in zinc sulfate solution of low acid content; (2) insoluble anodes in zinc sulfate solution of high acid content.

In the soluble anode process the wire or strip is generally annealed by passing it through molten lead; tight scale is generally removed by pickling in hydrochloric acid solution. The coating, being free from the brittle alloy layer, possesses great ductility, uniformity and adherence; the latter is a mechanical bond.

In the insoluble anode process, roasted zinc ore is leached with dilute sulfuric acid, the solution purified and the soluble zinc electroplated on wire (or strip) at high current density. The cathodic deposit from this solution using a lead-silver alloy anode (1% silver) is exceptionally pure (99.99% zinc) and ductile; the galvanized wire can be wound around its own perimeter without cracking.

For annealing, wires enter near the bottom of a pan of molten lead at 1,000° F. and pass upward in an inclined position. As they leave the lead they enter a molten caustic soda bath (700° F.) and are cleaned by cathodic electrolysis. The wires are then washed and pass into the electrolytic zinc cell in which a current of 700 to 1,500 amp. per square foot is applied. The coated wires are washed in water and then highly polished by a rotary mechanism using hard abrasive. Adherence of the zinc coating is greater than by the hot-dip process. (HT. R. H.)

GALVANOMETER. An instrument for measuring an electric (galvanic) current. See INSTRUMENTS, ELECTRICAL MEASURING.

GALVESTON, a city of Texas, U.S., the seat of Galveston county, a major port and resort area on the Gulf of Mexico, is about 50 mi. S.E. of Houston on the east end of Galveston Island, which extends east and west off the Texas coast for about 32 mi. The island is connected to the mainland by causeways, and a super-highway gives rapid access from Houston to Galveston and seven other county communities. Access from the east is by ferry from Bolivar peninsula across Galveston harbour. Pop. (1960) city. 67,175; standard metropolitan statistical area (Galveston county! including Texas City (140,364). (For comparative population figures see table in TEXAS: *Population.*)

Shipping and its allied industries, insurance. banking and resort business are the city's major economic assets. The county's economy was enriched after 1945 by expansion of the petrochemical industries centred at Texas City on Galveston bay. Galveston's port is publicly owned and tax-exempt. Chief exports are cotton. grain and sulfur; imports are sugar, tea and bananas. Wharf facilities are modern.

Early 18th-century maps of the Gulf of Mexico show an island recognizable as Galveston. Later maps name it San Luis. In July 1785. the bay was named Galveston (Galveztown) by Don José de Evía, a Spanish pilot who surveyed the Gulf coast by order of Don Bernardo de Gálvez. governor of Louisiana and, later. viceroy of Mexico. From 1817 to 1821 the privateer Jean Laffite made Galveston his headquarters. In 1836 the Republic of Texas granted Michel Branamour Menard land on the east end of the island. Menard platted a town site whose lots were first sold in 1838 by the Galveston City company. The city was incorporated in Jan. 1839.

Galveston grew ateadily until the American Civil War, but expansion after the war was greater. By 1885 the city had great commercial power. Two factors dislodged it from its leading position: the rise of competitive Texas ports, notably Houston, whose ship channel is entered from Galveston bay. and a destructive hurricane on Sept. 8, 1900. in which over 5.000 lives were lost and much of the city was destroyed. After the storm a 17-ft. high protective seawall was built and the city's grade raised proportionately to the wall's height. The wall is about 8 mi. long and is paralleled by a wide boulevard overlooked by the leading resort hotels.

Galveston's educational facilities include schools of medicine and nursing of the University of Texas. A major cultural asset is Rosenberg library, which serves the county. There is a civic symphony orchestra and a little theatre. The climate is humid but rarely brings extremes of temperature. (T. G. R.)

GÁLVEZ, JOSÉ, MARQUÉS DE LA SONORA (1720–1786), Spanish colonial administrator particularly noted for his work as inspector general (visitudor *general*) in New Spain (Mexico), 1765–71, was born in Vélez-Málaga, Spain. Among his important accomplishments were the reorganization of the tax system, the formation of a government tobacco monopoly, the reorganization of the defenses of the northern frontier of the viceroyalty and the Spanish occupation of Upper California. Upon completion of his inspection he recommended further administrative and fiscal reforms, the most important of which, the intendancy system, was introduced in 1786. Subsequently he was named minister of the Indies (1775) and was granted the title of marquis of Sonora (1785). (L. N. McA.)

GÁLVEZ, MANUEL (1882–), Argentinian novelist and biographer, was born in Paraná on July 18, 1882. Leaving the provincial milieu of his boyhood, he went to Buenos Aires to attend the university. and made that city his perfnanent residence. The founding of the literary magazine Ideas, residence in Europe and an appointment as inspector of secondary schools further enlarged the scope of his observation. Although he used many literary forms, he is most noted for his realistic novels on Argentinian life, especially his early ones: La *maestra normal* (1914), usually judged his best novel, based on customs in the provincial city of La Rioja; El *mal metafísico* (1916), on the materialism of Buenos Aires; La *sombra del convento* (1917), laid in Córdoba; and *Nacha Regules* (1919), dealing with social injustice in Buenos Aires. With a trilogy, "Scenes From the Paraguayan War" (1928–29), Gálvez began a series of historical novels which, together with novelized biographies of Argentinian figures, constituted his main output aiter 1938. The chief features of Gálvez' novels are conscientious documentation of a remarkably wide range of national scenes; concentration on social situations rather than individual psychology; and the injection of ideas into the fictional framework. (A. Cn.)

GALWAY, HENRI DE MASSUE, Marquis de Ruvigny and Earl of (1648–1720), Huguenot soldier who served Britain in Ireland and on the continent, was born in Paris on April 9, 1648, and saw service under Turenne, who thought very highly of him. At the revocation of the Edict of Nantes (1685) he went into exile with his fellow Huguenots and in 1690 entered the service of William III of England as a major general, thereby forfeiting his French estates. In July 1691 he distinguished himself at the battle of Aughrim, a decisive victory for the British, after mhich Ireland submitted to William, and in 1692 he was for a time commander in chief in Ireland. He was created Viscount Galway and Baron Portarlington, and received a large grant of forfeited estates in Ireland.

In 1693, during the War of the Grand Alliance (*q.v.*), he fought at Neerwinden, Belg., and was wounded, and in 1694, with the rank of lieutenant general, he was sent to command a force in English pay which was to assist the duke of Savoy against the French and at the same time to relieve the distressed Vaudois. But in 1695 the duke changed sides, the Italian peninsula was neutralized and Galway's force was withdrawn to the Netherlands. From 1697 to 1701, a critical period of Irish history, the earl of Galway (he was advanced to that rank in 1697) was practically in control of Irish affairs as lord justice of Ireland. After several years spent in retirement, he was appointed in 1704 to command the allied forces in Portugal during the War of the Spanish Succession (*q.v.*); he sustained the post with honour and success until the battle of Almanza in 1707, in which Galway, in spite of care and skill on his own part, was decisively defeated. But he scraped together a fresh army and, although infirm, served in one more campaign. His last service was rendered in 1715, when he was sent as one of the lords justices to Ireland during the Jacobite insurrection. He died on Sept. 3, 1720.

GALWAY, a county in the west of Ireland, in the province of Connaught, bounded north by Mayo and Roscommon: east by Roscommon, Offaly county and Tipperary; south by Clare and Galway bay; and west by the Atlantic ocean. Pop. (1956) 155,553: area 2,293.2 sq.mi.

To the east of Lough Corrib the surface rests on a limestone base and has extensive bogs. Its southern portion is partly a continuation of the Golden vale of Limerick and partly occupied by the Slieve Aughty mountains (highest points, about 1,200–1,250 ft.) in which Silurian and Devonian rocks appear. A broad mass of ice-morn gneiss and granite lies west of Lough Corrib, and its steep edge toward Galway bay suggests an east to west line of fracture. Quartzites, associated mith limestone and mica schist, stand out in "Beanna Beola," or the Twelve Bens or Pins (highest point, 2,395 ft.). The coast is much indented and studded mith islands.

The Suck, which forms the eastern boundary of the county, rises in Roscommon, and, passing by Ballinasloe, unites with the Shannon near Shannonbridge. The Shannon forms the southeastern boundary and, passing Shannon Harbour, Banagher, Meelick and Portumna, swells into the great expanse of water called Lough Derg, which skirts the county to 5 mi. N. of the village of Mount Shannon. The Clare flows southward through the centre of Galway and enters Lough Corrib 4 mi. above the town of Galway. The Ballynahinch, one of the best salmon-fishing rivers in Connaught, rises in the Twelve Pins, passes through Ballynahinch lake and enters Bertraghboy bay. Lough Corrib extends from Galway town northward for 29 mi. The district west of Lough Corrib is called Connemara arid is famed for its beauty.

History.—Galway was made a county about 1579 by Sir Henry Sydney, lord deputy of Ireland. There are many ancient monuments in the region surrounding Lough Corrib and in the Aran Islands off the west coast. Raths or encampments are numerous, and several cromlechs (prehistoric stone circles) are in good preservation. At Kilmacduagh, near Gort, is a 14th- to 15th-century cathedral, and a round tower 112 it. high, leaning considerably out of the perpendicular. Knockmoy abbey (about 7 mi. S.S.E. of Tuam), probably founded in 1189 by Cathal O'Connor, was adorned mith fresco paintings. The castle of Tuam was built in 1161 by Roderick (Rory) O'Connor, king of Connaught, at the period of the English invasion. The cathedral of Clonfert, mith a Romanesque doorway, is now in ruins.

Industries.—Wheat and sugar beets are grown extensively in the eastern part of the county. In coastal regions seaweed, which is plentiful, is used as manure. Crushed limestone is also used as fertilizer. Sheep are more numerous than cattle.

The splendid mountain, lake and coastal scenery and the excellent facilities for salmon and trout fishing attract many visitors. Salthill near Galway city is a leading holiday resort. Homespun tweeds and hand-knitted woolen goods are made in the western part of the county. Black marble is quarried near Galway city and green marble is found in Connemara. Galway, Cleggan and Kilronan are bases from which fishing trawlers operate. Offshore fishing in currachs is general. Tweeds, hats, chinaware, furniture and agricultural implements are made in Galway, sugar in Tuam, textiles in Louehrea and shoes in Ballinasloe.

Galway city is a borough; Ballinasloe is an urban district; Tuam and Louehrea are towns. The administrative authority for the remainder of the county is the county council which also administers health services. For representation in *dail eireann* the county is divided into three constituencies—West, North and South—each of which elects three members.

GALWAY, a seaport and the county town of County Galway, Ire., on the northern shore of Galway bay and 133 mi. W. of Dublin. Pop. of urban district (1956) 21,219. After the building of its walls by Anglo-Norman settlers (about 1270) it developed as a commercial centre, in later centuries doing much trade with Spain. Richard II's charter of incorporation, confirmed by Henry IV, was extended in 1545 to give the port jurisdiction over the Aran Islands, and to permit exportation of goods other than linens and woolens. A charter from James I formed the town and the land within a 2-mi. radius into a county. In the Civil War the town surrendered to the parliamentary forces, the inhabitants were dispersed and their property given to adventurers and soldiers.

St. Nicholas church, a cruciform building founded in 1320, was collegiate from 1484 until 1840, and Edward VI created the Royal College of Galway in connection with it. University college was founded in 1849 as Queen's college under an act of 1845, and its name was changed when it received a new charter in 1908 as a constituent college of the National University of Ireland.

Claddagh, mhich was the Irish part of the town in Norman times, is now a suburb engaged in sea and salmon fisheries. The harbour is connected with Lough Corrib by the Eglington canal, but the canal trustees have abandoned navigation on the canal. The chief exports are wool, agricultural produce, locally polished marble and china. The main industries are represented by corn mills, an iron foundry, a hat and furniture factories. The famous Galway races are held at the end of July or the beginning of August.

GAMA, VASCO DA (c. 1460–1524), Portuguese navigator and discoverer of the sea route to India, was born *c.* 1460 at Sines, Alentejo, Port. Little is known of Da Gama's early training, but in 1492 he was employed to seize certain French vessels lying in Setúbal and the Algarve. Later John II chose him to complete the work of Bartolomeu Dias (*q.v.*) in opening the sea route to India. Da Gama sailed from Lisbon on July 8, 1497. His fleet comprised four vessels: the flagship "S. Gabriel," which he commanded himself, the "S. Rafael," the "Berrio" and a storeship. Like Dias and Diogo Cam (*q.v.*), he carried *padrões* (stone pillars) which he set up as marks of discovery and overlordship. The expedition passed the Canaries on July 15 and reached the Cape Verde Islands on the 26th; it remained at São Tiago until Aug 3. Then, in order to avoid the currents oi the Gulf of Guinea, Da Gama took a circular course through the South Atlantic to the Cape and reached St. Helena bay (32° 40' S.) on Nov. 7. The expedition weighed anchor again on Nov. 16 but, because of unfavourable winds, did not round the Cape of Good Hope until the

22nd. Three days later Da Gama anchored in Mossel bay, erected a *padrão* on an island and ordered the storeship to be broken up. The fleet sailed again on Dec. 8 and reached the coast of Natal on Christmas day. On Jan 11, 1498. the fleet anchored for five days near the mouth of the Copper river. Rio de Bon Signaes (where another *padrão* was placed) was reached on Jan 25

After 32 days the expedition continued to Mozambique (arriving March 2), nhere the inhabitants believed the Portuguese to be Moslems like themselves. Da Gama learned that they traded nith Arab merchants and that four Arab vessels, laden with gold, jewels, silver and spices, were then in port and that Prester John, the long sought Christian ruler. lived in the interior but held many of the coastal cities. The sultan of Mozambique supplied Da Gama nith two pilots, one of whom deserted on finding that the Portuguese were Christians. The expedition reached Mombasa on April 7. Anchor was dropped at Malindi on April 14 and a pilot who knew the route to Calicut was taken aboard. After a 23-day run across the Indian ocean the Ghats were sighted and Calicut was reached on May 20. There Da Gama erected a *padrão* as proof of his having reached India. He was welcomed by the zamorın or Hindu ruler of Calicut (then the most important trading centre in southern India), but he failed to conclude a treaty because of the hostility of certain Moslem merchants.

Da Gama left Calicut at the end of August, taking with him five or six Hindus in order that King Manuel might learn about their customs. He visited Angediva Island before sailing again for Malindi where he erected a *padrão*. Because of unfavourable winds, the expedition took nearly three months to cross the Arabian sea and many of the crew died of scurvy. At Malindi, because of greatly reduced numbers, Da Gama ordered the "S. Rafael" to be fired. Mozambique (uhere he set up his last *padrão*) was reached on Feb. 1. On March 20 the "S. Gabriel" and the "Berrio" rounded the Cape together, but a month later were parted by a storm, the "Berrio" reaching the Tagus on July 10. Da Gama continued to Terceira Island in the Azores, from where he is said to have dispatched his flagship to Lisbon. He himself reached Lisbon on Sept. 9 and made his triumphal entry into the city nine days later, spending the interval in mourning his brother Paul, who had died on Terceira. Manuel I granted Vasco the title of "dom," an annual pension of 1,000 cruzados and lands.

To further Da Gama's achievement, Manuel I dispatched P. A. Cabral, who left Portugal on March 9, 1500, and succeeded in establishing a factory at Calicut; but the Portuguese whom he left behind were murdered by the Hindus at the instigation of Moslem traders. Da Gama was recalled to India and ordered to avenge this outrage. Shortly before he sailed in 1502, he received the title of admiral of the Indian seas and was granted other favours including the right to import merchandise to the value of zoo cruzados with every royal fleet from India, so that he became one of the richest men in Portugal. On reaching Calicut he bombarded the city and destroyed a fleet sent against him. He then proceeded to Cochin where he concluded a very favourable trade treaty. He returned to Lisbon in Sept. 1503. Soon after his return he retired to Évora but continued to advise Manuel I on Indian and maritime matters until 1505. He was created count of Vidiguerira in 1519 and mas nominated viceroy of India in 1524. He died at Cochin on Dec. 24, 1524.

(E. M. J. C.)

GAMALIEL. This name, which in Old Testament times figures only as that of a prince of the tribe of Manasseh, mas hereditary among the descendants of Hillel (*q.v.*). Six persons bearing the name are known.

GAMALIEL I, a grandson of Hillel, and like him designated "the elder," by which is apparently indicated that he was a member of the Sanhedrin. According to tradition Gamaliel succeeded his grandfather and his father as nasi, or president of the Sanhedrin. Though this tradition does not correspond with historic fact, and merely reflects later conditions after A.D. 70, it is at any rate certain that Gamaliel took a leading position in the Sanhedrin and enjoyed the highest repute as teacher of the Law. He was the first to whose name was prefixed the title rabban ("master!" "teacher"). It is related in Acts (v, 34 ff.) that he intervened in the Sanhedrin in favour of the disciples of Jesus, and in this connection he is referred to as a Pharisee of wide repute. In the Mishnah (*Gittin* iv, 1–3) he is spoken of as the author of certain legal ordinances affecting the welfare of the community. His function as a teacher is proved by the fact that the Apostle Paul boasts of having sat at the feet of Gamaliel (Acts xxii, 3). Of his teaching, beyond the saying preserved in Aboth i, 16, which enjoins the duty of study and of scrupulousness in the observance of religious ordinances, little is preserved. His renown in later days is summed up in the words (Mishnah, end of Sotah): "When Rabban Gamaliel the Elder died, regard for the Torah (the study of the Law) ceased, and purity and piety died."

GAMALIEL II, grandson of Gamaliel I. To distinguish him from the latter he is also called Gamaliel of Jabneh. In Jabneh (Jamnia), where during the siege of Jerusalem the scribes of the school of Hillel had taken refuge by permission of Vespasian, a new centre of Judaism arose under the leadership of the aged Johanan ben Zakkai (*q.v.*), a school whose members inherited the authority of the Sanhedrin of Jerusalem. Gamaliel II became Johanan ben Zakkai's successor: and rendered immense service in the strengthening and reintegration of Judaism, which had been deprived of its former basis by the destruction of the Temple and by the entire loss of its political autonomy. He put an end to the division which had arisen between the spiritual leaders of Palestinian Judaism by the separation of the scribes into the two schools called respectively after Hillel and Shammai. Gamaliel was recognized by the Roman government as patriarch. He devoted special attention to the regulation of the rite of prayer, which after the cessation of sacrificial worship had become all important. He gave the principal prayer, consisting of 18 benedictions, its final revision, and declared it every Israelite's duty to recite it three times daily. He died before the insurrections under Trajan. His son, Simon, long after his father's death and after the persecutions under Hadrian, inherited his office, which thenceforward his descendants handed on from father to son.

GAMALIEL III, son of Jehuda I, the redactor of the Mishnah (see TALMUD), and his successor as patriarch. The redaction of the Mishnah was completed under him, and some of his sayings are incorporated therein (Aboth ii, 2–4). Gamaliel III lived during the first half of the 3rd century A.D.

GAMALIEL IV, grandson of the above, patriarch in the latter half of the 3rd century; about him very little is known.

GAMALIEL V, son and successor of the patriarch Hillel II. Beyond his name nothing is known of him. He lived in the latter half of the 4th century.

GAMALIEL VI, grandson of the above, the last of the patriarchs, died in 425. (W. BA.; G. H. B.)

GAMBETTA, LÉON (1838–1882), French statesman, was born at Cahors on April 2, 1838. In his sixteenth year young Gambetta lost by an accident the sight of his left eye, which eventually had to be removed. Notnithstanding this privation, he highly distinguished himself at the public school of Cahors, and in 1857 proceeded to Paris to study law. His southern vehemence gave him great influence among the students of the Quartier Latin, and he was soon known as an inveterate enemy of the imperial government. He was called to the bar in 1859. In 1868 he defended the journalist Delescluze, prosecuted for having promoted the erection of a monument to Baudin, who was killed in resisting the coup d'dtat of 1851. Gambetta seized his opportunity and assailed both the coup d'dtat and the government with an eloquence of invective which made him immediately famous.

In May 1869 he was returned to the Assembly, both by the first circumscription of Paris and by Marseilles, defeating Hippolyte Carnot for the former constituency and Thiers and Lesseps for the latter. He elected to sit for Marseilles, and lost no opportunity of attacking the Empire in the Assembly. He was at first opposed to the war with Germany, but when it had become inevitable, he threw himself with all his energy into the work of national defence. After Sedan Gambetta himself proclaimed the fall of the emperor at the *corps législatif,* and the establishment of the republic at the *hôtel de ville.* He was minister of the interior in the new government of national defence. He advised his colleagues to leave Paris and conduct the government from some provincial city. This advice was rejected from dread of another revolution in Paris, and a delegation to organize resistance in the provinces was despatched to Tours, but when this was seen to be inefficient Gambetta himself (Oct. 7) quitted Paris in a balloon, and upon arriving at Tours took the supreme direction of affairs as minister of the interior and of war. Aided by M. de Freycinet, then a young officer of engineers, as his assistant secretary of war, he organized an army, which might possibly have effected the relief of Paris if Metz had held out, but after the surrender of Bazaine and the defeat of the French nezr Orleans early in December the seat of government had to be transferred to Bordeaux. When Paris surrendered at the end of January, Gambetta submitted to the capitulation concluded with Prince Bismarck. He immediately resigned his office. Elected by nine departments to the National Assembly meeting at Bordeaux (March 1, 1871) he chose to sit for Strasbourg, which by the terms of the treaty was to be ceded to Prussia, and when the treaty was adopted by the Assembly he resigned in protest and retired to Spain.

He returned to France in June, was elected by three departments in July, and agitated for the definitive establishment of the Republic. His new journal, *La République française,* soon became the most influential in France. His orations at Bordeaux on his return, and at Grenoble on Nov. 26, 1872, in which he spoke of political power having passed to *les nouvelles couches sociales* showed him at the height of his oratorical powers. But in spite of his republican convictions Gambetta urged moderation on his supporters on the fall of Thiers and the accession to power of the conservative MacMahon. His tact and parliamentary dexterity, no less than his eloquence, secured the voting of the constitution in Feb. 1875 This policy he continued during the early days of the now consolidated Republic, and gave it the appropriate name of "opportunism." It was not until May 4, 1877, when the peril from reactionary intrigues was notorious, and the clerical party had begun a campaign for the restoration of the temporal power of the pope, that he delivered his famous speech denouncing "clericalism" as "the enemy." On May 16 MacMahon perpetrated his parliamentary *coup d'ktat* in support of the clerical reactionaries and on Aug. 15, Gambetta, in a speech at Lille, gave him the alternative *se soumettre ou se dkmettre.* He roused the republican party throughout France in a campaign which culminated in a speech at Romans (Sept. 18, 1878) formulating its programme. MacMahon had no choice but to dismiss his advisers and form a moderate republican ministry under the premiership of Dufaure.

After the abdication of MacMahon, Gambetta declined to become a candidate for the presidency, but gave his support to Grévy; nor did he attempt to form a ministry, but accepted the office of president of the chamber of deputies (Jan. 1879). This position did not prevent his occasionally descending from the presidential chair to make speeches, one of which, advocating an amnesty to the communards, was especially memorable. Although he really directed the policy of the various ministries, he maintained a neutral attitude as far as possible; but events hurried him on, and early in 1881 he placed himself at the head of a movement for restoring the *scrutin de liste* in place of *scrutin d'arrondissement.* A bill to re-establish *scrutin de liste* was passed by the Assembly on May 19, 1881, but rejected by the Senate on June 19.

Gambetta's supporters were in a large majority, and on the reassembling of the chamber, he formed a ministry—known as Le *Grand Ministère.* Every one suspected him of aiming at a dictatorship; attacks, not the less formidable for their injustice, were directed against him from all sides, and his cabinet fell on Jan. 26, 1882, after an existence of only sixty-six days. His declarations leave no doubt that he would have cultivated the British alliance and co-operated with Great Britain in Egypt; and when the Freycinet administration shrank from that enterprise only to see it undertaken with signal success by England alone, Gambetta's foresight was quickly justified. His fortunes were in the balance. At his house in Ville d'Avray, near Sèvres, on Nov. 27, 1882, he was shot in the hand by a revolver which accidentally went off. He died on Dec. 31, as the result of this accident.

REAL STATESMANSHIP

Gambetta rendered France three inestimable services: by preserving her self-respect through the gallantry of the resistance he organized during the German War, by his tact in persuading extreme partisans to accept a moderate Republic, and by his energy in overcoming the usurpation attempted by the advisers of MacMahon. His death cut short a career which had given promise of still greater things, for he had real statesmanship in his conceptions of the future of his country, and a potent eloquence to secure their acceptance. The romance of his life was his liaison with Léonie Léon (d. 1906), with whom Gambetta fell in love in 1871. Gambetta himself constantly urged her to marry him during this period, but she always refused, fearing to compromise his career; she remained, however, his confidante and intimate adviser in all his political plans. The date of the marriage had been fixed, when the accident which caused his death occurred in her presence. It is certain that there was no question of suicide. Their correspondence is of absorbing interest. But in various matters of detail the serious student of political history must be cautious in accepting her later recollections.

Gambetta's *Discours et plaidoyers politiques* were published by J. Reinach in 11 vols. (1881–86); his *Dépêches, cirrulaires, décrets . . .* in 2 vols. (1886–91). The principal biographies are J. Reinach, *Léon Gambetta* (1884), *Gambetta orateur* (1884) and *Le Ministère Gambetta, histoire et doctrine* (1884); Neucastel, *Gambetta, sa vie, et ses idées politiques* (1885); J. Hanlon, *Gambetta* (1881); Dr. Laborde, *Léon Gambetta, biographie psychologique* (1898); P. B. Gheusi, *Gambetta, Life and Letters* (Eng. trans. by V. M. Montagu, 1910); P. Deschanel, *Gambetta* (1919). *See* also G. Hanotaux, *Histoire de la France contemporaine* (1903, etc.); H. Stannard, *Gambetta and the Foundations of the Third Republic* (1921). F. Laur's *Le Coeur de Gambetta* (1907, Eng. trans., 1908) contains the correspondence with Léonie Léon; *see* also his articles on "Gambetta and Bismarck" in *The Times* of **Aug.** *17* and **19, 1907,** with the correspondence arising from them.

GAMBIA, a British colony and protectorate comprising a narrow strip of land along the lower 288 mi. of the Gambia river, west Africa, reaching a point 200 mi. from the sea. It has an area of 4,003 sq.mi. (of which the protectorate is 3,974 sq.mi.). Pop.: colony (1951 census) 27,297; protectorate 252,389.

The territory is closely bound up with the river, which gives unequalled access to the interior of west Africa. However, apart from its unique but unrealized utility for penetrating a continent notable for its nature-made barriers to ingress, the Gambia valley is a fragment of the western Sudan. differing from the rest only in details. Torrential rains fall from early July to the end of October and average 35–45 in.

In the wet season the valley is subject to malaria and other mosquito-borne diseases, a condition aggravated among the mangrove-fringed marshes of the estuary, where Bathurst, the chief settlement and capital, is located. The rest of the year is rainless, and the temperature mounts toward the end of the dry season. Crop growth is restricted to the wet period, and harvesting takes place in the early weeks of the dry season.

The coastal plain bordering the estuary is flat and penetrated by tidal creeks, which are bordered with mangrove swamps. Larger trees line the low banks of the Gambia for a few miles above the estuary, but elsewhere the country is rolling or hilly, and the natural vegetation consists of coarse grasses with a spotting of low trees. Light soil predominates, and drainage is rapid except on flats near the coast. The land is somewhat subject to drought, and crops are accordingly restricted in variety. There are no valuable minerals in the Gambia.

History.—The Portuguese visited the Gambia in the 1 jth century, and in the beginning of the 16th century were trading in the lower river. Apart from a traffic in slaves their main object was to reach "the land of gold" supposed to be not far distant, and in fact considerable quantities of gold reached the lower Gambia from the interior. In 1588 Dom Antonio, claimant to the throne of Portugal. sold to certain English merchants the exclusive right to trade in the Gambia river. This grant was confirmed by letters patent from Queen Elizabeth I. This company's operations led to no permanent settlement in the Gambia In 1618 James I granted a charter to "the Company of Adventurers of London trading into Africa," formed at the instigation of Sir Robert Rich (afternard earl of Warwick) for trade with the Gambia and the Gold Coast. However, the company's first agent, George Thompson, was murdered by natives after his ship, the "Catherine," had been seized and the crew murdered by Portuguese and half-castes.

In about 1651 James, duke of Courland, acquired from a local chief an island a short distance from the river mouth, where he erected a fort. The island was then known as St. Andrew's Island, but later came to be known as James Island. A year later Prince Rupert entered the river with three royalist ships and captured some shipping belonging to patentees who had received a grant of trading rights from the commonwealth government in England. In 1661 Charles II granted a new patent to a body styled "the Royal Adventurers trading to Africa." The new patentees sent an expedition to the Gambia river under the command of Sir Robert Holmes, who found that the Courlander garrison on James Island had been reduced to seven Europeans. On being threatened with bombardment if they did not at once surrender the fort. the garrison had no alternative but to submit and Holmes took possession of the fort.

In 1677 the French wrested the Island of Goree (near Cape Verde) from the Dutch and about four years later established a small enclave at Albreda on the north bank of the Gambia river opposite to James Island. The history of the next century and a half records a continuous struggle between England and France for political and commercial supremacy in the regions of the Senegal and the Gambia. In the wars with France which followed on the English revolution of 1688 James fort was captured on four occasions by the French (1695, 1702, 1704 and 1708) but no attempt was made by them to occupy the fort permanently. At the treaty of Utrecht (1713) the French recognized the right of the English to James Island, while they in their turn were allowed to continue in occupation of Albreda.

In 1779 the French captured James fort for the fifth and last time. On this occasion they so successfully demolished the fortifications that at the end of the war it was found impossible to rebuild them. The Gambia river was reserved to Great Britain by the treaty of Versailles (1783), but the French were still allowed to retain their enclave at Albreda.

When in 1807 the slave trade was abolished by act of parliament, Great Britain was in possession of Goree. In co-operation with the royal navy the garrison of that place made strenuous efforts to put an end to the traffic in the Gambia river. When at the close of the Napoleonic Wars Goree was returned to the French, the British decided to establish a military post at the mouth of the Gambia river for the purpose of checking the trade. On April 23, 1816. the king of Kombo ceded to Capt. Alexander Grant the Island of Banjol (St. Mary's Island) and the settlement established thereon was called Bathurst after the then secretary of state for the colonies. A number of British traders, who had established themselves at Goree during the war, followed the military garrison to this new settlement.

In 1821 Bathurst was placed under the jurisdiction of the government of Sierra Leone. In 1843 it was made an independent colony, but in 1866 it was made a portion of the officially styled "West African Settlements" with the seat of government at Freetown, Sierra Leone. In 1888 it once more became a separate entity and remained such thereafter.

Soon after the founding of Bathurst in 1816 the local government began extending its territorial acquisitions in the upper reaches of the river by concluding treaties with native chiefs. In 1857 Albreda, a foreign enclave in the middle of British territory, had proved a constant source of friction between the British and French governments, was given to Great Britain, which in exchange renounced certain rights in respect of the gum trade at Portendic. Thereafter the navigable part of the river became solely British.

In 1870 and again in 1876 negotiations were begun between the British and French governments for the exchange of Gambia for other territory in west Africa, but on each occasion the proposal aroused such opposition in parliament and among various mercantile bodies in England as well as the native inhabitants of Gambia that the British government was constrained to break off the negotiations. The French continued to press forward actively in the Senegal and, when in 1889 an agreement was finally drawn up settling the international boundaries. Great Britain was able to secure only a narrow strip of territory on either bank of the river as far as Yarbutenda. Though these strips were somewhat wider in the lower reaches of the Gambia, they were limited in the upper reaches to 6.2 mi. on either side of the river.

Except for some trouble with the slave-raiding chiefs Fodi Silla (in 1894) and Fodi Kabba (in 1901) Gambia enjoyed peace after its final separation from Sierra Leone in 1888. In 1906 an ordinance was passed abolishing slavery throughout the protectorate.

During World War II Gambia proved its value not only by its contribution of fighting men for the Burmese campaign, but also as an air halt on the route to the middle east and far east and as a port of call for convoys.

Population, Education, Government and Judicature.—The African inhabitants of Gambia belong to a number of west African tribes, of whom the Mandinga (about 35% of total population), Fula, Wolof, Jola and Serahuli are the principal. Because of the artificial nature of the international boundary many of them are separated from their kinsfolk in French territory. The Mandinga and Serahuli are mainly Moslem, but the majority of the Jola tribe are pagans; there is a small Christian population, chiefly centred in Bathurst.

The government is responsible for primary education in Bathurst, though the schools have a religious grouping and are administered through management committees. on each of which the appropriate religious authority is represented. Secondary education is in the hands of the Methodist and Roman Catholic missions, which receive substantial grants from the government. A number of village schools were opened in the protectorate and there are also small elementary schools belonging to the Anglican and Roman Catholic missions. There is no postsecondary education in Gambia, except for a teacher-training college at Yundum.

Technically the British colony (29 sq.mi.), administered by a commirsioner, comprises the Island of St. Mary, upon which is the capital, Bathurst (pop., 1951 local census, 19,602), and the adjacent mainland district of Kombo St. Mary. The rest of Gambia was designated a protectorate by a Protectorate ordinance of 1935 and a number of ancillary ordinances. In practice, however, colony and protectorate are administered together on crown colony lines by a governor, executive council and legislative council.

Local government in the island is in the hands of the Bathurst town council, established in 1946 and presided over by the colony commissioner, which includes nominated and elected members, the latter being in the majority. Kombo St. Mary is administered by the Kombo rural authority, set up in 1947. The authority is presided over by the colony commissioner and consists of nominated members, chosen for the most part from the headmen of the villages of the district. There are four divisions of the protectorate administered by commissioners exercising supervision over the native authorities in the districts of each division. These native authorities consist of a district chief (who is president ex-officio) and a number of village heads and advisers in council. Each authority is responsible for the maintenance of law and order within its district and also has a limited power to make local government orders and rules. Each district also has a tribunal exercising a limited civil and criminal jurisdiction. In addition there are a number of higher tribunals, known as group tribunals, exercising a more extended civil and criminal jurisdiction in certain specified groups of districts. In Bathurst there is a police court (dealing with criminal matters), a court of requests (dealing with civil matters), a Mohammedan court (dealing with Mohammedan marriage, succession and guardianship) and a juvenile court (established in 1949). In Kombo St. Mary division and in the protectorate there are subordinate courts consisting of commissioners or assistant commissioners with a more extensive civil and criminal jurisdiction than that granted to native tribunals. The supreme court exercises full jurisdiction (original and appellate) within both the colony and the protectorate.

Economic Conditions.— Gambia is naturally situated to handle overseas trade for a large hinterland. The river, on which steamers ply regularly; is the principal means of communication and there are about 30 river stations in the protectorate. The only seaport is Bathurst; Basse, 240 mi. upstream, is the head of regular river navigation; the chief places between are Georgetown and Kuntaur. These four stations and Mansa Konko, headquarters of the central division. have radio connection with each other.

The output of Gambia is wholly agricultural. Some subsistence crops are raised. chiefly grain sorghum, but not enough to feed the inhabitants. Instead, nearly all the suitable land is planted with peanuts (groundnuts), grown for export (rarely less than 95% of the annual total exports by value, customs duty upon which provides most of Gambia's revenue). The light soil and short season of rains favour this above all other crops marketable overseas. Gambia is merely an arbitrary segment of a much larger peanut-growing region, reaching far into the Sudan. Cultivation of all cash crops is wholly an African enterprise, although it is stimulated by the ease of shipment to the European market and guided by the colonial government. Allotment of land is left in the hands of the headmen, including the right to grant short-term tenancy to "strange" nonindigenous farmers. who usually grow peanuts. Peanuts were exported as early as 1836, and by 1850 peanut-growing was the chief business of the country.

The only other exports usually listed are palm kernels, hides and beeswax. Cattle are moved with the seasons, and are frequently driven across the political boundary of Gambia in both directions. a practice that hampered efforts begun in 1933 to control rinderpest by inoculating the animals.

The cash crops buy most of the inhabitants' requirements, including rice, a staple of their diet, and kola nuts. The leading import by value is cotton cloth. followed by foodstuffs. Hardware ranks next below foodstuffs. Local industries are limited to'cotton weaving. garment making and fishing. The need to purchase food as well as manufactured goods raises the annual per capita import to a high figure for tropical Africa, about £9 in 1953. Most of the overseas trade is carried in British ships. There is a British preferential tariff on imports. The monetary unit is the West African pound. at par with sterling.

GAMBIA, a large river of West Africa, and the only river of Africa navigable by ocean-going vessels at all seasons for more than 200 mi. from its mouth. It rises about 11° 25′ N. and 12° 1j' W., within 150 mi. of the sea on the northeastern escarpment of the Futa Jallon highlands. Although the distance from the source to the mouth of the river is little more than 300 mi. in a direct line, the length of the stream because of its serpentine course is about 500 mi. It flows first north-northeast, receiving many left-hand tributaries, but about 12° 35′ N. takes a sharp bend northwest and maintains this direction until it leaves the fertile and hilly region of Bondu. The descent to the lower district is marked by the Earrakunda rapids, formed by a ledge of rock stretching across the river. From the Barrakunda rapids to the Atlantic the Gambia has a course of about 3jo mi. Throughout this distance the waters are tidal. At Yarboutenda, a few miles below Barrakunda the river has a breadth, even at the dry season, of over 300 ft. with a depth of 13 to 20 ft. From the falls to MacCarthy Island, a distance of 200 mi. the river valley; which here presents a parklike appearance, is enclosed by low rocky hills of volcanic character. For 50 mi. below the island, n-here the stream is about 800 yd. wide, the banks of the river are steep and thickly wooded. They then become low and are fringed with mangrove swamps. From Devil's point, a sharp promontory on the north bank. the river nidens and enters the Atlantic at about 13° 30' N. and 16" 30' W., by a broad estuary. Near the mouth on the south side is St. Mary's Island ($3\frac{1}{2}$ mi. long by $1\frac{1}{2}$ broad), and opposite is Barra point, the river being here contracted to $2\frac{1}{2}$ mi. Eighteen miles loner down the distance from shore to shore is 27 mi. There is a sand bar at the entrance to the river, but at the lowest state of the tide there are 26 ft. of water over the bar. Vessels draming 13 ft. can ascend to MacCarthy Island and those draming 6 ft, to Barrakunda all the year round. The Gambia is in flood from June to November, when the Barrakunda rapids can be passed by small boats, nhile above the rapids the stream is navigable for 160 mi. Politically the Gambia is divided betneen Great Britain and France —Britain possessing both banks of the river up to, but not including, Yarboutenda.

The Gambia was one of the rivers passed by Hanno the Carthaginian in his voyage along the west coast of Africa. It was known to Ptolemy and the Arabian geographers, and was at one time supposed to be a mouth of the Nile, and, later (18th century). a branch of the Niger. It nas possibly visited by Genoese navigators in 1291, and was certainly discovered by the Portuguese c. 1446, but was first explored for any distance from its mouth (1455) by the Venetian Alvise Cadamosto, who published an account of his travels at Yicenza in 1507 *(La Prima Navigazione per l'Oceano alle terre de' Negri della Bassa Ethiopia*). Afterwards the Gambia became a starting-place for explorers of the interior, among them Mungo Park. who began both his journeys (1795 and 1805) from this river. It was not until 1818 that the sources of the Gambia were reached. the discovery being made by a Frenchman, Gaspard Mollien, who had travelled by nay of the Senegal and Bondu. The middle course of the river was explored in 1851 by R. G. MacDonnell then governor of the Gambia colony, and in 1881 V. S. Gouldsbury also navigated its middle course. No native craft of any kind nas seen above Bairakunda.

GAMBIER, JAMES GAMBIER, Baron (1756–1833), British admiral, nas son of John Gambier. lieutenant-governor of the Bahamas. John Gambier nas the brother of Capt. (afterwards Yice-Admiral) James Gambier (1723–1839); of Samuel Gambier (1752–1813), first commissioner of the navy; and of Margaret, who married Capt. Charles Middleton R.N., comptroller of the navy 1j78–1790, and afterwards Admiral Lord Barham John Gambier's daughter, Margaret, married William Morton Pitt (1;54–1836). James Gambier nas therefore connected by marriage nith the Pitt family (and distantly with the prime minister) and also, through his aunt, nith Middleton. a relative of Henry Dundas, secretary of state and treasurer of the navy. He entered the navy by entry in the books of the guardship that his uncle commanded (1767) and reached post rank in America in 1778 nhen his uncle was rear admiral at New York under Lord Howe. His interest mas overnhelming but he chose to remain ashore between 1783 and 1793, gaining a reputation chiefly for piety. His ship the "Defence" was badly damaged in breaking the French line at the battle of the First of June. 1794. He then became a naval member of the board of admiralty, remaining there until 1801. by which date he was vice-admiral. He served for short periods afloat but was back at the admiralty again in 1804–06.

Gambier was appointed commander in chief in the Baltic in 1807 and directed the second bombardment of Copenhagen, after which he shared £300 000 prize money nith Lord Cathcart and returned to the admiralty nith a peerage. He was commander in chief of the Channel fleet in 1809 when Lord Cochrane came with orders to make a fireship attack on a French squadron in the Basque Roads. He disliked and disapproved of Cochrane and his methods and gave only halfhearted support to the attack. Cochrane's subsequent remarks induced Gambier to ask for a court-martial, by which he was acquitted, remaining nith the Channel fleet until 1811 and receiving further honours as G.C.B. in 1815 and admiral of the fleet in 1830. For an officer of such high rank he had exceptionally little sea experience; but the accounts most readily available of the Basque Roads episode came mainly from Lord Cochrane, and Gambler nas not the only flag-officer to think

Cochrane an intolerable nuisance.

GAMBLING AND BETTING. Terms related to gambling and betting require clarification. In United States usage. "gaming" is archaic, except in law. A wager (synonymous with "bet") may be prompted by knowledge, opinion or conjecture as well as by reliance on chance. Unless otherwise qualified. however, these terms all imply gambling. which has become the comprehensive term to denote any gaming. wagering or undertaking (whether or not lawful or respectable) n-hose determination is controlled or influenced by chance or .accident and nhich is undertaken with consciousness of risk. Nongambling contests are generally termed play, pastime or sport. Gambling in business is speculation.

Derivations.— Gambling has sometimes been called instinctive in man. but this view is not widely held. It is more usual to consider gambling unnatural. though an inevitable concomitant of man's basic cultural patterns.

The bushmen of Australia and South Africa had competitions for prizes. sometimes guessing games—rude intellectual contests. The most primitive aboriginals of the western hemisphere had crude dice (*q.v.*) and gambled on "bowl" games. Tacitus remarked that the Teutons ("without the excuse of liquor") gambled themselves into slavery. Sudanese and West African natives. after gambling away their wives and children (as did many peoples)! likewise staked their own liberty. Instances are reported in which Chinese gamblers staked their right hands and, losing them. cut them off. Great emotional response, as of religious fervour or superstitious fear. marks the behaviour of the participants in these primitive peoples' games.

The identification of gambling with religion is invariable in primitive societies. The Hebrews cast lots before the Lord (Joshua xviii. 10), hut the Lord decided (Proverbs xvi. 33). The earliest designs of dice and playing cards (*see* CARDS, PLAYING) have been convincingly related to contemporary divinatory devices. The games of the Germans were probably inspired by their trials. which were grounded on belief in divine intercession in matters of chance.

There is nevertheless no indication that belief in supernatural agency had a causative effect on the emergence of the gambling spirit. The rise of rationalism produced no discernible decrease in gambling. In the higher cultures the emotional response to gambling has not been so marked, but the degree of risk accepted has been no less. In Tacitus' own time wealthy Romans bet so heavily on chariot races that they lost their entire fortunes and their respectability. In modern times, when the betting is on horse racing, similar phenomena are common and there are frequent reports of embezzlement induced by gambling losses. The forfeit in either case is subjectively as great as the liberty which, according to Tacitus, the Germans gambled away.

In psychology. given the assumption that it is not in the nature of man to gamble. various suggestions have been advanced to explain the gambling urge. One such suggestion—that the gambler is maladjusted to society and is impelled by a feeling of insecurity —is not inconsistent with the identification of gambling with superstitious fear, but it can be reasonably argued that gambling and superstition are merely coincidental. A more or less standard explanation of the psychology of the playing of games—sublimation of a mock struggle for want of. or for fear of, the real one—does not necessarily apply to gambling. A child enjoys competition but does not willingly accept risk.

Moral and Juridical Sanctions.— Gambling has been generally opposed in philosophy. as wasteful.

There is no direct biblical injunction against gambling. A tract attributed to St. Cyprian held that gaming violates the First Commandment and charged Lucifer with inspiring dice, and the Christian Church generally has held gambling to be sinful. Among the English clergy the popular view has conformed to that of Jeremy Taylor. who defended the playing of games for amusement but held gambling to be immoral. The talmudic law holds the acceptance of gambling winnings to be thievery. The Koran forbids all games except chess.

The Puritans asserted the identity of chance with Providence and condemned all games as blasphemous in that they violate the Third Commandment. Most Protestant churches adhered to this dictum. but in the 1920s many of them began to relax their objection to games played for amusement only. Roman Catholic churches have frequently sought funds for parish uses by conducting card and lottery games for money and other prizes.

There is a long record of legislation against gambling. This has been inspired partly by the attitude of the church, but more by political and economic expedient. To promote military efficiency, ancient Rome forbade gambling on the grounds that it was effeminating. and the earliest English law (1388) discouraged other games in the interest of archery. An ancient Egyptian law had the same purpose as edicts in France (139;) and England (1495): to forbid gaming by workmen at the expense of their productiveness.

Other English legislation sought to prohibit or discourage gambling. Games used only for gambling. such as faro (*q.v.*), all dice games. roulette (*q.v.*) and others, were declared illegal in a series of statutes dating from 1739. Other statutes sought to discourage betting by making gambling debts uncollectible by law (1710, 1845) and to make it more difficult by punishing the gaming-house keeper (1853) and the common gambler (1867, 1906).

Antigambling legislation in the United States has followed the English pattern but is complicated by the fact that the power to regulate gambling is reserved to the respective states; there are different sets of laws in each state, not to mention countless local ordinances. which usually vary in severity with the moral pressure brought to bear by lay agencies on legislators.

In England and the United States a general distinction between lawful and unlawful gambling seems to be that where skill predominates. the gambling is lan-ful; where chance does. it is unlawful. A court must decide which is the predominant factor in the case of each game in question. Cases show that one cannot rely on the record. for it is full of reversals and contradictions.

There has been controversy for nearly 300 years on whether or not gambling should be legalized and state-controlled. The affirmative argument is that antigambling legislation is ineffectual because Ian.-enforcement officers are reluctant or unable to prevent minor gambling. while the profits of major gambling are so great that professional gamblers purchase immunity from prosecution with bribes. Legal gambling, its proponents say, would provide huge state revenues and reduce taxes: eliminate corruption of the police: and protect the public against dishonesty. exorbitant advantages retained by professional gamblers and other abuses. Opponents of legal gambling argue not only on moral grounds but also on statistics which, they say, indicate that licensed gambling stamps out no abuses and merely aggravates the problem by fostering the betting habit. The German princes maintained gambling as a state monopoly through the 18th and part of the 19th centuries, but this practice survived only in Monte Carlo.

Betting on horse races, the principal form of gambling in the English-speaking countries, grew in popularity so rapidly that legislation proved powerless to prevent it, and eventually it came to be legalized to a certain extent. The pari-mutuel system (which term will be used here to designate any mechanical device for betting on races; see HORSE RACING AND BREEDING) originated in France in the 1860s and was authorized by Kentucky a few years later (though it was not put into use there until 1908). It was adopted by Australia, New Zealand and by most states of the United States.

In England, despite long agitation for pari-mutuel betting, other expedients were tried first. An effort was made (by act of 1926) to license bookmakers and impose a tax on betting. Evasion of the tax was so general. however, that in 1928 the Race-course Betting act was passed, permitting the use of totalizators.

When the pari-mutuel system is used. deductions of as much as 8% of the total amount bet are taken for the state and an equal or larger percentage for the operators of the race track. This does not include. however, the large sums bet with bookmakers.

U.S. pari-mutuel machines by the late 19jos handled more than $2,000,000,000 yearly. When a bettor wishes to place a large bet he may prefer to do so with a bookmaker and not through the pari-mutuel machines. The reason will become apparent from an illustration of the operation of the pari-mutuel system. A bettor places $100 on the winning horse in a race. In that race the total of bets is $10,000, of which $2,700 was bet on the winning horse. From the $10,000 the state and track first take their cut: assume it in this case to be only 10%. This leaves $9,000, or $6.67 for each $2 bet on the winning horse. But the track also retains odd pennies (called breakage), so the actual pay-oti is $6.60 for every $2 bet. The bettor of $100 therefore receives $330. If this bettor had placed an additional $1,000 on the winning horse. however, he would have received considerably less per dollar bet. The total of bets would then have been $I I.000, which the 10% cut would have reduced to $9.900. This amount would have been divided among a total of $3,700 in winning bets, and the bettor of $1,100 would have received $2.915. Therefore the big hettor would place his $1,000 bet with a bookmaker, who would guarantee him track odds. In this case the bettor would then receive $330 for his $100 bet at the track and $3.300 for his $1.000 bet with the bookmaker, a total of $3.630. Because of the deductions plus the breakage, the bettor must be at least a 20% better handicapper than the average bettor if he is to escape loss.

In England and the U.S.S.R. racing continued with few interruptions even during World War II. In the United States it was temporarily discontinued in 194j on the unannounced grounds that it caused absence from factories engaged in war work. Racing employs thousands of persons directly and many more indirectly through its well-developed press. extensive statistical services. self-styled experts nho sell advice on how to bet, networks of telephone and telegraph wires which furnish to betting centres prompt information on results, bookmakers and their employees and hangers-on. and workers incidental to the care and breeding of the horses. (See also HORSE RACING AND BREEDING.)

Lottery has the longest record of legality. It was used by Augustus, Nero and other Roman emperors to finance building projects and increase imperial revenue. Lotteries were held in Europe from the 1jth century on; in England. the first lottery of record was announced in 1j69 with Queen Elizabeth I as patroness; and in the new world there were lotteries as early as the 17th century, chiefly for the benefit of schools, churches and public works.

The mechanics of a lottery are essentially as follows: Tickets bearing different numbers are placed on sale, and a date is set for a drawing. On that date is set up a device which contains numbered duplicates of all the tickets sold, and one or more numbers are drawn at random. From the money realized by the sale of tickets. the proprietors of the lottery deduct some amount, arbitrarily determined, for expenses and profits; the remainder is paid to the holders of tickets corresponding to those drawn.

The principal charge against lotteries is that they penalize the poor, who in ill-advised hope or desperation buy most of the tickets; Count Camillo Benso Cavour called lottery "a tax upon imbeciles.'! Even more valid is the complaint that very few ticket holders are at the drawing; those who are present cannot conveniently assure themselves that the device contains the numbers of all ticket holders, and therefore it is very difficult to safeguard a lottery against chicanery.

For these and other reasons. England prohibited private (unlicensed) lotteries in 1698 and did not license a lottery after 1824. Most states of the United States had outlawed private lotteries by IS50, and no state licensed a lottery after 1893. In Ireland and in Central America lotteries were permitted. however. and some European countries authorized occasional or regular state-operated lotteries. During World War II the U.S.S.R. used the lottery for war financing; a ticket was issued free to any purchaser of a war bond, and prizes were as high as 100,000 roubles.

The largest of the U.S. lotteries was the Louisiana state lottery. The state legislature licensed it in 1868 in consideration of an annual fee of $40,000, and the operators averaged almost $2,000,000 in ticket sales for each monthly drawing at the peak of the lottery's success. Charges of corruption were so widespread, however, that in 1890 the state refused $1,125,000 per year offered by the operators for a renewal of the licence.

The amount staked in the three sweepstakes sponsored annually by the Irish Hospitals trust totalled about £9.000,000 in 1954.

Despite their illegality and the iact that lottery tickets are barred from the mails. lotteries in various guises flourish on both sides of the Atlantic. In the United States, the popular forms came to be bingo and, in the big cities, policy or the numbers game.

The numbers game was devised to appeal to members of the lowest-income group, and it achieved its greatest popularity among Negroes, to many of whom a daily investment of one to ten cents became so habitual that it was looked upon as a normal expense of living rather than a gambling bet. While several methods were developed for the numbers game, in its usual form the player tried to guess three numbers (such as the three final digits of the daily clearinghouse receipts) which would surely appear in the daily newspapers and could not possibly be influenced by the operators of the game. When newspapers, co-operating with law-enforcement officers. omitted publication of these figures. others were substituted and the game went on. For guessing the three numbers in proper order, for example, the player might receive j39 to 1, whereas actual odds would be 999 to I.

Pools on football and (in the United States) professional baseball became popular in various forms. Usually the bettor's task is to name the winning teams in three or more games: or, in baseball, to predict the number of hits or runs a named team will make during the week. The payoff ranged from 3 to 1, when the actual odds were 1j or 16 to 1, up to 100 to 1 when the actual odds were 300 to I. In Great Britain the Pool Betting act of 1954 set certain requirements for the conduct of pool betting. including the registration of operators and inspection and publication of financial details. It also legalized ready-money pool betting conducted by mail by registered promoters.

Gambling houses on the order of the European casino spread through the United States: a survey made in 1944 by S. Michael MacDougall, a professional investigator of dishonest gambling practices, indicated that except in a few sparsely settled sections it was possible to find a gambling house within a go-mi. radius of any point. In these houses players may not bet among themselves but only against the house. which retains a mathematical advantage. often exorbitant. Crap shooting (see DICE) is the principal game; black jack (*q.v.*) is the leading card game played, and roulette (*q.v.*) is popular. Gambling houses must usually operate secretly or by bribery of governmental officers.

Slot machines, a sort of mechanical lottery device. help to support the gambling houses (many of which display rows of 2j to 50 such machines) and. when the police permit. add to the income of taverns, retail stores, clubs. restaurants. etc. In playing these machines the player inserts a coin in a slot..thus setting the machinery in motion, and gets back from 2 to 200 coins if a winning combination shows; such machines generally pay out about two-thirds of the money taken in.

Wagering on the results of boxing matches, other sporting events and miscellaneous contingencies is general. In the United States, bookmakers' odds on such events are often quoted in the newspapers several days in advance.

Card games are usually played for very low stakes. and in the United States they are commonly played for no stakes at all. Therefore the amount bet on such games is an insignificant part of the total. Nevertheless there are irequent prosecutions of clubs for permitting low-stake games of contract bridge and poker to be played. In the United States most courts have held that contract bridge is a game of skill and not subject to the antigambling laws, and some courts have held the same of poker: but convictions have been brought in connection with the operation of both these games. In England the courts have held poker .and occasionally contract bridge to be games of chance.

Speculation in stocks, shares and commodities is not illegal when the transaction is a bona fide purchase or sale. The once-prevalent bucket shops and quasi-legal brokers who did not in all cases complete the transactions for which they were commissioned were generally held to be in violation of gambling starutes and were largely eliminated by successful prosecution. To many persons. however. "playing the market" is merely a means by which they can gamble within the law. When they trade in the stock exchange they are in effect betting on the fluctuations in price. in that they have no intention to accept or make actual delivery unless it becomes necessary. Governmental regulation of buying and selling on margin tended to inhibit this practice but did not succeed in eradicating it.

Kefauver Committee. — In 1951 the U.S. senate special committee to investigate organized crime in interstate commerce: headed by Sen. Estes Kefauver of Tennessee, reported that illegal gambling in the United States totalled $20,000,000,000 annually. Evidence of political-criminal alliances reaching into city. state and federal offices was presented. Legislation resulting from the investigations required gamblers to register with the bureau of internal revenue, to pay a tax prorated at $50 a year and thereafter remit as tax 10% of their gross receipts. (See also CRIME: *United States.*j

Royal Commission on Betting, Lotteries and Gaming in Great Britain. — This commission reported in 1951 that net expenditures on gambling were approximately £70,000,000 a year. In comparison with the amounts spent on tobacco, drink or entertainment! however. the commission pointed out that the total amount spent on gambling was about 8% of the total personal expenditure. The commission's recommendations led to the enactment of the Pool Betting act of 1954 (see Pools, above).

GAMBOGE, a gum resin from *Garcinia hanburii,* a dioecious tree with leathery, laurel-like leaves, small yellow flowers and usually square-shaped and four-seeded fruit. indigenous to Cambodia and parts of Thailand and South Vietnam. The juice, which when hardened constitutes gamboge, is contained in ducts in the middle layer of the bark, and from this it is procured by making incisions. bamboo joints being placed to receive it as it exudes. Gamboge occurs in commerce in cylindrical pieces, known as pipe or roll gamboge, and also, usually of inferior quality, in cakes or amorphous masses. It is of a dirty orange colour externally, is hard and brittle, breaks with a conchoidal and reddish-yellow, glistening fracture, and affords a brilliant yellow powder; is odourless and has a taste at first slight but subsequently acrid; forms an emulsion with water; and consists of from 20% to 25% of gum soluble in water and from 70% to 75% of a resin. Its commonest adulterants are rice flour and pulverized bark.

Gamboge is a drastic hydragogue cathartic, less active only than croton oil and elaterium. A small quantity is absorbed, adding a yellow ingredient to the urine and acting as a mild diuretic. Its irritant action on the skin may cause the formation of pustules. Gamboge is used as a pigment and as a colouring matter for varnishes. It appears to have been first brought into Europe by merchants from the east at the close of the 16th century.

GAMBREL ROOF, a roof which has on each side of the ridge two slopes, the lower more steep, the upper less so. and which has gables at the end walls. It is particularly characteristic of American colonial work in New England, New York and New Jersey. although found in many parts of the world. The origin of its common use in America is not definitely known; it may have been purely an invention in the effort to obtain greater head room in the attic or upper floor.

In the New England examples the slope of the lower portion approximates 60°, that of the upper portion varying from 30° to 40°; in places where Dutch influence was strong, the lower slope was more nearly 45°, and the upper about 30°, and frequently there was a large projection at the eaves. In Europe the form occurred spasmodically in work of the 17th century and later throughout the Teutonic countries, especially in Scandinavia. There are also rare examples which may be seen in the south of England.

See ROOFS.

GAMBRINUS, a mythical Flemish king who is credited with the first brewing of beer. His name is usually derived from that of Jan Primus (*i.e.*, Jan [John] *I.* the victorious duke of Brabant, 1261–94), who was president of the Brussels guild of brewers; his portrait with a foaming glass of ale in his hand had the place of honour in the guildhall, and this led in time, it is suggested, to the myth of the beer king who is usually represented with a tankard in his hand.
