The largest exporting countries have a high per capita consumption of animal food products, a declining per capita consumption of grain as food, seaports within their territorial boundaries and, for the most part, relatively high per capita incomes. Grain used in the production of animal food products has a relatively low value use compared to its use as a human food. Because of the relatively stable consumption of grains as food in the major surplus areas, and its low value use as animal feed, the importing countries are able to outbid producers of animal food products for part of the grain supply in spite of generally higher transportation costs and, in many instances, lower per capita incomes. For many importing countries, imports supplement domestic production by serving as a source of grain with special characteristics, and by evening out swings in production. As a result many countries both export and import grain, as indicated by Table VI. Wheat in particular is imported by numerous countries. It is not produced in sufficient quantities in many countries and because it is used in many food products with wide consumer acceptance it has a world-wide market. For several countries (*e.g.*, western Germany, United Kingdom, Japan, Brazil) imports are a major source of supply because domestic production is consistently well below their requirements.

On a per capita basis trade in grains stagnated in the period following World War II. From 1934–38 to 1954–56, exports of the six grains listed in Table VI declined from 43 lb. to 38 lb. per capita. Smaller exports of the feed grains accounted for most of the decline, per capita exports declining from 14 lb. to 10 lb. Exports of the food grains declined from 29 lb. to 28 lb. Total rice exports declined 46% (4,400,000 metric tons) between the two periods, but total wheat exports increased 57% (9,900,000 metric tons). The larger wheat exports went largely to Asian countries who substituted wheat for rice because of the smaller supply of rice available for importation.

The stagnation in grain trade was due to both economic and institutional factors. Many countries, especially the relatively underdeveloped. found it necessary to use their holdings of foreign exchange for the importation of capital goods to implement industrialization programs and attempted to become self-sufficient in grain production in order to reduce imports. A few countries also reduced their per capita consumption in order to conserve their foreign exchange holdings. Other countries were able to increase production because of improved technology and cultural practices. Governmental subsidies in other instances resulted in increased production and a reduced dependence on imports. The formation of politically oriented trading blocs further tended to restrict international trade. Increased per capita incomes in western Europe, the major importing region, failed to increase net imports significantly because with higher incomes consumers substituted relatively expensive protective foods (primarily animal products and fresh fruits and vegetables) for starchy food grains.

The chief institutional arrangements which affect the pattern of world trade include import and export controls in the form of tariffs, quotas, embargoes, currency convertibility restrictions, cartel agreements and export and import subsidies. Other factors, such as production and marketing controls, production subsidies,

subsidies for diversion to lower value uses, etc., also affect production and consumption and thereby the pattern of world trade. The International Wheat agreement, first signed by participating countries in 1949 and periodically extended and modified subsequently, was designed to stabilize supplies and the price of wheat in international trade. Under this scheme signatory importing countries agreed to purchase a specified amount of wheat. usually about one-third of world trade, at a specified minimum price and the exporting countries agreed to supply this amount at a price of not more than the specified maximum price. The agreement had no provision for production controls, but United States domestic price supports and export subsidies stabilized the price of wheat in international trade.

GRAINS OF PARADISE, the seeds of *Aframomum melegueta,* a reedlike plant of the Zingiberaceae family. also called guinea grains and Nelegueta pepper. It is a native of tropical western Africa, and of Prince's and St. Thomas islands in the Gulf of Guinea, and is cultivated in other tropical countries. The seeds are contained in the acid pulp of the fruit and have a glossy dark-brown husk, with a conical light-coloured membranous caruncle at the base and a white kernel. They contain a neutral essential oil. and a viscid, brown resin. Grains of paradise were formerly used as a drug and a spice. the wine known as hippocras being flavoured with them and with ginger and cinnamon. They are exported almost exclusively from Ghana.

GRAM or GRAMME, the unit of mass in the metric system, equivalent to 15.4323564 grains avoirdupois or to 0.2572 drachms (drams) or to 0.7716 scruples. This metric unit is very nearly equal (it was intended to be exactly equal) to the mass in a vacuum of one cubic centimetre of pure water at maximum density. The scientific definition of the gram. accepted by international convention, is that it be a mass of 1/1000 part of the mass of the "International Prototype Kilogram," a platinum iridium alloy block carefully preserved at the International Bureau of Weights and Measures at Sèvres, France. The gram of force is defined as g dynes of force where g is the acceleration of gravity. It is the *weight* of a gram of mass and varies slightly from place to place on the earth as the factor *g* varies. *See* WEIGHTS AND MEASURES.

GRAM or CHICK-PEA, called also Egyptian pea or Bengal gram. *Cicer arietinum,* so named from the resemblance of its seed to a ram's head. It is a member of the family Leguminosae (*q.v.*), largely cultivated as a pulse food in the south of Europe, Egypt and western Asia as far as India. but is not known undoubtedly wild. The plant is an annual herb with flexuose branches, and alternately arranged pinnately compound leaves, with small, oval leaflets. The flowers are borne singly in the leaf axils on a stalk about half the length of the leaf and jointed and bent in the middle; the corolla is blue-purple. The inflated pod, 1 to 1½ in. long, contains two roundish seeds. It was cultivated by the Greeks in Homer's time under the name *erebintlzos.* Alphonse de Candolle (*Origin of cultivated Plants*) suggests that the plant originally grew wild in the countries to the south of the Caucasus and to the north of Persia. In the east the seeds are eaten raw or cooked in various ways, both ripe and unripe, and when roasted and ground serve the same purposes as ordinary flour. In Europe the seeds are used as an ingredient in soups.

The seed of *Phaseolus Mungo,* or green gram. a form of which plant with black seeds is termed black gram. is an important article of diet among the labouring classes in India. A variety, *var radiatus,* also known as green gram, is perhaps the most esteemed of the leguminous plants of India. where the meal of its seed enters into the composition of the more delicate cakes and dishes. Horse gram, *Dolichos biflorus,* which supplies in Madras the place of the chick-pea. affords seed which. when boiled. is used as a food for horses and cattle in south India, where also it is eaten in curries.

GRAMINEAE, the grass family (*see* GRASSES), comprising about 450 genera and 4,500 species.

GRAMMAR. According to the definition given by Henry Sweet a grammar gives the general facts of language, while a dictionary deals with the special facts of language. But the two domains frequently overlap, so that one and the same fact finds its place in the grammar as well as in the dictionary; this is because in order to state a rule correctly we must also state its limitations, *i.e.*, the special cases in which it does not hold good. If we give the rule that English substantives form their plurals in *-s,* we must add that besides this regular formation we have the irregular plurals *men, women, oxen,* etc. And as languages are not constructed after ideal patterns, such exceptions to the rules must necessarily take up much space in all books on grammar.

To the ordinary man, grammar means a set of more or less arbitrary rules which he has to observe if he wants to speak or write correctly. This is especially the case if he is engaged in the study of a foreign language, but he is often led to the same point of view by the grammar of his own native language, as taught in schools. Grammar treated in this way may be called *normative* or *prescriptive* grammar.

But to the scientific grammarian the subject has a different aspect: to him the rules are not what he has to observe but what he observes (in a different sense) when he examines the way in which speakers and writers belonging to a particular community or nation actually use their mother tongue. His attitude toward linguistic phenomena is therefore much more that of a naturalist observing the facts of nature; he stands more objectively outside the language he is studying, and perhaps never has to form one single sentence in it for himself. This we term *descriptive* grammar.

The grammatical observer, like the observer in other fields, seeks, wherever possible, to go beyond the mere facts in order to find their explanation. This is the function of *comparative historical* grammar, a creation of the 19th century (*see* PHILOLOGY). Many things which seem strange from the point of view of merely descriptive grammar find their natural explanation when viewed in the light of earlier periods of the same language or of related languages. Take such an abnormal plural as *feet* from *foot:* the historian finds that its long vowel goes back through a regular phonetic development to an earlier *ōē* which, wherever it was found, was treated in the same way (thus in *feed, green, sweet*) and like other *ōē's* was a mutated form of a still earlier *ō*—the vowel that is better preserved in the singular *foot,* where, however, it has now been shortened and raised. The mutation was here, as elsewhere, because of the existence of an earlier *i* in the final syllable, which was dropped in all analogous cases. Now we know that the ending in the plural in the earliest Germanic was very often *-iz,* which corresponds to a still earlier *-es,* preserved in Latin and Greek; the form *feet,* which from the one-sided Modern English point of view was an isolated fact, is thus seen to correspond to the Greek plural πόδες and to be connected with that form through a long series of perfectly normal historical changes, which do not only affect such plural forms but find parallels in other words as well. The historical and comparative method of explaining grammatical facts has been carried to a rare degree of perfection, but it is clear that it can only be employed to the full where we have early linguistic documents of the same language or of nearly related languages to refer to. The great majority of languages are only known to us in quite recent stages; here, however, a similar method of explanation may be used if there are other now existing languages that are akin to that we are examining, and the comparative method then sometimes allows us within certain limits to reconstruct a common basis from which the several languages have started, as with the numerous African languages known as Bantu.

Grammatical reconstructions should always be made with great caution, for the ways in which languages develop are not always easy to calculate. We may take the Romanic languages (Italian, French, Spanish, etc.) as a test case: all these languages have been known to us for several centuries; now in some cases it would be possible from existing forms in them to infer what the common basis must have been, and the forms thus reconstructed would agree pretty closely with the forms of what we know to have been the basis, namely Latin; but the method fails utterly, as has been well remarked, with regard to many other forms: no one would be able, for instance, to conclude from the forms of Romanic substantives that Latin had ever had an accusative in *-m*, for the only remnant is French rien from Latin *rem* "a thing"—and that now means "nothing" and can no longer be called an accusative.

The method of comparative grammar was especially developed in the study of our own family of languages, the Aryan or Indo-European (*q.v.*) family, and at a certain stage of its development scholars were naturally tempted to dwell on and to a certain extent exaggerate those features that were common to these languages, and to take less account of features which were peculiar to one or a few of them. There was always a tendency to think that these were survivals of primitive common phenomena which were lost in the other languages of the group. This may be true in some cases, but more often we see that something found in one language only is a recent development that has really nothing to do with the rest of the family and may constitute a new grammatical type or phenomenon. Comparative grammar should therefore always be supplemented by separative grammar which does full justice to what is peculiar to each separate language and treats each on its own merits.

Differences of Structure.—Languages differ very considerably in their grammatical structure; subtle nuances which in one language are considered absolutely necessary are utterly disregarded in others. Things which we should naturally look upon as belonging necessarily to the grammar of any language, are in other languages either not expressed at all or expressed by means that are utterly different from ours. We have separate forms for the superlative, but French simply uses the comparative form with a defining word: mon meilleur ami, "my best friend," la chose la *plus nécessaire*, "the most necessary thing." Semitic verbs originally had no indications of the three time distinctions, past, present and future, but possessed two forms that showed whether an action was completed or not, no matter whether it was in the past, present or future time—distinctions which were later partly utilized to show time relations as well. Chinese substantives have no separate forms for singular and plural, and their verbs none for different tenses. Inversely, where we have only one "third person," American Indian languages very carefully distinguish between the first and second "third person" mentioned; the English sentence "John told Robert's son that he must help him" is capable of six different meanings which in Chippeway would be carefully distinguished by different forms of the pronouns for "he" and "him." Many languages have separate reflexive pronouns, like Latin se, himself, herself, themselves, suus his, her, their (own); these indicate identity with the subject of the sentence, but their sphere of application varies very considerably from one language to another; sometimes they refer to all three persons, sometimes only to the third, sometimes only to the singular, not to the plural, etc. In the oldest English we find sin as a reflexive possessive pronoun, but afterwards this solitary survival of the reflexive pronouns beginning with s disappeared from English, while such forms are still found in German, Scandinavian, etc.

Thus not only separate grammatical forms, but whole grammatical categories may be dropped in course of time. Generally this does not take place all at once but gradually, those forms which are in constant use being sometimes preserved for a long time after the others have been given up. The old Aryan (Indo-European) languages had separate forms for the dual number, distinct from the plural, but that distinction has been nearly universally lost. In Greek the dual was an archaism in Homer, though it lived on as a colloquialism in Attic till finally it disappeared there too. In the oldest English a few pronominal forms such as *unc* us two, *inc* you two, are the only survivals of a separate dual, and from about 1250 they go completely out of use. In Russian the dual, which ended in -a, has left some curious traces which are no longer felt as a separate number: some words denoting parts of the body which are found in pairs, form their plural in -a: *glaza* eyes, roga horns, etc.; after the numerals 2, 3, 4 a form that looks like a genitive singular is used instead of the usual plural form: it is the old dual in -a, which is extended to three and four.

In dealing with any definite period of a language it is important to state exactly which categories are found and which not. Old English had, but Modern English has not, a dative case. When the old forms were given up in the Middle English period, traces of them were still preserved in some survivals, *e.g.*, in Chaucer of towne (with e pronounced as a separate syllable), yeer by *yere*, by weste; a few isolated remnants exist still, though no longer felt as separate case-forms: *alive*="on life" (dat.), *Atterbury*="at the (dat.) borough." In a sentence like "he gave his children food" or a phrase like "from his children," Old English used the form *cildrum*, while the form was cildru in the nominative and accusative plural. Now the distinction has disappeared. To say that English still uses a dative case in these combinations is just as unhistorical as to say that Normandy and Massachusetts still form parts of the British Empire. This does not, of course, amount to denying that children in the sentence above is an indirect object, to be distinguished from the direct object (food). If we were to speak of a dative case here we might just as well say that in "Tom and Mary are children" the last word is grammatically in the dual number, but who would say this?

A word or form belonging to one grammatical category may in course of time be shifted insensibly into another one. Thus near at first was the comparative of nigh, with a superlative next; but in such a sentence as "Come near!" the meaning might be equally well taken as "closer" or "close," and thus the word passed into its modern use as a "positive" and it became possible to form a new comparative and superlative nearer, nearest, while the old superlative next was specialized in its use, and nigh became obsolete.

New grammatical categories may develop; examples are the English "expanded" or "progressive" tenses: he is running, was *running*, has been running, etc., as distinct from he runs, ran, has run. The distinction between "absolute" (primary) and "conjoint" (adjunctive) possessive pronouns, e.g., mine, yours as distinct from my, your, is another case in point. There is in some languages a tendency in regard to personal pronouns to merge the distinction of nominative and objective in that of conjoint and absolute, the old nominative being used only when it stands in immediate connection with a verb as subject, and the old objective in all other positions. This has become the rule in French, where je is used only in combinations like je dis, dis-je (I say, say I) and *moi*, which is the stressed form of the accusative me, is found in *c'est* moi and Qui *l'a* dit? Moi (Who said it? I). In Italian we see similar tendencies, and in modern colloquial English me tends to supersede the literary I in *It* is me and Who's there? Me.

As languages are thus seen to be in constant flux, and as grammatical categories may to a certain extent change from language to language and even from one period to another—and as exotic and "savage" languages possess many categories unknown to our European languages, it will easily be understood how injurious it is to a scientific conception of grammar to measure it always and everywhere by the same standard. But that is what grammarians of former centuries and even recent writers have been and are in the habit of doing; for Latin was for centuries the only language studied grammatically, and its privileged position made people think it a pattern by which to measure all other languages. Not only those languages that were similar in structure to Latin, but even the most heterogeneous languages were indiscriminately saddled with the elaborate Latin system of tenses and moods, and by means of such Procrustean methods the actual facts of many languages were distorted and misrepresented. Discriminations which had no foundation in reality were nevertheless insisted on, while discriminations that happened to be non-existent in Latin were apt to be overlooked. As A. H. Sayce writes in the 9th edition of the *Encyclopædia Britannica*, "The endeavour to find the distinctions of Latin grammar in that of English has only resulted in grotesque errors, and a total misapprehension of the usage of the English language." Happily things are improving very considerably in this respect.

Spoken and Written Language.—A modem philologist always looks upon the spoken language as the essential thing to study; in languages with a traditional spelling he must constantly be on his guard against misconceptions arising from that source. To the uniform English plural ending in the written words *kings, dukes, princes* correspond three different forms in the spoken language; on the other hand the French forms *(je) donne, (tu) donnes, (ils) donnent,* though differently spelt, are the same in sound, and thus in numerous cases. Many things of great grammatical importance, like intonation, stress, etc., are not shown in our traditional spellings. Grammars of spoken as distinct from written English have been written by Henry Sweet and Harold Palmer. Dialect grammars and grammars of the languages of uncivilized races deal of necessity only with spoken words.

THE SYSTEM OF GRAMMAR

Most grammars, at any rate most of those dealing with our own family of speech, are built up in the traditional way with the following main divisions:—

I. Phonology. This treats of the general theory of the sounds and sound-combinations of the language concerned, and expounds the orthography, where there is occasion.

II. Accidence or Morphology, the theory of forms (German *Formenlehre* is a better term than those used in English). This generally treats of the traditional "parts of speech" in their usual order, substantives, adjectives, etc. The main subject is the changes words undergo in flexion, paradigms being given which show all the forms of one and the same typical word; but the point of view is not pursued consistently, for under "numerals" we generally find an enumeration of all these words in their natural order, though most of them are subject to no formal changes.

III. Word-formation, dealing with prefixes, suffixes and other means of forming one word from another.

IV. Syntax, generally in its first part taking the parts of speech separately as in II. and stating the rules for the use of each case, tense, mood, etc. A second part then deals with word-order, etc.

This system, which varies a good deal in details, has been repeatedly criticized (by J. Ries, Noreen, Jespersen), but no other system has been universally accepted. In France, F. Brunot has proposed basing the teaching of grammar not, as is usually done, on the forms from which the pupils proceed to their syntactical use, but on the inner meanings expressed by grammatical phenomena, stating in each case secondarily the external forms, etc., which are used to express them.

As a matter of fact, grammatical phenomena can be viewed from two different angles: one that of the hearer (reader), to whom a certain series of sounds (letters) is presented, the inner meaning of which it is his task to understand: he begins from the outside and moves inwards; the other that of the speaker (writer) : he has certain ideas which he wants to communicate to others; he therefore has to choose the forms (sounds, etc.) that serve best to express these ideas: he moves from within to without.

We are thus led to the following two main divisions of grammar: I. The theory of Forms. II. The theory of Notions. Both deal with the same grammatical facts but from opposite points of view.

I. The Theory of Forms.—The following is a systematic survey of the external means used in languages for grammatical purposes.

(1) A simple sequence of words. This is seen, for instance, in compound substantives like *post-ofice.* The importance of the order in which words are arranged, is seen in cases like *garden-flower* and *)lower-garden,* where the first element limits and defines the meaning of the second, and in the distinction between *Paul loves Ann* and *Ann loves Paul,* where word-order shows which is subject and which object.

(2) "Empty words," *i.e.,* words which have no proper meaning of their own, but merely serve to indicate the relations of other words. Examples: of in "the father of the boy" (=the boy's father), "the City of Rome," "that scoundrel of a servant"; to in "I want to hear," "he refused food to the poor"; *that* in "I saw that he came," etc. There is no hard-and-fast distinction between full and empty words; *to* in "I give food to the poor" has still something of its local meaning found in "go to London," etc.

(3) Prefixes, e.g., *for-* in *forbid, be-* in *besiege.*

(4) Infixes, e.g., *n* in Latin *vinco,* cf. the perfect *vici,* English *stand,* cf. *stood, messenger,* cf. *message.*

(j) Suffixes, e.g., *-ness* in *goodness, -en* in *blacken;* these cannot be separated from such "inflexional endings" as *-s* in *kings, -en* in *oxen.*

(3) (4) *(5)* together may be termed affixes. The origin of some of these is quite obvious: they were at one time independent words joined to other words like those in (1). A word may easily be accentually subordinated to another with which it is continually combined, especially if the combination acquires a meaning of its own, independent of that of each element, as in *blackbird;* in *postman,* the vowel of the second element is obscured, and in other cases further phonetic changes take place; *gentlemanlike* and *gentlemanly* show two stages in the development of a suffix from what was originally an independent word; *for-* in *forgive* is an old preposition, though perhaps not exactly identical with the ordinary *for; be-* is a weakened form of *by.* But it is not all affixes that originate in this manner from independent words: *-en* in *oxen* originally belonged to the stem of the word in all its forms, and it was only through the accident of this syllable having been lost in the singular, but not in the plural, that it came to be felt as an affix to denote the plural number. The origin of most of our affixes is hopelessly obscure.

(6) Change in intonation, stress or quantity, e.g., *Yes?* with a rising tone in a question, *Yes* with a falling tone as an affirmative answer; *object* with varying stress according as it is a substantive or a verb.

(7) Consonantal changes, e.g., *send, sent; half, halve; use* as a substantive with unvoiced, as a verb with voiced consonant.

(8) Vocalic changes, e.g., *feed, fed; see, saw; man, men; drink, drank, drunk.*

(6) (7) (8) are phonetic changes, which may be due to the most different causes; some are recent, others go back to the most remote times; some have only in various circuitous ways acquired significative grammatical importance.

(9) Combined changes, affixes like those in (3) (4) (5) being joined to phonetic changes like those in (6) (7) (8). Examples: *forgot* (3) (8), *forgotten* (3) (8) (5), *drunken* (5) (8), *halves* (5) (7), *men's* (5) (8), *won't* (5) (7) (8).

(10) Supplementing with different stems: *I, me, we, us; am, is, was, been; good, better.*

Some languages make a more extensive use of some of these grammatical means than of others. Chinese uses scarcely anything but word order and empty words; some languages are predominantly prefix-languages, as for instance, the Bantu family; others predominantly suffix-languages, *e.g.,* Eskimo and Turkish. As will be seen from the examples, English uses all these means freely, though there are few examples of infixes.

We must here mention a classification of all the languages of the world according to their morphological system, which played a great rôle in the discussions of the 19th century, but has now been given up as superficial, namely, into (1) isolating languages or root-languages like Chinese, (2) agglutinative languages like Finnish and Turkish, which use affixes, but have no internal changes in the roots, (3) flexional languages like those of the Aryan and Semitic families. The last were also supposed to have gone through the isolating and agglutinative stages in their prehistorical development, while Chinese was thought to represent the earliest childlike linguistic structure. The latter supposition has been shown to be wrong, as the earliest Chinese in some respects was "flexional," and those hundreds of languages that were formerly classed together as "agglutinative" represent the most diverse types of morphological structure. The world is more complex than our ancestors imagined:

II. The Theory of Notions.—A comprehensive system of all the notions that find expression in language would be impracticable on account of the infinite complexity of mental and physical phenomena. But we are here concerned with those notions only that have found grammatical expression, and this makes our task somewhat less difficult, though far from easy. The following necessarily very brief survey does not claim to be either complete or final.

(1) Parts of speech. It is usual to divide words grammatically into the following classes and to define them somewhat as is here (very succinctly) indicated: —

(a) Substantives — denoting "persons" and "things."
(b) Adjectives — showing qualities.

Substantives and adjectives are often classed together as "nouns." but many grammarians make the term "noun" equivalent to "substantives," and do not comprise under it adjectives.

(c) Pronouns — used instead of nouns "to designate a person or thing already mentioned or known or forming the subject of inquiry." Various well-known subclasses: personal, demonstrative, relative, interrogative, indefinite. The so-called articles, as well as numerals, are best treated as subdivisions of pronouns.
(d) Verbs — denoting actions, states or happenings.
(e) Adverbs — serving to modify adjectives or verbs.
(f) Prepositions — marking relations between words.
(g) Conjunctions — used to connect clauses or to co-ordinate words in the same clause.
(h) Interjections-ejaculations, standing outside ordinary sentences.

This division and the definitions usually given have, however, been subjected to severe criticism and should not be taken at their face value. One of the chief difficulties with substantives is the existence of such words as arrival and *kindness,* which are undoubtedly substantives and are treated grammatically as such, but cannot be termed names of "things"; they represent "nexus" (see below). Adverbs, prepositions and conjunctions are best classed together as "particles."

(2) Rank. While the division under (1) concerns words separately, we here have a distinction that has regard to words or word-groups in combinations, namely into:

(a) Primary
(b) Secondary
(c) Tertiary — words or word-groups.

The three ranks to some extent, but only to some extent, correspond to substantives, adjectives and adverbs respectively. Secondary elements serve to modify or delimit primaries, tertiary elements to modify or delimit secondaries, as will be seen from the following examples in which those words or groups are italicized which belong to the rank under which they are classed: —

(a) The King's palace. The King arrived. I know when he arrived.
(b) The *King's* palace. *A* big palace. The palace that he built.
(c) A really big palace. I was present when he arrived.

The combination of a primary and a secondary element in the way exemplified under (b) is termed junction; the adjective or (relative) clause standing as secondary is called an adjunct. Tertiaries are also termed *subjuncts.*

(3) Other classifications. Many languages classify words in such a way that a class is indicated either in the word itself or in the form required in those adjuncts, etc., which belong to it. Sometimes the distinction is into animate and inanimate, sometimes into big and small things, sometimes into male, female and sexless; but such distinctions are rarely indicated with what we should call consistency; some languages, for instance, that have the main distinction "animate: inanimate," reckon certain parts of the human body as animate, others as inanimate. Sometimes it is impossible to see what is really the notional basis of a classification. When the distinction is connected with sex, as in most of the Aryan languages, we speak of gender; but the actual distinction between masculine, feminine and neuter gender does not correspond at all exactly with that between male and female beings and sexless things; very often it is impossible to discern why one word belongs to one gender rather than to another. In Old English, for instance, *stan* stone, *daeg* day, *finger, wifmann* woman were masculine; niht night, ecg edge, hand feminine; and *treow* tree, gear year, *blod* blood, wif wife neuter. This word-gender, which is still found in German, and which influenced the flexion of the words and the form of the article and adjective belonging to them, disappeared gradually from English in the Middle English period. In Semitic languages, the sex of the subject influences the form of the verb.

(4) Number: On the dual number see above. The distinction between "one" and "more than one" is very easy from a notional point of view, but not always so easy grammatically, partly because some things may be looked upon either as units (as German brille) or as composite (Engl. spectacles), partly from other causes. A collective is a word which though singular in form denotes a plurality, hence such anomalies as twenty police; cf. also "my family is an old one" and "my family are early risers." Number properly belongs to primaries only, but many languages require secondaries to agree in number with their primaries, e.g., *those* trees, and German die hohen baume the big trees, where in English the article and adjective are invariable. In English verbs the distinction has been given up in all past tenses, e.g., he went, they went (except he was, they were), in the present tense it is preserved in the third person only: I go, we go; *he* goes, *they* go.

(5) Person, *i.e.,* the distinction between the speaker, the person (or persons) addressed, and what is neither speaker nor spoken to. The distinction is shown in pronouns and in many languages also in the verb. The plural "we" does not mean two or more "first persons," but "I+you" or "I+some one or more persons besides," and some languages make a distinction according as the second person is included or not. Such a pronoun as French on, Engl. one, may be considered a "common person." (On reflexive pronouns, see above.)

(6) Space. Some languages have different forms according to distance from the speaker, etc. Case-forms denoting existence in or at a place and movement to, towards or from a place are very frequent. In our languages, with a view to greater precision, such case-forms were frequently supplemented by adverbs, and these in time became prepositions governing the cases which at first were sufficient in themselves to denote the spatial relation; eventually the case-endings were often dropped as superfluous.

(7) Time. With substantives the same means (case-forms, adverbs, prepositions) as are used to indicate spatial relations are as a rule also used to denote time relations. But with verbs many, or perhaps most, languages have separate means of denoting time-relations, which cannot surprise us, as the idea of time is naturally associated with that of action or happening. But while the notional division of time into past, present and future is quite simple, mankind has not, as a rule, found correspondingly simple grammatical expressions for time and its subdivisions, such distinctions as that between permanent and transitory, or between finished and unfinished, or between once and repeatedly, or between stability and change, or between resultative and non-resultative action being often inextricably connected with real time-indications in the "tenses" of verbs. Expressions for the future are often much more vague than those for the past, and frequently expressions which at first had and still to some extent have the meaning of volition or obligation or motion are made to do duty as a kind of future tense, as in "he will come," "I shall come," "they are going to start" (French "on va partir"), etc. Some languages have very elaborate tense systems with separate forms for imperfect, aorist, perfect, pluperfect, future in the past, etc., others rely more on the context or on adverbs for such nuances, if they are conceived at all.

(8) Comparison. The superlative ("strongest," etc.) is really a kind of comparative: "he is the strongest of the boys" means the same thing as "he is stronger than the other boys," the difference being only that the result in the former sentence is stated with regard to all boys, himself included, while in the latter he is excluded. A comparison results in expression of inequality or equality, as in "he is stronger than X" (a), "he is as strong as X" (b), "he is less strong than X" (c); of these (a)

and (c) are closely connected as they both denote inequality and therefore use the comparative. Many languages even for this sense use the positive form and say "strong from X" or the like.

(9) Nexus. This is a comprehensive term for the combination of two words (or word-groups) which stand to another in the relation of subject to predicate. The simplest case is a sentence with a subject and a verb, as "the doctor arrived" or with a subject, an "empty" verb ("copula") and a predicative, as "the doctor is clever." Compare also sentences without a verb like "Happy the man who. . . ." and "He a doctor!" There are other cases of nexus, in which the nexus does not in the same way as here form a whole sentence, but only part of one, as in "the doctor's arrival," "the doctor's cleverness," "(I saw) the doctor arrive," "(we thought) the doctor clever," "(we count on) the doctor to arrive," "(he slept with) the window open," "every thing considered (he must be clever)."

A nexus of a different kind exists between a verb and its object, as in "we saw the doctor," or its two objects, as in "we offered the doctor money." Further, the theory of nexus leads to a contemplation of the relation between the active and the passive expression for one and the same thought: what in the active turn is an object, is made into a subject in the passive turn: "the doctor was seen (by us)," "money was offered (to) the doctor," "the doctor mas offered money."

(10) Affirmation and negation. In some languages the verb has special forms for negation: this is to a certain extent true of English, especially in its colloquial form: *won't,* cf. *will, shan't,* cf. *shall;* note also the use of the auxiliary *do* in most negative sentences which contain no other auxiliary: "The doctor did not arrive."

(11) Subjective attitude of the speaker. By the side of simple ("flat") assertions me find others in which the speaker does not want to commit himself, but speaks with a certain hesitation, doubt, hope or fear. and such emotional repressions often manifest themselves grammatically, either in particles like Greek αν or in special forms of the verb (chiefly the subjunctive mood). The same means are frequently applied in conditioned clauses, which range from those in which doubt is not expressed at all or slightly hinted at, to those in which unreality is expressly indicated. In the latter kind some languages use a special conjunction, while others show that "the condition is rejected" by shifting the mood into the subjunctive and the tense into the preterite or by the latter means alone. In connection with this must be mentioned the expression of diffidence or modesty in questions like "Could you (Would you) lend me a pound?" as against the simple and direct "Can you (Will you) . . . ?" and the difference between the unrealizable wish in "Would he were still alive!" and the realizable wish in "May he be still alive !"

(12) Relation to the will of the hearer. In one class of utterances (ordinary statements and exclamations, for example) the speaker does not want to influence the will of the hearer. The aim of another class is to influence the will of the hearer, that is, to make him do something. This may be effected by requests, which range from brutal commands or orders through demands, implorations, invitations, etc., to the most humble entreaty or supplication. One of the linguistic forms for requests is the imperative, other forms are seen in "One minute!" and "Hands off !" Questions belong to requests, as they imply a request (command, prayer, etc.) to give the original speaker a piece of information. They are of two distinct kinds according to the existence or nonexistence of an "unknown quantity" expressed by means of an interrogative pronoun or adverb: "Who said that?" "What did he say?" and "When did he say that?" are examples of one kind, "Did he say that?" of the other kind. Questions, and requests generally, are naturally liable to those influences which were dealt with under (11) ; questions are likewise notionally related to negations, whence they often employ similar grammatical means; this is seen, for instance, in the English use of the auxiliary *do* in both kinds of sentences.

The system here given shows how a notional arrangement leads to the separation of things which in the ordinary grammatical system are placed together. Under case, accordingly, we have thinrs which have relation to junction (the chief use of the genitive is to make a word the adjunct of another word), to space (the so-called locative cases) and to nexus (nominative to denote the subject, accusative and dative, for various kinds of objects). Here, as elsewhere, we see that linguistic phenomena are capable of being viewed from different angles and that they present all kinds of intersections and overlappings.

In the treatment of each particular language we meet with units which are units neither from the purely formal nor from the purely notional point of view, but which nevertheless must be taken together as what might be called functional units. Take the English preterite: it is not a formal unit, because it is formed in different ways: *ended* from *end, sent* from *send, thought* from *think, put* from *put, saw* from *see, was* from *be,* etc. Neither is it a notional unit, for sometimes it indicates the past time pure and simple, sometimes unreality ("if he came"), or modesty ("Could you . . . . ?") or even future time ("it is time you went to bed"), and it has even more spheres of application. Yet all these formal and notional things go together and form one separate unit in English grammar, which is different from such units in any foreign grammar as in some ways correspond to it: in French, for instance, we have two or three tenses (*je finissais* and *je finis* or colloquially *j'ai fini* corresponding to I *ended),* each of which is a unit in the' same way as the English preterite is. But all the units we arrive at through our analysis of grammatical phenomena are at best symbols or shadowings of the innermost notional categories. (O. J.)

GRAMME: *see* GRAM.

GRAMONT, ANTOINE AGENOR ALFRED, DUC DE, DUC DE GUICHE, PRINCE DE BIDACHE (1819–1880), French diplomatist and statesman, was born in Paris, Aug. 14, 1819. He was educated at the École Polytechnique, but entered the diplomatic service. On May 15, 1870 he was appointed minister of foreign affairs in the Ollivier cabinet, and was thus concerned in the bungling of the negotiations between France and Prussia arising out of the candidature of Prince Leopold of Hohenzollern for the throne of Spain, which led to the disastrous war of 1870–71. The famous declaration read by Gramont in the chamber on July 6, the "threat with the hand on the s ord-hilt," as Bismarck called it, was the joint work of the whole cabinet; the original draft presented by Gramont was judged to be too "elliptical" in its conclusion and not sufficiently vigorous. The history of the affair is given by Emile Ollivier himself in his *Empire libéral* (vol. xii, 1909). It was Gramont who pointed out to the emperor, on the evening of the 12th, the dubious circumstances of the act of renunciation of the prince of Hohenlohe-Sigmaringen on behalf of his son. On the same night, without informing Ollivier, he dispatched to Benedetti at Ems the fatal telegram demanding the king of Prussia's guarantee that the candidature would not be revived. The supreme responsibility for this act must rest with the emperor, "who imposed it by an exercise of personal power on the only one of his ministers who could have lent himself to such a forgetfulness of the safeguards of a parliamentary régime." says Ollivier.

Gramont resigned office with the rest of the Ollivier ministry (Aug. 9) and after the revolution of September went to England, returning after the war to Paris, where he died on Jan. 18, 1880. He published various apologies for his policy in 1870, notably *La France et la Prusse avant la guerre* (1872).

GRAMONT, PHILIBERT, COMTE DE (1621–1707), French courtier of Gascon origin, the hero of Anthony Hamilton's *Mémoires du comte de Grammont,* was the younger son of Antoine II de Gramont, viceroy of Navarre, whose mother Diane d'Andouins, comtesse de Gramont, called "la belle Corisande," had been a mistress of Henry IV of France. Philibert was educated for the church but preferred a secular career. Known at first as the chevalier de Gramont, he served in the French army at the siege of Trino in Piedmont under Thomas of Savoy (1643) and in Germany under his half-brother the marshal Antoine III de Gramont and under the duc d'Enghien. When the latter became prince de Condé he gave Gramont a high post in his household. Gramont remained with Condé's faction during the Fronde until 1654, when he made his peace with the French government after Condé's withdrawal to the Spanish Netherlands. In 1662, however, he was exiled from France — some said for competing with Louis XIV for Mlle. de la Mothe-Houdancourt's favours. Arriving in England in Jan. 1663, he found a congenial atmosphere at Charles II's court. There he paid such attentions to the beautiful Elizabeth Hamilton, his future biographer's sister, that her brothers made him marry her in Dec. 1663. Allowed to return to France in 1664, he made three visits to England (1670–71) in connection with the negotiations preceding and following the treaty of Dover. Between campaigns in the Dutch Wars of 1672–78 he was in England again in 1676; he conveyed Louis XIV's congratulations to James II on the birth of a son in 1688. In his old age he provided Anthony Hamilton (*q.v.*) with the material for the *Mémoires.* After an apoplectic stroke in 1706, he died in Paris in the night of Jan. 29–30, 1707.

Hamilton portrays his hero candidly but with such skill that Gramont's grand air imposes on the reader just as it did on his contemporaries. But the subject matched the artist. Hamilton calls him an inimitable character, an amazing compound of good and bad, in fact *"l'admiration de son siècle"* (the wonder of his age). Even Gramont's enemies agreed as to his wit, impudence and ebullience. He was the sort of man about whom stories gather. He scandalized those about his deathbed who were repeating the Lord's Prayer, by remarking that it was a beautiful prayer, who had written it? He would seem to be the original of the outburst that Gascon noblemen would never have deserted Christ as His disciples, common fishermen, did. The duc de Saint-Simon, who hated him and accuses him of cowardice, has left a living picture of this "vieux sacripant de cour et de monde" (old court and society blusterer) with the face of an old monkey and never-failing success with ladies and with kings. a man to whom "everything was permitted and who permitted himself everything."

H. Lewis, *Assault on Olympus: the Rise of the House of Gramont between 1604 and 1678* (1958). (W. G. ME.)

GRAMOPHONE: see PHONOGRAPH.

GRAMPIANS, THE, mountains forming a part of the Scottish Highlands. The name is applied by some authors to the whole mountain mass lying between Glenmore and the great fault which runs from Stonehaven on the North sea to Dumbarton on the Clyde. This is now more frequently called the Central Highlands. Others limit its application to the southern edge of this mountain mass where it overlooks the Lowlands. The name originated in a misreading of Mons Graupius, the site (not ascertained) of the battle in which Agricola defeated the Picts in about A.D. 83–84. This was shown on Hector Boece's map of 1527 as Mons Grampius. On historical grounds the latter usage therefore would appear to be the more correct. This southern edge is the most striking relief feature in Scotland. From the Lowlands it presents the appearance of a continuous mountain range, stretching for over 100 mi. without a break and including peaks reaching to over 3,000 ft. (Ben Lomond 3,192, Ben Alder 3,757). It is not, however, the formidable barrier it appears for it is broken by deep, if narrow, passes such as the Pass of Leny, the Pass of Killiecrankie and the Spittal of Glenshee. The rocks are chiefly schists and gneisses with some granite masses.

A mountain range in southwest central Victoria, Australia. is also called the Grampians. (T. HER.)

GRAMPUS (Grampus orca), a cetacean belonging to the *Delphinidae* or dolphin family! characterized by its rounded head without distinct beak, high dorsal fin and large conical teeth. The upper parts are nearly uniform glossy black, with a white eye-stripe and the under parts white. The animal is also known as the "killer," in allusion to its ferocity in attacking its prey, which consists of fishes: seals. porpoises and the smaller dolphins. It is very voracious. In the antarctic several will combine to break the ice in order to throw their prey (and, it is said, even men) into the water where they can kill it. These cetaceans sometimes hunt in packs and commit great havoc among the belugas (*q.v.*) and other whales. The grampus inhabits hoth northern and southern regions and is common in British waters. The number of species is doubtful, but only one is usually recognized. *Grampus* was formerly used as the generic name of Risso's dolphin. See WHALE.

GRANADA, LUIS DE (c. 1504–1588), Spanish Dominican preacher and spiritual writer, who made important contributions to teaching on Christian perfection, was born of poor parents at Granada, where he entered the order in 1524. He became prior at Cordoba (1544) and Badajoz (1554) and provincial of Portugal (1556–60). He was spiritual adviser to Queen Catherine of Portugal. He died at Lisbon on Dec. 31. 1588.

Luis' principal works, important also as Spanish prose: are: *Libro* de la oracidn y meditacidn (1554), on methodical prayer, akin to the systems of Ignatius Loyola and Garcia de Cisneros; *Guia* de pecadores ("Sinners' Guide," 1556), on practical Christian virtue (hoth proscribed by the Inquisition in 1559. when any vernacular devotional book was suspected of illuminism, but reinstated in 1564); *Memorial* de la *vida christiana* (1566) and *Adi*ciones to it (1574), on prayer. Spiritual classics that have enjoyed lasting popularity, they were translated during his lifetime into Latin, French, Italian and English (by R. Hopkins, 1582), and were esteemed by St. Teresa of Avila and St. Francis of Sales. Luis also published sermons. catechetical works, biographies and a translation of the *Imitation of* Christ. A critical edition of his works by J. Cuervo was published in 14 volumes (1906–08).

See biography *by* J. Cuervo (189;) ; E. A. Peers, *Studies* in *the Spanish Mystics*, vol. i, 2nd ed. (1951); M. H. Lavocat in A. Vacant, *Dictionnaire de théologie catholique* (1926), s. v. Louis. (S. BII.)

GRANADA, a department and city in Nicaragua. Central America. The department has an area of 541 sq.mi. and a population (1959 est.) of 70.257. It is bounded on the north by the department of Managua. on the west by Masaya and Carazo, Rivas on the south and Lake Nicaragua on the east. It is crossed by the Pan American highway and the Pacific railroad. The clustered islands on the lake near Granada called Las Isletas (the little islands) are famous for their beauty and are favourite excursion spots for the Granadinos.

Principal towns besides the capital city, are Nandaime and Diriomo. Main products are cattle and hides, cacao, sugar, cotton, rice and coffee.

GRANADA, the city, capital of the department and terminus of the Pacific railroad from the port of Corinto, is 36 mi. S.E. of Managua, the national capital. Pop. (1959 est.) 31.648. It lies at an altitude of 180 ft. above sea level near Mombacho volcano, on the northwest shores of Lake Nicaragua where steamers and launches connect it with the lake towns. Granada is remarkable for its churches, schools and institutions, including the Colegio Centro-América founded by the Jesuits. It is the seat of the bishop and as headquarters of the Conservative party has greatly influenced the political life of the country.

The city is typically Spanish and is laid out on a rectangular gridiron style. The houses are mostly one story, but include many fine mansions of the old families; the churches are massive and some are ornate.

Granada was founded in 1523 by Francisco Hernández de Córdoba and early became the hub of the Conservative life and trade of the region. From earliest times it has been a keen political and trade rival of Leon (*q.v.*), farther north, the centre of the Liberal party and now a more prosperous and populous business rival of Granada. Managua (*q.v.*) was founded between the two older cities as a political compromise. Granada was raided by pirates from the Caribbean many times in the 17th century. William Walker (*q.v.*) the U.S. filibuster: made Granada the centre of his attacks and his headquarters; he sacked and burned the city in 1857. (M. F.-G.)

GRANADA, a maritime province of southern Spain, formed in 1833 of districts belonging to Andalusia, and formerly centre of the ancient kingdom of Granada. Pop. (1960 est.) 828.525: area 4.838 sq.mi. Granada is bounded on the north by Córdova, Jaén and Albacete, east by Murcia and Almería, south by the Mediterranean sea and west by Málaga. It includes the western and loftier portion of the Sierra Nevada (*q.v.*), a vast ridge rising parallel to the sea and attaining its greatest altitudes in the Cerro de Mulhacén (11,411 ft.) and Picacho de la Veleta (11,128 ft.), which overlook the city of Granada. Lesser ranges, such as the sierras of Parapanda, Alhama, Almijara, Harana or Baeza, adjoin the main ridge. In this central watershed rise the three principal rivers of the province. Southward flows the Guadalféo to the Mediterranean, westward the Genil and northward the Guadiana Menor and its many tributaries draining the northeastern districts. Both the Genil and the Guadiana join the Guadalquivir outside the province. Summer drought predominates and only the mountain slopes are forested, mainly with pine trees. The soil of the high basins north of the Sierra is, however, fertile, that of the Vega of Granada being considered the richest in the whole peninsula, and from the days of the Moors it has been systematically irrigated. Sheep and goats are reared in the Sierra and esparto grass is obtained from the upland areas. Fine alabaster, jasper and other precious stones occur in the mountains behind Granada, but are little worked. The only important industry is sugar refining. This developed rapidly after the loss of the Spanish West Indies and the Philippine Islands in 1898, with the consequent decrease in competition, and there are now factories in many towns. especially in the Vega and along the coast.

See also ANDALUSIA and, for the history of the ancient kingdom, the city of GRANADA.

GRANADA, the capital of the province, and formerly of the kingdom of Granada, in southern Spain; on the Madrid-Granada-

Algeciras railway. Pop. (1950) 154,589. Granada is well situated, 2,195 ft. above the sea. on the northwestern slope of the Sierra Nevada. overlooking the fertile lowlands known as the Vega de Granada on the west and overshadowed by the peaks of Veleta (11.128 ft.) and Mulhacén (11,411 ft.) on the southeast. The southern limit of the city is the river Genil, the Roman *Singilis* and Moorish *Shenil,* a swift stream flowing westward from the Sierra Nevada, with a considerable volume of water in summer, when the snows have thawed. Its tributary, the Darro, the Roman *Salon* and Moorish *Hadarro,* enters Granada on the east. flows for more than a mile from east to west and then turns sharply southward to join the main river. which is spanned by a bridge just above the point of confluence. The waters of the Darro are much reduced by irrigation works along its lower course. and within the city it has been canalized and partly covered with a roof.

Granada comprises three main divisions, the Antequeruela, the Albaicin and Granada, properly so-called. The first division, founded by refugees from Antequera in 1410, consists of the districts enclosed by the Darro, besides a small area on its right, or western, bank. It is bounded on the east by the gardens and hill of the Alhambra (*q.v.*), the most celebrated of all the monuments left by the Moors. The Albaicin (Moorish *Rabad al Bayazin,* "Falconers' Quarter") lies northwest of the Antequeruela. Granada, properly so-called, is north of the Antequeruela, and west of the Albaicin. The origin of its name is obscure; it has been sometimes derived from *granada,* a "pomegranate," in allusion to the abundance of pomegranate trees in the neighbourhood. A pomegranate appears on the city arms. The Moors, however, callec! Granada *Karnattah,* or *Karnattah-al-Yahud,* and possibly the name is composed of the Arabic words *kurn,* "a hill," and *nattah,* "stranger" — the "city" or "hill of strangers."

Granada is the see of an archbishop. Its cathedral, begun in 1529 by Diego de Siloe, and finished only in 1703, is profusely ornamented with jasper and coloured marbles, and surmounted by a dome. The interior contains many paintings and sculptures by Alonso Cano (1601–67), the architect of the fine west façade, and other artists. In one of the numerous chapels, known as the Chapel Royal (*Capilla Real),* is the tomb of Ferdinand and Isabella, the first rulers of united Spain. The Cartuja, or Carthusian monastery, north of the city, was built in 1516 in memory of the great captain Gonzalo de Córdoba (1453–1515), whose tomb is in the convent of San Jeronimo.

After the Alhambra, and such adjacent buildings as the Generalife and Torres Bermejas, which are more fitly described in connection with it, the principal Moorish antiquities of Granada are the 13th-century villa known as the Cuarto Real de San Domingo, admirably preserved and surrounded by beautiful gardens; the Alcazar de Genil, built in the middle of the 14th century as a palace for the Moorish queens; and the Casa del Cabildo, a university of the same period, converted into a warehouse in the 19th century. Granada has an active trade in the agricultural produce of the Vega, and manufactures liqueurs, soap, paper and coarse linen and woollen fabrics.

History. — The identity of Granada with the Iberian city of *Iliberris,* or *Iliberri,* which afterward became a flourishing Roman colony, has never been fully established; but Roman tombs, coins, inscriptions, etc., have been discovered in the neighbourhood. Under the caliphs of Cordova the family of the Zeri, Ziri or Zeiri maintained itself as the ruling dynasty until 1090; it was then displaced by the Almorávides, who were in turn overthrown by the Almohades, in 1154. The dominion of the Almohades continued unbroken, save for an interval of one year (1160–61), until 1229. From 1229 to 1238 Granada formed part of the kingdom of Murcia; but in the last-named year it passed into the hands of Abu Abdullah Mohammed ibn Al Ahmar, prince of Jaen and founder of the dynasty of the Nasrides. Al Ahmar was deprived of Jaen in 1246, but united Granada, Almeria and Malaga under his sceptre, and made peace with Castile. Al Ahmar and his successors ruled over Granada until 1492, in an unbroken line of 2j sovereigns. Their encouragement of commerce — notably the silk trade with Italy — rendered Granada the wealthiest of Spanish cities; their patronage of art, literature and science attracted many learned Muslims such as the historian Ibn Rhaldun and the geographer Ibn Batuta, to their court, and resulted in a brilliant civilization, of which the Alhambra is the supreme monument.

The two noble families of the Zegri and the Beni Serraj, better known in history and legend as the *Abencerrages* (*q.v.*), encroached greatly upon the royal prerogatives during the middle years of the 15th century. A crisis arose in 1462, resulting in the dethronement of Abu Nasr Saad, and the accession of his son Muley Abu'l Hassan, whose name is preserved in that of Mulhacen, the loftiest peak of the Sierra Nevada. Muley Hassan weakened his position by resigning bfalaga to his brother Ez Zagal, and incurred the enmity of his first wife, Aisha, by marrying a beautiful Spanish slave, Isabella de Solis, who had adopted the creed of Islam and taken the name of Zorayah, "morning star." Aisha, or Ayesha, who thus saw her sons, Abu Abdullah Mohammed (Boabdil) and Yusuf, in danger of being supplanted, appealed to the Abencerrages. *(See* ALHAMBRA.) In 1482 Boabdil deposed his father, who fled to Malaga, but the Christians under Ferdinand and Isabella forced him to resign the task of defense into the more warlike hands of Muley Hassan and Ez Zagal (1483–86). In 1491 Boabdil signed away his kingdom; and on Jan. 2, 1492, the Spanish army entered Granada, and Moorish power in Spain ended. Nationalists captured Granada during the civil war of 1936–39.

GRANADOS, ENRIQUE (1867–1916), Spanish pianist and composer. was born at Lérida on July 27, 1867. After studying at Barcelona with Joan Pujol and Felipe Pedrell. he went to Paris in 1887, where he worked chiefly under Charles Wilfred de Bériot. In 1898 his first opera, *Maria del Carmen,* was produced in Madrid. Two years later he founded the Sociedad de Conciertos Clásicos and. in 1901, the Academia Granados. He had a brilliant career as a pianist, playing chiefly in France and Spain, but visiting the United States in 191j and 1916. when his opera *Goyescas* was performed in New York city. On his return he met his death in the English channel on board the "Sussex," which was sunk by a German submarine on March 24, 1916.

Granados' most characteristic writing is to be found in his piano music, which is full of the colour and rhythm of Spanish folk tunes. Especially in the *Goyescas*—two sets of pieces from which he took much of the material for his opera of that name—he produced melodies of great beauty, drawing inspiration from Francisco Goya's paintings and etchings, and the life of the period in Madrid. Among his other piano compositions are 12 Spanish dances, 3 sets of children's pieces, 6 pieces based on Spanish folksongs, *Romantic Scenes, Poetic Scenes, Book of Hours* and *Expressive Studies.* His remaining operas are *Petrnrca, Picarol, Follet, Gaziel* and *Liliana.* He also wrote a symphonic poem, *La cl del mort;* another on Dante's *Divina commedia;* and suites for orchestra; a suite, *Elisende,* for piano and orchestra; and three sets of songs. (E. W. BM.)

GRANARIES AND GRAIN ELEVATORS. Grain storage facilities range widely from simple provisions—in certain dry climates grain is sometimes stored in piles on the ground—to elaborate structures with equipment for mechanical filling and emptying, turning, blending, weighing. fumigating. drying or ventilating. Some buildings are for storing only a few bushels; others have capacity for several million bushels.

The character of a grain storage, as well as its size, depends upon the service required of it. On a livestock farm the granary usually has several separate bins for the various kinds of grain to be fed. Each bin may be filled or partly filled several times a year. Usually grain will not be stored for more than one season. The bins may be emptied a little at a time. and convenience of location for feeding and easy accessibility for removing grain are important.

On cash grain farms, from which most of the grain is sold, storage bins are for disposing of the grain at harvest time until it is sold later in the season. In this case ease of filling is most important. Larger grain storages on farms have built-in elevators but portable elevators or conveyors came to be used extensively.

Country elevators, located in smaller towns. serve to collect grain from farmers and ship it to terminals. Little grain is held for long periods. They are equipped with scales and with conveying equipment for filling, emptying and blending. They frequently also have driers.

Terminal elevators are the grain storages located at railroad centres. They collect grain from the producing areas and supply the processors and feed mixers and distributors in deficit areas. The terminal elevators have many separate bins and usually are of concrete construction. A typical bin may be 100 ft. deep and 20 ft. in diameter. Sloping floors are used so that the grain may drain out by gravity. Conveyor systems are installed so that grain may be moved into or out of the building or from any bin to any other.

In the United States during the 1930s the federal government entered into a program of grain price stabilization which resulted in government acquisition of large quantities of some grains to be held for relatively long periods. Other governments have taken more or less similar action. This results in the need for still another class of grain storage buildings where grain may be held for several years or at any rate for a longer period of time than had been the customary practice. Such storages are located on farms on government-owned bin sites or at grain elevators where they are operated in conjunction with storage and merchandising functions of the elevators.

In addition there are special storage facilities for segments of the grain industry. The storage of seed grains, for example, has special requirements. It is necessary in this case to avoid mixing of various lots since even a few kernels of the wrong variety may reduce the value of the lot.

Each kind of grain imposes its own requirements on storages and handling equipment. For example, rice is customarily harvested before it is dry enough to store; thus rice storages must have driers. Frequently rice is dried and stored in the same establishment where it is later milled.

Control of **Moisture** Content. — All grains contain water even when they are what is called dry. A bushel of wheat as ordinarily handled or stored contains about three quarts of water. Control of moisture content is important in successful storage of grains. Moulds develop and insects thrive in grain only if it has enough moisture for their needs. The safe limit of moisture is usually between 10% and 15%, depending on the kind of grain, the climate and the length of storage period. Since grains do not lose moisture readily when stored in bulk, it is important to accept for storage only grain that has been tested for moisture and found dry enough to keep.

One of the problems in storage of grains in large bins is the movement of moisture from one part of the bulk to another. This may occur even in grain that is initially dry enough for safe storage. The local increase in moisture results in caking or moulding and favourable conditions for insect breeding. The causes of the increase in moisture at the upper surface came to be understood only relatively recently.

The temperature of the interior grain in a large bin changes much more slowly than the atmospheric temperature. By late summer or fall the grain reaches its maximum temperature. The top surface and outer layers cool as winter approaches, but the centre stays relatively warm. About 40% of the space in a full bin is occupied by the air between the kernels, so there is a column of warm air in the centre of the bin surrounded by colder air near the walls. Since the warm air at the centre is light, it moves upward through the grain, being replaced by the colder heavier air near the walls which moves downward. This movement is very slow, but it continues as long as the temperature difference persists, which may be for several months. This continuous stream of warm air must pass through the grain at the top surface which, during the fall and winter. is cold. On coming in contact with the cold surface grain some of the moisture from the warm air is condensed or absorbed on the cold grain. The slow increase in grain moisture content at the surface continues for several months and may result in serious damage.

The damage from moisture migration usually is limited to the top foot or two, but it becomes a possible source of insect infestation. In elevators the grain can be turned, that is, moved from one bin to another.

If the grain is turned before serious increase in moisture has occurred, the surface grain will be mixed with the rest. At the same time the warm and cold grain will be mixed together so that convection air currents will be checked temporarily. Turning, however, affords only temporary relief. Repeated turning damages the grain by breaking kernels.

From the late 1940s onward mechanical ventilation was used to prevent damage from moisture migration in both elevators and storages of intermediate size when storing large quantities of grain for several years. A fan draws air downward through the grain during cooler months. This eventually cools the grain to near the atmospheric temperature, and at the same time the natural upward convection is reversed so that warm air cannot contact the cold grain at the surface. (W. V. Hl.)

GRANBY, JOHN MANNERS, Marquess of (1721–1770), British soldier. the eldest son of the third duke of Rutland, was born in 1721, educated at Eton and at Trinity college, Cambridge, and elected M.P. for Grantham in 1741. He received a commission as colonel of a regiment raised to assist in quelling the Highland revolt of 1745. This corps never got beyond Newcastle, but as a volunteer on the duke of Cumberland's staff Granby saw active service in the last stages of the insurrection. He was in the Flanders campaign of 1747, was promoted major-general in 1755, and three years later was appointed colonel of the Royal Horse Guards (Blues). He had married the daughter of the duke of Somerset, and in 1754 had begun his parliamentary connection with Cambridgeshire, for which county he sat until his death.

Dispatched to Germany in 1758 during the Seven Years' War, he was at the battle of Minden and succeeded to the command of the British contingent after Lord Sackville's disgrace. On July 31, 1760, Granby stormed Warburg at the head of the British cavalry, capturing 1,500 men and ten pieces of artillery. A year later (July 15, 1761) the British defended the heights of Vellinghausen with great bravery, and in the last campaign Granby's men bore the brunt of the fighting.

Returning to England in 1763 the marquess found himself the popular hero of the war. He was appointed to the Ordnance on July 1, 1763, and three years later he became commander in chief. In this position he was attacked by "Junius." He died at Scarborough on Oct. 18. 1770.

Two portraits of Granby were painted by Sir Joshua Reynolds, one of which is now in the National gallery, London. His contemporary popularity is indicated by the number of inns and public-houses which took his name and had his portrait as signboard.

See W. E. Manners, *Some Account of the Military, Political and Social Life of the . . . Marquis of Granby* (London, *1899).*

GRAN CHACO, an extensive region in the heart of South America belonging to the La Plata basin, stretching from 20° to 29° S. lat. Its area is estimated at 300.000 sq.mi. The greater part is covered with marshes, lagoons and dense tropical jungle and forest. and is still unexplored. On its southern and western borders there are extensive tracts of open woodland, intermingled with grassy plains, while on the northern side in Bolivia are large areas of open country subject to inundations in the rainy season. It is traversed by two great rivers, the Pilcomayo and Bermejo, the sluggish courses of which are not navigable. The greater part of its territory is occupied by nomadic tribes of Indians, some of whom are still unsubdued, while others like the Matacos, are sometimes found on neighbouring sugar estates and *estancias* as labourers during the busy season. The forest wealth of the Chaco region is incalculable, consisting of a great variety of palms and valuable cabinet woods, building timber, etc. Its extensive tracts of *quebracho colorado* (*Loxopterygium Lorentzii*) are of very great value because of its use in tanning leather. Both the wood and its extract are largely exported. Its possession was the cause of serious dispute and armed conflict between Bolivia and Paraguay between 1928 and 1935. (See Chaco.)

GRAND, SARAH (pseudonym of Frances Elizabeth [Clarke] M'Fall) (1855?–1943), British novelist and suffragist, was born in Ireland of English parents.

She travelled in the orient, visiting Japan and China. for five years and in 1888 published *Ideala*. She was best known for the novel The *Heavenly Twins* (1893), a best seller. Sarah Grand was a pioneer in the movement to gain suffrage for women in Great Britain and repeatedly served as mayor of Bath, Eng. She died at Calne, Wiltshire, on May 12. 1943

GRAND ALLIANCE, WAR OF THE, sometimes called the WAR OF THC LEAGUE OF AUGSBURG, a war fought by England. Holland the Holy Roman emperor and a number of other allies against France between 1689 and 1657. The uncertainty over its name is reflected in a similar misunderstanding about the mar's aims, character and results. To this misunderstanding the lack of skill of the military commanders and the ineffectiveness of their methods of making war have been held to have contributed. The French commanders have suffered by comparison with the great Condé and the maréchal de Turenne, who had disappeared from the scene. the one retired and the other killed, in 1675; and William III's reputation as a soldier has been eclipsed by that of Marlborough. Sieges rather than battles appear to have marked the progress of the war, with results obviously less striking to the modern eye Yet the deadlock which characterizes the war was not so much military as diplomatic. The Spanish succession (see SPAIN *History)*, on which the balance of poner betneen Bourbon and Habsburg in Europe depended was perhaps its main issue; and so long as Charles II of Spain remained alive (against every reasonable expectation), this question could not be settled. any war fought in the meantime being only an interlude in which the great powers sought to strengthen their bargaining position against the day when Charles should at last die If, then, rhere was for the time nothing important to fight about. it is not surprising that the generals found it difficult to achieve anything by fighting. But war could not easily be avoided since in its absence the circumstances of the rival powers might alter drastically Thus Louis XIV's ambitions depended upon the emperor Leopold I's being unable to exert full authority over the German princes and upon his entanglement with the Turks on his eastern frontier. Louis dared not allow his adversary a lengthy interval of peace in which he might extricate himself from his difficulties. In a sense then, Louis nas throughout his reign the aggressor. Yet from a major war he could hope for nothing, for. if Charles of Spain were to die while he was so engaged, his enemies mould allow him nothing from the Spanish inheritance. Thus it was that he began in 1688 the hostilities in the Palatinate which led to the general outbreak of war in the folloaing year He did so primarily to prevent Leopold from exacting a peace from the Turks. yet he was willing to surrender almost all his military gains to secure peace in 1697 nhen the crisis about the Spanish succession threatened at long last to come to a head. There is. therefore, little doubt as to the real issue at stake in the last quarter of the 17th century. It was the balance of power between Bourbon and Habsburg monarchies. as it had been since Henry IV became king of France, and the outcome of this struggle depended more upon diplomacy than upon war War was an adjunct to diplomacy, as important as. but no more important than, marriage alliances. So long as diplomacy nas stultified by the uncertain issue of the Spanish succession, so long would the wars be devoid of lasting consequences whatever the brilliance of the military commanders. The War of the Grand Alliance might not be north investigation were it not that the long-lasting diplomatic deadlock produced new factors in the situation, notably the accession of England as a European power of first importance, which were to prove decisive in the eventual settlement of the Spanish succession in the war of 1701–13.

Character of the War.—.Although their importance has been misunderstood some notice must be taken of the military developments which altered the character of war during the 17th century. Most obviously, the size of armies increased. The increasing wealth at the disposal of European governments allowed them to maintain larger armies, and improvements followed in military administration and supply. The effectiveness of infantry had been much increased during the previous wars of the 17th century not only by better regimental organization and drilling but also by improvements in the musket, which were to culminate in the introduction of the flintlock; and experiments were being made with the bayonet (instead of the pike). But infantry could move only slowly, and a large army of foot soldiers presented a considerable supply problem. This could be solved only by living off the country, and that involved dispersal over a fairly wide area. Only by occupying fortified places could an army in such a situation feel safe. During the vital weeks of a campaigning season the component parts of an army might be combined for offensive action, and it was necessary to collect supplies in advance for such an operation. This need called for large bases equally well fortified. So the capture or recapture of fortresses was frequently an indispensable prelude to more ambitious strategic operations. Such operations were not impossible, though until the development of the tactical possibilities of cavalry and artillery had caught up with those of infantry they were difficult. They were especially difficult where geographical obstacles lay between an army and its objective; and France, since the acquisition of the Franche-Comté and the occupation of Lorraine in the earlier wars of Louis XIV, was surrounded by natural barriers save for the southeastern coastal route from Italy and the northeastern frontier between the Moselle and the sea. Sébastien Le Prestre de Vauban (*q.v.*), the great builder of fortresses, provided for the northeastern frontier what nature had omitted. Flanders has always provided a natural gateway from Germany into France and vice versa, and it was there that the fiercest fighting of the war was to take place. In the event, the combination of a complicated river network and an elaborate defensive system of fortresses proved too much for the military commanders in the time available to them. Such a result, however, was not inevitable, but arose as much from the near balance of the forces engaged as it did from the intractability of the natural and man-made obstacles.

One other aspect of the character of the war needs to be considered. Since wars avowedly concerned the personal ambitions of princes. the clothing of religious controversy having been discarded, the civilian population ceased at ordinary times to be concerned directly in the struggle and came more and more to assume that role of neutral onlookers which Frederick the Great was later to regard as proper to them. The war began with a devastation of the Palatinate as harsh as any similar operation of the Thirty Years' War; but this proved to be exceptional as larger supplies of money and better methods of credit finance came to enable army commanders to purchase their supplies instead of seizing them by force. The burden of war thus became a financial one, borne by the countries responsible for the fighting rather than those fought over.

The Spanish Succession.——The problem of the Spanish inheritance, including territories in the Pietherlands, in Italy and in the Americas as well as Spain itself, began with the accession in 1665 of the epileptic Charles II, whose continual ill-health made it unlikely that he would have any direct male heirs. Inheritance through a female line would involve the rival Bourbon and Habsburg dynasties. Louis XIV had married the elder daughter of Philip IV and Leopold I the younger. and their fathers had similarly married daughters of Philip III. Whereas both the wives of the French kings had renounced their claims on the Spanish succession at the time of their marriages, Leopold's wife was named in the will of Philip IV as the direct line of succession. So far, however, no male heir had resulted from this line and the problem remained unsolved and full of danger, the more so since as early as 1662 Louis had suggested that his wife's renunciation, which was conditional, might have to be considered invalid. The possibility of securing at least a part of the Spanish inheritance was never far removed from Louis's calculations. After the treaties of Nijmegen (1678–79; see DUTCH WARS), he sought to anticipate as far as he could the death of Charles of Spain by laying claim to various fragments of territory on his borders on the grounds that they were dependencies of territories ceded him by the treaty of Münster (Westphalia). The French annexation of Strasbourg and of Casale in Sept. 1681, followed by the siege of Luxembourg in November, brought about fighting with Spain and Holland. A large-scale war was averted by the Turkish advance to Vienna in July 1683; but after relief of that city by John Sobieski, king of

Poland, in September fighting began again. A 20-year truce concluded at Regensburg in Aug. 1684 terminated this "War of the Reunions," leaving Louis in possession of Strasbourg. Luxembourg and Oudenarde He uas now perhaps at the summit of his power, and he showed his confidence nowhere more than in the revocation of the Edict of Nantes (168;). He could afford to stand by and watch the emperor embroiled in the war with Turkey. while he alone would be free to act when the testing time came in Spain. Meanwhile he had great hopes of pressing his son's claim to the Spanish throne (having by now definitely stated that his wife's renunciation was invalid) in Spain itself through the friendly offices of his niece Marie Louise of Orléans, who had been married to Charles II of Spain in 1679.

Leopold meanwhile had not himself been inactive. The infanta Margaret, his first wife, through whom the best claim of his family to the Spanish throne had arisen, had died in 1673 leaving only a daughter, Maria Antonia, born in 1669 and now of marriageable age. He agreed to her otherwise not very desirable marriage to the elector Maximilian Emmanuel of Bavaria, formerly an ally of France, on condition that she renounce all claims to the Spanish throne, thus in his opinion making the line of succession run through his own mother. Philip III's daughter. The candidate whom he had in mind for Spain was a second son of his own, the archduke Charles born in 1685 (the year of his daughter Maria Antonia's marriage) to his third wife Eleanor of Neuburg. Leopold's proposals brought no response from the Spanish government, which was beginning to seek a solution of its own. Moreover, Leopold was during these years fully occupied nith events in the war with Turkey. After the relief of Vienna in 1683, he had deliberately sacrificed nhat opportunity he had of uniting Germany in opposition to Louis XIV in order to concentrate upon an offensive against Turkey. This was his motive in agreeing to the truce of Regensburg. and his idea was that if Hungary could be recovered and the hereditary lands of the Habsburgs freed from the continuous burden of defense against the Turks, then he would be strong enough to challenge Louis XIV without depending upon the assistance of the German princes So the League of Augsburg concluded betneen himself, the kings of Sweden and of Spain (in their capacity of princes of the empire), the elector of Bavaria, the Ernestine house of Saxony and the circle of Franconia on July 9 (new style; old style, June 29), 1686, was not an important part of his policy. This alliance has been represented as the forerunner of the Grand Alliance by some historians nho have therefore given its name to the war of 1689–97. In fact it was quite ineffective, providing no machinery for combined military action; and the states which constituted the mainstay of the Grand Alliance were not parties to it. Leopold during these years was concerned as much with Turkey as with Germany; and a much more important alliance than the League of Augsburg was that already concluded with the elector Frederick William of Brandenburg. Frederick William, who had previously aligned himself with France, sent a contingent to help Leopold on the Danube in Jan. 1686 and entered into a secret understanding with him against France in March. Habsburg troops then advanced across Hungary in 1686 and in 168;; and on Sept. 6 (N.S), 1688, after the rejection of Turkish offers of peace in the previous year, Belgrade was taken. Turkey now prepared to make much more attractive offers of peace, and Louis XIV saw the control of the situation slipping from his grasp. He determined therefore on another military demonstration like those of 1681–84, hoping that this would keep the Turks fighting and restrain Germany from rushing into the Habsburg camp.

Cologne and the Palatinate. — Apart from the existence of the League of Augsburg and the emperor's refusal to perpetuate the truce of Regensburg, two disputes furnished Louis with pretexts for military intervention. The more immediate of the two was concerned with the archbishopric-electorate of Cologne The archbishop-elector Maximilian Henry had in Jan. 1688 appointed Wilhelm Egon Cardinal von Furstenberg to be his coadjutor; and when Maximilian Henry died in the following June, Fiirstenberg put himself foraard as a candidate for his succession. Fürstenberg, however, had all his life been a protégé of France, and his accession to Cologne was unacceptable both to the emperor and to the pope, who gave their support to the rival candidate Joseph Clement, brother of the elector of Bavaria and first cousin once removed of Maximilian Henry. Louis thereupon sent French troops to uphold Fiirstenberg. This move alarmed the German Protestant princes, who took measures to secure the Dutch against the possibility of a French attack; and the emperor, with papal encouragement, persisted in his recognition of Joseph Clement.

The other controversy in which Louis now decided to assert his claim mas about the succession to the Palatinate. Charles, the last elector Palatine of the Simmern line. had died without heirs in 1685 and had been succeeded by the head of the Zweibriicken line, Philip William of Neuburg, the emperor's father-in-law. It was possible, however, to claim that some part of the succession ought to have gone to the elector Charles's sister Elizabeth Charlotte (Liselotte), the second nife of Louis's brother Philip, duke of Orléans. Though the duchess of Orléans was herself disinclined to insist on this pretension, the fall of Belgrade determined Louis to enforce it. On Sept. 24 (N.S.), 1688, he issued a manifesto setting forth the French grievances. A French army under the command of the dauphin then advanced into the Palatinate.

The English Succession and the War in Ireland. — It is very doubtful whether France intended its action to lead to a major war. But at this point, in the autumn of 1688, other developments occurred which took the determination of events out of French hands. Both William of Orange and Louis XIV had sought to intervene in English politics since the restoration of the Stuart king Charles II in 1660, with the object of preventing hostile activity by the English on the continent. Since 1685 James II had lost the loyalty of nearly all of his subjects, and an important body of them looked to William of Orange, the husband of the heiress apparent Mary. as their only salvation from the tyranny of a Roman Catholic sovereign. William. for his part, being an inveterate opponent of Louis XIV, welcomed the prospect of securing England as an ally. The birth of a male heir to James in June 1688 brought matters to a state of crisis in England, and William agreed to land an army there to force James to act as his subjects wanted. Louis XIV was well aware of this intended invasion when he sent his troops into the Palatinate and in fact welcomed it as ensuring the absence of William from the continent so long as the expected civil war lasted in England.

When James was expelled from England without hostilities, Louis was able to restore his original plan by sending James to Ireland, which had remained loyal to him. Thus, although William succeeded in becoming king of England as William III and in involving his new kingdom in the continental war, he was for two years occupied in reducing Ireland. Almost the whole of Ireland was controlled by the Jacobite earl of Tyrconnel (Richard Talbot) with an army of 40,000 men of uncertain quality. In the north, however. the Protestant population declared in favour of William III and secured Enniskillen and Londonderry. On March 22 (N.S.; 12, O.S.), 1689, James II landed at Kinsale with a small French force and at once accompanied Tyrconnel to the north. The siege of Londonderry began on April 29 (N.S.; 19, O S.), but without a siege train no assault could be mounted. An English relieving force for Londonderry, sent by sea under Col. Percy Kirke at the end of May, was needlessly dilatory, but the blockade was eventually broken by Capt. John Leake's ships on Aug. 7 and the siege raised on Aug. 9–10 (N.S.; July 28 and 30–31, O.S.). At the same time a detachment of the Jacobite army was defeated by local forces organized by Col. William Wolseley, whereupon the siege of Enniskillen was likewise abandoned. The Williamite forces proceeded to overrun the whole of Ulster, and when the duke of Schomberg, sent with an army by William at the insistence of his English advisers, landed at Bangor near Belfast in August, he was able to advance southward immediately. He reached Dundalk, but there was held up. His army was small, much of it insufficiently trained. and rapidly being reduced by sickness. He was therefore unwilling to risk battle and eventually repaired to winter quarters in the north.

William at last became convinced of the necessity of making a serious effort in Ireland and in June 1690 went there himself with a considerable army, including Dutch and other foreign veteran troops. He advanced on Dublin with 40,000 men and came across James II entrenched behind the Boyne river with a slightly smaller force: including a French contingent landed under the comte (later duc) de Lauzun in March. James's army had some good cavalry, but it was the infantry which settled the day in favour of William on July 11 (N.S.; 1, O.S.), 1690. James fled once more to France, but his army made a good retreat, though abandoning all of Ireland save the west and southwest. William advanced in Ireland, but failed to take Limerick, which was defended by Patrick Sarsfield, in August; and after the earl (later duke) of Marlborough had taken Cork in September and Kinsale in October, fighting ended for the year with the war not yet completely over.

In 1691 Godart van Ginkel commanded for William in Ireland and the marquis de Saint-Ruth for James. Their armies met at Aughrim on July 22 (N.S.; 12, O.S.), where Saint-Ruth, after appearing to have the battle won, was killed and his army defeated. Even now, though the town of Galway surrendered and Athlone was already lost, Sarsfield held out in Limerick until Oct. 13 (N.S.; 3, O.S.) when a treaty was signed which brought the Irish war to a close. The war in Ireland had lasted for more than two years, and its outcome must not be allowed to disguise the fact that Louis XIV had succeeded in keeping William of Orange and 40,000 of his troops absent irom the continent for the important campaign of 1690. So far! indeed, William's inheritance of the English crown had proved a liability.

The Grand Alliance and the Continental War.—Louis had underestimated the reaction of Europe to his invasion of the Palatinate. True, Turkey was no longer milling to make peace with the emperor on acceptable terms and William of Orange had become involved in England. But William had been quickly and completely successful in accomplishing his mission to England, and the recent victories enabled the emperor to contain the Turks below Belgrade without much affecting the strength of his forces in the west. Moreover, the other German princes had been aroused rather than cowed by the French show of military strength; and France was already committed also against the Dutch and against Spain when the Dutch and the emperor concluded the treaty of Vienna on May 12 (N.S.), 1689. with the avowed aim of restoring the peace settlements of Westphalia (1648) and of the Pyrenees (1659). This treaty. to which England. Brandenburg, Hanover, Saxony, Bavaria. Savoy (see below) and Spain adhered in the course of the following 18 months. was the kernel of the Grand Alliance. The French found themselves faced at once by two strong armies: by the Dutch and the north German forces in Flanders and by the imperial and Bavarian troops on the Rhine. In these circumstances they were compelled to withdraw from the advanced positions occupied in 1688. Bonn and Mainz were evacuated on the Rhine. while in Flanders an English contingent under Marlborough assisted George Frederick, prince of Waldeck. in defeating the French at Walcourt on Aug. 25 (N.S.; 1j. O.S.), 1689.

Now. however. the situation in Ireland saved Louis from the consequences of his precipitate action. The allies had ambitious plans for a triple invasion of France, from Flanders. from the Rhine and irom Savoy. But with the death of Charles of Lorraine. who had been the leading figure in the south German opposition to France, on April 18 (N.S.), 1690. the Rhine offensive died away early In Flanders. with 40.000 allied troops away in Ireland, Waldeck's forces were outnumbered by those of the duc de Luxembourg; and while awaiting reinforcements preparatory to an advance upon Dinant. Waldeck was attacked and deieated at Fleurus (*q.v*) on July 1 (N.S.). Great hopes, honever. were still entertained by the allies of Savoy. The western irontiers of that country offered an easy route into Provence. and on the other side was the Spanish Milanese, giving easy access to the hereditary territories of the Habsburgs in Austria. This strategic position had compelled (or enabled) the dukes of Savoy to adopt a vacillating policy toward the Franco-Spanish conflicts of the 17th century. In 1689, though French garrisons in Pinerolo (Pignerol) and in Casale and the army under Nicholas Catinat on the Alpine frontier seemed to make France's influence over Savoy secure, the apparent strength of the Grand Alliance nevertheless caused the duke, Victor Amadeus II, to hesitate before committing himself to Louis XIV; and in 1690, when compelled by the French to choose. he joined the allied cause in the hope of securing Pinerolo and Casale. Catinat reacted at once and, advancing into Piedmont, defeated Victor Amadeus at Staffarda on Aug. 18 (N.S.), 1690. A further setback overtook the allies in October, when the Turks retook Belgrade and the hopes of a Turkish peace disappeared. The year 1690 had been one of continuous allied disaster on the continent.

Nor did 1691 bring much comfort. William III commanded in person in Flanders, but, operating from Brussels, failed to prevent Luxembourg from taking Mons (April 8 [N.S]). Without the support of the Brandenburg troops occupied in defending Cleves against a French diversion, he was unable to command favourable circumstances in which he could bring Luxembourg to battle, and the remainder of his campaign that year in Flanders was taken up with ineffective manoeuvring. After William's return to England in the autumn, Waldeck, while moving the army into winter quarters. was attacked and defeated by Luxembourg at Leuze (Sept. 20 [N.S.]). Meanwhile Catinat continued his progress into Piedmont, and the French army of Catalonia, under the duc de Noailles, took Urgel. Thus, for two years, France had more than countered all the threats of the Grand Alliance; the command of interior lines and great resources of manpower and of wealth had made it possible to defy the rest of Europe. This fact, and not the technicalities of the laws of inheritance, was to constitute the Bourbons' real claim to the Spanish succession.

What hopes remained to the allies lay in the contribution of England to the cause now that the war in Ireland was over. A French army led by the king himself, assisted by Vauban and covered by Luxembourg, began the campaign of 1692 by laying siege to Namur (May 25 [N S]). An unexpected period of heavy rain disrupted William's plans for relieving the city, and on June 5 (N S.) the town surrendered; the last stronghold, however. held out until July 1 (N S.). William then spent the rest of the summer endeavouring to bring Luxembourg to battle; he succeeded, but Luxembourg commanded a strong defensive position at Steenkirk (*q.v.*) In another battle of infantry (Aug. 3 [N.S.; July 24, O S.]), a determined attack by the British forces won some ground; but William's dispositions had been faulty, the success was not followed up, and at length his army was compelled to withdraw. Luxembourg, however. though left in possession of the field. had been sufficiently troubled to make him choose not to pursue the enemy. The year 1692 thus saw two considerable reverses sustained by the allied land forces.

William now recognized that the original aims of the Grand Alliance uere unattainable, but Louis was in no hurry to make peace. He spent the year 1693 instead in a series of disconnected offensives. Catinat once more defeated the duke of Savoy at Marsaglia (Oct. 4 [N S.]). the army of the Rhine captured Meidelberg, the army of Catalonia took Rosas and Luxembourg threatened Likge. William sent 20 000 men to relieve Likge and stood the rest of his army at Neerwinden. near Landen. to cover this force. There he was attacked by Luxembourg in superior force on July 29 (N.S.) and, despite an obstinate defense, was again defeated The campaign in Flanders closed with the French capture of Charleroi (Oct. 11 [N.S.]). while in the east the year's record was capped by the Austrian failure to recapture Belgrade.

The War **at** Sea.—Although the combination of English and Dutch sea power might have been expected to prove too much for France to contest. it was not until 1692 that the allies were able to secure a decisive naval supremacy in the English channel and not for a further tno years that they extended this to the Mediterranean. Colbert's achievements stood the French navy in good stead for a time (see COLBERT, JEAN BAPTISTE); but Colbert had died in 1683, and his work could not forever withstand Louis XIV's own indifference and neglect. On the other hand, the reforms in the English navy, in which James himself had shared after his appointment as lord high admiral on his brother Charles II's restoration. began to bear iruit as the political climate became more settled under William III. The first two years of the war, then, went in favour of France. Reinforcements on the way to James II in Ireland in 1689 were successiully covered by the Brest fleet under the marquis de Château-Renault, and the battle of Bantry Bay

(May 11 [N.S.; 1, O.S.]) which resulted when Adm. Arthur Herbert attacked it, though it won him the title of earl of Torrington, was reckoned a victory also by France. The next year the comte de Tourville was reinforced by the Toulon fleet and so enjoped a numerical superiority over Torrington, who, in reply, at first refused battle and subsequently, when worsted at the battle of Beachy Head (*q.v.*; July 10 [N.S.; June 30, O.S.], 1690), took the first opportunity of making a further withdrawal back to the Thames. Torrington maintained that so long as he avoided a decisive defeat and kept his "fleet in being" the French would not dare to invade England; and his phrase has been employed ever since to describe an important strategic concept. The French did not follow up their success but spent the next year, 1691, in making raids on shipping; and when in 1692 Tourville, acting upon orders from home, sought battle, he was heavily defeated by the English admirals Edward Russell and George Rooke at the battle of La Hogue (*q.v.*; May 29–June 3 [N.S.; May 19–24, O.S.]). The French never again during the war sought a general engagement at sea. and to some extent a permanent decline in France's naval fortunes may be dated from the battle of La Hogue.

For some time, however, the allies made little use of their victory, concentrating their strength on protecting their commerce and on defending the English channel and leaving the French still masters of the Mediterranean. Colonial rivalry in India, in North America and in the Caribbean brought sporadic fighting to those parts also; and though the English and the Dutch enjoped the better of their exchanges with the French, the distances involved prevented any concerted operations by either side. In 1693 the series of reverses that the allies sustained on land was accompanied by a serious naval setback when a convoy of 400 ships bound for Smyrna was attacked and dispersed by Tourville off Lagos on its way into the Mediterranean, and about 100 ships were lost (June 27–28 [N.S.; 17–18 O.S.]). The escorting warships, commanded by Rooke, were quite inadequate for their task, and the episode pointed out the desirability of taking more offensive and direct action against the French at sea.

William now abandoned the hope of achieving anything spectacular in Flanders. English hopes were centred instead upon the possibilities of combined military and naval operations against Brest and in the Mediterranean. In 1694, therefore, operations in Flanders were confined to attacking towns. William was again unsuccessful, but he could at least claim to have contributed to stopping the French advance. The reason the French were halted was partly that, thanks to a further effort on the part of England, the allies were at last enjoying a superiority in numbers there; and partly that the cost of the war was beginning to bear heavily upon France. Moreover the diplomatic situation relating to the Spanish succession called for caution. In Catalonia, however, Noailles crossed the Ter on May 28 (N.S.) and proceeded to take Palamos, Gerona, Ostalrich and Castel-Follit. In fact, the interior lines of communication enjoyed by the French armies enabled them to counter a check in one theatre of war by a successful offensive in another, and William resolved upon employing his fleet to offset this advantage. Russell left for the Mediterranean in June 1694 and stayed on the Catalan coast until well into the autumn when he withdrew to minter and refit—not in England but at Cádiz. Thus he was able to operate off Catalonia again early in the spring of 1695, and it was this almost continuous protection that saved Barcelona from a combined attack by Noailles and the Toulon fleet under Tourville. This experiment. which marks the beginning of the concept of a British Mediterranean fleet, was ended when Rooke, who had taken Russell's place in Sept. 1695, was recalled in the spring of 1696 on the reappearance of a French fieet under Château-Renault at Brest which, it was feared, might be the prelude to an invasion of England. The results produced by the experiment while it lasted did however indicate that the sea power of the allies might indeed prove to be the answer to the interior lines of communication enjoyed by France. The combined assault against Brest begun at the same time in 1694, however, turned out to be just one more allied disappointment, for the troops which were landed at Camaret bay (June 8 [N.S.; May 29, O.S.]) under Lieut. Gen. Thomas Talmash (Tolleinache) found the French prepared for them and had to be withdrawn almost at once.

The year 1695 saw the death of Luxembourg, whose replacement by the less able maréchal duc de Villeroi provided William with the opportunity of securing his one tangible success of the war. After a two months' siege of Namur, he compelled the maréchal duc de Boufflers to capitulate on Sept. 1 (N.S.; Aug. 22, O.S.).

The Peace of **Ryswick.**—By 1695 a number of reasons were inclining Louis XIV to investigate the possibilities of a general peace. His resources were stretched in maintaining armies upon four fronts; the value of the Turkish diversion had declined after the recapture of Belgrade, after which only desultory fighting occurred on that front; and William III became a less stubborn opponent as his continuous record of defeat and disappointment began to arouse serious opposition to his war policy in England.

But the most important motive for peace lay in new developments in the contest for the Spanish succession. A son, Joseph Ferdinand, had been born to Maria Antonia and the elector of Bavaria on Oct. 28 (N.S.), 1692, and in the mind of the Spanish government it was in this boy alone that there lay any prospect of maintaining the Spanish dominions intact on the death of Charles II. Neither Louis XIV nor the emperor Leopold was prepared to acquiesce in such a settlement?and for both of them the support of other European powers was vital. In 1695 Louis found himself still engaged in war and without an ally. His rival had succeeded in engaging his allies in the Grand Alliance to support his claims to the Spanish inheritance. Both Holland and England did this willingly since they hoped for commercial advantages from what they believed would be a continuation of the lax Spanish dominion over the American possessions. Moreover, Louis's main support at the Spanish court. Marie Louise of Orléans, the queen consort, had died on Feb. 12 (N.S.), 1689, and her successor was Maria Anna of Neuburg, sister to the empress. Despite his military successes, Louis's diplomatic position mas insecure. At this moment news came from Spain that Charles might really be dying at last. Louis began the task of making peace first with Savoy. Victor Amadeus had seen his troops twice defeated and was doubtful of the determination of some of his allies to continue the war. When, therefore, Louis offered surprising concessions, he agreed, as he had so often done before and was to do again. to change sides. The treaty of Turin, concluded in June 1696 after negotiations conducted with the utmost secrecy, not only restored all that France had conquered in the course of the war but also ceded Pinerolo and Casale to Savoy. Savoy then turned round on its allies and insisted that all fighting cease in Italy. The emperor could do nothing but agree. The fighting in Flanders in 1696 brought William III no successes, and he too began secret negotiations in the winter. The emperor still stood out, but further French successes in 1697, the naval raid on Cartagena in May and the capture of Barcelona in August, convinced him too. Official negotiations were conducted during the summer, at Ryswick near The Hague; and the treaty of Ryswick (*q.v.*), which ended the war, was signed by the powers concerned between Sept. 20 and Oct. 30 (N.S.), 1697. Once again, France agreed to restore all its military conquests and, in addition, made commercial concessions to Holland. Louis XIV also recognized William III as king of England and promised not to give any aid to his enemies (including, by implication, James II).

At first sight, Louis appears to have surrendered all that he had won in the war, and a closer examination of the terms of the peace supports that view. In any future war France could, in the military circumstances of the time, make a considerable military impression upon its enemies only if it began the war already in possession of the vital fortresses which ringed its frontiers. Yet, almost without exception, all such towns as had been captured were given up in 1697. Even so, it is misleading to conclude simply that France had been worsted in the War of the Grand Alliance. There is some truth in the suggestion that Louis had misjudged the reaction of Europe to his ambitions and overplayed his hand. In particular he had underestimated William of Orange, unsuccessful though that statesman was in war; for it was the advent of England into the affairs of the continent that both turned the balance of power against France and also, by involving the overseas world in the destinies of Europe, introduced forces which a predominantly continental power such as France could not control. In this last fact lies perhaps the worst mistake of Louis: his abandoning of the scheme of colonial and maritime expansion that had been advocated by Colbert in favour of the purely European policy followed by the marquis de Louvois. But the decisive role that England was to play lay still in the future. So far as the War of the Grand Alliance is concerned: Louis XIV's ambitions had not been seriously disturbed. His main objective was the Spanish succession. He had begun the war by invading the Palatinate in 1688 in order to prevent the emperor from making peace with the Turks and uniting Germany against him. In this he had to some extent succeeded; and his armies had succeeded also in preventing William from crowning his lifelong opposition to him with success. The war, in fact, was never more than an interlude in the diplomatic struggle for the Spanish succession and the century-old conflict between Bourbon and Habsburg. When the death of Charles II of Spain appeared imminent, Louis withdrew from the war without much difficulty. That to do so he surrendered most of his military gains was not important. They were insignificant beside the gains offered by the Spanish succession. In the event, Louis's timing proved sound. The Austrian advance against the Turks was resumed in 1697 and resulted in the victory of Zenta (Sept. 11 [N.S.]) under the young Prince Eugène of Savoy. The treaty of Karlowitz followed in Jan. 1699. whereby the sultan surrendered all of Hungary and Transylvania. In Spain, the crisis of the succession followed almost immediately upon the conclusion of peace, and it was the emperor, not Louis XIV, who was isolated and to a large extent ignored in the subsequent negotiations.

An appraisal of the significance of the War of the Grand Alliance must be related in the first place to its origins. Both Louis XIV and Leopold I sought predominance in Europe, the former through the medium of the Spanish inheritance, the latter in contesting Louis's claim by establishing his power in his hereditary territories. There is little doubt that on balance Louis was the more successful. So it may be concluded that his generals had successfully accomplished what had been asked of them. Leopold had had some success in defeating the Turkish menace and in building up an effective resistance to France. But the real credit for building up that resistance belongs to William III. It was he who had engaged England in the war and he who had made the most effective military effort. What he lacked was military success, and that might be remedied in the future. So. in the final analysis, the definite but necessarily indecisive achievements of Louis XIV and the potential consequences of the work of William III must be set against one another.

GRAND BANKS. A portion of the continental shelf in the Atlantic ocean extending about 350 mi. off the southeast coast of Newfoundland; noted as an international fishing ground, the Grand Banks include a number of separate banks, chief of which are Grand bank, St. Pierre bank and Green bank. Depths on these banks average approximately 30 fathoms, but there are many places with depths reaching 100 fathoms. The vicinity of the Grand Bahks is the meeting place of the cold Labrador current and the relatively warm Gulf stream. Air masses passing over these contrasting water bodies produce fog frequently. The mingling of the cold and warm waters produces favourable conditions for plankton on which fish depend directly or indirectly for their food supply.

The fish of the Grand Banks have been looked upon as a great natural resource ever since John Cabot reported these riches more than four centuries ago. Among the species most plentiful are cod, haddock, rosefish, pollock, various flatfish, herring and mackerel. The trawler fleets of many nations, including Canada, the Cnited States, the United Kingdom, Portugal, Spain and France, fish the Grand Banks. An international commission was organized in 1949 to study fish populations and to guard against depletion.

See also Newfoundland. (C. N. F.)

GRAND CANARY (Gran Canaria), an island forming part of the Spanish archipelago of the Canary Islands (*q.v.*). Pop. (1950) 334,986; area, 592 sq.mi. Grand Canary, the most fertile island of the group, is nearly circular in shape, with a diameter of 24 mi. and a circumference of 75 mi. The highest peak, Los Pechos, is 6,398 ft. Large tracts are covered with native pine. Las Palmas (1950, [mun.] 153,856), the capital, is described in a separate article.

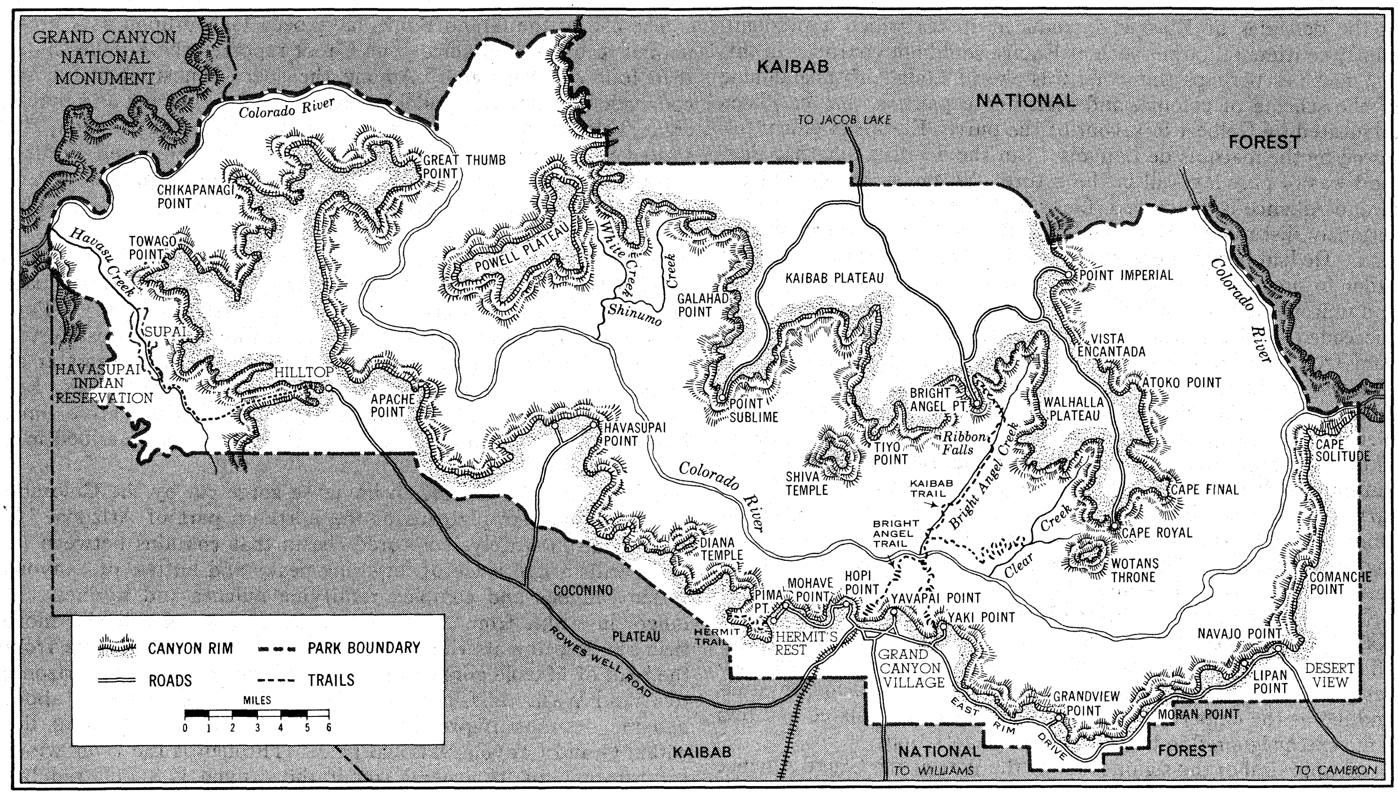
GRAND CANYON, an immense gorge cut by the Colorado river into the high plateaus of the northern part of Arizona. It is a broad, intricately-sculptured chasm that contains between its outer walls a multitude of imposing peaks and buttes, of canyons within canyons and complex ramifying gulches and ravines. It ranges in width from 4 to 18 mi., its greatest depths lie more than a mile below its rim and it extends in a winding course from the head of Marble gorge, near the northern boundary of Arizona, to Grand Wash cliffs, near the Nevada line, a distance of about 280 mi. Its most impressively beautiful section, j6 mi. long, lies within Grand Canyon National park. Through it the river winds for 105 mi. In its general colour the canyon is a dull red but each strata or group of strata has a distinctive hue—pale buff and gray, delicate green and pink and, in its depths, chocolate-brown, slate-gray, a violet and other sombre hues.

The impact of this scene was thus expressed by geologist F. E. Matthes: "The alpine mountain ranges of this country are equaled and exceeded in height, if not in spectacular beauty. by those of other lands, but though there are elsewhere deep canyons, some of even greater depth than the Grand Canyon of the Colorado, there is not one that can match its vastness, its majesty, its ornate sculpture, and its wealth of color. Whoever stands upon the brink of the Grand Canyon beholds a spectacle unrivaled on this earth."

History.—Discovery of Grand canyon is credited to members of the Coronado expedition of 1540. Two Spanish priests, Francisco Garcés and Silvestre Vélez de Escalante, rediscovered it in 1776. Beaver trappers examined it and members of government expeditions exploring the west looked it over. John Wesley Powell and companions descended the river in rowboats in 1869, and again in 1870 and published reports on the geography, geology and ethnology of the area. Prospectors in search of minerals explored its side canyons.

National Park.—Grand Canyon National park, containing 645,296 ac., was created in 1919. The north and south rims are connected by a paved road (217 mi.) and by a transcanyon trail (21 mi.) Scenic drives and trails lead to all important features. Campgrounds and a wide range of accommodations are available on both the north rim (8,200 ft.) and the south rim (7,000 ft.). There are more than 1,000,000 visitors annually. The famous mule ride into the canyon has increasing competition from the adventurous scenic rides down the river in motorboats, or inflatable rafts. Pueblo and cliff-dweller ruins, with accompanying artifacts, are numerous, indicating prehistoric occupation, and living on reservations nearby are five Indian tribes.

Geology.—From the rock record of the canyon a large part of geologic history is revealed more clearly than in any other place in the world. Two stories are superlatively presented: (1) the building of the earth's crust featuring the kind, origin and age of exposed rocks; and (2) the cutting of the canyon. a story of erosion. Furthermore. all the processes of earth building are exemplified: submergence, deposition, uplift, folding and faulting and erosion. Extending from the river to Bryce canyon to the north, there is exposed a 23.000 ft. cross section of sedimentary



MAP OF GRAND CANYON NATIONAL PARK. ARIZONA

rocks from old to recent in normal sequence. The "greatest single geological story" pertains to an unconformity where rocks of Algonkian, or Proterozoic (late Pre-Cambrian), Age have been eroded away completely, leaving only a line, where third era rocks rest upon first era rocks, indicating a missing record of 500,000,000 years of second era deposition.

The rock strata of the canyon's walls are mostly marine limestones. fresh-water shales and cemented sandstones of wind-blown origin (Paleozoic Age), the result of limey ooze, mud and sand laid down in water. later hardened into rock by the great neight of layers above. The crystalized. twisted and contorted unstratified rocks of the inner gorge are granite and schist (Archean or Early Pre-Cambrian Age) believed to be more than 4,000,000,000 years old. They constitute the roots of lofty mountains, their tops eroded away. Likewise, the superimposed Algonkian rocks are the roots of still another ancient mountain system planed down by prolonged erosion. O erlying the canyon rocks are butte remnants of Mesozoic Age and the vermillion, white and pink cliff terraces of southern Utah. which have been entirely eroded away to the south. Of recent origin are the sheets of black lava and the volcanic cones covering portions of the plateau tops, some estimated to have been active within the past 1,000 years.

An event of recent geologic history has been the cutting of the mile-deep Grand canyon by the Colorado river! a river with volume, speed and cutting tools in the form of mud, sand and gravel. Sediments carried by the Colorado have been measured and reported to average 500,000 tons per day. conditions favourable to vigorous erosion were brought about by the up warping of the region, which steepened the river's path and allowed deep entrenchment. The depth of the canyon is due to the cutting of the river but its ten-mile width is explained by rain, wind, temperature and chemical erosion. helped by the rapid wear of soft rocks, all of which steadily widens it.

Amazingly, the canyon was cut by a reverse process for the river remained in place and cut as the land moved slowly upward against it. Only thus can be explained the canyon's east to west course across a south facing slope and the presence of plateaus which stand across the river's course without having defected it. Minerals. mostly asbestos. copper. lead and some uranium exist but not in sufficient quantity and availability for profitable mining.

In the sedimentary rocks plant and animal fossils are abundant. ranging from primitive algae in the lower strata to trees in the upper strata and from seashells and trilobites to the remains of dinosaurs (both bones and footprints), and camels, horses, ground sloths and elephants. These fossils give a picture of evolving life through the ages.

Biology.—There are great ranges in soil. temperature and elevation and of the five life-zones, only that of tropical vegetation is absent. In the interior of the canyon vegetation is sparse and of desert type but on the plateaus grow forests of pine, fir. aspen and spruce. Animal life consists of about 100 varieties of birds. 60 mammals and 25 reptiles and amphibians. A half dozen kinds of fish live in the river and trout have been planted in tributary streams.

Plant and animal life on one rim differs somewhat from that on the other as shown in the Kaibab white-tailed squirrel of the north rim compared with the Abert grey-tailed squirrel of the south rim, which are regarded as varieties developing in a mutual isolation imposed by the barrier of the canyon.

Both the south rim (open year round) and the north rim (closed in winter) are accessible by automobile, railroad, bus and airplane.

Survey Bright Angel Quadrangle Map (1906, 192;). (H. C. B.)

GRAND DUKE, a title borne by princes ranking between king and duke (Fr. *grand-duc*, Ital. *granduca*, Ger. *Gross-herzog*). The dignity was first bestowed in 1567 by Pope Pius V on Duke Cosimo I of Florence, his son Francis obtaining the emperor's confirmation in 1576; and the predicate "royal highness" was added in 1699.

In 1806 Napoleon created his brother-in-law Joachim Murat, grand duke of Berg, and in the same year the title was assumed by the landgrave of Hesse-Darmstadt, the elector of Baden and the new ruler of the secularized bishopric of Würzburg (formerly Ferdinand III, grand duke of Tuscany) on joining the Confederation of the Rhine. According to the decision of the Congress of Vienna, the title was borne by the sovereigns of Luxemburg, Saxe-Weimar (grand duke of Saxony), Mecklenburg-Schwerin, Mecklenburg-Strelitz and Oldenburg (since 1829), as well as by those of Hesse-Darmstadt and Baden. The emperor of Austria included among his titles those of grand duke of Cracow and Tuscany, and the king of Prussia those of grand duke of the Lower Rhine and Posen.

The title is also retained by the dispossessed Habsburg-Lorraine dynasty of Tuscany.

Grand duke is also the conventional English equivalent of the Russian *velikiy knyaz,* more properly "grand prince" (Ger. *Grossfürst*), at one time the title of the rulers of Kussia, who, as the eldest born of the house of Rurik, exercised overlordship over the *udyelniye knyazi* or local princes. On the partition of the inheritance of Rurik, the eldest of each branch assumed the title of grand prince. Until 1886 this title grand duke or grand duchess, with the style "imperial highness," was borne by all descendants of the imperial house. It was then confined to the sons and daughters? brothers and sisters and male grandchildren of the emperor.. The other members of the imperial house bore the title of prince *(knyaz)* and princess (*knyaginya* if married, *knyazhna* if unmarried) with the style of "highness." The emperor of Austria, as king of Hungary, also bore this title as "grand duke'! of Transylvania, which was erected into a "grand princedom" (Grossfürstentum) in 176j by Maria Theresa.

GRANDEE, a title of honour borne by the highest class of the Spanish nobility (Span. *Grande*). It would appear to have been originally assumed by the most important nobles to distinguish them from the mass of the *ricos hombres,* or great barons of the realm. It was thus. as Selden points out, not a general term denoting a class, but "an additional dignity not only to all dukes, but to some marquesses and condes also" (*Titles* of *Honor,* ed. 1672, p. 478). It formerly implied certain privileges; notably that of sitting covered in the royal presence. Until the time of Ferdinand and Isabella, when the power of the territorial nobles was broken, the grandees had also certain more important rights; *e.g.,* freedom from taxation, immunity from arrest save at the king's express command, and even—in certain cases—the right to renounce their allegiance and make war on the king. Their number and privileges were further restricted by Charles I (the emperor Charles V), who reserved to the crown the right to bestow the title. The grandees of Spain were further divided into three classes: (1) those who spoke to the king and received his reply with their heads covered; (2) those who addressed him uncovered, but put on their hats to hear his answer; (3) those who awaited the permission of the king before covering themselves. All grandees were addressed by the king as "my cousin" (*mi primo*), whereas ordinary nobles were only qualified as "my kinsman" (*mi pariente*). The title of "grandee," abolished under King Joseph Bonaparte, was revived in 1834, when, by the *Estatudo real,* grandees were given precedence in the chamber of peers. The designation later, however, became purely titular, and implied neither privilege nor power.

GRAND FORKS, a town in the boundary district of British Columbia, Canada, at the junction of the north and south forks of the Kettle river, 2 mi. N. of the international boundary, on the Canadian Pacific and (for freight) Great Northern railways. Pop. (19) 1,995. It is in a good agricultural district. noted for fruit production by irrigation, but owes its importance largely to works for smelting gold. copper and silver ores. It is a trade centre, with sawmills. wood works. machine shops, etc.

GRAND FORKS, the second city in size in North Dakota. U.S.. and seat of the county of the same name. is situated at the confluence of the Red River of the North and the Red Lake river, 90 mi. S. of the Canadian border in the northeast corner of the state. The city is surrounded by prairies and is 350 mi. N.W. of Minneapolis, the nearest large U.S. city. It was originally the site of a North-West Fur company post in 1801, but Lord Selkirk, a Hudson's Bay company official, purchased the land for a colony of Scottish settlers, the Red River settlement (*q.v.*). However, only mixed-bloods settled about it.

Permanent settlement began in 1871 and from 1873 to 1875, the Hudson's Bay company operated a hotel and a retail store there. The town's future was assured when the Great Northern railway arrived in 1880 and established headquarters for its large Dakota division. There was a flood of settlers, many Norwegian or Canadian. and by 1910. 66% of its population were immigrants or the children of immigrants.

Primary dependence on retail merchandising and shipping of a large volume of spring wheat, potatoes and sugar beets ended with World War I. The large state-owned flour mill and elevator, a meat packing plant and a beet sugar refinery (in its twin city. East Grand Forks. Minn.) were opened. Despite the decline in the state's population, Grand Forks almost doubled in size from 1930 to 1955. (For comparative population figures *see* table in NORTH DAKOTA : *Population.*)

After World War II, manufacturing firms grew in size and number until they employed one-tenth of the labour force. but more than 1.000 retail and wholesale establishments were the chief employers. Much growth was stimulated by construction of an air force base 15 mi. W. Rail transportation by Northern Pacific and Great Northern railroads was supplemented by airlines using the municipal airport, an international port of entry.

In 1947 Grand Forks adopted the council-manager form of government. The University of North Dakota, under state control. n-as established there by territorial act in 1553. By the second half of the 20th century, it enrolled more than 3.500 full-time students. (R. P. WI.)

GRANDGENT, CHARLES HALL (1862–1939), U.S. philologist, an expert in phonetics and in the history of Romance languages. was born at Dorchester. Mass., on Nov. 14. 1862. He attended Roxbury Latin school and graduated from Harvard summa cum laude and head of his class in 1883. After three years' postgraduate study in Europe, he returned to Harvard as tutor in Romance languages (1886–89), then was director of modern language instruction in the Boston public school system for seven years. In 1886 he married Ethel \\'right Cushing, who predeceased him by five years.

From 1896 he was professnr of Romance languages and literatures at Harvard, becoming emeritus in 1932. He was acting dean of the faculty of arts and sciences in 1929, and exchange professor at Paris in 1915–1916 and again in 1930–31. The University of Chicago (1916). Michigan (19223. Oberlin (1927) and Harvard (1923) conferred honorary doctorates on him.

Grandgent's scholarly publications included grammars of French and Italian. Old Provençal, Vulgar Latin. and a work called *From Latin to Italian,* all of them distinguished by a skillful and highly selective presentation. His lectures showed this same power of selection. He lectured for many years on Dante as well as on Romance linguistics and phonetics. and produced an edition of Dante (1917). in addition to *The Ladies of Dante's Lyrics* (1917), *The Power of Dante* (1918), and *Discourses on Dante* (1923). He was decorated by the governments of France and of Italy; and he was a corresponding member of the Xccademia della Crusca. Grandgent's volumes of lighter essays give some idea of the man's humour and charm. He died on Sept. 11, 1939, at Cambridge, Mass. (J. WH.)

GRAND ISLAND, a city and the seat of Hall county, in southeastern central Nebraska. U.S., on the Platte river. is 85 mi. W. of Lincoln and 130 mi. S.W. of Omaha. The ton-n's name comes from the Grand island in the Platte. The island n-as a landmark for early travelers and of importance to the Oregon, California and Mormon trails.

German settlers established Grand Island in 1857, about 50 mi. W. of the then westernmost community in the area. A major factor in Grand Island's development was its strategic location for transportation. The Union Pacific and Burlington railroads crossed there, developing a railroad centre, and it became later the major highway centre in central Nebraska. An important supply point for the surrounding agricultural area: Grand Island also became an irrigation centre as the Platte valley turned to irrigation early in the 20th century.

Industrial activity, largely based on agricultural production. includes sugar beet processing, meat packing and grain storage.

A veterans hospital, a soldiers and sailors home, and an ordnance depot are among the federal institutions in the city. The present town was laid out in 1866 when the Union Pacific reached the settlement; it was incorporated in 1873. For comparative population figures *see* table in NEBRASKA: *Population.*

(W. D. A.)

GRAND JUNCTION, a city of western Colorado, U.S.. elevation 4,600 ft., at the confluence of the Colorado and Gunnison rivers, from which its name derives, is the seat of Mesa county. Immediately following expulsion of the Ute Indians, white settlers rushed in and founded the town in 1881. It was incorporated in 1882, and in 1922 adopted the council-manager form of government.

It is the centre of an extensive irrigated region (fruit, truck gardening and general farming) and industrial and jobbing centre of a large area. In the 1950s it became the business, administrative and milling headquarters of a large uranium-producing area. The lake-jeweled Grand Mesa is 30 mi. E., said to be the world's largest flat-topped mountain, and a favourite scenic and recreational area. Colorado national monument. 8 mi. W., contains spectacular specimens of erosion, and is threaded by famed Rimrock drive.

For comparative population figures *see* table in COLORADO: *Population.* (L. R. HA.)

GRAND'MERE, an industrial city in Laviolette county, Quebec, Canada, on the St. Maurice river, 21 mi. N. of Three Rivers, and on the Canadian National and Canadian Pacific railways. It is situated in a good farming district with excellent water-power facilities, which operate pulp and paper mills. Its industries include the manufacture of textiles, leather goods and electricity.

Population (1956) 14.023.

GRANDMONTINES, a religious order founded by St. Stephen of Thiers in Xuvergne toward the end of the 11th century. St. Stephen was so impressed by the lives of the hermits whom he saw in Calabria that he desired to introduce the same manner of life into his native country. He was ordained. and in 1073 obtained the pope's permission to establish an order. He went to Xuvergne, and in the desert of Muret, near Limoges, he made himself a hut of branches of trees and lived there for some time in complete solitude. A few disciples gathered around him, and a community was formed. The rule was not reduced to writing until after Stephen's death, 1124.

'The life was eremitical and very severe in regard to silence, diet and bodily austerities. It was modeled after the rule of the Camaldolese, but various regulations were adopted from the Augustinian canons.

About 11jo the hermits, being compelled to leave Muret. settled in the neighbouring desert of Grandmont, whence the order derived its name.

Louis VII founded a house at Vincennes near Paris, and the order had a great vogue in France, as many as 60 houses being established by 1170, but it seems never to have found favour out of France. Later centuries witnessed mitigations and reforms in the life. and at last the order came to an end just before the French Revolution.

See art. "Grandmont, order of" in the *Catholic Encyclopaedia;* Max Heimbuchcr, *Orden und Kongregationen* (1896), i, §31; and the art. in Wetzer and Welte, *Kirchenlexicon* (ed. 2), and in Herzog-Hauck, *Realencyklopädie.*

GRAND NATIONAL: *see* HORSE RACING AND BREEDING.

GRAND PRAIRIE, a city of central Texas, U.S., between Dallas and Fort Worth. Industries include aircraft and boat manufacture. Settled at the close of the American Civil War, Grand Prairie was originally called Alexander Deckman in honour of its founder. Principally an agricultural town during its early years, Grand Prairie boomed after the establishment of an aircraft factory in 1940–41. Incorporated in 1909, it has a council-manager form of government.

For comparative population figures *see* table in TEXAS: *Population.* (E. C. BE.)

GRAND PRIX: *see* HORSE RACING AND BREEDING.

GRAND RAPIDS, a city of Michigan, U.S., is in Kent county on the Grand river, 30 mi. from Lake Michigan and about 60 mi. W.N.W. of Lansing. It was founded in 1826 by the Frenchman Louis Campau as a trading post where several important Ottawa Indian trails (now diagonal streets) converged at the rapids. It was incorporated as a village in 1838 and as a city in 1850. Ample water power generated in the 18 ft. fall of the river, and the availability of valuable lumber from nearby pine and hardwood forests caused the establishment of many sawmills and woodworking industries. Following the display of Grand Rapids furniture at the Philadelphia centennial in 1876, the city gained a reputation as the furniture capital of America. Buyers the world over went to the furniture markets, first held in 1878. Diversification of industry began with the advent of World War I and the metal trades thereafter exceeded furniture in value and output. Nevertheless, Grand Rapids home, office, school and church furniture produced by skilled craftsmen in more than 70 factories maintained its supremacy in quality, style and design. Other important products are business machines, carpet sweepers, aircraft instruments, auto parts and accessories, hardware, tools, machinery, baked goods, paper boxes, gypsum products and refrigerator cabinets. More than 100 plants are engaged in the field of graphic arts. Grand Rapids is the principal trading centre of western Michigan. including a large area devoted to fruit farming and truck gardening, and serves a population of 1,600,000.

The elevation of Grand Rapids is 638 ft. above sea level. The average rainfall is 31.5 in. and the average temperature in summer is 69.3" F., and in winter, 24.9° F.

The city has a commission-manager form of government, adopted in 1916.

Higher education is provided by Calvin college, chartered in 1876 and affiliated with the Christian Reformed Church; Aquinas, a Roman Catholic coeducational college established in 1886; a University of Michigan extension centre for western Michigan and Michigan State university centre for continuing education. Kendall School of Design offers courses in iurniture and interior design and allied fields of art.

Cultural institutions include a municipal museum: the Public museum (founded in 1854) devoted to natural history and ethnology and including historical and contemporary furniture exhibits; the public library containing the country's most important collection of books on furniture design and manufacture; an art gallery; a symphony; and a civic theatre.

Grand Rapids has about 50 parks. playgrounds and park-school areas. Nearby are a number of Kent county parks, while 250 lakes and streams are within an hour's drive. Pop. (1960) city 177,313; standard metropolitan statistical area (Kent county) 363.187. For comparative population figures *see* table in MICHIGAN: *Population.* (F. L. D. M.)

GRAND RIVER, the name of several rivers in the central part of the United States.

Iowa-Missouri. — One of the more important branches of the Missouri river, the Grand rises in south-central Iowa near the city of Creston and flows almost due south into Missouri where it takes a southeasterly course! joining the Missouri near Brunsnick in north-central Missouri. The only city of importance in the Grand's drainage basin is Chillicothe. Mo., which lies near the confluence of the Grand and the Thompson.

Michigan. — Commercially the most important river in west-central Michigan, the Grand rises near Jackson and flows almost due north to Lansing where it turns west to Spring Lake. which empties into Lake Michigan through a short channel near Grand Haven. The major cities on the Grand are Lansing and Grand Rapids. Navigation is possible as far as Grand Rapids which owes its location to the development of water power from the river.

Missouri. — The Grand, sometimes known as the South Grand, rises in western Missouri about 30 mi. S. of Kansas City. It flows due east to join a west arm of the Lake of the Ozarks.

South Dakota. — Formed by the confluence of the North and South forks in Perkins county, S.D., the Grand flows eastward to join the Missouri near Mobridge, S.D. (R. R. D.)

GRANDSON (Ger. *Grandsee),* a town in the Swiss canton of Vaud, near the southwestern end of the Lake of Neuchâtel, and 20 mi. S.W. of Neuchâtel and 3 mi. N. of Yverdon by rail. Its population in 1950 was 1,800, mainly French-speaking and Protestant. The old church (once of a Benedictine monastery) contains Roman columns, etc., from Avenches and Yverdon. It has a tobacco factory. Its lords were vassals of Savoy, till in 1475 the castle was taken by the Swiss at the beginning of their war with Charles the Bold, duke of Burgundy, whose ally was the duchess of Savoy. It was retaken by Charles in Feb. 1476, and the garrison put to death.

The Swiss avenged this deed in a famous battle (March 2, 1476), defeating Charles with great loss. The battle was between Concise and Corcelles, at a place marked by several columns. *(See* SWITZERLAND: *History.)*

GRAND TETON NATIONAL PARK, established in 1929, is located in the Jackson Hole region of northwestern Wyoming. U.S., near the Idaho line and about 25 mi. S. of Yellowstone National park. Comprising 310,350 ac., or 484 sq.mi., it includes most of the former Jackson Hole national monument. The snow-covered peaks of its spectacular Teton range, sculptured from the sheerest rock, rise to a maximum height of 7,000 feet above the valley of the Snake river — itself nearly the same distance above sea level. Formed by a series of titanic upthrusts: this gigantic fault-block is traversed by great glaciers which have slowly crunched their way down the stream-cut canyons. Melting as they reached the bottom, they deposited their cargo of rock and debris into accumulations known as moraines. These are often beautifully forested with the sharp-pointed Engelmann spruce and pines so singularly straight and tall as to merit the designation of lodgepole.

These wooded deposits form the shores of frigid glacial lakes, which in varying size dot the region. Perhaps the most beautiful, and certainly the best known; is Jenny lake, but there are others with great individuality, such as Leigh, String, Bradley, etc.. fed from roaring torrents, exemplified by the unforgettable Hidden falls. On the other hand, the largest body of water. Jackson lake, is formed by a dam across the Snake river. The streams in the park abound in fish, while herds of buffalo, elk and antelope roam at ill, Throughout the summer season a succession of different varieties of wild flowers present ever-changing tapestries, even beginning their bloom underneath the snow.

The highest peak, Grand Teton (13,766 ft.), is one of the most difficult to climb in the United States. (R. R. MN.)

GRANDVILLE (professional name of JEAN IGNACE ISIDORE GÉRARD) (1803–1847). French caricaturist, whose works are characterized by a marvelous fertility of satirical humour, was born at Nancy on Sept. 13, 1803. He received his first instruction in drawing from his father, a painter of miniatures: and at the age of 21 went to Paris, where he soon afterward published a collection of lithographs entitled *Les Tribulations de la petite propriété.* He followed this by *Les Plaisirs de toutâge* and *La Sibylle des salons;* his success was made with *Métamorphoses* du *jour* (1828), a series of 70 scenes in which individuals with the bodies of men and faces of animals played the human comedy. Grandville contributed drawings to many periodicals, including *La Caricature* and *Le Charivari,* and his political caricatures came to enjoy a general popularity. He illustrated several classic works of literature. He died on March 17, 1847.

GRANET, FRANÇOIS MARIUS (1775–1849), French painter and the only landscapist of his day to emerge from the neo-classical school, was born at Aix-en-Provence on Dec. 17, 1775. He was the pupil first of J. A. L. Constantin, a local landscape painter, and later, in Paris, of J. L. David. With a number of other artists —Ingres, Bartolini, Gros, Girodet — he lived and worked in the Capuchin convent in the Boulevard des Capucines. There he found the subjects which are most characteristic of his work— cloisters, cells and large quiet sunlit rooms, with mild historical compositions in the same tranquil settings. In 1802 Granet went to Rome where he stayed for 17 years. On his return to Paris in 1819 he exhibited in the Salon his "Choeur de l'Église des Capucins," which was so successful that 16 replicas were commissioned. His paintings and water colours influenced the evolution of Corot's style. In 1826 Louis-Philippe made him curator of the pictures at Versailles. In 1848 he retired to Aix, where he died on Nov. 21 in the following year, leaving to his native town the greater part of his fortune and a collection of his works. (AA. B.)

GRANGE, THE, known officially as the National Grange, originally the National Grange of the Patrons of Husbandry, is a fraternal organization of farmers founded in Washington, D.C., in 1867 by Oliver Hudson Kelley and six associates. Growing slowly at first, the organization advanced rapidly during the agrarian discontent of the early 1870s, when its members, together with those of other groups, joined what was known as the "Granger" movement. Through political action centring in the middle west, an impetus was given to regulation of railways and grain elevators.

Local and state Granges in the same region also sought to circumvent monopolies by extensive co-operative business enterprises. Their general failure, coupled with internal dissensions, caused a heavy decline in the membership between 1875 and 1880, though the organization retained a strong influence. In 1875 the first Grange was organized in Canada, but the order never attained a dominant place there. After 1880 the Grange gradually increased its membership, and its centres of strength in the second half of the 20th century were found in Ohio, New York and Pennsylvania in the east and Washington, California and Oregon in the west.

The following definition of the Grange was selected in 1938 as the prize-winning entry in its national contest: "The Grange is a great farm fraternity: building character; developing leadership; encouraging education; promoting community betterment; instilling an appreciation of high ideals; teaching through work and play the value of co-operation and service in the attainment of happiness." There are seven degrees in the Grange, and the names of these, as well as the ritual of the order, carry agricultural connotations. Membership is open to all members of farm families 14 years old or over. Local subordinate Granges are usually organized on a community basis and often adopt the community name. Many local Granges own their own meeting halls and carry on a variety of social, educational and recreational programs. State Granges carry out policies agreed upon by the local and county Granges. Each state Grange sends two delegates, a man and his wife, to the annual meetings of the National Grange. These delegates are the policy forming body and elect the officers of the National Grange.

In the 1930s the National Grange supported the agricultural adjustment legislation. Its continued criticism of some features of it was an important factor in improvements in the parity formula and other price support legislation in the 1940s and 1950s. One of its major interests in the 1940s and early 1950s was the improvement of the co-operative farm credit agencies and their removal from direct government control. Beginning in the 1940s the Grange began taking a more active part in national legislative issues than at any time since the 1870s. A distinctive feature of the Grange program in the second half of the 20th century was its advocacy of using a commodity-by-commodity approach in dealing with farm problems. It supported domestic parity programs for wheat and other important export crops. *See* also AGRICULTURAL ORGANIZATIONS; UNITED STATES (OF AMERICA). GRANGEMOUTH, a small burgh and seaport of Stirlingshire, Scot., on the southern shore of the Forth estuary and at the mouths of the Carron and its former right-hand tributary, the

Grange Burn, 23 mi. W.N.W. of Edinburgh by road. Pop. (1951) 15,432. Its history begins in 1768 when digging was started for the Forth and Clyde canal. built by John Smeaton, which crosses the narrow "waist" of Scotland and enters the Clyde at Bowling. In 1777 the first foundation stone of Grangemouth was laid at the eastern end of the canal. which was opened in 1790. In 1843 the Old dock was opened and in 1859 the Junction dock was built to be followed by two wet timber basins for the Baltic trade. In Scotland Grangemouth is second in tonnage only to the port of Glasgow. Residential and industrial, it was early divided into two towns, an old and a new. Experiments in steam navigation were carried out on the canal in 1802 with the "Charlotte Dundas," which was built at Grangemouth. The chief industries are oil refining and the manufacture of its by-products, dyestuffs and other chemicals, timber importing and shipbuilding.

GRANGER, JAMES (1723–1776), English clergyman and print-collector, published a Biographical History *of* England (1769) "consisting of characters dispersed in different classes, and adapted to a methodical catalogue of engraved British heads." The work was supplemented in later editions by Granger, and still further editions were brought out by the Rev. Mark Noble, with additions from Granger's materials. Blank leaves were left for the filling in of engraved portraits for extra illustration of the text, and it became a favourite pursuit to discover such illustrations and insert them in a Granger, so that "grangerizing" became a term for such an extra-illustration of any work, especially with cuts taken from other books.

GRANICUS, BATTLE OF THE (May–June, 334 B.C.). In the spring of 334 Alexander the Great, having by various campaigns established a secure base of operations in Greece, set sail from Sestos to Abydos to carry out the invasion of Persia. His army consisted of about 30,000 foot and 5,000 horse, and it was accompanied by a siege train, a baggage train and a corps of engineers. Having visited Ilium to crown the tomb of his traditional ancestor Achilles, he moved northward through Lampsacus and came upon the Persian army on the Granicus river (Bigha-Chai), an army which, according to Arrian, numbered 20,000 Persian cavalry and 20.000 Greek mercenaries under Memnon. Memnon, an able general, had suggested to Arsites and Spithridates, who were in joint command. that they should withdraw and lay waste the country, and then land an army in Macedonia and attack Alexander's base. This they refused to do, and in place drew up their cavalry on the northern bank of the river with Memnon's infantry in the rear. Alexander, seeing this faulty distribution, determined on immediate attack, and deployed his army as shown in the diagram. From the accounts of this battle as given by the classical historians, it is obvious that Alexander's intention was to refuse his left wing, pivot his right wing on the phalanx, and rapidly moving this wing forward concentrate his main blow against the Persian left. In brief the action was as follows:—

The Battle.—The battle opened by a charge on the Persian left by the right wing light cavalry, who, after a severe engagement, were driven back. Under cover of this attack Alexander advanced at the head of the Companion cavalry and charged the left centre of the Persian horse, for it was here that their leaders had posted themselves. Little by little the Persians were pushed back until their left centre broke, whereupon both wings dispersed in flight. Alexander did not pursue them far; instead, he turned on the Greek mercenaries, and as Arrian says: "leading the phalanx against these, and ordering the cavalry to fall upon them from all sides," he soon completely surrounded them and cut them up. According to Diodorus, 12.000 Persians were killed, and 20.000 were made prisoners. Alexander is said to have lost less than 150; this figure is probably an understatement.

Tactics.—Though this battle was purely a cavalry action, it was not a blind charge of the Prince Rupert type, but an operation rendered possible only by the scientific organization of the Macedonian army which was the masterwork of Philip. Alexander's father. In the centre was the phalanx which possessed immense protective poner, and on its flanks were two wings which could, like the fists of a pugilist, punch out from it. Holding his left wing back, Alexander, under protection of the phalanx, which stood like

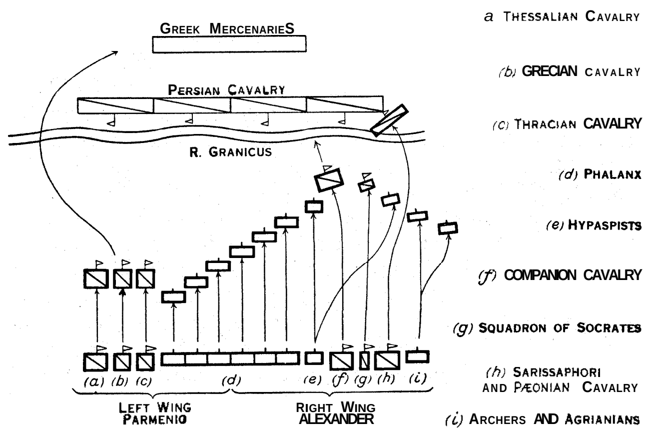

DIAGRAM SHOWING FORMATION OF TROOPS IN THE BATTLE OF THE GRANICUS. 334 B.C.

This, the first battle fought by Alexander the Great in his conquest of Asia, ended in victory for the Greeks. Alexander displayed the highest courage, first leading cavalry and then phalanx across the river in face of stubborn Persian resistance, and with his own hand slaying two Persian grandees

a wall on the left of his right wing, first sent forward his light cavalry, protected on their outer flank by light infantry, to hold the Persian left wing by engaging their cavalry and simultaneously disorganize them. Next he rapidly advanced the companion cavalry (the decisive attack); this advance drew the phalanx into an oblique order. This decisive attack was not directed on the Persian left flank (that is, it did not strike where the light cavalry had struck), but, instead, at the centre of the Persian left, for there the brains of the army (the generals) were assembled. This decisive attack moved down a protective funnel of men, for on its right were the light cavalry and light infantry, and on its left the hypaspists and the phalanx, both echeloned backward. While the Persian left flank was being pushed in confusion toward the centre. this centre was suddenly struck a terrific blow by a wedge of heavy cavalry followed closely by armoured infantry (the hypaspists), which worked into the enemy's shattered front and "ate" it away.

GRANITE, a word apparently already used in the Renaissance to designate granular rocks, taken over almost in this very broad sense by early geologists, but in petrography, that is, the systematic classification and description of rocks, nearly always used in a much more restricted sense as referring to coarse or medium grained rocks rich in quartz and feldspar. The restricted usage was not only common among the early scientific petrographers but was also favoured by their precursors. naturalists such as A. F. Cronstedt and J. G. R'allerius. for instance.

Even in this restricted sense granite is by far the most common plutonic rock known or suspected to be of magmatic origin. So abundant is it that in the various earth models proposed by geophysicists and geologists a shell of granite is supposed to underlie the immediately visible portions of the lithosphere.

Because of its use both for paving block and as a building stone, the quarrying of granite was at one time a major industrial activity. The widespread introduction of macadam and concrete for roads together with the cessation of building in the depression of the 1930s produced a paralysis which lasted until well after World r 11 As the postwar building boom penetrated into the large cities the demand for structural stone and veneer led to a considerable revival of the industry. Except for tombstones, however, for which there is a continuing demand. the production of granite is geared to the fluctuating market for curbing in highway construction and veneer used in the facing of large industrial and commercial buildings (see also QUARRYING).

Composition and Occurrence.—Granite may occur in dikes or sills but more characteristically it forms irregular masses of extremely variable size. For the smaller of these—up to five miles or so in maximum dimension—a floor may sometimes be inferred on stratigraphic grounds but can rarely be proven beyond reasonable doubt. For the larger masses. known as batholiths, often hundreds or thousands of square miles in area, thicknesses cannot be estimated; such masses are often assumed to take their origin directly from the (hypothetical) underlying granite zone or shell of the lithosphere.

Intrusive rocks containing in excess of 40% (by volume) of quartz are virtually unknown. A lower limit to quartz content of granite is not so easily set, but rocks containing less than 20% of quartz are almost never named granite by those who describe them. Considerable evidence suggests that intrusive rocks of intermediate quartz content are less abundant than those rich in quartz (granite) or those in which quartz is scarce or lacking (gabbro).

The principal constituent of granite is feldspar (*q.v.*), both plagioclase and alkali-feldspar ordinarily being abundant. The relative abundance of the two kinds of feldspars has provided the basis for so many attempts at classification that even a brief review of the matter would turn this into an article about taxonomy rather than rocks. It is safe to say that in most rocks described as granite the ratio of dominant to subordinate feldspar is less than 2. In this category fall most of the granites of the eastern, central and southwestern United States, southwestern England (Cornwall, Devon), the Fennoscandian (Baltic shield) area, western and central France, Spain, etc. Indeed, examples are so numerous that it is difficult to select among them. Granites in which there is a great excess of plagioclase over alkali-feldspar are not at all rare, however. and in large regions of the western United States this is the common type; indeed, it is thought to be characteristic of the great series of batholiths stretching from Alaska and British Columbia southward through Idaho and California into Mexico. The least abundant granites appear to be those with a great excess of alkali-feldspar over plagioclase—the alkali granites. In the United States these are well known from Quincy and Cape Ann, Mass.! Conway, N.H., Mt. Dessert, Me. They occur in smaller bodies at numerous sites in rocks of the Tertiary period in Great Britain and in the Christiania region of Norway. but their most extensive development is in northern Nigeria. Like most alkaline rocks, they have received attention out of all proportion to their abundance. In New England. for instance. a region relatively rich in alkali-granites, they probably account for no more than a few per cent of the known outcropping of granite.

The relative abundance of the different kinds of granite is a bothersome matter because the roots of many granite classifications go back to a time when the plagioclase series was either unknown or poorly known. If a granite was to consist primarily of feldspar and quartz it was thus necessarily what we now call an alkali-granite, and in most classifications these, by all odds the rarest members of the class, are still the "true" granites.

The minor essential minerals of granite may include muscovite, biotite, amphibole, pyroxene or, rarely, iron-olivine (fayalite). Usually no more than two or three of these are present. Amphibole or pyroxene-bearing granites never carry muscovite in significant amount. Biotite may occur in granite of any type and is usually present, though sometimes in very small amount. The sodic-amphiboles and pyroxenes (riebeckite, arfvedsonite, aegirine) are characteristic of the alkali-granites. When plagioclase is in great excess over alkali-feldspar the ferromagnesians usually include hornblende, and augite may be present as well; the principal, and sometimes the only, potash bearing mineral in such rocks is biotite. If neither feldspar is in great excess of the other, neither amphibole nor pyroxene is likely to be an essential constituent; the dark minerals will then ordinarily be either or both biotite and muscovite. The maximum permissible dark mineral content varies from classification to classification, but rocks containing more than 20% (by volume) of dark minerals are rarely named granite, and in most granites the "colour index" is very much less than this. As with quartz. massive intrusives of intermediate colour index appear to be considerably less abundant than those either rich in heavy silicates (gabbro) or poor in them (granites).

Theories of Origins.—Controversy concerning the origin of granite has been alternately raging and simmering since the birth of scientific petrography, and there is as yet no general agreement on the subject; indeed, there are probably few areas of inquiry in which acknowledged specialists are in such unequivocal disagreement.

The principal contesting hypotheses may be classified as (1) magmatic or (2) transformist. The proponents of the former argue that granites are derived by intratelluric crystallization of a parent liquid or liquid-crystal mush (magma). The proponents of the latter argue that granites have formed without the intervention of magma. and sometimes even with no liquid at all, by the solid state metamorphism of pre-existing sedimentary rocks. A third group advances the metasomatic or hydrothermal hypothesis and regards granites as products of reaction between a dilute, largely aqueous fluid and previously consolidated sedimentary or metamorphic rocks. During the early 20th century the controversy was to a surprising extent regional or even national, the Scandinavians and French being devout metasomatists, the Germans and British equally devout magmatists. In the decade following World War I, however, a revival of transformism began almost simultaneously in France and Britain, and soon spread. By the middle of the century the controversy had lost all of its national and much of its scientific character. The theory of magmatic origin is perhaps strongest in the Soviet Union and the United States.

For further discussion of these hypotheses *see* GEOCHEMISTRY: *Geochemistry of the Lithosphere;* METAMORPHISM; METASOMATISM. *See* also PETROLOGY. (F. Cs.)

GRANITE CITY, an industrial city of Illinois, U.S.. is located in Madison county on the Mississippi river, 10 mi. N.E. of St. Louis. The land on which Granite City stands was countryside until 1891. when Frederick G. and William F. Niedringhaus, St. Louis manufacturers, acquired a site for the expansion of their graniteware industry. From the Niedringhaus plant Granite City has grown to impinge on the borders of older communities and blend into the heavily industrialized area extending north from East St. Louis. Xlore than a dozen railways help to feed Granite City's industries and distribute its manufactures. The production of steel. originally an auxiliary of the graniteware (enameled ironwear) industry, has assumed the premier place in the city's economic life. Graniteware. which gave the city its name, is no longer manufactured there. Granite City also manufactures metal containers. railway equipment, chemicals and stoves.

The city was founded in 1893 and incorporated in 1896. For comparative population figures *see* table in ILLINOIS: *Population.* (R. E. M.)

GRAN SASSO D'ITALIA ("Great Rock of Italy"), mountain of the Abruzzi e Molise provinces of Italy, culminating point of the Apennines, 9.560 ft. in height. It resembles the limestone Alps of Tirol and its elevated plateaus have a number of *doline* or funnel-shaped depressions into n-hich melted snow and rain sink. The summit is covered with snow for the greater part of the year. 'The Alpine region beneath its summit is still the home of the wild boar. and here and there are dense woods of beech and pine. The group has other lofty peaks. the Pizzo d'Intermesole (8.680 ft.). the Corno Piccolo (8,652 ft.), the Pizzo Cefalone (8,307 ft.) and the Monte della Portella (7,83j ft.). The most convenient starting point for the ascent is Assergi, 10 mi. N.E. of Aquila, at the south foot of the Gran Sasso with its interesting Romanesque church (Sta. Maria Assunta).

GRANT, DUNCAN JAMES CORROWR (1885–), Scottish painter and decorative artist, whose style, particularly influenced by Paul Cézanne and modern French painting, is marked by bold brushwork and bright colours, was born at Rothiemurchus, Inverness-shire on Jan. 21, 1885. Educated at St. Paul's school, London, he afterward studied at Westminster School of Art and visited Paris, Italy, Greece and Tunisia. He worked with Roger Fry at the Omega workshops, London, in 1913, designing fabrics and furniture, besides executing some highly individual paintings such as "The Lemon Gatherers" (1910, Tate gallery, London) and "The Tight-Rope Walkers" (1918, Ralph Partridge). His later easel pieces were often less well composed than the three large decorative panels originally intended for R.M.S. "Queen Mary" (1935).

Grant also designed stage décor and lithographs, holding his first one-man show at the Carfax gallery in 1920. Grant became a member of the London Group in 1919.

See *Duncan Grant,* with introduction by Roger Fry, new ed. (1930); Raymond Mortimer, *Duncan* Grant (1944); Retrospective Exhibition Catalogue, Tate Gallery (1959). (D. L. FR.)

GRANT, SIR FRANCIS (1803–1878), Scottish portrait painter, whose portraits generally have a superficial brilliance suited to their subject, was born at Edinburgh on Jan. 18, 1803. Educated at Harrow, he gave up law for painting in 1827, and exhibited at the Royal Academy in 1834. At first a painter of animals and hunting scenes like "The Melton Hunt, going to draw the Ram's Head Cover" (1839), he turned to portraiture, chiefly of society sitters. He painted many of the celebrities of his day, including Scott, Macaulay, Disraeli, Palmerston and Russell, his brother Sir J. Hope Grant and his friend Sir Edwin Landseer. Grant's works were not of the highest artistic rank, a distinguished exception being "The Duke of Portland" (1853). Grant was elected a member of the Royal Academy in 1851, and became president arid was knighted in 1856. He died at Melton Mowbray, Leicestershire, on Oct. 5, 1878. (D. L. FR.)

GRANT, GEORGE MONRO (1835–1902), Canadian educator, principal of Queen's university, Kingston, Ont., was born in Nova Scotia in 1835 and educated at Glasgow university, where he had a brilliant academic career. Entering the ministry of the Presbyterian Church, he obtained a pastoral charge in Halifax. N.S., which he held from 1863 to 1877. When Canada was federated in 1867 Nova Scotia was strongly opposed to federal union. Grant threw his influence in the federal scale, and his oratory played an important part in securing the success of the movement. When the consolidation of the dominion by means of railway construction was under discussion in 1872, Grant traveled from the Atlantic to the Pacific with the engineers who surveyed the route of the Canadian Pacific railway, and his book *Ocean to Ocean* (1873) helped to show Canadians the value of the heritage they enjoyed. In 1877 Grant was appointed principal of Queen's university at Kingston. A tour in 1888 to Australia, New Zealand and south Africa strengthened the imperialism that was the guiding principle of his political opinions. He died at Kingston on May 10, 1902.

GRANT, SIR JAMES HOPE (1808–1875), English general, son of Francis Grant of Kilgraston, Perthshire, and brother of Sir Francis Grant, president of the Royal Academy, was born on July 22, 1808. He entered the army in 1826, becoming captain in 1835. In 1842 he was brigade-major to Lord Saltoun in the Chinese War, and received the rank of major and the companion of the Bath for his services at the capture of Chin-Kiang. He fought in the first Sikh War of 1845–46 and in the Punjab campaign, winning further promotion. He took a leading part in the suppression of the Indian mutiny of 1857. After the recapture of Lucknow he was appointed to the command of the force employed for the final pacification of India. Before this task was quite completed he was created knight commander of the Bath. In 1859, in command of the British land forces in the French and British expedition against China, he accomplished the object of the campaign within three months of the landing at Pei-tang (Aug. 1, 1860), occupying Peking. For his conduct in this, which has been called the "most successful and the best carried out of England's little wars," he received the thanks of parliament and was gazetted knight grand cross of the Bath. In 1861, as lieutenant general, he was appointed commander in chief of the army of Madras; on his return to England in 1865 he n-as made quartermaster general at headquarters, and in 1870 was transferred to the command of the camp at Aldershot. He took part in the reform of educational and training plans of the forces after the Franco-German war, and was largely responsible for the introduction of annual army maneuvers. In 1872 he was gazetted general. He died in London on March 7, 1875.

Incidents in the Sepoy War of 1857–58, compiled from the Private Journal of General Sir Hope Grant, K.C.B., together with some explanatory chapters by Capt. H. Knollys, Royal Artillery, mas published in 1873, and *Incidents in the China War of 1860* appeared posthumously under the same editorship in 1875.

GRANT, SIR PATRICK (1804–1895), British field marshal, second son of Maj. John Grant. was born on Sept. 11, 1804, at Auchterblair, Inverness-shire. He entered the Bengal native infantry in 1820 and became captain in 1832. He served in Oudh from 1834–38 and raised the Hariana Light infantry. He became adjutant general in 1846. He served under Sir Hugh Gough and was present at the battles of Maharajpur (1843), Moodkee (1845), Ferozshah (1846) and Sobraon (1846), receiving the companion of the Bath and the brevet rank of lieutenant colonel. He was appointed aide-de-camp to the queen, and served in Kohat in 1851. From 1856 to 1861 he was commander in chief of the Madras army, was made knight commander of the Bath in 1857, and succeeded General Anson in command of the army in India. He directed operations from Calcutta until the arrival of Sir Colin Campbell. He left India in 1861, was promoted lieutenant general in 1862, and was governor of Malta from 1867 to 1872. He was promoted general in 1870, field marshal in 1883 and colonel of the Royal Horse guards and gold-stick-in-waiting to the queen in 1885. From 1874 he was governor of the Royal hospital, Chelsea, until his death there on March 28, 1895.

GRANT, ROBERT (1814–1892), British astronomer whose *History of Physical Astronomy* (1852) took a leading place in astronomical literature, was born at Grantown-on-Spey, Scot., on June 17, 1814. He became interested in astronomy at an early age and conceived the idea of his history while working in a counting house in London. In 1859 Grant succeeded J. P. Nichol as professor of astronomy in the University of Glasgow. His principal work at Glasgow consisted in determining the places of a large number of stars with the Ertel transit circle of the observatory. The results, extending over 21 years, are in the *Glasgow Catalogue of 6,415 Stars* (1883), which was followed by the *Second Glasgow Catalogue* of *2,156 Stars*, published a few weeks after Grant's death at Grantown-on-Spey, Oct. 24, 1892. (O. J. E.)

GRANT, ULYSSES SIMPSON (1822–1885), U.S. soldier and 18th president of the United States, was born at Point Pleasant, Ohio, on April 27, 1822. He was a descendant of Matthew Grant, a Scotsman, who settled in Dorchester, Mass., in 1630. His earlier years were spent in helping his father, Jesse R. Grant, upon his farm in Ohio. In 1839 he was appointed to the military academy at West Point, and it was then that his name assumed the form by which it is generally known. He had been christened Hiram, with Ulysses for a middle name. Since he was usually called by his middle name, the congressman who recommended him for West Point supposed it to be his first name, and added thereto the name of his mother's family, Simpson. Grant was the best horseman of his class, and took a respectable place in mathematics, but at his graduation in 1843 he ranked only 21st in a class of 39. In Sept. 1845 he went with his regiment to join the forces of Gen. Zachary Taylor in Mexico; there he took part in the battles of Palo Alto, Resaca de la Palma and Monterey, and, after his transfer to Gen. Winfield Scott's army, which he joined in March 1847, served at Vera Cruz. Cerro Gordo, Churubusco, Molino del Rey, and at the storming of Chapultepec. He was breveted 1st lieutenant for gallantry at Molino del Rey and captain for gallantry at Chapultepec. Three days later, Sept. 16, 1847, he was commissioned 1st lieutenant.

In Aug. 1848, after the close of the war, he married Julia T. Dent (1826–1902), and was for a while stationed in California and Oregon. In 1853 he was commissioned captain, but in 1854 he resigned his commission. His reputation had suffered from allegations of intemperate drinking which, whether well founded or not, certainly impaired his usefulness as a soldier. For the next six years he lived in St. Louis, Mo., earning a scanty subsistence by farming and dealings in real estate. In 1860 he removed to Galena, Ill., and became a clerk in his father's leather store. At that time his earning capacity seems not to have exceeded $800 a year, and he was regarded by his friends as a broken and disappointed man. He was living at Galena at the outbreak of hostilities between the North and South. (J. F.)

Grant's **Civil** War Career.—At the beginning of the war Grant offered his services as a colonel, but the war department ignored his application. He drilled the militia company organized in Galena and went to Springfield, where he worked in the office of the state's adjutant-general until he received appointment as colonel of the 21st Illinois infantry regiment. Shortly after, Lincoln appointed him a brigadier general. Assigned to command at Cairo, Grant won his first distinction by seizing, on his own responsibility, Paducah, Ky., at the confluence of the Tennessee and the Ohio rivers (Sept. 6, 1861). On Nov. 7 he led his troops to Belmont, Mo., won a momentary victory, and then was forced to retreat. Early in 1862 he persuaded Gen. Henry W. Halleck, commanding in St. Louis, to give him permission to advance on Fort Henry, located on the Tennessee river at the Tennessee-Kentucky border. Aided by a flotilla of gunboats, Grant easily took the fort, from which the Confederates fled to Fort Donelson on the Cumberland. Grant followed and launched an attack on the larger fort, which surrendered with its garrison of 15,000. After Donelson, the Confederates abandoned Nashville, and Grant occupied the Tennessee capital.

Failure of communications led Halleck to remove Grant from command temporarily, but he rejoined his army at Savannah, where it was preparing for a campaign against Corinth, Miss. On April 6, 1862, the Confederates attacked Grant's camp at Shiloh church, or Pittsburg Landing, and drove them back to the river bank. The next day, joined by the army of the Ohio under Gen. Don Carlos Buell, Grant drove the Confederates from the field. Immediately after Shiloh Halleck arrived to take command in person, and with Grant removed from all important duties and second in command, began to advance on Corinth. After the Confederates abandoned Corinth and federal forces occupied it, Halleck went to Washington as general in chief, and Grant resumed command of his army and of the army of the Mississippi under William S. Rosecrans. Two victories (Iuka and Corinth) by Rosecrans in the fall of 1862 enabled Grant to secure his position on the Mississippi, and late in the year he began an advance on Vicksburg, the last important Confederate stronghold on the river.

Slowly, with experience, Grant was gaining strategic concepts and displaying his particular qualities as a commander. He displayed a willingness to fight, the ability to make decisions, a bulldog determination and an absence of fear. He recognized the importance of cutting the Confederacy in two and in gaining control of the Mississippi and other rivers of the South. He was fortunate in being away from the political controversies and the interference which congress and the civil authorities in Washington exerted on the armies in Virginia, and he had the support of Lincoln, who admired his fighting qualities.

Through the winter of 1862–63 Grant maneuvered about Vicksburg, seeking an approach to the city. Much of the effort was expended in digging a canal into which he hoped to divert the river and thereby isolate Vicksburg. The effort proved futile, and late in the spring federal gunboats ran past the city's batteries and secured the banks south of the stronghold. Then Grant led his armies around the city, took Jackson, Miss.: and defeated the Confederates at the battle of Champion Hill (Baker's creek). As the Confederates retreated into Vicksburg, Grant besieged the city, and on July 4, 1863, the fortress surrendered with nearly 30,000 men. Lincoln promoted Grant to major general in the regular army.

The fall of Vicksburg cut the Confederacy in two, and Grant planned to follow his victory by an attack on Mobile and the rivers which flowed into the Gulf of Mexico. The defeat of Rosecrans at Chickamauga, however, forced a change of plans. Grant went to Chattanooga, where the federal army mas under siege. Joined there by troops under W. T. Sherman and Joseph Hooker, Grant launched an attack on the Confederates who surrounded him and drove them from the field.

Eastern Campaign.—Congress revived the rank of lieutenant general, and Lincoln promoted Grant to the new grade. In hlarch 1864 he went east and took up headquarters with George Gordon Meade's army of the Potomac and directed the campaign in Virginia. He advanced against R. E. Lee's armies in the Wilderness campaign and, although defeated. flanked the Confederates and renewed the attack. In a series of battles from the Wilderness to Cold Harbor: Grant suffered enormous casualties but succeeded in pushing Lee back toward Richmond. Although after Spottsylvania he wired Halleck. "I propose to fight it out on this line! if it takes all summer,'! he abandoned the approach across Virginia, shifted his base to the south and east of Richmond, and began a campaign against the Confederate capital and the nearby important railroad junction of Petersburg. The campaign of attrition lasted until Petershurg fell and Lee and the Confederate government abandoned Richmond in April, 186;. Grant pressed Lee's retreating armies until, on April 9, Lee surrendered to him at Appomattox Court House.

Although he gave his major attention to the Virginia campaign, Grant furnished general direction and supervision to the other armies advancing against the Confederates. He kept in close touch with Sherman, advancing against Atlanta and then moving to Savannah and turning northward across the Carolinas. and! with George H. Thomas, commanding in Nashville. An efficient command system, with Lincoln defining general objectives, Grant furnishing strategical advice and Halleck, as chief of staff, supervising technical details, evolved from experience and enabled the North to make effective use of its vastly greater resources of man power and industry.

At the close of the war Grant's superior military qualities received general recognition. His great opponent Robert E. Lee was clearly a better tactician, but Grant's concepts of strategy, though evolving slowly, surpassed that of any other commander on either side. He was less competent as an organizer than George B. McClellan, less brilliant than Rosecrans and less cautious than Thomas. But he displayed more capacity for growth than any of them. Decisiveness and persistence were the foundation stones of his success. For a fuller account of his role in the war, *see* AMERICAN CIVIL WAR.

Grant's Presidency (1869–77).—After Lincoln's assassination his successor, Andrew Johnson, at first showed a disposition to deal harshly with Confederate leaders and rumour had it that General Lee would be punished. Lee appealed to Grant, who protested to Johnson that the Confederate general was protected by the terms of his parole given at Appomattox. Johnson abandoned any intention oi bringing Coniederates to trial for treason. The president's plan for reconstructing the South brought him into conflict with radical Republicans in congress and both the president and the radical leaders angled for Grant's support. In 1866 congress created the grade of general and Johnson appointed Grant to the office. In that same year Grant accompanied Johnson and a number of other dignitaries on a "swing around the circle" to Chicago, which Johnson arranged in the hope of carrying his cause to the people. Radical tactics in creating disturbances at Johnson's appearances and the outcome of congressional elections in the fall convinced Grant that Johnson did not have popular support. The general avoided open commitment. however, until the following year, nhen he became involved in Johnson's attempt to remove Secretary of War Edwin M. Stanton from office. Grant took over the war department as ad interim secretary but nhen the senate, acting under the Tenure of Office act. refused to approve Johnson's act, Grant turned the office back to Stanton. Johnson had hoped to force Stanton to sue for his office in the courts and thus test the constitutionality of the Tenure of Office act and believed that Grant had deceived him and betrayed him. The bitter recriminations between the two drove Grant into the radical camp. After his quarrel with Johnson the Republicans rallied to him as a candidate and nominated him for the presidency. The Democrats chose Horatio Seymour. wartime governor of New York, to oppose him. Due to the Republican control of the Negro vote in the South. Grant had a majority of the popular votes and received 214 electoral votes to Seymour s 80.

Grant came into the presidency in 1569 without political experience and immediately began to make political mistakes. He selected able men for his cabinet, though few of them were prominent in political circles. Republican leaders. guided by Massachusetts senator Charles Sumner, forced Grant to withdraw the nomination of William T. Stewart, prominent merchant whom Grant had named secretary of the treasury, and accept George S. Boutwell, a Massachusetts politician instead. Thereafter the politicians were watchful lest Grant depart from party regularity. Soon a rift developed between such practical politicians as Benjamin F. Butler, Roscoe Conkling and Oliver P. Morton and such men as Sumner and Missouri's Carl Schurz, making claim to advocate reform. The division became sharper when Sumner defeated a treaty which Grant h'ad negotiated through his private secretary, by which Santo Domingo would be annexed to the United States. Thenceforth, those who sided with Sumner lost patronage and the support of the administration. The reforming element investigated the "Black Friday" episode—in which Jay Gould and James Fisk attempted to corner the New York gold market on Sept. 24, 1869—in hopes of implicating Grant in the scandal. They uncovered only the connections of Grant's brother-in-law with the speculators.

In 1872, a presidential election year, the disgruntled politicians combined with various types of reformers to launch a "Liberal Republican" party. Free traders, currency reformers and advocates of civil service assembled in convention in Cincinnati in May to select a candidate for the presidency in the almost certain belief that their candidate would receive the endorsement of the Democrats. Political ineptitude characterized the meeting and a clique of newspaper men dominated the proceedings which ended with the nomination of Horace Greeley, editor of the *New York Tribune*. The choice was unwise. Greeley had been an abolitionist, a high tariff protectionist and a lifelong opponent of the Democrats. Nevertheless the Democrats nominated him. In a campaign characterized by excessive mudslinging and the vicious lampooning of Greeley, Grant won an easy re-election—272 to 66 in the electoral college.

Scandals dominated public attention during Grant's second administration, 1873–77. Congressional investigation exposed the methods by which the Crédit Mobilier of America (*q.v.*) constructed the Union Pacific railroad and bribed congressmen, and newspapers turned upon congress to denounce a "salary grab" by which congressmen raised their own salaries. Investigators probed into the Sanborn contracts, uncovered a "whiskey ring" which defrauded the internal revenue bureau, and found that Secretary of War Belknap had received bribes. None of these involved Grant personally, but his private secretary was mixed up in the whiskey ring, and others close to the White House were involved in the corrupt activities of "Boss" Shepherd's board of public works in the city of Washington. One result of the scandals was a declining confidence in government which contributed to the panic of 1873 and to Democratic victory in the congressional and state elections of 1874. By 1876 it seemed that the Republican party's had odour would result in a Democrat's entering the White House. The era of scandals, however, was capped by the manipulations of the disputed presidential election of 1876 in which the votes of three Southern states were taken from the Democratic column and given to Republican Rutherford B. Hayes, who became Grant's successor in office (*see* UNITED STATES: *History*).

Three national problems moved closer to solution during Grant's administrations. One was the gradual disappearance of the problem of the reconstruction of the South. In 1870 the states ratified the 15th amendment to the constitution, forbidding the denial of suffrage because of race. Slowly, one by one, the Southern states were "redeemed" as conservative Democrats regained control and ousted corrupt carpetbagger and Negro governments. For the most part Grant refused to interfere in the South in support of Republican governments. He did, however, suspend the writ of habeas corpus in parts of South Carolina where the Ku Klux Klan was terrorizing Negro voters. A few weeks after Grant left the White House. in 1877, the last of the carpetbag governments disappeared from the South. The question of the public debts and currency inflation received Grant's attention. The secretary of the treasury slowly reduced the debt and retired greenbacks from circulation. In 1874 Grant vetoed a legal tender bill which would have inflated the currency. In 1875 congress passed and Grant approved a Resumption act providing for such resumption four years later. In foreign affairs, the outstanding event of Grant's administration was the settlement of the "Alabama claims" against England, nhich grew out of the Civil War. The British had allowed commerce destroyers, built for the Confederates, to slip away from England and destroy American shipping. By the treaty of Washington in 1871 the British agreed to submit these claims to an arbitration court—nhich awarded $15,500,000 damages to the United States. (W. B HE.)

Later Life.—After the close of his presidency in the spring of 1877 Grant started on a journey around the world, accompanied by his wife and one son. He was received with honours in England and on the continent. whence he made his way to India. China and Japan. After his return in Sept. 1880 he went back to his old home in Galena (Ill.). A faction among the managers of the Republican party attempted to secure his nomination for a third term as president, and in the convention at Chicago in June 1880 he received a vote exceeding 300 during 35 consecutive ballots. Nevertheless his opponents made such effective use of the popular prejudice against third terms that the scheme was defeated and Garfield was named in his stead. In Xug. 1881 General Grant bought a house in New York city. His income was insufficient for the proper support of his family, and accordingly he had become partner in a banking house, Grant and Ward. in nhich one of his sons nas interested. The ex-president invested in it all his available property, but paid no attention to the management of the business. His facility in giving his confidence to unworthy people nas now to be visited with dire calamity. In 1884 the firm became bankrupt, and it was discovered that two of the partners had been perpetrating systematic and gigantic frauds. This blow left General Grant penniless, just at the time when he was beginning to suifer acutely from the disease which finally caused his death. Up to that time Grant had never made any pretensions to literary talent, but on being approached by the *Century Magazine* with a request for some articles he undertook the work, which led to the writing of his *Personal Memoirs,* a frank, modest and charming book, which ranks among the best military biographies. The sales earned for the general and his family something like $500,000. The circumstances in which the book was written made it an act of heroism comparable with any that Grant ever showed as a soldier. During most of the time he was suffering from cancer of the throat, and it was only four days before his death that he finished the manuscript. In the spring of 1885 congress had passed a bill creating him a general on the retired list, and in the summer he mas removed to a cottage at Mt. M'Gregor, near Saratoga, where he passed the last five weeks of his life before his death on July 23, 1885. His body was placed in a tomb monument in Riverside drive, New York city, overlooking the Hudson river.

His misfortunes and the heroism he displayed when confronted with adversity did much to restore Grant in the affections of the American people. During his presidency, his opponents described the corruption and scandals as "Grantism" and dimmed the glory of his military achievements. As president he was conservative, suspicious of the motives of the reformers, and eager to restore both economic and political stability to the country. He did not conceive of himself as a parliamentary leader. "I shall have no policy to enforce against the will of the people," he said on accepting his nomination. Gradually, as he did during the Civil War, he learned from experience. Longer perspective, too, has thrown Grant's military accoinplishments into stronger relief, and ranked him among the great captains of history.

GRANT, in law, the transfer of property by an instrument in uriting, termed a deed of grant. According to the old rule of common law, the immediate freehold in corporeal hereditaments lay in livery (*see* FEOFFMENT), whereas incorporeal hereditaments, such as a reversion, remainder, advowson, etc., lay in grant, that is, passed by the delivery of the deed of conveyance or grant without further ceremony. The distinction between property lying in livery and in grant is now abolished, the Real Property Act 1845 providing that all corporeal tenements and hereditaments shall be transferable as well by grant as by livery. What in many other countries is termed a "concession" is in England usually called a "grant."

GRANTH, the sacred "book" of the Sikhs (*q.v.*). It is a notable compilation of later Indian protestant writings, inculcating monotheism, yet not excluding praise of the goddess Durga (*q.v.*), denouncing caste privileges, concremation of widows and female infanticide, the use of hemp and alcohol (though the latter prohibition is disregarded), and any indulgence in tobacco. It consists of two parts, the Adi Granth or "Original Book," and the Dasam Padshahi dā Granth, or "Book of the Tenth Reign," *i.e.*, of the 10th Gurū, Govind Singh. This latter is accepted by all Sikhs. Its difficulties of interpretation have hindered Sikh progress and expansion. Written in a special Sikh script (*Gurmukhi*) without separation of words in various dialects and even partly in Persian its earliest manuscripts have perished. It still awaits definitive exegesis.

See M. A. Macauliffe, ***The Sikh Religion; Its Gurus, Sacred Writings*** *and Authors*, 6 vol. (Oxford, 1909); Ernst Trumpp, *The Adi Granth* or *Holy Scriptures of the Sikhs* (London, 1877).

GRANTHAM, a municipal borough in the Grantham parliamentary division of the Parts of Kesteven, Lincolnshire, Eng., on the Witham river, 25 mi. S.S.W. of Lincoln by road. Pop. (1951) 23,555. Area 6 sq.mi. It is an important junction on the main railway line to Scotland. Of Saxon origin, the town (Grandham) is given in the Domesday survey as part of the royal demesne, the manor having belonged to Edith. queen of Edward the Confessor. It remained a royal possession until the time of William III, though often granted for a lifetime to such feudal families as the De Warennes. from whose famous checky shield the borough coat of arms is derived. The charter of incorporation was granted by Edward IV in 1463 and self-government of the town and soke was thereafter exercised through 13 "comburgesses," one of whom was annually elected alderman—the title retained by the town's chief citizen until the Municipal Corporations act of 1835. The town remained a parliamentary borough until 1918. The wool trade of the middle ages added to Grantham's prosperity. The parish church of St. Wulfram, mainly Early English and Decorated, is one of the finest mediaeval churches in England, the tower and spire (14th century) rising magnificently to a height of almost 280 ft. A small priest's room over the south porch houses a chained library which was presented to the church in 1598. Grantham was created a bishopric suffragan in the diocese of Lincoln in 1905. King's school, refounded early in the 16th century by Richard Fox, bishop of Winchester, still uses the old school building and headmaster's house of about that period. Edward VI granted the school's present name by charter of 1553. The greatest of its pupils was Sir Isaac Newton, who was born at Woolsthorpe, a few miles south of Grantham. The Angel hotel is said to be where Richard III signed the death warrant of the duke of Buckingham in 1483. The 18th-century George hotel is described in Charles Dickens' *Nicholas Nickleby* as one of the best inns in England. A market is held in Grantham's ancient market place on Saturdays.

The chief industries are concerned with mechanical engineering, including particularly oil engines and road rollers. A local firm invented the "caterpillar" track at the beginning of the 20th century, and it was so named by troops during a trial at Xldershot in 1908.

GRANTIA, a genus of the lesser calcareous sponges. It contains several species, of comparatively small size. common in the inshore waters of Great Britain and North America. (*See* SPONGES.)

GRANTOWN-ON-SPEY, a small burgh of Morayshire, Scot. Pop (1951) 1,541. Area .7 sq.mi. It lies in the Highlands near the boundary of Inverness-shire, on the left bank of the Spey, 34 mi. S.E. of Inverness by road. There are two railway stations. It was founded in 1776 by Sir James Grant of Grant, and became the chief seat of that ancient family, whose members had lived on their adjoining estate of Freuchie (Gaelic *froachach,* "heathery") since the beginning of the 15th century, and hence were usually described as the lairds of Freuchie. The town, built of gray granite and situated in the midst of beautiful woods, is known for its salmon fishing and is a holiday resort.

GRANTS, a town of Valencia county, N.M., U.S., 78 mi. W. of Albuquerque, is called the "uranium capital of the world" because of the extensive uranium mining and milling activities in the vicinity. The town dates from 1881 when the Grant brothers, contractors building the Atlantic and Pacific railroad, established a construction camp at what became known as Grants station. Originally a livestock shipping centre. Grants later was supported by lumber and vegetable growing industries. Uranium ore was first discovered near Grants in 1950 by Paddy Martinez, a Navaho Indian, and further exploration revealed that more than 70% of the world's known uranium reserves were located in the area. For population (which increased 282% between 1950 and 1960) *see* table in NEW MEXICO: *Population.* (H. T. B.)

GRANULITE. To German. Scandinavian and most English and North American petrologists a granulite (from Lat. *granulum,* "a little grain") is a crystalline schist or gneiss which contains certain mineral assemblages characteristic of high pressure and fairly high temperature; *i.e.,* granulite facies. The typical minerals in granulites are anhydrous, such as pyroxene. garnet, cordierite, sillimanite and kyanite (cyanite), together with feldspars and quartz. The hydrous minerals biotite and hornblende are not abundant in granulite. Muscovite is never present in a true granulite. The typical granulite is a quartzofeldspathic rock with magnesium-rich garnet (pyrope) and sillimanite or kyanite: the *Weisstein* of Saxony. Rutile is a common accessory.

Certain basic gneisses with diopside or hypersthene and a characteristic brown hornblende are also called granulites; *e.g.,* the norite granulite of Lapland in north Finland.

The alkali feldspar in granulites is often a microperthitic orthoclase or a feldspar with a triclinicity intermediate between orthoclase (which is monoclinic) and microcline (which is distinctly triclinic). Mesoperthites, *i.e.,* perthites with about 50% albite and 50% orthoclase. are much more common in granulites (and charnockites) than in other kinds of deep-seated rocks.

Antiperthitic plagioclase, *i.e.,* plagioclase with exsolved blebs of potash feldspar. is typical for granulites, as well as rocks belonging to the charnockite kindred.

Granulites may be fine grained or coarse grained; the texture is a sugary mosaic of irregular grains fitted together.

Occurrence.—Granulites occur chiefly in the pre-Cambrian basement complexes in various parts of the world, the areas in Saxony and Lapland perhaps being the best known. Such rocks have also been described from India. Ceylon. Madagascar, Norway, the United States, Canada, Greenland and Brazil. Granulites are intimately associated nith rocks of charnockitic affinity in the field. Some granulites are actually identical to rocks of the charnockite (*q.v.*), family.

Origin.—Although some petrologists consider granulites to be of magmatic origin (P. Eskola in his study of the Lapland granulites), most students believe that they are metamorphic rocks recrystallized under the high P,T (pressure, temperature) conditions of granuiite facies. *See* METAMORPHISM. (H. RG.)

GRANULOMA INGUINALE, a chronic, mildly contagious venereal disease initiated by an organism called the Donovan body. It is treated successfully with antibiotics. *See* VENEREAL DISEASES.

GRANVELLE, ANTOINE PERRENOT DE (1517–1586), French cardinal, a high-ranking member of the Spanish administration under Philip II, active in Brussels at the beginning of the Netherland revolt, was born at Besançon on Aug. 20, 1517, the son of Nicolas Perrenot de Granvelle. chancellor of Emperor Charles V. Granvelle was educated in Padua, Italy, and Louvain, Belg., ordained priest and, in 1540, consecrated bishop of Arras, France; in 1560 he was made archbishop of Malines, Belg, and the next year a cardinal. Together nith his brother Thomas Perrenot de Chantonay, Granvelle received thorough instruction in public affairs; he also derived from his father a high regard for the absolute, unrestricted authority of the monarch (as opposed to the ambitions of wealthy noblemen), which was to lead to a clash between him and the Netherland aristocrats.

In 1560 Philip appointed Cardinal de Granvelle, who was not a foreigner to the Netherlands (to the intellectual atmosphere of which he was also tied through his interest in painting and poetry and his somewhat epicurean outlook), chief counselor to Margaret of Austria, regent in the Netherlands. His political principles and possibly also his class consciousness (as a member of the lesser nobility) contributed to a gradual estrangement between him and the leaders of the Netherland magnates, William the Silent and the counts of Egmont and Horn. In his reports to Philip, Granvelle denied that any serious trouble was in the offing. The king himself was slow to discern the real character of the discontent and—owing perhaps to the influence of Margaret, who sided with the noblemen—regarded Granvelle's difficulties as a personal affair. On his order Granvelle left the Netherlands on March 12, 1564.

Later Philip concluded that the Netherlands revolution would have never developed had he supported Granvelle. After serving for some time in Italy, where he prepared the victory at Lepanto, Granvelle was appointed to the Spanish council of state, becoming the only non-Spanish member of that body. There his principles, hardened by experience, certainly did not make Philip's attitude to the Netherlands less intransigent. Granvelle died in Madrid on Sept. 21, 1586.

GRANVILLE, GRANVILLE GEORGE LEVESON-GOWER, 2ND EARL (1815–1891), English statesman, was foreign secretary in William Gladstone's first and second administrations. and succeeded him as leader of the Liberal party for a time. He was the grandson of the 1st marquess of Stafford (1721–1803). His father. the 1st earl (1773–1846), who married a daughter of the 5th duke of Devonshire, was, as Lord Granville Leveson-Gower, a member of parliament from 1795 to 1815, and a successful diplomat; he was a special ambassador to the tsar during 1804–07, and in 1824 his friend George Canning made him ambassador to Paris where he remained till 1841.

The 1st earl's eldest son was born in London on May 11, 1815, and educated at Eton and at Christ Church, Oxford. After a short spell as attaché to his father in Paris, he was elected Whig member of parliament for Morpeth in 1836 and 1837, and for Lichfield in 1841. In 1840 he married the widowed Lady Acton, heiress of the great Rhineland house of Dalberg, who died in 1860. Granville held various minor offices under Lord John Russell (*q.v.*) from 1846, and promoted the great exhibition of 1851 with such success that he was admitted to the cabinet while paymaster general. In Dec. 1851 he succeeded Lord Palmerston as foreign secretary for the remaining three months of the government's life. He was president of the council (1852–54) and chancellor of the duchy of Lancaster (1854–55) in Lord Aberdeen's coalition; he returned to the former office under Palmerston in 1855, and also became leader of the Liberal peers in the house of lords, a post he retained, save for an interval during 1865–68, until his death. In 1856, borrowing his cousin's gold plate from Chatsworth, he went on a special embassy to attend the coronation of the tsar. He was chancellor of the University of London, 1856–91, during which time he supported the admission of women.

In 1859 he attempted. without success, to form a government. He resumed the presidency of the council under Palmerston and Russell from 1859 to 1866. This post brought him into further contact with Queen Victoria, whose favourite Liberal minister he was henceforward. His most important political services were rendered as intermediary between her and Gladstone (*q.v.*). He was Gladstone's closest political friend from 1868, and served in three of his cabinets; he was secretary of state for the colonies in 1868–70 and in 1886, and for foreign affairs in 1870–74 and 1880–85.

Granville was an ideal negotiator, but as an initiator of policies Gladstone overshadowed him. The Franco-Prussian War, which broke out a few days after Lord Clarendon's death brought Granville to the foreign office, took both him and Gladstone by surprise. and brought on the only serious difference between them. Granville got the cabinet to override Gladstone's wish to protest at the annexation of Alsace-Lorraine. Otherwise they worked in close. constant and harmonious co-operation; and Gladstone found that. as he once wrote to Granville, "it is impossible for any man to talk over a difficulty with you and not to find himself nearer to a solution at the end than he was at the beginning." In the winter of 1870–71 Granville handled the Russian denunciation of the treaty of Paris with dexterity, and secured the point of form that future treaty denunciations would require in law the consent of all signatories; but had to concede the point of substance, a Russian fleet in the Black sea. The only other significant negotiation of these years was the settlement of the "Alabama" arbitration (*q.v.*). Granville became the official leader of the whole Liberal party when Gladstone first retired, and protested more mildly at Conservative policy in the great eastern crisis of 1876–78. He was again asked to form a government in 1880, but at once gave way to Gladstone. During his last spell at the foreign office Bismarck, in effect, dictated much of British foreign policy (*see* EUROPE. History), and Granville's own powers were clearly failing. He was one of the few Whig peers who stood by Gladstone in the Irish home rule crisis of 1886.

He died in London on March 31,1891, and was succeeded by the 3rd earl (1872–1939), the son of his second marriage, in 1865, to Castalia Campbell of Islay, Argyllshire.

See his *Life* by Lord Edmond Fitzmaurice, 2 vol. (London, 1905); *The Gladstone-Granville Political Correspondence, 1868–1876,* ed. by Agatha Ramm, 2 vol. (London, 1952). (M. R. D. F.)

GRANVILLE, JOHN CARTEBET, EARL (1690–1763), English statesman, known as Lord Carteret, was born on April 22, 1690, the son of George, 1st Lord Carteret, and great grandson of the Elizabethan admiral, Sir Richard Grenville. He succeeded his father in 1695 as 2nd baron Carteret. He was educated at Westminster, and at Christ Church, Oxford, and acquired a wide knowledge of modern languages and literatures, being almost the only Englishman of his time who knew German. He took his seat in the house of lords on May 25, 1711. An adherent of the Hanoverian dynasty, the friend of Stanhope and Sunderland, he took a share in defeating the Jacobite conspiracy of Bolingbroke on the death of Queen Anne and supported the Septennial act. His interests were, however, rather in foreign than in domestic policy. Early in 1719 he was appointed ambassador to Sweden, a post which he held for two years with great success. He gained an exceptional knowledge of European and, in particular, of German affairs.

Named secretary of state for the southern department on his return to London, he came into conflict with Townshend and Sir Robert Walpole. Walpole, who resented his ability to speak German with the king, arranged for him to succeed the duke of Grafton as lord lieutenant of Ireland, when the violent agitation in Ireland against Wood's halfpence (*see* SWIFT, JONATHAN) made a new appointment necessary. He was in Dublin from Oct. 23, 1724 until 1730. He had to deal with the opposition to Wood's halfpence, and to counteract the effect of Swift's *Drapier's Letters*. It is doubtful whether he could have reconciled his private friendship with Swift with his duty to the crown if Wood's patent had not been withdrawn. When he returned to London in 1730 Walpole was firmly established as master of the house of commons, and as the trusted minister of George II and he took no share in public affairs until the fall of Walpole in 1742. Carteret is credited with having paid the expenses of the first edition of Don *Quixote* to please Queen Caroline, but he lost her favour through becoming entangled in the scandalous family quarrel betaeen Frederick, prince of Wales, and his parents. His sympathies were with Maria Theresa in the War of the

Austrian Succession, on the ground that the fall of the house of Austria would increase the power of France. George II welcomed these views and made him secretary of state in 1742, a post which he held until 1744, accompanying the king to Germany in 1743. He succeeded in promoting an agreement between Maria Theresa and Frederick. His support of the king's policy was denounced as subservient to Hanover, but a few years later William Pitt adopted an identical policy and confessed that whatever he knew he had learned from Carteret. In 1751 he became president of the council and was still liked and trusted by the king but had little active share in the government.

In 1756 Newcastle asked him to become prime minister as the alternative to Pitt, but Granville, understanding why the offer was made, declined and supported Pitt. When in Oct. 1761 Pitt threatened to resign unless his advice to declare war on Spain was accepted, Granville replied that "the opinion of the majority (of the cabinetj must decide." He resisted Pitt's claim to be considered as a "sole minister," or in the modern phrase, "prime minister." Granville remained in office as president until his death in London on Jan. 22, 1763.

The title descended to his son Robert, who died without issue in 1776, when the earldom became extinct.

A somewhat partisan life of Granville was published by A. Ballantyne, *Lord Carteret, a Political Biography* (1887). His correspondence is in the British Museum.

GRANVILLE, at one time a town in New South Wales, Australia: 13 mi. W. of Sydney by rail near the head of the so-called Parramatta river, a salt-water extension of Sydney harbour. It became a municipality in 1885, but from 1949 was incorporated as part of the city of Parramatta. It was an important railway junction and manufacturing town, producing agricultural implements, locomotives, motor bodies, asbestos sheeting, aluminum ware, cream of tartar, tires. kalsomine, pipes, tiles and bricks; there are tanneries, flour mills and oil refineries.

GRANVILLE, a fortified seaport and bathing resort of northwestern France, in the *département* of Manche, at the mouth of the Bosq, 85 mi. S.W. of Cherbourg by rail. Pop. (1954) 9,858. The upper town stands on a promontory and is surrounded by ramparts; the lower town, with the bathing beaches and promenade, and the harbour lie below it. The barracks and the church of Notre Dame are in the upper town. The port consists of a large tidal harbour and a floating basin and is the port of Normandy for British goods. Its principal exports are eggs, vegetables, fish, lard and butter, and it imports mainly coal, timber and raw materials. Granville is a great centre for yachtsmen and tourists and for visitors to the Channel Islands. Deep-sea fishing is carried on, and the industries include shipbuilding, the preserving of vegetables, metal founding, ropemaking, the manufacture of chemical manures, shoes and biscuits.

GRANVILLE-BARKER, HARLEY (1877–1946), British dramatist, producer and critic, who profoundly influenced the 20th-century theatre and the presentation of Shakespeare's plays, was born in London on Nov. 25, 1877. He began his stage training at 13, and at 1j Charles Hawtrey gave him a London part. He preferred work uith William Poel s Elizabethan Stage society and Ben Greet's Shakespeare repertory company to a West End career, however, and in 1900 joined the experimental Stage society. In 1904 he undertook management of the Court theatre with J E. Vedrenne and made theatrical history by introducing the public to Ibsen. Maeterlinck, Galsworthy, John Masefield, Gilbert Murray's translations from Greek, new plays by Shaw and many other works. His wife Lillah McCarthy played most of the leading roles. The Court became an authors' theatre, and among new plays produced there were several of his own: *The Voysey Inheritance* (1905), the most famous, showing Shaw's influence; *Prunella* (1906), a charming fantasy written with Laurence Housman; *Waste* (1907); and *The Madras House* (1910).

Also revolutionary was his treatment of Shakespeare. Instead of traditional scenic décor and declamatory elocution, Barker successfuliy introduced, in the Savoy productions of *Tlze Winter's Tale* and *Twelfth Night,* continuous action on an open stage and rapid. lightly stressed speech. He was active in promoting a national theatre and by 1914 had every prospect of a brilliant dramatic career.

After World War I, however, during which he served with the Red Cross, he found the mood of the postwar theatre alien and contented himself with work behind the scenes, as president of the British Drama league, for instance. He settled in Paris with his second wife, Helen, an American, collaborating with her in translating Spanish plays, and writing his five series of brilliant *Prefaces to Shakespeare* (1927–48), an important contribution to Shakespearian criticism, which threw fresh light on the plays by analyzing them from the standpoint of a practical playwright with firsthand stage experience.

In 1937 Barker became director of the British institute of the University of Paris. He fled to Spain in 1940 and then went to the United States, uhere he worked for British information services and lectured at Harvard university. He returned to Paris in 1946 and died there the same year, on Aug. 31.

See W. Bridge-Adams, *The Lost Leader* (1954); C. B. Purdom, *Harley Granville-Barker* (1955). (W. A. DN.)

GRAPE. The grape genus *Vitis* of the family Vitaceae comprises about 50 species native to the north temperate zone, especially North America. Fossilized grape leaves, stem pieces and seeds unearthed from Miocene and Tertiary deposits in the northern hemisphere—the European continent, Korth America, England, Iceland—indicate the long existence and wide distribution of the vine. Certain of the present species closely resemble the fossil forms.

This article is divided into (1) a general viticultural and botanical discussion and (2) a detailed discussion of cultivation.

VITICULTURE

History.--Old world viticulture dates far back. Seeds found in the remains of the Swiss lake dwellings of the Bronze Age and entombed with mummies in Egypt closely resemble seeds of the oldest and most extensively cultivated species of today. Viticulture's tradition is nearly as old as man; details for grape and wine production figured in the hieroglyphics of the 4th (2400 B.C.), 17th and 18th dynasties of Egypt. According to the Bible, Noah planted a vineyard. In Homer's time wine uas a regular commodity among the Greeks. Pliny described 91 varieties of grapes, distinguished 50 kinds of wines and described vine-training methods.

Viticulture probably had its beginnings in the area around the Caspian sea, generally recognized as the place of origin of *V. vinifera,* the best known grape. From there grape growing in the old world spread to other parts of Asia Minor, then to Greece and from there to Sicily. The Phoenicians carried the grape into France about 600 B.C.; the Romans planted grapes on the Rhine not later than the 2nd century A.D.; and there is evidence that they introduced them into England. Coinciding with the westward

GRAPE CLUSTERS. LEAVES AND VINE

spread of grape culture, grapes were moved into the orient by way of India. As new lands were colonized the grape mas taken along, so that today it is cultivated on all continents and islands where the climate is favourable.

Kinds **of** Grapes.—On the basis of use, grapes are grouped as wine grapes, raisin grapes, table grapes. sweet juice grapes and canning grapes. The mature fruit of all varieties—about 8,000—will ferment into a kind of wine when crushed, and most of them can be dried or eaten fresh. But only a limited number of varieties produce standard or higher quality wines; three varieties account for most of the raisins of commerce; only 1j to 20 varieties are grown extensively as table grapes; a single variety yields the bulk of sweet juice produced in America; and only a few varieties are used for canning.

A wine grape may be defined as a variety known to be capable in some locality of producing an acceptable wine. Table (dry) wines require grapes of high acidity and moderate sugar content, while dessert (sweet) wines are the product of grapes that are high in sugar and moderately low in acidity. In addition, high quality wines—those of outstanding bouquet, flavour and general balance—require grapes that possess individuality. Examples of such grapes are the White Riesling. Semillon, Cabernet Sauvignon, Tinta Madeira and similar varieties when they are grown under favourable climatic conditions.

Raisin grapes are those varieties that produce an acceptable dried product: soft in texture, of little tendency to stickiness, pleasing in flavour. large or very small and seedless. Only the Thompson Seedless, Muscat of Alexandria and Black Corinth varieties meet most of these requirements (see RAISIY).

Grapes used fresh, either as food or for decoration. are called table grapes. They must be pleasing to the eye and to the palate. Large size, brilliant colour and unusual form are appreciated. When grapes must be shipped long distances to markets or stored for a considerable period, important qualities are firmness of pulp, toughness of skin, adherence to the stem (pedicel) and resistance of the stems to desiccation or browning. These qualities are possessed to a degree by the Tokay, Emperor, Malaga, Red Malaga, Almeria and Ribier (Xlphonse Lavallee), all of which are grown in California, South Africa, Australia, Chile, Argentina and elsewhere. The raisin grape Thompson Seedless (Sultanina) is also, because of its seedlessness, a popular table grape.

Sweet juice grapes are those varieties that produce a juice acceptable as a beverage when preserved by pasteurization, germproof filtration or freezing. The juice must retain the natural, fresh-grape flavour. In America, grape juice has generally been preserved by pasteurization. When vinifera varieties, including the strong-flavoured Muscats, are pasteurized by the usual methods they lose their fresh flavour and acquire an unpleasant, cooked taste. The taste of strong-flavoured American varieties, particularly the Concord, is less affected by pasteurization, which largely accounts for the general use of Concords for juice in the United States. In central Europe a sweet juice of renown is made of certain vinifera varieties. Preservation is effected by germproof filtration or storing under carbon dioxide pressure. Freezing is a valued technique in grape juice preservation.

Grapes are largely canned in combination with other fruits as fruit salad and fruit cocktail. Only seedless types are used. Grapes are also prepared as jams, jellies and conserves.

Species.—For centuries, one species, V. vinifera, supplied all of the grapes grown by civilized man. It is the grape mentioned in the Bible, the grape of myths and poets, the grape that provides the wines and raisins of commerce and most of the world's table grapes. It is the old world grape, the European grape and, more recently in America, the California grape.

There was no real need for other species until eastern North America was colonized. But there *V.* vinifera was destroyed by phylloxera (the plant louse Dactylosphaera vitifoliae) and several other diseases. Fortunately, North America had many native species of Vitis that had lived with these enemies and developed resistance. The colonists were then able to turn to the native V. *labrusca* and hybrids of it with vinifera and other American species, to create a new and different grape industry in that part of America. Varieties with a preponderance of V. labrusca blood, the so-called slip skins, have a pronounced aromatic, or foxy, flavour.

In the southeastern part of the United States, varieties of V. rotundifolia are cultivated. These are muscadines not true grapes. The berries are borne in very small clusters, mature irregularly and drop when ripe. In all but the most recently created self-fruitingvarieties, the flowers are pistillate, making it necessary to interplant a limited number of male vines. These varieties are nevertheless important, since they and their fruit are very hardy under hot and humid conditions.

Europeans introduced American grapes when these became available. The early importations, in mid-18th century, were grown without mishap. However, in 1845 powdery mildew (*Uncinula necator*) was discovered on grapes in a hothouse in England. Two years later it was observed in France, where in the space of ten years, until a control measure could be found, it reduced production 70%. Downy mildew (*Plasmopara* viticola) and black rot (Guignardia bidwellii), two other diseases of American origin, were identified in the south of France in 1878 and 1885, respectively. While powdery mildew was ravaging the French vineyards additional American grapes resistant to it were imported, 1858–1862, and with them phylloxera. Phylloxera took little more than two decades to destroy most of the vineyards of France, and in the early 1870s resistant rootstocks were sought out in America by French viticulturists. The magnitude of this effort is indicated by the fact that by 1890 2,400,000 acres of vineyard were again flourishing, this time on rootstocks of American species or hybrids. Among widely used rootstocks are selections of V. *rupestris, V. riparia* and *V. Champinii;* hybrids of these, and V. cinerea, V. *Berlandieri*, V. candicans, V. *solonis* and V. monticola; or hybrids of vinifera varieties with certain American species.

The fight against phylloxera also involved attempts to develop resistant vines, by hybridizing V. *vinifera* varieties with American species. Resistance to both phylloxera and various diseases was sought. Because of their resistance to fungus diseases, some of these hybrids are grown extensively in certain parts of Europe. They are grafted on phylloxera-resistant stocks.

Influence **of** Climate.—Vinifera grapes require long, dry, warm-to-hot summers and cool winters for their best development. Humid summers favour the development of diseases that attack the fruit. while severe winter conditions (0° F. or below) will destroy unprotected vines. Spring frosts occurring after the vines start growth will kill the shoots and clusters. Winter rains are needed for soil moisture; summer rains make disease control more difficult; rains during the ripening and harvest periods may cause rotting of the fruit if they are of considerable duration. Where raisins are produced by natural sun-drying, as in California, a month of clear, warm, rainless weather is essential after the grapes are mature.

Varieties possessing the characteristics of V. labrusca will withstand humid summers and cold winters better than will the vinifera. They may in fact do better where summer rains of short duration are the rule. Varieties of V. rotundifolia thrive in the very warm, humid regions of the southeastern states of the U.S.

Just as climate broadly limits grape growing to the temperate zone, it further limits the highest development of individual varieties to specific localities within this zone. For example, the table grape Tokay fulfills itself only in a ten-square-mile area of central California—the warm, dry vineyards at Lodi. In certain areas of Europe individual climate is so subtly suited to the needs of the White Riesling, Pinot Noir, Cabernet Sauvignon, and Chardonnay varieties that only highly localized areas produce some of the greatest table wines of the world.

Temperature is by far the most important climate factor, affecting maturity date and palatability. Time of maturity is established by the total summation of heat, between full bloom and a given degree of maturity. Palatability, however, is influenced more by the summation of heat during the ripening period. Cool weather will mean higher acid content and a sour taste; hot weather will mean lower acid content and a sweet taste.

Vineyard Soils.—Grapes are adapted to a wide range of soils.

METHODS OF PRUNING AND HARVESTING GRAPES

1. A mature head-trained, spur-pruned vine
2. 4 mature head-trained, cane-pruned vine
3. Harvesting Thompson Seedless grapes for raisins. The fruit is placed on paper trays between the vine rows for drying

Although growers often express a preference for certain soil types, surveys of soils used successfully in grape production in many different localities show a great variety of types. ranging from blow sands to clay loams, from shallow to very deep soils. from highly calcareous to noncalcareous soils and from very low to high fertility.

Extremes are not generally desirable, however, and poor drainage or excess salts are to be avoided. The highest tbnnages are produced on the deeper and more fertile soils. They are especially preferred for raisins and common wine grapes.

Extent and Distribution of the Industry. — Acreage devoted to cultivation of grapes averaged more than 3.350.000 in the second half of the 20th century in France. Italy. Spain: more than 1.000.000 in Hungary, Turkey and the U.S.S.R.; and more than 500,000 in Algeria, Argentina, Greece, Portugal, Rumania, Yugoslavia and the United States.

Other principal grape-producing countries. with more than 100,-000 ac. of vines. included Australia, Bulgaria, Chile, Germany, Syria and the Union of South Africa.

The larger areas of grape production in eastern North America border on the Great Lakes around Ontario. Can., and in the U.S. in New York, Pennsylvania. Ohio and Michigan. Districts of less importance are in Missouri, Arkansas. Iowa and Washington with scattered plantings in almost every other state. The Concord is the variety most extensively grown.

California, the principal grape-growing state of the U.S., produced about 3% of the wines of the world, and led all countries in the production of table grapes (20%) and raisins (40%).

CULTIVATION

Establishing the Vineyard. — Commercial grape varieties are propagated with cuttings, segments of canes or grafts. These are usually grown for one year in a nursery to develop roots. The use of clean soil permits the use of cuttings of fruiting varieties, but the presence of either phylloxera or nematodes (round worms) requires the use of grafts or rootstocks. The grafts consist of a segment of a stem of a fruiting variety placed on a rootstock cutting. Both grafts and rooted rootstock cuttings are employed. The latter are field budded to the desired fruiting variety in late summer after being planted in the vineyard. The union of grafted or budded vines must be above the soil, to prevent the production of scion roots.

Planting distances may vary widely. In European and most other countries the planting distances range from 3 ft. to 4 ft. in either direction; in California. where cultivation is largely mechanized, the widest vine spacing, 6 ft. by 12 ft. and 8 ft. by 12 ft., is generally employed. Similar distances are used in Australia.

Training is necessary to develop a vine of desirable form. It is accomplished by pruning the young vine and then tying it and its growth to a support. Two vine forms are generally used; headed vines and cordon vines. In the headed vine there is a straight, vertical trunk or stem of desired height, with arms radiating out from its top to form the head. The most widely used cordon is the bilateral, in which the trunk rises vertically to the desired height, where it is divided into two branches extending horizontally in opposite directions along the row. Arms rise from the horizontal parts of the divided trunk. Headed vines are common for wine and raisin grapes and some table varieties. The bilateral cordon is useful for large-clustered grapes. These are the common commercial systems. but minor variations occur in some producing areas. and in addition the vine can be readily trained to walls. pergolas and arbours.

Stakes are standard supports for all head-trained and spur-pruned vines, while trellises are usual for vines that are cordon-trained and spur-pruned or head-trained and cane-pruned. Stake lengths vary with country and variety of grape — from 4 to 8 ft. The stakes used in California are usually 2 in. by 2 in. split redwood. The trellis most generally used has two wires, placed 34 and 48 in. from the ground. while a flat or sloping top trellis with two or three additional wires is widely used for table grapes.

Pruning. — Pruning is the most important single vineyard operation. With wine and raisin varieties, it is usually the sole means of regulating crop, largely determining not only the quality of the fruit but also the quality of the wood for the next year. At the annual pruning, from 90% to 95% or more of the year's growth is removed, leaving the spurs or fruit canes. or both. Spurs may be used on varieties whose basal buds (near the point of origin of the canes) are fruitful; and fruit canes are necessary when the buds near the basal end of the cane are unfruitful or when the variety produces such small clusters that many are required for a full crop.

Shoots and Flowers. — Grapevines have climbing stems. which late in the spring start a rapid growth that reaches a peak in early summer, then slowing. with little further shoot elongation after the fruit begins to ripen. The leaves continue to function until the end of the season.

The leaves. tendrils, flowers and lateral shoots arise from the nodes The flowers are borne in a cluster. The primordium of the flower cluster is formed during the year preceding its bloom, differentiation into a fruitful bud beginning with the accumulation of carbohydrates in the shoots soon after their growth slows down, in early summer. By leaf fall, the cluster primordia have developed into initial points for individual flowers. Thus, the number of flowers and the shape of the clusters are determined in the year prior to that in which the fruit is produced. The formation of the flower parts (calyx. corolla, stamen and pistil) follows leafing out in spring, requiring six to eight weeks, depending on weather and variety, before the complete flower has developed to the point of blooming.

Set of the Berries. — In normal setting (development) of the fruit, pollination is folloned by fertilization, and this in turn by seed development. But normal fruit setting may fail in a number of varieties, either partially or nearly completely. As a result these varieties typically show a wide variation in berry size and shape. Four definite types of fruiting or fruit setting occur among varieties. Although all these types are found in many varieties, the proportion of types within an individual variety is relatively constant. The most common type of setting is that in which normal seed development occurs. Each carpel (see FLOWER) has one, two or more seeds. and the berries are relatively uniform in size and shape. According to variety. they are round, oval or fusiform (tapering at ends). Some varieties of this type are not perfect in set and produce at most only one or two seeds to a berry. With much elongated berries. the presence of a single or two adjacent seeds may cause the berries to be falciform (gherkinlike) in shape.

In a second type most of the seeds produced are empty. Empty seeds result from embryo abortion after the seed is well advanced in its development. Some varieties produce less than 3% of viable seeds. The berries of such varieties are nonuniform in both size and shape.

Two other types of setting produce seedless fruit. In one, fertilization takes place, but early abortion prevents seed development (stenospermocarpy). producing a fruit setting common to a number of important varieties, such as Thompson Seedless. In the other seedless type, fruit setting is by stimulative parthenocarpy (see PLANTS AND PLANT SCIENCE: Plant Physiology: *Growth*). Here the berries are very small and round. with no trace of seeds. Seedlessness and small size. however, have made the Black Corinth (representative of this type) of commercial importance. It supplies the dried currants of commerce.

Thinning Table Grapes. — Three methods of thinning have been developed as an aid in correcting fruit setting in certain table grapes, for not all varieties set equally well. Some set clusters that are too compact; the clusters of others are well filled; those of others are loose to the point of being straggly; and still others set shot berries (of parthenocarpic origin) along nith the normal berries. Berry thinning will improve quality when an overabundance of berries makes the clusters too compact, or overlarge clusters interfere with proper colouring and maturing. In California. berry thinning consists in cutting the rachis to leave only the desired number of berries; in other areas individual berries are removed. Thinning soon after fruit set gives a marked increase in the size of seeded berries. Thinning flower clusters soon after they emerge is another method. It improves the carbohydrate nutrition of the flowers retained, giving a better set of normal berries. Flower-cluster thinning is useful on varieties that have loose or straggly clusters or tend to set shot berries with standard pruning methods.

A third method, cluster thinning, involves removal of entire clusters soon after the berries have set. By leaving enough fruiting wood at pruning to produce a full crop in poor years and then reducing the overload by cluster thinning in good years, larger crops of high-quality fruit can be produced every year. Cluster thinning improves the nutrition of the fruit that is retained, enhancing seeded berry size and colour.

Girdling. — This operation (also called ringing) involves the removal of a complete ring of bark, $\frac{3}{16}$ to $\frac{1}{4}$ in. wide, from the trunk or from a cane below the fruit that is to be influenced. The girdle prevents downxvard movement of carbohydrates (through the phloem) improving the nutrition of the fruit. For best results the girdle must be open to be effective. During bloom it increases the set of seedless berries; during the period of rapid growth of seedless berries it increases berry size; during the early ripening period of seeded varieties it may accelerate colouring and ripening. These effectsof girdling in seedless grape varieties can be produced by spraying with the proper concentration of plant growth regulators, such as 4-chlorophenoxyacetic acid and gibberellin.

Cultivation and Irrigation. — In areas of rainless summers and where periods of drought are a common occurrence, meeds are destroyed to prevent their robbing the vines of soil moisture. A winter cover crop or growth of native plants is usually encouraged. On rolling soils and hillsides it is of great value in checking erosion. The minter cover is destroyed at the end of the rainy season or at the spring cleanup. Cultivation is repeated only often enough to destroy or prevent weed growth. This conserves soil moisture only by eliminating weeds and not by virtue of loosening or pulverizing the soil.

In irrigated vineyards the matter of weed competition is of less importance. Such vineyards are usually cleaned up in spring and kept free of weeds during the period of rapid vine growth. When ample soil moisture is available weed growth after mid-summer is controlled only to prevent undue interference with the various vineyard operations.

Vinifera grapes do best in dry, warm-to-hot summers. Irrigation is required where the rainfall is insufficient or the soil too shallow to store sufficient water to meet the moisture requirements of the vine. The soil must be wetted as deep as the roots penetrate during the late fall, winter or early spring. After growth starts, irrigation is not needed until the vines have almost exhausted the available water in the soil area containing most of the roots. Irrigation should be repeated as often as this point is reached. The amount and frequency of the applications of water are determined by the texture and depth of the soil, climatic conditions and type of grapes grown.

Insects and Diseases. — The grapevine and its fruit are seriously attacked by a number of insects and diseases. In California and other arid regions there are fener pests. The principal insects attacking the vine are the phylloxera *(Dactylosphaera vitifoliae)* and the root knot nematode *(Meloidogyne javanica)*. They are combatted by using resistant rootstocks. The grape leafhopper *(Erythroneura elegantula)* is controlled with DDT or Malathion; the grape root worm (*Adoxus obscurus*) and the grape leafroller *(Desmia funeralis)* are controlled with arsenicals or cryolite; and the red spiders (*Tetranychus pacificus* and *Tetranychus Wilmetti*) can be controlled by some of the new organic phosphate miticides, either as dusts or sprays. In more humid regions there are in addition the berry moths (*Polychrosis botrana* and *Clysia ambiguella*) and various beetles and caterpillars. They may be controlled with DDT or arsenicals.

Diseases affecting the grape under arid conditions are powdery mildew (*Uncinula necator)*, prevented by dusting elemental sulfur on all green parts of the vine; and black measles, whose cause is unknonn but which can be controlled by sodium arsenite spray while the vines are completely dormant. Under humid conditions the grape is also attacked by black rot (*Guignardia bidwellii*), anthracnose *(Gloeosporium ampelophagum*) and downy mildew (*Plasmopara viticola*), which are controlled with Bordeaux sprays; *Cryptosporella viticola Reddick*, which is controlled with sodium arsenite; and numerous minor diseases.

A number of viruses infect the vine. Fanleaf (infectious degeneration), Yellow Mosaic, Pierce's disease and White Emperor do extensive damage in many grape areas. There is no cure. Much can be done to prevent spread by the careful selection of buds and cuttings. Selection of vines for cuttings is most effective when the vines are observed in late spring and again when the crop is almost mature. An important project in the University of California's college of agriculture, at Davis, is the production of virus free planting stock of all grapes. At present such planting stock is available in limited quantity of some 22 fruiting sorts and five rootstocks.

Harvesting. — A grape is ripe when it has reached the stage best suited for the use to which it is to be put. The containers in which table grapes are moved to market and the methods of packing the fruit in the containers vary greatly from country to country. The least amount of handling that is consistent with thorough trimming and efficient packing is imperative. The sooner the grapes are cooled after picking, the better will be their quality when they reach the market. When grapes are to be shipped long distances or held in storage (at 31° F.) for prolonged periods, it is advisable to treat them with sulfur dioxide. In shipment, the sulfur dioxide is applied by displacing the air of the standard refrigerator car with sulfur dioxide diluted with air to a concentration of approximately 1.5% by volume. Grapes in cold storage are treated at given intervals by releasing .2% sulfur dioxide into the air as it enters the storage room.

To make raisins by the natural sun-drying process, as in California, grapes are picked from the vines and spread evenly on wooden or paper trays without pretreatment of any kind. When the berries on the upper side of the clusters have shriveled and turned brown, the bunches are turned over onto another tray. The slow oxidation that takes place within the berries during sun-drying is instrumental in the development of the typical raisin flavour. Wooden trays are stacked, and paper trays rolled, when the raisins are three-fourths dry. Grapes to be dehydrated are usually dipped in a caustic solution, to facilitate water loss, and treated with sulfur dioxide to produce a translucent, golden-coloured product. Dehydrated grapes do not possess a raisin flavour. See also WINE; FRUIT; FRUIT FARMING; HORTICULTURE.

GRAPEFRUIT (*Citrus paradisi*), also known as pomelo, a tree and its citrus fruit, belonging to the family Rutaceae. It is probably an offshoot of the pummelo or shaddock (*q.v.*). Certainly the grapefruit and pummelo are closely related, and some students consider it probable that the grapefruit originated from the pummelo as a mutation. In 1814, John Lunan in his *Hortus Jamaicensis* mentioned that there was a small variety of the shaddock resembling the grape in flavour. The place of origin of the grapefruit is not certain. but it probably originated in Jamaica, for, in spite of careful search, it has not been found native in southeastern Asia or in the East Indian archipelago, where the parent species, C. *grandis*, is widely grown, or in any other region where any other *Citrus* species is native.

The grapefruit tree grows to be as large and vigorous as an orange tree; a mature tree may be from 1j to 20 ft. high. The foliage is very dense, leaves dark shiny green, larger than those of sweet orange but smaller than those of the pummelo, nearly glabrous, with petioles broadly winged. Flowers are large, white, borne singly, or in clusters in the axils of the leaves; petals are similar to those of sweet orange but usually larger. The fruit, which is lemon yellow when ripe, ranges from 4 to 6 in. in diameter and averages twice as large as a medium-sized orange, the size depending upon the variety and upon cultural conditions; the pulp is usually of a light yellowish colour, somewhat intermediate between that of the orange and that of the lemon, tender and usually very full of juice, with a distinctive, mildly acid, very pleasing flavour. Several varieties, originated by bud mutations, have pink or red pulp of varying intensity of colour; some of these varieties have a slightly pinkish cheek overlying the normal yellow colour of the peel.

At least 23 varieties of grapefruit with normal-coloured pulp and 4 varieties with pink or reddish pulp, have been propagated in the United States. Most of the fruit produced in the U.S. is of either the Marsh or Duncan, yellowish-pulp varieties. The Ruby and Webb are the principal varieties having red pulp; the actual quality of these varieties is comparable to that of the normal-coloured varieties, and they have become increasingly popular in the fresh fruit market because of their attractive appearance, for use at banquets and other social functions.

The grapefruit hybridizes readily with other species of Citrus. The tangelo, an intrageneric hybrid, is the result of a cross between the mandarin orange (some varieties of which are known as tangerines) and the grapefruit (also known as pomelo). One of the most promising of these hybrids, the Sampson tangelo, was produced in 1897, in Florida, by W. T. Swingle, an investigator employed at the time by the United States department of agriculture. This fruit has considerable merit as a juice fruit and as a source of seed for rootstock purposes.

As a fruit for home consumption, grapefruit became well established in the islands of the West Indies before its culture spread to the mainland. By the late 1950s, 90% of world production was in the United States, concentrated in Florida, Texas, Arizona and California. Grapefruit has become popular as a breakfast fruit in various parts of the world and production has expanded to other citrus-growing countries, notably Israel and Jordan, South Africa and Brazil.

Grapefruit trees thrive and produce the best quality fruit on sandy but relatively fertile soils. Supplementary fertilization is necessary in practically all the producing areas in the U.S.

In addition to the usual nitrogen, phosphorus and potassium, the fertilizers or sprays should contain supplementary nutrients or microelements in the form of copper, manganese, zinc, iron and boron. In Florida the area of greatest grapefruit production is on the light sandy soils which require additional micronutrients applied as a fertilizer to the soil or as a spray to the foliage. The trees come into bearing early and may be expected to produce commercially profitable crops by the fourth to sixth year after being planted in the orchard. Mature trees may produce remarkably large crops — 1,300 to 1,500 lb. of fruit per tree. Culture and pest-control problems of grapefruit are comparable to those of other citrus crops (see LEMON and ORANGE).

The rapid expansion of grapefruit acreage in the U.S. caused serious problems in the sale and distribution of the fruit. Fresh fruit from Florida and Texas is not available throughout the entire year. The season of shipment is primarily from late fall to early spring, with the peak of the marketing season in midwinter. To avoid an overproduction at one period, and a shortage of grapefruit at another, the preservation of the fruit by canning developed into an important industry. The two products which have taken most of the fruit off the fresh-fruit market are the juice and the prepared segments. The latter product is very frequently used as a basis for salad making. The segments may be packed in a 40° Brix sugar syrup.. The increase in these two methods of processing grapefruit has been very rapid. After 1941 at least 50 per cent of the crop produced in the United States was marketed in the processed form. This makes grapefruit available to the general public the year round and is an important service to both the consumer and the producer of this popular fruit. The processing of grapefruit juice is comparable to that of orange juice. It is sometimes advisable to add cane or beet sugar to grapefruit juice as it is canned. The yield of grapefruit juice under factory conditions will approximate 70 to 90 gal. per 2,000 lb. of fruit.

The total soluble solids of the juice (principally sugars) increases during fruit growth and development and at maturity usually varies from 8 to 12 per cent (fresh-weight basis). The concentration of the total acidity of the juice gradually decreases during fruit growth and, at maturity, the fruit may contain from 1 to 1.4 per cent total acids (fresh-weight basis). The grapefruit is richer as a source of vitamin C than most of the fruits and vegetables normally consumed by man; it is exceeded only by the orange and the lemon. The vitamin C content of grapefruit juice depends upon the variety, soil fertility and the season of the year when the fruit is picked; it may average from 39 to 47 mg. per 100 gr. Early in the season of maturity, the vitamin C content is higher than it is later.

Webber, "Cultivated Varieties of Citrus," *The Citrus Industry*, vol. I, chap. v (1943). (L. D. B.; W. B. SR.)

GRAPE HYACINTH, the name given to any species of Muscari, a genus of the lily family (Liliaceae, *q.v.*), comprising about 50 species, natives chiefly of the Mediterranean region and southwest Asia. They are small bulbous plants with narrow fleshy basal leaves and small usually blue urn-shaped or globose flowers, nodding or pendulous, in a more or less dense cluster terminating a single flowering stalk.

The common grape hyacinth (M. botryoides), called also grape-flower, babies'-breath and bluebell, widely cultivated in gardens, is native to southern Europe and western Asia and has run wild in meadows and thickets in the eastern United States. It has narrow erect leaves about as long as the flower stalk, which usually grows from 4 in. to 12 in. high, bearing at the top about 12 globose blue, or in some varieties white, or pink, faintly scented flowers, about $\frac{1}{8}$ in. long, crowded in a cluster. The starch grape hyacinth (*M.* racemosum), native to Europe and found in sandy fields in England and Scotland, has become naturalized in the eastern United States. It grows about a foot high. and bears very narrow, almost cylindrical, recurved leaves and numerous starchy-scented, urn-shaped blue flowers in a dense raceme. About a dozen other species are cultivated, notably the musk hyacinth (M. *moschatum*), the tassel hyacinth (M. comosum) and the beautiful feather hyacinth (M. *comosum monstrosum*). The latter two produce mostly sterile flowers. All make sheets of colour when naturalized en masse in the lawn.

GRAPHIC METHODS IN MATHEMATICS. It is often found helpful to devise some scheme to show to the eye the relations between the different quantities involved in certain mathematical and statistical problems. In the simplest cases, the purpose of such "graphic methods" is merely to present the results of mathematical or statistical analysis. For instance, in the Statistical Atlas of the United States, the census statisticians use various graphic devices to make readily available to others important results such as the average number of persons per square mile in various states or counties.

The selection from a mass of statistical work of the results that are to be shown graphically, and the determination of the best statistical device for each case, are tasks which require both close familiarity with the details of the aork and a broad view of the problems in which the results may be significant and of the mental attitude of those who will use the results.

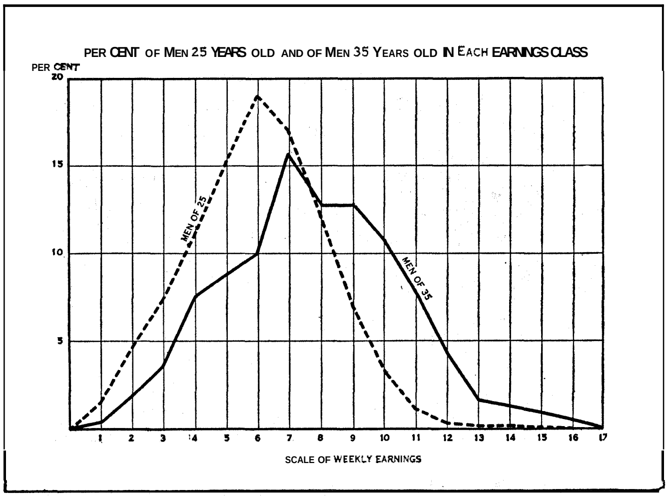
Graphic presentation, if it is attempted at all, should be regarded as the culmination of a statistical study and not as an incidental diversion.

Graphic Methods As an Aid to Thinking. — In some cases graphic methods are much more than a vehicle for conveying information. Without their aid it is difficult to formulate the ideas which underlie many investigations of complicated quantitative relations, or to carry through the various steps of the investigation. The ordinary graph, obtained by plotting on co-ordinate paper various values of one quantity against corresponding values of another quantity, has become so familiar that we sometimes use it without realizing it.

For instance, consider the following (hypothetical) description of the relation between average wages and term of service in a certain company:

"On the average, wages rise, though at a decreasing rate, until about the 10th or 12th year of service, and then flatten out. except for workmen appointed to supervisory positions. Salaries, on the other hand, continue to rise at a pretty uniform rate until the 20th or 25th year of service, after which the averages are based on too few cases to establish a trend."

While no graph is mentioned specifically, this statement would hardly be made except with the graph of earnings as a function of years of service definitely pictured in the mind of the writer, and would not be understood except with the same graph pictured in the mind of the reader.



AN EXAMPLE OF GRAPHICAL METHODS SHOWING HOW STATISTICAL DATA ARE SO REPRESENCED THAT THE COMPARISON BETWEEN TWO RELATED VALUES CAN BE SEEN AT A GLANCE

As a second illustration of the use of graphic devices as an aid to thought, consider the graphs cf frequency distributions, as constructed by statisticians. The accompanying diagram, for instance. compares the percentage distribution according to weekly earnings of male nage earners 25 years old and of those 35 years old, in a certain factory.

After inspection of these two frequency polygons, statements like the following may be made:

(1) The earnings of different individuals of the same age differ considerably; therefore an average for any group is of little value as an indication of the number below any particular standard of pecuniary well-being.

(2) Relatively high earnings are more common among men of 35 than among men of 25; therefore a single distribution by earnings of men of all ages is-inadequate to measure the extent to which earnings are large enough for all needs, which obviously vary with age.

(3) The earnings of men of 35 more frequently vary considerably from the most typical amount than do those of men of 25. There is no point on the scale at which as large a percentage of 35 year old men are concentrated as of 25 year old men at "6" or "7" on the scale.

PERCENTAGE DISTRIBUTION

Earnings scale	Men of 25	Men of 35	Earnings scale	Men of 25	Men of 35
1	1.5	0.4	9	6.9	12.7
2	4.6	1.8	10	3.2	10.7
3	7.4	3.6	11	1.1	7.7
4	11.1	7.5	12	0.3	4.3
5	15.3	8.8	13	0.2	1.6
6	19.0	10.0	14	0.2	1.2
7	17.0	15.6	15	0.1	0.9
8	12.1	12.7	16		0.5

As these statements show, a diagram of this type provides a basis for beginning to think about the problems of variation which are the subject matter of statistical science. In such cases the graph is an instrument whereby a real idea can be definitely formulated, made clear to others, and used for guidance in the solution of problems.

Securing Approximate Numerical Results Rapidly. — On the basis of a limited number of paired values of the quantities x and y, obtained either by substitution in a formula or by observation of phenomena, a graph may be constructed by drawing a smooth curve through the points representing these paired values. From the graph me may then read other pairs of values, thus avoiding additional observations or substitutions in the formula. In many cases this process of graphic interpolation is much shorter than the processes which it replaces, although it is usually not as accurate.

A variation of this scheme is to construct a scale on the basis of the given pairs of values. Distances on this scale from an indicated starting point are measured off proportional to the various values of y, and each such point on the scale is labeled with the value of x corresponding to the value of y. This scale can then be used in further calculations, by estimating the values of x corresponding to points between those labeled. If, for instance, y is the logarithm of x, the well-known properties of logarithms make it possible to perform multiplication or division by mechanical addition or subtraction on the logarithmic scale or on two such scales that are combined in a slide rule. (See COMPUTING MACHINES, ELECTRONIC.)

To show graphically a relationship among three quantities, as, for instance, that connecting the pressure, volume and temperature of a gas, me assign a series of values to one of the three quantities and plot on the same sheet the graphs of the resulting formulas connecting the other two quantities, each such graph being labeled to indicate the value of the first quantity to which it corresponds. This method may be varied by using logarithmic or other scales in constructing the field on which the graphs are plotted. The purpose in such cases is to facilitate plotting by reducing the graphs to straight lines or at least to simple curves.

When a three-variable relationship has thus been plotted in a series of "contour lines," it is a simple and rapid process to read off approximately the value of one quantity corresponding to any specified values of the other two. The process is often more simple and rapid if a nomographic or alinement chart is constructed (see NOMOGRAPHY) and that method can also take care of relationships involving four or more variables.

While in general the aim of graphic methods of this type is merely to do simply and rapidly what could otherwise be done at the cost of more time and labour by arithmetic, algebra or measurement, in some cases the alternatives are so laborious as to be prohibitive. For instance, graphic analysis makes clear the nature of the solution of certain differential equations which cannot be solved in terms of elementary functions. In certain cases, moreover, mechanical methods whose basis is mainly graphic provide many of the numerical results which are the real reason for desiring to solve the differential equation.

Limitations of Graphic Methods. — The unquestionable value of graphic methods if properly handled has been sometimes obscured by cases in which they have not accomplished the purpose intended as well as other methods, or more skilful use of graphic methods, would have done. If a proposed method of presenting the results of a statistical investigation does not make the results clearer to the audience than if the results had been presented merely in words or in a table, the method should be discarded or improved. If a proposed scheme for graphic computation is less accurate than is necessary or less rapid in actual use than other methods, the true friend of graphic methods will be the first to turn to some other mode of computation.

A serious difficulty with graphic computations is the existence in most charts of regions in which the results have a larger margin of error than is acceptable. If, for instance, a point is to be located by tbe intersection of two arcs, the location is accurate if the arcs are nearly perpendicular. but if they run in about the same direction, a slight error in one of the radii or one of the centres will shift the point of intersection to a much greater extent. This difficulty can sometimes be avoided by using a second chart modified by change of scale or otherwise in order to shift the region of inaccuracy.

The careful maker and user of charts always bears in mind this possibility of serious error, and determines the probable size of such errors, either by experiment or by analysis of his methods and formulas.

See PROBABILITY AND STATISTICAL THEORY; STATISTICS.

(R. W. B.)

GRAPHITE, a mineral consisting of the element carbon, crystallizing in the hexagonal system. in contrast to the same element crystallizing in the cubic system as diamond. Usually such dimorphous pairs are rather similar in their physical properties, but not so in this case. Graphite is black, opaque and very soft (hardness = 1); diamond may be colourless and transparent, and is the hardest naturally occurring subs'tance known. Graphite is a good conductor of electricity; diamond is a poor conductor. The specific gravity of graphite is 2.2, and for diamond, 3 5. Diamond has a perfect octahedral cleavage. while graphite has basal cleavage. Graphite crystals are rare, and only occasionally are six-sided plates found. The plates or cleavage flakes are flexible but not elastic. Graphite has a greasy feel and rubs off on anything it touches, leaving a black mark, thus the name from the Greek verb *graphein,* "to write." The lustre is bright metallic and the colour dark gray to iron black; the streak on glazed porcelain is dark gray. Graphite, also known as plumbago or black lead. bears a striking resemblance in many physical properties to molybdenite (*q.v.*), consisting of molybdenum disulfide, which also has a greasy feel and is soft enough to write on paper.

Although differing so markedly from diamond in physical properties, graphite has a closely related structure. In both minerals each carbon atom is bonded to four adjacent carbon atoms. In diamond these four strong bonds are arranged tetrahedrally, giving great strength in three dimensions. In graphite, three equal bonds lie nearly in the horizontal plane. while the fourth is weaker and is in a vertical position. Thus while there is good bonding in two dimensions, it is lacking in the third, and allows easy separation into thin sheets.

Graphite occurs mainly in the older crystalline rocks, gneiss, schist, quartzite and marble; sometimes in granite and pegmatites; and is found as isolated scales embedded in these rocks, or as large masses or vein fillings. It has also been observed as a product of contact metamorphism in carbonaceous clay slates near their contact nith granite, and where igneous rocks have been intruded into beds of coal; in these cases the mineral has clearly been derived from organic matter. The graphite found in granite and in veins in gneiss. as well as that contained in meteoric irons, cannot have had such an origin. As an artificial product, graphite is nell known as scales in gray pig iron, and in the graphitic ponder. or "kish," that forms in iron furnaces; it is also produced artificially on a large scale in electric furnaces (see *L'ses* below). The graphite veins in the older crystalline rocks are probably akin to metalliferous veins and the material derived from deep-seated sources The decomposition of metallic carbides and the reduction of hydrocarbon vapours have been suggested as possible modes of origin. Graphite veins often reach a thickness of several feet, and sometimes possess a columnar structure perpendicular to the enclosing walls. These are found in the crystalline limestones and other Laurentian rocks of New York and Canada, in the gneisses of the Austrian Alps and of Ceylon. Other localities which have yielded large amounts are the Alibert mine in Irkutsk, Sib.. the Borrowdale mine in Cumberland and the Santa Maria mines of Sonora, Mex. (L. S. RL.)

Natural Graphite Production. — Most natural graphite, both flake and amorphous, is recovered from shallow open-pit mines by stripping the overburden, and removing the graphite-bearing rock with power shovels and trucks. In Ceylon, Mexico and North Korea, however, where the graphite veins are folded or dip steeply, underground mining is required. Because of the nature of its occurrence, graphite must be subject to a refining process. The character of the graphite in a particular deposit and its intended use determine the extent of refining. Flake graphite is processed by net and dry grinding to remove the larger impurities, and flotation removes the remaining impurities. The flotation product is filtered, dried and passed over an air table to obtain a uniform product. Amorphous graphite is processed by grinding and air separation except in Ceylon, where there is a preliminary hand sorting at the mine and later grading by combined manual and machine methods. Refined natural graphite contains at best 90% to 98% carbon. with the major part containing 90% to 94%.

Manufactured Graphite Production. — The original discovery that graphite could be manufactured was made by Edward G. Acheson (*q.v.*) while experimenting with the effect of high temperatures on carborundum or silicon carbide (*q.v.*). It was found that carborundum decomposed at about 7,500° F., the silicon being vaporized and the carbon being left behind in the graphitic form. In 1896, Acheson was granted a patent for the manufacture of graphite and commercial production began in 1897. Petroleum coke, anthracite culm (hard coal dust), or mixtures of carbon, quartz, sand and sawdust were used as late as 1918 to produce manufactured graphite. Since 1918, however. petroleum coke. which consists of small imperfect crystals of graphite surrounded by organic compounds, has been almost the only raw material utilized. After heating until all the volatile material has been driven off the remaining product. graphite. with a carbon content of 99% to 99.5% or better, is cooled, pulverized and graded to uniform sizes.

Uses. — The value of graphite to industry is based upon suitable application of one or more of its inherent qualities, such as unctuousness, or plastic qualities; refractoriness, or ability to withstand high temperatures; conductivity of heat and electricity; inertness to a large range of reagents; and miscibility with other materials and liquids. The most important uses of natural graphite are in lubricants. crucibles, foundry facings, shoe and stove polishes, brake linings, pencils, packings, steelmaking, batteries and carbon brushes.

Manufactured graphite competes with natural graphite in some uses; among which are lubricants, foundry facings, pencils, polishes, batteries and carbon brushes.

Only manufactured graphite of a purity of better than 99.5% is suitable for use as a reactor moderator. for which it is used more extensively than any other material, and as structural material in atomic energy plants. Other major uses are in electrodes. electrolytic cells, bushings, disks, electrical contacts and furnace linings.

GRAPHOLOGY: see HANDWRITING.

GRAPHS: see STATISTICS: Graphs; GRAPHIC METHODS IN MATHEMATICS.

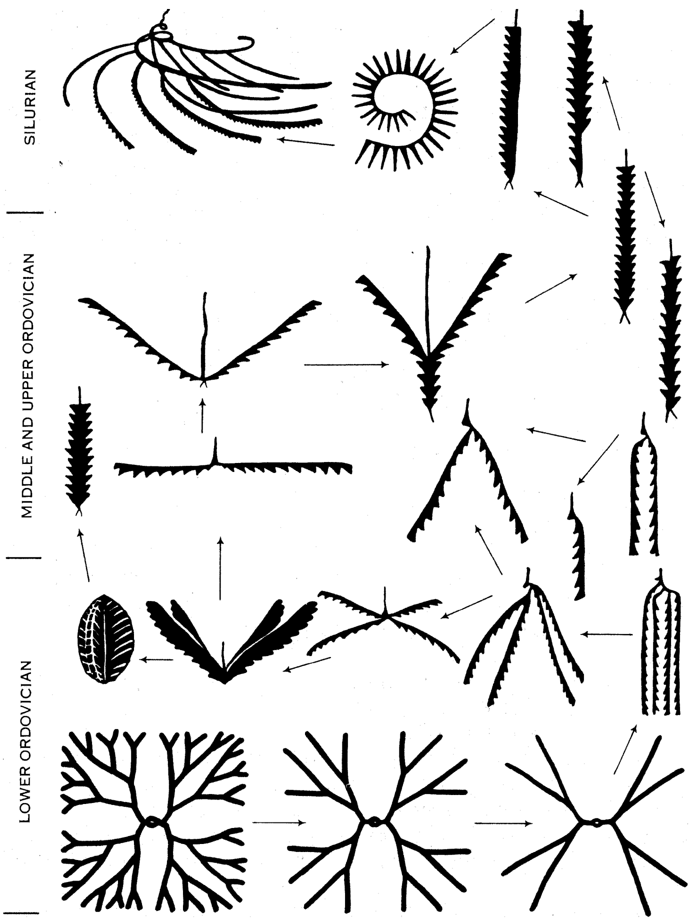
GRAPPA, MONTE, a mountain or rather mountainous group. 17 mi. long and 10 mi. wide. lies between the Brenta and the Piave rivers in Italy. The highest peak, 10 mi. N. of Bassano, rises to 5,827 ft.

The area was the scene of extremely heavy fighting during World War I (*q.v.*) between Nov. 1917 and Oct. 1918.

GRAPTOLITE, a class, Graptozoa or Graptolithina. of extinct colonial marine animals of uncertain relationship. They are preserved most commonly on bedding planes of black shale as flattened. leaflike. twiglike or weblike films of carbon that resemble pencil marks (graptos, "write"; lithos, "rock"). Their remains are restricted to the lower half of the Paleozoic era with greatest abundance in the Ordovician and Silurian periods during the interval from about 500,000,000 to 350,000,000 years ago.

Uncrushed examples shoning fine details of structure, *e.g.*, impressions of muscle attachment are occasionally found in limestone and flint, and may be recovered by acid dissolution of the rock matrix surrounding the remarkably resistant chitinous skeletal material

Many groups of graptolites show marked evolutionary changes in time. and many species are diagnostic of restricted time units. They, therefore, are important as indicators of geologic age Four



FROM MOORE, LALICKER AND FISCHER, "INVERTEBRATE FOSSILS," REPRODUCED BY PERMISSION OF MCGRAW-HILL EOOK CO , INC.

EVOLUTIONARY TRENDS OF GRAPTOLITE COLONIES DURING THE ORDOVICIAN AND SILURIAN PERIODS SHOWING CHANGES IN NUMBER AND POSITION OF BRANCHES

successive graptolite faunas are recognized over the world. each in characteristic stages of evolutionary development. From older to younger, these are: Xnisograptid. Dichograptid. Diplograptid and Monograptid faunas. The first three occur in the Ordovician, the last in the Silurian. They are further subdivided by O M. B. Bulman into nine chronological subfaunas and many zones of local extent.

The first individual of a graptolite colony is the conical sicula, which was attached to the sea bottom by a flexible stalk or was suspended by a chitinous thread (the nema) to a floating object. One or more series of successive cuplike buds (thecae) comprise the branches (stipesj whose growth direction is characteristic of particular genera and species. One or both edges of each stipe may be saw-toothed.

Evolution of graptolites was characterized by persistent tendencies or trends that affected independent groups (fig. 1). These tendencies include progressive reduction in the number of stipes from many to one during the Ordovician; gradual changes in the direction of stipe growth from downward (pendent) to upward along the nema (scandent) ; and elaboration of the apertures of the thecae.

Most of the primitive graptolites, the tiny bushlike Dendroidea, with thickened stems and expanded attachment bases. apparently were attached to the sea floor. Their weblike remains usually are associated with bottom-dwelling organisms of shallow waters and are restricted in geographic distribution; but Dictyonema *flabelliforme,* one of the most advanced and most widely distributed species of the group, probably lived suspended from floating objects which carried it throughout the world.

It is believed that the more advanced graptolites of the order Graptoloidea also were attached to floating seaweeds, the decomposition of which supplied carbonaceous material to the fine-grained black shales in which graptolites are so characteristically found.

The biological affinities of the graptolites are in doubt. The chitinous exoskeleton reflects little of the original anatomy. leaving as evidence only the form and mode of colony development. Graptolites have been considered members of such divergent groups as sponges. corals, plants, bryozoans, cephalopods, coelenterates and pterobranchs; however, only the last two groups deserve serious consideration as possible graptolite relatives.

The comprehensive work of R. Kozlowski in 1948 pointed to pterobranch (protochordate) affinity, since the wall structure characteristic of graptolites is also found in a living pterobranch (Rhabdopleura).

However, B. Bohlin and. earlier, C. E. Decker, impressed by a discovery of supposed nematothecae (cups bearing nematocysts or stinging cells) in Cambrian graptolites, tended to regard them as specialized coelenterates.

GRASMERE, a village and lake of Westmorland, England, in the heart of the English Lake district which, in 1951, was made a national park (see LAKE DISTRICT). Pop. (1951) 1,043. The village lies near the head of the lake, into which the Rothay river flows, 13 mi. S.S.E. of Keswick and 4 mi. N.W. of Ambleside by road.

The scenery is very beautiful; the valley of Grasmere and Rydal Water is well wooded. and on its eastern flank there rises boldly the range of hills which includes Rydal Fell and Fairfield (to the north). On the south is Loughrigg Fell and on the west Silver How.

The village, though a favourite tourist centre, preserves its picturesque and sequestered appearance. In Dove cottage, still standing, lived William and Dorothy Wordsworth at intervals from 1799 to 1808 and, later, Thomas de Quincey. Dove cottage is now the Wordsworth museum, and his tomb, with that of Coleridge, is in the churchyard of the ancient church of St. Oswald. The church contains a memorial to Wordsworth with an inscription by John Keble and also one to A. H. Clough.

The Rushbearing festival, held on the Saturday nearest Aug. 5 and including a procession and general holiday, is of ancient origin.

The lake of Grasmere is 1 mi. in length and about $\frac{1}{2}$ mi. in breadth.

A ridge divides the basin from north to south and forms an island about the middle.

GRASSE, FRANÇOIS JOSEPH PAUL, MARQUIS DE GRASSETILLY, COMTE DE (1722–1788), French naval commander who engaged British forces during the American Revolutionary War, was born at Bar (Alpes Maritimes). In 1734 he took service on the galleys of the order of Malta, and in 1740 entered the French service.

Shortly after France and the United States joined forces in the Revolutionary War, he was dispatched to America as commander of a squadron.

In 1779–80 De Grasse fought the English off the West Indies. In 1781 he was promoted to the rank of admiral and was successful in defeating Adm. Samuel Hood and in taking Tobago. When Washington and Rochambeau determined to march to Virginia to join forces with Lafayette's army against Cornwallis, Washington requested the co-operation of De Grasse's fleet. De Grasse therefore sailed from the Indies to the Chesapeake river, where he was joined by a fleet under Count de Barras.

A British force under Adm. Thomas Graves attempted to prevent this juncture by engaging De Grasse's fleet when it arrived at the Chesapeake but was unsuccessful. French naval supremacy in the waters off Yorktown was instrumental in the success of the siege of that city.

After Cornwallis' surrender, De Grasse returned to the West Indies, where he captured the island of St Kitts in Jan. 1782. In April, however, he was defeated by Admiral Rodney and taken prisoner.

On his return to France, he published a Mdmoire *justificatif* and was acquitted by a court-martial in 1784. He died in Paris, Jan. 11, 1788.

See Alexandre de Grasse, Notice bibliographique *sur* l'amiral comte de Grasse *d'après les* documents intdits (1840); Georges Lacour-Gayet, La *Marine* militaire de la France *sous* le *règne* de Louis *XV* (1902).

GRASSE, capital of an arrondissement, ddpartement of Alpes Maritimes (until 1860 in that of Var), France, 12½ mi. by rail N.N.W. of Cannes. Pop. (1954) 14,078. From 1244 (when the see was transferred there from Antibes) to 1790 it was an episcopal see, but was then included in the diocese of Fréjus until 1860, when the region was annexed to the newly formed *département* of the Alpes Maritimes. It has a 12th-century cathedral. now a simple parish church; and an ancient tower, of uncertain date, near the town hall. formerly the bishop's palace (13 century). The library contains the muniments of the abbey of Lérins, on the island of St. Honorat opposite Cannes. In the chapel of the old hospital are three pictures by Rubens.

Grasse is built in an amphitheatre at a height of 1.066 ft., on a south slope facing the Mediterranean. It possesses a mild and salubrious climate, and is well supplied with water. That used for the purpose of the factories comes from the fine spring of Foux. But the drinking water used in the higher portions of the town flows, by a conduit. from the Foulon stream. Grasse is particularly celebrated for its perfumery. Oranges and roses are cultivated abundantly in the neighbourhood. It is stated that the preparation of attar of roses (which costs nearly £100 per 2 pounds) requires alone nearly 7,000,000 roses a year. It manufactures nax, soap and the finest quality olive oil. There are a sub-prefecture and a tribunal of commerce

GRASSES, a group of plants possessing certain characters in common and all members of a single monocotyledonous family (Gramineae or Poaceae). No other family of flowering plants is of as great importance to man, or more widespread; and only a few comprise a greater number of species. Although only those plants which belong to the Gramineae may properly be called grasses, the term grass is commonly used for many other plants of widely different affinities nhich superficially resemble true grasses in their foliage; *e.g.,* knotgrass (*Polygonum*), cotton grass (*Eriophorum*), rib grass (Plantago). blue-eyed grass (*Sisyrinchium*), yellow-eyed grass (*Xyris*), star grass (*Hypoxis*), bear grass (*Xerophyllum*) and eelgrass (Zostera). The grass tree of Australia (Xanthorrhoea), a desert plant allied to the lilies and rushes. has a tall. unbranched. soft-woody, palmlike trunk which bears a cronn of long, narrow, grasslike leaves and stalked heads of small densely crowded flowers. In agriculture the word "grass" has an extended significance in that it may include the various forage plants, especially the legumes.

Grasses were recognized as a natural group long before there was a science of botany or a system of classification. Common lawn, pasture and meadow grasses such as bluegrass, bent grass, timothy and fescue are the best known and the wild prairie grasses and such weeds as crab grass and quack grass also are familiar. The grains or cereals, such as wheat, rice, oats, barley and maize, are also true grasses, as are sugar cane, sorghum and millet, and even the giant woody-stemmed bamboos.

In early attempts at a scientific classification of plants a group of Gramina was recognized, and this, though bounded by nothing more definite than habit and general appearance, contained the Gramineae of modern botanists. The early systematists, however, often included also in the group the Cyperaceae (sedge family), Juncaceae (rush family) and some other monocotyledonous plants with inconspicuous flowers. The sexual system of classification developed by Linnaeus (1753), which was based on the numbers of stamens and pistils, served to separate the true grasses more distinctly; most of them fell under the order Digynia of his class Triandria, whereas the allied plants, with few exceptions, were distributed under other classes and orders.

Geographic Distribution. — The Gramineae are the world's most universally distributed flowering plants. R. Pool estimated in 1948 that perhaps 30% of the land vegetation of the globe is dominated by grasses. or at least may be classified as potential grassland. Probably the best-kno n and most extensive of these areas are the steppes of the U.S.S.R. and the prairies and plains of North America. Other regions in which grasses are dominant, although sometimes mixed with scattered trees, are to be found in South America, Africa and Australia. In number of species the Gramineae are far exceeded by the Compositae. Orchidaceae and Leguminosae, but with respect to numbers of individuals, grasses hold undisputed first place. Numerous species, moreover, have such wide ranges that the proportion of grasses to other families in the various floras of the world is much higher than the number of species would indicate.

Species of grasses are most numerous in the savannas of the tropics, while the number of individuals is greatest in temperate and cold regions of the world. As the colder latitudes are approached. grasses become relatively more numerous, and in arctic and antarctic regions they comprise about one-fourth of all the species. They reach the limits of vegetation, except for some lichens and algae, in the polar regions and on mountain tops. Indeed. on all the great mountain systems of the world, grasses are the dominant plants above timber line. They are dominant also in arid regions, as aell as on sand dunes, in salt marshes and in other places where conditions for plant life are exceedingly severe. Grasses are essentially plants of the open and are rarely seen in dense forests. A few broad-leaved species grow on the forest floor in the tropics, and in temperate regions, also, there are a few woodland grasses.

Some species of grasses are almost cosmopolitan. such as the common reed, *Phragmites communis.* A number of others are found throughout the warm regions of the earth: e *g.,* Hackelochloa *granularis, Eleusine* indica, Cynodon *dactylon* and such weeds as Echinochloa and *Setaria.* In contrast to these aide-ranging grasses are the relatively few genera nith extremely limited distribution. Examples of such endemics are Anomochloa of Brazil, *Opizia* of Mexico and Buergersiochloa of New Guinea.

Structure. — Grasses, even when not in flower, may be recognized and readily distinguished from members of other plant families by the following structural features: the stems are jointed. hollow as in nheat or oats or pithy as in maize. sugar cane and sorghum. The leaves are alternate in two ranks. and consist of two parts, the sheath and the blade. The sheath surrounds the stem like a tube but is usually open along one side. nhile the blade is more or less divergent. At the junction of the sheath and blade there is usually a small membranous organ (sometimes represented only by hairs. or missing) known as the ligule. Members of the closely related sedge family are often confused with grasses, but for the most part they have solid triangular stems on which the leaves are borne in three ranks. The leaf sheath, moreover, is always closed and the ligule is lacking.

Root.—In grasses the roots are fibrous and are often much branched and widely spreading. These, in combination with underground and creeping aerial stems, serve to anchor the plants firmly in the soil. Roots of many grasses are extensive, and in some species the roots of a single plant, if dug up and placed end to end, would total a length of several miles. These extensive root systems enable grasses to hold the soil in position against the forces of water and wind, thus rendering them of great value in the prevention of erosion and floods and in the reclamation of devastated areas.

The cord grasses (species of *Spartina*) are important soil builders, and many square miles of salt marshes have been reclaimed due to their presence. One species, S. townsendii, has been planted extensively along the coast of the Netherlands, where it is adding to the usable land area at a spectacular rate.

Stem.—In perennial grasses underground stems or rootstocks (rhizomes) are often well developed; they may be long and creeping as in quack grass (Agropyron) and marram grass (Ammophila). That rhizomes are stems and not roots is evident from the fact that they have distinct joints (nodes) and sheathing scales (leaves). features which are lacking in roots. Rhizomes are always solid and the internal structure is that of the usual monocotyledonous stem. Some grasses produce, instead of rhizomes. extensive horizontal stems which creep along the surface of the soil (stolons). An example of a stoloniferous species is buffalo grass (*Buchloë*) of the North American plains. Both rhizomes and stolons, being stems, give off branches from their nodes, and adventitious roots are also formed. Thus each node is potentially capable of giving rise to a new plant. Grasses possessing these structures, and especially rhizomes, are able to form dense sod, and for this reason bluegrass (Poa pratensis) and bent grass (Agrostis) are valuable for lawns and golf greens. In the formation of rhizomes and stolons, which are really branches from the main shoot, these break directly through the sheath in the axil of which they originate. In other cases, the branches grow upward inside the sheath, which is ultimately pulled away from the parent culm. This latter mode of growth is seen in the tillering of cereals, and results in a tufted plant with many erect branches from the lower nodes of the young stem. It is also the manner of growth of the bunch grasses so common in arid grasslands.

The upright stems (culms) of grasses are usually cylindrical (rarely flattened) and conspicuously jointed. The nodes are always solid, whereas the internodes (fig. 1) are commonly hollow but occasionally solid as in maize and sugar cane. At the base of each internode there is an actively growing (meristematic) region in which the cells continue to divide for a considerable period, and this causes the stem to elongate. When the culms are forced into a horizontal position, due to the action of rain, wind, animals or other agents. they tend to rise again by bending at the nodes. This is accomplished by the action of a growth hormone (auxin), which, under the influence of gravity, tends to accumulate on the lower side of the stem, causing increased multiplication and enlargement of the cells. Auxin is present even when the culm is erect, but it is evenly distributed around the stem with the result that growth is uniform and no bending occurs.

The exterior of the culm, which is more or less concealed by the leaf sheaths, is usually smooth and often highly polished, the epidermal cells containing an amount of silica sufficient to leave after burning a distinct skeleton. A white siliceous material (tabasheer), found in the joints of several bamboos, was once thought to have medicinal properties. In some grasses a few of the lower nodes become swollen and subglobular. these functioning as storage organs. Examples of such bulbous grasses are timothy (*Phleum*) and tall oat grass (*Arrhenatherum*).

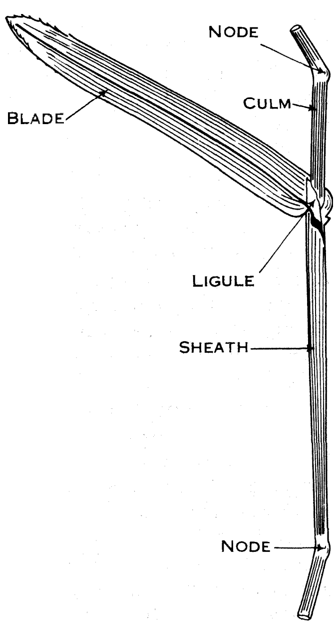

FIG. 1.—INTERNODE OF A GRASS CULM WITH ITS LEAF

Although many grasses produce only simple culms, branching from the upper nodes is not uncommon. Branches originate in the axils of sheaths and at the point of origin there is produced, on the side next to the parent culm, a characteristic two-keeled organ (prophyllum), which is the first leaf of the branch. Many tropical grasses are much branched. particularly the bamboos. *Dinochloa,* a Malaysian genus, is scandent and climbs over trees as much as 100 ft. in height. Among grasses other than bamboos, Olyra and *Lasiacis* are also woody climbers, and their culms and branches often attain a length of many metres.

Grass culms grow with great rapidity. In bamboos a height of 25 ft. may be attained in a single month, and some species have been known to grow 2 or 3 ft. in a period of 24 hours.

Leaves.—These are borne singly at each node and are two-ranked. the leaf at each succeeding node being turned 180° from that immediately below. The leaf consists of two distinct portions, the sheath and the blade. The sheath encircles the stem and may be shorter or longer than the internode. It forms a firm protection for the internode, and particularly for the younger basal portion (growing zone or meristem), which remains delicate and fragile for a considerable period. As a rule the sheath is split down its entire length. but in a few grasses (species of Poa, *Bromus*, etc) the margins are united. Occasionally the sheaths are much dilated, and in Hygroryza, a Malaysian aquatic, they actually serve as floats. At the summit of the sheath, at its junction with the blade, there is usually a small membranous appendage (sometimes an inch or more in length) called the ligule. In some species this organ is represented only by a tuft of hairs. while in others it is lacking altogether. In certain grasses (species of Muhlenbergia and others) in addition to the ligule there is a green, erect. tongue-like process extending upward from each margin of the sheath.

The blade is borne at the summit of the sheath and diverges from the culm at a more or less acute angle. In some cases there are produced. one on either side at the base of the blade. small outgrowths which tend to clasp the culm. These appendages, known as auricles, are most frequently seen among members of the tribe Hordeae. The usual form of the blade is familiar—sessile. more or less ribbon shaped, tapering to a point and entire at the edge. In a few grasses, such as Pharus, Pariana, *Zeugites* and bamboos. there is a short petiole between the sheath and the blade. In most bamboos. moreover, the blade is articulated with the sheath from which it is deciduous. Although most grasses have narrow linear leaves, there are some (*e.g.,* Streptochaeta, Olyra, Pharus) in which the blade may be two inches or more wide and not more than twice this dimension in length. In all grass leaves, however. the venation is strictly parallel, although in a number with broad blades (including the bamboos) there are connecting cross veins as well. The tissue is often raised above the veins. forming longitudinal ridges, usually on the upper face; the stomata are in lines in the intervening furrows.

The blades of many grasses, particularly those of arid regions, are capable of rolling up or folding along the midrib. This is accomplished by means of large thin-walled cells (bulliform or motor cells) situated between the veins. As the humidity decreases, these cells lose water and the blade folds or rolls toward the face on which they occur. This rolling or folding serves to protect the plant against excessive desiccation, since the majority of the stomata occur on the protected surface.

Epidermal appendages of various sorts commonly occur on blades and sheaths. Frequently the leaf has a rough (scabrous) texture, due to the presence of numerous sharp-pointed siliceous spicules These may occur on all surfaces, and are sometimes of sufficient size and frequency to impart a serrate appearance to the leaf margin. Epidermal hairs are also common, and these may be weak or stiff, long or short and sparse or dense. Sometimes the base of the hair is enlarged and bulbous or papillalike. Examples of extreme hairiness are found in the common velvet grass (Holcus lanatus) and *Alopecurus lanatus* of Asia Minor.

Inflorescence.— In grasses the unit of the inflorescence is the spikelet and not a single flower as is the case with most other plants.

Spikelets, discussed below, almost never occur singly on a plant, but a number of them are aggregated to form an inflorescence. Familiar grass inflorescences are the tassel of maize, the head of wheat and the panicle of oats. The simplest type of inflorescence is the spike, as seen in wheat or rye, in which the spikelets are sessile along the main axis. A raceme differs from a spike in that the spikelets are pedicelled. Simple racemes are rare in grasses, an example being semaphore grass (Pleuropogon). The commonest type of inflorescence found among grasses is the panicle, characterized by having pedicelled spikelets borne on a branching axis. Strictly defined, a panicle is a compound raceme, but in the Gramineae the term is applied to any branching inflorescence! even though some of the spikelets in the group may be quite sessile. Panicles may be open and diffuse. as in bluegrass. or much contracted and spikelike. as in timothy. Sometimes the panicle branches are directed to one side. as in orchard grass or cocksfoot (Dactylis) and dog's tail (*Cynosurus*). Spikes or racemes also may be asymmetrical. with spikelets borne on one side of the axis only. as in crab grass (*Digitaria*), cord grass (Spartina), and grama (Bouteloua).

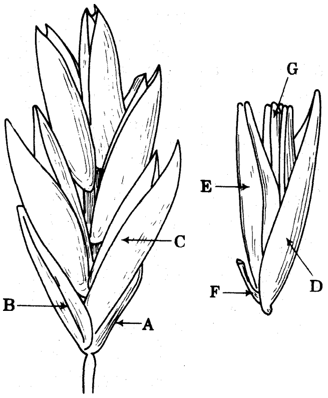

FIG. 2.— FIVE-FLOWERED SPIKELET OF FESTUCA, WITH A PARTIALLY OPENED FLORET AT THE RIGHT: (A) FIRST GLUME; (B) SECOND GLUME; (C) FLORET; (D) LEMMA; (E) PALEA; (F) RACHILLA JOINT; (G) STAMENS

The spikelet, as the name suggests, is itself a miniature inflorescence—a spike (fig. 2. 3). A generalized spikelet consists of a short axis (rachilla) bearing, in two-ranked arrangement. a series of modified leaves (bracts), some of which produce flowers in their axils. The two lowermost bracts. which are empty. are called glumes. These are not borne at precisely the same level, but one (lower or first glume) is slightly below the other (upper or second glume). The bracts above the glumes are designated lemmas (formerly called flowering glumes). Facing each lemma and partially enclosed by it. is a second bract (palea) which bears the flower. The lemma and palea with the enclosed flower are termed the floret (fig. 2). The lemma bears an odd number of nerves or veins (1. 3, 5, *j*. etc.), while the palea is two-nerved and somewhat flattened on the back, which is next to the rachilla.

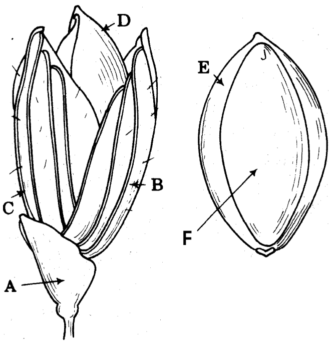

FIG. 3.—LEFT. SPIKELET OF PANICUM SHOWING THE VARIOUS PARTS: (A) FIRST GLUME; (B) SECOND GLUME: (C) LOWER FLORET. WHICH IS STERILE OR STAMINATE AND OF THE SAME TEXTURE AS THE GLUMES; (D) UPPER OR FERTILE FLORET. WHICH IS INDURATED AND OFTEN SHINY RIGHT FERTILE FLORET SEEN FROM THE PALEA SIDE: (E) LEMMA; (F) PALEA

The flower in grasses is much reduced, consisting typically of a single pistil bearing two feathery stigmas. and three stamens. At the base of the pistil there are two small scales (lodicules), which are thought to represent the perianth. At flowering time (anthesis) the lodicules become much swollen. and this causes the lemma and palea to separate, exposing the stamens and stigmas (fig. 4). In the flowers of some bamboos there are three lodicules, six stamens and three stigmas. Such flowers are considered to resemble most closely the ancestral type. In the flowers of some other grasses (*e.g., Oryza* and *Ehrharta*) six stamens also are found occasionally, and three lodicules rarely occur in flowers of genera other than bamboos (*e.g.*, Stipa). Infrequently in the flowers of of some bamboos and in those of Pariana and Luziola (which are unisexual), more than six stamens occur; up to roo have been counted.

When the typical flower of Gramineae is compared with that of the general monocotyledono'us type, as represented by Liliaceae, it is found to differ in the following ways: (1) the outer perianth whorl (sepals) is missing entirely; (2) the inner whorl (petals) has one member missing, the remaining two being represented by lodicules; (3) the inner whorl of stamens is lacking; (4) one stigma is no longer present, and only one carpel of the ovary is functional. As indicated above, however, each of the usually missing organs can be found normally, or as an occasional development, in some genera.

The flowers of grasses are so reduced and exhibit such uniformity in their structure that they are of minor importance in classification. The spikelets, on the other hand. show great variability, and their modifications and arrangements are very useful in identification and in suggesting relationships. Glumes are almost universally present, although occasionally one (*e.g., Lolium, Paspalum*) or even both (*e.g.*, Leersia, *Reimarochloa*) may be wanting. Usually they are similar in shape and texture. but the first is often smaller and with fewer nerves. Sometimes the midnerve is extended as a bristle (awn), and the glumes may be reduced entirely to bristles as in some species of Elymus. Among members of the tribe Andropogoneae, the first glume is usually indurate, sometimes strongly so, and may be sculptured (Hackelochloa'). In the more primitive grasses, lemmas are similar to the glumes, but many modifications occur. In certain genera (*Panicum, Phalaris*, Olyra) the lemma is hard and shining. while the glumes are of the usual membranous texture. In most members of the Andropogoneae, on the other hand, the lemmas are very thin and may be hyaline. The firm lemmas of Stipa and *Aristida* have a sharp-pointed base (callus). which is formed where they break away obliquely from the rachilla. Awns are very common on lemmas, and these may be straight or bent one or more times. When they are bent (geniculate) the basal segment is often more or less twisted. In addition to the median awn. there may be additional ones formed by the extension of the lateral nerves (e g, *Pappophorum*). The palea. which is considered to be homologous with the prophyllum, is two-nerved and usually two-keeled, although the two nerves may be so close together that they appear as one (*Cinna*). The keels may be broadly winged (*Distichlis*) and are sometimes ciliate (*Eragrostis*). or bearded (Triplasis). Occasionally the palea is much reduced or completely lacking. as in some species of *Agrostis*. Ordinarily the palea falls from the plant attached to its lemma. but in numerous species of Eragrostis it persists upon the rachilla after the lemma has fallen.

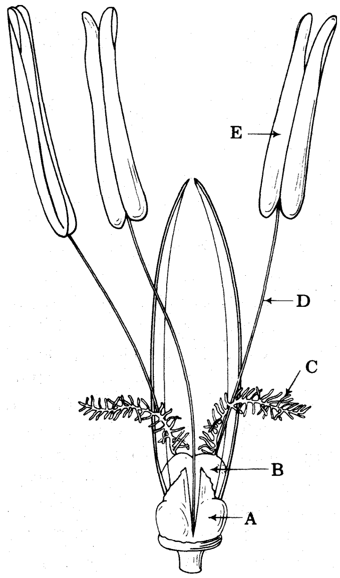

FIG. 4.— FLOWER OF LOLIUM PERENNE ATTACHED TO ITS PALEA: (A) LODICULE (B) OVARY, (C) STIGMA: (D) FILAMENT OF THE STAMEN. (E) ANTHER OF THE STAMEN

The number of florets per spikelet varies from one {Agrostideae) to nearly 60 in some species of *Eragrostis*. In grasses which have their spikelets composed of several florets. these are usually similar in size and shape. but those toward the summit may be somewhat smaller. sterile or may lack paleas. Occasionally reduced or sterile florets occur at the base of the spikelet just above the glumes (*Uniola*). Sterile florets also occur below the fertile one in some apparently one-flowered spikelets. Thus in the Phalarideae a pair of staminate or neuter florets subtend the single perfect one. Spikelets of the Paniceae and Andropogoneae also have one functional floret, and below this is a sterile one which may be reduced to the lemma. Spikelets may be strcngly flattened either from the side or from the back, or plump and even circular in cross section. In outline, too. they exhibit a wide range of variation, from those of Eragrostis or Distichlis, often narrow in proportion to their length and with the margins nearly parallel, to those of Paspalunt, which are sometimes almost circular. Another important characteristic of spikelets is the manner in which they break apart. thus freeing the seed from the parent plant. In some cases (*e.g., Panicum*) the spikelet falls as a unit, in certain other cases, such as the Festuceae. the rachilla breaks up above the glumes and between the florets. each of the latter falling separately and with an internode of the rachilla attached.

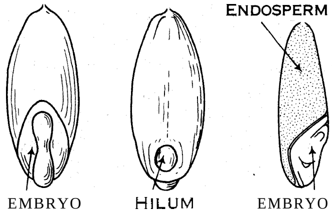

FIG. 5.— CARYOPSIS OF DIGITARIA SANGUINALIS IN FRONT AND BACK VIEWS. AND IN LONGITUDINAL SECTION

True involucres. consisting of subtending bracts, are rare in the Gramineae, although involucrelike structures do occur. being formed in various ways. In *Setaria, Pennisetum*, etc.. the one or more whorls of simple or feathery bristles which occur below the spikelet represent abortive branches of the inflorescence. In *Cenchrus* these become fused and more or less indurated. forming a sort of bur which encloses the spikelets. In Job's-tears (*Coix*) the hard and shining beadlike structure is a much-modified bract or leaf sheath.

FLOWERING, GERMINATION AND DISPERSAL

Flowering. — Most grasses are chasmogamous—*i.e.,* their florets open to expose the stamens and pistil — but some are cleistogamous, the pollination taking place within the closed spikelets. There are a few species (*e.g., Amphicarpum* and *Chloris chloridea*), moreover, which in addition to the usual inflorescence bear cleistogamous spikelets on special underground stems, while still others (*e.g., Danthonia*) produce them within the lower sheaths. Cross-pollination is affected by wind, and the pollen is well adapted to this means of transport, being very light and with a perfectly smooth surface. Most annual grasses are self-fertile, but many perennials and some annuals are self-sterile: being unable to set seed without cross-pollination, These latter species usually have large anthers which become fully exserted from the floret. The self-fertile annuals. in contrast, often have very small anthers, which may protrude from the open floret slightly, if at all.

The process of flowering in a typical grass proceeds somewhat as follows: The first noticeable sign is that the inflorescence becomes much more open, the branches spreading from the axis. This is accomplished by means of the swelling of a pad of spongy tissue (pulvinus) located in the axil of each branch. When this has occurred, and if conditions are favourable, the lodicules become greatly swollen and exert sufficient pressure at the base of the floret to force the lemma and palea apart. The filaments of the stamens next elongate rapidly, pushing the anthers from the floret. where they hang in the air. At the same time the feathery stigmas spread and project laterally. one on each side of the open floret. The anthers next split longitudinally, releasing the pollen, which is scattered by the slightest breeze. At the completion of flowering, the lodicules lose their turgidity, and the floret gradually closes.

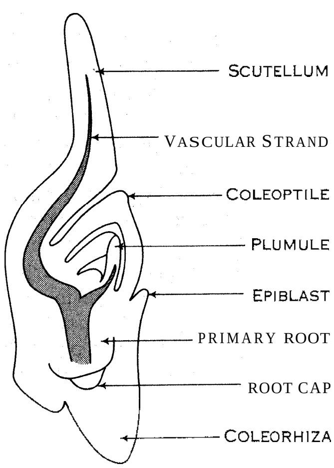

FIG. 6.—EMBRYO OF BECKMANNIA SHOWING THE VARIOUS PARTS

A few species of grasses are dioecious. the spikelets of an individual plant bearing either stamens or pistils but not both. Others are monoecious. unisexual flowers occurring on the same plant. in which case entire spikelets may be either staminate or pistillate, or some of the florets within the same spikelet may bear only stamens while others have only pistils. A somewhat comparable condition (polygamy), in which both perfect and unisexual flowers occur on one individual and often within the same spikelet. is also common among grasses, especially among members of the Paniceae and Andropogoneae. When unisexual flowers of both sexes. or unisexual flowers along with perfect ones, occur on the same plant, it is usual for these to bloom at slightly different times. thus promoting cross-pollination. Even when the flowers are all perfect, often the stamens shed their pollen either before or after the stigmas are mature, and this also decreases the possibility of self-fertilization.

Fruit and Seed. — The fruit. which develops from the ovary of the pistil, is usually small: ovoid or rounded, and furrowed along one side. It is entirely occupied by the single seed, from which it is not to be distinguished, the thin pericarp of the fruit being completely united with the testa of the seed. This characteristic fruit is properly termed a caryopsis (fig. 5), although it is often referred to as a grain. This latter term, however, is less precise, since it is often applied to fruits of a quite different nature, such as those of buckwheat and seeds of some species of Amaranthus.

Although the caryopsis is of almost universal occurrence among grasses, other types of fruits rarely occur. In *Sporobolus,* Eleusine and some other genera, the fruit is a utricle, the pericarp being quite free from the seed. Among the Bambuseae, the pericarp is sometimes hard: forming a nut. and in others it becomes thick and fleshy, forming a berry which is often as large as an apple. In *Melocanna*, one of the bamboos, the berry is edible, somewhat pear shaped and may attain a length of three or four inches. The small seed germinates within the fruit. the shoots often attaining a length of six inches or more before the fruit falls from the parent plant.

Ordinarily the pericarp and testa are thin and the outline of the embryo is clearly visible. It occupies a position at the base of the caryopsis on the side facing the lemma. Often the embryo is small, but in some cases (*e.g., Echinochloa* and *Spartina*) it is nearly as long as the seed. Opposite the embryo, on the other side. is a more or less evident dot or line (the hilum) which marks the point of attachment of the ovule to the ovary wall. The space inside the seed coat which is not occupied by the embryo is filled with endosperm. starchy material which. when the seed germinates, serves to nourish the developing plantlet. The outermost layer of endosperm, the aleurone, consists of regular cells filled with small protein granules. The remainder is made up of large polygonal cells containing numerous starch grains in a matrix of protein.

The structure of the embryo (fig. 6) and its position within the seed is unique and quite different from that in the Cyperaceae or other monocotyledons. On the side next to the endosperm is the single cotyledon or scutellum. This platelike organ bears, on the surface in contact with the endosperm, an epithelial layer containing enzymes which aid in the digestion of the starchy tissue during germination. On the side opposite the scutellum, and inserted at about the same level, there may be a small organ (epiblast) which some authors have considered to be a reduced second cotyledon. In some grasses the epiblast is large and conspicuous. in others it is small, and in many it is altogether lacking. The primary root is enclosed in a sheath (coleorhiza). The epicotyl or plumule is also enclosed in a sheath (coleoptile), which typically has two vascular bundles, one on either side. Vascular tissue extends from the root into the shoot with a side branch to the scutellum. Neither the coleorhiza nor the epiblast develops vascular tissue. Although there has been a certain amount of disagreement with respect to the homologies of the parts of the grass embryo, it has come to be generally agreed that the scutellum is the cotyledon and that the coleoptile represents the first leaf of the plant.

Germination. — When a seed germinates, the coleorhiza expands, lengthens and ruptures the pericarp. The coleoptile, with its enclosed epicotyl, next appears. Soon afterward the primary root breaks through the coleorhiza, as do also secondary roots in those cases in which they are formed in the embryo. Filaments closely resembling root hairs often develop on the coleorhiza, and these probably serve as absorbing organs. At the same time that these external changes are taking place, the scutellum is elongating and pushing deeper into the endosperm, which is being digested slowly to feed the developing plantlet. In the meantime the coleoptile is pushing vertically upward through the soil. Finally the first leaf appears, emerging through the tip of the coleoptile. The primary root persists for only a short time, the function of absorption being assumed by adventitious roots which arise from the nodes at the base of the primary shoot.

Dispersal and Migration. — In grasses the seed rarely falls free, and among wild species even the grain seldom separates from the parent plant devoid of its lemma and palea. Often whole spikelets serve as propagules, and these may have parts of the inflorescence attached to them. In some cases short spikes fall from the parent plant; in others the axis of the inflorescence breaks up at the joints, each spikelet falling attached to an internode of the rachis. In grasses with several-flowered spikelets, the rachilla usually breaks apart between the florets, each of these falling with a short rachilla joint attached. The persistent lemma and palea, and other parts when present, serve to decrease the specific gravity, and the grain is thus more readily carried by the wind. Lemmas and paleas may also afford a certain amount of protection in that they prevent excessive desiccation or too rapid wetting of the embryo. Among cultivated cereals there has been a conscious selection for those in which the grains fall free from their enveloping scales, as this greatly facilitates their harvest. In some cases. however, the combination of easily separating caryopses and high yield has not been achieved, and such grains as oats and barley, when harvested, are tightly enclosed between their lemmas and paleas.

The awn, which frequently occurs on the lemma, is often a very efficient agent in the dispersal of fruits. It may catch in the fur of animals or in the plumage of birds, or. when long and feathery (species of *Stipa*) may act as a sort of parachute. The awn, moreover, may serve to bury the fruit in the soil, thus hastening germination and the establishment of a new plant. The florets of *Stipa* and species of *Avena,* and the spikelets of *Heteropogon* and others, often have a sharp callus which easily penetrates the soil and also short stiff hairs which oppose its withdrawal. The bent and twisted awn, which is hygroscopic, serves as a driving organ. twisting and untwisting with changes in humidity. When the upper part of such an awn is caught in the ground or in vegetation, the repeated twisting causes the fruit to be driven deeper and deeper into the soil. Grass fruits of this type sometimes cause injury to sheep when they catch in the wool and burrow through the skin. A very efficient means of seed dispersal is seen in those grasses in uhich the large open panicles break off at maturity and are blown long distances by the wind, scattering their fruits as they go.

Examples of such tumbleueeds are *Eragrostis spectabilis* and *Panicum capillare.*

Vivipary, or the germination of seeds within the fruit upon the parent plant, was mentioned above as occurring in *Melocanna.* The condition has also been observed in some other bamboos and is occasionally seen in other grasses. The conversion of the spikelet, above the glumes, into a leafy shoot (proliferation) is often confused with vivipary. Proliferated spikelets are occasionally found among many genera of grasses, and these are often the result of particular environmental conditions. In some grasses, however, this peculiarity is genetically determined; there are races known in which it occurs regardless of the conditions of the environment.

At one time it was believed that proliferated spikelets were of considerable importance in reproduction. but it has been found that under natural conditions these seldom grow into new plants.

CLASSIFICATION

There are about 500 genera and perhaps 5,000 species of grasses known, and each year more are discovered and described. Although it is relatively easy to recognize members of the family, their great complexity, as well as the extreme reduction and uniformity of the flowers, renders classification very difficult. Since the flowers themselves offer few clues as to relationships, reliance must be placed upon other characters; hence the classification of grasses has been built up largely from a study of vegetative structures. Thus glumes, lemmas and paleas, while associated with flowers, are in reality all more or less modified leaves. The difficulty of classification is further increased by the realization that much parallel evolution has occurred, with the result that superficial similarity does not necessarily indicate close phyletic relationship. A classification system on which all botanists can agree has not been formulated.

Grasses may be separated rather readily into two great groups or subfamilies. Robert Brown (1814) was apparently the first author to record the observation that in one group (Panicoideae) there is a tendency for aborted flowers to be borne at the base of the spikelet, while in the other (Festucoideae) aborted or rudimentary flowers occur above the fertile ones. It was pointed out later by George Bentham (1882) that in the Panicoideae the spikelet usually breaks away below the glumes, thus falling as a unit, while in the Festucoideae the spikelets disarticulate above the glumes and between the florets, these falling individually. Further, in the Panicoideae the spikelets are flattened from the back (dorsally). while in the Festucoideae the compression is from the sides (laterally), and the glumes and lemmas are often somewhat keeled. Not only are these groups recognizable on morphological grounds, but they have been found to differ also with respect to chromosome size and number, leaf epidermis and anatomy, embryo and seedling and in some other characters.

In his monograph on the Gramineae. E. Hackel (1887) further divided the family into 13 tribes. This system, often with some slight modifications, has been used widely through the world and is probably the best-known classification of the grasses. The principal change made in Hackel's system was to reverse the order of the tribes. The classification outlined below, a modified Hackel system. is essentially that used in A S. Hitchcock's *Manual of Grasses of the United States,* the standard work on the family for America. The first nine tribes are treated as members of the subfamily Festucoideae, while the remaining four fall under the Panicoideae.

Tribe I: **Bambuseae.**—This is a group—the bamboos — of usually tall grasses with woody stems. The blades are often broad and articulated to the sheath, to which they are attached by a short petiole. The spikelets bear from two to several florets which are usually awnless, and these are arranged in panicles. racemes, fascicles or compact heads. The tribe numbers about 60 genera, most of ahich are tropical; one genus. *Arundznaria,* is native to the United States. In those parts of the world where bamboos are abundant. they are of great economic importance. The woody culms are used in all kinds of construction. for vessels, and water pipes. and also furnish fibre from nhich an excellent quality of paper is manufactured. Bamboo shoots are an article of food in the orient, and the grains are also eaten, especially in time of famine.

Tribe II: **Festuceae.**—In this tribe — the fescues — the spikelets are also tao- to several-flowered and are borne in open. contracted or spikelike panicles, or sometimes in racemes. The glumes are usually shorter than the lowest floret. The lemmas are awnless or awned, the ann straight or flexuous and borne on the tip or from between the teeth of a minutely bifid apex. When mature. the spikelets disarticulate above the glumes and between the florets As circumscribed here, the tribe includes about 12j genera, most of which are characteristic of temperate or cool regions Many common meadow grasses belong in this tribe. such as bluegrass brome grass, fescue and orchard grass or cocksfoot.

Tribe III: **Hordeae.**—Spikelets in members of the Hordeae—the barley tribe — are often similar to those of the Festuceae (sometimes they are reduced to one flower), but the inflorescence is always a symmetrical spike, the spikelets borne on both sides of the rachis. which may be continuous or break apart at the joints when mature. Often the glumes are reduced to bristles or awns, or one may be lacking (Lolium). This tribe comprises only about 25 genera, but although small it is very important economically. Some of the most valuable cereals, wheat (Triticum), barley (*Hordeum*) and rye (*Secale*) are members of the Hordeae.

Tribe **IV: Aveneae.**—As in the preceding tribes, the spikelets in this group — the oat tribe — are also two- to several-flowered. They are borne in open or contracted panicles or occasionally in racemes. The glumes are longer than the lowest floret, and may be as long as the spikelet, more or less obscuring the florets within. The lemmas are usually awned from the back (dorsally), the awn commonly bent and twisted. The rachilla and callus of the florets are often hairy, and frequently the inflorescence has a shiny or silvery appearance. There are about 45 genera in this tribe, among them velvet grass (Holcus), tall oat grass (Arrhenatherum) and the cultivated oat (*Avena*).

Tribe **V: Agrostideae.**—This—the bent tribe — is somewhat unnatural. containing a number of unrelated genera. The characters which these share in common and which delimit the tribe are one-flowered spikelets borne in open, contracted or spikelike panicles. The inflorescence is never a true spike or a one-sided raceme. The lemma may be awnless or awned. and the awn may be straight or bent and twisted, and borne either terminally or dorsally. The floret usually disarticulates above the glumes, falling free from them, but in some cases the spikelet falls as a unit. The Agrostideae comprises about 65 genera, most of which are found in temperate and cool regions. Timothy (Phleum), bent grass (Agrostis), and marram grass (*Ammophila*) are members of this tribe.

Tribe **VI: Phalarideae.**—In this — the canary grass tribe — the spikelets have one perfect terminal floret; below this are two others which are staminate or neuter, sometimes reduced to small scales. The inflorescence'is an open or contracted panicle. As treated by Hackel and many subsequent authors. the tribe consists of six genera, among them sweet grass (Hierochloe) and canary grass (*Phalaris*).

Tribe **VII: Chlorideae.**—The form of the inflorescence is the most characteristic feature among members of the Chlorideae, the grama tribe. The spikelets may be one- or several-flowered, awned or awnless. sessile or pedicellate, but they are always borne in two rows on one side of a continuous rachis. These spikes or racemes may be solitary, digitate or arranged as branches of an elongated axis. In some cases only the lowest floret of the spikelet is fertile, the others being sterile and often much reduced or rudimentary. There are perhaps 40 genera in this tribe. most of them inhabiting warm regions. Included are such important forage grasses as buffalo grass (Buchloe), and the grama grass (*Bouteloua*) of the southwestern United States and northern Mexico.

Tribe **VIII: Zoysieae.**—As in the preceding tribe, the form of the inflorescence is of prime importance in delimiting this group, the tobosa grass tribe. The spikelets are usually one-flowered, sessile or subsessile in short spikes of two to five (single in Zoysia), each spike falling entire from the continuous rachis. All the spikelets may be perfect, or perfect and staminate ones may occur together in the same inflorescence. Often three are found together, the central one being perfect while the two laterals are staminate. This tribe comprises about 17 genera of tropical distribution, particularly in dry regions and on seashores. Mesquite grass (Hilaria) is a member of the tribe, as is also Zoysia, the genus from which the tribal name is derived.

Tribe **IX: Oryzeae.**—In this — the rice tribe — the spikelets, which are borne in open panicles, are one-flowered and perfect or unisexual. The glumes are occasionally well developed, but usually they are small or may be completely lacking. The stamens are often six in number. As defined by Hackel, the tribe includes about 16 genera. but some of these are of doubtful affinities. The best-known member, cultivated rice (Oryza sativa), is one of the most important food plants in the world.

Tribe **X: Melinideae.**—Members of this group have well-developed glumes and two-flowered spikelets. The upper floret is perfect, the lower being staminate or neuter and often represented only by a lemma. There are seven or eight genera in this tribe, all occurring in tropical regions. Most are unimportant, but Thysanolaena, a native of Asia, is often a troublesome weed. Melinis, with a single species, found in both South America and Africa, is prized for forage and is sometimes cultivated.

Tribe **XI: Paniceae.**—The spikelets in the Paniceae — the *Panicum* tribe — are distinctive, being dorsally compressed and two-flowered. although appearing one-flowered until examined carefully. The glumes are membranous in texture, the first often shorter than the second. Occasionally the first glume is completely lacking. The upper floret is perfect, the lemma and palea indurated or firmer than the glumes, often hard and shiny. The lower floret is staminate or neuter, sometimes reduced to the lemma, this of the same texture as the glumes. Awns occasionally occur on the glumes or on the lower lemma, but almost never on the fertile one, and when present on this latter organ, the awn is usually short. The Paniceae comprises 80 or more genera, most of them found in tropical and warm regions. Many are troublesome weeds, such as crab grass (Digitaria), foxtail (Setaria) and witch grass (Panicum capillare). A few are grown for the grains—*e.g.*, millets (Panicum miliaceum and *Setaria italica*)—and some are used for forage.

Tribe **XII: Andropogoneae.**—The spikelets of the Andropogoneae — the sorghum tribe — are also two-flowered, with the upper floret perfect and the lower staminate or neuter. The glumes, however, are firmer than the lemmas, and the latter are commonly auned, the awn often well developed, bent and twisted. The spikelets usually occur in pairs on the inflorescence axis or its branches, the usual arrangement being that one of the pair is sessile and fertile, while the other is pedicellate and staminate or neuter. Rarely the upper spikelet is wanting. The axis usually disarticulates at the joints, and the pair of spikelets fall attached to a short internode. This tribe comprises 50 or more genera, most of which are tropical. Some are important forage grasses, and the group also includes sugar cane (*Saccharum*), Sorghum and oil grasses (*Cymbopogon*), this latter group furnishing citronella oil. an important source of perfume.

Tribe **XIII: Maydeae.**—In this tribe (also called Tripsaceae)—the Indian corn tribe — the plants are monoecious, the spikelets being unisexual. The staminate spikelets are borne in pairs, or occasionally in threes. The pistillate spikelets are more or less embedded in a thickened axis or enclosed within a thickened sheath. The glumes and lemmas are awnless. This small tribe of seven genera is closely allied to the Andropogoneae, the chief distinction being that in the Maydeae the staminate and pistillate spikelets are borne in different inflorescences or in different parts of the same inflorescence. Maize (Zea mays) is a member of this tribe, as is also Job's-tears (Coix *lachryma-jobi*).

Other Classifications. — The classification outlined above, although quite unnatural in many respects, is perhaps the most satisfactory available. Other systems have been suggested, the most notable, perhaps, being that of C. Hubbard (1934), in which 27 tribes were recognized. many of which previously had been designated as subtribes. In several respects this system is more natural than Hackel's, although it is someuhat less satisfactory for the nonspecialist because of the large number of tribes, often based on minor characters.

R. Pilger presented in 1954 an even more detailed system, in which he recognized 9 subfamilies and 35 tribes. Although he indicated that it was based on the latest information from all disciplines, his system is far from natural in many respects and, because of the large number of subfamilies and tribes, is unwieldy and difficult to use.

Even though a natural classification for the Gramineae acceptable to all botanists has not been worked out, data bearing on the subject are accumulating as the result of researches along various lines. Perhaps the most useful information has come from the study of the epidermis of the leaf and its anatomy, the structure of the embryo, and chromosome size and number, although root-hair development, starch-grain structure and other studies also prove helpful in some cases. Using the newer techniques, the subfamily Panicoideae, as classically treated, proves to be quite natural, but this is not true of the other subfamily. The tribes Chlorideae and Zoysieae, for example, are misplaced in the Festucoideae, even though this is not evident from a study of the gross external features alone. These are the only complete tribes for which a shiit to the other subfamily is indicated. Among several of the other tribes, however, there are genera which prove to be unrelated to the majority with which they have been associated. This is especially true with respect to the tribes Festuceae and Agrostideae, in which numerous genera have been found to have panicoid affinities, even though most of the genera are festucoid.

GRASSHOPPER, a name applied to insects of the families Tettigoniidae and Acrididae (see ORTHOPTERA). They are strong leapers with enlarged hind femora; the males are often loud stridulators, while the females are mostly silent. The Acrididae or short-

horned grasshoppers have short, rather stout antennae, three-jointed tarsi and a short four-valved ovipositor. They stridulate by scraping a toothed ridge on the hind femur against sharp-edged veins on the closed tegmen. Some make buzzing or crackling noises in flight. Auditory organs are present on the base of the abdomen Eggs are usually laid in soil in masses of 30 to 100 or more, enclosed in a capsule of hardened secretion. Acrididae include most of the common grasshoppers, and also the locusts. The name locust is often used for any member of the family, but refers properly to the destructive swarming and migratory species (see LOCUST). The Tettigoniidae (katydids [*q.v.*] or long-horned grasshoppers), formerly termed Locustidae, have long threadlike antennae four-jointed tarsi and a prominent ovipositor. They stridulate by rasping a filelike vein on the base of the left fore wing across a scraper vein on the right wing, causing taut drum areas on these tegmina to vibrate. Auditory organs are present on the fore tibiae. Mostly herbivorous like Acrididae, many Tettigoniidae are omnivorous or partly carnivorous. Eggs are laid singly in soil. or in rows in plant stems or on leaves. Many terrestrial species are wingless or short-winged; the winged forms mainly frequent bushes or trees.

The green Phaneropterinae of North America and the large green Phasgonura viridissima of southern England are noteworthy stridulators. (T. H. HL.)

GRASSI, GIOVANNI BATTISTA (1854–1925), Italian zoologist who investigated the life cycle of protozoa, intestinal worms and insects: was born on March 27, 1854, at Rovellasca, and died in Rome on May 4, 192j. He graduated in medicine at the University of Pavia. and after studying zoology at the universities of Heidelberg and Würzburg, was appointed professor of zoology at the University of Catania in 1883, and of comparative anatomy at the University of Rome in 1895. Grassi's researches concerned the life history of eels, the Chaetognatha, the social life of the termites; the sporozoan malarial parasite of the mosquito and the transmission of malaria in man.

GRASSLAND may be considered as any area devoted to the production of forage grasses, legumes, or combinations oi grasses and legumes with other herbage plants, used for grazing, hay. grass silage or green feeding. Green feeding, soiling, zero pasture, green chop and other terms are used to describe the process of harvesting and feeding green pasture crops mechanically, instead of grazing directly by livestock.

Grassland agriculture is as old as the domestication of animals, which n-as achieved about 10,000 B.C. Dairying in Europe based upon feed from grassland was under way by 4000 B.C. In some areas dairying has changed little since its beginning between 4000 B.C. and 2000 B.C., nor has the culture of grassland which supplies the feed for livestock, including the improvement of the forage plants themselves.

This article deals with the role of grassland in agriculture, the various kinds of grassland and their improvement and uses and the improvement of forage grasses and legumes. For specific information about the occurrence and agricultural uses of grassland, the reader is reierred to the articles on individual countries, *e.g.,* ARGENTINA; AUSTRALIA, and especially to the sections of those articles dealing with physical geography and agriculture. Botanical characteristics are discussed in the article GRASSES and there are separate articles appearing under the common names of the more important species of grasses and legumes. See also AGRICULTCRE; RANGE (IN AGRICULTURE).

Following are the main divisions of this article:

I. IMPORTANCE OF GRASSLAND

Grassland produces the world's most extensively grown crop. Its acreage exceeds the combined acreage of wheat, corn (maize), cotton, oats, barley. rye. soybeans. sugar beets, rice, flax, peanuts, potatoes and tobacco. In terms of the livestock feed supply. grassland furnishes over half of the total in many countries and as much as 85% to 90% of the total in others.

Grassland and the grass crop dominate the nonforested agricultural land area of every continent. Over 200 major grass and legume species and thousands of species of limited distribution adapted to various soil and climatic conditions are grown on the world's grassland. One or several of the many kinds of grasses and legumes grow in each of the numerous grassland habitats from the tropics to the permafrost of the arctic region, and from regions oi high rainfall (over 100 in. a year) to semiarid regions that receive less than 10 in, of precipitation a year. The annual production of grassland varies from a few pounds to several tons to the acre. depending upon the climate, soil productivity and management of the crop. Land that will grow any crop can be made into grassland, but much grassland is not suitable for the economic production of any other crop.

Livestock feed for domesticated animals is the major contribution of grassland. but not its only one. In certain situations the soil and water conserving attributes may be more important than the feed produced, since a grass or grass-legume cover retards water runoff, increases the rate of infiltration into the soil and reduces or prevents soil erosion by wind or water. As a rotation crop, well-managed grassland restores productivity that is lost by growing cultivated crops (see ROTATION OF CROPS).

Grassland also supplies the major portion of the feed for many kinds of game animals and especially big game. More specialized uses of grassland are to maintain highway shoulders, separation strips and embankments; to provide a suitable surface of pleasing appearance for recreational areas, such as golf courses, playing fields, parks and lawns; and to provide protective cover on roadways of limited use, firelanes, waterways, airstrips, around buildings and on other normally turfed areas.

II. KINDS OF GRASSLAND

1. Sown or Seeded Grassland. — This is the largest and by far the most productive supplier of nutritious forage; it includes tame pasture, tame hay, ley. meadow, rotation hay or pasture, temporary pasture and annual forage crops. Generally these are found in areas of moderate to heavy rainfall on land once occupied by natural forest. Soils in these areas are well supplied with moisture during much of the year, with some leaching occurring due to the percolation of excess water. They are the grasslands that support the intensive, highly developed livestock industry in New Zealand, western Europe, the United Kingdom, humid regions of North America and other parts of the world. Smaller acreages of sown grassland have been established on submerged areas reclaimed from the sea, and on irrigated deserts. During most of the growing season, and when properly managed, herbage from these grasslands constitutes an adequate diet for sheep and cattle. Dairy cattle produce nearly as much milk when their entire ration comes from well-managed pastures as they produce with any other feed or combination of feeds. Beef cattle make optimum growth and may be fattened satisfactorily on forage alone. Sheep seldom receive anything but feed from grassland whether kept on somn or natural grassland Horses that have access to ample amounts of good quality hay or pasturage may receive no other feed except during periods of heavy work. Swine and poultry obtain less, but often an important fraction, of their rations from grassland (see also FEEDS, ANIMAL).

Annual yields, on a dry forage basis, of 12,000 lb. to the acre are not uncommon from sown pastures or meadows. This amount of high-quality forage is sufficient to meet the feed requirement of one high-producing dairy cow for one year. Occasionally, acre yields of 20,000 lb. or more have been obtained with alfalfa (*Medicago sativa*). Tropical and subtropical grasses have given yields of dry matter in excess of 40,000 lb. to the acre. These high yields more closely approach the maximum potentials than the average yields of somn meadows and pastures, but can be realized over substantial areas with good management.

While the term sown implies the establishment of grassland by planting seed, which is usually the case, it is used here to include grassland established by planting stolons or budded shoots or other plant parts that root to produce new plants.

Sown grassland may be used as a temporary crop grown in rotation with other cultivated crops or it may be nearly permanent. Within these extremes will be found pastures and hay fields ranging from a few months to several years of age. The permanence and productivity of sown grassland depend upon intended use as well as good management, soil and climatic factors. These, in turn, usually determine the life span of a permanent pasture. The improvement of forage plants through selection and breeding, and improved establishment methods, have encouraged short-term stands (two to four years) of forage grass or legume, interspersed nith small grain and other cultivated crops. On productive cropland or irrigated land, the grass crop may be grown only one year out of ten or more (*see* ROTATION OF CROP;

Hilly land too steep to plow without serious danger of erosion is seldom cropped and should remain in grass most of the time. if farmed at all. Such areas may be seeded, limed and fertilized with aircraft adapted for such uses. Thus treated, and properly grazed, hill land not suitable for the production of other crops becomes an efficient producer of livestock feed.

Species of the following grasses and legumes are those often used to establish sown grasslands:

Grasses

Bermuda grass (*Cynodon*)
Bluegrasses (*Foa*)
Bluestems (*Andropogon*)
Brome grasses (annual and perennial) (*Bromus*)
Buffalo grass (*Buchloë*)
Canary grasses (*Phalaris*)
Carpet grass (*Axonopus*)
Cocksfoot, orchard grass (*Dactylis*)
Dallis, Bahia, etc. (*Paspalum*)
Dropseeds (*Sporobolus*)
Fescue grasses (*Festuca*)
Grama grasses (*Bouteloua*)
Kikupu, napier grass, etc. (*Pennisetum*)
Love grasses (*Eragrostis*)
Meadow foxtail (*Alopecurus*)
Millets and bristle grasses (*Setaria*)
Molasses grass (*Melinis*)
Needle grass (*Stipa*)
Oat grasses (*Arrhenatherum*)
Pangola grass (*Digitaria*)
Pará grass, guinea, switch grass, etc. (*Panicum*)
Redtop (*Agrostis*)
Rhodes grass (*Chloris*)
Rye grass (*Lolium*)
Smilo and rice grass (*Oryzopsis*)
Sudan, Johnson, etc. (*Sorghum*)
Timothy (*Phleum*)
Veldt grass (*Ehrharta*)
Wheat grasses (*Agropyron*)
Wild rye (*Elymus*)

Legumes

Bird'sfoot trefoil (*Lotus*)
Bur clover, alfalfa, etc. (*Medicago*)
Chick-pea (*Cicer*)
Clover (*Trifolium*)
Crotalaria (*Crotalaria*)
Fenugreek (*Trigonella*)
Hyacinth bean (*Dolichos*)
Kaimi and Spanish clover (*Desmodium*)
Koa haole (*Leucmna*)
Kudzu (*Pueraria*)
Lespedeza (*Lespedeza*)
Lupines (*Lupinus*)
Milk vetch (*Astragalus*)
Pigeon pea (*Cajanus*)
Sainfoin (*Onobrychis*)
Soybean (*Glycine*)
Sweet clover (*Melilotus*)
Vetch (*Vicia*)

2. Natural Grassland. — This group embraces a wide array of types ranging from desert grass-shrub combinations to the tall grass prairie. Unlike the sown grasslands that occupy areas cleared of forest vegetation, natural grasslands are themselves the end product of natural forces that favoured grass and other plant growth more than that of trees. When undisturbed by man's activities or by fire, natural grasslands are not easily invaded by trees or other scrub growth, but when subjected to overgrazing or plowing for crop production, brush or scrub may invade rapidly. The scattered tree growth that is found in typical savanna grassland thickens if the surrounding grass is damaged by overgrazing or fire.

Natural grasslands generally occupy those areas between the climatic extremes of humid woodlands and dry desert shrub. The transition belts, therefore, between typical grass prairie and either of these extremes contain more or less tree growth on the one hand, or desert shrub on the other. Soil moisture, rather than total rainfall. usually determines the extent of natural grassland. If the upper layers of soil are moist during part of the year, but the deeper layers remain dry. tree growth cannot compete with grass. The savannas of the tropics annually receive substantial total rainfall, but a prolonged dry period each year, combined with high temperatures and evaporation, prevents the development of forests.

Temperature or soil moisture may limit the effective growing season in natural grasslands to a few weeks of the year. Thus, tender grass feed of high nutritive quality is available for relatively short periods compared with the season of lush growth in sown grasslands. However, the absence of a long season of green forage growth is supplemented by naturally cured, leafy forage of acceptable feed value for several weeks after growth has stopped, particularly in arid regions. Generally, those species found in arid regions tend to exceed those of the wet tropics in feed value after maturity. Associated browse plants, including some species of sagebrush, also reinforce the feed supply of natural grasslands in semiarid regions. especially between growing seasons. In addition to carbohydrate and protein, some of them supply exceptionally high quantities of vitamin A. The productivity of natural grassland varies widely but averages much less than that of sown grassland. Forage production may range from a few pounds to several hundred pounds to the acre.

Some of the more important grasses found in natural grasslands include one or more species of the following:

Big bluegrass, etc. *(Poa)*
Bluestems *(Andropogon)*
Bristle grass, etc. *(Setaria)*
Brome grasses *(Bromus)*
Buffalo grass *(Buchloe)*
Cogon grass *(Imperata)*
Cord grasses *(Spartina)*
Danthonia, etc. *(Danthonia)*
Dropseed *(Sporobolus)*
Grama grasses *(Bouteloua)*
Jaragua grass, etc. *(Hyparrhenia)*
Kangaroo grass *(Thenzeda)*
Love grasses *(Eragrostis)*
Muhly grasses *(Muhlenbergia)*
Needle grass *(Stipa)*
Oil grass *(Cynzbopogon)*
Panic grass, switch grass, etc. *(Panicum)*
Reed grass *(Calamagrostis)*
Sand paspalum *(Paspalum)*
Sickle grass *(Ctenium)*
Three-awn grasses *(Aristida)*
Tobosa, etc. *(Hilaria)*
Wheat grass *(Agropyron)*
Wild rye grass *(Elynzus)*

III. GRASSLAND IMPROVEMENT

Previous to about 1930 little research attention had been given to the improvement of grasslands, compared with the work on such crops as wheat, cotton, rice, maize and many others. Thus, the grass crop, too often, has been less profitable than it should have been. Moreover, a profitable return from the grass crop (since three-fourths or more of it is harvested by grazing) is as dependent upon proper utilization by livestock as it is upon the successful growing of the crop. Wise animal husbandry, therefore, is an essential ingredient of successful and profitable grassland agriculture.

Grassland improvement research must take into account the end use of the crop. Higher feed value, better seasonal distribution of production or greater palatability are often more important objectives than higher forage yields, per se, since the final measure of profit from grassland is milk. beef. mutton or other products from forage-consuming animals. Increased use of applied fertilizers, especially nitrogen, phosphorus, calcium, magnesium, potassium and sometimes molybdenum, cobalt and other trace elements. has improved both yield and quality of humid area grasslands. Conservation and the return of animal manures are essential unless heavy applications of chemical fertilizers are made. With few exceptions, larger applications of fertilizer nutrients on sown grasslands have been profitable. Forage yields in humid areas are often doubled or tripled by good soil fertility practices alone.

Reseeding is sometimes essential to obtain the maximum output from grassland. Natural grassland that has deteriorated from misuse may require reseeding after the destruction of brush and weeds. Sown grassland may require occasional cultivation or plowing and reseeding to re-establish a good legume-grass balance for maximum production of nutritious forage. Also, as superior varieties of forage grasses and legumes are developed by plant breeders, reseeding is required to utilize them promptly. Occasionally, top seeding without any land preparation is possible, but successful establishment of grassland by this method is the exception rather than the rule. Immediate seeding in the ash following burns is, perhaps. the most noteworthy exception.

Improvement by proper grazing management is difficult to achieve. Yet this is the principal method of economically maintaining and improving the natural grassland of subhumid and semiarid regions around the world. The vegetative cover is usually sparse, yet surface protection is essential to increase water intake and to reduce erosion by wind and water. To provide adequate cover with living or dead vegetation, as much as 50% of the grass growth should remain on the land. Continuous overgrazing reduces the vigour of the grass. invites encroachment of weeds and brush and brings on general deterioration. These grassland areas are often too extensive in size and too low in yield to justify large-scale, costly renovation treatments that may be profitable in humid grasslands. Improvement may be accomplished by (1) reseeding selected sites of higher yield potential; (2) by construction of water-spreading systems that divert runoff and aid in the more uniform infiltration of water; and (3) adjusted grazing practices that allow natural reseeding and the accumulation of desirable vegetative cover. On areas of more abundant moisture, fertilization may be profitable when coupled with grazing management systems designed to relieve the pressure on overgrazed areas. With all these improvement measures, however, success is dependent upon proper grazing management.

IV. UTILIZATION OF GRASSLAND

Pasturage, hay and grass silage are derived from grassland, in that order of importance. Because the grazing animal is the most economical harvester yet developed for most grassland conditions, three-fourths or more of the world's grass crop is grazed off. However, grazing is not always available throughout the year, or the feed value of the crop available for grazing during part of the year is so low that other high-quality forage is essential. Such forage is provided by hay or grass silage that is harvested when the grass or grass-legume combination is at a nutritious stage of growth.

1. Pasturage.—At the same time. good-management practices and forage crop sequences that provide high-quality pasture during most of the growing season can minimize the need for other feeds. The value of legumes in grassland agriculture is best realized in this connection. As a supplier of nitrogen to the associated grass, as well as to itself, the nitrogen-fixing legume helps maintain a satisfactory protein level in the legume-grass mixture during much of the growing season. In addition, for reasons not yet fully understood, the animal performance on grass-legume pastures is often superior to that on grass alone, even on grass nitrogen-fertilized to maintain the same protein level. Although the higher content of phosphorus and calcium in legumes is sometimes beneficial, properly fertilized grass supplies most animal requirements for these minerals. The high-digestible energy content of lush-growing clover or growth-regulating substances found in some legumes may partially explain this phenomenon.

To provide such pasturage, no other group of legumes has been utilized as extensively as several species of *Trifolium*. Grass-legume combinations that include these species comprise some of the best grazing lands in the world. Rye grass and white clover, Ladino clover and orchard grass (cocksfoot) and crimson clover and rye grass are examples. Where adapted. these pasture combinations produce large yields of top-quality forage that satisfies the needs of high-producing grazing animals. At the same time. these grass-legume associations thrive under properly managed continuous or rotational grazing systems (see also LEGUMINOSAE).

To supplement permanent pastures, temporary grazing, including feeding on root crops, is provided. Crops for temporary grazing are planned to be at their peaks of production during periods of low production from the permanent pasture. Such annuals as Sudan grass, pearl millet and lupine may be planted especially for this purpose. Winter grazing may be provided by reseeding crimson clover in a sequence of Bermuda grass and crimson clover. The same field produces Bermuda grass abundantly throughout the warm and hot periods of the year after the crimson clover has matured and died. Winter grains also are used for grazing, either for brief periods in advance of heading to permit the harvest of a grain crop later, or for grazing off completely.

On natural grasslands in many areas, plant growth is permitted to cure "on the stump" for grazing during periods when there is no growth. Often such feed is supplemented with a protein concentrate, such as cottonseed cake or soybean oil meal. Considerable grazing may be obtained also from adjacent grain stubble or recently planted winter grains if the natural grassland borders cropped areas. Over vast areas, however, the green and cured forage alone, which may or may not include browse plants, comprise the feed supply. When concentrates or high-quality preserved forage (hay or silage) are not available to balance low-grade roughages, the grazing animals lose weight, may fail to produce offspring or even die of starvation. Nevertheless, many flocks and herds go through this seasonal cycle and make phenomenal gains when the season of good pasturage returns.

2. Hay.—The making of hay is the most general means of preserving high-quality forage for later use. The same grasses and legumes grown for pasture may also be used for hay, although certain legumes, particularly alfalfa (lucerne), and a number of grasses, are better suited for hay production than for pasturing. The protein content and digestibility of forage grasses and legumes decrease as the growing plants advance in maturity. Total yield continues to increase as protein content declines. Since there is a correlation between protein content and digestibility, the crop should be cut for hay well in advance of maturity to produce feed of highest quality. The protein content at this time may be 20% or higher To obtain maximum hay yields from a meadow on a sustained basis. including the maximum protein, the crop must be permitted to advance in maturity beyond the point of optimum feed quality. The most satisfactory compromise is to cut the crop for hay during the early bloom stage while the protein content (dry basis) is 14% to 18%. (Young legume growth may contain over 30% protein and mature grass less than 4% on a dry basis.)

For good hay, the crop must be cut at the proper stage of maturity, handled so as to retain the leaves, and cured to prevent spoilage or discoloration. Under field conditions, during periods of rainy weather, losses may exceed 50%. To avoid such losses, hay may be mow cured in the barn with forced air either heated or not heated. The cost of special machinery and equipment for this purpose has limited this procedure. Or, the hay may be placed in small piles or stacks in the field until it is dry enough for storage in large stacks or in the barn. Properly cured hay with 20% or less moisture may be stored for months without danger of spoilage (*see* CROP DRYING AND PROCESSING).

3. Silage. — Where weather conditions preclude the possibility of making high-quality hay. making silage has become important as a forage preservation measure. Compared nith corn silage, grass silage is low in total energy. but in other respects it is equal to or better than corn silage. when properly made. Grass-legume combinations can be made into good silage easier than protein-rich legumes alone. The green material should be chopped fine enough to assure good packing and the exclusion of air from the mass of chopped material, whether placed in a tower silo, stack, trench or pit. The crop should be cut at the same or slightly earlier stage of maturity as is required to make high-quality hay. A high-moisture content in the ensiled material facilitates compaction and the exclusion of air. However, excess moisture (above 70%) seeps away and carries valuable nutrients with it. Excess moisture in the silo may also interfere with the fermentation processes that produce the best quality silage. Since freshly harvested forage contains from 75% to 80% moisture, it is difficult to adjust the moisture content of the forage precisely throughout the ensiling period. It is considered good practice to fill the bottom half or two-thirds of the silo with forage as near the optimum moisture content as possible (68% to 70%), and the remainder with material known to contain excess moisture. The heavy wet material on top helps to pack the entire mass and seals the exposed top surface better than drier material. Airtight covers properly installed practically eliminate the danger of loss due to spoilage. Though it is possible to make and preserve silage in a trench, pit or stack, losses may approach or exceed 50% unless precautions are taken to protect all exposed surfaces from air. Lightweight covers have been developed for this purpose. Such covers also protect the stack from outside moisture due to rain or snow. Good silage has a clean, acid odour and taste, no mold or sliminess, and a pH (acidity) of 3.5 to 4.j.

See also ENSILAGE.

4. Green Feeding. — In addition to pasture. hay and silage, the grass crop may be cut and fed fresh. This practice of green feeding (soiling) is not new, but has been revived for a number of reasons. Some of these reasons are associated with special problems, such as the inaccessibility to adequate pasturage of large, commercial dairy herds or cattle-feeding establishments. Other reasons include: (1) reduction of the danger of bloat that may occur when grazing animals are given unlimited access to pasture legumes; (2) unsuitability of the herbage species for grazing, but adaptability to mechanical harvest at regular intervals; (3) higher net feed recovery per unit area; and (4), higher net financial returns from the enterprise. The latter two reasons are not generally valid. They depend upon several conditions and alternatives such as topography and soil-moisture conditions, cost of machinery. labour and fencing. and the skill of the operator in managing grazing animals. Though green feeding is practiced with justification and profit under some conditions, its disadvantages have limited its use (*see* also FEEDS, ANIMAL).

V. BREEDING AND IMPROVEMENT OF FORAGE GRASSES AND LEGUMES

Although significant advances have been made in the development of superior forage grasses and legumes in the second half of the 20th century, the major effort to improve the forage plants grown in many parts of the world continues to be through the introduction and testing of species and strains in new environments, rather than through the breeding and improvement of the plants themselves.

The scope of forage plant improvement work is enormous because so many different species are involved. Reduction in the number of species may be attained by improvements that extend the use of certain species into new areas, and thus remove the need for some other species. Nevertheless, a great many species are needed to meet the climatic, soil and use requirements throughout the world, or even within a single country.

The forage plant breeder has many objectives, depending upon the species and the problems recognized as most pressing in his area. Disease resistance, greater seed size and seedling vigour that aid in establishment, insect resistance, tolerance to specific weather hazards. leafiness. persistence under grazing and higher yield may be sought. Elimination of or reduction in toxic or growth-retarding substances in the plant may be desired. Improved palatability is a worthy objective with productive grasses or legumes otherwise well adapted. To accomplish these and other objectives, the application of many basic sciences is required including genetics, physiology, chemistry, nutrition, pathology, entomology, mathematics, microbiology and taxonomy.

Interspecific and intergeneric hybridization may be used to transfer desirable germ plasm from one species to another or to produce new combinations of characteristics that possess the advantages of both parental species. This crossing technique is used also to produce segregating populations of plants in normally apomictic (egg not fertilized) species. Chromosome doubling has been used to create new varieties, to facilitate the crossing of species with different chromosome numbers and to restore fertility in sterile hybrids. Seeds or other plant parts may be irradiated to produce desired characteristics not found in the species. Segregating plant populations produced by these and other methods are then selected and tested for one or more of the desired characteristics listed in the foregoing objectives.

Occasionally it is possible to select superior plants for a new variety within an existing variety or plant population without resorting to more involved methods. Regardless of the procedure followed, the desired end product is a variety better in one or more important characteristics than the one it replaces.

A few examples of new or improved varieties are cited to illustrate the past accomplishments of forage plant breeders in various parts of the world:

Borre sweet blue lupine.—A vigorous, high-yielding sweet blue variety palatable to livestock.

Climax *timothy*.—A leafy variety of medium late maturity better suited to delayed hay harvesting in its area of adaptation than ordinary timothy.

Coastal Bernzuda *grass*.—A high-yielding, tall-growing hay type that produces no seed (a sterile hybrid) is resistant to root-knot nematode and is of good forage quality.

Dixie crimson clover.—Developed and released for its wide adaptation and reseeding characteristic.

Du Puits *alfalfa*.—Noted for vigour of establishment, early season production and high yield.

H-I rye *grass*.—A leafy, vigorous, high-yielding variety that produces more forage in short-term leys than longer-lived perennials.

Kenland red clover.—Southern anthracnose-resistant, superior yielding variety with greater persistence in its area of adaptation.

Lahontan alfalfa.—Developed for resistance to stem nematode, this high-yielding variety is also resistant to bacterial wilt and the spotted alfalfa aphid.

Madrid sweet clover.—A frost-resistant, high-yielding variety with outstanding seedling vigour and high seed yielding capacity.

Merkeron Napier grass.—Developed and released for high yield and resistance to eyespot disease.

Mt. Barker subclover.—A widely adapted, superior reseeding, high-yielding variety.

Sew *Zealand* white clover.—A persistent, higher yielding, more uniform variety in its area of adaptation.

Nordan crested wheat grass.—Developed with large seed size, seedling vigour and high seed quality to facilitate establishment of crested wheat grass under suboptimum soil moisture and seeding conditions.

Piper Sudan grass.—A high-yielding, heavy tillering variety low in prussic acid potential developed and released to reduce the danger of prussic acid poisoning in animals that graze on Sudan grass

Potomac orchard grass.—A hay and pasture type with some resistance to foliage diseases, particularly rust.

Ranger alfalfa.—A winter-hardy variety developed and released for its resistance to bacterial wilt, a disease that has destroyed alfalfa crops within two or three years after establishment. Wilt-resistant Ranger has persisted and remained productive in wilt-infested areas for ten or more years.

Rowan Korean lespedeza.—Root-knot nematode-resistant variety with high yield.

S23 rye grass.—A leafy type especially adapted for grazing and with greater persistence in its adapted area.

S100 white clover.—Released for its higher yield and wider range of adaptation.

S143 orchard grass.—A late maturing, leafy pasture variety better suited for grazing than the taller growing, early maturing hay types.

Starr pearl millet.—A late-maturing, leafy, high-yielding variety superior for grazing.

Sweet Sudan grass.—A widely adapted, sweet, juicy variety.

Tetra alsike.—A tetraploid variety of high yield and nutritive value.

GRASSMANN, HERMANN GÜNTHER (1809–1877), German mathematician chiefly remembered for his major work, Die Ausdehnungslehre or calculus of extension. was born at Stettin, Ger. (now Szczecin. Pol.) on April 15, 1809, where he taught until his death on Sept. 26, 1877. In Die *Ausdehnungslehre* (1844), he developed the idea, due to Leibnitz, of an algebra in which symbols representing geometric entities (points, lines, planes . . .) are manipulated according to certain rules. In suitable circumstances this calculus proves far more powerful than earlier methods of co-ordinate geometry. To Grassmann is due also the notion of representing subspaces of a given space (*e.g.,* the lines in three-dimensional space) by co-ordinates; this leads to a mapping by points of an algebraic manifold, called the Grassmannian.

Somewhat similar ideas were propounded independently and contemporaneously by W. R. Hamilton in his quaternion theory; indeed Grassmann, Hamilton (and also G. Boole) were the pioneers in the field of modern algebra. Although Grassmann's methods were only slowly adopted, because of his obscure exposition, they eventually inspired the continental school of vector analysts Later, through the work of E Cartan, they have shonn their utility in the study of differential forms, with its important applications to analysis and geometry.

For an introduction to Grassmann's work *see* H G. Forder, *The Calculus of Extension* (1941). (L R.)

GRASS-OF-PARNASSUS, any herbaceous plant of the genus Parnassia (family Saxifragaceae; *q.v.*), found throughout the north temperate zone.

GRASS-OF-PARNASSUS

At left is flower with front sepals, etc., removed to show pistil, nectaries and two of stamens, one of which has lost its anther and the other is in a position ready to shed pollen as the stigma is touched by a visiting insect. On right is honey-bearing scale

The white regular flower is rendered attractive by a circlet of scales. opposite the petals, each of which bears a fringe of delicate filaments ending in a yellow knob. These glisten in the sunshine and look like a drop of honey. Honey is secreted by the base of each of the scales.

There are about 40–45 species of Parnassia, of which the commonest is P. *palustris.* About 13 other species occur in North America, mostly in the northern United States and Canada. (N. Tr.)

GRASS PINK, one of the common names for Dianthus *plumarius,* a low-growing garden perennial with small, fragrant flowers of white, pink or shades of red and purple (some variegated). It is also called garden pink and cottage pink (see Pink; Caryophyllaceae).

The grass-pink orchid is an American swamp plant, Calopogon *pulchellus* (see Orchid).

GRASSQUIT, any small finch of the genera Sporophila and Tiaris common in tropical and subtropical America and the West Indies. One species, S. torqueola *sharpei,* Sharpe's seedeater, ranges into the Rio Grande valley of Texas; and two others, T. bicolor, the Bahama or black-faced grassquit, and T. *canora,* the Cuban melodious grassquit, occur as stragglers in Florida. The birds, about 4 in. long, dull coloured, with poor song, feed on seeds.

GRASS TREE (Xanthorrhoea hastilis), a well-known Australian plant represented by five species and belonging to the family Liliaceae. One of the species (X. *preissii*) is commonly known as blackboy. The plants have the habit of an aloe, with a long spike of flowers resembling that of the bulrush. A resin is obtained from the bases of the old leaves.

GRATIAN (Flavius Gratianus Augustus), Roman emperor 375–383, son of Valentinian I by Severa, was born at Sirmium in Pannonia on April 18 or May 23, 359. On Aug. 24. 367, he received from his father the title of Augustus. On the death of Valentinian (Nov. 17, 375) the troops in Pannonia proclaimed his infant son (by a second wife Justina) emperor under the title of Valentinian II (*q.v.*). Gratian acquiesced in their choice; reserving for himself the administration of the Gallic provinces. he handed over Italy, Illyria and Africa to Valentinian and his mother, who fixed their residence at Milan. The division. however, was merely nominal, and the real authority remained in the hands of Gratian. The eastern portion of the empire was under the rule of his uncle Valens. In May 378 Gratian completely defeated the Lentienses, the southernmost branch of the Alamanni, at Argentaria, near the site of the modern Colmar.

When Valens met his death fighting against the Goths near Adrianople on Aug. g in the same year, the government of the eastern empire devolved upon Gratian, but feeling himself unable to resist unaided the incursions of the barbarians, he ceded it to Theodosius (Jan. 379). With Theodosius he cleared the Balkans of barbarians. Gratian governed at first with energy and success, but gradually he sank into indolence, occupied himself chiefly with hunting, and became a tool in the hands of the Frankish general Merobaudes and bishop Ambrose. By taking into his personal service a body of Alani, and appearing in public in the dress of a Scythian warrior, he aroused the contempt and resentment of his Roman troops. A Roman named Maximus raised the standard of revolt in Britain, and invaded Gaul with a large army, upon which Gratian. who was then in Paris, being deserted by his troops, fled to Lyons, where, through the treachery of the governor, he mas delivered over to one of the rebel generals and assassinated on Aug. 25, 383.

During the reign of Gratian orthodox Christianity for the first time became dominant throughout the empire. In dealing with pagans and heretics Gratian, who during his later years was greatly influenced by Ambrose. bishop of Milan, exhibited severity and injustice at variance with his usual character. He prohibited heathen worship at Rome; refused to wear the insignia of the pontifex maximus as unbefitting a Christian; removed the altar of Victory from the senate house at Rome, in spite of the remonstrance of the pagan members of the senate and confiscated its revenues; forbade legacies of real property to the Vestals; and abolished other privileges belonging to them and to the pontiffs.

For Gratian's treatment of the heretics the church histories of the period should be consulted.

See Ammianus Marcellinus xxvii–xxxi; Aurelius Victor, *Epit.* 47; Zosimus iv, vi; Ausonius (Gratian's tutor) especially the *Gratiarum actio pro consulatu;* Symmachus x, epp. 2 and 61; Xmbrose, *De fide,* prolegomena to *Epistolae* 11, 17, 21 *Consolatio de obitu Valentiniani;*

Schiller, Geschichte der *römischen Kaiserzeit*, iii, iv, 31–33 (1883–86); Gibbon, Decline and Fall, ch. 27; R. Gumpoltsberger, Kaiser Gratian (1879); T. Hodgkin, Italy and her *Invaders,* vol. i (1892); J. Wordsworth in Smith's Dictionary of Christian Biography.

GRATIAN (GRATIANUS, MAGISTER GRATIANUS) (fl. *c.* 1140) has been called the father of the science of canon law, because his writing and teaching initiated a new branch of learning in the 12th century. the study of church law as a discipline distinct from theology. By confusing him with later personalities, bibliographers have sometimes given his name wrongly as Johannes Gratianus or Franciscus Gratianus. Yery little is known about Gratian's life. He was born. presumably in the late 11th century, in central Italy somewhere between Orvieto and Chiusi, perhaps at the hamlet of Carraria-Ficulle. Professed as a monk in the Camaldolese congregation of the Benedictine order, he became lecturer (magistcr) at the monastery of Sts. Felix and Nabor in Bologna, the city which just then began to acquire fame as centre of the revived study of Roman law and a new civil jurisprudence. There he completed, in 1140 or shortly thereafter, his Concordia discordantium canonum, a collection of nearly 3.800 texts touching upon all fields of church discipline, which he presented in the framework of a treatise designed to resolve into harmony (concordia) all the contradictions and inconsistencies existing in the millenary tradition of rules accumulated from divers sources (discordantes *canones*). Gratian is once mentioned in 1143 as consultant to a papal judge, and there is evidence that he was dead before 1159.

Later generations of chroniclers tacked several legends onto this meagre record of his life, pretending that he was a half-brother of the celebrated theologian Peter Lombard, or that he became a bishop or even a cardinal. Actually his person is entirely effaced by his work. Although by no means the first systematic compilation of canon law. it proved to be the right book at the right time because of its completeness and because of its superior method in combining the juristic with the scholastic approach. For the former, Gratian was indebted to the Bolognese doctors of civil law; for the latter, some directives had already been given by earlier canonists—*e.g.*, Yves de Chartres — but a more direct influence came from the trends of contemporary theology in France.

The *Concordia* discordantium canonurn, soon to be cited for short as *Decreta* or *Decretum Gratiani,* became the basic text on which the masters of canon law lectured and commented in the schools, first at Bologna. soon also at Paris. Oxford and other centres of learning. What is more, without ever receiving formal approbation, it was used as a book of authorities for the "old" law in the practice of the papal Curia. Even after much of its contents had become obsolete by later papal legislation, it remained the first part of the traditional corpus of canon law of the Roman Catholic Church until the codification of 1917 See also CANON LAW.

GRATRY, AUGUSTE JOSEPH ALPHONSE (1805–1872), French author and theologian, was born at Lille. March 10, 1805. Educated at the École Polytechnique in Paris, he was ordained a priest in 1832. After being a professor of the Petit Séminaire at Strassburg, he was appointed director of the College Stanislas in Paris in 1842 and in 1847 chaplain of the École Normale Supérieure. He became vicar-general of Orleans in 1861. professor of ethics at the Sorbonne (1862) and in 186; a member of the French academy where he occupied the seat formerly held by Voltaire. Together with M. Pététot, curé of Saint Roch, he reconstituted the Oratory of the Immaculate Conception, a society of priests mainly devoted tb education. Gratry was one of the principal opponents of the definition of the dogma of papal infallibility, but in this respect he submitted to the authority of the Vatican council.

His chief works were De la connaissance de Dieu (1855), opposing Positivism; La *Logique* (1856); *Les Sources*, *conseils* pour la conduite de *l'esprit* (1861–1862); La Philosophie du credo (1861); Commentaire *sur l'évangile* de Saznt *Matthieu* (1863); *Jésus-Christ,* lettres *à M.* Renan (1864); Les Sophistes et la critique (in controversy with E. Yacherot) (1864); La *Morale* et la loi de l'histoire, setting forth his social views (1868); Mgr. *l'évêque d'Orléans* et Mgr. *l'archevêque* de *Malines* (1869), containing a clear exposition of the historical arguments against the doctrine of papal infallibility.

Gratry died at Montreux, Switz., Feb. 6, 1872.

GRATTAN, HENRY (1746–1820), Irish statesman, son of James Grattan, for many years recorder of Dublin, was born in Dublin on July 3, 1746. At Trinity college, Dublin, he began a lifelong devotion to classical literature and especially to the great orators of antiquity. He was called to the Irish bar in 1772, but never seriously practised. Like Flood he cultivated his natural genius for eloquence by study of good models, including Bolingbroke and Junius. Flood influenced Grattan's political aims; and it was through no design on Grattan's part that when Lord Charlemont brought him into the Irish parliament in 1775, in the very session in which Flood damaged his popularity by accepting office, Grattan quickly superseded his friend in the leadership of the national party. His speeches were packed with epigram, and expressed with rare felicity of phrase; his terse and telling sentences were richer in profound aphorisms and maxims of political philosophy than those of any other statesman save Burke; he possessed the orator's incomparable gift of conveying his own enthusiasm to his audience and convincing them of the loftiness of his aims.

The principal object of the national party was to set the Irish parliament free from constitutional bondage to the English privy council. The menacing attitude of the Volunteer Convention at Dungannon greatly influenced the decision of the government in 1782 to resist the agitation no longer. It was through ranks of volunteers drawn up outside the parliament house in Dublin that Grattan passed on April 16, 1782, to move a declaration of the independence of the Irish parliament. "I found Ireland on her knees," Grattan exclaimed, "I watched over her with a paternal solicitude; I have traced her progress from injuries to arms, and from arms to liberty. Spirit of Swift, spirit of Molyneux, your genius has prevailed! Ireland is now a nation!" After a month of negotiation the claims of Ireland were conceded. The gratitude of his countrymen to Grattan found expression in a parliamentary grant of £100,000, which had to be reduced by one half before he would consent to accept it.

One of the first acts of "Grattan's parliament" was to prove its loyalty to England by passing a vote for the support of 20.000 sailors for the navy. Grattan himself never failed in loyalty to the crown and the English connection. He desired moderate parliamentary reform, and, unlike Flood, he favoured Catholic emancipation. The Irish House of Commons was still subject to the influence of corruption, which the English government had wielded through the Irish borough owners, known as the "undertakers," or more directly through the great executive officers. "Grattan's parliament" had no control over the Irish executive. The great majority of the people were excluded as Roman Catholics frdm the franchise; two-thirds of the members of the House of Commons were returned by small boroughs at the absolute disposal of single patrons. It was to give stability and true independence to the new constitution that Grattan pressed for reform. Having quarrelled with Flood over "simple repeal" Grattan also differed from him on the question of maintaining the Volunteer Convention. He opposed the policy of protective duties, but supported Pitt's commercial propositions in 1785 for establishing free trade between Great Britain and Ireland, which, however, had to be abandoned.

In general Grattan supported the government for a time after 1782, and in particular spoke and voted for the stringent coercive legislation rendered necessary by the Whiteboy outrages in 1785; but as the years passed without Pitt's personal favour towards parliamentary reform bearing fruit in legislation, he gravitated towards the opposition, agitated for commutation of tithes in Ireland, and supported the Whigs on the regency question in 1788. In 1792 he succeeded in carrying an Act conferring the franchise on the Roman Catholics; in 1794 in conjunction with William Ponsonby he introduced a reform bill which was even less democratic than Flood's bill of 1783. The defeat of Grattan's mild proposals helped to promote more extreme opinions, which, under French revolutionary influence, were now becoming heard in Ireland.

In 1794 Lord Fitzwilliam became lord-lieutenant of Ireland. It was arranged that Grattan should bring in a Roman Catholic emancipation bill, and that it should then receive government support. But finally it appeared that the viceroy had either misunderstood or exceeded his instructions; and on Feb. 19, 1795, Fitzwilliam was recalled. The English cabinet was now determined firmly to resist the Catholic demands, with the result that Ireland rapidly drifted towards rebellion. Grattan warned the Government in a series of masterly speeches of the lawless condition to which Ireland had been driven, but his words were unheeded. He retired from parliament in May 1797, and departed from his customary moderation by attacking the government in an inflammatory "Letter to the citizens of Dublin." The rebellion of 1798 was sternly and cruelly repressed. The project of a legislative union between the British and Irish parliaments was taken up in earnest by Pitt's government. Grattan from the first denounced the scheme with implacable hostility.

When in 1799 the government brought forward their bill it was defeated in the Irish House of Commons. Grattan was still in retirement. His popularity had temporarily declined, and the fact that his proposals for parliamentary reform and Catholic emancipation had become the watchwords of the rebellious United Irishmen had brought upon him the bitter hostility of the governing classes. He was dismissed from the privy council; his portrait was removed from the hall of Trinity College; the Merchant Guild of Dublin struck his name off their rolls. But the threatened destruction of the constitution of 1782 quickly restored its author in the affections of the Irish people. On Jan. 15, 1800 the Irish parliament met for its last session; on the same day Grattan secured by purchase a seat for Wicklow; and at a late hour, while the debate was proceeding, he appeared to take his seat. "There was a moment's pause, an electric thrill passed through the House, and a long, wild cheer burst from the galleries." (Lecky, *Leaders* of *Public Opinion in Ireland.)* Grattan's strength gave way when he rose to speak and he obtained leave to address the House sitting. For more than two hours he kept his audience spellbound by a flood of epigram, of sustained reasoning, of eloquent appeal. After prolonged debates Grattan, on May 26, spoke finally against the committal of the bill, ending with an impassioned peroration in which he declared, "I will remain anchored here with fidelity to the fortunes of my country, faithful to her freedom, faithful to her fall." (Grattan's Speeches, iv. 23). These were the last words spoken by Grattan in the Irish parliament.

For the next five years Grattan took no active part in public affairs; in 1805 he became a member of the parliament of the United Kingdom. He modestly took his seat on one of the back benches, till Fox brought him forward to a seat near his own, exclaiming, "This is no place for the Irish Demosthenes!" When Fox and Grenville came into power in 1806 Grattan was offered, but refused to accept, an office in the government. In the following year he showed the strength of his judgment and character by supporting, in spite of consequent unpopularity in Ireland, a measure for increasing the powers of the executive to deal with Irish disorder. Roman Catholic emancipation, which he continued to advocate with unflagging energy though now advanced in age, became complicated after 1808 by the question whether a veto on the appointment of Roman Catholic bishops should rest with the crown.

Grattan supported the veto, but a more extreme Catholic party was now arising in Ireland under the leadership of Daniel O'Connell and Grattan's influence gradually declined. He seldom spoke in parliament after 1810, the most notable exception being in 181j, when he separated himself from the Whigs and supported the final struggle against Napoleon. His last speech of all, in 1819, contained a passage referring to the union he had so passionately resisted, which exhibits the statesmanship and at the same time the equable quality of Grattan's character. His sentiments with regard to the policy of the union remained, he said, unchanged; but "the marriage having taken place it is now the duty, as it ought to be the inclination, of every individual to render it as fruitful, as profitable and as advantageous as possible." He died on June 6, 1820, and was buried in Westminster Abbey close to the tombs of Pitt and Fox. His statue is in the outer lobby of the Houses of Parliament at Westminster. Grattan had married in 1782 Henrietta Fitzgerald, a lady descended from the ancient family of Desmond, by whom he had two sons and two daughters.

The most searching scrutiny of his private life only increases the respect due to the memory of Grattan as a statesman and the greatest of Irish orators. Sydney Smith said with truth of Grattan soon after his death: "No government ever dismayed him. The world could not bribe him. He thought only of Ireland; lived for no other object; dedicated to her his beautiful fancy, his elegant wit, his manly courage, and all the splendour of his astonishing eloquence." (Sidney Smith's *Works*, ii, 166–167.)

(C.)

GRATZ, HEINRICH (1817–1891), German-Jewish historian. was born at Xions. Posen, Oct. 31. 1817. He spent three years at Oldenburg as assistant and pupil of S. R. Hirsch. He matriculated in 1832 at Breslau. headquarters of Abraham Geiger, leader of Jewish reform. whose attitude repelled him. Gratz remained a conservative, in spite of the radical views on the Bible and tradition which made him an opponent of Hirsch. He fought for freedom of thought. but not of ritual practice. In 1853 he became famous by the publication of the fourth volume of his history of the Jews, in which he dealt with the Talmud. In 1869 he became a professor of Breslau university. His *Geschichte der Juden* (11 vol., 1853–1875, Eng. trans. 5 vol., 1889–95) is a work of genius, in spite of his biased judgments and lack of sympathy with mysticism.

Gratz died at Munich on Sept. 7, 1891.

A full bibliography of Gratz's works and a memoir are in the *Jewish Quarterly Review,* iv, 194. A memoir was prefixed to the "index" volume of the *History* in the U.S. reissue of the Eng. trans., 6 vol. (1898).

GRAUBÜNDEN (Fr. GRISONS; It., GRIGIONI), most easterly of the Swiss cantons and the largest, though relatively sparsely populated. Pop. (1950) 137,100, giving a density per sq.mi. of 49.9. Its area is 2,745 sq.mi., of which more than a half is classed as productive (forests covering about one-fifth of the total), but it has 138.6 sq.mi. of glaciers, ranking in this respect next after the Valais and before Bern. The whole canton is mountainous; the principal glacier groups are those of the Tödi, N. (11,876 ft.), of Medels, S.W. (10,531 ft.), of the Adula Alps, S.W. (Rheinwaldhorn, 11,161 ft.), with the chief source of the Rhine. of the Bernina, S.E. (13,284 ft.), the most extensive of the Albula, E. (Piz Kesch, 11,214 ft.), and of the Silvretta, N.E. (Piz Linard, 11.191 ft.).

The principal valleys are those of the upper Rhine and of the upper Inn (or Engadine, *q.v.*). The three main sources of the Rhine are in the canton. The valley of the Vorder Rhine is called the Biindner Oberland, that of the Mittel Rhein the Val Medels and that of the Hinter Rhein (the principal), in different parts of its course, the Rheinwald, the Schams valley and the Domleschg valley; the upper valley of the Julia is named the Oberhalbstein. Other streams join the Ticino and so the Po, the Adda and the Adige. The inner valleys are the highest in Central Europe; among the loftiest villages are Juf, 6.998 ft. (the highest permanently inhabited village in the Alps)! at the head of the Avers glen, and St. Moritz, 6,037 ft., in the upper Engadine.

Below Chur, near Malans, good wine is produced, while in the Val Mesocco, etc.. maize and chestnuts flourish. Forests and the mountain pasturages are the chief source of wealth. There are many mineral springs. The climate, except on the southern slope of the Alps, is severe. Many tourists visit different spots in the canton, especially Davos (*q.v.*), Arosa and the Engadine. A railway runs from Maienfeld to Chur (*q.v.*), the cantonal capital, with a branch line from Landquart to Davos. From Chur the line bears west to Reichenau whence one branch runs beneath the Albula pass to St. Moritz, and another up the Vorder Rhine valley to Disentis. There are roads across the passes leading toward Italy.

The German-speaking part of the population live mainly around Chur and Davos, the Italian-speaking in the Val Mesocco, Val Bregaglia and the valley of the Poschiavo. The characteristic tongue of Graubunden is a survival of an ancient Romance language which has a scanty printed literature, but is still widely spoken. It is distinguished into two dialects: Romansh, which prevails in the Bundner Oberland and in the Hinter Rhein valley, and Ladin, which survives in the Engadine and in the neighbouring valleys of Bergun, Oberhalbstein and Munster. There are; however, in these regions German-speaking people, mostly as a result of immigration from the upper Valais in the 13th century. Much of the population is engaged in catering to tourists, but there is a considerable trade with Italy, particularly in the wines of the Valtellina. Some lead and silver mines were formerly worked, but are now abandoned.

The canton is divided into 14 administrative districts and includes 224 communes. It sends members to the federal *Standerat* and to the federal *Nationalrat.* The cantonal constitution has created a legislature (*Grossrat*—no numbers fixed by the constitution) elected by universal suffrage. The "obligatory referendum" obtains in the case of all lams and important matters of expenditure and revisions of the constitution.

History. — The greater part (excluding the three Italian speaking valleys) of the modern canton of Graubunden formed the southern part of the province of Raetia (*q.v.;* probably the aboriginal inhabitants, the Raeti, were Celts rather than, as was formerly believed, Etruscans), set up by the Romans after their conquest of the region in 1j B.C. The Romanized inhabitants were to a certain extent Teutonized under the Ostrogoths (A.D. 493–537) and under the Franks (from 537 on). Governors called *Praesides* are mentioned in the 7th and 8th centuries, while members of the same family occupied the episcopal see of Coire (founded 4th to 5th centuries).

About 806 Charles the Great made this region into a county, but in 831 the bishop procured for his dominions exemption ("immunity") from the jurisdiction of the counts, while before 847 his see was transferred from the Italian province of Milan to the German province of Mainz (Mayence) and was thus cut off from Italy to be joined to Germany. The bishop became a prince of the empire in 1170 and later allied himself with the rising power (in the region) of the Habsburgers. This led in 1367 to the foundation of the League of God's House or the *Gotteshausbund,* chiefly in order to stem his rising power, the bishop entering it in 1392. In 139j the abbot of Disentis, the men of the Lugnetz valley and the great feudal lords of Razuns and Sax, joined in 1399 by the counts of Werdenberg, formed another league, called the *Oberbund* (as comprising the highlands in the Vorder Rhine valley) and also wrongly the Grey league (as the word interpreted "grey" is simply a misreading of *graven* or counts, though the false view has given rise to the name of Graubiinden or Grisons for the whole canton.

Finally, in 1436, the third Raetian league was founded by the former subjects of the count of Toggenburg, whose dynasty then became extinct; they include the inhabitants of the Prattigau, Davos, Maienfeld, the Schanfigg valley, Churwalden and the lordship of Belfort (*i.e.,* the region round Alvaneu), and formed ten bailiwicks: whence the name of the league—*Zehngerichtenbund* or league of ten jurisdictions. In 1450 the *Zehngerichtenbund* concluded an alliance with the *Gotteshausbund* and in 1471 with the *Oberbund;* but of the so-called perpetual alliance at Vazerol, near Tiefenkastels, there exists no authentic evidence in the oldest chronicles. though diets were held there. In 1496 the possessions of the extinct counts of Toggenburg passed to the elder Habsburgers, the head of whom, Maximilian, was already emperor-elect, and desired to maintain the rights of his family there and in the Lower Engadine. Hence in 1497 the *Ober Bund* and in 1498 the *Gotteshausbund* became allies of the Swiss confederation.

War broke out in 1499, but was ended by the great Swiss victory (May 22, 1499) at the battle of the Calven gorge (above Mals) which, added to another Swiss victory at Dornach (near Basel), compelled the emperor to recognize the *practical* independence of the Swiss and their allies of the empire. In 1526, by the articles of Ilanz, the last remaining traces of the temporal jurisdiction of the bishop of Coire was abolished. In 1512 the three leagues had conquered from Milan the rich and fertile Valtellina, with Bormio and Chiavenna, and held these districts as subject lands until in 1797 they were annexed to the Cisalpine Republic. After the emperor had formally recognized, by the treaty of Westphalia (1648), the independence of the Swiss confederation, the rights of the Habsburgers in the Prattigau and the Lower Engadine were bought up (1649 and 1652). In 1803, after a brief inclusion in the Helvetic republic, it entered, under the name of canton of the Graubünden or Grisons, the reconstituted Swiss confederation.

GRAUN, KARL HEINRICH (1701–1759), German composer, the youngest of three brothers, all musicians, was born on

May 7, 1701, at Wahrenbrück, Saxony. Graun's beautiful soprano voice secured him an appointment in the choir at Dresden. At an early age he composed a number of sacred cantatas and other pieces for the church service. He completed his studies under Johann Christoph Schmidt (1664–1728), and profited much by the Italian operas which were performed at Dresden under the composer Antonio Lotti. He made his début as a tenor in opera at Brunswick, in a work by Schürmann, an inferior composer of the day; but not being satisfied with the arias assigned him he rewrote them, and in the result was commissioned to write a complete opera for the next season. This work, *Polydorus* (1726), and five other operas, together with two settings of the Passion, belong to the Brunswick period. In 1735 Frederick the Great, at that time crown prince of Prussia, engaged Graun for his private chapel at Rheinsberg. There he remained for five years, and wrote a number of cantatas, mostly to words written by Frederick himself in French, and translated into Italian by Boltarelli. On his accession to the throne in 1740, Frederick sent Graun to Italy to engage singers for a new opera to be established at Berlin. Graun remained a year on his travels singing in the chief cities of Italy. After his return to Berlin he was appointed conductor of the royal orchestra (*Kapellmeister*) and in this capacity he wrote 28 operas, all to Italian words, of which the last, *Merope* (1756), is perhaps the best. It was, however, in his oratorio *Der Tod Jesu* (1755) that he revealed to the full his powers and produced a work which gained for him the highest applause. In Germany, indeed, *Der Tod Jesu* long held a place similar to that occupied by *The Messiah* in England, being regularly performed in Holy Week for a century and a half after the composer's death. The *Te Deum* written to celebrate the victory of Prague (1757) was another of Graun's sacred choral works which found great favour and showed him at his best.

Graun died on Aug. 8,1759, at Berlin, in the same house in which, 32 years later. Giacomo Meyerbeer was born.

See K. Mennicke, *Hasse und die Brüder Graun als Sinfoniker* (1906), in which a thematic catalogue of Graun's works will be found

GRAU SAN MARTÍN, RAMON (188;–), Cuban statesman, was born Sept. 13, 1887, in Pinar del Río, Cuba, the son of a wealthy tobacco merchant. He was educated at the University of Havana, receiving his M D. degree in 1908, and continued medical studies at several European schools. Grau San Martin, who became titular professor of physiology at the University of Havana in 1921, resigned in 1927 in protest against the dictatorship of Gerardo Machado. Two years later he was imprisoned by the police for revolutionary activities.

After Machado was ousted in the revolution led by Col. Fulgencio Batista y Zaldívar in 1933, Grau San Martin became president and held office for four months, resigning in Jan. 1934. As head of a Centrist political group, he announced in 1940 that he would run as opposition candidate to Batista for the presidency. He declared the Centrists were committed to a policy of economic and political co-operation with the United States and denounced the Batista followers as "Reds." He was defeated by Batista in the election of July 1940.

Grau San Martin again became a presidential candidate in 1944, this time successfully; his opponent was Carlos Saladrigas Zayas, a Cuban attorney who had Batista's support but lacked the dynamism and popularity of his mentor.

Assuming the presidency on Oct. 10, 1944, Grau San Martin pledged democratic rule. The first two years of his tenure were marked by rumblings of revolutionary plottings against his regime. While his personal popularity remained high, he was attacked by Cuban conservatives.

He was also accused of being too lenient with the Cuban Communists. Grau San Martín, however, maintained that the influence of the Communist party in Cuba was negligible.

In 1945 and 1946, Grau San Martin's government put down two short-lited revolts. He was succeeded in the presidency by Carlos Prío Socarrás in 1948.

GRAVAMEN, a complaint or grievance, the ground of a legal action and particularly the more serious part of a charge against an accused person. In English the term is used chiefly in ecclesiastical cases, being the technical designation of a memorial presented from the lower to the upper house of convocation, setting forth grievances to be redressed, or calling attention to breaches in church discipline.

GRAVE. (1) A place dug out of the earth in which a body is laid for burial (see CEMETERY). The verb "to grave," is used of the making of incisions in a hard surface (see ENGRAVING, LINE). (2) A title, now obsolete, of a local administrative official for a township in certain parts of Yorkshire and Lincolnshire; it also appears in the form "grieve," which in Scotland and Northumberland is used for sheriff (*q.v.*), and for a bailiff or understeward. It is probably connected with the German *graf,* count, and thus appears as the second part of many Teutonic titles, such as landgrave, burgrave and margrave. "Grieve," on the other hand, seems to be a form of O.E. *gerefa,* reeve. (3) To grave a ship's bottom is to clean it in a specially constructed dock, called a "graving dock."

GRAVE CREEK MOUND, a prehistoric earthwork, near Moundsville, Marshall county, West Virginia, known since 1734, as appears from the date cut in a tree growing from its summit. It is the largest of the conical type of mounds in the United States, having a basal diameter of 320 ft., a height of 70 ft. and about 1,870,000 cu.ft. of solid contents. It is symmetrical in form and has a depression in the top. In 1838 excavation disclosed a burial vault at the base and another 30 ft. above, each built of logs and covered with stones. The lower contained two human skeletons, the upper vault one; and with each were thousands of shell beads, mica ornaments, copper bracelets and several stone articles, including it was said, one with an inscription which gave rise to much discussion. Subsequent investigation, however, failed to establish the authenticity of the stone or to prove that it came from the mound.

GRAVEL, an aggregate of more or less rounded rock fragments coarser than sand, technically more than two millimetres in diameter. Gravel beds in some places contain accumulations of heavy minerals, such as metallic ores, as cassiterite, a major source of tin, or native metals in nugget form. A notable example of the latter is the extensive auriferous gravel of Tertiary age in California, goal of much hydraulic mining. Gravels also are widely used building materials (see CONCRETE; FOUNDATIONS).

The rounding of gravel results from abrasion in the course of stream transport or milling by the sea. Gravel deposits accumulate in parts of stream channels or on beaches where the water action is too rapid to permit sand to remain. Because of changing conditions, gravel formations are generally more limited and more variable in coarseness, thickness and configuration than are sand or clay deposits. .Persistent accumulation of gravel or pebble beds may take place along an inner breaker zone, on a beach otherwise sandy. Cobble and pebble beaches (shingle beaches) often take their origin from the points of rocky cliffs.

In many regions there are marine gravels wholly resembling those of the seashore, at levels tens of hundreds of feet above tide level. Such gravel terraces (or raised beaches) may extend great distances and indicate that the sea at one time stood relatively higher. River gravels occur mostly in the middle and upper parts of streams where the currents are most active. Ancient terraces of gravel are found at levels much above those of the present rivers. They mark a former greater activity of streams or are evidence of uplift of the land or lowering of the sea, whereby the rivers have been able to cut their beds to a lower level. The Lafayette and related terrace gravel formations of the Atlantic and Gulf coastal plains of North America are products of both fluvial and marine action.

Fragments in gravels range from pebble to boulder size. Prolonged weathering and extended transport by long rivers on continental masses result in more complete rounding and selection as to size and physically and chemically durable rock materials. Gravels on smaller land masses, and where siliceous rocks are missing, are less well selected and less recognizable as definite rock formations. Conglomerates (*q.v.*) are cemented gravels. See also ALLUVIUM; BEACH; SEDIMENTARY ROCKS. (C. K. WE.)

GRAVELINES, (Flem. Gravelinghe), a seaport town of northern France, in the *département* of Nord and arrondissement of Dunkirk, near the mouth of the Aa, 15 mi. S.W. of Dunkirk on the railway to Calais. Pop. (1954) 2,078.

The canalization of the Aa by a count of Flanders (about mid-12th century) led to the foundation of Gravelines (grave-linghe, meaning "count's canal"). It finally passed from the Spaniards to the French by the treaty of the Pyrénées in 1659. It is fortified by a double circuit of ramparts and by a tidal moat.

The river is canalized and opens out beneath the fortifications into a floating basin. Its trade has suffered because of the nearness of Calais and Dunkirk and the silting-up of the channel to the sea. It is a centre for the cod and herring fisheries. Imports consist of timber from northern Europe and coal from England, to which eggs and fruit are exported. Gravelines has paper manufactories, sugarworks, fish-curing works, salt refineries, chicory-roasting factories, a cannery for preserved peas and vegetables and an important timberyard.

The greater part of the population of Gravelines dwells in the maritime quarter of Petit-Fort-Philippe at the mouth of the Aa, and in the village of Les Huttes (to the east of the town), which is inhabited by the fisherfolk.

GRAVES, ROBERT RANKE (1895–), English poet and author, the son of A. P. Graves, the Irish song writer, author of "Father O'Flynn." Robert Graves was educated at Charterhouse, and at St. John's college, Cambridge. During World War I he served in France with the royal Welsh fusiliers, and was seriously wounded at the Somme.

After 1915 Graves published several volumes of poetry, and critical essays. His Collected *Poems* were published in 1927, 1938 and 1948. His prose works include: The Meaning of Dreams (1924); *Contemporary* Technique of Poetry (1925); Goodbye to *All That* (1929); *I,* Claudius (1934); The Island of *Unwisdom* (1949).

GRAVES, THOMAS GRAVES, 1st Baron (1725?–1802), British naval officer, commander of the British forces in the battle of the Virginia Capes, during the American Revolution, was the son of Adm. Thomas Graves of Cornwall. Graves met De Grasse's fleet, which had sailed from the West Indies to aid the American and French land forces, off the entrance to Chesapeake bay on Sept. 5, 1781, and was decisively defeated. De Grasse then drew Graves to the south for three days so as to permit a squadron from Newport to enter the Chesapeake. Although the battle cost the British only one ship, it sealed the fate of Lord Cornwallis, who was penned in on the Yorktown peninsula and expecting rescue by the Royal Navy. Cornwallis surrendered on Oct. 19. Graves became a vice-admiral and then admiral, and was made a baron for his share in the battle of June 1, 1794, during the war with France. A severe wound in the right arm, received during this battle, caused him to resign his command. He died in Feb. 1802.

(J. B. Hn.)

GRAVESEND, a municipal borough and river port in the Gravesend parliamentary division of Kent, Eng., on the right bank of the Thames, 22 mi. E.S.E. of London by road. Pop. (1951) 44,560. Area 6.3 sq.mi. At Swanscombe, about 2 mi. W., parts of the skull of Smanscombe man were found during quarrying (1935–55). They date from the Great Interglacial Age. Nearby was situated the Roman settlement of Vagniacae. Gravesend is mentioned in Domesday Book as Gravesham, possessing a landing place, or hithe, on the river. Although the town was originally concerned with agriculture, Richard II granted sole ferry rights for conveying passengers to London. Arising out of these ferry rights, for more than four centuries many illustrious persons were received in the borough on their way to and from the capital. The borough was incorporated by charter in 1562, the present charter dating from 1632. Pocahontas, the American Indian princess, died at Gravesend in 1617, and was buried in St. George's church, now known as St. George's Chapel of Gnity (Pocahontas memorial).

For a variety of reasons, not least of them the ferry rights mentioned above, the town for centuries has been closely associated with administrative duties in relation to shipping on London's river. From the 16th century onward it became increasingly active in the handling of Britain's expanding maritime trade. Today Gravesend is the centre for customs, the Port of London Health authority and the Trinity House pilots. There is a passenger and vehicle ferry across the Thames to Tilbury.

The town's prosperity increased greatly during the first half of the 19th century when, as a result of the coming of the steamboat, Gravesend became well known as a health resort and watering place. This period saw rapid growth, the building of the Town pier and the Royal Terrace pier, and the purchasing and layout of many parks and public gardens.

There followed a process of transition to its present state as a modern industrial, commercial and maritime centre. Jetties of paper mills, cement factories, engineering works, tire and rubber works, printing works, shipbuilding and repair slipways flank the river frontage opposite Tilbury docks. Today Gravesend is the shopping, commercial, educational and entertainment centre for a prosperous industrial belt stretching along several miles of the south bank of the Thames. To the south and east on rising ground lie the residential areas of the town, which are bounded by agricultural land.

GRAVES WINES are made from grapes grown in the vineyards of the Graves district of the Gironde, France. This district, which owes its name to its gravel soil, begins just outside Bordeaux and extends about 5½ mi. west of that city and 13 mi. to the south, along the left bank of the Garonne. It produces about 1,000,000 gal. of white wine (which is 3½% of the average annual production of white wine within the whole Bordeaux area) and just under one-third of this quantity of red wine. Generally the red Graves are inferior to those from the Médoc although there are important exceptions such as Château Haut-Brion, Château La Mission Haut-Brion and Château Pape Clément, but for dry white wines the Graves cannot be excelled.

The best white Graves — Domaine de Chevalier, Château La Tour Martillac and Château Carbonnieux among them — are dry or medium dry and possess a full subtle flavour; they are crisp but lack all sharpness. They have a low percentage of acidity and this causes them to age or mellow considerably, after four or five years in bottle. The bouquet becomes pronounced and the wine turns deep yellow: generally they are preferred when drunk young and fresh. The best red Graves have great quality and will improve and keep in bottle for many years; they can sometimes be distinguished from the wines of other districts in Bordeaux by a special flavour that seems to derive from the high proportion of gravel in the soil.

Château Haut-Brion is the best-known château of the whole district and it produces fine red and white wines, the red being classed as a "first growth," together with three from the Médoc, in the classification of 1855. Appellation *contrôlée* has been permitted to Graves wines which fulfil the legal standard since the beginning of the 20th century ("Graves Supérieures" being wines which possess a little more alcohol than "Graves"). An attempt was made to classify the individual chbteaux in 1953, but the result has been impartially criticized in France and cannot be considered definitive.

For the red wines the same grapes are used as in the Médoc (*q.v.*), while for the white wines a mixture of the Sémillon and Sauvignon is customarily used in the same vineyards.

The name "Graves" is often applied to white wines from other countries; although they never rival true Graves, they may approach its style.

See A. Lichine and W. E. Massee, Wines of France (1951); J. R. Roger, "Vignoble Girondin" in ***Revue*** du ***Vin*** de *France,* no. 168 and 172 (1957).

(C. C. H. F.)

GRAVIES. A gravy is a sauce made from the juices and fats extracted from meats in cooking. The term is also applied to the thickened liquid of stews. Ordinary meat gravies are distinguished from sauces by their predominating element (osmazome), which gives them their characteristic meat flavour. **A** plain meat gravy is the diluted juices of meat. It may be made: (a) by pouring hot water over a dripping pan, adding salt and pepper and boiling until the sediment in the pan has coloured to a brown colour; where a plain gravy is not well coloured, extra colouring may be added in the form of browned flour or of an artificial colouring made for the purpose; (b) by stewing shank-ends of legs of mutton or other bones, gravy beef, etc., to form a stock; (c) by artificial means; *i.e.*, gravy powders sold for the purpose. Meat gravies are often thickened with flour, and milk is sometimes added. Gravy is used with roast meat, game and poultry, but where meat is stuffed with forcemeat it is usual to serve a thickened gravy. In certain cases it is advisable to have extra flavouring added to the gravy, such as garlic, spices, walnut or mushroom ketchup, lemon juice, etc. Generally speaking, these are used for stews and inferior meats, etc., to give extra flavour. For varnishing galantines, savoury rolls, etc., glaze is used. This is made by reducing a good brown gravy (generally made from brown stock) until it is of sticky, glazelike consistency. (J. A. SI.)

GRAVINA, a town and episcopal see of Apulia, Italy, in the province of Bari, 36 mi. S.W. from Bari by rail (29 mi. direct), 1,148 ft. above sea level. Pop. (1936) 21,909 (town), 23,208 (commune). The town perhaps occupies the site of the ancient Blera, a post station on the Via Appia. The cathedral is mainly of the 15th century. The town is surrounded with walls and towers, and a castle of the emperor Frederick II rises above the town, which later belonged to the Orsini, dukes of Gravina; just outside it are dwellings and a church (S. Michele), all of which have been hewn in the rock.

GRAVING DOCK, a narrow basin, closed by gates or by a caisson, in which a vessel may be placed and from which the water may be pumped or let out, leaving the vessel supported on blocks. In this way the ship is left dry and accessible for the purposes of examination, cleaning and repairs of the under-water parts of the hull. In British ports the term "dry dock" is more often used than graving dock. The word "graving" was originally used to denote the cleaning of a ship's bottom by means of scraping or burning and coating with tar. (*See* DOCKS.) (N. G. B.)

GRAVITATION. Few physical phenomena are roughly as well known to everybody as gravitation. The common fact that any unsupported body falls to the ground was certainly known even to primitive man. The attempt to understand the laws of, and the reasons for, this very ordinary observation has given occasion to several fundamental advances in scientific thought, It is the purpose of this article to sketch briefly the main developments of the theory of gravitation.

The first to unravel the law of motion of a falling body was Galileo Galilei, one of the founders of the scientific method. He not only showed that the acceleration of any falling body is constant and has the same value for all bodies, but brought together, perhaps for the first time, mathematical analysis and experiment. This combination of analysis and experiment is a true landmark in the history of science, and is easily the most fruitful innovation that has ever been introduced for the purpose of discovering scientific truth.

The next to add a fundamental discovery to our knowledge of gravitation was Sir Isaac Newton. He found out the inverse-square law, according to which any two bodies in the universe attract each other in proportion to the product of their masses and inversely as the square of their distance apart. He worked this into a self-consistent scheme of dynamics and formulated completely the fundamental laws of mechanics. His work is another landmark in the history of science.

The task of developing Newton's ideas from the mathematical point of view fell to the great French mathematicians of the early 19th century, mainly Siméon Poisson, Pierre Simon Laplace, Joseph Lagrange and Jean d'Alembert. In their hands the Newtonian theory of gravitation reached its highest perfection, and became what is known in our day as the classical theory of gravitation. This is sketched briefly in the first of the following sections.

Almost a century elapsed before any significant progress was made towards understanding gravitation. In the first quarter of the 20th century, however, Albert Einstein made a number of revolutionary discoveries. First he showed that the Newtonian assumption that time is a universal parameter independent of the reference system, is not correct. As a consequence the fundamental Newtonian equations of motion must be revised. Next he set up his famous equivalence principle and proved the equality of inertial and gravitational mass. Following in the footsteps of Hermann Minkowski he built up the concept of four-dimensional space-time and suggested that matter determines the geometry of space-time. According to him gravitation is a consequence of the fact that the space-time around matter is not flat, but curved. This is discussed briefly in the second section below.

The development of Einstein's ideas is accompanied by huge mathematical complications, the root of which lies in the use of arbitrary variables to describe events in space-time. To these must be added the difficulty of ascribing clear-cut physical meaning to such arbitrary variables. These complications and difficulties more recently led George David Birkhoff to see how far one could build up a self-consistent theory of gravitation by using a flat space-time and Lorentz variables alone. He thus gave up the connection between matter and geometry of space-time, but, by way of compensation, achieved a very considerable simplification of the mathematical machinery required to develop the theory of gravitation. Experiment alone can decide whether the Einstein or the Birkhoff theory is closer to the facts, although from the point of view of philosophical depth and beauty the advantage is unquestionably on the side of the former. Birkhoff's theory forms the subject of the third section below.

Another significant attempt to depart from Einstein's formulation of the theory of gravitation and to simplify the concepts used, is due to E. A. Milne. His theory has led to a reformulation of the fundamental law of gravitation, in which the Newtonian law appears as a first approximation. He has shown that an observer may at will describe events in terms of either one of two times, "kinematical time" or "dynamical time," but that his choice of time also determines his choice of the geometry of space-time. In the hands of Milne and his collaborators this theory has led to far-reaching results. It forms the substance of the fourth section in this article.

Part II of this article is concerned with the measurement of gravitational forces.

PART I. THEORIES OF GRAVITATION

Classical Newtonian Theory.—The classical formulation of the well-known Newtonian theory, expressed by the inverse-square law of attraction, and due mainly to Laplace and Poisson. may be briefly sketched as follows: there is a scalar gravitational potential, φ, which obeys Poisson's equation,

$$\nabla^2\varphi = -4\pi\rho \qquad (1.1)$$

where p is a function of position, *i.e.*, a function of the space variables (x, y, z), defining the distribution of matter in space. This function thus expresses essentially the density of matter (mass per unit volume) in space. For example, in a region where matter is uniformly distributed, $\rho=$ const.; in a region where the density varies exponentially, $\rho = e^{-kr} (r = \sqrt{x^2+y^2+z^2})$, etc. In empty space $(\rho = 0)$ this reduces to Laplace's equation

$$\nabla^2\varphi = 0. \qquad (1.2)$$

If a solution of (1.1) or (1.2) can be found, the force is given by

$$F = -\rho\nabla\varphi \qquad (1.3)$$

and the equation of motion of matter is, by Newton's second law of motion

$$\frac{d}{dt}(\rho v) = F \qquad (1.4)$$

where v is the velocity of p. The latter expresses the mass density.

Example.—Suppose it is desired to find the motion of a particle of mass m in the gravitational field of a large spherical body of mass M. In the space outside the latter, the solution of (1.2) satisfying the condition of spherical symmetry, regular everywhere ($r=0$ excluded) and vanishing at infinity is

$$\varphi = A/r$$

where A is an integration constant. From the condition that at the surface of the sphere of mass M, the potential is M/r, it is seen that $-A=M$, and

$$\varphi=-M/r.$$

From (1.3) the force is

$$F=-m\frac{\partial}{\partial r}\left(-\frac{M}{r}\right)=-\frac{mM}{r^2}$$

and from (1.4) the equation of motion is,

$$\frac{d}{dt}\left(m\frac{ds}{dt}\right)=m\frac{d^2s}{dt^2}=-\frac{mM}{r^2}$$

where r is the distance from the centre of the sphere generating the gravitational field and s is the path described by the mass particle.

In order that equations (1.1) to (1.4) may have a meaning, it is necessary to introduce a reference system. It is shown without difficulty that (1.1) and (1.3) are invariant with respect to changes of the space co-ordinates. With regard to (1.4) the situation is more complex. For $\rho=$const. (1.4) can be written

$$\rho\frac{d^2s}{dt^2}=F. \qquad (1.5)$$

Let us now investigate for what transformations (1.5) is invariant. In Newtonian mechanics it is assumed that the time is independent of the reference system, and hence also independent of the observer. Let us consider two cartesian reference systems moving with respect to each other with uniform velocity. Without loss of generality we may assume that the velocity is parallel to one of the axes, say the x-axis. Then, according to classical mechanics the transformation from the first co-ordinate system, S_1, to the second, S_2, is:

$$\begin{aligned} x_2&=x_1-vt_1\\ y_2&=y_1\\ z_2&=z_1\\ t_2&=t_1 \end{aligned} \qquad (1.6)$$

For a particle moving in any way whatever, the equations of motion in S_1 are

$$F_x=m\frac{d^2x_1}{dt_1^2},\ F_y=m\frac{d^2y_1}{dt_1^2},\ F_z=m\frac{d^2z_1}{dt_1^2}. \qquad (1.7)$$

In S_2 we have, from (1.6):

$$\frac{dx_2}{dt_2}=\frac{dx_1}{dt_2}-v\frac{dt_1}{dt_2},\ \frac{dy_2}{dt_2}=\frac{dy_1}{dt_2},\ \frac{dz_2}{dt_2}=\frac{dz_1}{dt_2},\ 1=\frac{dt_1}{dt_2}$$

and therefore

$$\frac{d^2x_2}{dt_2^2}=\frac{d^2x_1}{dt_1^2},\ \frac{d^2y_2}{dt_2^2}=\frac{d^2y_1}{dt_1^2},\ \frac{d^2z_2}{dt_2^2}=\frac{d^2z_1}{dt_1^2};$$

hence the equations of motion in S_2 are, from (1.7)

$$F_x=m\frac{d^2x_2}{dt_2^2},\ F_y=m\frac{d^2y_2}{dt_2^2},\ F_z=m\frac{d^2z_2}{dt_2^2} \qquad (1.8)$$

bearing in mind that m is assumed to be independent of the reference system. Hence the equations of motion are *invariant* with respect to the transformation (1.6). It may also be readily shown that they are invariant under rigid rotations.

The transformation (1.6) is known as a Galilean transformation. It can be easily shown that the Galilean transformations form a group (*see* GROUPS), which is known as the Galilean group. The theorem may therefore be stated: The Newtonian equations of motion are invariant with respect to the transformations of the Galilean group.

A number of interesting conclusions may be drawn from this theorem. In the first place it is clear that if *one* reference system exists in which the Newtonian equations of motion hold, then they also hold in an infinite number of reference systems obtained by applying to the first the transformations of the Galilean group. Reference systems in which the equations of motion hold are known as *inertial systems*. The theorem above may therefore be restated as follows: If an inertial system exists, then all other reference systems obtained from it by applying transformations of the Galilean group are also inertial. This is known as Mach's principle. The fundamental question in classical mechanics, therefore, is the discovery of a fundamental inertial system of reference. Without it, the formulation of the Newtonian theory of gravitation has no meaning. Since Mach's analysis it is known that this problem is essentially insoluble, and that the existence of a fundamental inertial system is a *postulate* of classical Newtonian mechanics and therefore also of the classical theory of gravitation. From this point of view, the latter may therefore be characterized as follows: (1) The time of an event is independent of the reference system. (2) There exists a fundamental inertial reference system. (3) In the fundamental reference system the Newtonian equations of motion hold.

Einstein's Relativistic Theory.—In 1905 Einstein formulated his special theory of relativity. Among other fundamental contributions, he first recognized clearly that to compare the time which holds in different reference systems one must make use of a physical experiment; *i.e.*, one must send a signal from the observer anchored to one reference system to the observer anchored to another. Since the only kind of signal which can be sent in general between two reference systems in motion with respect to each other is a light signal, and because the speed of propagation of light in space is finite, Einstein showed that, as a consequence, time depends on the co-ordinate system. Hence he reached the following essential conclusion:

(a) The time of an event is one of its co-ordinates, and depends on the reference system.

In place of the postulates of classical gravitational theory stated at the end of the preceding section, the Einstein theory of gravitation begins with the following postulates: (1) All systems of reference are equivalent for the description of natural laws, in particular for the laws of gravitation. (2) Gravitation is a consequence of the geometry of physical space. (3) Matter determines the geometry of physical space.

Since, according to the results of Karl Gauss and Georg Riemann, the geometry of any space is determined by its metric fundamental from,

$$ds^2=g_{\mu\nu}dx^\mu dx^\nu \qquad (2.1)$$

and since according to conclusion (a) the three space co-ordinates (x_1, x_2, x_3) and the time co-ordinate (x_4) are all of the same kind, it follows that physical space is four dimensional, and the indices μ, ν in (2.1) have the values 1,2,3,4. In accordance with well-known conventions, repeated indices, as in (2.1) are summed over all values of these indices.

In accordance with postulate (2), the law of gravitation must be expressed in terms of the tensor $g_{\mu\nu}$. Since this tensor is symmetrical, ($g_{\mu\nu}=g_{\nu\mu}$) there are ten different components of $g_{\mu\nu}$ which play the role of the gravitational potential of classical theory. Since $g_{\mu\nu}$ is a tensor, its use as a gravitational potential also satisfies the requirements of postulate (1).

It now remains to satisfy the requirements of postulate (3); *i.e.*, to determine $g_{\mu\nu}$ in such a way that, just as in classical theory, the distribution of matter (and energy) determines the gravitational potential $g_{\mu\nu}$. The inclusion of energy is essential because, from the restricted theory of relativity it follows that to an energy E corresponds an amount of matter E/c^2, where c is the velocity of light in vacuum. Further, since classical theory correctly describes gravitational phenomena, at least in the first approximation, it is necessary to require that the new equation determining the potential should reduce for weak fields to Poisson's equation (1.1) and that the new equation of motion should also reduce, for the same case, to the classical Newtonian equation (1.3).

The above considerations limit considerably the choice of the law of gravitation. Since Poisson's equation (1.1) is of the second order the new law should involve at most second-order derivatives in the components of $g_{\mu\nu}$. There is only one fundamental geometrical tensor satisfying this requirement, *i.e.*, the Riemann-Christoffel tensor $R^{\alpha}_{\mu\nu\beta}$ or its contracted form for $\alpha=\beta$, $R_{\mu\nu}$. Guided by such considerations, Einstein chose for his law of gravitation in empty space

$$R_{\mu\nu}=0 \qquad (2.2)$$

which reduces to Laplace's equation (1.2) for weak fields outside of matter. In the presence of matter, one must generalize the function ρ expressing its distribution in the classical static case: one builds up the energy-momentum tensor $T_{\mu\nu}$ which expresses the distribution of matter and its motion. In order to obtain Poisson's equation as a limiting case, as described above, and to satisfy the conservation of energy and momentum, one must write,

$$R_{\mu\nu}-\frac{1}{2}Rg_{\mu\nu}=-8\pi T_{\mu\nu} \tag{2.3}$$

where R is the scalar R^{α}_{α}. It is important to notice that the divergence

$$T^{\nu}_{\mu;\nu}=0 \tag{2.4}$$

because of the conservation of energy and momentum. The semicolon indicates covariant differentiation (see TENSOR ANALYSIS). But, because of Ricci's theorem, the divergence $(R^{\nu}_{\mu}-\frac{1}{2}Rg)^{\nu}_{\mu;\nu}$ vanishes identically.

It now remains to determine the equation of motion. In the absence of gravitation the motion of a particle is a straight line, *i.e.*, a geodesic in the Minkowski space characterized by

$$ds^2=dx_1^2+dx_2^2+dx_3^2-dx_4^2 \tag{2.5}$$

since in this case $g_{11}=g_{22}=g_{33}=1$, $g_{44}=-1$, $g_{\mu\nu}=0(\mu\neq\nu)$. This geodesic, as is well known, satisfies the condition $\delta\int ds=0$. Einstein then showed that acceleration of the reference system is equivalent to the appearance of a gravitational field in the accelerated reference system (principle of equivalence) and inferred that the path of an exploring particle in any gravitational field must be a geodesic satisfying the condition

$$\delta\int ds=0 \tag{2.6}$$

with respect to the ds^2 (2.1), where the tensor $g_{\mu\nu}$ is found from (2.3) (or [2.2]). He later showed that (2.6) reduces to (1.3) for the case of weak fields.

The principle of equivalence can be more accurately stated as follows: In any infinitesimal region of any gravitational field it is always possible to find a local reference system with respect to which $d^2x\mu/ds^2=0$ for all world-lines through a point.

From the above it is seen that the language adequate for the expression of Einstein's theory of gravitation is that of tensors. The fundamental group of transformations is that of the arbitrary transformations of four independent variables,

$$x_1'=x_1(x_1, x_2, x_3, x_4),\ x_2'=x_2(x_1, x_2, x_3, x_4),\ \text{etc.} \tag{2.7}$$

This is an extremely complicated group and its complete structure has not yet been worked out. As a result the Einstein theory of gravitation is also very complicated and its consequences have only been worked out in a limited number of cases. Of the cases where the field equations (2.2) or (2.3) have been solved, perhaps the most important is the solution of $R_{\mu\nu}=0$ for the static field having spherical symmetry (Schwarzschild's solution). It is

$$ds^2=\frac{dr^2}{1-2m/r}+r^2d\theta^2+r^2sin^2\theta d\varphi^2-(1-2m/r)dt^2 \tag{2.8}$$

where r is the distance from the origin and m is the mass of the particle at the origin, which generates the gravitational field. From (2.8) and (2.6) when applied to the motion of a planet in the gravitational field of the sun, follows the formula for the advance of the perihelion

$$\frac{6\pi m}{a(1-e^2)}\quad \text{seconds per revolution} \tag{2.9}$$

where a is the semimajor axis of the elliptical path and e is the eccentricity. The path itself may be described as an ellipse in which the major axis revolves slowly with sun as axis, in the way described by (2.9). For Mercury the advance of the perihelion is 42 sec. per century, in good agreement with observation.

For light the path is a geodesic, subject from (2.5) to the condition that $ds=0$. Applied to the sun, there follows for the deflection of a light ray going by the limb of the sun,

$$4m/p \tag{2.10}$$

which amounts to 1.78 sec. for the case in question, in fairly good agreement with experiment.

Lastly, for a stationary atom placed on the surface of a heavy body $dr=d\theta=d\varphi=0$. Hence, if one compares the radiation emitted by two identical atoms, one on the surface of a star and the other on the surface of the earth, and assumes that the proper time (ds) for both is the same, one obtains for the ratio of the frequencies emitted by the two atoms

$$\frac{\nu_e}{\nu_s}=\frac{1-2m_s/r_s}{1-2m_e/r_e} \tag{2.11}$$

m_s, m_e, mass of the star and earth, respectively; r_s, r_e, radius of the star and earth, respectively. Hence, a spectral line emitted by the atom on the star has a greater frequency than the same spectral line emitted by a similar atom on the earth. The spectral line emitted by the atom on the star is shifted towards the red (red shift). It is to be noted that in this derivation of the red shift no mention is made of the light signal which conveys the information from the star to the earth. Formula (2.11) is in fairly good agreement with experiment.

It should be noted that the space described by Schwarzschild's form (2.8) is curved. The distance r from the origin is therefore not to be confused with the Euclidean distance, nor the variables θ, φ with the Euclidean angles. Nor is the time the same as the local time of restricted relativity. As a consequence it is impossible to compare the results obtained from (2.8) with experiments using local time and Euclidean distances and angles.

Cosmological Consequences.—Since the field equations (2.3) claim general validity, they may be applied to the study of the universe as a whole. However, analysis shows that they, just like the classical equation of Poisson (1.1), are incapable of being so applied as they stand. If one makes the simplest possible assumption, *i.e.*, that the distribution of matter in the large is homogeneous and isotropic, and space is unbounded, it follows from (1.1) (1.3) that F is undefined at a point. If one attempts the same analysis using (2.3) it turns out that the $g_{\mu\nu}$ are still undefined at any point, or else it is impossible to satisfy the proper regularity conditions. In the classical case it was proposed by Carl Neumann to use in place of (1.1) the equation

$$\nabla^2\varphi+\lambda\varphi=-4\pi\rho \tag{2.12}$$

whose fundamental solution is $e^{-\lambda r}/r$ instead of $1/r$ and gives a definite force at any point. In analogy with this, Einstein suggested that for cosmological applications one should write in place of (2.3) (λ=cosmological constant)

$$R_{\mu\nu}-\frac{1}{2}Rg_{\mu\nu}+\lambda g_{\mu\nu}=-8\pi T_{\mu\nu} \tag{2.13}$$

which reduces to (2.12) for weak fields. Einstein, W. De Sitter, N. F. Friedmann and Georges Lemaitre have found solutions of (2.13); of these, Einstein's solution corresponds to an unstable universe, De Sitter's to an empty one. The only solution of real physical interest is that due to Friedmann and, independently, to Lemaitre. This leads to an expanding universe in which the velocity of any point from any other chosen arbitrarily as origin is proportional to the distance. This has important applications to the recession of extragalactic nebulae discovered by E. C. Slipher and studied by Edwin Hubble, which show a red shift (Doppler effect) corresponding to a radial velocity of recession proportional to their distance from the earth. However, according to Hubble the experimental distribution, after all relativistic and other corrections have been applied, is not uniform. Rather the density of nebulae seems to increase as the distance increases. This contradicts the initial assumption and is a serious difficulty in relativistic cosmology.

Birkhoff's Theory of Gravitation.— The inherent complication of Einstein's theory and the difficulty about assigning definite physical meaning to the arbitrary variables employed to describe physical phenomena led G. D. Birkhoff (about 1941) to try a new theory of gravitation using a flat space-time ($R^{\alpha}_{\mu\nu\beta}=0$) and the Minkowski line element (2.5) ("electromagnetic space-time," as he calls it) as a basis. The variables used are thus the local space co-ordinates and the local time of restricted relativity, and have perfectly definite physical meanings, as made clear by Einstein himself. In place of Einstein's postulate (1), Birkhoff assumes that for the description of physical laws there is a fundamental Lorentz frame of reference, from which all others are obtained by applying a Lorentz transformation. The laws of physics, in particular of gravitation, are thus expressed invariantly or covariantly with respect to such transformation. The fundamental group of transformations is now the 10-parameter Lorentz group and thus much simpler than Einstein's group. From this point of view Birkhoff's theory is closer to classical Newtonian theory than Einstein's. As a consequence, the language adequate to express Birkhoff's theory is that of vectors in Minkowski's space-time. Birkhoff gives up the connection between matter and geometry and does not assume that gravitation is connected with the geometry of space-time.

The fundamental equation determining the gravitational potential is now, according to Birkhoff

$$\Box h_{ij} = -8\pi T_{ij} \tag{3.1}$$

where $\Box$ is D'Alembert's operator, h_{ij} is the gravitational potential and T_{ij} is the momentum-energy tensor. (3.1) clearly reduces to (1.1) for static distributions of matter and static gravitational fields. Thus the velocity of propagation of the gravitational potential and field is always that of light.

By generalizing (1.3) Birkhoff sets for the force equation

$$f_i = \left(\frac{\partial h_{ij}}{\partial x^k} - \frac{\partial h_{jk}}{\partial x^i}\right) u^j u^k \tag{3.2}$$

where u^j is the velocity. The equation of motion is obtained similarly, *i.e.*,

$$f^i = \frac{d}{ds}\left(m\frac{dx^i}{ds}\right). \tag{3.3}$$

Example: Field of a particle.

Let us try to find the field outside a single particle of mass m at rest at the origin. In empty space, (3.1) reduces to

$$\Box h_{ij} = 0; \tag{3.4}$$

h_{ij} can have singularities only at the points of world-lines where the mass-particle is. The asymptotic form of h_{ij} in the vicinity of m, and in a reference system where m is at rest is,

$$h_{11} = h_{22} = h_{33} = h_{44} = m/r,\ h_{ij} = 0 (i \neq j). \tag{3.5}$$

Further, $h_{ij} \to 0$ as $r \to \infty$ and of course all the components h_{ij} satisfy D'Alembert's equation. The conditions mentioned determine h_{ij} uniquely and (3.5) is therefore the only solution of the problem. Knowing the potential, the field of force is determined using (3.2).

It is worth noticing carefully that, as a consequence of the fact that (3.1) is linear, Birkhoff's theory is linear in the potential and the field, that is, the potentials and fields of several particles simply add together just as in classical theory. In contrast, Einstein's theory is not linear, and the field of several particles is not the sum of the separate fields of each particle.

It is apparent that Birkhoff's theory of gravitation is inherently much simpler than Einstein's. While very few problems of any physical interest have been solved with the help of the latter, the former may be used to attack certain questions of great physical and astronomical interest, among which may be mentioned the two-body, three-body and n-body problems. In Einstein's theory the first has already proved to be attended by very serious difficulties, and its solution can be obtained (T. Levi-Civita, Einstein and Leopold Infeld, Banesh Hoffmann) only by making approximations, the meaning of which is not entirely clear. In Birkhoff's theory, as shown by C. Graef (1943), the solution of this problem is fairly simple and direct. The orbit of each body may be described as an ellipse of which the apsidal line of the system advances at the rate of

$$\frac{3m_1^2 + 7m_1m_2 + 3m_2^2}{m_1 + m_2} \frac{2\pi}{a(1-e^2)} \tag{3.6}$$

seconds per revolution. Here m_1 and m_2 are the masses of the two bodies, a is the semimajor axis and e the eccentricity. For $m_2 = 0$ this reduces to Einstein's formula. The immediate suggestion is to compare this with observations made on binary stars. Unfortunately the test, which would be crucial if sufficiently accurate measurements could be made, is not easy because the components of most known double stars are so close together that important tidal forces come into consideration which also produce an advance of the apsidal line and mask the effect sought. Where conditions are most favourable, as in the white dwarf binary discovered by Willem Luyten, the time of a single revolution is of the order of centuries, so that no check is possible for the present.

Important applications of Birkhoff's theory to the cosmological problem have also been made by Graef, and the comparison with observational material has been made by L. E. Erro. The cosmological constant is not introduced ad *hoc*, but now appears simply as an integration constant. Again the velocity of recession of extragalactic nebulae is proportional to the distance. The theory, moreover, indicates a way out of Hubble's dilemma by showing that an additional correction to the observational data must be applied. This correction, known as the simultaneity correction, is needed because the density of matter in the universe should be determined, not when light was emitted from distant nebulae, but at the place where such nebulae are now. Using Lorentz variables, and a frame of reference attached to the earth, as done in Birkhoff's theory, this correction acquires a perfectly definite meaning.

A. Barajas has pointed out that Birkhoff's and Einstein's theories predict different relativistic corrections even for the case of weak fields (except for the advance of the perihelion) and further that in the former the trajectory of a particle is not a geodesic in any curved four-dimensional space. He has shown that the principle of equivalence holds in Birkhoff's theory just as in Einstein's, *i.e.*, that it is possible to introduce in a gravitational field a local reference system in which the trajectories of mass particle are straight lines and the field vanishes.

The comparison between Einstein's and Birkhoff's theories is most readily seen in the following table:

EINSTEIN

Four arbitrary Gaussian variables.
Fundamental group: Transformations of four arbitrary functions of four arbitrary variables.
Doubtful physical meaning of variables employed.
Curved Riemann space.
Restricted relativity valid in infinitesimal region of space-time.
No fundamental reference system.
Matter determines geometry of physical space.
Inertial mass proportional to gravitational mass.
Principle of equivalence valid.
Nonlinear gravitational equations.
Mechanical equations of motion are a consequence of field equations.

BIRKHOFF

Four Lorentz variables.
Fundamental group: Lorentz group with ten arbitrary parameters.
Local co-ordinates and local time of restricted relativity.
Flat Minkowski space.
Restricted relativity valid everywhere.
Fundamental Lorentz reference system.
Matter does not determine geometry of physical space.
Principle of equivalence valid.
Linear gravitational equations.
Mechanical equations of motion are not a consequence of field equations.

Finally, in Birkhoff's theory gravitational waves propagate with speed of light everywhere. The question of gravitational waves is difficult to discuss in Einstein's theory as a consequence of the introduction of arbitrary variables.

Milne's Theory of Gravitation. — Milne has also tried to get rid of the difficulties which accompany the use of arbitrary variables to describe gravitational phenomena and has built up a theory of gravitation where the variables employed are Lorentz variables.

Milne starts from the following postulates: (1) observers attached to different reference frames can signal to one another by means of light; (2) the speed of light in any reference frame is constant; (3) any set of particles presents the same appearance to all observers.

From these postulates he deduces that, if observers attached to a galaxy use Euclidean space, they will conclude that all galaxies are receding from one another, as they do if the red shift of spectral lines is to be interpreted as a Doppler effect. If, on the other hand, they prefer to regard one another as at rest, they must use a different time scale and hyperbolic, not Euclidean, space. Further, if a particle moves under forces which depend only on its distance from other particles, and if every observer has to give the same description of these forces, the only possible law of force is,

$$\frac{\Gamma m_1 m_2}{ct_0^2 \sin h^2(r/ct_0)} = \frac{\Gamma m_1 m_2}{r^2(1+r^2/6c^2t_0^2+r^4/120c^4t_0^4+\ldots)} \quad (4.1)$$

where m_1, m_2 are the masses of any two particles, Γ is a constant, c is the constant speed of light, t_0 is the "present" and r is the distance between the two particles. The present time t_0 is 2×10^9 years$=6.3\times10^{16}$ sec. as inferred from the red shift of distant nebulae, and is not very accurately known. ct_0 is thus of the order of two billion (2,000,000,000) light-years, so that for all distances less than millions of light-years the law of force is the classical Newtonian law $\Gamma m_1 m_2/r^2$. The constant of gravitation Γ is calculated from the mean density of matter in the universe.

According to Milne's theory an observer can choose any time scale he likes, but the choice of his time scale fixes his geometry. However there are two kinds of time scales which give the simplest results. The so-called kinematical time scale gives the simplest account of radiation, and of a minority of the properties of matter. Using this time scale, the past is finite.

The second kind of time scale gives the so-called dynamical time, which is related to the kinematical time t by a logarithmic transformation.

$$\tau = t_0(\log t/t_0+1). \quad (4.2)$$

The past is infinite (negative) and the time is the same for all observers.

On this scale all observers in the universe would assign the same instant to the appearance of a nova, just as in classical Newtonian theory. But the geometry now is hyperbolic, not Euclidean. The galaxies are not receding from one another, and neither stellar nor planetary systems are expanding. Energy and angular momentum are constant and dynamics is very nearly Newtonian.

The logarithmic transformation connecting kinematical and dynamical time thus transforms a one-way infinite time scale (kinematical) into a two-way infinite scale (dynamical). We may choose for our calculations either scale, at will, and the results will be the same. But it appears that, roughly, kinematical time is most appropriate for calculations having to do with radiation while dynamical is best fitted for those relating to matter. The present is so chosen that at present the two scales coincide. It is clear, however, that if they coincide now they did not in the past and will not in the future. Thus the wave length of the red line of cadmium, say, measured in terms of a material standard, will shrink about 5×10^{-8} per century. The disagreement between the scales of time of matter and radiation of course becomes most important when dealing with huge intervals of time such as occurring in astronomy and geology.

Milne's cosmology thus solves the old problem as to whether the age of the universe is finite or infinite. According to him the answer depends on which time scale is used, *i.e.,* on whether one depends on radiation or matter to assign an age to the universe.

(M. S. V.)

PART II. THE MEASUREMENT OF GRAVITATIONAL FORCES

General Considerations.— The law of gravitation of classical mechanics first deduced by Newton (1665) from a study of Johann Kepler's empirical laws of motion of the planets states that: mutual action exists between masses of matter such that each mass is attracted toward every other mass with a force varying directly as the product of the masses and inversely as the square of the distance between them. This law is formulated as:

$$F=G\frac{M_1M_2}{d^2}, \quad (5.1)$$

where: F is the force between the two particles of mass M_1 and M_2, d is the distance between them, and G is a constant for all kinds of matter—the *gravitational constant.* This constant has the dimensions $L^3M^{-1}T^{-2}$ and a numerical value depending on the units used.

Although this law was first formulated rigorously by Newton, the existence of the gravitational action was seen more or less clearly by others. Even Ptolemy (A.D. 150) had a vague conception of a force tending toward the centre of the earth which not only kept bodies on its surface but in some way upheld the order of the universe. Kepler (1609) inferred that the planets move in their orbits under some influence or force exerted by the sun; but the laws of motion were not then sufficiently developed, nor were Kepler's ideas of force sufficiently clear to permit a precise statement of the nature of the force. C. Huggens and R. Hooke, contemporaries of Newton, saw that Kepler's third law implied a force tending toward the sun which, acting on the several planets, varied inversely as the square of the distance. But two requirements necessary to generalize the law were missing. One was to show that the law of the inverse square not only represented Kepler's third law but his first two laws also. The other was to show that the gravitation of the earth extended to the moon. Newton's researches showed that the attraction of the earth on the moon was the same as that for bodies at the earth's surface, only reduced in the inverse square of the moon's distance from the earth's centre. He also showed that the total gravitation of the earth, assumed as spherical. would be the same on external bodies as if the earth's mass were concentrated at its centre. This led at once to the statement of the law in its general form (equation [5.1]).

The existence of the gravitational phenomenon is exhibited in the simple observation that any body on the surface of the earth is attracted to the earth by a force proportional to its mass. This force we commonly term the *weight* of the body. Thus, from equation 5.1, the force acting on a body of mass M_1, due to the attraction of the whole earth, whose mass M_2 may be considered as concentrated at its centre, would be

$$F=W=GM_1M_2/r^2 \quad (5.2)$$

where r is the radius of the earth.

The force *per unit mass* is therefore F/M_1, or:

$$F_0=GM_2/r^2. \quad (5.3)$$

The force acting on the body M_1 also may be considered as defined by Newton's second law of motion; *i.e.,* $F=M_1a$, where a is the acceleration that would be caused by the gravitational attraction of the earth if the body were allowed to fall freely. Thus the force on the body is exactly the same as if it were being accelerated at a rate $a=F/M_1$ which is given by equation 5.3. And, when the attraction of the earth is expressed as a force per unit mass, it is exactly equivalent to an acceleration. Therefore, we often speak of the *acceleration* of *gravity* synonomously with the *intensity of gravity, g,* of the earth.

The gravitational constant G of the foregoing equations is one of the fundamental constants of nature. It can not be determined, however, by astronomical data such as led Newton to the formulation of the general law as expressed in equation (5.1). But. if all other quantities in equation (5.1) can be measured experimentally, then G can be calculated. Thus, in view of its fundamental importance, the experimental determination of the numerical value of the gravitational constant became an important problem to physicists immediately the gravitational law was formulated.

On the other hand, in reviewing the efforts of the earliest workers in this field, it might appear that they were primarily interested in determining A, the density of the earth rather than the gravitational constant G. However, these two problems are so closely related that the determination of one leads quite directly to the evaluation of the other. This circumstance arises as follows:

If we assume the earth to be a nonrotating sphere of mass M, density Δ and radius r, the intensity of gravity g at its surface (from equation [5.3]) is

$$g=\frac{GM}{r^2}=\frac{G}{r^2}\left(\frac{4}{3}\pi r^3\Delta\right)=\frac{4}{3}\pi r(G\Delta) \qquad (5.4)$$

$$G\Delta=\frac{3g}{4\pi r}. \qquad (5.41)$$

Thus, if g and r are known, the determination of G and Δ are equivalent problems since the measurement of either determines the other within the limits of accuracy of the known quantities.

The Determination of the Gravitational Constant.—In view of the above statement formulated in equation (5.41), we see that the determination of the gravitational constant G, the really fundamental problem, may be regarded either as the determination of the mass of the earth in grams, most conveniently expressed as its mean density Δ (mass/volume), or the determination of the gravitational constant G. Corresponding to these two aspects of the problem there are two modes of attack.

(1) Suppose that a body of mass m is suspended at the earth's surface where it is pulled vertically downward with a force w, its weight. At the same time let it be pulled laterally with a force p by a measurable mass M which may be a mountain, or an artificially prepared mass brought very near to m, and let d be the distance between the centres of mass m and M whether M be the mountain or the artificial mass. The earth pull may be regarded as the same as if its mass were concentrated at its centre, distant r.

Then $$w=G\frac{4}{3}\pi r^3\Delta m/r^2=\frac{4}{3}m\pi r(G\Delta) \qquad (6.1)$$

and $$p=GMm/d^2. \qquad (6.2)$$

By division $$\Delta=\frac{3M}{4\pi rd^2}\left(\frac{w}{p}\right) \qquad (6.3)$$

and we can obtain the mean density of the earth if the ratio $\frac{w}{p}$ can be observed experimentally.

But the same observations permit the evaluation of G, the gravitational constant. For, putting $m=\frac{w}{g}$ in equation (6.2), we get

$$G=\frac{d^2}{M}\left(\frac{p}{w}\right)g \qquad (6.4)$$

and g, the acceleration of gravity, is known from, say, measurements of the acceleration of a falling body or from pendulum measurements.

(2) In the second method of attack the pull p between two artificially prepared measured masses M_1 and M_2, is determined when they are a distance d apart. From the measured value of the pull p, we obtain directly from equation (5.1),

$$G=pd^2/M_1M_2. \qquad (6.5)$$

But again, having determined G, we can determine the mean density of the earth, Δ, for $m=\frac{w}{g}$ put in equation (6.1) gives immediately

$$\Delta=3g/4\pi rG. \qquad (6.6)$$

Experiments of the first type in which the pull of a known mass is compared with the pull of the earth may properly be termed experiments on the mean density of the earth, while experiments of the second class in which the pull between two known masses is measured directly may be termed experiments on the gravitational constant. However, for purposes of describing such experiments, a slightly different classification is desirable, viz.:

(1) Comparison of the earth's vertical pull on a body with the lateral pull of a natural mass such as a mountain or other massive natural feature.

(2) Comparison of the earth's pull on a body with the vertical pull of an artificial mass as in experiments with the common balance.

(3) Determination of the attraction between two artificial masses as in the Cavendish experiment.

It is interesting to note that the possibility of gravitational experiments of this kind was first considered by Newton in both of the forms (1) and (3). In the Systems of the World (3rd edition, p. 40, 1737) he calculates that the lateral pull of a hemispherical mountain of radius 3 mi. and of the earth's density will cause a plumb line at its side to be deviated less than 2 minutes of arc. He also calculates (though with an error in his arithmetic) the acceleration towards each other of two spheres each a foot in diameter and of the earth's density, and comes to the conclusion that in either the case of the deviation of the plumb line or the attraction of the spheres, the effect is too small for measurement. In the *Principia,* Book iii, Prop. x, he makes the celebrated estimate that the earth's mean density is five or six times that of water. Adopting this estimate, the deviation by an actual mountain or the attraction of two terrestrial spheres would be of the orders calculated, and regarded by Newton as immeasurably small.

Whatever method is adopted, the force to be measured is indeed very minute. This may be realized if we here anticipate the results of the experiments which show that when the masses are in grams and the distances in centimetres, the values are approximately $\Delta=5.5$ and $G=1/15{,}000{,}000$. The latter may be expressed as $G=6.6\times10^{-8}$ (c.g.s. units).

Comparison of the Earth's Pull with That of a Natural Mass—*Bouguer's* Experiments.—The earliest experiments were made by Pierre Bouguer about 1740 and they are recorded in his Figure de la Terre (1749). They were of two kinds. In the first he determined the length of the seconds pendulum and thus g at different elevations. Thus at Quito, Peru, which may be regarded as on a tableland with an elevation of about 9,400 ft., and again on the Isle of Inca at sea level, he determined g with pendulum apparatus. From the known difference in elevation of the two points of observation the measured value at sea level was projected to the elevation of the plateau by the inverse r^2 law, assuming that only free air occupied the intervening space. Actually his observed value of g at the elevated station was $\frac{1}{6{,}983}$ greater than this calculated value, which difference he immediately assigned to the attraction of the 9,400 ft. of plateau material actually underlying the elevated station. Thus the experiment indicated that the attraction of the whole earth was 6,983 times that of the plateau. Since the attraction of the plateau could be calculated on the assumption that it was effectively an infinite slab of known thickness Bouguer concluded that the density of the earth was 4.7 times that of the plateau. This result is obviously much too large.

In the second type of experiment he attempted to measure the horizontal pull of a 20,000 ft. mountain by suitable observations on the deflection of a plumb line. Because of experimental difficulties his results are not of interest but the importance of the experiment was in indicating the possibilities of the method.

Maskelyne's Experiment.—In 1774 Nevil Maskelyne (*Phil. Trans.*, p. 495, 1775) made an experiment on the deflection of the plumb line by a mountain, Schiehallion, in Perthshire, Scotland. It has a short east-west ridge with steeply sloping north and south flanks. He selected two stations on the same meridian, one on the north and the other on the south slope and by means of a zenith sector, a telescope provided with a plumb bob, he determined at each station the meridian zenith distances of a number of stars. From a survey of the district made in the years 1774–76, the geographical difference of latitude between the two stations was found to be 42.94 sec. The difference in meridian zenith distances of the same star at the two stations would have been this value if the mountains were absent and the plumb line thus maintained a true vertical. But at the north station the plumb bob was pulled south and the apparent zenith deflected northward, while at the south station the effect was reversed. The observed zenith distances of the same star at the two stations was 54.2 sec. as against the surveyed difference of 42.94 sec. Thus the difference representing the double deflection of the plumb line was 11.26 sec. From the results of this survey, Charles Hutton *(Phil. Trans.*, p. 689, 1778) computed the relative density of the earth and mountain as 9/5. Assuming the mountain density as 2.5, the mean density of the earth, A, would be 4.5.

Airy's Experiment.—A modification of Bouguer's experiment was carried out by Sir G. B. Airy (Phil. *Trans.*, p. 297, 1856) in 1854 at Harton mine near South Shields. This consisted in comparing gravity at the top and bottom of a mine by the swings of the same pendulum and thus finding the ratio of the pull of the intervening strata to the pull of the whole earth. The principle of the method may be understood by assuming that the earth comprises concentric homogeneous spherical shells, the last being of thickness h equal to the depth of the mine. Let the radius of the earth to the bottom of the mine be r and the mean density up to that point be Δ. This will not differ appreciably from the mean density of the whole. Let the density of the strata of depth h be 6. Denoting the values of gravity above and below by g_a and g_b we have

$$g_b = G\frac{4}{3}\frac{\pi r^3\Delta}{r^2} = G\frac{4}{3}\pi r\Delta \qquad (6.7)$$

and

$$g_a = G\cdot\frac{4}{3}\frac{\pi r^3\Delta}{(r+h)^2} + G\cdot 4\pi h, \qquad (6.71)$$

the added term being the attraction of a shell h thick observed at a point on its outer surface. The ratio of equation (6.7) and (6.71) may be reduced to

$$\frac{g_a}{g_b} = 1 - \frac{2h}{r} + \frac{3h\delta}{r\Delta} \text{ (approx.)} \qquad (6.8)$$

or

$$\frac{\Delta}{\delta} = \frac{3h}{r}\Big/\left(-1+\frac{2h}{r}+\frac{g_a}{g_b}\right). \qquad (6.81)$$

Stations were chosen in the same vertical, one near the head of the shaft and the other 1,250 ft. below in an abandoned working. Two *invariable* seconds pendulums were swung and timed by a comparison clock at each station. The seconds pendulums were interchanged at intervals. The final result taking into account the ellipticity and rotation of the earth is $\Delta = 6.565$, a value about 20% higher than currently accepted values.

Von Sterneck's Experiment.—(*Mitth. des K.V.K.* **Mil.** *Geog. Inst. zer Wien*, ii, p. 77, 1882; p. 59, 1883; vi, p. 97, 1886.) R. von Sterneck repeated the mine experiment in 1882–83 at the Adalbert shaft at Pribram in Bohemia, and in 1885 at the Abraham shaft near Freiberg. He swung two invariable half-seconds pendulums simultaneously, one at the surface and the other below, interchanging them at intervals. Von Sterneck introduced an important improvement by comparing the swings of the two pendulums with the same clock using an electrical connection between stations. This method eliminates the clock rates from the final calculations of the relative gravity values and begins a new era in the determination of local variations of gravity.

The values of **A** obtained by Von Sterneck were not consistent but increased with the depth of the second station. All such experiments to determine *A* by the attraction of natural masses are open to the serious objection that the distribution of density in the neighbourhood can not be determined with sufficient accuracy.

Comparison of the Earth's **Pull** on a **Body** with the Vertical Pull of an Artificial Mass by Means of the Common Balance.—The principle of the method is as follows: Suppose a sphere of mass m and weight w to be hung by a wire from one arm of an ordinary balance. Let the mass of the earth be E and its radius be r. Then

$$w = GEm/r^2.$$

Now introduce beneath m, a sphere of mass M and let d be the distance between the centres of the two masses. Its pull increases the apparent weight of m by, say, δw. Then

$$\delta w = GMm/d^2.$$

Dividing, we obtain

$$\delta w/w = Mr^2/Ed^2, \text{ whence}$$

$$E = M\left(\frac{w}{\delta w}\right)\left(\frac{r^2}{d^2}\right).$$

Hence the mass of the earth is obtained in terms of the known mass M. Indirectly the gravitational constant G may then be determined from the relation

$$g = GE/r^2;\ G = gr^2/E$$

and the known value of g as measured by pendulum or falling-body experiments.

Von Jolly's Experiment.—*(Abhand. der K. bayer. Akad. der Wiss.* 2 Cl. xiii, Bd. 1, Abt. p. 1j7 and xiv. Bd. 2 Abt. p. 3.) About 1878–81, Philipp von Jolly performed experiments using a common balance. Some of these experiments involved measurements of the change in weight of a mass due to change of elevation of the mass above the earth's surface. Coupled with these experiments he built up a lead sphere about 1 metre in diameter beneath one of the lower pans of the balance. He found that the weight of a 5 kg. mass was increased by 0.589 mg. when it was placed on the lower pan of the balance directly over the lead sphere as compared with its weight on the upper pan so remote from the lead sphere as to be influenced a negligible amount by the artificial mass.

He obtained as a result,

$$G = 6.465\times 10^{-8}; \qquad A = 5.692.$$

Experiments of Richarz and Krigar-Menzel.—(*Anhang zuden Abhand. der k. preuss. Akad. der Wiss. zu Berlin 1898.)* In 1884 A. Koenig and F. Richarz proposed a similar experiment which was ultimately carried out by Richarz and 0. Krigar-Menzel. In this experiment a balance mas supported about 2 metres above the floor and with scale pans above and below as in Von Jolly's experiment. Weights 1 kg. each were placed say in the top right pan and the bottom left pan. Then they were shifted to the bottom right and top left, the result being, after corrections for the change in density of air displaced through pressure and temperature changes at the two elevations, a gain in weight on the right of 1.2453 mg. due to the change in level of 2.2628 metres. Then a rectangular column of lead 210 cm. square cross-section and 200 cm. high was built up under the balance between the pairs of pans. On repeating the weighings there was now a decrease on the right when a kg. weight was moved on that side from top to bottom while another was moved on the left from bottom to top. This decrease was 0.1211 mg., showing a total change due to the lead mass of $1.2453+0.1211=1.3664$ mg. and this is obviously four times the attraction of the lead mass on 1 kg. The changes in the weights were made automatically, the results gave

$$G = 6.685\times 10^{-8};\ A = 5.505.$$

Poynting's Experiment.—*(Phil. Trans.*, vol. 182, *A*, p. 565, 1891.) In 1878, J. H. Poynting published an account of a preliminary experiment of the type of Von Jolly's but on a smaller scale with the view to demonstrate that the common balance could be adapted to gravimetric work. In 1891 he gave an account of the full experiment carried out with a large balance and with much greater care. The balance had a 4 ft. beam. The scale pans were removed and from the two arms were hung lead spheres, each weighing about 20 kg. at a level about 120 cm. below the beam. The balance was supported in a case above a horizontal turntable, the axis of which was vertically below the central knife-edge of the balance. On this turntable was mounted the attracting mass, a lead sphere weighing 150 kg. The centre of the large sphere was 30 cm. below the level of the centres of the hanging weights. The turntable could be rotated between stops so that the attracting mass was first directly below one of the hanging weights and then directly below the other. It was found necessary to add a second balancing mass to the turntable at twice the radius of the large mass in order to eliminate a spurious tilting of the balance support due to the shifting weight of the turntable.

The balance beam was equipped with a special mirror arrangement which magnified the tilt of the beam about 150 times. About 5 metres from this mirror was a telescope and scale for observing the tilt of the mirror. The experiment indicated that in moving the attracting mass from under one weight to a position under the opposite weight the balance beam changed deflection a little more than 1 second of arc—equivalent to a change in weight of about 0.4 mg.

Poynting's results were

$$G=6.698\times10^{-8};\ \Delta=5.493.$$

Determination of the Attraction between Two Artificial Masses, Cavendish's Experiment.—(Phil. Trans., p. 469, 1798.) This celebrated experiment was planned by the Rev.

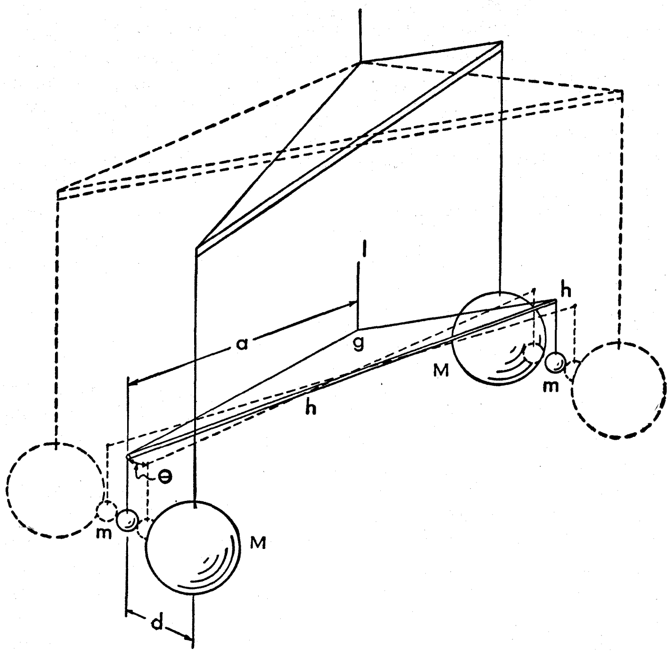

FIG. 1.—CAVENDISH BALANCE

John Michell. He completed an apparatus but did not live to begin the work on the experiment. After Michell's death the apparatus came into the possession of Henry Cavendish, who largely reconstructed it and in 1797–98 carried out the experiment.

The essential feature of the experiment consisted in the determination of the attraction of a lead sphere 12 in. in diameter on another lead sphere 2 in. in diameter, the force measurement being made with a torsion balance. Fig. 1 shows the essential features of the apparatus. A horizontal beam *hh*, 6 ft. long, was suspended at its centre by a torsion wire *lg*. Two lead balls, m, m, each 2 in. in diameter, were suspended at the ends of the beam. One end of the beam carried a suitable index whereby its angular position with respect to a horizontal scale could be determined very accurately by viewing through a distant telescope. The torsion balance mas enclosed in a case to shield it from convection currents. Outside the case, two 12 in. diameter lead spheres, *M, M,* were hung from an arm which could be turned on a vertical axis colinear with the suspension *lg* of the torsion balance.

Suppose that first the spheres are so placed that one is a distance d in front of the left-hand ball m and the other is the same distance behind the right-hand ball m. The gravitational attraction of the two pairs of balls will be additive in tending to turn the torsion balance counterclockwise as viewed from above. If the big spheres are then moved around so as to be on the opposite sides of their adjacent small balls m, *m*, the torque on the torsion arm will be reversed and it will turn clockwise. The angle 2θ between the two rest positions of the balance arm is four times as great as the deflection that would result due to the approach of one sphere to one ball. (We have neglected the cross-attraction of the right sphere on the left ball and the left sphere on the right ball.)

By operating the torsion balance as a torsion pendulum and determining its period, or by other means, it is obvious that the torsion constant of the suspension may be determined. Thus the force acting at lever arm length a to produce the observed deflection 2θ may be calculated, and with the values of *M, m* and d known, equation (5.1) in principle gives directly the value of the gravitational constant G.

The work of Cavendish was undoubtedly very accurate for a pioneer experiment; in fact, it was not really improved upon until nearly a century later. After making various corrections, Cavendish's results were:

$$G=6.754\times10^{-8}\ \text{(c.g.s. units), and}\ \Delta=5.448.$$

These results are within about 1.2% of currently accepted values.

Reich's Experiments.—In 1838 F. Reich published an account of a repetition of the Cavendish experiment carried out in the same manner but with somewhat smaller apparatus. (Versuche *über* die Mittlere Dichtigkeit der Erde *mittelst* der Drehwage, Frieberg, 1838; "Neue Versuche mit der Drehwage," *Leipzig* Abh. Math. Phys., i, p. 383, 1852.) The principal differences were in the methods of measuring the times of vibration and the deflection, and the changes were hardly improvements. His result after revision was $\Delta=5.49$. In 1852 he published an account of further work giving as a result $\Delta=5.58$.

Baily's Experiment.—In 1841–42 Francis Baily made a long series of determinations by the Cavendish method and with apparatus of almost the same dimensions. (Memoirs of the Royal Astron. *Soc.,* XIV.) The attracting masses were 12 in. lead spheres and as the attracted balls he used various materials, lead, zinc, brass, glass, etc. The suspension was also varied, sometimes consisting of a single wire, sometimes being bifilar. There were systematic errors in the work difficult to explain. His final result, $\Delta=5.6747$, is not of value compared with later results.

Boys' Experiment.—(Phil. Trans., **A.,** pt, i, p. 1, 1895.) Professor C. V. Boys, having found that it is possible to draw quartz fibres of practically any degree of fineness, of great strength and very constant elastic properties, determined to repeat the Cavendish experiment. He first investigated the question of optimum dimensions for the apparatus and concluded that the dimensions should be reduced until the determination of the linear dimensions became the limit of accuracy. These conclusions were based on the fact that smaller dimensions would reduce temperature variations and resultant air disturbances and in other ways would make the experiment more manageable.

Fig. 2 shows diagrammatically his arrangement of the apparatus. The horizontal beam was a small rectangular mirror about 2.4 cm. long. From the sides of this mirror gold balls of about 2.6 gm. mass each were hung by quartz fibres at levels differing by 1 j cm. The attracting masses were lead spheres, about 11 cm. in diameter and weighing about 7.4 kg. each, so arranged that the torque resulting from the attraction was a maximum. The vertical displacement of the spheres and balls served to minimize the attraction of opposite pairs and permitted the use of the very short beam. The horizontal mirror comprising the beam reflected a scale 700 cm. distant by which the deflection could be read. The result of this experiment, as given by Boys, was $G=6\ 6576\times10^{-8}$; $\Delta=5.5270$. However, the last figure is not significant since

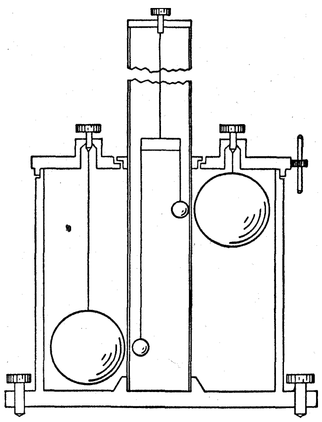

FIG. ,?.—BOYS' CAVENDISH BALANCE

the individual observations ranged from 6.653 to 6.671.

Braun's Experiment.—(*Denkschr. Akad. Wiss. Wien. Math. Naturw.*, Cl. 64, p. 187, 1896.) In 1896 Dr. K. Braun, S.J., gave an account of a very careful and excellent repetition of the Cavendish experiment with apparatus much smaller than that used in the older experiments, yet much larger than that used by Boys. A notable feature of the work consisted in the suspension of the torsion apparatus in a receiver exhausted to about 4 mm. of mercury, a pressure at which convection currents almost disappear while radiometer forces have hardly begun. The attracted balls weighed 54 gm. each and were 25 cm. apart. The attracting masses were spheres of mercury, each weighing 9 kg. and brought into position outside the receiver. Braun used both the deflection method and the time of vibration method suggested by Reich and John Forbes. The methods gave almost identical results and his final values were:

$$G=6.6579\times 10^{-8};\ \Delta=5.5275.$$

Ignoring the 5th figure, which is not significant, the results agree with Boys' values. Braun reported 46 separate experiments, 26 by the time-of-swing method and 20 by the method of direct deflection, the individual results being weighted from 1 to 4. The individual results vary as much as 4 units of the third significant figure.

G. K. Burgess' Experiment.—(*Thèses présentées à la faculté des sciences de Paris pour obtanir le titre de docteur de l'université' de Paris*, 1901.) This was a Cavendish experiment in which the torsion system was buoyed up by a float in a mercury bath. The attracted masses could thus be made large (2 kg.) and yet the torsion fibre could be kept fine. From the centre of the beam depended a vertical steel rod with a varnished copper float at its end, entirely immersed in mercury covered with dilute sulphuric acid to remove disturbances due to varying surface tension acting on the steel rod. The size of the float was such that the quartz torsion fibre 35 cm. long supported a weight of only j to 10 gm. The results gave:

$$G=6.64\times 10^{-8};\ \Delta=5.55.$$

Eötvös' Experiment. — (*Ann. der Physik und Chemie*, 59, p. 354, 1896.) In the course of investigations on local variations of gravity by means of the torsion balance, R. Eotvos devised a method for determining G somewhat like that used by Reich and Braun. Two pillars 30 cm. × 30 cm. × 60 cm. high were built up of lead blocks, the pillars being 30 cm. apart. The torsion balance consisted of a platinum wire suspension about 150 cm. long supporting a beam somewhat less than 30 cm. long with small weights at the ends and enclosed in a shallow double-walled brass case with the view to minimize convection currents. The balance beam was first set in the line joining the centres of the pillars and its time of vibration determined. It was then set with its length perpendicular to the line joining the centres of the pillars and the period of oscillation again measured. From these periods Eötvös was able to determine the provisional value,

$$G=6.65\times 10^{-8},\ \text{whence } A=5.53.$$

Heyl's Experiment.—(*U.S. Bureau* of *Standards Journal of Research*, vol. 5, p. 1243, 1930.) After a careful review of the work of Boys and Braun, Paul R. Hey! concluded that increased precision in the determination of G could hardly be expected of the direct deflection method, whereas, as stated by Braun, the possibilities of the time-of-swing method had not been fully utilized. In his repetition of the Cavendish experiment, Heyl therefore decided to use only the time-of-swing method. The apparatus was designed after the general pattern of Braun's but with a considerable increase in the attracting masses.

The torsion pendulum consisted of two small spheres, 50 gm. each, hung from the ends of a very light separator rod about 20 cm. long which in turn was supported from its ends by truss wires attached to a fine tungsten filament about 1 metre long which comprised the torsion suspension. A small mirror attached at the point of suspension in conjunction with a telescope and scale 3.5 metres distant permitted observations of the angular motion of the moving system. A motion of one minute of arc of the moving system was exhibited as a shift of about 2 mm. of the scale in the field of the telescope. The timing of the torsion pendulum was accomplished by manually keying the observed transits of the pendulum and thus recording them on a chronograph which also carried seconds signals derived from a Riefler clock rated daily against Naval observatory signals. By well-known methods the chronograph record was then used for accurate calculation of the timing of the torsion pendulum, reduced to zero-amplitude time.

The attracting masses used by Heyl were two 66 kg. steel cylinders mounted with axes vertical and suspended from a rotatable support such that the line forming their mass centres could be made coincident with the line of centres of the masses on the torsion pendulum or at right angles thereto (as in Eotvos' experiment). Clearly in the former position the gravitational forces add to the restoring force of the torsion wire and the period of the pendulum is a minimum. With the large masses at right angles to the axis of the pendulum the period is at a maximum. As might be anticipated, particularly in the "near" position, the attracting masses produce a nonuniform gravitational field and the pendulum oscillations are not strictly sinusoidal (nonisochronous), a detail which must be considered in timing the pendulum. It is of interest to note that as stated by Heyl, "the time of swing in the 'near' position was usually about 1,754 seconds and in the 'far' position about 2.081 seconds, and each could be measured to about 0.1 seconds. The difference, 327 seconds, formed the critical quantity of the whole measurement and may be presumed accurate to about 1 part in 3.300." The original intent was to time the pendulum photographically but because of optical difficulties reliance was placed on the manual observations.

Precautions were taken that all mass and length measurements were well within the tolerance required to assure that such quantities could not introduce errors in the derived value of G within say 1/10,000. The use of steel cylinders rather than the usual lead spheres was with the view to assure accuracy of measurement, uniform density and permanency of measured values at the cost of some inconvenience and mathematical labour.

Heyl used as masses on the moving system, gold, platinum and glass balls, but not with the idea of obtaining any different value of G due to difference in material. The original gold balls were found to absorb mercury from the trap used in the evacuating system, such that in a period of five months their weights increased from 49.1067 gm. by 0.1379 gm. To avoid this difficulty the platinum balls were coated thinly with lacquer. The glass balls were made of high-quality optical glass ground truly spherical. This material was selected because it would permit visual examination to insure perfect homogeniety of the mass.

The moving system was housed in an air-tight container exhausted to a pressure of about 2 mm. of mercury to decrease the damping and minimize convection disturbances. The lower portion of the housing containing the beam system was of soft iron material to shield the pendulum magnetically. This was required because the massive steel cylinders when moved from one to another of the two observation positions altered the earth's magnetic field. And while the small masses used on the beam were not of ferromagnetic material, they were either paramagnetic or diamagnetic and the resultant magnetic effect would be appreciable. The effectiveness of the magnetic shielding was tested by artificial magnetic fields before gravimetric observations were made.

In order to start the pendulum swinging for an observation, bottles of mercury served as portable masses which were moved manually and in resonance with the gravitationally induced swings of the pendulum until the desired amplitude of oscillation had been attained. Thereafter these masses were removed from the vicinity and because of the low damping, adequate amplitude remained for the duration of the observation.

The following data mere obtained by Heyl, the results using the gold balls having been corrected for an assumed steady rate of absorption of mercury.

Heyl preferred to weight the results with the gold balls at $\frac{1}{3}$ the neight given to the platinum and glass results and gives as a final value:

$$G=6.670\times10^{-8}\pm0.005.$$

Heyl and Peter *Chrzanowski Experiment.*—(*Jour.* of Research, *Nat'l. Bur. of Stds.*, vol. 29, RP 1480, p. 1, July 1942.) In view of the unexplainable inconsistencies in the several experiments of Heyl's 1930 work, it was repeated mith such improvements as were suggested by careful reconsideration of the details of the earlier experiment. Two improvements were found worthy of adoption: photographic recording, and a change in the position of the large attracting masses.

In the 1930 experiments the 66 kg. steel cylinders were arranged nith their axes vertical. In the later work the axes of these cylinders were laid horizontally. This simplified the measurement of distances and also eliminated some difficulties with slight departures from isochronism caused by the nonuniform field encountered by the pendulum when swinging with appreciable amplitude. In all other respects the general arrangement of the apparatus mas the same as in the 1930 experiments. The balls used on the torsion pendulum were of platinum and weighed about 87 gm. each. The suspensions used were of two kinds: ordinary commercial hard-drawn tungsten lamp filament, 0.0012-in. diam. of 288 gm. tensile strength, and a specially straight-drawn and annealed filament of 0.0014-in. dia. and 284 gm. tensile strength. As will be evidenced in the results, the hard-drawn filament was superior for this work. This may be explained by the statement taken from the paper, "The times of swing with the annealed filament were about 1,880 and 1,640 seconds in the 'far' and 'near' positions respectively, with a difference of 240 seconds. With the hard-drawn filament (smaller diameter), the times of sning were increased to 2,920 and 2,200 seconds, with a difference of 720 seconds. This three-fold increase in sensitivity nith the hard-drawn filament apparently overbalanced any slight advantage of stability on the part of the annealed filament."

The time standard used was derived from the bureau of standards' 100 kc. quartz oscillator precision standard and comprised light flashes at 5 sec. intervals obtained from a suitably slotted disk driven from the time source by a synchronous motor. By a suitable lens system the image of the signalling slit, after reflection from the mirror on the torsion pendulum, was focused on a photographic plate. As the pendulum swung an image was recorded on the plate every 5 sec. The distance from the mirror to plate was 490 cm. and a deflection of 1° at the mirror corresponded to a distance of 17 cm. at the plate. The sharpness of the lines recorded was such that 3 lines per mm. could be resolved by a low-power microscope.

The results of the observations were:

	Hard-drawn Filament	*Annealed Filament*
	$G=6\ 6739\times10^{-8}$	$G=6\ 6670\times10^{-8}$
	56	667
	69	703
	62	707
	51	680
Mean,	$G=6.6755\times10^{-8}$	$G=6.6685\times10^{-8}$

These data indicate that the results for the hard-drawn filament give a precision twice that obtained with the annealed filament. Weighting the results in proportion, the weighted mean is given:

$$G=6.6732\pm0.0031\times10^{-8}$$

and in view of the average departure from the mean appearing in the third decimal place, the final result:

$$G=6.673\pm0.003\times10^{-8}(\text{cm.}^3\ \text{gm.}^{-1}\ \text{sec.}^2)$$

The final result in the 1930 experiments was:

$$G=6.670\pm0.005\times10^{-8}(\text{cm.}^3\ \text{gm.}^{-1}\ \text{sec.}^3).$$

The authors conclude with the statement that "a carefully planned and executed attempt to increase the precision of the 1930 results has met with but slight success. The conclusion may be drawn that the limit of the possibilities of the torsion balance has been reached."

Zahradnicek's Resonance *Method.*—(*Phys. Zeits.*, vol. 34. p. 126, 1933.) In 1932 J. Zahradnicek introduced a modification of the torsion balance methods which shows considerable promise. His apparatus comprises two coaxial torsion balances. The outer or primary balance is a U-shaped beam supported at its midpoint by a steel suspension wire. At the lower terminals of the inverted U-beam, heavy lead weights are attached. The inner secondary balance is smaller and its axis is vertically below that of the primary balance. Its beam is a light horizontal bar mith small equal lead spheres at the ends and is supported at its centre by a fine torsion wire. The suspensions of the balances each carry a small mirror so that oscillations may be recorded photographically on a drum camera. The rest positions of the two balances are adjusted to be in the same vertical plane and each balance when displaced and released executes damped harmonic oscillations about the rest position. The balances are protected from air currents by a housing and, in addition, the secondary balance is shielded from air currents induced by oscillations of the primary balance by an inner housing of its own.

It will be evident that the two balances are coupled by gravitational forces and, in particular, the small secondary balance mill be markedly affected by the much larger primary balance. The experiment comprises the adjustment of the period of the primary balance until resonance occurs; that is, when the amplitude of the secondary compared with the primary is a maximum. The amplitudes and the logarithmic decrement of the secondary as determined by observing a number of turning points on the photographic record of the oscillations, together with measurable dimensions including the moment of inertia of the secondary balance and its period in the absence of the primary, permit calculation of G. The theory involves the complexities of coupled oscillators and may be obtained from the reference publication. The method appears to be capable of accurate results. Zahradnicek gives

$$G=6.659\pm.02\times10^{-8}.$$

Summary of Experimental Determinations of the Gravitational Constant *G*.—It is to be noted that in any experiment of class (1) or (2) as described above and involving a comparison of the earth's pull with the attraction of an artificial mass. the significant measurement involves a very small force superposed on the total attractive force of the earth. The experiment is therefore handicapped, so to speak, in the ratio of the radius of the earth to that of the artificial mass. That is, the apparatus must have a very high sensitivity indeed if the significant portion of the measurement is to have any reasonable degree of precision. Thus, while a modern spring gravity meter may be constructed to measure relative g within 10^{-8}, if used in an experiment of the type described by Poynting, the value of G could scarcely be determined within two significant figures. And while the use of natural rather than artificial masses may appear to offer possibilities, actually such determinations can hardly compete due to spurious effects caused by undeterminable nonhomogeneities in density distribution within the earth's crust.

Experiments in class (3), therefore. appear to offer the only promise of precision in determinations of G. Heyl and Chrzanowski made a serious attempt to push the precision of the Cavendish experiment beyond that of previous attempts and concluded that the gain was inappreciable. Perhaps Zahradnicek's resonance method is worthy of further careful instrumentation. The most significant experiments up to 1945 and their results were:

(1)	Boys—1895	$G=6.658$
(2)	Braun—1896	6.658
(3)	Heyl—1930	$6.670\pm.005$
(4)	Zahradnicek—1932	$6.659\pm.02$
(5)	Heyl and Chrzanowski—1942	$6.673\pm.003$

Since (3) and (5) showed the lowest probable error and selecting the latter as probably the best determination to date, we have

$$G=6.673\pm0.003\times10^{-8}\ (\text{cm.}^3\ \text{gm.}^{-1}\ \text{sec.}^{-2}).$$

Variations in *G*.—While theoretical considerations (Part I) show that the gravitational constant G is independent of the nature of material composing the mass, experiments have been made to test the universal applicability of the constant. Eotvos and others working with the torsion balance showed that when the nature of the attracting masses was varied over a wide range of substances, it was independent of the nature of the masses within the experimental error of $10^{-9}G$. The same work showed G to be independent of the chemical combination of the elements in the masses. Various experimenters have investigated the effect of anisotropic bodies, *i.e.*, the value of *G* remains independent of the direction of the crystallographic axes to within 10^{-9} G, the limit of experimental error. Herman Shaw has shown that within experimental error, any variation in *G* with temperature must be less than 2×10^{-6} G per degree C. Q. Majorana and L. W. Austin, and Thwing have investigated the effect of shielding layers of different media and obtained negative results. Thus in one case 5 cm. of lead interposed between the attractive masses produced no change exceeding 2×10^{-11} G. Accordingly, G may be considered a universal constant independent of the state or nature of the mass body (not to be confused with the relativistic change of mass with velocity).

MEASUREMENT OF THE INTENSITY OF GRAVITY

General **Considerations.**—Measurements of the intensity of gravity or synonymously, the acceleration of gravity, g, of the earth comprise a class of measurements of more practical significance perhaps than determinations of the gravitational constant G by methods already described. While equation (5.4) gives the theoretical intensity, g, at the surface of a homogeneous, nonrotating, spherical earth, the actual intensity at any point on the earth's surface departs considerably from the value so derived. Actually the value of g observed at any point at or near the earth's surface is the resultant of the earth's attractive force and the oppositely directed centrifugal force due to the earth's rotation. Therefore the value of g at the poles where centrifugal force is zero will be greater than at the equator where the rotational effect is a maximum. Moreover, g is modified by the shape of the earth and related factors. In particular, the earth's figure of equilibrium under the influence of gravitation and its own rotation is closely an ellipsoid of revolution, its minor axis through the poles being some 42.95 km. or 26.69 mi. shorter than the equatorial diameter. Normal gravity at sea level according to the formula of Cassinis, accepted as standard by the 1930 meeting of the International Union for Geodesy and Geophysics, is given by:

$$g_o=978.049\ (1+0.0052884\ \sin^2\phi-0.0000059\ \sin^2 2\phi)\ \text{cm./sec./sec.} \qquad (7.1)$$

where ϕ is the latitude of the sea-level station and the rotational and polar flattening effects are properly considered.

If, however, the station is at a height h metres above the sea-level datum because of the increased distance from the centre of the earth, normal g is given approximately by:

$$g_h=g_o-0.0003086\ h\ (\text{cm./sec./sec.}).$$

In geophysical literature unit g has been named the "gal" (after Galileo); 1 gal= 1 cm./sec./sec., or, 1 milligal (abbreviated mg.) =0.001 gal= 0.001 cm./sec./sec. It represents about 1×10^{-7} *g* and the notation mg. will be used in the remainder of this discussion. Thus the above elevation correction has a value of -0.3086 mg. metre or -0.09406 mg./ft. approximately.

However, the above simple formula or "free-air" elevation correction assumes that only free air occupies the space between the point of observation and sea level, the attraction of the mass of earth between the observation point and sea level being ignored. The additional correction for the attraction of this material is commonly called the "Bouguer" correction and, if the topography is fairly flat, is given quite closely by the attraction of an infinite slab of thickness h and density σ. The attraction of such a slab is

$$+0.04185\ \sigma h\ (\text{mg./metre})\ \text{or}\ +0.01276\ \sigma h\ (\text{mg./ft.})$$

and is to be added algebraically to the "free-air" correction. If the topography is irregular, additional "terrain" corrections are required which are too complicated for consideration here.

Now it will be evident that in calculating normal g on the basis of an ellipsoidal rotating earth with corrections for the effects of elevation above sea level and topography, it has been tacitly assumed that any density variations in the material below the selected sea-level datum are uniformly distributed as concentric shells comprising the earth's crust. Actually this is not the case and studies in isostasy (see GEODESY) indicate that significant lateral variations in the density of the crustal material persist to a depth, called the "depth of isostatic compensation" some 114 km. below the sea-level datum. Thus measurements of g at points on the earth's surface may differ by varying amounts from the value as calculated above for the idealized earth, and these differences or anomalies reflect the nonhomogeneous density distribution in the crustal material. If such nonhomogeneities did not exist, an equigravity surface would everywhere be parallel to the sea-level datum. Hence in modern geodetic studies involving gravity observations covering large areas, the observed values are compared with theoretical values only after suitable isostatic corrections have been made in addition to the more obvious elevation and topographic corrections. (William Bowie, *Effect of Topography and* Isostatic Compensation *upon the Intensity* of Gravity, U.S. Coast and Geodetic Survey, Special Publ. No. 12, 1912.) When such complete corrections are included, the residual anomalies are relatively small as illustrated by the fact that out of 122 scattered stations in the United States the *maximum* residual anomalies are about ±60 mg. with a very localized area near Seattle, Wash., having the unusual residual of -95 mg. Doubtless such values may be considered representative of the order of magnitude that may be observed generally over the entire earth. And since with few exceptions these maximum residuals amount to say ±50 parts per million of total *g* and in general are far less, a high degree of isostatic adjustment within the earth's crust is indicated. Indeed, as stated in the above reference, gravity observations in the United States "indicate that the excesses or deficiencies of mass represented by the residual gravity anomalies correspond to a mass excess or deficiency averaging about 630 ft." However, it is to be noted that these conclusions refer to averages. Actually individual areas may show anomalies far in excess of these figures and it has been shown conclusively that some regional anomalies are closely related to regions of abnormal tectonic activity in the earth's crust and that local anomalies are definitely related to local density variations associated with geological features.

Evidently the intensity of gravity varies in anomalous fashion over the surface of the earth. The anomalies of a regional nature are associated with broad-scale isostatic, tectonic and geological factors and even possible departures from the assumed ideal shape of the earth. Herein lies the interest of geophysicists and geodesists (see GEODESY) in regional and world-wide gravity data. On the other hand, in addition to this somewhat academic value, a very practical interest exists in the local gravity anomalies resulting from the perturbations superposed on the regional gravity field as a result of density variations associated with the more superficial geologic features. It is the relation of such local gravitational anomalies to structural geology that has given rise to an important application of gravity measurements in the field of exploration geophysics, particularly as applied to petroleum exploration. The very considerable economic importance attached to the latter has resulted in the expenditure of great effort and vast sums in the development of gravimetric methods and in extensive and detailed surveys in known and potential petroliferous areas. Indeed, it may be said that the most significant advances in instrumentation have been made in this field since such methods were first applied on a large scale for exploration purposes about 1923.

Methods of Gravity Measurement. — Measurements of the intensity of gravity may be divided into two classes: (1) absolute, and (2) relative gravity. As will be evident later, and in common mith all absolute measurements of forces or similar quantities, the precision attainable in absolute gravity measurements is considerably less than in the case of relative measurements. Fortunately, from a practical viewpoint the relative method is adequate for the purposes desired and moreover its precision increases somewhat in proportion as the areal extent of the desired survey decreases. Thus while a precision of say 2×10^{-6} g may be adequate to define semiregional anomalies, for exploration purposes involving very local and hence very minute variations, relative measurements within 10^{-7} or even 5×10^{-8} g are required.

Absolute Gravity Measurements. — Measurements of the intensity of gravity have long been made by means of the pendulum and prior to the middle of the 18th century a small weight suspended by a thin thread was usually employed. The length was adjusted so that the pendulum oscillated a little faster or slower than the escapement of a chronometer-type clock and accurate comparisons of the period of the pendulum with the gravity-independent timing of the clock were made by the method of coincidences. Assuming the pendulum bob to be a point mass and its support a weightless thread, the relation between its period T and the intensity of gravity g, when oscillating with an infinitesimally small amplitude, is given by

$$T=2\pi\sqrt{l/g} \text{ or, } g=4\pi^2 l/T^2. \quad (8.1)$$

However, any practical pendulum comprises some form of rigid rod carrying a supporting axis, usually a knife-edge, at one end and perhaps a mass or bob at the other end. For such a compound pendulum equation (8.1) becomes:

$$T=2\pi[(K^2+l^2)/lg]^{\frac{1}{2}} \quad (8.2)$$

where K is the radius of gyration of the whole pendulum about its centre of gravity, and l is the distance from the knife-edge to the centre of gravity of the pendulum.

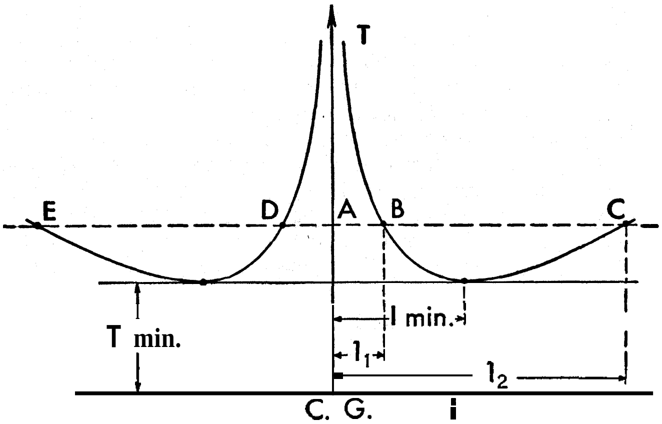

FIG. 3.— CHARACTERISTICS OF COMPOUND PENDULUM. PRINCIPLE OF "MINIMUM" PENDULUM (EFFECTIVE LENGTH=RADIUS OF GYRATION)

In the design of pendulums for gravity measurements it is important to look further into the properties of the compound pendulum. If a rigid rod be equipped so that the length l between the centre of gravity of the rod and the knife-edge may be varied over a wide range, the period T of the pendulum will be related to l as shown in fig. 3. Thus it will be found that there are two values of 1 when the point of support is on the same side of the centre of gravity, for which the period of oscillation is the same: points B and C at l_1 and l_2 respectively. The period of such a pendulum is given by

$$T=2\pi[(l_1+l_2)/g]^{\frac{1}{2}}. \quad (8.3)$$

On the other side of the centre of gravity there are two other points D and E for which the period is the same. $AD=AB=l_1$, and $AE=AC=l_2$. Also $CD=BE=(l_1+l_2)$. Thus C and D are two points, unsymmetrically placed with respect to the centre of gravity, whose distance apart is equal to the length of a simple pendulum whose period of oscillation is the same as that of the compound pendulum. This relation holds even though the pendulum is not a uniform bar.

Kater's *Pendulum* for *Measurements* of *Absolute g*.—The best method known for absolute determinations of g involves the above properties of a compound pendulum. This was suggested by Gaspard de Prony (1800), by J. G. von Bohnenberger (1811) and by Capt. Henry Kater (1817). Kater was probably the first to make pendulums to which equation (8.3) could be applied precisely.

About the year 1818 Kater employed the invariable pendulum for determining the variation in g at the principal stations of the Trigonometric Survey of Great Britain. (Phil. Trans., p. 337, 1819.) The pendulum comprised essentially a rod fitted with two knife-edges at opposite sides of the mid-point and so adjusted that the period of oscillation was the same about both of them. When this adjustment had been made the distance between the knife-edges was equal to the length of a simple pendulum of the same period (equation [8.3]). Thus the absolute value of g could be determined from the period of oscillation and measurements of the distance between the knife-edges.

Kater's pendulum still remains the best method of measuring the absolute value of g, since the measurement of the distance between its knife-edges is a relatively simple problem. In a later form Kater's pendulum comprises a metal bar carrying two fixed knife-edges. These are set facing each other on opposite sides of the centre of gravity of the bar and serve as axes of oscillation. On the bar are also mounted two masses, one of which is much larger than the other. By adjusting the position of the larger mass the period of oscillation about the two knife-edges is easily made approximately equal. The small mass can then be adjusted until the difference of the two periods is arbitrarily small. With this form of pendulum equation (8.3) still applies and the distance between the fixed knife-edges is the only measurement, other than the period of oscillation, required to determine g. There are, however, certain corrections required if very accurate determinations are to be expected and since similar corrections are required in all types of pendulum measurements the factors involved are given here.

(1) *Amplitude.*—The amplitude of the actual oscillations are not infinitely small as required of the simple pendulum theory and the period T must be corrected to zero amplitude.

(2) Buoyancy. — The pendulum swinging in air is buoyed up by the mass of air displaced. Evidently this buoyancy is equivalent to a reduction in g acting on the pendulum and the result must be corrected accordingly.

(3) *Aerodynamic.*—The pendulum drags a certain amount of air along with it in its motion and the increased effective mass thus produced increases the moment of inertia and hence the period of the pendulum. For a Kater-type pendulum it can be shown that this correction is zero if the external form of the pendulum is symmetrical about its mid-noint. the knife-edges heing placed equidistant from the centre of its geometrical figure though not its centre of gravity (c.g).

(4) Damping. — The viscous resistance of the air as well as energy dissipation at the knife-edge causes a damping of the pendulum oscillation which increases its period slightly as in all oscillating systems. This effect may be introduced along with the amplitude correction if the initial and final amplitudes are carefully observed.

(5) Temperature. — Temperature changes will change the length of the pendulum in accordance with the thermal expansion co-

efficient of the pendulum material.

(6) Sway of Support.—The supports on which the knife-edge rests will yield very slightly to the horizontal forces imposed by the swinging pendulum. Since the sway will be in phase with the pendulum oscillations it will be seen that the sway effect is analogous to a slight increase in the effective length of the pendulum and increases its period. In practical cases the sway may be measured by means of an optical interferometer or computed from the known mass of the pendulum, its amplitude, and the resilience of the knife-edge support as measured by an interferometer when a known horizontal force is applied at the support.

(7) Rounded Knife-Edge.—In theory, the knife-edge is assumed to be infinitely sharp. Actually it must have, effectively, a slight radius of curvature. As a result the pendulum swings on a "rolling" contact which tends to shorten the period. In the case of Kater-type pendulums, this correction is avoided if the radii of curvature of the two knife-edges are equal.

In practical cases, amplitude corrections (1) are minimized by holding the amplitudes to small values—but they must be measured. The buoyancy, aerodynamic and damping corrections (2, 3, 4) are minimized by swinging the pendulums in an evacuated case at relatively low air pressure (about 4 mm. Hg.). Temperature effects (5) are minimized by the use of material having low thermal expansion coefficients and by controlling the temperature. The sway of the support (6) can not be eliminated when swinging a single pendulum though it may be minimized by the use of a very rigid support for the entire pendulum case.

Relative Gravity Measurements—Pendulum Equipment.—Geodetic and geophysical problems concerning gravity may be adequately studied by means of relative measurements since only the differences in gravity at various points on the earth's surface are required with a high degree of accuracy, while the absolute numerical value is of secondary importance. Fortunately such relative determinations may be made with considerably higher precision than absolute measurements with the Kater pendulum. Thus a notable advance in gravimetric apparatus was made in 1882 when Von Sterneck introduced the quarter-meter invariable pendulum, which beat half-seconds (period = 1 sec.). Its compactness made it more practical to minimize some of the extraneous disturbances than was the case with more cumbersome apparatus. Moreover the pendulum itself, having no adjustable parts, was more rugged, and by virtue of the method of operation, length measurements were eliminated.

In principle, the period of an invariable (fixed length) pendulum was determined at a base station at which the absolute value of g had previously been determined by the Kater method. Using this period as the standardized value, and assuming that the pendulum remained fixed in length, observations were then made at other stations and any change in period observed was assumed to be due to a change in g as compared with the value at the base station, in accordance with equation (8.1). In effect the value of g at the base station is-transferred to the new stations and this transfer is effected with a higher precision than would ordinarily be obtained by a repetition of the Kater pendulum work at the new locations. For this reason all geodetic and related gravity pendulum observations are made by relative measurements using this principle.

Available information to date indicates that perhaps the most accurate pendulum measurements of relative g have been made with apparatus designed for use in geophysical exploration. Since this equipment incorporated all of the refinements developed during the period from Von Sterneck's day to about 1936 when other instruments replaced the pendulum, a brief description of this equipment should present an adequate outline of modern gravity-pendulum equipment.

Minimum Pendulums.—Referring to fig. 3 showing the properties of a compound pendulum it will be noted that at a certain length $l_{min.}$, the pendulum has a minimum period and any change of the length in either direction results in an increase in period of oscillation. Practical use of this property is made in the construction of an invariable pendulum by so designing it that the knife-edge is located at the point l_{min}. Because of the slow change in slope of the T vs. l curve on either side of the minimum point, such a pendulum will be far less sensitive to slight changes in l, caused by wear or inadvertent slight shifts of the knife-edge position, than is the more common pendulum comprising a heavy weight on a relatively long staff. It may be shown that this condition is realized when the distance from the knife-edge to the centre of gravity of the pendulum is equal to its radius of gyration about an axis through the c.g. and by suitable measurements this adjustment may be attained with adequate precision. (For theory see O. Meisser, *Zeitschr*. f. Geophysik, vol. 6, pp. 1–12.) However, this device does not eliminate certain other variables which may appear to be equivalent to a physical change in l_{min}.

Since changes in temperature will change the length of a pendulum in accordance with its thermal coefficient of expansion, a material having a very low coefficient is desired. Early pendulums were made of brass, probably to eliminate magnetic effects and because no superior nonmagnetic material was then available. Later invar, a relatively nonmagnetic nickel-iron alloy having a low thermal coefficient of expansion, was used. However, while its expansion coefficient is about 1×10^{-6} compared with about 18×10^{-6}/C.° for brass, the magnetic effects are not negligible and it is somewhat unstable physically, as evidenced by sudden unexplainable shifts in period. Fused quartz. having a thermal expansion coefficient of 0.25×10^{-6}/C.° is the most suitable material to minimize temperature corrections and is extremely stable physically. These desirable properties outweigh the disadvantages both of difficult fabrication and low density which decreases the energy of the swinging pendulum with a resultant increase in damping.

Such minimum pendulums designed for geophysical exploration are shown in Plate, fig. 1. They are about 30 cm. long, weigh 590 g. and have a period (complete oscillation) of approximately 0.89 sec. They are ground from a single piece of fused quartz except for the fused quartz plugs that form the knife-edges. These one-piece plugs, with a suitable ground and polished knife-edge, closely fit and are cemented in a hole in the head of the pendulum. Massive blocks of Pyrex glass with the top face ground and polished to an optically flat surface constitute the knife-edge supports or bearings. A conical centring hole is ground in the bottom face at one end of the knife-edge plug and with a V-groove at the other end, means are provided whereby two ball-point supports on a lifting device insure that the knife-edge is always returned to exactly the same spot on the flat supports. Since the pendulums must be lifted and clamped for transportation, after the centring lift-device has carried the knife-edge off the support, a secondary lifting device engages the bottom of the pendulum while the upper end enters a suitable socket whereby the pendulum is firmly clamped while the knife-edge plug is relieved of any load.

The adjustment of the K = l relation required of a minimum pendulum is attained with sufficient accuracy by preliminary adjustment of the design of a homogeneous metal pendulum and duplicating this replica in the quartz. Matching of the periods of a pair of pendulums to high precision as required in two-pendulum apparatus may be accomplished by grinding material from the lower end of the slow pendulum. Those of Plate, fig. 1 are matched within 2×10^{-6} sec.

Modern pendulum apparatus uses a pair of pendulums swinging with equal amplitude and 180° apart in phase, the matching of their periods being sufficiently accurate to assure that the phase opposition will be retained within sufficient tolerance for a run which may be for an hour's duration. This method of operating a pair of pendulums in phase opposition accomplishes two important results: (1) The horizontal acceleration imposed on the support by one pendulum is balanced by an opposite acceleration of the second pendulum thus eliminating the cause of sway and the sway correction which normally is very important but difficult to ascertain. (2) It permits elimination of the perturbations in phase and hence the periods of the pendulums caused by extraneous horizontal accelerations of the support such as seismic or similar random disturbances which may not average out over the duration of a run. Because any horizontal acceleration imposed on the support and advancing the phase of one pendulum will retard the other, the average of the two periods will be equivalent to a "fictitious" pendulum whose period is unaffected by the disturbance. ("Observations de pendule dans les pays bas," F. A. Vening-Meinesz, Pub. de la *Commission Geodesique Neerlandaise,* p. 12, 1923.) By recording each pendulum separately, the magnitude of any disturbing seismic effect may be observed while permitting its elimination by averaging the two periods.

The details of the remainder of the pendulum apparatus will depend upon the method of operation. In the exploration equipment two pendulums are mounted in a vacuum-tight cast-aluminum case. Clamping, starting and stopping of the pendulums are all done from the outside through vacuum-tight stuffing boxes without disturbing the vacuum. The cases will normally maintain a 0.1 mm. Hg, vacuum for months without pumping out. The case is surrounded by a net of electric heating nires and is covered completely by a thick eiderdown cover. A suitable thermostat controls the portable battery power to the heater and maintains the case within 0.1° of a fixed temperature some few degrees above the highest ambient temperatures encountered. By careful attention to these details the magnitude of corrections may be minimized and particularly, by keeping the operating conditions very nearly constant, variation of the corrections, which is the most troublesome factor in relative measurements, is thereby minimized. As a further example, amplitude corrections may be eliminated by always starting the pendulums at the same amplitude through careful maintenance of the adjustment of the operating levers, and with constant pressure in the case, the decrement is quite constant so that final amplitudes are the same from one run to another. The pressure is indicated by a suitable low-pressure gauge and an efficient drying agent in the case assures that no density changes result from humidity variations. Electrostatic charges on the pendulums which may be very serious because of frictional effects in the padded clamping device are completely eliminated by the ionizing effect of a small amount of radioactive material in the case.

Associated with the pendulum apparatus itself is the recorder equipment which, again, may depend on the method of operation. In the exploration equipment the recorder contains a small straight filament lamp to serve as a light source from which a beam of light passes into the pendulum case. This beam is divided into two beams, each of which is reflected four times from the faces of the two pendulums and a set of fixed mirrors. Finally the two beams are returned to the recorder where they fall on a moving photographic tape. The tape also records light reflected from two oscillograph elements. One of these is used for recording radio time signals and the other for recording a 500-cycle A.C. reference trace obtained from an electrically driven tuning fork. This joo-cycle trace serves to subdivide the second signals so that the transit of a pendulum through its equilibrium position and its phase with respect to any given time signal may be measured within about 0.0001 sec. regardless of slight variations in tape speed. A few seconds' running of the tape suffices to establish the phase of the pendulums with respect to an initial time signal and at the end of the run, say an hour later, another few seconds of recording provides the phase positions at the final signal. The periods of the pendulums are known accurately enough so that the number of whole swings in the run can be determined from the number of seconds (measured with a chronometer) between the starting and ending time signals. The fractions of a swing are obtained accurately from the tape measurements. Thus the measurements give for each pendulum the total number and fractions of swings over the interval of the time signals. With a reading error of the order of 0.0001 sec. it is not difficult to attain an observational accuracy of about 1 part in 10,000,000 for a run of 30 minutes' duration.

Evidently, if the above time signals are derived from a standard clock of high precision or from a modern crystal controlled clock, the periods of the pendulums and their average or "fictitious" pendulum period may be determined with high precision. Since the pendulums are assumed to be invariable, any changes in period from one point of observation to another are assigned to variations in g in accordance with equation (8.1) which may be written in the form

$$T=K/\sqrt{g} \text{ or } g=K^2/T^2$$

where K is a dynamic constant of the fictitious or average pendulum. It will be understood hereafter that in a two-pendulum apparatus the pendulum period T refers to this average. Then if T_0 is the period of the pendulum at the base station where gravity has the value g_0 and T_1 is its period at a field station of value g_1:

$$g_0= K^2T_0^{-2} \text{ and } g_1=K^2T_1^{-2},$$

and in the ratios,

$$g_0/g_1=(T_1/T_0)^2 \text{ or } g_1=g_0\left(\frac{T_0}{T_1}\right)^2,$$

the dynamic constant of the pendulum, being invariable, drops out. It will be noted that the periods enter as the square, hence the timing of the pendulums must be twice as good as the desired accuracy in the gravity differences.

For geophysical work it has been found convenient to use two or more identical pendulum units. In such operation one set of pendulums is operated at the base station where it is used in place of the above-mentioned standard clock. It is then only necessary to transmit suitable start and finish time signals which are recorded simultaneously at all stations. The number of swings of all pendulums over the identical time interval recorded on the several tapes may then be determined very accurately. The ratio of total swings of each pendulum to every other one is first determined with all pendulums operating at some base station. These ratios comprise the standardization of the pendulums. Thereafter when the pendulums occupy different stations during an observation, the changes in ratio of total swings, which ratios are independent of the absolute time involved, are assigned to the gravity differences between stations. Modern pendulums operated in this manner and in routine field work on stations separated up to 50 mi. have given probable errors of a single observation averaging about 0 25 mg. The customary duration of such observations was 30 min. With special care, as in establishing calibration stations for gravity meters, probable errors as low as 0.10 mg. (1 part in 10,000,000 of total g) have been attained. With similar equipment and the exercise of proper caution in handling it, somewhat comparable accuracy should be attainable on more widely separated stations. Several units of such exploration equipment including recorders are shown in Plate, fig. 2.

Gravity *Measurements* at Sea.—The success of the two-pendulum method of operation in the gravity surveys on unsteady terrain in the Netherlands led Frederik van Iterson, director of the Dutch government mines, to suggest to F. A. Vening-Meinesz the practicability of pendulum observations for gravity measurements at sea. In 1923 preliminary experiments in a Netherlands navy submarine showed such promise that extensive surveys nere planned and actually carried out. (F. A. Vening-Meinesz, Gravity *Expeditions* at *Sea, 1923–30,* Pub. of Netherlands Geodetic Commission, 1932.) This work, carried out in a submarine, established a belt of stations encircling the earth in a belt between 10°–40° N. latitude together with an extensive network of stations in the Netherlands Indies area. The accuracy of these stations, as given in the Vening-Meinesz report, was about 3 to 4 mg.

The apparatus used comprised essentially the twn-pendulum method although the older Yon Sterneck type bronze pendulums were used instead of the minimum period type already described. Two pairs swinging in planes go° apart were actually used instead of one pair. Also the recording was continuous against chronometers which were rated daily against radio time signals. The entire pendulum apparatus including the recorder was mounted in gimbals to minimize disturbances due to tilt of the submarine. In quiet harbour waters observations were made with the craft surfaced, but in the open sea observations were generally made while submerged at sufficient depth to minimize wave action.

It is of interest to note that gravity observations made from a moving craft must be corrected for the Eotvos effect, *i.e.,* the eastward speed of the craft adds to the earth's centrifugal effect while a westward component subtracts. Vening-Meinesz checked the underwater speed of the submarine from time to time by making an observation with eastward speed and again westward. The difference in the observed g gives twice the Eotvos effect. Thus he records Obs. No. 185—speed 3.7 knots, Obs. So. 222—speed 3.8 knots. He estimates the error in g due to uncertainty of speed and estimated ocean currents as about 2 mg. at the equator. At higher latitudes it would be multiplied by the cosine of the latitude.

Measurements of gravity from a ship at sea are handicapped not only by the horizontal accelerations but particularly by vertical accelerations of the apparatus. Theoretically the two-pendulum method is capable of eliminating the horizontal components of acceleration provided they are not of sufficient magnitude to cause skidding of the knife-edges. However, any vertical accelera-

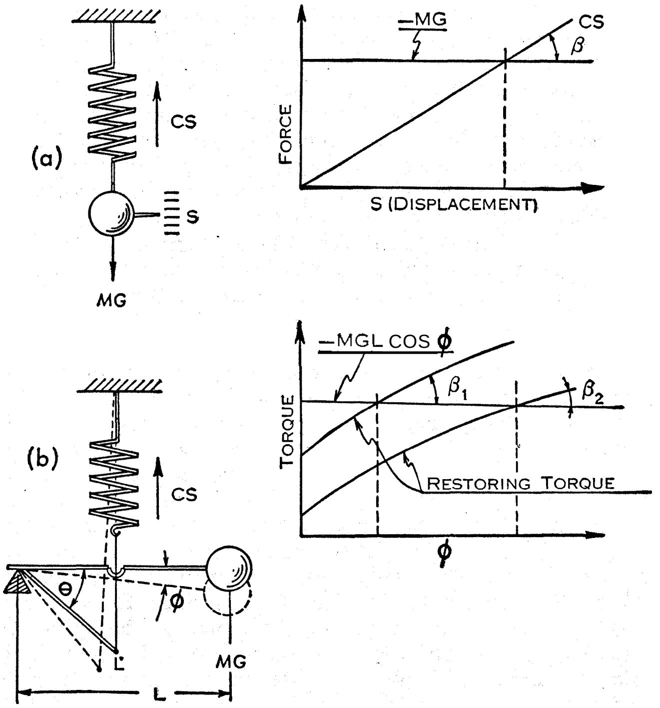

FIG. 4.— PRINCIPLE OF UNASTATIZED (A) AND ASTATIZED (B) GRAVIMETERS

tions are exactly equivalent to changes in the earth's gravitational acceleration and are measured as such with any gravity-measuring equipment that can be devised. On the other hand, over a sufficiently long period of time the up-and-down wave motions are of equal magnitude since the surface of the water maintains its average elevation. Hence to the extent that the up-and-down accelerations are averaged out, *i.e.,* integrate to zero over the duration of the observation, the resultant g will be free from motional acceleration errors. It is for this reason that to date the pendulum method as used by Vening-Meinesz constitutes the most accurate method yet devised for observations at sea. Any direct-reading gravity meter such as will be described later would have to be equipped with an accurate continuous integrating device whereby 'the indicated g would represent an average value over a sufficient interval of time to assure that the residual vertical motional acceleration was of negligible magnitude.

Relative Gravity Measurements by Gravity Meters.— The gravity meter or gravimeter is simply a spring balance comprising a constant mass supported by a spring system, the changes in elongation of which may be read with precision.

The total elongation S of a spring supporting a weight mg is

$$S=mg/c$$

where c is the spring constant or force per unit elongation. Since over any reasonable range a spring follows Hooke's law, the system is linear and any change in g is accompanied by a proportional change in elongation, S. The proportionality factor or sensitivity is m/c, *i.e.,* the ratio of the mass to the spring constant, and hence we may say that in such a simple spring gravimeter the sensitivity is proportional to the initial elongation of the spring.

The practical applications of gravimeters require an instrument capable of detecting differences in g of 0.1 mg. or less, and since such differences are unalterably superposed on a total g of some 980,000 mg., the instrument must have sensitivity of at least 1/10,000,000 g. That is, a simple gravimeter comprising a spring with a mass at the lower end and having an initial elongation of, say, 10 cm., would exhibit a change in gravity of 1 mg. as a change in elongation amounting to 1×10^{-6} cm. or about 1/50 the wave length of visible light. This example suffices to illustrate the magnitude of the sensitivity requirements.

On the basis of the means used for measuring these minute changes, gravimeters may be separated into two broad classes, (1) unastatized or stable type, (2) astatized or unstable type. In principle these two types are illustrated in fig. 4. Here at (a) is shown schematically the simple unastatized system. The accompanying force v. displacement diagram shows the constant downward force due to the weight mg and the upward restoring force CS of the spring, proportional to displacement. Obviously, the equilibrium displacement of the spring will be at the intersection of the two force curves and the sensitivity of the system will increase as the angle β decreases, a result which, because of the linearity of the curve CS, can be accomplished only by increasing the length and the equilibrium elongation of the spring if the spring loading is to be held within tolerable limits. This provides a direct-deflection instrument with a linear scale over any range of gravity, and a calibration constant which is a function only of the spring constant and the suspended mass regardless of any operational adjustments. However, as already outlined, such an instrument must be provided with a high order of mechanical and optical magnification to permit accurate measurement of the small deflections due to the small changes in gravity to be detected.

On the other hand, fig. 4 (b) illustrates the principle of astatization and the resulting torque v. displacement characteristics. Here the moving system comprises an arm hinged at one end and carrying a weight mg at the other end. With the spring attached to the weight arm, the system would have characteristics similar to the unastatized system (a). But the spring is attached to a lever arm L' at an angle θ with respect to the weight arm L and if the angle 0 is quite large the spring restoring-torque curve becomes strongly nonlinear. A similar effect results if the spring is attached to the weight arm L but its upper support is moved to the left so that its force is applied at an angle 0 to the moving arm. Now by adjustment of the system such as a change in the angle θ, the restoring torque curve may be made to have any desired characteristic intersecting the gravitational deflecting torque curve with angles β_1, β_2, or even vanishingly small angles. Thus angle β may be made arbitrarily small and the sensitivity arbitrarily great, up to the point of instability when $\beta=0$. By devices equivalent to fig. 4 (b) it is possible to simulate the behaviour of extremely long springs and thereby attain very high sensitivities. However, it is evident that with each change in adjustment the sensitivity and hence the scale value of such an instrument will be changed. Moreover, even for a fixed adjustment, if the astatization is pronounced the nonlinear feature precludes a strictly linear scale. This practically dictates the design of a null rather than a direct-deflection type instrument. Thus in astatized types a very fine auxiliary spring with linear restoring-torque characteristics is used to bring the moving system back to a fixed zero, this auxiliary spring having a linear scale calibrated to read gravity changes. Since the range of such an auxiliary scale may be limited, special provision must then be made to cover wider ranges.

Numerous embodiments of the astatizing principle are represented in a wide variety of gravimeter designs, a few of which have been developed into commercially successful instruments. It is of interest to note that some of these are basically vertical seismographs, since the sensitivity problems are identical, the gravimeter requiring high sensitivity to the steady acceleration g, while a vertical seismograph must record the periodic motional accelerations associated with seismic waves. It is pertinent to consider the relation between the sensitivity of a gravimeter and its period.

As already mentioned, the elongation S of a spring supporting a weight mg is

$$S=mg/c$$

where c is the spring constant or restoring force per unit elongation. The period of the same system. vibrating in simple harmonic motion is

$$T=2\pi\sqrt{m/c}.$$

From these two equations

$$S=gT^2/4\pi^2$$

and the elongation δS due to a change in gravity δg is

$$\delta S=\delta g T^2/4\pi^2.$$

Thus for a simple unastatized gravimeter the sensitivity is proportional to the square of the period.

The same considerations apply to the astatized type except that in all such instruments the geometry of the system permits adjustment of the effective spring constant to arbitrarily small values so that the period and sensitivity are correspondingly increased. Consider, for example, the elemental spring balance previously mentioned, having an initial displacement of 10 cm. and a sensitivity of 1×10^{-6} cm. per 10^{-7} g. The period of the system, fig. 4 (a) would be approximately 0.63 sec. Now to obtain an increase in sensitivity of 100-fold the astatizing device of fig. 4 (b) may be adjusted to a period of 6.3 sec., assuming the rotational moment of inertia of the beam system to be negligible. With such an adjustment the instrument simulates the performance of an elemental balance having an initial equilibrium elongation of the spring of about 1,000 cm. and yet the actual elongation need not exceed a few centimetres. Evidently the mechanical or optical magnification required in an astatized system, to obtain adequate gravimetric sensitivity, decreases with the degree of astatization. The practical limits are determined by the attainable stability of the adjustments. Clearly the astatized instruments represent a very attractive design from the viewpoint of attaining adequate sensitivity for portable instruments.

Attention is again called to the fact that the gravimeter and the seismograph are both acceleration-sensitive devices and moreover the sensitivity criterion of both instruments is identical—a long period. Since g represents a steady state vertical acceleration while seismographic disturbances are periodically varying accelerations having strong vertical components, a gravimeter having low seismic sensitivity without sacrifice of gravimetric sensitivity must incorporate a very low frequency filter between the moving system and the indicating device. In most devices this is wholly impractical and in any type the best that has been done is the elimination of high-frequency microseismic disturbances with some suppression of the long-period (10–20 sec.) earthquake waves. Thus no gravimeter has yet been designed that permits operation during earthquake disturbances and for this reason field operations may be effectively shut down for periods of many hours during which these transient accelerations far exceed the required gravimetric reading accuracy.

These considerations serve also to indicate the problem involved if direct-reading gravimeters were to be used on unstable supports such as ships or aircraft. Such use would be practicable only if an integrating device could be incorporated in the design so that the periodic vertical accelerations of the support could be averaged out over sufficiently long periods to assure that no residual unidirectional motional accelerations were included in the readings. And as an illustration of the minuteness of the accelerations involved, assume an aircraft sufficiently stable to permit the operation of a gravimeter in flight. Then a continuous unidirectional vertical acceleration sufficient to produce a total change in elevation of the aircraft of about 20 ft. in one hour would show on the gravimeter as a spurious reading of 10^{-7} g. Moreover the 20 ft. change in altitude itself would result in an actual change in g, or elevation effect, amounting to about 1.9 mg. or 1.9×10^{-6} g. Thus the impracticability of operating high-precision gravimeters on unstable vehicles while in motion is clearly indicated.

Design **of** Gravimeters. — The practical design of high-sensitivity gravimeters involves the following most serious problems: (1) The spring material must be stable so that creep rates and hysteresis effects are small. (2) Disturbances due to thermal effects may distort the system and modify the adjustment. Also changes in temperature will affect directly the spring displacement depending on the thermal coefficient of elasticity of the spring material. Nonuniformity of the temperature within the housing may create disturbing convection currents in the air resulting in spurious forces on the moving system. (3) The level sensitivity of the system must be carefully considered since the level tolerances for a given gravimetric sensitivity may be unattainable with any practical levelling device. (4) The moving system must be adequately damped if used for field observations and to minimize fluctuations induced by seismic disturbances. (5) Sensitivity to atmospheric pressure changes resulting in changes of buoyancy of the air must be eliminated by sealing the instrument against pressure changes. (6) Sensitivity of the instrument to magnetic fields due to ferromagnetic properties of the spring material should be eliminated.

Secrecy concerning the design details of many of the most modern gravimeters used in geophysical prospecting preclude a comprehensive outline of the expedients used in solving the above problems. In general, however, the following outline covers the subject broadly.

Spring Material. — The excellent mechanical properties of fused quartz have led to the use of this material in some instruments both in the form of helical springs or torsion fibres though its thermal coefficient of elasticity is relatively high. However, most commercial instruments use metal springs and certain nickel-chromium-iron alloys have excellent characteristics when properly cold-drawn or rolled, and heat treated. They are sufficiently magnetic to make shielding desirable in some designs. The creep of some of these alloys under load may be made very small by proper adjustment of the loading of the spring. The hysteresis effects resulting from changes in elongation of the spring are minimized by designing the weight-clamping device so that the spring displacement is always substantially constant. In many gravimeters this clamping means holds the weight in a fixed position within a few ten-thousandths of an inch.

Temperature Effects. — Practically all field instruments are provided with thermostatically controlled heaters to maintain the temperature at some fixed value above the ambient temperature. Such controls may inhibit short-period temperature fluctuations within 0.001°C. Because temperature changes may affect the instrument operation due to several causes, control of the temperature appears more practical than methods of compensation although reasonable diligence in providing such compensation is customary.

Level Sensitivity. — This is a very difficult problem in many cases and its solution depends entirely on the type of instrument and particular details of the design. In a few instruments the moving system comprises two separate systems operating in 180° relation so as to permit averaging of their readings and thereby eliminate the most serious component of level error.

Damping Devices. — The damping of all vibrational modes of the moving system is particularly important for portable field instruments. Air damping is commonly used and is satisfactory when carefully designed. The damping forces must be free of any minute unidirectional forces induced by periodic motions. Electromagnetic damping using permanent magnets with copper vanes in the air gaps is practical out careful attention must be given to the elimination of all traces of ferromagnetic material in the vanes.

Magnetic Shielding.—If necessary, due to the nature of the spring material, magnetic shields of a well-known type may be used for shielding the spring alone or the entire instrument. Alternatively, the instrument may be carefully oriented always in the same direction in the earth's magnetic field.

Typical Gravimeter Designs.—The idea of using direct-reading gravity meters rather than pendulums is old but the early aim was primarily to provide a gravity-measuring device sufficiently sensitive to record temporal variations in g rather than to use it as a portable instrument in the field. Thus as early as 1862 M. Perrot used the angular deflections of a disk suspended by a long helical spring in attempting to record the minute time variations in g resulting from tidal forces. Such an instrument is evidently equivalent to the simple spring balance of fig. 4 (a) except that advantage was taken of the rotation induced by vertical displacements of the helical spring to permit easy optical magnification by the use of long optical levers.

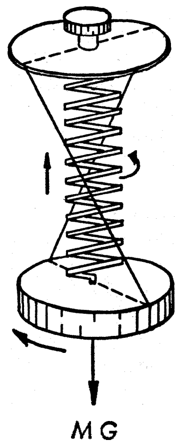

FIG. 5.— PRINCIPLE OF BIFILAR GRAVIMETER

Because the temporal variations in g (tidal forces) are of the order of only a few parts in 10,000,000 of total g, the sensitivity sought in these gravimeters was of the order of 10^{-9} g. This led to the early use of astatized instruments wherein the attainable sensitivity is limited only by the practical limits of maintaining their stability.

In 1837 C. F. Gauss had introduced the bifilar magnetometer. In 1898 A. Schmidt (*Beitr.* Geophys., vol. 4, pp. 109–115, 1900) replaced the restituting moment of Gauss' magnet by a helical torsion spring and created the trifilar gravimeter. Since then, bifilar and trifilar gravimeters have been perfected chiefly by W. Schweydar, A. Berroth, and particularly R. Tomaschek and W. Schaffernicht (Annalen der Physik, vol. 15, p. 787, 1932) who apparently were the first to use the nickel-chrome-iron (Krupp WT-10) alloy for the spring material.

While the trifilar instrument is somewhat more stable mechanically, in principle it is identical to the bifilar arrangement shown schematically in fig. 5.

In this class of astatized instruments the weight mg is supported partly by the helical spring and partly by the fine suspensions. The suspensions are held at an angle with respect to the vertical plane by a counterclockwise torsion of the helical spring. The vertical load mg, part of which is supported by the twisted suspensions, tends to pull the suspensions into a vertical plane with a resultant lowering and clockwise rotation of the lower disk. On analysis which is too complex to present here, it will be found that by proper adjustment of the relative load carried by the spring in tension, the load on the fibres, and the angle of twist of the fibres, the system may be brought to the point of instability characteristic of astatized systems. By adjusting the apparatus close to this point but within the zone of stability, very high gravimetric sensitivities may be attained. Considerable optical magnification of the rotational displacement of the system due to changes in g may easily be obtained by an optical lever using a mirror fixed on the lower disk. Tomaschek and Schaffernicht have reported that their gravity variometer is capable of a sensitivity of about 0.001 mg. or 10^{-9} g. However, the apparatus was by no means portable.

Evidently many mechanical modifications of this general type of instrument are possible. In some of these the central helical spring is eliminated and the necessary spring-restoring force obtained by using relatively stiff suspensions with torsional twist imposed on the suspensions. Plate, fig. 3 shows a developmental model of a typical bifilar gravimeter designed as a portable instrument for field use but not actually put into service. The thermostated and airtight container is not shown. The bifilar astatizing suspensions are drawn in to make them visible.

Another class of astatized gravimeters is designed with a horizontal torsion fibre or spring restoring force. This type is probably well exemplified in the G. Ising instrument (*Amer. Inst. Min. & Met. Engrs.*, vol. 1, p. 665, 1937) originally designed about 1918. The essential feature is a horizontal torsion fibre with a small rod mounted vertically at its mid-point. When the instrument is level the rod stands vertically. The instrument as a whole is then tilted through a small angle, resulting in a deflection of the rod towards a horizontal position. Measurements are made by tilting the instrument successively to one side and then the other by a known angle and measuring the resultant angular deflections of the small rod which serves as the active mass. Obviously the scale is very nonlinear and the quartz fibre used has a temperature coefficient of elasticity of about 10^{-4} per C.° so that very close control of temperature is required. An accuracy of about 0.5 mg. is claimed. By taking the readings of opposite deflections as described, levelling errors are effectively eliminated.

Similar in principle is the Wright gravimeter (F. E. Wright and J. L. England, "An Improved Torsion Gravimeter." Am. Jour. *Sci.*, Fifth Series, vol. 35A, p. 373, 1938) except that the torsion fibre is replaced by a horizontal "hourglass-shaped coil spring of quartz." At the centre of the spring is attached a short rod carrying a small weight at its outer end. As the ends of the horizontal spring are simultaneously rotated the weight is raised against gravity. As it nears a horizontal position it approaches a condition of instability. A reading of the angular rotation of the spring is made when it is adjusted to bring the rod to a fixed

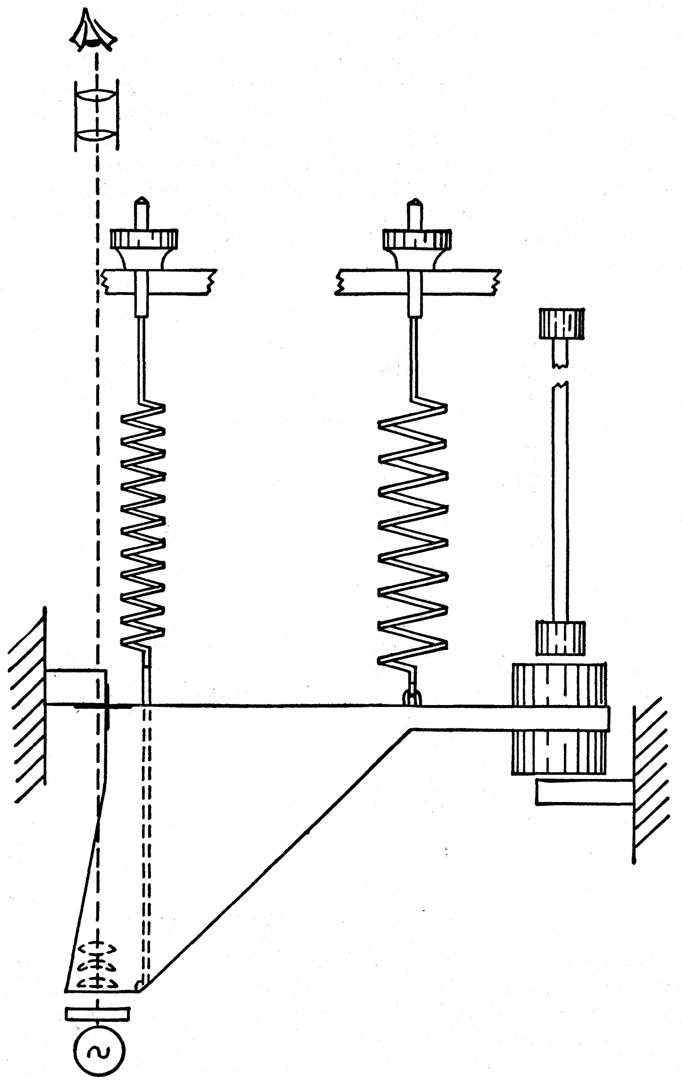

FIG. 6.— TRUMANASTATIEED GRAVIMETER

reference position near but just below the instability point. The reading is repeated with reversed rotation of the spring until the rod is brought up to a similar reference point in the opposite side. With a total rotation of some 1,400 degrees readable to about 10 sec., gravity can be read to about 10^{-6} g. Theoretically the reversed readings eliminate level errors but due to hysteresis effects inherent in all spring materials and since in the observations the spring is put through an entire stress cycle from zero to maximum and reverse, the attainable sensitivity is inherently limited. A similar limitation should apply to the Ising gravimeter. On the other hand, it is claimed that since the spring is normally under zero stress it has no detectable zero drift and therefore is a suitable instrument for relative gravity measurements between remotely separated stations. It was claimed in 1946 that a model at the Carnegie Geophysical laboratory, Washington, D.C., gave reliable readings within 1 mg.

The Mott-Smith gravimeter (L. M. Mott-Smith, *Geophysics*, vol. 2, p. 21, 1937) was designed particularly for gravimetric exploration. It comprises essentially a horizontal quartz fibre carrying at its mid-point a horizontal weight arm which is connected by a fibre to a light spring. The geometry of the linkage is such that the system is astatized, the torsion in the fibre and the tension of the "labilizer" fibre being nearly balanced. The entire system is constructed of fused quartz and is very small. The instrument proper is housed in a sealed container about 5 in. in diameter and 2 in. deep which in turn is contained in a liquid thermostat which holds the temperature constant to about 0.001°C. It is claimed that no clamping device is required because of the extremely light moving system and resultant high degree of air damping. The moving system, operated as a null device, carries an index point which is read with a microscope. These instruments have been used quite extensively in petroleum exploration and measurements to better than 0.1 mg. are claimed.

Another class of astatized gravimeters may be illustrated by

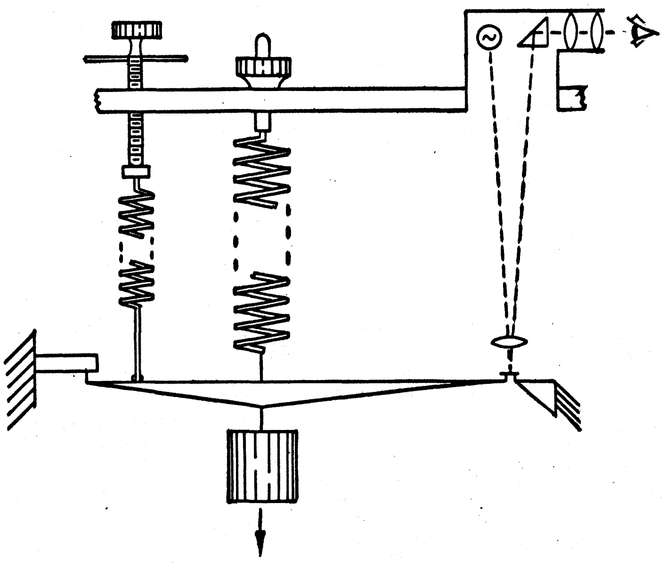

FIG. 7.— HARTLEY UNASTATIZED GRAVIMETER

the Truman instrument (described by A. B. Bryan, *Geophysics*, vol. 2, p. 301, 1937) and shown schematically in fig. 6. It, together with several others in commercial use, is similar in principle to astatic vertical seismographs. A mass is carried horizontally on a hinged triangular lever connected to two vertical springs. One spring is attached on the horizontal member between the hinge and the mass while the other spring is attached at the lower vertex of the triangular lever so that its line of action passes almost through the hinge point. By careful adjustment of the geometry of the system and the tensions of the springs the system may be brought close to the point of instability. Instruments of this type if carefully designed may be operated at very high sensitivity with springs of very short length, thus making for compactness. An index point is derived by optical levers or read directly from the mechanical lever system by means of a microscope. In general such instruments are provided with a very fine auxiliary spring whereby the index is always returned to zero so as to operate as a null instrument. The tension of the auxiliary spring is adjusted through a suitable micrometer arrangement calibrated linearly to read gravity changes. Obviously, auxiliary damping devices are required to insure adequate damping of all vibrational modes of the moving system and usually air-damping methods are used.

The Truman instruments or derivations thereof have been used extensively by the Humble Oil & Refining company and the Carter Oil company. It is safe to say that modern portable instruments of this type are capable of operating in the field with a probable error of the order of 0.05 mg. though exact data are not available. Of the more than 100 gravimeters which at times have operated simultaneously in geophysical explorations within the United States, doubtless the majority have been of this general type.

Unastatized Gravimeters--One of the earliest descriptions of an instrument designed for commercial geophysical exploration is that by K. Hartley *(Physics*, vol. 2, p. 123, 1932). As shown in fig. 7 it consists of a mass suspended on a spring. The position of the mass with respect to the supporting structure is determined by an optical lever. In Hartley's instrument the ratio of the motion of the fiducial spot of light reflected from the moving mirror to the motion of the suspended mass was about 60,000. A fine auxiliary spring served to bring the suspended system back to a fixed reference position for null operation. It is not known whether the device was used commercially.

It has been mentioned that in 1862 M. Perrot used the angular rotation accompanying the elongation of a helical spring to observe the changes in equilibrium position of a mass hung on a spring. F. Mielberg ("Uber perodische Veranderungen der Schwerkraft"—Pub. de L'Observatoire Astrononique de l'Universite de Tarter, vol. XXVII, no. 4, 1932) used a similar apparatus, again to measure temporal variations in g. About 1934, A. Hoyt in attempting to use the same principle in a portable gravimeter found the elongation-rotational conversion efficiency of a round wire helical spring inadequate for the purpose and moreover that the efficiency of conversion was a function of the internal stress distribution of the wire. Much greater rotation *v.* elongation was obtained using a thin ribbon helix. Fig. 4 in the plate shows the complete moving system of the Hoyt gravimeter. (Described by R. Wyckoff "The Gulf Gravimeter," *Geophysics*, vol. 6, no. 1, p. 13, 1941.) A ribbon helical spring about 10 in. in length and prestressed to decrease the equilibrium elongation, carries a mass at the lower end. The mass includes a mirror whereby the angular rotation may be measured and three arms carrying copper vanes which operate in the air gap of three small permanent magnets to provide damping. At the supporting end the helix is tapered to compensate rotational effects induced by bending of the spring at this point when the support is not exactly level. Also between the support and the main spring is a bimetallic loop which, with changes in temperature, introduces a slight rotational component to compensate for temperature effects in the spring.

The equilibrium displacement of the spring under total mg. results in a total angular rotation of the mirror of approximately 2,880° or 8 revolutions. Thus a rotation of about 1 sec. of arc results for 10^{-7} change in g. The rotation is observed by a multiple-reflection arrangement through the partially aluminized suspended mirror. Using the fourth reflection and an optical lever 22 in. in length, 0.1 mg. corresponds to 0.001 in. displacement under the micrometer-microscope. The reading accuracy at the micrometer is actually about 0.0001 in. The total range of the micrometer reading device is 25 to 30 mg. but the instrument may be adjusted for operation in any area by merely turning the spring supporting head to bring the readings back on scale. Such adjustments do not affect the scale constant since only a change in the spring constant itself or the mass can change the calibration of the instrument. Instruments in service for several years have checked their original calibrations to better than 0.5%.

The spring material is nickel-chrome-iron alloy hard-rolled and aged at somewhat elevated temperatures. The direction of creep is a function of applied stress so the mass is adjusted to operate the spring near its reversal point of zero drift. Drifts of 0.3 mg./24 hrs. are typical of a new instrument though in general the stability of the springs increases with age. It will also depend on operating conditions, for although the suspended mass is very carefully clamped in a fixed position for transportation the spring itself may be subject to some rather violent jars.

In the system of Plate, fig. 4 conditions are rather favourable for the elimination of short-period microseismic disturbances. Such disturbances cause vertical displacements of the weight but such displacements are observable in the optical system only when translated into rotation. The longitudinal period of the spring system is aboct 0.7 to 1 sec. whereas the rotational period is approximately 7 sec. and is quite heavily damped. This disparity in natural periods between the vertical and rotational modes, of which only the latter affects the optical system, results in a very inefficient conversion of short-period seismic disturbances to scale deflection. This filtering effect might be improved by increasing the disparity in periods but it would be impractical to carry it to a point that might eliminate normal long-period earthquake disturbances.

Observations at some hundreds of thousands of field stations have been made by the Gulf Oil corporation with this instrument with indicated probable errors of a single observation of 0.02 to 0.05 mg. depending on operating conditions.

Underwater Gravimeters. — The use of gravimetric surveys for reconnaissance exploration in the petroleum industry has led to the adaptation of gravimeters for work in coastal and other shallow waters. Such work has been accomplished, particularly in the case of null-type instruments, by the use of diving bells or similar devices whereby the operator may be lowered to bottom along with the instrument. In this manner a firm support is obtained and the observations are made as in the case of land stations. In other cases the gravimeter alone is housed in an adequate pressure-tight casing which is lowered and firmly planted on bottom. A cable to the surface craft provides electrical connections whereby the level of the instrument may be observed and corrected by remotely controlling small motors operating suitable levelling gear in the instrument casing. When accurate levelling has been achieved the moving system is unclamped by operating a suitable actuating motor, recording lamps are energized and a small camera with a moving photographic film records the instrument deflections. By such means observational accuracies equal to those on land stations have been achieved. There seems to be no special limit to the depths attainable with this latter type of device although other practical difficulties pertaining to exploitation problems have limited such work to water depths of 100 or 200 ft. A typical remote-controlled underwater gravimeter is shown in Plate, fig. 5.

Temporal Variations of Gravity. — Some modern gravimeters are well suited to the measurement of the temporal variations of gravity associated with the tidal forces caused by the attraction of the sun and moon. Measurements of this type have been rather sporadic to date, largely because the major effort since about 1930 has, for obvious economic reasons, been the development of instruments suitable for geophysical exploration. The work of Tomaschek and Schaffernicht already mentioned probably represents the most diligent recent effort on the subject concerning which there is any available information. However, sufficient data have been accumulated from various sources clearly to indicate that recording gravimeters are capable of measuring the temporal variations of gravity with sufficient accuracy to provide useful data pertinent to broad-scale geophysical studies. Thus gravimeter data have shown, as by other methods, that tides of very appreciable magnitude exist in the earth's crust. It is of interest, in conjunction with other associated methods of measurement, to obtain a considerable quantity of statistical data of high accuracy so as to permit proper analysis.

While the theoretical aspects of the analytical problem are too complex to be discussed here, in principle the possibilities may be made clear. Thus if we were to assume a perfectly rigid earth, any observed temporal variations in g must agree with the calculated tidal forces caused by the moon and sun. On the other hand, if the earth yields to these tidal forces in a perfectly elastic manner, tidal perturbances would appear on the earth's crust in response to the tidal forces. A gravimeter resting on the surface would thus observe an elevation effect added to the tidal force itself and the observed gravity variations would exceed those calculated on the basis of tidal forces alone by the amount of the change in elevation. Actually this greatly oversimplifies the case but serves to illustrate the nature of the results.

In addition to the broad-scale effects it may be said that the available scattered gravimeter observations prior to 1945 indicate that the earth tides differ from one geographical location to another; they are affected by loading of the land surface by ocean tides: and locally are doubtless affected by geological features (*i.e.*, W. D. Lambert, "Report on Earth Tides," 1936–38, *Spec.* Pub. 223, U.S. Department of Commerce, Coast & Geodetic Survey, 1940). And while other methods have long been used in an attempt to study these phenomena the gravimeter should provide very useful data in the attack on some phases of the problem. (*See* **TIDES.**)

FIG. 8.— SUSPENDED SYSTEM OF AN EOTVOS TORSION BALANCE

Measurement of Gravity Gradients. — Previous to 1888 researches on gravity were confined almost exclusively to investigations with the pendulum and the bubble level, but Eotvos (*Ann.* der *Phys.* und *Chem.*, B59, p. 354, 1896) using a different attack endeavoured to measure the variation of the force of gravity in the vicinity of a point. More exactly. he proposed to measure the rate of change or erddients in the gravitational field a< a point. Since these variations are extremelv small in comparison with the total force. Eotvos concluded that the method employed should measure the gradient directly. The result was the design of a torsion balance somewhat similar to the Cavendish balance. and which was capable of measuring with considerable accuracy gradient components of the gravitational field at a point.

Evidently a suitable integration of the gradient results at a network of stations would permit the mapping of the intensity of gravity over the area.

The Eötvös instrument, fig. 8, differs from the earlier Cavendish balance in that it consists of a light horizontal beam which supports at its extremities two weights at different vertical heights, the whole being suspended on a very fine torsion wire and enclosed in a double- or triple-walled metal case which can be rotated about a vertical axis. A mirror attached to the centre of the beam system enables its angular deflection to be observed or recorded on a photographic plate.

In the instrument made by Süss, observations are taken visually and the instrument is rotated manually to the next azimuth position after each reading. In other types, *e.g.*, Bamberg and Oertling, fig. 9, the observations are recorded photographically and the instrument rotated to the next azimuth position automatically.

In order to reduce the dimensions of the instrument, without reducing the sensitivity unduly, or employing very thin wires, William Schweydar introduced a Z-shaped beam having one weight rigidly fixed above and the other below the plane of the beam. A reduction of the length of the torsion wire enables the height of the instrument to be reduced to 120 cm., the centre of gravity of the system remaining 70 cm. above the ground as customary in the larger instruments. In a design by Shaw and E. Lancaster-Jones the beam system is made irresponsive to "curvature" effects and is called a gravity gradiometer. The suspended system comprising a single beam carries a series of masses arranged in plan at the apices of a regular polygon, one mass being rigidly mounted well above the beam and the remaining masses fixed directly to the beam. The total length of the beam has thus been reduced to 4.5 cm.. resulting in more rapid operation and increased compactness and portability.

The Eotvos torsion balance measures the magnitudes usually expressed U_{yz} and U_{xz} which are the components of the gravity "gradient" in the north and east directions respectively, and represent the increase of the vertical component of gravity per unit distance north and east in the horizontal plane. The maximum "gradient of gravity" is the resultant of these components, its value being $[(U_{yz})^2+(U_{xz})^2]^{\frac{1}{2}}$ and its direction, tan $\Phi=U_{yz}/U_{xz}$. Two other magnitudes $U\Delta$ and U_{xz} give the "curvature value," or the deviation of the level surface of gravity from the spheroid. The meaning of this "curvature value" and the sensitivity of the balance to it may be visualized by noting intuitively that the beam of a Cavendish balance would tend to align itself parallel to an elongated cylindrical mass located with axis horizontal directly below the axis of the balance.

FIG. 9.—EÖTVÖS TORSION BALANCE —OERTLING AUTOMATIC PHOTO. VISUAL TYPE

The theory of the Eotvos balance is too complex to warrant presentation here. (See L. L. Nettleton, Geophysical Prospecting for Oil, 1940.) In practice, a single-beam balance would require readings of the beam deflections at five azimuthal orientations of the system in order to determine the desired gravitational quantities. Since the period of the balance beam is very long and may require from *30* to 50 minutes to attain its proper rest position for recording purposes, some *3* to 5 hours would be required for a single station observation. Commercial instruments are therefore designed with two identical beam systems oriented 180° apart whereby readings in three azimuthal positions suffice to determine the gravity quantities.

The sensitivity of the instrument is such that the unit chosen for expressing the results and known as the Eotvos unit (E), is 1×10^{-9} c.g.s. unit and represents a gravity gradient such that the vertical component of g changes by 1×10^{-9} gal per horizontal centimetre. In average field practice a probable error of about 3 to 4 E is attained. Because of the high sensitivity of the instrument to gradients caused by very local features, in the choice of field stations careful selection is required to minimize the spurious effects of "terrain" irregularities. It is the usual practice to grade level the station site for a radius of some 15 to 20 ft. and at greater distances measure the surface elevations carefully by levelling radially to about 100 ft. The effects of such terrain irregularities as well as more distant ones are then computed and applied as corrections to the observed data.

The torsion balance, introduced in the United States for petroleum exploration (particularly Gulf Coast salt domes) about 1923 saw extensive use by that industry until about 1936. At that time and progressively thereafter the gravimeter has replaced the torsion balance. This preference for the gravimeter arises from the greater speed of observation and the fact that its relative insensitivity to very superficial and hence spurious irregularities permits the construction of accurate gravity intensity maps adequate for geophysical exploration purposes, with far fewer stations than would be required from the very localized gradient observations such as are obtained by the torsion balance. The integration of a net of torsion-balance gravity-gradient observations into a total intensity map may be likened to the derivation of a topographic map from observations of the slope of the ground measured with a spirit level a few feet in length. Thus the torsion balance is essentially a detailing instrument whereas the usual application of gravimetric methods in geophysical exploration is for reconnaissance purposes. It is certain that the advent of the modern gravimeter has relegated the Eotvos balance to its logical function, the measurement of very local perturbations in the gravitational field.

(H. SH.; R. D. W.)

GRAVURE, one of the major processes in commercial printing, is used to produce a wide range of printed materials, including newspaper supplements (*e.g.,* book-review sections, feature magazines), catalogues, illustrated magazines. illustrated books, advertising literature, calendars, greeting cards and wallpaper and patterns in textiles, linoleum and oilcloth. It is also employed for printing labels and wrappers on aluminum foil, glassine, cellophane, vinyl and similar materials.

Gravure is an intaglio process, so-called because the design to be printed is etched or engraved below the surface of the plate. At the start of the gravure printing process, the plate is covered with ink and the surface is then wiped clean. When paper is pressed against the inked plate, the paper penetrates the sunken parts slightly and draws out the ink. Examples of intaglio printing produced by traditional hand methods (*i.e.,* in which plates are inked by hand and printed on a hand-operated press) are etchings, engravings and aquatints. Hand methods are still used in some countries in printing postage stamps: paper money, bonds and other securities. Modern photomechanical applications are rotary photogravure, or rotogravure, which is used in the bulk of gravure printing; sheet-fed gravure, a slower method employed when high-standard reproductions are desired; and the original and now almost-extinct photogravure method, which is slowest of all but produces the finest results.

Rotogravure is a high-speed process that can print (from a roll of paper) the equivalent of 25,000 sheets per hour in one colour or 16,000 sheets per hour in four colours. with each sheet being about 44 by 70 in. or larger. The process is financially practical only on runs of 100.000 or more impressions. Sheet-fed gravure, in which sheets of paper are fed to the press mechanically and slower presses are used. is best for runs of 10.000 to 100,000. For press runs of less than 10,000 copies, the letterpress method usually is most economical (see PRINTING).

All copy (the material reproduced, or printed) in photomechanical gravure printing is photographed through a halftone screen; other printing processes employ screens only for reproducing photographs and other copy with tonal gradations. Type matter, therefore: is slightly hazier in gravure than in other processes but is quite readable. (See PHOTO-ENGRAVING: Halftone Plates.)

History.— In 1826 Joseph Nicéphore Niépce of France first used the action of light to make a plate for the printing press. He coated a pewter plate with a solution of Judean pitch (asphalt) and over this comparatively light-sensitive surface placed an engraved portrait of Georges Cardinal d'Amboise that he had previously made translucent by oiling. After the surface was given a long exposure to light to harden the asphalt, the soft lines were dissolved and the plate was etched and printed. *(See* PHOTOGRAPHY: *The Beginnings of Photography.)*

The basic principle of photogravure, and of almost all other photomechanical processes as well, was contributed by an Englishman, William Henry Fox Talbot. In 1852 he patented the first practical application of a phenomenon noted by Mungo Ponton in 1839 and Edmond Becquerel in 1840—that gelatin, when sensitized with a dichromate salt, hardens when exposed to light. The earliest form of the Talbot process involved coating a steel plate uith gelatin and dichromate of potash, exposing it under a positive, washing away the unhardened gelatin and etching with platinous dichloride. In a later version of the process, Talbot coated the plate first uith powdered resin to provide a stronger ink-holding grain, heated it to make it adhere and etched with ferric chloride.

Paul Pretsch of Vienna in 1853 bathed the exposed gelatin in cold water, thereby causing the soft parts of the gelatin to swell. An electrotype could be made directly from this relief, or from a gutta-percha mold. Pretsch patented his process in England in 1854 and set up the first commercial firm for photomechanical printing.

Karl Klic (Rlietsch) of Bohemia was instrutnental in making photogravure a practical commercial process. In 1878 he exposed a positive transparency over carbon tissue, a film made of coloured gelatin sensitized with potassium dichromate and backed by a sheet of paper. (Carbon tissue film had been invented in 1864 by Sir Joseph Wilson Suan of England.) The film was pressed down on a copper plate coated with an even layer of resin or asphalt powder. The carbon tissue was developed in water; this method of development made the softest gelatin swell and removed the paper backing. The plate was etched with ferric chloride in successive baths of varying strengths Klic's process produced sure and predictable results and became the preferred method for later workers.

Klic. working with Samuel Fawcett of Lancaster, Eng., also developed and introduced the method of rotogravure printing now in general use. In 1895 Klic formed the first rotogravure firm. the Rembrandt Intaglio Printing company, in Lancaster. The principle of the rotogravure press. however. was already known. Thomas Bell of England in 1783 had suggested using a doctor blade to remove ink from the surface of the plate. The most important early improvements in the design of rotogravure presses were made after 1904 by Edouard Mertens in Germany. *(See* PRINTING PRESS.)

Rotogravure Plates.—Procedures for making hand photogravure plates by the Klic method have already been described.

In rotogravure, separate negatives of type matter, other line copy and continuous-tone copy are assembled and positioned according to a prepared layout. After the negatives are retouched. a continuous-tone positive is made and also retouched to ensure opacity where desired. A sheet of carbon tissue is next exposed under a gravure screen. This screen is a film or sheet of glass on which fine transparent lines cross at right angles to form opaque squares. A screen nith 150 lines per inch (called a 150-line screen) therefore has 22 500 squares per square inch. The lines of the screen allow the light to penetrate to the film and harden the gelatin. The square "islands" remain soft. Gravure plates are usually made with 150-line or 175-line screens.

The continuous-tone positive is placed in contact with the carbon tissue and exposed under an arc light. The soft squares are hardened in proportion to the amount of light that penetrates the varying grays of the positive. The carbon tissue is squeegeed (pressed with a rubber roller) to a cylinder that has been previously coated with copper by electrolytic action. The squares are etched to varying depths depending upon the degree to which they were hardened. The crossing lines of the screen, which are entirely hardened, are not etched at all. In this way, pits or wells of different depths are etched into the copper. For very long press runs the cylinder can be plated with nickel or chromium. *(See* ELECTROTYPING.)

Rotogravure Printing.—In rotogravure printing, the cylinder usually is arranged so that during its rotary movement it passes through a trough filled with a thin solution of fast-drying ink. On some presses the ink is applied to the cylinder by other methods; *e.g.,* spraying. A thin steel blade (the doctor) moves across the cylinder with a slight oscillating action and removes the ink from the surface but not from the wells beneath. The plate cylinder then comes in contact with the paper, which travels around an impression cylinder, and the paper draws the ink out of the wells in the plate. After being printed, the paper shows through thin deposits of translucent ink, thus creating pale grays; heavier ink deposits from the more deeply etched wells appear correspondingly opaque. Thus a full range of tonal values can be printed. Since some ink is carried on the surface of the plate cylinder, particularly in the darker areas, the marks of the screen are almost entirely obliterated. In colour printing, a separate cylinder is prepared for each colour. *(See* PRINTING.)

Other Methods.—The Dultgen halftone intaglio process is widely used in colour work. Two positives are made from the continuous-tone copy, one through the conventional letterpress halftone screen and the other without a screen. For four-colour printing eight positives are made, two for each colour. The screened positive, which breaks up the image into soft dots on the carbon tissue, is exposed first, followed by the unscreened positive, which hardens the dots to varying degrees. When etched, the dots are therefore of different sizes and also of different depths. This method thus uses two methods for controlling tonal values.

Other methods in general use are the Henderson process, which prepares plates rapidly; the Huebner method, which dispenses with the use of carbon tissue; and Intaprint, which produces intaglio dots without depth gradations.

GRAY, **ASA** (1810–1888), U.S. botanist whose *Manual of Botany* (1848) remained the outstanding book in its field for a century, was born in Paris, N.Y., on Nov. 18, 1810. From James Hadley, professor of chemistry and materia medica, he obtained his first instruction in science (1825–26). In the spring of 1827 he first began to collect and identify plants. His formal education, such as it was, ended in Feb. 1831, when he graduated in medicine from the Fairfield Medical school. In 1836 his first botanical textbook appeared under the title *Elements of Botany,* followed in 1842 by *Botanical Text-Book for Colleges, Schools and Private Students,* which developed into his *Structural Botany* (1879). He published later *First Lessons in Botany and Vegetable Physiology* (1857); *How Plants Grow* (1858); *Field, Forest and Garden Botany* (1869); and *How Plants Behave* (1872). These books served the purpose of developing popular interest in botanical studies. His most important work, however, was his *Manual of the Botany of the Northern Cnited States,* within its geographical limits an indispensable book for the student of American botany, the first edition of which appeared in 1848. Throughout his life Gray mas a diligent writer of book reviews on natural history, and his reviews themselves often became treatises of literary and scientific value. The greater part of Gray's strictly scientific labour was devoted to a *Flora* of North America, the plan of which originated with his early teacher and associate, John Torrey of New York. Volume two of Torrey and Gray's *Flora* was completed in 1843; but for 40 years thereafter Gray gave up a large part of his time to the preparation of his *Synoptical Flora* (1878).

Gray's labours in the then new field of discovery and systematization of North American flora placed him at the head of U.S. botanists and on a level with the most famous botanists of the world. In 1856–57 he published *Statistics of the Flora of the Northern United States.* This paper was followed in 1859 by a memoir on the botany of Japan and its relations to that of North America, which Sir J. D. Hooker, English botanical explorer, called "in point of originality and far-reaching results its author's magnum *opus.*"

From 1855 to 1875 Gray was both a critic and exponent of the Darwinian principles, having been for years in correspondence with

Darwin. Though his religious views were those of the evangelical bodies in the Protestant Church, he openly avowed his belief that the present species were not special creations, but rather were derived from previously existing species.

In 1842 Gray accepted the Fisher professorship of natural history in Harvard university. He brought together by widespread exchanges a herbarium (later named the Gray herbarium), which became the largest and most valuable in America, and a library where there had been none and arranged the small garden already existing. Thereafter, the development of these botanical resources was part of his regular labours. His scientific life was mainly spent in the herbarium and garden in Cambridge, Mass.; but his labours there were relieved by numerous journeys to different parts of the United States and to Europe, all of which contributed to his work on the *Synoptical Flora.* He received from learned societies at home and abroad abundant evidence of their profound respect for his attainments and services. In 1872 he was elected president of the American Association for the Advancement of Science, and he was an original member of the National Academy of Sciences. He died in Cambridge, Mass., on Jan. 30, 1888.

His *Letters* (1893) were edited by his wife; and his *Scientific Papers* (1888) by C. S. Sargent. Also see *Gray's Manual of Botany,* 8th (centennial) edition—illustrated—largely rewritten and expanded by Merritt Lyndon Fernald, *et al.* (1950). (C. W. E.; X.)

GRAY, ELISHA (1835–1901), U.S. inventor, who had a famous legal battle with Alexander Graham Bell over the invention of the telephone. He was born in Barnesville, Belmont county, Ohio, on Aug. 2, 1835. Gray worked in a machine shop, reading in physical science at the same time, and for five years (1857–62) studied in Oberlin (O.) college, where he was professor of dynamic electricity from 1880 to 1901. On the same day (Feb. 14, 1876) that Alexander Graham Bell filed an application for a patent for a telephone Gray applied for a caveat announcing his intention of filing a claim for a patent for the same invention.

When Bell first transmitted the sound of the human voice over a wire ("Mr. Watson, come here; I want you") on March 10, 1876, he used a liquid transmitter of the microphone type previously developed by Gray and unlike any described in Bell's patent applications to that date and an electromagnetic-metal diaphragm receiver of the kind contrived and publicly used by Gray several months earlier. In the legal cases in which the Gray and Bell claims to have invented the telephone came into direct conflict it seems to have been established that Bell had first transmitted the sound of the human voice by electric currents in a wire, but evidence seems to show that the transmission took place by means of mechanisms developed by Gray. *(See* also TELEPHONE.)

His later years were spent in further electrical experiments. Gray died suddenly at Newtonville, Mass., on Jan. 21, 1901.

See the article on Elisha Gray in the *Dictionary of American Biography* and, especially, Lloyd W. Taylor, "The Untold Story of the Telephone," *The American Physics Teacher,* vol. 5, pp. 243–251 (Dec. 1937). (F. G. T.; R. S. FR.)

GRAY, SIR JAMES (1891–), British zoologist, outstanding for his work on the mechanism of cellular and animal movement, was born in London, Oct. 14, 1891. He was educated at Merchant Taylor's school and at King's college, Cambridge, where he was elected fellow in 1914. During World War I he served in the infantry. Returning to Cambridge in 1919, he gradually established one of the major schools of biological research in Britain. He became professor of zoology in 1937. For his own contributions to knowledge he received the royal medal of the Royal society.

He played a leading part in changing the main objective of 20th-century zoological research from evolutionary comparative anatomy to the functional analysis of living cells and living animals, particularly through his long and successful editorship of the *Journal of Experimental Biology.* Beginning research as a cytologist, his work was first particularly concerned with the mechanics of various kinds of cellular movements, and he is the author of a standard work on experimental cytology. Later he extended this application of mechanical principles to the analysis of animal movement in general. He has published numerous works, both specialist and popular, on movement of living systems of every size, from the spermatozoon to fish, whales, snakes and a great variety of terrestrial animals; and he has shown the interest and importance of the application of engineering principles to such biological problems. Among his publications are *Ciliary Movement* (1928), *Experimental Cytology* (1931) and *How Animals Move* (1953). (C. F. A. P.)

GRAY, JOHN DE (d. 1214), bishop of Norwich, Eng., a close supporter of King John, whose service he entered before his accession (1199), was rapidly promoted in the church until he became bishop of Norwich in Sept. 1200. By attempting in 1205 to make him archbishop of Canterbury King John started his long quarrel with Pope Innocent III, who quashed the election in favour of Stephen Langton. In 1209 De Gray was sent to Ireland to replace the baronial justiciar. There he extended the English frontier northward and westward, fighting campaigns on the Shannon and in Fermanagh but being defeated in 1212 by Art O'Maelsechlainn. He also carried out the reforms initiated by King John whereby the laws and customs of England were introduced into Ireland and a new coinage was struck.

On Gray's return to England in 1213 he brought 500 knights to Barham Downs, near Canterbury, for the muster assembled against the expected invasion of Philip II of France. He also acted for the king on embassies to the French king (*c.* Dec. 1203) and the emperor Otto IV (July 1213). After the king's reconciliation with Innocent in 1213 De Gray, with others of the king's chief advisers, was excluded from the general pardon and made to go to Rome; there he so greatly impressed Innocent that he was recommended for the bishopric of Durham, but he died on his homeward journey at St. Jean d'Audely in Poitou on Oct. 18, 1214. He is buried in Norwich cathedral. (M. DK.)

GRAY, LOUIS HERBERT (1875–1955), U.S. linguist and orientalist, whose work combined traditional and modern approaches with an insistence on thorough mastery of the languages investigated, was born in Newark, N.J., April 10, 1875. After studying at Princeton and Columbia (Ph.D. 1900), he devoted most of his life to teaching and research, except for a brief span at the Peace commission (Paris, 1919–20). He taught at Princeton, Nebraska and Columbia, retiring from Columbia as professor emeritus of comparative linguistics in 1944. His competence also included Celtic, Germanic, Armenian, Georgian and Semitic; he was expert in hagiography and church history. Besides numerous articles he published some ten books, including *Indo-Iranian Phonology* (1902), *Introduction to Semitic Comparative Linguistics* (1934) and *Foundations of Language* (1939). He died in New York city on Aug. 18, 1955.

GRAY, PATRICK GRAY, 6TH BARON (d. 1612), was descended from Sir Andrew Gray (*c.* 1390–1490) of Broxmouth and Foulis, who played a leading part in Scottish politics and was created a Scottish peer as Lord Gray, probably in 1445.

Brought up as a Protestant, and early married to the daughter of Lord Glamis, he soon repudiated his wife and became a Roman Catholic. By treachery and intrigue he gained the favour of James (afterward king of England). In 1584 he acted as an intermediary between James and Elizabeth I, whose support he gained by promoting a plot to secure the fall of the earl of Arran. Three years later he was again dispatched to England, ostensibly to save Mary's life, but his representations had no weight, and her execution led to his fall from power in Scotland. Though imprisoned and proved guilty of many crimes, he was saved by the king's favour, and rose to further honours. In 1609 he succeeded his father as 6th Baron Gray and died in 1612. In 1585 Gray married Mary Stewart and had by her six daughters and a son Andrew (d. 1663) who succeeded him as 7th baron.

GRAY, ROBERT (1809–1872), first bishop of Cape Town and metropolitan of South Africa, was born at Bishop Wearmouth, Durham, on Oct. 3, 1809, and was the son of Robert Gray, bishop of Bristol. He was educated at Eton and Oxford, and took orders in 1833. After holding various English livings, he was consecrated bishop of Cape Town in 1847. In 1853 he was appointed metropolitan of South Africa in view of the contemplated establishment of the suffragan dioceses of Graham's Town and Natal. In that capacity his coercive jurisdiction was called in question in the case of Bishop Colenso (*q.v.*), and the judicial committee of the privy council decided against him. During his episcopate Bishop Gray effected a much-needed organization of the South African church, to which he added five new bishoprics, all carved out of the original diocese of Cape Town.

Gray died on Sept. 1, 1872.

See H. L. Farrer, *Life of Robert Gray, Bishop of Capetown* (1876, 2nd ed., 1883).

GRAY, SIR THOMAS (d. *c.* 13691, English chronicler, was present at the battle of Neville's Cross in 1346; in 1355, while acting as warden of Norham castle, he was made a prisoner, and during his captivity in Edinburgh castle he studied the English chroniclers, Gildas, Bede, Ranulf, Higden and others. Released in 1357, he was appointed warden of the east marches toward Scotland in 1367, and he died about 1369. Gray's work, the *Scalacronica*, is a chronicle. written in ?Torman-French, of English history from the earliest times to about the year 1362.

GRAY, THOMAS (1716–1771), English poet, whose *Elegy Written in a Country Churchyard* is one of the best-known English poems for its eloquent expression of universal feelings, was the son of Philip Gray, a prosperous scrivener in the City of London, by his wife Dorothy Antrobus. Born at their house in Cornhill on Dec. 26, 1716, he was a delicate boy, the only one of a large family who survived his infancy. He had a troubled childhood, because of his father's harsh and at times violent treatment of his mother, who was obliged to run a milliner's shop in order to pay for their son's education. This situation, however, had eased considerably before Philip Gray's death in 1741.

Thomas was sent to Eton in 1725, and was extremely happy there. His closest friends were Horace Walpole, a son of Sir Robert Walpole, the prime minister, and Richard West, whose father was a distinguished lawyer. The influence of Eton, with its beauty and its ancient traditions, remained with him throughout life. In 1734 he became a scholar at Peterhouse, Cambridge, and left without taking a degree in 1738. His habits, as at Eton. were studious and reflective, and he began to write Latin verse of considerable merit. Apart from a few translations, he had not yet composed any English poetry.

Early in 1739 he set out with Walpole on a prolonged Grand Tour. They spent the remainder of that year in France, and crossed the Alps in November. The whole of 1740 was passed in Italy, with a long sojourn in Rome and shorter excursions to Naples and elsewhere. The spring months were spent with Horace Mann, the British minister at Florence. They returned to Florence from Rome in August, and remained there until April 1741, when they set out for Venice. On the way there a violent quarrel took place at Reggio; the two friends parted in anger, and were not reconciled until 1745.

Gray spent a few weeks in Venice, and returned to England alone. On his way he stayed at the monastery of the Grande Chartreuse which had deeply impressed him on a brief visit earlier, and wrote there the beautiful alcaic stanzas beginning *O Tu, severi Religio loci.*

Throughout his years abroad Gray had continued his studies, and had acquired an intimate knowledge of classical and modern art. But at the age of 25 he had not prepared himself for any sort of career. He spent the first few months after his return to England at Stoke Poges in Buckinghamshire, where his mother and her sisters had retired to live after Philip Gray's death. He then took up residence as a fellow commoner at his old college of Peterhouse, in order to read for the degree of bachelor of laws, with a not very serious intention of an eventual career at the bar.

The spring and summer of 1742—the interval between his return from abroad and his establishment at Cambridge—witnessed a remarkable spell of creative activity. The sights and sounds of the Buckinghamshire countryside inspired him to write the "Ode on the Spring." Almost immediately after this he received news of the death of Richard West, to whom he had drawn closer since his estrangement from Walpole, and who was indeed his only intimate friend. His sorrow and loneliness found expression in the poems which now followed in close succession—the *Ode on a Distant Prospect of Eton College*, the "Hymn to Adversity," and the "Sonnet on the Death of Richard West." He also added to the ambitious philosophical poem *De Principiis Cogitandi*, which had been begun at Florence, some lines of remarkable intensity of feeling and beauty of expression. This passage was the culmination and the close of his Latin writing.

These poems hold an important place in Gray's exceptionally small output of verse. The "Ode on the Spring" and the Eton ode in particular revealed his ease and felicity of expression, his wistful melancholy, the evocative power which he possessed in so singular a degree. On the other hand not even his own century could wholly applaud the abstractions and personifications which abound in the Eton ode and the "Hymn to Adversity." The former poem was published in 1747; and it appeared again in Robert Dodsley's *Miscellany* of 1748, together with the "Ode on the Spring" and the graceful trifle about the cat drowned in a bowl of goldfish. They met with little attention, and there was no awareness that a new poet had arrived on a scene lately impoverished by the death of Pope.

Perhaps in 1742, perhaps at a later date, Gray embarked on a long meditative elegy. Opinions will continue to differ about the progress and the several stages of this poem's composition; but it was completed in its final form, and sent to Walpole, in the summer of 1750. In order to forestall its publication in a piratical magazine, which had chanced to obtain a copy, the *Elegy Written in a Country Churchyard* was hastily printed in the following year. Its success was instantaneous and overwhelming. It remains the most celebrated poem of its century, the most familiar perhaps of all English poems, the most frequently quoted, the best loved by the ordinary man. Tennyson, a century later, spoke of its "divine truisms that make us weep." The voice of Johnson, a critic not usually disposed to be cordial toward Gray, summed up the contemporary reaction: "it abounds with images which find a mirrour in every mind, and with sentiments to which every bosom returns an echo."

Among the admirers of the *Elegy* were the Dowager Viscountess Cobham, the *grande dame* of Stoke Poges, and her young relation and companion Miss Henrietta Jane Speed. They introduced themselves to Gray, and he celebrated their first meeting in a poem entitled "A Long Story," a gay and fanciful example of the humorous vein in which he too seldom indulged. An attachment developed between him and Miss Speed, and at one time there were rumours that they intended to marry. But Gray was a man tvhose emotions had been deflected into the channels of friendship. Miss Speed w-as a lively young woman of the fashionable world. A marriage between them would have been incongruous and almost certainly unsuccessful; and in any case the lady soon found a more appropriate husband elsewhere. Another outcome of the success of the *Elegy* was the publication in 1753 of the first collected edition of Gray's poems, in a handsome volume with remarkable illustrations by Walpole's friend Richard Bentley.

Through these years Gray had been living quietly at Peterhouse, reading, studying, taking short summer tours about England, cultivating his modest circle of friends and writing his admirable letters. He took no part in university or college business, but simply resided in college as a gentleman of leisure. Nor did his neu-found celebrity make the smallest difference to his habits. In 1756 he migrated from Peterhouse across the street to Pembroke hall, in consequence of a practical joke attempted by some undergraduates, who had become aware of his timidity about fire and the precautions he had taken in the event of an alarm. At Pembroke he continued, in a more friendly and congenial atmosphere, his accustomed way of life for the remainder of his days.

The popularity of the *Elegy* seems not wholly to have pleased him. Always distrustful of the popular voice, he chose for his next important poems the motto "vocal to the intelligent alone" from an ode of Pindar. The poems themselves were odes in the strict Pindaric form; and he intended that they should form the crown of his achievement. In "The Progress of Poesy" he set himself to glorify, with every adornment of rhetoric and eloquence, the poet's high calling. In "The Bard" he depicted a traditional episode during the final conquest of Wales. An ancient seer curses the invading forces and foretells the doom of the English monarchs who are to come, until a Welsh dynasty in the persons of the Tudor sovereigns ruled over the whole land of Britain. During the composition of this ode Gray was seized with an unwonted fervour of inspiration, so that, as he said later, "I felt myself the Bard."

The odes were published together in 1757. in a slender volume which was the first production of Walpole's private press at Strawberry Hill. They met with a mixed reception, and were widely criticized for their obscurity. Vnquestionably they are difficult poems, and were still more difficult without the aid of the footnotes which Gray refused to provide in the original edition. They are full of metaphor and veiled allusion. rhapsody and incantation. And yet certain passages have an authentic note of mystery and romance, a foreshadowing of Coleridge and Keats. By contrast, melodies almost Wordsworthian in their pure simplicity were sounded in a poem of this time which Gray left unfinished. and to which his editor, W. Mason, in an edition published in 1775, gave the title of "Ode on the Pleasure Arising From Vicissitude."

The reception of the two Pindaric odes brought deep disappointment to Gray, and thereafter he virtually ceased to write poetry. He burled himself even more completely in private study. and especially in English antiquities and in natural history. He greatly admired the productions which that dubious figure James Macpherson published as *The Poems of Ossian,* and made investigations of his own into the Celtic and Scandinavian past. He had long contemplated a history of English poetry, and made some translations from Welsh and Icelandic originals for incorporation into this work. "The Descent of Odin," "The Fatal Sisters." "The Triumphs of Owen" and the rest have their place in the history of the romantic revival in England and indeed in Europe His only other nritings during this stretch of years were occasional verses in a satirical vein. Most of these were destroyed after his death; but tao pieces, a political squib entitled "The Candidate" and the sombre and impressive lines on Lord Holland's villa on the North Foreland, have fortunately survived.

In 1768 the professorship of modern history was bestowed upon Gray by the duke of Grafton, the newly appointed chancellor of the university. He treated this office as a sinecure, although he had at first intended to deliver lectures and was much disturbed in conscience by his failure to do so He expressed his gratitude to the duke by writing an ode to be set to music and sung at the ceremony of his installation. This *Installation Ode* (published in 1769) contained some noble passages, and was indeed a return to the grand manner which he had seemed to abandon after the failure of his Pindarics 12 years before.

During the last decade of his life Gray's summer tours sometimes took him further afield than had previously been his custom. He visited Scotland in 1765, and the English lakes in 1767 and 1769, describing the landscapes through which he passed in some of his finest letters. Late in 1769 he made the acquaintance of a young Swiss nobleman. Charles Victor de Bonstetten, and conceived for him a romantic devotion, the most profound emotional experience of his life. De Bonstetten only remained a few months in England, and Gray's letters after his departure reveal how intensely he felt their separation. His health, which was never robust, and about which he displayed a solicitude almost amounting to hypochondria, had been declining for some years; and he died in his rooms at Pembroke, after a sudden illness which was probably an acute form of uremia, on July 30, 1771. He was buried in the churchyard of Stoke Poges.

As a poet Gray was admired and influential out of all proportion to his modest output of verse. He was unquestionably the dominant poetic figure of the middle decades of the 18th century, and a precursor of the romantic revival which was soon to come. He was also one of the supreme letter writers in English literature. A man of studious instincts. of a retiring and somewhat melancholy temperament, he nevertheless set his mark upon his age; and in one poem, the *Elegy Written in a Country Churchyard,* he made a lasting contribution to the English heritage.

BIBLIOGRAPHY.—*Editions:* The last collection published in Gray's lifetime and supervised by him, *Poems by Mr. Gray* (1768), forms the basis of *The Poetical Works of Gray,* ed. with those of William Collins, for the "Oxford Standard Authors Series" by A. Lane Poole (1917; rev. ed. by L. Whibley, 1937), which also includes the text approved by Gray of poems not included in the 1768 edition. The *Poems* were also ed, by L. Whibley for the "World's Classics" (1939). *The Correspondence of Thomas Gray* was ed. by P. Toynbee and L. Whibley, 3 vol. (1935). Biographical and Critical *Studies:* The authorized biography, by W. Mason, *Memoirs of the Life and Writings of Mr. Gray* (1775) was prefixed to his edition of the *Poems. A* life by Sir Edmund Gosse appeared in the "English Men of Letters Series" (1882). D. C. Tovey, *Gray and his Friends: Letters and Relics* (1890) includes additional material. The standard modern life is R. W. Ketton-Cremer, *Thomas Gray* (1955). *See* also R. Martin, *Chronologie de la vie et de l'oeuvre de Thomas Gray* (1931) and *Essai sur Thomas Gray* (1934); W. Powell Jones, *Thomas Gray, Scholar* (1937); Lord David Cecil, *Two Quiet Lives* (1948); C. S. Northup, *A Bibliography of Thomas Gray* (1917), continued by H. W. Starr, *1917–51* (1953) which includes works on Gray as well as by him. (R. W. K.-C.)

GRAY (GREY), **WALTER DE** (d. 1255), English prelate and statesman, nephew of John de Gray, bishop of Norwich, was educated at Oxford. He owed his rapid preferment to the favour of King John. He became the king's chancellor in 1205, and in 1210 was elected bishop of Lichfield by the chapter at the king's orders. But the papal legate quashed the election. He became bishop of Worcester in 1214, resigning his office of chancellor in the same year. Gray was with John when the king signed Magna Carta in June 1215; in the autumn he left England on the king's business, and during his absence was forced into the archbishopric of York, owing his election 'to the good offices of John and of Innocent III. He took action against the French invaders on the accession of Henry III and played a leading part during the young king's minority. When Henry took over the government he continued to employ de Gray, who carried out many important diplomatic missions and acted as the king's chief justiciar during Henry's absence in France (1242–1243). As archbishop of York de Gray's insistence on his right to have his cross borne erect in the southern provinces involved him in a dispute with Archbishop Stephen Langton, and he maintained his claim to the point of absenting himself from the king's second coronation in May 1220. The archbishop of Canterbury had an interview with him at Lincoln in 1222 on the subject, but no decision was reached. Later the archbishop absented himself altogether from public business for a time. but in 1255 he visited London to attend a meeting of parliament, and died at Fulham on May 1, 1255.

Gray was always anxious to assert his archiepiscopal authority over Scotland, and sought to assert it on the occasion of the coronation of Alexander II, but Innocent III, who desired the continued independence of the Scottish church, intervened in favour of the Scotch claim. De Gray built the south transept of the minister at York and is said to have built the west front of Ripon cathedral.

GRAYLING, a troutlike gamefish of the genus *Thymallus,* often placed in the family Salmonidae. It is a handsome silvery-purple fish, reaching a length about 18 in., distinguished by rather large scales; unusually large eyes; a small mouth with feeble teeth; and a long dorsal fin, with 20 to 24 rays. Six species are known from the cold. clear streams of Europe. Siberia and northern North America. Pollution of streams in North America has: however, seriously reduced the numbers of this excellent food fish.

GRAYSON, WILLIAM JOHN (1788–1863), U.S. poet, writer and politician. whose *Hireling and the Slave* is his best-known work, was born Nov. 12. 1788, in Beaufort, S.C. He graduated from South Carolina college in 1809, taught briefly, and then, after travel in the north, studied law and was admitted to the bar. He practised law in Beaufort county and served both as state representative and state senator in South Carolina.

From 1833 to 1837 Grayson was in the national house of representatives: he became collector for the port of Charleston in 1841. In 1854 he published *The Hireling* and *the Slave,* which contrasted the idyllic life of the southern slave with the difficult life of the northern worker. His other writings include *Letter to Governor*

Seabrook (1850), opposing secession; *Letters* of *Curtius* (1851), defending slavery; *The Country* (1858), praising rural life; *Marion* (1860); and *Life of James Lewis Petigru* (1866). Grayson died in Newberry, S.C., October 4, 1863. His autobiography, edited by Samuel Gaillard Stoney, was published serially in the *South Carolina Historical and Genealogical Magazine*, vol. xlviii–li (1947–50).

GRAYWACKE (GREYWACKE). The term graywacke, derived from German *grauwacke* for gray stone, was apparently first applied to certain Devonian and Lower Carboniferous rocks in the Harz mountains. Graywacke is a clastic rock, a microbreccia made up of fragments of pre-existing rocks, characterized by its dark-gray colour and toughness. Most graywackes consist mainly of angular quartz and rock particles, together with some feldspar and mica, set in a finer-grained matrix of shredlike chlorite and sericite. The rock fragments usually include slate, siltstone, phyllite, chert and a little felsitic material. Authigenic, that is, crystallized after deposition, carbonate and pyrite are common.

Graywackes occur in thin layers several inches to several feet thick, interbedded with shales or slates with which they form thick sequences. These are the "gray flags" or "grits" of the older petrographic literature. Associated rocks commonly include interbedded ellipsoidal greenstones, tuffs and thin-bedded cherts.

Graywackes may resemble basic tuffs but differ in their high quartz content and lack of volcanic glass. Although commonly feldspar-rich. graywackes differ from arkose (*q.v.*) sandstones in their dark colour, which results from the fine-grained chloritic matrix. Graywacke has been erroneously defined as the basic equivalent of an arkose, perhaps because of its superficial resemblance to wacke, the partially weathered residue from basalts and related rocks. Related to graywacke is subgraywacke (low-rank graywacke), which differs in its better-rounded constituents and in its precipitated mineral cement.

Graywacke occurs extensively in the Lower Palaeozoic of the Caledonian chain and in the Carboniferous of the Hercynian chains of Great Britain and Europe. In North America typical graywackes occur in the Pre-Cambrian of the Lake Superior region, in the Rensselaer grit of New York and Vermont, in the Carboniferous of the Ouachita mountains of Arkansas and Oklahoma, in the Franciscan (Jurassic) of California and in the Eocene of the Olympic mountains of Washington. In short, graywackes occur only in old orogenic belts.

Graywackes are probably of marine origin, perhaps deposited by turbidity currents in relatively deep water. This hypothesis explains the associated radiolarian cherts — supposedly of deep-water origin — and the lack of ripple marks, cross-bedding and benthonic (bottom-living) fossils, which characterize normal shallow-water sands, and the deposition of coarse debris concurrently with fine mud (of the matrix) as well as the graded structure seen in many graymackes. (F. J. P.; X.)

GRAZ, the capital of the Austrian Bundesland of Steiermark, on both banks of the Mur, at the opening of this valley into the broad fertile basin known as the Grazer Feld. The town (pop., 1951, 226,453) is enclosed on three sides by forested heights of the Styrian Alps, a small outlier of which, the Schlossberg, dominates the old town on the left bank of the river. This height (1,552 ft. and about 3jo ft. above the general level of the town) was an important fortified stronghold from pre-Roman times, but from 1839 has been laid out with beautiful parks. On its top is a bell toner (115 ft.) and a clock tower (92 ft.). Fine panoramas are to be seen of the town, the Mur valley and the mountains — to the north the Schockel (4,741 ft.), to the northwest the Upper Styrian Alps, to the southnest the Koralps and to the south the Possruck. At the foot of the Schlossberg to the west lies the river and to the east the town park with many marble and bronze monuments.

In the old town cluster the principal buildings of note. The 16th-century Landhaus in Renaissance style, the 17th-century Zeughaus or arsenal, maintained as it was 250 years ago, with its rich collection of 1jth–17th century weapons, and the 19th-century tonn hall in German Renaissance style and the 11th-century castle, now used as government offices, are worthy of mention. Among the many ecclesiastical buildings the most important is the 15th-century cathedral of St. Aegidius, mainly in late Gothic, though later decorations and modifications in baroque have altered the original purity of style. The interior is remarkable for its costly stained-glass windows, shrines and paintings. In the vicinity is the mausoleum church in baroque style (1614–1714).

Graz is rich in educational institutions, at the head of which is the university, founded in 1586 by the Austrian archduke Charles Francis and restored in 1827 after an interruption of 45 years. It is magnificently housed with well-equipped laboratories and a rich library and is attended by about 2.500 students annually. There is also a technical college, founded in 1814 by the archduke John Baptist, who also founded the Joanneum museum (1811). The museum has extensive collections of antiquities and natural history specimens in its old building and in the collections illustrative of the development of Styrian culture.

The outer suburbs of the town include the numerous factories, and this is particularly true of those on the right bank of the river, between it and the railway. For its active trade three factors are responsible. viz., the local situation at the contact of mountain and fertile Tertiary downland, the position with reference to important routes from Danube to Adriatic and their branching toward the Hungarian plain, and the presence of good lignite in the vicinity (Koflach). In addition to an active trade in the cereals, fruit and wine of the hill lands, large manufactures have developed. Iron-and steelworks, physical and optical instrument factories, brewing, milling, leather and paper and cloth industries, the preparation of chemicals, printing and lithographic trades and great railway workshops are among its major operations while visitors to the many interesting places and spas in the neighbourhood swell the growing volume of trade.

The early history of the town is obscure and it is first definitely mentioned in a document of A.D. 881, after which it became the residence of the rulers of Styria. Its strength and importance in the 15th and 16th centuries are exemplified by successful resistances to Hungarian (1481) and Turkish (1529, 1532) attacks. Protestantism established itself early there (1530) and flourished until oppressive measures by the archduke Charles restored the authority of Rome. After a long and fairly quiescent period the town figured largely in the Napoleonic Wars, being held by the French in 1797 and again in 1805, while in 1809 the citadel on the Schlossberg was blown up by Marshal Alexandre Macdonald in accordance with the terms of the peace of Vienna, only the bell tower and clock tower being left. The development of the town was most rapid during the 19th century, when it received many civic privileges through the interest of the archduke John. *See* also STYRIA.

GRAZIANI, RODOLFO, MARCHESE DI NEGHELLI (1882–1955), Italian soldier and administrator, notable for his service in Libya and East Africa, mas born at Filettino, near Frosinone, It., on Aug. 11, 1882. Before World War I he served in the army in Eritrea and later in Libya. In 1919 he was in command in Macedonia; he then served in Tripolitania until 1927. Graziani commanded the Italian forces in Libya in 1930–34. During this time he pacified the country, but in so doing became notorious for his harsh treatment of the natives. Graziani mas governor of Italian Somaliland (1935–36), viceroy of Ethiopia (1936–37) and honorary governor of Italian East Africa in 1938.

In 1939 Graziani commanded the Italian forces in Libya, and the following year advanced slowly against the British as far as Sidi Barrani. In 1941 his forces were heavily defeated by General Archibald Wavell and he resigned his post. After the Italian armistice in 1943 he took the side of the Germans and became defense minister in the Italian Republican government. In 1945 he surrendered to the U.S. forces, which imprisoned him until 1946, when he was handed over to the Italian government for trial. He was kept in Rome and in the spring of 1950 sentenced to 19 years' imprisonment. In August of the same year, however, he was released and later became president of the neo-Fascist Italian Socialist movement. He died at Rome on Jan. 11, 1955.

(E. B. BN.)

GRAZZINI, ANTON FRANCESCO (1503–1584), Italian writer mho played an active part in the literary and linguistic controversies of his day. Born in Florence. March 22. 1503, he becgme an apothecary. He was a founder of the Accademia degli Umidi, in which he was known as I1 Lasca.

In his numerous burlesque verses (mod. ed. *Le rime burlesche*, 1882), written in the manner of Francesco Berni, he strongly opposed humanism and Petrarchism, and in the discussions on the development of an Italian literary language he defended the Tuscan tradition. His own language is lively, at times approaching dialect, both in his comedies *(Gelosia, Spiritata, Strega, Pinzochera, Sibilla, Parentadi, Arzigogolo,* written 1540–50; mod. ed.. by G. Grazzini, 1953), and in his *Cene* (mod. ed.. by C. Verzone, 1890), a collection of 22 stories which, in the manner of Boccaccio. are told by a party of young people during a carnival. Although theoretically he maintained that modern comedies should not follow classical patterns, his own plays showed no originality of inspiration.

Grazzini died in Florence, Feb. 18, 1584. (G. A.)

GREASEWOOD, a North American shrub (*Sarcobatus vermiculatus*) of the goosefoot family (Chenopodiaceae). and a characteristic plant of strongly alkaline and saline soils in the high plains of the Rocky mountain region from Montana to Mexico. It is a much-branched, somewhat spiny shrub. 2 ft. to 10 ft. high, with small, fleshy, toothless and stalkless leaves. The creosote bush (*q.v.*), certain species of saltbush (*q.v.*) and various other plants are also called greasewood.

GREAT AWAKENING, a remarkable religious revival centring in New England in 1740–43; but covering all the American colonies by 1750. Its way was prepared by Jonathan Edwards (*q.v.*), who in 1734 inaugurated at Northampton the revival that, in 1740–41, was taken up by George Whitefield (q v.) in Massachusetts and Connecticut. He and his untrained clerical and lay followers by their emotional and dramatic preaching roused their hearers to so high a pitch of excitement and made such violent attacks on the many clergy who did not join them that it became necessary for Edwards personally to reprimand Whitefield; and when the latter returned to the colonies from England in 1744 he found that the faculties of Harvard and Yale had officially "testified" and "declared" against him and that most pulpits were closed to him.

The Awakening resulted in the formation of some separatist churches, which died out or became Baptist congregations; and the religious apathy of New England during the late 18th century may have been. at least in part, reaction against the gross methods often employed.

GREAT BARRIER REEF: *see* BARRIER REEF.

GREAT BASIN, THE, named by John C. Frémont, nho crossed the area in 1843 and 1845 and described its physical features. is a unique natural basin-and-range region in the western United States. It occupies the western third of Utah and the entire state of Nevada and on its margins spills over into western California and southern Oregon and Idaho. The 189,000 sq mi. of the area resembles an inverted triangle with its 300-mi. base extending across northern Utah and Nevada and tapering on either side to the Mojave desert of California. The boundaries are rather sharply defined by the Wasatch mountains and Colorado plateau on the east and the Sierra Nevada on the west. To the north the Great Basin merges with the Columbia plateau. and the Mojave desert marks a rather indefinite southern border.

The topography, climate and drainage of the area set it apart from other natural regions of the United States. The Great Basin is divided about equally between rugged mountains and broad basins. The important mountain ranges are oriented north-south; they are commonly from 50 to 75 mi. in length and from 6 to 15 mi. in width. The mountains rise from 3.000 to 5.000 ft. above the surrounding valley floors. They have been referred to as fault-block mountains and their steeper faces are regarded as fault scarps. Between the ranges are the broad alluvial-filled basins. The elevation of these basins above sea level varies from 6,000 ft. in central Nevada to about 4,000 ft. on the east and west margins and 3,000 ft. on the south.

The climatic controls of the Great Basin tend to produce aridity. The high Sierras block the rain-bearing winds from the west. The annual rainfall averages about 10 to 12 in. in the basins, decreasing to 4 to 6 in, in the south. The limited summer rain comes in the form of torrential storms that cut arroyos and develop mud-rock flows; winter precipitation is generally in the form of snow. Summers are hot and winters cold, except in the south, where latitude and lower elevation combine to produce a mild winter.

The name "Great Basin" suggests the third natural feature of the. region, namely, interior drainage. It is not, however, one large basin, but a composite of many separate basins. Interior drainage is, in part, an expression of the dry climate of the area. The balance between evaporation and precipitation is a delicate one; lakes fluctuate greatly and some of them occasionally become dry. The water in many of them, notably Great Salt lake, is brackish or salty. Klamath, Pyramid, Carson and Utah lakes are all fresh water.

The vegetation of the Great Basin is an expression of the climate, soil and topography. Salt grass and greasewood grow on the alkaline soils of the valley bottoms; cottonwood trees edge the few streams that cross the lowlands; sagebrush, scrub oak and juniper appear on the better-drained slopes. In the southern part of the basin subtropical desert plants and species of cactus and other thorny growth are common. At the higher elevations forests of pine and spruce appear.

The valleys along the eastern edge of the region were occupied by the Mormons in 1847 and Salt Lake City has become the metropolis of that area. In a similar manner the valleys on the western edge were developed with Reno as the major centre of activity. The primary economic activities of the Great Basin are copper and iron mining, irrigated agriculture and livestock production and. more recently, manufacturing.

The population density of the area is less than 6 per square mile in contrast with 50 per square mile for the United States as a whole.

GREAT BEAR LAKE, in Mackenzie district, Northwest Territories, is the largest body of fresh water entirely in Canada; 390 ft. above the sea, with depths that exceed 270 ft., it is 232 mi. long and 12,275 sq.mi. in area. From the northeast, reading clockwise. the five main inlets are Dease, McTavish, McVicar, Keith and Smith Arms. The eastern third lies in the Canadian Shield, the western two-thirds in the Interior Plains. Western and southern shores are well wooded, eastern and northern less so.

The outlet is by 70-mi.-long Great Bear river (used with a portage road as a freight route) to the Mackenzie river. The lake freezes over in winter and much ice may be present in mid-July. Radioactive ores, principally pitchblende. were mined from 1933 near the company town of Port Radium at the eastern end of McTavish Arm: during World War II production went to the U.S. Manhattan atomic bomb project. Twenty-five years of nearly continuous mining exhausted the reserves.

The settlement of Fort Franklin is at the western extremity of Keith Arm. (J. R. M.)

GREAT BEND, a city of central Kansas, U.S., on the Arkansas river, and the-seat of Barton county, was on the old Santa Fe trail, which passed through the courthouse square. The city was founded about 1870 and incorporated in 1871. East of the city are the ruins of Fort Zarah (established 1864), from which soldiers escorted wagon trains through the dangerous stretch beyond.

The region west of Great Bend was the home of vast herds of buffalo, antelope and deer, and was a famous hunting ground for the Indians of the plains and the scene of innumerable conflicts among the tribes. Near Great Bend was the alleged site of the mythical city of Quivira. sought by Coronado.

Great Bend became a shipping point for wheat, livestock and other agricultural products, and there are grain elevators and flour mills. For comparative population figures see table in KANSAS: *Population.*

GREAT BRITAIN, the official title of the political unity of England, Scotland and Wales. The name was used in 1604, after James VI of Scotland had succeeded to the English throne, and it was formally adopted in 1707 at the date of the union of the parliaments of England and Scotland. The following article deals with those subjects which concern Great Britain as a whole; *e.g.*, constitution, defense, finance and economics, etc. For those subjects which essentially concern each country separately (*e.g.*, geography. geology. population, religious denominations, etc.), the articles ENGLAND; SCOTLAND; and WALES should be consulted. (See also COMMONWEALTH OF NATIOKS; EKGLISH HISTORY; IRELAND; IRELAND, NORTHERN; IRELAND, REPUBLIC OF; LOCAL GOVERNMENT; and UNITED KINGDOM.)

CONSTITUTION

The British is unique among existing constitutions in antiquity of origin, length of endurance, continuity of growth, adaptability to circumstance and extent of influence. The distinguishing characteristic of this constitution is the sovereignty of parliament, combined with the exceptional importance of the sovereign's position as a constitutional link between several equal and sovereign nations of the Commonwealth of Nations. Following the Norman Conquest in 1066, the 12th century was the first of many centuries of almost uninterrupted and intense constitutional development in the parliamentary, judicial and administrative fields in England. The effective union of the principality of Wales with England dates from 1301 when Edward I's son was created prince of Wales, but Wales was not enfranchised until the reign of Henry VIII. After the Act of Union with Scotland in 1707, the representatives of the three nations met in the first parliament of Great Britain. By the end of the 18th century the structure of its constitution was solid enough to enable Great Britain in the 19th century to develop and elaborate governmental machinery for the greatest empire that the world had ever seen and, later, to modify that machinery by creating partnerships in a commonwealth of free and equal nations, each with similar institutions of its own.

Much of the peculiar genius of the constitution is attributable to the fact that it is partly unwritten and wholly flexible. It means that there is no basic constitutional document, comparable with the written constitution of the United States, the main sources of the British constitution being (1) legislative enactments of parliament, such as Magna Carta, 1215; (2) decisions of the courts of lam; (3) conventions of the constitution, such as the conduct of the crown, parliament and the cabinet in cases for which there is no formal law (*e.g.*, resignation of office by the government); and (4) literary sources, such as the textbooks of political theorists like A. V. Dicey. Since parliament, comprising the sovereign, the house of lords and the house of commons acting in concert, is sovereign, it has unlimited legal power, and acts of parliament, if complete and perfect. must be obeyed by all. though the right to test in the courts the legality of various applications of that power cannot be denied to the citizen. The action of one house of parliament was successfully challenged in the courts in the late 1830s when in the case of Stockdale v. *Hansard* a resolution of the commons claiming the protection of parliamentary privilege for certain documents printed by order of the house was held to be of no legislative effect. In the case of *Bowles* v. *the Bank of England,* 1913, the collection of taxes by authority of resolutions of the house of commons was held to be illegal since the resolutions had not yet been given the force of law by embodiment in an act to which the house of lords and the king had given their formal assent. Again, the crown is liable in tort and may be sued under the Crown Proceedings act, 1947, "in respect of torts committed by its servants or agents or for any breach of those duties which a master owes to his servants or agents at common law or in respect of any breach of the duties attaching at common law to the ownership, occupation, possession or control of property" (section 2). This legislative provision is of particular interest in providing an illustration of a change in the constitution by parliament; the act reversed a long-standing common law rule that the sovereign could do no wrong and that the subject had no remedy against torts committed by the crown's servants save by presenting a petition of right.

The theory that the legislative authority of parliament extends to all overseas possessions of the crown has long been modified in the case of the self-governing nations within the Commonnealth of Nations. By the Statute of Westminster, 1931, the British parliament virtually renounced all its former powers over the dominions (as they were then called) such as Canada and New Zealand. In 1947 acts of the British parliament conferred independence on India, which was partitioned into India and Pakistan, and Burma, which became an Independent republic. India became a republic within the Commonwealth of Nations in 1950 and Pakistan changed to the same status from that of a dominion in 1956. In 1949 another act recognized the establishment of the Republic of Ireland, while maintaining the separate status of Northern Ireland as an integral part of the United Kingdom.

The liberty of the subject under this flexible constitution is secured, as has already been indicated. by the rule of law, based on the essential constitutional assumption that all governmental powers rest on lam. Dicey claimed that this essential aspect of the constitution was characterized by the absence of arbitrary poaer, the subjection of officials to the courts and the ordinary common law, and that the constitution, being not the source but the consequence of individual rights, itself formed part of the ordinary law of the land. Dicey's view that there is no special privilege for officials and that equality before the law for officials and citizens alike distinguishes the British constitution from that of France, where special administrative law and tribunals exist side by side with the "ordinary law" and law courts, has been criticized as unreal; but since the distinction between the British system and others exists, it should be given due emphasis.

Although parliament is legally omnipotent, there are, even within Great Britain, many de facto limitations on its sovereignty. There have been cases of organized resistance to particular enactments; the tithe acts were resisted by groups of farmers for many years until an alteration in the law was made. The pressure of public opinion on members of the house of commons is constant and has proved a powerful sanction against any measure which has not the general support of the subjects. The doctrine of the "mandate," too, may become increasingly restrictive of freedom of action by the political parties in parliament. The doctrine is that no important measure should be passed unless the political party supporting the government has first included it in its program at a general election and so obtained the mandate or endorsement of popular approval. Although the principle of the mandate has not invariably been observed, its importance in the development of constitutional practice seems to be growing. In 1923, for example, the government of the day resigned because its desire to introduce trade tariffs had not first been submitted to the electorate.

The four main elements in the constitution of Great Britain are the legislature, the executive, the judiciary and the churches. The government, in the most general sense, comprises the first three, with many functions overlapping, since there is no separation of powers. The classical example of these overlapping functions is furnished by the office of lord chancellor. Its holder presides over the house of lords as speaker in his capacity as member of the legislature; he also presides in a judicial capacity over the supreme court when the house of lords meets as such. In addition he is a minister of cabinet rank.

Crown.—The crown unites all four main elements in the constitution. The legislature is comprised of the crown, the lords spiritual (bishops) and temporal and the commons; the crown is head of the judiciary, and justice is administered in the sovereign's name. Supreme executive power is vested in the sovereign and many executi e acts are also performed in the sovereign's name; and in 1534 the Act of Supremacy declared that the king was "the only supreme head on earth of the Church of England." This is the ultimate statutory authority for the appointment of the bishops by the sovereign on the advice of a prime minister (who, however, need not be and frequently is not a member of the Church of England).

This interlocking of the organs of central government is a result of their common origin in the *curia regis* of the Norman kings, a body which performed all the functions of government without differentiating between them. It was the king's court meeting to do the king's business, and the same is true of all the descendants to which in course of time, with the multiplication and elaboration of business, it gave birth, although the sovereign has long since ceased to attend in person, save on formal occasions at his privy council and in his high court of parliament. The crown is now held in hereditary succession as limited and defined in the Act of Settlement of 1701 and as modified by His Majesty's Declaration of Abdication act. 1936. This legislation, the first affecting the dominions under the terms of the Statute of Westminster, amended the Act of Settlement of 1701 by excluding Edward VIII (who became the duke of Windsor) and his descendants from succession to the throne and provided that the Royal Marriages act of 1772 should not apply to him. The influence of the monarch, though difficult to estimate, should not be underrated. He is kept fully informed, his advice, based upon uninterrupted public experience, is extremely valuable, and his consent is obtained to all measures; moreover, with the growth of the empire, and especially since the recognition of the dominions as coequal partners with the mother country, 'the crown has achieved unique significance as at once the symbol and chief constitutional safeguard of imperial union. Parliament authorized the monarch, by the Regency act of 1937, to appoint counsellors of state to exercise specified royal functions in the event of his absence from the country or his temporary incapacity to act. Those to be appointed counsellors of state by letters patent were the wife or husband of the sovereign and the four persons who were next in succession to the throne, excluding any person who would be disqualified from being regent.

Judiciary. — In Anglo-Saxon times the earliest forms of customary law were administered in three sets of courts: (1) national. those of the hundred and of the shire; (2) private. those of the thegns and of the lords of manors; and (3) municipal, those of the chartered boroughs. After the Conquest the local courts were slowly superseded by central courts and judges whose power emanated from the king, and the infinite varieties of customary law thus gave place to or were welded into one common law. This process was mainly achieved by extension of the use of royal writs; by introducing and extending the use of the jury (at first employed only where royal interests were concerned); by the institution and regulative influence of itinerant justices, who provided the necessary link between central and local government; and by the evolution from the *curia regis* of the three courts of common law at Westminster — common pleas, king's bench and exchequer. But, since the common law developed slowly and procedure lagged behind the needs of a progressive society, the *curia* was still called upon to mitigate and to supplement, and there grew up, in spite of the jealousy of common lawyers, a body of equity rules alongside the common law; the administration of the two was finally fused by the Supreme Court of Judicature act, 1873. As a result of the Judicature act and subsequent supplementary acts, all the existing superior courts were consolidated into one supreme court of judicature consisting of two primary divisions. the high court of justice, with the subdivisions chancery, king's bench (from 1952, queen's bench), and probate, divorce and admiralty; and the court of appeal from the decisions of the judges of each of these divisions. The old chancery procedure by way of petition for a rehedring was extended to the courts of common law, the decisions of which could till then be questioned only by alleging error apparent in some part of the proceedings. The house of lords became the final court of appeal from all the courts (other than ecclesiastical) of Great Britain, though the Administration of Justice (Appeals) act, 1934, stipulated that there could be no such appeal unless either the court of appeal or the house of lords itself gave leave, and that the jurisdiction of the house could be exercised only by peers judicially qualified. An appeal could not be heard or determined unless there were three or more of the following lords of appeal present: the lord chancellor of Great Britain; a member of the judicial committee of the privy council; a lord of appeal in ordinary; or a judge of the supreme court of England or of Northern Ireland or of the court of session in Scotland. The judicial personnel of the house of lords, together with such other members of the privy council as held or had held "high judicial office"as defined by the Appellate Jurisdiction acts, 1876 and 1887 (mainly commonwealth judges), constituted the judicial committee of the privy council, which was the final court of appeal from the rest of the empire and from the ecclesiastical courts of Great Britain; its jurisdiction was abolished in some instances, and from Canada appeal lay to the privy council only by special leave of the dominion supreme court.

Executive. — The *curia regis,* composed of the tenants in chief, royal officials and anyone else whom the king chose to summon, expanded or contracted according to the nature of its work. Daily routine would be left mainly to officials; the more serious the business the larger the attendance of tenants in chief; and on occasions of greatest importance the officials formed a numerically insignificant technical element in a large feudal assembly. The epithets employed to distinguish the larger and smaller gatherings achieved in time a technical significance until at last the larger assembly developed into the great council and the parliament, the smaller into the king's council. The latter, in spite of baronial machinations, had become, by the time of Henry VII, the instrument of the crown, and was used by the Tudors as the medium of prerogative government. True offspring of an undifferentiated *curia,* its authority was not confined to the exercise of any one function. Thus, though from it was to evolve the national executive, it retained also powers of legislation by ordinance and proclamation only vaguely subordinate to statute and common law, and a wide, if undefined, jurisdiction supplementary to the common law. Part of the latter had devolved on chancery, and much of the mercantile and marine business was absorbed by the court of admiralty constituted in the middle of the 14th century; but the stupendous labour involved in the Tudor conception of conciliar government necessitated further subdivision and specialization; thus, as in earlier times and for analogous reasons the *curia* had given birth and place to a number of descendant courts and councils, so now the king's council and its functions were split up and divided among the privy council, the courts of Star Chamber, of requests and of high commission. At the Restoration. of all the offspring of the king's council, there survived only the privy council, with nothing left of its former legislative authcrity, meeting to transact mainly formal business.

The cabinet, which in the 17th century evolved from a committee of the privy council as the effective national executive, was composed of an inner ring of confidential advisers of the crown. The king at first presided, but, when George I for lack of English ceased to attend, his place was taken by a minister, usually the first lord of the treasury, who in time became known as the prime minister. The latter, normally the head of the party commanding a majority in the house of commons, is appointed by the sovereign, with whose consent he in turn appoints the rest of the ministry and decides, though his choice is in practice narrowly restricted, which of them shall be members of the cabinet. Just as their predecessors sat originally in the parliament chamber, so now are all ministers members of one or other house of parliament, according as to whether they are peers or commoners. And they are individually and collectively responsible to crown, prime minister and parliament.

LEGISLATURE

Parliament was .originally a periodic public assembly of the *curia regis* at its fullest expansion. It was therefore competent to perform all functions of government. But the one mainly stressed was the judicial function, for law declaring precedes law-making. Any subject might present a petition, and parliament acted as a clearinghouse for such petitions, referring the suitor to the appropriate court and reserving for its own consideration in full assembly only such cases as were particularly difficult, protracted or important In the 13th century, however, the practice of summoning occasionally and ezperimentally delegates, sometimes from the shires. sometimes from the boroughs and sometimes from both simultaneously, was instituted for certain purposes. One of these nas the granting of money. To the demand for money the commons replied with a demand for the granting of the petitions they had brought with them. Considerations of these common petitions came to occupy so much of parliament's time that it was obliged more and more to leave the private petitions to be dealt with by council or chancery after parliament had broken up. In other words. it was abandoning the righting of individual wrongs a judicial function, in favour of the righting of the wrongs of the nation. a legislative function. It was Henry VIII, more than anyone else who helped parliament to climb by precedents toward a sovereignty which it finally wrested from his successors at the Revolution of 1688. For. though despotic, he liked to preserve legal forms and, still more, to shelve responsibility. Thus even to his most unconstitutional actions (e g., the Erastianization and spoliation of the church) he made parliament his partner; and particularly did he flatter the pretensions of the commons, of which he had no fear.

House of Lords.—In the parliament chamber sat originally the king. his counsellors and his greater tenants in chief, lay and spiritual. But the sovereign is now present only on rare and formal occasions, and with the growth of the doctrine of the peerage the presence of commoners became anomalous, so that counsellors who were neither peers nor bishops preferred, unless incapacitated by tenure of judicial office, to seek election to the commons The total membership in the house of lords of about 850 comprises peers who hold their seats by hereditary right or by the creation of the sovereign (about half of them created since 1906); law lords (peers who hold or have held high judicial office and life peers specially appointed); spiritual peers (2 archbishops and 24 bishops of the church of England); Scottish representative peers (16 elected for the duration of parliament); and 5 (in 1956) Irish representative peers (elected for life, but vacancies being no longer filled).[1] The Parliament act of 1911 disabled the house of lords from amending any bill certified by the speaker to be a money bill and limited the lords' veto on money bills to one month and on other bills to three successive sessions within two years; it also reduced the maximum duration of a parliament from seven to five years. The Parliament act of 1949 affected the lords' veto only on bills other than money bills; it was reduced to a period of two successive sessions and one year. Offsetting the monopoly of parliamentary taxation enjoyed by the commons, the house of lords became a court of appeal (see above, ***Judiciary),*** hearing being left to those members who were past or present holders of high judicial office or law lords specially appointed for life.

House of Commons.—The greatest power of state vested in the legislature is the power to impose taxes and to vote money to, or withhold it from. the various public departments and services. The exercise of this power is the right of the house of commons alone, making that house the chief authority in the state. By a convention of the constitution not established till the 20th century, the prime minister is always a member of the house of commons. instead of, as formerly, a member of either house; by thus directly submitting himself and a majority of his senior ministers to the daily criticism of that house, he further enhances its authority as compared with that of the house of lords.

Steps which led, over the course of centuries, to the financial ascendancy of the commons began in the second half of the 13th century, when counties and boroughs first received the royal writs of summons to send to Westminster representative knights and burgesses with full power to commit their constituent electors to the payment of taxes. The members of the commons so summoned took the opportunity to raise grievances, and by one of the earliest and strongest conventions of the constitution they established the principle of "grievances before supply."

In 1340 a statute recognized that no tax should be levied without parliamentary consent, but parliamentary control of taxation was not yet complete. The crown's taxes on imports were held by Tudor lawyers not to be taxes on English subjects. and it was held that exports could be taxed in view of the royal prerogative to regulate trade.

The last attempt of the crown to evade parliamentary control by devices in this manner was that of Charles I during the 11 years of absolute monarchy supported by revenue from "ship money." The parliament of 1640 declared the collection of tonnage and poundage without the consent of parliament to be illegal, and since the Restoration parliamentary control of taxation has never been challenged. Concurrently, the commons was establishing its supremacy over the lords in matters of finance by claiming the sole right of initiating taxation. In 1395 the grants demanded by the crown were made "by the Commons with the advice and assent of the Lords." In 1407 Henry IV conceded that "any grant by the Commons granted and by the Lords assented to" should be reported to him only by the speaker of the house of commons, a practice still maintained. Finally, in the decade 1660–70, the commons established the right to be the sole body to initiate measures proposing taxation when it refused to proceed with a number of lords bills which sought to impose taxes.

The house of commons consisted in 1953 of 625 members, 288 of them representing county divisions and the remainder borough (*i.e.*, urban) constituencies, while 12 of the total number represented Northern Ireland. Those disqualified for membership include minors, clergymen of the Church of England, ministers of the Church of Scotland, Roman Catholic clergymen, government contractors and judges. Provision was first made in 1911 for salaries of £400 a year for all members of the commons (but not of the lords) other than those receiving salaries as officers of the house, as ministers or as officers of the sovereign's household; the Appropriation act of 1937 authorized increased salaries of £600 a year, while in 1946 salaries were raised to £1,000 a year. In 1954 the recommendation of a select committee for a further increase to £1,500 was confirmed by a free vote of the commons; but in face of criticism in the country an allowance of £2 per sitting day (except Fridays) was granted instead.

Franchise.—The extension of the franchise by stages culminating in universal suffrage made the house of commons representative of practically all adults in the kingdom except the individuals who compose the house of lords.

The knights of the shire from 1429 to 1832 were elected in the county courts by the 40-shilling freehplders. Representation in the counties, therefore, though arbitrary (since other forms of tenure were ignored), was not the monopoly of class or wealth. But in the boroughs no such uniformity prevailed, and, as time went by, the franchise tended to become more and more restricted. For in early days popular indifference was content to leave the duty of nominating representatives to the authorities, who thus in time developed a prescriptive monopoly, and charters of incorporation, issued later on, when representation had come to be regarded as a privilege, usually conferred (or were interpreted as conferring) the exclusive right of election on the governing body. But, in condemning the old electoral system, critics usually base their calculations on the proportion of voters to population (2% in England, 2 per 1,000 in Scotland, at the close of the 18th century), forgetting that representation was not meant to be of population but of communities, and that. just as the county court stood for the county, so the corporation might stand for the borough. A sounder indictment would stress the point that the system had ceased to do what it was intended to do—to represent communities. For many boroughs returning members to parliament had decayed and some had actually ceased to exist, while many large and flourishing towns remained unrepresented; and, in county and borough alike, the franchise, as a result of corruption, was no longer a political privilege so much as an extremely marketable property. It was the agitation of the American colonies and the disasters resulting from George III's attempt at per-

[1] In Feb. 1956, there mere 4 peers of blood royal and 829 hereditary peers (21 dukes, 27 marquesses, 135 earls, 106 viscounts and 540 barons).

sonal government that at last aroused public interest in the matter. But reformers were divided on the question of compensation for expropriated borough owners, and the French Revolution and Napoleonic wars afforded an excuse for shelving the subject for another generation. The Reform act of 1832 marked the first stage in the process, continued by the acts of 1867, 1884, 1885 and 1918, of extending the franchise to all adult males and reshaping constituencies into fairly equal electoral districts. The act of 1918 further conceded the principle of woman suffrage, and the act of 1928 carried that concession to its logical conclusion by placing women on the same footing as men.

LIBERTY OF THE SUBJECT

The freedom of the individual, apart from the protection afforded by the franchise, is secured indirectly "by the strict maintenance of the principles that no man can be arrested or imprisoned except . . . under some legal warrant or authority, and . . . by the provision of adequate legal means for the enforcement of this principle." The most important of such means is the writ of habeas corpus, which enables the judiciary to review the actions of the executive, while the jury system protects the subject from judicial abuses; and the Bill of Rights reinforced by the Mutiny act (called after 1881 the Army act) removes the threat to liberty inherent in the existence of a standing army. Freedom of discussion and freedom of the press are secured by the law of libel (and more especially by Fox's Libel act, 1792) and amount to "the right to write or say anything which a jury, consisting of 12 shopkeepers. think it expedient should be said or written." The citizen is further protected in airing his views and grievances by the right to petition, secured by the Bill of Rights; by the right of public meeting, all meetings being legal until some illegal act has been committed; and by the right of association.

Curtailment of Liberty. — During time of war or national emergency the common good necessitated drastic limitation on individual freedom. In World War I the Defence of the Realm acts (D.O.R.A.), 1914–15, abridged the common law rights of the subject in many directions. The Emergency Powers act, 1920, permanent successor to this wartime measure, became effective only by proclamation of an emergency; the proclamation could [illegible] ([illegible] might be renewed) and emergency regulations under the act could continue in force for only a week unless parliament voted for their continuance. The act was brought into operation for a coal strike in 1921, for a general strike in 1926 and for other strikes in 1948 and 1949.

On the eve of World War II parliament passed the Emergency Powers (Defence) act, 1939, which authorized the making of defense regulations by order in council; unlike D.O.R.A., the regulations were subject to possible annulment by parliament within 28 days of being made. Some of the regulations created criminal offenses (as looting and sabotage), while others gave blank powers to be filled in by ministerial orders. Further wartime limitations upon individual freedom were imposed by the Control of Employment act, 1939, later superseded by the amending Emergency Powers (Defence) (No. 2) act, 1940, which gave complete governmental control over persons and property. Under the Civil Defence Duties (Compulsory Enrolment) order millions of men and women were compelled to serve part time or whole time as fire guards or in the wardens, rescue and casualty services, and after Jan. 1942 those working part time were no longer allowed to resign from their civil defense employment. The judiciary was also affected by wartime conditions. The Administration of Justice (Emergency Provisions) act, 1939, relaxed statutory requirements for the sittings and jurisdiction of courts (and also dealt a new and severe blow to the right of trial by jury), while the Courts (Emergency Powers) act, 1939, protected those unable to pay their debts because of circumstances attributable to the war, by preventing certain remedies from being exercised save by consent of the court.

CHURCH

Constitutionally, the Church of England enjoys the paramount position among religious bodies in England. The Act of Settlement, 1701, requires the sovereign to be a member of the Church of England, and he takes an oath of adherence to the faith of that church on accession to the throne. The clergy of the Church of England conduct the coronation and all other religious functions of the state; while the archbishop of Canterbury has special privileges in the granting of marriage licences and the conferring of degrees on notable ecclesiastical scholars. Since 1539 the state has had the power to alter the doctrine and articles of belief of the church by means of legislation, and the prayer book imposed in Edward VI's reign by the Act of Uniformity, 1549, is the basis of that in modern use, with only slight modifications permitted by subsequent acts. In 1928 an attempt by the authorities of the church to obtain a revised prayer book did not secure the necessary parliamentary approval.

Until the time of Henry VIII there was no church of England, but only two provinces of the church universal in England. The church had its own head, the pope, its own law, the canon law, and each province, Canterbury and York, had its own officials, archbishop and bishops, its own assembly, convocation, and its own courts of law. This diarchy of church and state was bound to lead to friction, more especially as the border line was vague and disputed and jurisdiction in some matters overlapped. Yet ecclesiastics, more than any other section of society, influenced the shaping of the constitution. They filled the chief offices of state; they were a permanent majority in the parliament chamber; for a time even representatives of the lower clergy attended the parliament; and for a century or more after the Conquest the archbishop of Canterbury had the chief say in determining the succession. After the Reformation their political influence declined. Few of them sat at the council board, and the disappearance of abbots and priors with the dissolution of the monasteries left them in a minority in the lords.

The final result of the Reformation, then, may be summed up as the abolition of the dual control of church and state, the transference to the state of complete control over the church and the substitution for the canon law of the king's ecclesiastical law; though a measure of legislative autonomy has since been restored to the established church by the Church of England Assembly (Powers) act, 1919. As a result of repeated quarrels between the two houses of convocation the latter was prorogued by royal writ in 1717 and not allowed to resume its sessions until 1852. Soon afterward, annual church congresses began to be held in which laymen took part, and in 1885 a house of laymen was formed in Canterbury and another a little later in York, elected by the diocesan conferences for the purpose of conferring with the respective convocations. From 1904 to 1919 there met annually a representative church council composed of the three houses in the two provinces sitting together; and the act of 1919 delegated to the newly constituted assembly of the church, subject always to the control of parliament, powers of legislature affecting the affairs of the church.

Although the ecclesiastical power has thus since the Reformation been subordinated to the secular power, the Church of England has retained much of its mediaeval structure, forms and titles. England is still divided into the mediaeval archbishoprics of Canterbury and York, and both archbishops sit with the judicial committee of the privy council when it is constituted the final court of appeal in all ecclesiastical causes. By 1953 there were 43 bishops, but only 26 (viz., the two archbishops, the bishops of London, Winchester and Durham and 21 other diocesans in order of seniority, excluding the bishop of Sodor and Man) had seats in the lords. There was numerous suffragan and assistant bishops. The established Church of Scotland is Presbyterian in constitution and is governed by its general assembly. It is presided over by a moderator (chosen annually by the assembly), to whom the sovereign grants precedence in Scotland, during his term of office, next after the lord chancellor of Great Britain. The sovereign is represented by a lord high commissioner. The Church in Wales was disestablished by the Welsh Church act in 1914.

Religious liberty, of which the first landmark is the Toleration art of 1689, was gradually attained by the repeal, one after another, of the many statutes penalizing persons not of the Anglican persuasion. There is no longer any restriction on freedom of worship in Great Britain; Roman Catholics and Nonconformists maintain their own organizations and churches, and the only disability attaching to public office is in the case of the Lord chancellor, who cannot be a Roman Catholic, as he performs many duties directly connected with the established church, such as administering to the sovereign the oath of adherence to the Anglican faith and summoning the bishops and clergy to meet in convocation, the ancient legislative body of the church.

DEFENSE: ARMY

Historical. — Before the Norman Conquest the English land forces, whether for defense or for maintaining order, comprised all freemen able to bear arms. For such training as they had and for inspection of their arms the sheriffs were responsible. But the county levy or fyrd was not intended or organized for anything but home defense, and Canute and his successors maintained, in addition, a body of household troops (*huscarles*); it was these which formed the core of resistance at the battle of Hastings.

After 1066 the Norman kings introduced into England the established continental system of warfare in which the decisive arm was the mailed horseman or knight. To be effective, the knight and his horses needed elaborate training, equipment and supply, and European society was largely organized so as to ensure the knight's maintenance and efficiency. Mediaeval land tenure was usually based on the obligation to provide knights, in number proportionate to revenue, for 40 days in the year. It was soon, however, found preferable to accept the money equivalent of this service (see KNIGHT-SERVICE; SCUTAGE) and use it to pay those willing to serve for the whole campaign.

Although the armoured knight was the unit in terms of which a mediaeval army's strength was calculated, it would be wrong to suppose that the. knights fought unaided. The knight, the actual combatant, needed. in the field, a team of auxiliaries — squire, page, groom, spare horse and pack animal, with the services at hand of the shoesmith and armourer. Mounted troops needed the support, in addition, of infantry and artisans for sentry duty, bridging and siege warfare. Nor, in Britain, was the general population freed from the older Saxon obligation to serve in person, an obligation which came to be exemplified in the posse *comitatus* and, later, the militia (*q.v.*). The sheriff, in summoning the posse *comitatus,* called together all males able to bear arms — in practice those more immediately at hand. This was usually to maintain order. The system was regularized by Henry II in 1181 and again by Edward I in 1285, their object being to define and subject to periodic inspection the weapons which each man, according to his means, was supposed to provide and maintain.

The British contingents which served in the crusades and the armies which successive kings of England led in continental wars were organized and equipped in the approved fashion of the day. Against Welsh and Scottish neighbours, however, orthodox tactics were found to be ineffective. In mountainous country the armoured horseman was often at a disadvantage, lacking forage, lacking a feasible path and lacking even any tangible opponent. There evolved, therefore, on the Scottish and Welsh borders, a type of frontier warfare in which light infantry played an increasing part and in which the knight tended to become a mere mounted officer. Just as elsewhere in Europe the cavalryman's ascendancy came to be limited by the crossbow and, later, the pike and halberd, so in Britain he was dismounted by the longbow. This weapon, developed in the Welsh wars of Edward I, differed from previous bows in being made from imported Spanish yew, in being six feet long and in shooting a yard-long shaft. In the hands of a strong man, trained in its use from boyhood, it was accurate at 100 yd. or more and effective, to some extent, against armour. It was Edward III who discovered that troops organized, paid and equipped as for warfare in Wales and Scotland, and reinforced by some of their former opponents, were more than a match for the chivalry of France.

The great period of the English archer extends from Crécy (1346) to Agincourt (1415) and on into Tudor times. For an astonishingly long period a divided France was dominated by a relatively small army of English mercenaries. They were mainly archers, riding while on the march, dismounting to fight and being led by officers of great experience. The wave of national feeling which eventually drove them out of France led indirectly to the Wars of the Roses in England. With the termination of those wars in 1485 there began a period during which warfare in Britain became extremely rare and warfare in France (for Englishmen) no longer attractive. The Tudor monarchy rested securely on the newly established navy (see below), on a monopoly of artillery, on a few household troops (the gentlemen pensioners and the yeomen of the guard) and on a male population armed with the bow and compelled by law to be proficient with this now traditional weapon.

It was the proved efficacy of the longbow which, perhaps as much as anything, retarded the adoption in Britain of the firearm. Cannon found ready acceptance in Tudor times, but the hand gun met the opposition of those who maintained that its adoption would lead to physical decadence. Musketry was therefore developed first in other countries, especially in Spain during the time of Gonzalo Fernández de Córdoba, and Tudor Britain profited only tardily by foreign example. The longbow, still the characteristic English weapon in 1519, did not in fact disappear until long after the next century had begun.

Serious large-scale warfare did not begin in Tudor times until the later years of Elizabeth's reign. The national forces raised in 1588 to resist a Spanish invasion threat included many officers with experience gained in the Netherlands, but the county levies were of doubtful quality and the main army was deficient in fire power and cavalry. The Elizabethan army made its chief task the conquest of Ireland, which would otherwise have become a Spanish base, and it was in Irish campaigns that generals such as Mountjoy learned their business. The Cadiz expedition of 1597 exemplified a growing British skill in combined operations, and the pacification of Ireland in 1600 showed that the soldiers were at least abreast of the times. Soon, however, the Dutch, technically in the ascendant in large-scale warfare, were able to improve their lead, for, from the accession of James I in 1603, England was at peace. A period of rapid development in weapons, tactics and organization began to which the British contributed little or nothing save through such English and Scots mercenaries as took service with the Swedish or Dutch. There were still no regular British land forces and no system for raising any except in the militia and the city-trained bands. Oldest of these nonregular corps was the Honourable Artillery company, dating from 1537, which remains the senior unit of the English land forces and perhaps the oldest regiment in the world.

The outbreak of the civil war between king and parliament in 1640 found no regular military forces in existence on either side, except for an English garrison in Ireland. Charles I had intervened in the Thirty Years' War to the extent of raising an army of 10,000 men, and it was a part of this force which he afterward billeted — a normal wartime practice — on householders. It was indeed one of the grievances held against Charles I that he tried to finance his army by forced loans and exacted the loans by the threat of billeting troops on those who failed to pay. These were among the matters set forth in the Petition of Right, and, in undertaking as he did to abandon these practices, Charles surrendered, in effect, his chance of maintaining an army at all. The immediate cause of the Great Rebellion lay in Charles's effort to raise an army against the Scots, which he mas unable to do without the sanction of parliament (see CIVIL WAR, ENGLISH).

By 1640 land warfare had assumed, in Europe, what was for long to be its permanent form. The mediaeval titles of rank—duke, baron, knight—had given way to the new ranks of general, colonel, lieutenant colonel, captain and lieutenant. Armies had become balanced forces of cavalry, artillery, infantry and engineers, with an organization based on regiments, companies and troops. But some of the problems implicit in the use of firearms remained unresolved. The massing of the infantry to combine fire power with pike thrust had produced a rigidity of formation from which no very decisive result was normally to be expected. The cavalry, on the other hand, improved as it was in speed by progress in horse breeding, was also equipped with firearms and had thereby partly sacrificed what should have been its advantage in impetus and weight. But for Gustavus Adolphus of Sweden, who taught his men to charge in with the sword after discharging their pistols, this sacrifice of impetus would have been complete. In the Great Rebellion the two sides, both officered by men with experience gained in foreign armies, were not unevenly matched as regards organization and skill. Royalists and Parliamentarians were alike the pupils of Maurice of Nassau and Gustavus Adolphus, and neither army could do more, at first, than emulate acknowledged continental masters.

The soldier most feared in the earlier phases of the war was Prince Rupert, the king's nephew, a foreign military expert. As a cavalry leader he found himself at the head of units whose disadvantage in equipment was outweighed by their excellent horses and fearless men. His innovation of the charge with the sword without any pause to fire pistols was initially caused, perhaps, by his men's having no pistols to fire. But he at once realized that pistols in any event represented a waste of time and impetus. Several Royalist successes (*e.g.,* near Worcester and at Edge hill in 1642 and at Chalgrove field in 1643) were the result of Rupert's reintroduction of shock tactics and charging at the gallop.

On the Parliamentary side there were officers as interested in horse breeding as were the Royalist duke of Newcastle (later to write standard works on the subject) and the king himself. But they realized that their chief tactical handicap lay in an organization derived from the militia. Regiments raised on a county basis were subject to desertion in proportion to their distance from home, even the officers being sometimes reluctant to subordinate the safety of their estates to any large-scale strategic plan. From this realization sprang the idea of the New Model army, first paraded in Windsor park on Feb. 15, 1645. Symbolic of its national basis of recruitment was the scarlet uniform chosen for all its infantry, superseding the county uniforms and remaining in use for 300 years. The strength of the New Model lay in its cavalry, which was particularly well paid, armed, equipped, horsed and disciplined, and the final Parliamentarian success was mainly attributable to Oliver Cromwell, who outmatched Prince Rupert as a cavalry leader.

Cromwell's achievement was primarily one of discipline. He accepted the Royalist innovation of charging with the sword but reduced the pace to a trot in order to maintain formation. What he thus lost in impetus he more than recovered in control and simultaneous impact. His units reformed knee to knee after initial success and could wheel, advance or withdraw as ordered by trumpet signal. The effectiveness of these tactics was shown not only against the Royalists, whose discipline remained weak, but against continental soldiers to whom this technique was a novelty. The professional discipline and nonlocal character of the New Model army made it a strong basis for Cromwell's dictatorship as protector, but the unpopularity of his military rule was to exercise a profound influence on later British history. The idea of a standing army was associated with political tyranny, and Charles II, on his Restoration in 1660, felt bound to disband the army (80,000 strong) as almost his first and most popular act. To this general dispersal there was one significant exception. The Restoration had been mainly brought about by one of Cromwell's generals, George Monk (later 1st duke of Albemarle), and his own infantry regiment, now the Coldstream Guards, was retained. Efforts to find employment for ruined Royalists led to the almost simultaneous formation of the troops which became, and remain, the Life Guards and Horse Guards, together with another infantry regiment which became the Grenadier Guards. This minimum provision for the king's safety, involving about 3,000 men in all, represented at that time the furthest extreme of militarism to which a jealous parliament would reluctantly assent.

Anxious to prevent a renewal of civil war and worried latterly about the succession, Charles II took what steps he could afford to strengthen the monarchy. His marriage with Catherine of Braganza, which brought him Tangier and Bombay, gave him a good pretext for forming garrisons in which his subjects could see no immediate threat to their liberties. Tangier (soon to be evacuated) was held by the 2nd or Queen's regiment of foot (1661) and a troop which later became the 1st Royal Dragoons. The Queen's regiment had to yield seniority in line to Dumbarton's regiment, the Royal Scots, which had a long record of service (representing, in fact, the Scots brigade of Gustavus Adolphus' army), but retained its seniority over the 3rd regiment (The Buffs), formed from soldiers who had similarly served with the Dutch and in units which had existed since 1572. A regiment formed to garrison Bombay was transferred to the East India company, and other units, raised to meet special needs in 1664, were disbanded when the immediate danger had passed.

Charles II's unpopular successor, James II, needed all the military support he could find. He used Monmouth's rebellion, which was crushed very largely by the Queen's regiment ("Kirke's Lambs," so called from their badge), as pretext for raising further units, including the Royal Fusiliers, and so finally brought his forces up to a total of 20,000. With this army, encamped at Hounslow, he hoped to overawe London, and he proposed, moreover, to disband the "constitutional" force, the militia. But any dreams he may have had of establishing his monarchy on a military basis were abruptly ended in the revolution of 1688. On the approach of William of Orange and his Dutch forces, James's officers mostly deserted to the enemy, while some of his regiments quietly disbanded themselves, to be reformed afterward in the army of William III. If the conduct of James II demonstrated afresh the dangers of a standing army, the revolution provided William and Mary with a permanent enemy in James and an example of how easily a throne can be overturned. Parliamentary opposition to a permanent land force was thus temporarily overcome by a desire to preserve the revolution settlement. More than that, the need to secure the loyalty of the troops to the new regime was now apparent. It was in fact a mutiny in favour of James which led parliament to pass the Mutiny act of 1689, which, while safeguarding the constitution, empowered the crown to try by court-martial any soldier accused of mutiny or desertion.

The accession of William III brought Great Britain into a large-scale continental war, affording scope both to the cavalry of the Cromwellian tradition and to the infantry regiments, which soon numbered 28. In 1690 parliament voted the maintenance of 62,000 men, thus sanctioning the Whig policy of intervention in Europe. While there may have been substance in the Tory contention that this policy was mistaken, it is beyond dispute that the modem British army first established its name during the period 1688–1713. John Churchill, 1st duke of Marlborough, was perhaps the greatest of English soldiers. Inheriting the regiments which had fought under William III at Steinkirk, Neerwinden and Namur, he made a European reputation for himself and for them. British infantry was famous for its steadiness, and the cavalry regiments distinguished themselves in the march across Germany in 1704 and in the battle which followed at Blenheim. The victories of Ramillies (1706) and Oudenarde (1708) further confirmed a British ascendancy which was upheld, though with heavy losses, at Malplaquet in 1709.

After the peace of Utrecht (1713) the army was reduced to 8,000 men in Great Britain and 11,000 overseas, the garrisons now including those at Gibraltar and Minorca as well as those in the colonies. The troops immediately needed on service, however, were those stationed in Scotland. These, after the accession of George I, had to suppress the rising of 1715. The subsequent period, from 1726, saw the disarming of the clans and the road-making activities of Field Marshal George Wade (1673–1748). Perhaps the oldest barracks in England are those at Berwick-on-Tweed, which date from 1717–21, at which period the billeting system was still, however, more normal. The 18th century was a period of relatively small standing armies, rigidly disciplined and trained. The Hanoverians had usually some German troops in British pay, perhaps because of the difficulties of recruiting in England. German influence was also apparent in the drill, the bugle calls and in military music. In administration the system remained personal. the colonel receiving an annual sum from which he was to recruit, clothe and pay his unit, whether at a profit or a loss. Regiments were raised by men of wealth, who often recovered something by selling commissions. This system of purchase did not prevent the ranker from reaching the rank of captain, but it enabled men of good family to achieve the rank of major early in life. While the dangers of this practice are obvious, it had the merit of enabling some officers to combine professional seniority with youth. For the lower ranks discipline was strict and often savagely enforced, partly because the tactics of the period demanded a rigid obedience and partly because recruitment was mainly from the lowest classes of the community.

In the War of the Austrian Succession (1740–48) British troops took part in continental campaigns, fighting at Dettingen in 1743 under the personal leadership of George II, the last king so to accompany his army. In the midst of these campaigns, in 1745, troops were hurriedly summoned to meet the danger of a Jacobite invasion based on the Scottish highlands. The defeat of the clans led to the final pacification of the highlands and this led in turn to the subsequent raising of the highland regiments, a plan to divert warlike instincts into a more useful channel. In 1745 (the year of Fontenoy) the army numbered 74,187 but was afterward reduced to a peace establishment (in 1750) of 18,857.

The Seven Years' War (1756–63) led to the raising of new regiments on an establishment which, in 1761, reached the number of 67,776. To the royal artillery was now added the horse artillery, used for close co-operation with the cavalry and copied from the army of Frederick the Great of Prussia, England's chief ally between 1756 and 1763. Fully maintaining the British fighting reputation (*e.g*, at Minden in 1759), the British army of this period gained greater success in colonial warfare and combined operations, the 39th regiment, for example, being present at the battle of Plassey. Other troops took part in raids on Rochefort in 1757, St. Malo and Cherbourg in 1; 58 and Belleisle. Still more conspicuous, however, was Gen. James Wolfe's capture of Quebec in showing the possibilities inherent in co-operation between navy and army, provided that the commanders could agree—as they sometimes failed to do. Afterward, however, in the American Revolution, it was painfully shown that the British army as then organized was quite insufficient to guard the now extensive empire without a superiority, both general and local, at sea. Even a temporary failure in sea power led to military reverses (as at Yorktown in 1781) which, though small in themselves, brought about strategic disaster. The loss of the American colonies simultaneously underlined the tactical implications of the rifle and the resulting importance of fieldcraft.

The army which had numbered 90,734 during the American Revolution was placed on a peace footing in 1783 and had been further reduced to 17,013 when war broke out in 1793. It was, in fact, being reduced in that year to 13,701, of which a large proportion were stationed overseas. With the French Revolution the character and scale of continental warfare had abruptly changed, small professional armies being replaced by conscript armies of vastly greater numbers, fighting not for adjustments of frontiers but for something approaching mutual destruction. The British regular army shared the fate of other similar forces at the outset of the war (1793–94) and withdrew to the British Isles. Thereafter the augmented land forces were destined for several years to operate mainly in the West and East Indies. The destruction of the French colonial empire was largely completed, and British overseas territory was widened at the expense of the Netherlands as well as of France. West Indian conquests were dearly purchased, however, in loss of life, not because of battle but because of yellow fever. During the same period of the war there were numerous combined operations, many on the French coast, which served (it was hoped) to dissipate the enemy forces in coastal defense. They were of more practical use, perhaps, in developing the technique which underlay later and better-planned landings on more promising shores; for example, in Egypt, Mauritius and Java.

Great Britain itself, meanwhile, was repeatedly threatened with invasion, sometimes from Ireland (as in 1798) and sometimes directly across the channel (as in 1803 and 1805). These threats came to nothing because of British naval superiority but led nevertheless to great efforts of military preparation. Besides the raising of new regiments and multiplication of battalions in the regiments already formed, and besides the embodiment of the militia, there was the volunteer movement. This began in 1793–94, the Dover volunteers being among the first units to be formed. In 1803 the younger Pitt was busy at Walmer, while out of office, in raising and training 3,000 men for the Cinque Ports volunteers, undergoing "the fatigue of a drill sergeant" in the process. The king reviewed 27,000 volunteers in Hyde park in 1803. Volunteer units were largely for middle-class spare-time soldiers and were based, in some instances, on existing professional or business associations, the East India house or the inns of court (The Devil's Own). Even so the toast "The Volunteers and a speedy meeting with the enemy on our own shores" expressed a confidence which events, had Napoleon's veterans landed, might not have justified. The volunteers reached a peak number of 380,000 and were later transformed into the local militia in 1808. This organization numbered 215,000 in 1812 as compared with the 70,000 volunteers still enrolled as such. These various associations, raised, uniformed, armed and equipped by voluntary effort, made a creditable appearance on parade but were never tested in battle.

Involuntary abstention from continental warfare for several years gave the government ample opportunity to study recent developments, absorb lessons, reorganize and retrain. Nor was this chance thrown away. The duke of York, whose reputation even as a commander in the field has been underrated, became commander in chief in 1798 and made it his business to introduce a new and uniform system of infantry training. This was based on the work of Sir David Dundas, who, after making a particular study of the Prussian and other continental armies, published the *Principles* of *Military Movements* in 1788. This in turn became the basis for the official *Rules and Regulations* of 1792 which the duke now sought to enforce. When the duke was out of office, moreover, in 1809–11, it was Dundas who took his place. Copying the French model, battalions were grouped in brigades and brigades in divisions, with artillery attached and formation headquarters developed. Whereas earlier drill aimed first and foremost at the maintenance of a continuous and steady volume of fire, the introduction of the backmoodsman's rifle. with its greater range and accuracy, suggested the reed for marksmanship and camouflage. In the green-uniformed rifle brigade there was introduced a skirmishing technique, with use of ground and open formation. In 1803–06 some line regiments learned something of the same art in the training camp at Shorncliffe under Sir John Moore, but they adhered nevertheless to the scarlet uniform and to close formation in battle.

It was a newly trained army which took the field in Portugal in 1809, soon proving itself up to the standard of the French in everything but numbers. In leadership the choice might seem to lie between generals who had been defeated in 1775–83, generals whose experience was of combined operations and raids. and generals with no war experience at all. But Britain had another army in India, and it was from this that there now came Sir Arthur Wellesley, the victor of Assaye, with a reputation already made. The command in Portugal fell to him soon after the death of Sir John Moore at Corunna, and it was he who raised the British military reputation to the height it had reached under Henry V, under Cromwell and under Marlborough. His army was a balanced force of all arms but it was on infantry that he mainly relied for victory. The Iberian peninsula was not the main theatre of war but it was the grave of the French legend of invincibility. In successive battles Wellesley (later duke of Wellington) gained an ascendancy over his opponents, and when the war ended for the time in 1814 he was leading his veterans into France. As the most uniformly successful of the allied generals he led the mixed army which defeated Napoleon at Waterloo, and by 1815 British military prestige was perhaps at its highest. The army in 1812 comprised 245,996, of which a fair proportion were serving or had served overseas. During the peace which lasted, almost without interruption, until 1854, military stagnation was all but complete. The army, fixed at a fairly high figure (71,790) in 1822, with the duke of York still commander in chief until 1827, rested on the legend of Waterloo. The duke of Wellington (commander in chief, 1842–52) was no reformer, and the army owed much to the prince consort, who joined with the duke in preventing duelling among the officers. More important than this reform mas the general superseding during this period of the flintlock smooth-bore musket by the rifle and percussion cap.

The army which was sent to the Crimea in 1854 was led by veterans of the Peninsular War but was without recent experience of warfare. The problems presented by the campaign were new in that the lines of supply were exceptionally long. Nor was it easy to maintain a force on hostile territory with no local friends nearer than the Turks and no more reliable ally than Napoleon III. The army was an agglomeration of battalions, individually of fine quality but unused to working together, without trained staff, administrative departments or army organization of any kind. The lesson of the winter before Sevastopol was dearly bought, but mas not thrown away. From that time several war ministers and one commander in chief laboured perseveringly at the thankless and difficult task of reforming army organization. Foremost in the work was Sidney Herbert (later Baron Herbert of Lea), the soldier's friend, who fell a sacrifice to his labours (1861) but not before he had done much for the army. The whole system of administration was revised. In 1854 it was inconceivably complicated and cumbersome. The secretary of state for war and colonies, sitting at the colonial office, had a general but vague control, practically limited to times of war. The secretary at war was the parliamentary representative of the army. The commander in chief was responsible to the sovereign alone in all matters connected with the discipline, command or patronage of the army but to the secretary at war in financial matters. The master general and board of ordnance were responsible for the supply of material on requisition, but were otherwise independent, and had the artillery and engineers under them. The commissariat department had its headquarters at the treasury, and until 1852 the militia was under the home secretary. In 1854 the business of the colonies was separated from that of war and the then secretary of state assumed control over all the other administrative officers. In the following year the secretary of state was appointed secretary at war also, and the duties of the two officeswere amalgamated; the commissariat office was transferred to the war department, and the board of ordnance was abolished, its functions being divided between the commander in chief and the secretary of state. The minor departments were gradually absorbed, and the whole administration divided under two great chiefs, sitting at the war office and Horse Guards, respectively. In 1870 these two were welded into one. and the war office now existing was constituted.

Corresponding improvements were effected in every branch. The system of clothing the soldiers was altered, the contracts being taken from the colonels of regiments, who received a money allowance instead, and the clothing supplied from government manufactories. The pay, food and general condition of the soldier were improved; his ordinary education and the military education of the officer were taken in hand. The Indian Mutiny of 1857, followed by the transference of the government of India, led to important changes. The East India company's white troops were amalgamated with the queen's army, and the whole was reorganized.

But it is not a British habit to profit by military experience. The mere fact that the difficulties of 1854 and 1857 had been surmounted ultimately led the nation and its representatives to forget their cost and waste. And the nation-wide rejoinder to the French threats of 1859—the creation of the volunteer force—contributed to a false sense of security. Thus the two obvious lessons of the German successes of 1866 and 1870—the power of a national army for offensive invasion, and the rapidity with which such an army when thoroughly organized could be moved—created the greatest sensation in England. The year 1870 is, therefore, of prime importance in the history of the regular forces, and the ensuing period of reform is connected indissolubly with the name of Edward Cardwell (later Viscount Cardwell), secretary of state for war, 1868–74. In the matter of organization the result of his labours was seen in the perfectly arranged expedition to Ashanti (1874); as for recruiting, the introduction of short service and reserve enlistment together with many rearrangements of pay, etc., helped to treble the number annually enlisted as well as to build up a reserve which in the South African War yielded 80,000 men to maintain the strength of the army in the field. The localization of the army, subsequently completed by the territorial system of 1882, was commenced under Cardwell's regime, and a measure which encountered much powerful opposition at the time, the abolition of the purchase of commissions, was also effected by him (1871). The machinery of administration was improved and autumn manoeuvres were practised on a scale previously unknown in England. In 1871 certain powers over the militia, formerly held by lords lieutenant, were transferred to the crown, and the auxiliary forces were placed directly under the generals commanding districts. In 1881 came an important change in the infantry of the line, which was entirely remodelled in two-battalion regiments bearing territorial titles. This measure (the "linked battalion" system) aroused great opposition; it was dictated chiefly by the necessity of maintaining the Indian and colonial garrisons at full strength and was begun during Lord Cardwell's tenure of office, the principle being that each regiment should have one battalion at home and one abroad, the latter being fed by the former, which in its turn drew upon the reserve to complete it for war. On these general lines the army progressed up to 1899, when the severe trials of the South African War hastened new schemes of reform, leading up to Richard (later Viscount) Haldane's "territorial" scheme (1907), which put the organization of the forces in the United Kingdom on a new basis.

Cardwell had left office before one of his most important reforms had been completed, organizing the forces in the United Kingdom in larger formations so that they could be employed as a field army, of which the strength was based solely upon the number of troops serving abroad, not upon any estimate of war requirements. The question of the uses to which such an army would be put was one that had never been properly determined. The army school of thought visualized an invasion of the British Isles and the primary need for a large field army to deal with such an emergency, while the navy considered that, given sufficient naval strength, invasion by foreign armies could be prevented by action at sea. The army view was reflected in the organization of the higher formations. These consisted of army corps, composed not only of regular forces but also of auxiliary elements under no obligation to proceed abroad. One of the first steps taken by Haldane was to advocate clear thinking in connection with army problems, and he developed the general staff, initiated by his predecessor, Arnold Forster, to undertake this important but previously neglected branch of military preparation. Within a few months, three principles had been laid down and officially accepted to govern the military defense of the empire. The first of these was the essential need for a navy strong enough to ensure the safety of troops crossing the seas. This was a natural outcome from Cardwell's system of cutting down oversea garrisons to a bare minimum on the assumption that the troops in the United Kingdom could be sent as reinforcements to any part of the world in times of emergency. The second principle was that of local provision for military defense in all parts of the empire. to the utmost extent to which such provision could be furnished. The third was that of mutual military support in times of emergency.

Instead of paper army corps, available only for home defense, the Haldane reforms provided for the organization of the troops in the United Kingdom in six infantry divisions, one cavalry division, and line-of-communication troops, as an "expeditionary force" (composed entirely of regulars) available for oversea service either as reinforcements for the small garrisons of different parts of the empire in the event of internal or external menace, or, if need be, as a field army capable of fulfilling treaty obligations. Furthermore, the need for strong drafts of men to keep units in the field in a protracted campaign was realized. In the Manchurian war of 1904–05 the Russians had made the mistake of reinforcing their field army with fresh formations, while leaving the veteran units already in the field to melt away for want of drafts to replace wastage in personnel. In order to avoid this mistake in British military policy, the militia was called upon to provide drafts of trained men in time of war for the expeditionary force. and its name was changed to the "special reserve" of the regular army.

A further point that was realized was that, whether the British Isles were or were not subject to the menace of invasion, they could not be left denuded of troops. Material in manpower lay readily to hand in the force of yeomanry and volunteers who, from patriotic motives, had volunteered to take part in the military defense of the United Kingdom in grave emergencies and to spend such time as they could spare from their civil vocations in undergoing training for the purpose. Lacking neither in zeal nor in numbers. they lacked all else required by a field army in the way of organization and training in higher units and most of the transport, material and equipment, of which the provision comes under the term understood by the expression "mobilization." Units of the different arms and departments had sprung up haphazard, according to the preference expressed by those who had been instrumental in raising them. No attention had been paid to the proportion of each arm and department needed for a grouping in such higher formations as divisions. In face of opposition and criticism similar to that faced by Cardwell, Haldane, with the loyal co-operation of the units concerned, used this material to establish the territorial force, of which the first units appeared under arms in April 1908. The act which established this force provided that either the units or the individuals serving therein might volunteer for oversea service in grave emergencies. The extent to which this appeal met with response during the years 1914–18 belongs to the story of World War I (*q.v.*). By Dec. 1914, 2,413 officers and 66,805 men in the territorials were serving abroad. By April 1917 these numbers had risen respectively to 17,859 and 487,237. Up to the close of 1915, the voluntary direct enlistments in wartime into the territorial force numbered 725,842. Apart from individuals who volunteered for the regular army, the yeomanry provided 1 complete division for oversea service, the territorial force of all arms 24 divisions.

Thirty "new army" divisions were also raised on a plan instituted by Lord Kitchener to supplement the 11 "regular" divisions employed overseas. The need for more troops compelled parliament to pass a conscription measure in March 1916, drafting men between the ages of 18 and 40, though soldiers were not to be sent out of the United Kingdom until their 19th birthday; the maximum age was later raised to 45 and, in 1918, to 50, while, because of the imminent peril, youths of 18 were also sent to fight in France. In Dec. 1918 the British field army comprised 4 mounted and 67 infantry divisions, of which all excepting 1 mounted (cyclist) and 4 infantry divisions were serving outside the United Kingdom. With a total establishment of 256,798, the British regular army began World War I with an actual peace strength of 247,432, an army reserve of 145,347 and "special reserve" of 63,933. The territorial force, with an establishment of 316,094, numbered 268.777. including 766 members of the officers' training corps, also established by Haldane, with an establishment fixed at 1,110. Between the outbreak of war and conclusion of the Armistice, England provided 4,006,158, Scotland 557,618, Wales and Monmouthshire 272,924 and Ireland 134,202 men for the British army, a total of nearly 5,000,000 for the United Kingdom. The total permanent wastage in British (Isles) military personnel up to Jan. 1919 amounted to 1,892,100, including 500,000 killed or died of wounds or other causes overseas, and about 37,000 in the United Kingdom.

Roughly speaking the number of British troops serving in various expeditionary forces at the time of the Armistice in Nov. 1918 may be put at about 2,100,000, with 1,380,000 in the United Kingdom (excluding about 250,000 volunteers), 94,000 in India and 11,200 as garrisons of defended ports. The total was about 3 600,-000. Some idea of the strain brought upon the British army in the days of unrest in the world after the Armistice can be gathered from a return showing that the numbers demobilized up to May 26, 1920, amounted to the vast total of 163,563 officers and 3,595,717 men, altogether nearly 3,660,000; while during the same period grave military responsibilities were undertaken in north Russia (up to Oct. 1919), in east Russia (Vladivostok), in Germany (Cologne area of occupation), in Arabia, in Trans-Caucasia (up to April 1919), in the Caucasus (up to Aug. 1919), in Mesopotamia. Syria (up to Jan. 1920), Palestine and East Africa. involving fighting in most of those areas. as well as in India and in Ireland; and while Britain was still technically at war with Turkey and actively at war with Afghanistan (May to August 1919). The tale is told elsewhere of these operations and of the strain brought subsequently upon the army by operations in India: in attempting to hold neutral zones covering the Dardanelles and Bosporus nhen the Turkish army had been allowed years to recuperate after the conclusion of an armistice in Oct. 1918; in attempting to maintain order in Ireland; and in military activities elsewhere.

Notwithstanding the necessity to preserve order in, and to defend, increased areas of territory in Asia and Africa, it was the policy of the British government for several years following World War I to maintain military forces of minimum strength. It was not until the training season of 1925. when four regular divisions and an extemporized cavalry division took part in army manoeuvres for the first time in 12 years. that normal conditions of peace organization and training again began to prevail. Behind this small expeditionary force stood a reconstituted territorial army of 14 divisions, liable to overseas service in grave emergencies, to which a definite promise had been made that, in such circumstances. they would go as units and not be called upon to provide drafts for the regular army, although that force had lost the special reserve which formed so valuable a feature of the Haldane reforms.

Year by year, however, hope for enduring peace in Europe gradually maned. Great Britain was in the forefront at every attempt to concert international amity, and not even the failure of the Conference for the Reduction and Limitation of Armaments in 1933 sufficed to persuade the country's leaders that the necessity for rearmament was inescapable. Nevertheless, the groning strength of potential adversaries began to make it imperative to introduce into the army some degree of modernization in weapons and organization. The territorial army was accorded full status in 1937, gaining access to the same standards and sources of instruction as the regular army; the following year, after the deeper implications of the Munich pact had been understood, a definite rearmament program was undertaken. Army life was made more attractive to junior officers in 1938, promotion by vacancy up to the rank of major being abolished. every subaltern automatically becoming a captain in eight years and every captain a major in another nine years. Early in 1939 parliament sanctioned the doubling of the strength of the territorial army. and in May of that year Great Britain, for the first time in its history, introduced peacetime conscription, the Military Training act requiring all youths of 20–21 years of age to undergo a special course of training for six months.

THE EVE OF WORLD WAR II

Recruitment and Service.—Until the measure of compulsion introduced in May 1939, all recruiting for the British army had been on a voluntary basis. For the regular army, normal engagements were for long service (12 years with the colours) or short service (in part with the colours and in part, to total 12 years, in the reserve); short periods of enlistment (one to four years) were also possible for all arms. Men enlisting on a normal engagement for general service were between the ages of 18 and 25. For the territorial army, enlistment for all arms was from 18 to 38 years, the term of service being four years; members were required to attend an annual training camp and to carry out prescribed annual drills.

Organization and Strength. — The peacetime composition of the regular army in the United Kingdom (excluding British troops in India) was five infantry divisions (14 brigades); one mobile division (2 cavalry brigades and 1 tank brigade) and 2 anti-aircraft brigades. One anti-aircraft brigade constituted a supplementary reserve, and the territorial army was composed of 12 infantry divisions (36 brigades), 5 anti-aircraft divisions (22 brigades), 1 tank brigade and 3 cavalry brigades. The officers' training corps provided students at schools (junior division) and universities (senior division) with elementary military training to provide a potential reserve of young officers to meet a national emergency.

While the regular army counted 237,736 men on July 1, 1939, the authorized establishment when the year began was 162,707. At that time, the establishment for other troops in Great Britain provided for the army reserve (estimated), 144,000; supplementary reserve, 67,945; territorial army, 249,480; and officers' training corps (officers and permanent staff), 1,034. This made a total of 625.166 officers and men available at home stations.

Colonial Forces.—While the self-governing dominions maintained their own permanent and nonpermanent military forces, Great Britain was responsible for the defense of the colonies and protectorates. On the assumption that reinforcement by sea in times of emergency would always be a practicable proposition, a mere handful of British troops was kept abroad, though permanent forces (in all totalling about 2,000) included the royal Malta artillery and the Hong Kong and Singapore royal artillery. Except that one British battalion was stationed in Jamaica with a detachment in Bermuda, the West Indies, the Americas and the islands in the Atlantic depended for their defense upon volunteer forces. East African possessions had, besides armed native police forces, the king's African rifles and the Somaliland camel corps (regular troops with native personnel), and in Kenya Colony a territorial force in which service was compulsory for Europeans. In West Africa local defense was provided primarily by the royal West African frontier force (also regular troops with native personnel), comprising the Nigeria and Gold Coast regiments, the Sierra Leone battalion and the Gambia company. In South Africa, outside the Union (for which *see* South Africa, Union of); Basutoland and Bechuanaland had native armed police forces. the Rhodesias had white volunteers and Swaziland a British rifle club and native police. Colonial possessions in Asia and islands in the Indian ocean had similar forms of protection. Volunteer defense forces were maintained in Ceylon, Hong Kong, the Straits Settlements and Mauritius; British North Borneo had a police force of various races, liable for military service; the Federated Malay States maintained volunteer forces of Europeans, Indians, Malays and Chinese; and Johore, in the Unfederated Malay States, had native regulars and volunteers as well as a European volunteer corps. In the Pacific ocean, small defense forces and armed police were found in Fiji, the Gilbert and Ellice Islands and the Solomon Islands.

Territories placed under the mandate of Great Britain had restricted defense facilities. Local forces in Palestine and Trans-Jordan consisted of the Trans-Jordan frontier force, a military unit, and the Palestine police and the Trans-Jordan police (or Arab legion), armed constabulary; the Cameroons and Togoland had armed police: in Tanganyika Territory were battalions of the king's African rifles and also the Tanganyika police force.

Egypt, the Anglo-Egyptian Sudan. Aden and the Arabian hinterland are dealt with elsewhere; *see* also the information under India for defense responsibilities that fell upon the British army. In connection with the principle of mutual defense, *see* also Austkai.i.i: Canada; New Zealand; and South Africa, Union of.

Higher Command. — The government of the British army was vested in the crown, command being placed in the hands of the army council. The army council, of which the secretary of state for war was president, included the chief of the imperial general staff, adjutant general, quartermaster general, master general of the ordnance and financial secretary. The war office included the army council, departments, a board for selection of officers for promotion to lieutenant colonel and higher ranks, and the judge advocate general's office. Excepting when in training camps or on actual military service, the territorial army was administered by county associations. The committee of imperial defense, of which the prime minister was chairman, had no executive powers, being an advisory and consultative body concerned with the co-ordination of defense policy.

Military Education. — Principal military educational establishments were the Royal Military academy, Woolwich (for artillery, engineer and signal corps cadets), the Royal Military college, Sandhurst (for cadets of cavalry, infantry and other arms), the Senior Officers' school, Sheerness (for senior regimental officers), and the Royal Staff college, Camberley (for the staff). Various other schools for specialists were also conducted, and an Imperial Defense college in London was for senior officers of the army, navy and air force.

THE ARMY OF WORLD WAR II

On Sept. 3, 1939, the day Great Britain declared war against Germany, the Military Training act of the previous May was superseded by the National Service (Armed Forces) act, which extended the liability for military service to all men between the ages of 18 and 41 years. At the outbreak of war, too, the territorial army, the strength of which had been doubled in the spring of 1939, was merged with the regular army. With the increased demand for men in the armed forces the maximum age for compulsory service was raised from 41 to 51 in 1941, and, in order to provide a pool of partially trained youths, the war office recognized the army cadets and also the junior and senior training corps, which had carried on the work performed prior to hostilities by the officers' training corps. Educational institutions for cadet-officers were closed when war began. Thereafter all commissions granted to officers were temporary and were obtainable only after passing through officer-cadet training units, candidates having to serve first in the ranks. Various independent organizations co-operated with the war office in providing educational facilities of a general nature in all units of the army.

Composition. — The infantry, main bulk of the army, was affected in its work by mechanization. While troop-carrying companies of the royal army service corps transported most of the men, headquarter, company and platoon trucks carried ammunition, tools, heavier weapons and packs. In rifle battalions, carrier platoons were provided with small-tracked, armoured vehicles for light Bren machine guns, tommy guns, anti-tank rifles and two-inch and three-inch mortars. Machine-gun battalions, entirely motorized, were equipped with medium machine guns, and reconnaissance battalions rode in light cars, carriers, motorcycle combinations and motorcycles. The tank corps of World War I was succeeded by the royal tank regiment, and this, in 1939, was united with mechanized cavalry and yeomanry units to constitute the royal armoured corps. Light tanks performed the reconnaissance previously carried out by cavalry; cruiser tanks, more heavily armoured, attacked under mobile conditions of open warfare. and infantry tanks, organized into army tank battalions, assisted infantry attacking enemy positions; armoured car regiments of the R.A.C. were employed in fighting reconnaissance ahead of attacking troops.

With the exception of mule-borne mountain and pack artillery and superheavy guns on railway mountings, all artillery in World War II was mechanized. The field branch, which included anti-tank artillery, supported the armoured and infantry divisions; the anti-aircraft branch had heavy, light and small guns for both static and mobile defense; and the coast artillery branch comprised counterbombardment, close defense and searchlight units. The royal engineers consisted of a field (or combat) branch working with the divisions and corps; line-of-communication troops providing construction, electrical and mechanical services and the like; and transportation services, concerned with railways ports and inland water transport. Companies were also trained in bomb disposal and in the location of anti-tank mine fields. Stemming from the royal engineers was the royal corps of signals, formed in 1920, which operated wire and wireless telegraph and telephone services and also maintained communication by motorcycle dispatch riders and pigeons. The royal army service corps, the supply and transport branch of the army, brought up foodstuffs by land or water, moved the infantry, carried the heavy stores of the engineers and drove the vehicles of the royal army medical corps and the army dental corps (royal army dental corps after 1946). The supply and maintenance of all stores for all units of the army was the primary duty of the army ordnance corps and of the royal electrical and mechanical engineers (separated from the R.A.O.C. and established in Oct. 1942).

The Queen Mary's army auxiliary corps of World War I was the pattern for the auxiliary territorial service, which was organized in 1938 and became the largest of the women's services; it was granted full military status on April 10, 1941, pay being roughly two-thirds that for male soldiers of equivalent ranks. Follouing passage of the National Service act, 1941, single women between 20 and 30 were drafted into the A.T.S. (which became the women's royal army corps in 1949). Besides working as cooks, telephonists and drivers of army vehicles, the women were employed in radiolocation, almost every duty with anti-aircraft batteries except actual operation of the guns, and in kine-theodolite duties.

The local defense volunteers were organized in May 1940 to supplement field troops, and in November were incorporated in the army as the home guard; enrolment became compulsory in March 1942 for all men from 17 to 6j in civil defense regions. Fully equipped, men served a maximum of 48 hours every four weeks, receiving subsistence allowances while on duty but no pay. Their primary role was defense, to delay the enemy until regular formations moved to the attack. Men up to 50 years of age were also enrolled in the pioneer corps (royal pioneer corps after 1946), which built huts and defenses for the army and cleared debris after cities had been bombed; open to alien volunteers, it contained many European refugees.

At the outbreak of war the regulars, with their reserves, and including British components of the Indian army. numbered about 400,000, and a like number was in the territorials. These numbers were augmented by volunteers and conscripts, and though heavy casualties were suffered abroad, the armed forces in Great Britain by the middle of 1942 were put at 1,500,000–2,000,000 men. To compare these figures with those of 1918, when British troops numbered about 3,600,000, would give the impression that the military effort in World War II was far smaller than in World War I. This was in fact the case, the difference being largely accounted for by the enormous manpower required to maintain, equip and supply a modern army and air force. In practice, moreover, the distinction between soldier and civilian had become less important. Whereas munition workers were subject to air attacks and were also liable for part-time service with the home guard, the proportion of enlisted soldiers who actually fought was relatively low, vast numbers of men being needed for administrative and technical work in base areas. The supply of men for actual fighting was exhausted by 1944 and it was found necessary to disband some formations in order that others might be up to something like establishment in 1945.

Preparation. — The expeditionary force which went to France under Viscount Gort in 1939 comprised the 1st corps under Sir John Dill and the and corps under Gen. Alan Brooke (later Viscount Alanbrooke); it totalled ten divisions in all, of which one was motorized. This force showed, if only in its shortage of tanks, the extent to which Britain had thrown away the lead in tank design which had been gained by the end of World War I. In the intervening years the army had suffered from unpopularity, from obsolete equipment, from unrealistic training and from a tactical doctrine which inclined to the defensive. It was almost as much through luck as through judgment that the bulk of the troops mere rescued from Dunkirk beaches when French resistance collapsed. Although the fall of France brought Italy into the war as an enemy, and although most of the British heavy equipment had been lost in the evacuation, the events of 1940 were a blessing in disguise. Instead of becoming involved in another continental war of the 1914–18 pattern, with casualties on a scale which Britain could certainly not have survived, the British army was given the opportunity (as in 1794) to withdraw to the British Isles, re-equip and reclothe itself, retrain its units and revise its ideas. Nor was the opportunity thrown away. For a period the threat of invasion, the guarding of concrete emplacements, the manning of road blocks and the training of the local defense volunteers (later the home guard) took up more time than was otherwise desirable. But as the pressure relaxed the army began to prepare for its future battles. With Sir John Dill as chief of the imperial general staff and Sir Alan Brooke as commander in chief, home forces, the army trained for mobile rather than static warfare. Tactical doctrine was revised in terms of armoured divisions and paratroops, individuals and units were trained in battle schools and the offensive spirit was recreated by the example of the commando units which raided the coasts of occupied France. Even so, it would have taken long to overtake the German lead and longer to regain lost confidence had not the Italian army been met and defeated in Egypt and Eritrea.

Initially, the troops with which Sir Archibald (later Earl) Wavell met Marshal Rodolfo Graziani in Sept. 1940 comprised only three divisions (including one Indian and one Australian), but the prompt collapse of the Italians had a tonic effect on the whole army. It also had the effect of drawing German troops into the African conflict, and it was these, under Field Marshal Erwin Rommel, which turned the tables in 1941, endangering Egypt afresh after troops from there had been diverted to Greece and Abyssinia. The same year, however, saw the whole situation changed by two major events: the German attack on the U.S.S.R. with 150 divisions and the Japanese attack on Pearl Harbor which brought the United States into the war against Germany. This made it possible to gain superiority in one theatre of war in 1942, and Africa was the obvious front to reinforce even if it meant, as it did, sacrificing Malaya to the Japanese. Forces in the Western desert were built up to a strength of two armoured and seven infantry divisions, and it was these, the 8th army, which faced Rommel in August.

Operations. — The results of recent training and re-equipment were shown at the battle of El Alamein soon after Gen. Sir Harold Alexander (later Earl Alexander of Tunis) had assumed command in the middle east with Lieut. Gen. Sir Bernard Montgomery (later Viscount Montgomery of Alamein) as commander of the 8th army. Rommel was defeated and then driven back into Tunisia. Simultaneously, the results of the United States' participation in the war were shown by the appointment of Gen. Dwight D. Eisenho er to a combined Anglo-U.S. command with headquarters at first in London and later at Gibraltar. This was the prelude to the landing of the British 1st army and U.S. 2nd corps in Algeria and Morocco, which began on Nov. 8, 1942. German and Italian forces had now to face pressure from two directions without anything like equality inaircraft. tanks or even infantry. Operations ended with the axis troops surrounded at Cape Bon, and there Gen. D. J. von Arnim surrendered with 250,000 men of May 12, 1943. From this point the British army began to display its historic genius for combined operations but with the added refinements of co-operating aircraft, gliders and paratroops. The introduction of aircraft had tended in itself to solve the problem of command which had so often in the past proved insuperable. The solution found was to appoint a supreme commander with commanders in chief for land, sea and air. This technique was proved in the opposed landings in Sicily (July 1943), which were themselves merely the prelude to the Italian campaign of 1943–45. This campaign was opportunist in character, being designed rather to exploit the collapse of Italy than to defeat the Germans on ground chosen for the purpose. It served to occupy 18 German divisions under Albert Kesselring for months of intense conflict leading up to the capture of Rome on June 4, 1944, two days before the invasion of France began.

While the actual landing in Normandy represented the culmination of British skill in combined operations, the later campaign, after Montgomery's initial success, witnessed the building up of the U.S. forces to a total (by Jan. 1945) of 60 divisions. Montgomery, the land commander under Eisenhower (as supreme Allied commander) until Sept. 1, was responsible for much of the initial success but yielded place to Eisenhower as the forces became, in fact, predominantly American. Meanwhile, on Aug. 15, a fresh landing was made in the south of France which had little effect on the campaign but which deprived Alexander of resources which he needed to finish the campaign in Italy. France was reconquered in 1944 and Eisenhower was on the Rhine early in 1945, with only 56 depleted German divisions to oppose him. The German air force had, moreover, exhausted its last resources in supporting Field Marshal K. R. G. von Rundstedt's offensive in Dec. 1944. The invasion of Germany began in March 1945 and the offensive of the 15th army group began in Italy in April. The German forces crumbled in both theatres of war, their troops surrendering in Italy on May 2, those opposite Montgomery's 21st army group surrendering two days later on May 4.

Commentary.— There can be no doubt that the army had suffered before 1939 from current pacifist talk as well as from peacetime economies. Its initial reverses showed, in some instances, a decline in fightipg spirit. As against that, national education had provided reserves of men sufficiently literate to learn a new trade and learn it quickly. The result was an army of high technical competence, with perhaps too high a proportion of specialized noncombatants and too low a proportion of infantry. But the infantry soldier himself had now to be master of as many as nine weapons and, apart from that, even the fighting units themselves contained a large number of specialized signallers, mechanics and drivers. The outstanding development, as compared with World War I, was undoubtedly in the air, and there were instances, as at Pantelleria, when a ground force was defeated by air power alone. More commonly, however, victories were won by a close cooperation between the troops and their supporting air force, and the army with air superiority had a physical (and, still more, moral) advantage even before battle was joined. The use of paratroops and gliders introduced a new element into warfare without revolutionizing accepted tactics. They were found to be of use only in conjunction with ground forces and when dropped, as at Arnhem, too far from the main columns, they were apt to suffer heavy casualties. What was essentially more revolutionary was the development of a system of air-borne supply. This was first tried in Burma, where the 14th army battled to keep the Japanese out of India and finally to destroy the Japanese forces in Burma itself. Under the supreme command of Lord Louis Mountbatten (later Earl Mountbatten of Burma) and under the immediate direction of Gen. Sir George Giffard and Gen. Sir William Slim, the technique was developed of maintaining communications by air alone. It was found possible to supply a ground force of as much as two divisions for at least a limited period, while columns of brigade strength could operate independently for three months or more at a time—at least when led by as resolute an officer as Brig. Orde C. Wingate. Operations on this small scale were possible only in the jungle, but their success pointed the way to a strategy in which ground communications would no longer play so vital a part. The development of such a strategy on the grand scale had to wait, in effect, until after the war and was exemplified by the air lift supply to Berlin, during what was virtually a siege in 1948–49. The daily average of 4,000 tons of food and fuel was proof of what could be done in this way, and further technical progress might enable a higher total to be reached in time of war.

THE ARMY AFTER WORLD WAR II

With the end of hostilities in 1945 it became clear that certain peacetime changes in army organization would be necessary. In the infantry it was decided to retain the well-tried regimental system. Operational organization — as in the war—was based on the armoured division and the infantry division. It was, however, apparent that for a long time the bulk of the regular army would be stationed overseas — in Germany. Austria, the middle east and the far east. This necessitated the abandonment of the Cardwell system (see above; by which units were linked in pairs, one serving at home and one overseas), which had served so well in the past. Conscription, first introduced in peace in May 1939, was continued, the period being for 2 years (except for a short time when it was 18 months) with the regular army and 3½ years part-time service with the territorial army or army emergency reserve. For the time being the need for a reserve for the regular army was met by the class Z reserve, consisting of fit men of certain age groups who had served during World War II. The territorial army provided most of the units of anti-aircraft command. Its field force units consisted of armoured and infantry divisions, and one air-borne division, organized on prewar lines; but with modern equipment and drawing most of their officers and men from national servicemen who had completed their two-year period of full-time service. The system for the supply of regular officers was changed to the extent that all potential officers had to serve in the ranks, but their training as cadets remained the same. In 1952 the home guard was reconstituted, on a full establishment in vulnerable areas and on a cadre basis in areas of less importance. For ten years this system, with minor modifications, met the country's needs. The main weakness was that, due to heavy overseas commitments, there was no strategic reserve of regular troops in Great Britain. By 1952 the territorial army had, however, been built up to strength by the influx of national servicemen.

By the end of 1954 circumstances had arisen which made a change in organization desirable in both the regular and territorial armies. These changes were necessary as a result of new weapons — nuclear weapons in particular — and changing political conditions overseas, which made essential some redeployment of the regular army. The main changes, which began in 1954, were as follows:

1. New scientific inventions had made existing anti-aircraft defenses obsolete. In 1955 anti-aircraft command was abolished and the anti-aircraft defense of the United Kingdom became the responsibility of the R.A.F. Existing anti-aircraft units — mostly territorial—were either disbanded or converted to other roles.

2. The Anglo-Egyptian agreement of 1954, by which all British troops were to be withdrawn from Egypt within 20 months, resulted in the redeployment in 1955 of army units which had been stationed in the Suez canal zone. A little more than one division was brought home to form the nucleus of a strategic reserve which had been lacking for so long. During the latter months of 1955 and the early part of 1956 part of this reserve had to be sent to Cyprus to deal with terrorist activities.

3. In Dec. 1955 a reorganization and modification in role of the territorial army was announced. Two infantry divisions were put on a "higher" establishment with the role of reinforcing the regular NATO division in the event of war. The remainder were placed on a "lower" establishment, the armoured divisions being converted to infantry and the air-borne division being disbanded—except for one parachute brigade which was retained. The task of the "lower" establishment divisions was home defense, including help in civil defense. They could also be used for expansion in time of war. The necessity for a home guard in war continued to be accepted, but the force was reduced to a cadre establishment.

4. In 1955 there was also a change in the conditions of national service. The two-year period of full-time service was retained, but the age of call-up (previously 18) was to be increased gradually to 19 (by March 1958). There was also a considerable reduction in a man's statutory liability during his three and a half years' part-time service. The latter was acceptable in view of the changed organization and role of the territorial army.

In 1956 the strength of the regular army was approximately as follows: regular personnel 196,000; national servicemen 201,000; women, 6,700. Of these, the equivalent of two divisions were in Great Britain, that of four divisions in Germany and that of about five and a half divisions were elsewhere overseas. As overseas contingents are often in small garrisons, these divisional strengths are approximate. The reserve army included about 264,000 in the territorial army (organized into ten divisions in 1956), about 189,000 in the army emergency reserve and about 6,000 women.

In April 1957 the government announced drastic changes in the fighting services, likely to result in a reduction in strength of the regular army to about 160,000 officers and men and the abolition of the national service call-up in 1960.

DEFENSE: NAVY

Age of the Rowing **Vessel.**—Although the Romans must have brought to Britain some Mediterranean ideas of seamanship, shipbuilding and navigation, their tradition was subsequently broken, leaving the British to relearn the seaman's art from the Norsemen. Thus. to this day, such basic nautical expressions as "starboard" and "keel" are Scandinavian, and it was probably from the vikings that the 9th-century Britons had learned how to reach the neighbouring shores of France or Ireland. Sea fights are recorded as early as A.D. 833 and 840, but it was not until the time of Alfred the Great that the vikings were defeated (A.D. 878) by their English pupils. The vessels on both sides were at the time propelled by oars, with auxiliary sails, and were accordingly limited in size. Alfred himself possessed several of the larger 60-oared vessels, and the remainder were provided by the coastal shires. Nor was this system much changed at the time of the Conquest, the subsequent Norman kings similarly calling for aid in an emergency. Seaports rendered feudal service in this fashion, their bailiffs or port reeves being made responsible for equipping and manning a stated quota of ships. But the 11th and 12th centuries saw only a limited naval activity, for the kings of England were also dukes of Normandy and ruled both sides of the channel. For the Norsemen they were now clearly too strong. Thus established astride the Straits of Dover, the Norman and Angevin kings had continual need for a ferry service between England and the continent. In return for providing the passage of mails and troops, the port offering the shortest sea routes, the Cinque Ports (*q.v.*), were given special privileges, which they tended to abuse. The situation altered abruptly in 1207 when King John lost his Norman possessions and so brought his frontier back to the French coast line. The straits themselves he claimed as his from 1213 and later kings did the same. With French enemies so near at hand, naval defense became an urgent problem. It is in his reign that we first find mention of an administrative officer (William of Wrotham) called "keeper of the king's ships." These ships, 50 or more of them, were still rowing vessels and intended for use in the channel. They were thus logically based on Southampton, only rarely venturing as far as the Irish sea.

Age of the Sailing Vessel.—English overseas trade (as apart from coasting and fishing enterprise) began in the period after the loss of Normandy when Gascony still remained a possession of the English kings. The coastwise voyage to Bordeaux was thus an overseas but not a foreign voyage, being politically safe and only moderately venturesome as a feat of navigation. It was readily extended, moreover, to Spain and Portugal. the latter country being in normal alliance. These almost oceanic voyages involved the outward shipment of wool and the homeward lading of wine, both fairly bulky cargoes and unsuitable for any vessel which oarsmen could row. There accordingly developed on the Atlantic coast a type of ship in which the only oar was for steering, the ship itself being propelled by a single square sail on a single mast. Such a vessel was primarily a cargo carrier but could be converted into a temporary man-of-war by the addition of a fighting top at the masthead and a wooden superstructure at either end. These additions, being castellated to shelter the archers and crossbowmen, were called castles. The forward platform was thus called—and is still called—the forecastle. The ship was steered from the starboard (or steerboard) side of the aft castle, and it was near the helmsman that the military leader placed himself, making this the captain's part of the ship for centuries to come. During the 13th century the rowing galley and the broad-beamed sailing ship existed side by side, but rowing vessels. scarce in 1327, had disappeared altogether from Edward III's fleet of 1340–50. This Plantagenet sailing fleet had a measure of success but suffered neglect under Richard II (1377–99) and was not re-established in the channel until the time of Henry V (1413–22). He needed control of the channel in order to safeguard his communications while invading France. Such was his military success that his foothold in France seemed permanent, rendering his fleet (which included some large ships) almost needless. But Henry V's continental conquests and aspirations came to nothing under his successor, and the channel became once more the frontier, though with Calais still in English hands. Subsequent development of the sailing warships was steady despite the Wars of the Roses, and Edward IV's ships had three or even four masts instead of the single mast which had previously sufficed. These masts probably developed from flagpoles, the sails multiplying in proportion, and the steering oar gave place to the rudder. Guns were mounted on board English ships as early as 1410 but involved no revolutionary change in design. The established practice was to discharge arrows, bolts and stones and then close with the enemy and finish the action hand to hand. The small guns used in the 15th century merely added variety to the approach phase of the conflict; they did not alter the nature of the conflict itself, and whether the missiles were arrows or gunstones, the ship with the higher castle had an advantage. It was the tendency for these castles to rise to an impressive height, little suited for oceanic voyaging.

The **Tudor** Navy.—English seamen were used to bad visibility and did not expect, as did the Greeks, to be normally in sight of land. They did expect, however, to be within soundings, and it was only with reluctance that they went far outside the belt of shallow water which fringes the coasts of France and Spain. In the great age of Columbus and Magellan, therefore, the oceanic navigators did not come from England but from Genoa, Venice and Portugal. News of the Spanish discoveries led Henry VII (1485–1509) to employ the Genoese Cabots in exploring the North Atlantic, but the results were not obviously remunerative and the first Tudor king spent rather more effort in protecting his own coasts and his own disputed throne. His larger ships, the "Regent" and "Sovereign," were based on his new base at Portsmouth and were not intended for operations outside the channel. The Bristol seamen who had learned how to reach Newfoundland sailed in ships of about 100 tons and would have regarded any larger vessel as extremely dangerous, as on an unknown coast she certainly would have been.

The basis of Henry VII's maritime policy lay in the fact that he had abandoned the Lancastrian policy of invading France and substituted for it a policy of unifying the British Isles themselves. The limit to his marifime enterprise lay in the fact that the two long-distance trades—the trade to the Baltic and the trade to the Mediterranean—were in foreign hands. With the Hanseatic league and the Venetians the English merchants and seamen were in no position to compete. For a permanently strong navy the first necessity was a merchant service, providing funds, recruits and political support. No such merchant service existed and Henry VII limited his effort to what he could afford. His son, Henry VIII, observed no such moderation. His policy was essentially continental and his ships, designed for war with France, were not of an oceanic type. But his despoliation of monastic property gave him ample funds with which to secure the Reformation in England against foreign interference and he used a part of his wealth for that purpose. The result was a fleet, at one time of 85 vessels, with the "Great Harry" as flagship. This force served its immediate purpose but was excessive for the normal revenue of the crown and out of proportion to any trade it could protect. The interest, in fact, of Henry VIII's fleet lies in its organization rather than in its achievement. The mediaeval office of admiral was more legal than military. Various county officials had admiralty jurisdiction over certain stretches of coast line, and the lord high admiral combined a general supervision with legal rights over coasts not otherwise allocated. Only the highest of the nobility could aspire to this office and Henry VIII transferred the strictly naval duties to a deputy, the lieutenant of the admiralty, who was assisted by the treasurer of the navy, the comptroller of the ships, surveyor of the ships, clerk of the ships and general surveyor of victuals for the seas.

In each ship, when manned for war, the crew fell broadly into three divisions, the soldiers, the mariners and the gunners. The first group comprised the captain, the lieutenant, gentlemen, servants and soldiers; the second group comprised the master, pilot, boatswain, carpenter, sailmaker, cook and seamen; the third group comprised the gunner, his mate and assistants. The importance of the gunner increased in this period with the growth in the size of cannon. Larger guns were now being mounted below decks and made to fire through ports cut in the ship's side, an invention with far-reaching consequences but one which it is difficult to attribute to any one country, dockyard or shipwright.

In the later years of Henry VIII and during the reign of Edward VI, there was a tendency to regard Spain as a possible enemy, and this was perhaps reflected in the growth of the dockyards at Woolwich and Deptford and the creation (c. 1550) of the Chatham dockyard with Sheerness fort to protect it. These all faced the Spanish Netherlands just as Portsmouth faced France. The chief arsenal was at Calais, which was lost during the reign of Mary I (1553–58) at a time when England was nearly brought by marriage into the Spanish orbit. The main arsenal was then established at the Tower of London, where it was for long destined to remain. Elizabeth I's reign brought in an anti-Spanish reaction which encouraged private adventurers to raid the Spanish empire overseas. These activities centred on the Atlantic port of Plymouth and were initially bound up with the fortunes and enterprise of the Hawkins family. A feature of one privately organized expedition in 1564–65 was the loan of a queen's ship, the "Jesus of Lubeck" of 700 tons, contrasting in size with the privateers of 30 to 120 tons which accompanied her. One immediate result of this experience coupled with further experience with the "Minion" was evidently a firm refusal to brave the Atlantic again in a ship of that "high-charged" class. John Hawkins' return from a disastrous voyage in 1567–69 coincided with a worsening of relations between England and Spain and led the queen to accept his advice in the matter of ship design. The result was the construction of the 300-ton "Foresight" of 1570, followed by the "Swiftsure" and "Dreadnought" of 1j73 and the "Revenge" (450 tons) of 1575–77. These were ships of the new "Galleon" class, combining the lines of the galley with the strength of a ship, the fire power of the warship with the seaworthiness of the ocean-going privateer. These ships, to be based upon Chatham or Portsmouth, were designed in the light of experience gained at Plymouth. The "Revenge" was thought the perfect galleon and further ships were modelled on her, some older ships being rebuilt on the same lines. The process was intensified when John Hawkins became treasurer of the navy in 1577. With Lord Burleigh's support, he strengthened the defenses of Chatham, reorganized the system of refitting and ensured that the royal ships should be in good order when needed.

Open war between England and Spain broke out in 1585 and Philip II's admiral, the marquis of Santa Cruz, drew up a plan in 1586 for the invasion of England. It involved an expedition from Spain with 60,000 soldiers and 77,000 tons of shipping—a tonnage not in fact available even with ships hired from the Hansa and from Italy. Because of this shortage and Francis Drake's attack on Cádiz in 1587, the Spanish expedition was not ready until 1j88 and even then in a modified form. Instead of transporting an army from Spain, the fleet mas to embark the duke of Parma's army, already in the Netherlands, and land it in the vicinity of Margate. This was a more complicated program than that originally planned, and the whole conception was indeed fundamentally unsound. The two sides were roughly equal in strength and for the one fleet to attempt a landing while the other was undefeated was against all reason. It was not, however, at that time against all experience, for the principles of combined operations had still to be discovered and enunciated. Santa Cruz had died and the duke of Medina Sidonia, commander of the expedition, was hampered by strict orders enjoining him to concentrate on his ferrying task and not so much to overcome naval opposition as to ignore it. But for these orders Medina Sidonia might have surprised the English fleet at Plymouth, where it had been concentrated. Missing his chance on July 19, he was engaged in the channel by Lord Howard of Effingham on July 21 and again on July 25–26. The novelty of the action lay in a tactical device probably attributable to Sir Francis Drake. Whereas the practice in all previous naval engagements had been for the opposing sides to discharge all their guns and small arms and then close with the sword, Elizabeth's fleet never closed at all. The idea was to fight the whole battle at cannon range, making use of English skill in gunnery and preventing the Spanish from deriving any advantage from their superiority as soldiers. While these tactics clearly disconcerted the Spaniards, they produced no very tangible results. It would appear, in fact, that the guns were mostly ineffective at the range chosen. What was more serious, the scale of ammunition carried bore no relationship to this new idea of an artillery duel. There was not enough powder available or even perhaps in existence. The result was an indecisive battle in which the Spanish exhausted most of their ammunition without perhaps being aware of the shortage that troubled their opponents. The successful fireship attack on July 28, which dislodged the Spaniards from their anchorage at Calais, was the more effective in that Medina Sidonia probably thought the fireships explosive; as indeed they would have been had there been the powder to spare. As it was, they broke up the Spanish fleet, which was defeated in the battle of Gravelines on July 29 before any formation had been regained. This reverse compelled Medina Sidonia to lead his fleet round Scotland and so back to Spain without attempting to invade England and without having had the chance to refit, water and reprovision his fleet. As a voyage from Spain to England and back was utterly beyond the storage capacity of his ships, half of them foundered or were wrecked, and of his men only about a third survived the disaster.

The limitations of the Elizabethan navy were soon apparent in the years after 1588. A counteroffensive against Spain failed in 1589. An attempt to blockade the Azores in 1590–91 led merely to the loss of the famous "Revenge," and a new expedition to the West Indies in 1595 led merely to the deaths of both Hawkins and Drake. The Spanish fleet was rebuilt and sent against England again in 1597, only to be scattered by a gale, and Philip II died (while planning another expedition) in the following year. Spanish troops actually reached Ireland and were not evicted until 1601, two years before the death of Elizabeth and the end. shortly afterward, of the war. From all these operations the fact emerged that England lacked the overseas trade upon which its sea power might rest. Only commerce could have sustained a prolonged naval offensive and, lacking enough commerce, efforts at sea dwindled for lack of money, lack of seamen, lack of gunpowder and lack of political support. It was under the Stuarts and during a period of naval decline, from 1603 to 1650, that British trade and colonization grew to the point at which a strong government could maintain a large fleet without incurring financial ruin. But sea power had passed meanwhile to the Dutch, and it was Charles I's attempt to re-establish the royal navy by means of ship money (*q.v.*) that caused, or partly caused, the Great Rebellion. It was the development of shipbuilding and gunnery in his time which made men-of-war (now more fully differentiated from merchantmen) more costly to build and equip. The "Sovereign of the Seas" (of 1637), the first ship to carry heavy guns on three decks, symbolized at once the king's ambitions and a heavy expenditure which lie could not afford.

The Commonwealth Navy.—The effect of the Great Rebellion was to establish, by 1649, a strong government which soon turned into a dictatorship under Oliver Cromwell. Rivalry with the Dutch over trade and fisheries—a rivalry, essentially, for maritime supremacy in a field from which Spain had largely retired and in which French competition had still to arise—was now more possible. Cromwell could impose a scale of taxation (initially on defeated opponents) which Charles I would never have dared to contemplate. The result was a vast building program beginning in 1649 and reaching its peak in 1654. The Cromwellian fleet inherited from Charles I its aspirations and its ship design and from Elizabeth its tradition of gunnery. It evolved for itself, however, its discipline, administration, organization, officering and tactics. The policy was to apply to the navy the reforms which had been applied with such success to the New Model army (see *Defense: Army* above; *see* also CROMWELL, OLIVER). The ships were divided into six rates, each rate with its own establishment and scale of pay. Regulations were made governing prize money, pensions for widows and treatment or compensation for the sick and wounded. By 1656–57 £809,000 out of a total revenue of £1,050,000 was being spent on the navy. Initially the Commonwealth fleet included a number of merchantmen, bought in 1650–51, but these were mostly sold in 1652. Apart from that, the most significant development was the gradual withdrawal of merchantmen from the battle line. They made almost their last appearance at the battle of Scheveningen in 1653, and even before then the fighting had mostly fallen to the two-decked men-of-war of the third rate (of from 44–52 guns). With merchantmen thus eliminated, discipline became easier to enforce on military lines. Remembering, moreover, that it was by strictly maintaining formation that the Cromwellian cavalry had won its battles, the generals at sea (Robert Blake, Richard Deane, George Monk and William Penn) trained the fleet to fight in divisions, each in line ahead. This tactical method produced good results in the battle of the North Foreland in June 1653 and again at Scheveningen, and led to the advantageous peace which ended the first Dutch War in 1654.

The Navy of the Restoration. — The royal navy's continuous history dates from the Restoration of Charles II in 1660 and his establishment of the admiralty office under his brother, the duke of York, as lord high admiral. The outbreak, moreover, of the second Dutch War in 1665 found the fleet organized regularly into three squadrons (the red, the white and the blue), each under an admiral, vice-admiral and rear admiral. The English and Dutch were still very evenly matched, and Charles II drew sufficient revenue from the customs to pay for the upkeep of a regular navy in time of peace. He lacked, however, Cromwell's dictatorial powers in time of war and faced a more complex situation in which the new French fleet, organized by J. B. Colbert between 1660 and 1670, played a distracting role. The Dutch were defeated off Lowestoft by the duke of York, but in 1666 Monk was outnumbered in the Four Days' battle, while Prince Rupert was watching for the French fleet, and suffered a reverse. Recovery was rapid, however, and the Dutch were soon afterward defeated in their turn off the North Foreland. It was at this point that Charles, lacking funds to continue the war, laid up his main fleet in the Medway and began negotiations for peace. The Dutch under Adm. Michael de Ruyter seized their chance and attacked the Thames and Medway, with all the effects of a naval victory. The Peace of Breda was signed in 1667, marking a stage in an indecisive war which broke out again in 1672. This time the French fleet was, through Charles II's diplomacy, on the English side. But the third Dutch War, notable for hard fighting by the duke of York and the earl of Sandwich, was still more notable for the tactical brilliance of De Ruyter, who, outnumbered as he was, avoided defeat and exploited every failure in co-operation between English and French. Although ruined by a process of attrition, the Dutch were still undefeated when Charles II made a separate peace in 1674, leaving the French to continue the war until 1678, defeating the Dutch finally in the battle of Palermo. From the administrative point of view, the Restoration navy was notable for the work of Samuel Pepys (clerk of the acts from 1660, secretary of the admiralty 1673–79 and 1684–88), who established the admiralty as an organization. From this period dates the *Articles of War* of 1661 (governing discipline and courts-martial), the *General Instructions* (of 1663) and the fixing of war and peace establishments in 1677. He was largely responsible for the great building program of 1678–79 and also for the growing tendency to make experience, rather than influence, a claim to promotion. There existed by 1688 a professional body of officers whose service had begun as midshipmen and whose commissions had been granted only after examination. Although most of those who reached flag rank were gentlemen by birth, they had been bred as seamen and are recognizable as naval officers in the modern sense. When the revolution of 1688 brought William of Orange to the throne it was evident that these officers were more loyal to their class than to their king. Adm. Arthur Herbert and Adm. Edward Russell (later earl of Orford) joined the Dutch fleet which brought William to England, and Lord Dartmouth did little to oppose them — perhaps because his officers had been won over by George Byng. The fleet submitted to William III and Herbert (later earl of Torrington) took command of it.

War of the Spanish Succession. — Louis XIV had, in effect, allowed William to sail, thinking to see England plunged into civil war. The suddenness of James II's collapse took him by surprise and he tried to retrieve the situation by recognizing James and launching against William the French navy, at the height of its efficiency (due to Colbert) and fresh from its successes against the Dutch and Spanish. Disaster was barely averted in 1689 and 1690, but Louis failed to use his advantage and, allowing his Toulon fleet to return to the Mediterranean, left the count of Tourville to be defeated by superior forces at Barfleur and La Hogue in 1692. There was no further battle of note and the war ended in 1697. By then it was manifest that Dutch sea power was almost at an end and that maritime Supremacy lay either with England or France. And France was a more formidable opponent, in size and position, than the Netherlands had been. Despite its potential strength, however, the French fleet had been neglected since 1692, so that the outbreak of war in 1701 found Louis in no position to contest British supremacy in the channel. Instead the naval war shifted to the Mediterranean, where the French and Spanish fleets were in alliance. Adm. Sir George Rooke defeated a vastly inferior allied squadron at Vigo in 1702 and acquired in the following year the use of Lisbon as a base for future operations. Making use of this, he captured Gibraltar in 1704 and defeated the allies at the battle of Málaga. The French Toulon fleet was mostly destroyed in 1707 as a result of a combined operation, and this success led in turn to the capture of Minorca in 1708, which fairly interposed British sea power between the two main French bases at Brest and Toulon. This dominating position was still held after the war ended in 1715 and enabled Sir George Byng to destroy a Spanish fleet afterward in 1718. The peace from then until 1739 was a period of vast trade expansion under Robert Walpole's rule. It provided the economic strength for future naval efforts. But the navy itself was neglected, no ships being built after 1722 and peacetime establishments being reduced to a minimum. The older part of the present admiralty building dates from 1723–25, but there is little else to record of this period unless it be the decision taken in 1718 that future promotion to flag rank should be on seniority alone, and the appearance in 1731 of *King's Regulations and Admiralty Instructions.* Both these measures tended, perhaps, to produce an undue rigidity of ideas.

War of the Austrian Succession. — When war with Spain began in 1739, as the result of trading disputes and complaints from British merchant seamen, the earlier operations were relatively unimportant but sufficed to show the extent of British naval decline, especially in the Mediterranean. ,Apart from a voyage of circumnavigation by Commodore George Anson in the "Centurion" (174—44), the war entered its first significant phase in 1744 when France joined Spain and tried to unite its two main fleets at Brest. The Toulon fleet made, with the attached Spanish squadron, 28 sail, and it put to sea with the object of reaching the Atlantic. It was engaged by Adm. Thomas Mathews with a fleet of equal strength, the indecisive action which followed leading to Mathews' court-martial but not to any very useful result. It was not until 1747 that England could provide separate fleets for the channel and for the Mediterranean, and the French had by then ceased to attempt more than small-scale operations. They allowed themselves to be destroyed in detail by Anson and Edward Hawke, scoring their only success when Count Bertrand Mahé de la Bourdonnais took Madras. This war was notable for Lord Anson's work at the admiralty which began in 1744 and continued afterward until 1756 and again from 1757 to 1762. With periods at sea in 1746–47 and again in 1761, Lord Anson did great work in administration and in creating naval tradition. He tightened up discipline, resisted political influence and attempted to reform the dockyards. It was during his period of office that the frigate was introduced, copper sheathing invented (1761), the chronometer made (1761) and uniform clothing, for officers only, made compulsory by an order issued in 1748. More important still were the experiments in gunnery carried out by Benjamin Robins from 1743 to 1750, which eventually led to the invention of the carronade, the priming tube and the gun lock. It was Anson again who originated the system of close blockade. By contrast, he was no tactical innovator and Britain entered the next war with no advantage either in fleet movements or signals.

The Seven Years' War.--France began war in 1756 by a simultaneous threat against England and Minorca, and the invasion scare sufficed to ensure that the reinforcement of Minorca came too late. Vice-Adm. John Byng arrived with a small fleet and fought an indecisive action against a French fleet of equal strength. For failing to save Minorca—for failing, at least, to do all that was in his power to do—Byng was sentenced to death by court-martial and shot. With Minorca lost, Adm. Edward Boscawen had no base other than Gibraltar. He was able, however, to destroy a part of the Toulon fleet at Lagos in 1759. Hawke in the same year destroyed most of the Brest fleet at Quiberon bay. Thenceforward the French fleet counted for little and Great Britain was able to make a clean sweep of the French colonies in Canada, India, West Africa and the West Indies. Spain came into the war in 1762 and suffered for it in the sack of Manila and Havana with heavy naval losses. When the war ended in 1763 the British fleet was practically unopposed. The subsequent years of peace until 1775 saw the consolidation of the British position in India and the development, from 1770, of the trade with China. An empire had been built up on the basis of sea power and was now to contribute largely toward increasing the sea power to which its existence had been due.

The American Revolution.—By 1775, when war began between Great Britain and its American colonies, the royal navy was weakened by neglect and especially by the reduction of the estimates in 1767–69. It was weakened even more seriously by the revival of party politics after the accession of George III, and, once war began, it was weakened most of all by the loss of America itself as a source of manpower, ships, mast timber and naval stores. Britain had turned to North America as its principal source of mast timber in 1652 and was now dependent on New Hampshire for a supply which ended abruptly in 1775. It also appeared that many ships had been hurriedly built of unseasoned timber during the crisis of the previous war. As a result, no fewer than 66 ships foundered during the war, one, the "Royal George," sinking at her moorings. The results of this false economy might not have been serious in themselves but news of the British reverse at Saratoga brought France into the war on the American side in 1779. More than that, the French had rebuilt their navy from 1759 and, during the years 1763–70 (when the duc de Choiseul was in power), had reorganized and retrained their sailors, developing in the process a new system of tactics and signals, the invention of the vicomte de Morogues. To make matters still more serious, the French were presently joined as allies by the Spanish and Dutch. Against this alliance the royal navy was inferior in strength, unable to spare ships for the Mediterranean and slow even to reinforce the squadron in North American waters. Aware of the British shortage of mast timber, the French fired at their opponents' rigging, gaining several tactical successes. The worst period came in 1779 when Sir Charles Hardy with 35 ships was confronted in the channel by an allied fleet of 65. America was lost in 1781 through failure in sea power, and the West Indies were saved at the 11th hour by George (later Lord) Rodney's victory at the battle of the Saints in 1782. India and Gibraltar were both held, though with difficulty, and were still in British hands when peace was made at Versailles in 1783.

The Wars of 1793–1815.—The French Revolution destroyed the discipline and tactical advantage of the French navy and left it almost leaderless in 1793 to face a British navy trained in adversity and yet encouraged by the example of Rodney and Sir Samuel Hood. The French were everywhere defeated by 1796, but then found allies in Spain and Holland, causing the British Mediterranean fleet to be withdrawn. This and the feint against Ireland in 1796 left the French free to invade Egypt. Worse still, the British sailors mutinied in 1797, successfully demanding improvements in pay and allowances. The French failed to seize their advantage, however, and the Spanish and Dutch were severally defeated at Cape St. Vincent and Camperdown. This restoration of the British margin of superiority allowed the royal navy to re-enter the Mediterranean and end the threat to India by destroying the French fleet at the battle of the Nile (1798). Horatio Nelson, the commander in that action, was a tactical innovator and the officer who introduced into sea warfare the ruthless and total destruction which Napoleon had introduced on land. When peace was made in 1802 the French attempts to invade England, Ireland and India (via Egypt) had all failed and a last possible allied fleet—that of Denmark—had been neutralized at Copenhagen in the previous year. The French fleet was still in existence but too closely blockaded to gain experience at sea. As against that, British efforts against France had been ineffective and those against French colonies in the West Indies had been costly in lives.

War was renewed in 1803. Napoleon, having again found an ally in Spain, hoped to combine the French and Spanish fleets and use them to cover an invasion of the British Isles. The complex plan by which he hoped to lure the British fleet away from the channel proved impracticable, and the allied fleet ended not off Boulogne but in Cádiz. Giving up the invasion plan, Napoleon ordered his admiral to sail for Sicily. He did so and was brought to action off Cape Trafalgar in 1805, the allied fleets being defeated at the cost of Nelson's life. But while it is true that the French fleet never risked a general action again in the course of the war, it would be wrong to assume that the French thenceforward had no fleet. They soon had a fleet of some size and it became an object of British strategy to prevent any other fleet's falling into their hands. This policy led to the British capture of the Danish fleet in 1807, the removal of the Portuguese fleet to Brazil and the destruction of the Dutch squadron in Java. The same policy led to the Walcheren expedition in 1809, which failed to destroy the Dutch fleet, and the attempt by Thomas Cochrane at the Basque Roads. Efforts to annihilate every actual or potential enemy fleet were only partially successful, and French shipbuilding was on such a scale as to provide Napoleon with more than 60 sail of the line in European waters even after every effort had been made to reduce that number. But the morale of the blockaded squadrons had gone. By their existence they put a continued strain on British naval resources, but they lacked the experience and confidence needed to give battle even to inferior numbers. The British, by contrast, were by now overconfident, as events were soon to show.

By 1809 it was clear that sea power alone could do no more against Napoleon save through the slow pressure of blockade. By 1810, however, this pressure was beginning to yield results, especially in its effect on Russia. Simultaneously the British army was operating in Spain, and it is the measure of French naval impotence that it could there operate in safety. But the pressure which was felt by Napoleon's allies was also felt by the United States, which finally declared war on Britain in 1812. The operations which followed were unimportant in themselves and even trivial when compared with the simultaneous events in Russia and Europe, but they revealed a fact which had already been demonstrated on a small scale at Mauritius in 1810: that British naval efficiency had declined for lack of a worthy opponent. Nothing in this could affect the result of the war after 1812, which ended in French collapse and peace made triumphantly in 1815. Peace ushered in an era during which the British merchant service found itself with a tremendous initial advantage, with competing merchantmen largely swept from the seas and the trade routes opened, protected and surveyed by the royal navy. Actions such as those at Algiers in 1816 and at Navarino in 1827 showed that British sea power was being, and would be, upheld.

Beginning of the Age of Steam.—The inventions which ended the epoch of the sailing ship had mostly been made before or during the Napoleonic era, but the nature of the war had not called for much mechanical ingenuity and it was left to the next generation to see the transformation begin. The earliest steam vessels to have a revolutionary effect were the tug and the dredger but it was merely a question of time before sailing warships had auxiliary engines. In fact the finest wooden men-of-war (as regards design and material) were built with screw propellers after 1845. The navy of the period 1825–50 did not escape the reforming spirit of the age, the admiralty office being reorganized so as to absorb the navy board in 1832. Still more important was the introduction of the long-service system, creating a body of petty officers and seamen as permanently employed as were the officers of commissioned rank. The training of cadets was also regularized under various reforms culminating in the establishment of H.M.S. "Britannia" at Dartmouth in 1863. In the meanwhile, in 1854, the wooden sailing ships with auxiliary engines had taken part in the Crimean War and gained their first experience of the shell gun, with armour introduced as its antidote. The result of this was the building of the revolutionary "Warrior" of 1860, quickly followed by other ships of the same class. Retention of masts and yards was at first a problem for designers, who had also to plan machinery to work the far heavier guns which had now to be mounted. The broadside arrangement gave place to a central battery type, with a few heavy guns mounted in an armoured citadel in the centre of the ship. This method was in turn superseded by the revolving turret containing one or two heavy guns. The first seagoing turret ships in the British fleet were the "Monarch" and "Captain," carrying four 12-in. guns in pairs in turrets amidships. Both ships were fully rigged and had a large spread of canvas. In 1870 the "Captain," while under sail in the Bay of Biscay, capsized and foundered with the loss of nearly all hands, and this disaster brought about the final abolition of masts and yards. In the next decade a number of different types of ship were evolved in the search for the standard modern battleship, and by 1880 the British battle fleet was a collection of samples, no more than two ships being alike. It became recognized that the strength of a modern fleet depended to a great extent upon the similarity of the units composing it and hence the policy of building battleships and cruisers in classes was instituted. In 1880 the ships of the "Admiral" class, the first group of battleships built as a class, were laid down. With their heavy guns mounted in pairs at each end and a broadside battery of smaller guns, these ships were the prototypes of the battleships of the world for the next 25 years.

Growth of the Modern Navy.—The Naval Defence act of 1889 closed the transition period and laid down a settled building policy for the modern navy. The "Royal Sovereign" class, with the "Hawke" and "Intrepid" classes of cruisers, were the first outcome of the act, and the battle fleet was gradually built up by the "Majestic," "London," "Duncan" and "King Edward VII" classes, which, with their contemporary cruisers, joined the fleet in successive groups, each more powerful than its predecessor. The invention of the watertube boiler, followed by the turbine, and the use of oil fuel revolutionized engineering practice and greatly increased the speed and endurance of all classes of ships. The first destroyer, the "Havock," was built in 1893 and was followed by a host of others of ever-increasing size and speed. Large armoured cruisers came into being, ships of high speed, moderate protection and heavy armament, and 1901 saw the building of the first British submarine. In this department of naval warfare England had been outstripped by France, which had ordered its first submarine as early as 1886. This boat, the "Gymnote," was launched in 1888. Naval science made rapid strides in the closing years of the 19th century, especially in naval gunnery and in the use of the torpedo. Early in the 20th century the German menace, then "a cloud no bigger than a man's hand," was met by the gradual concentration of Great Britain's naval strength in home waters and by increased activity in training and practice.

The "Dreadnought" Era.—In 1906 the whole forces of naval science were embodied in the design of one ship, the "Dreadnought." Built with rapidity and secrecy, she sailed on her trials exactly a year after her first keel plate was laid. A battleship of 18,000 tons and 21 knots, she mounted ten 12-in. guns in five double turrets. In offensive power, protection and speed she eclipsed any fighting ship that had ever been built and she marked a new epoch in warship construction. The "Dreadnought" was followed by nine other ships with the same armament, and in 1910 a new and powerful 13.5-in, gun passed successfully through its trials. With this gun the "Orion," "King George V" and "Iron Duke" classes were armed, and 12 of these ships were in commission by 1914. Meanwhile the armoured cruiser had developed into a new type of capital ship, the battle cruiser, ships with the armament of a battleship, in which protection was sacrificed to speed. Cruiser duties with the fleet devolved upon yet another new type, the light cruiser, which appeared in 1913. These little ships of 3,000 to 4,000 tons were unprotected but had great speed and were armed with six-inch guns. By the middle of 1914 the British fleet was at the highest state of power and efficiency that it had ever attained in its long history. The ships were all that the scientific knowledge of the time could make them, the administration was sound and highly efficient, the dockyards were in first-class order and nothing was lacking to equip the fleet. More important still, the long-service personnel, officers and men, were incomparable and had been trained in the belief that a great war was coming in their time. The high command at sea was in the hands of a band of seamen who, when the test came, proved their worth. Under them, in 1914, the royal navy calmly faced the uncertainties of the titanic struggle before it; for its performance therein reference must be made elsewhere (see WORLD WAR I: Naval).

The Navy After World War I.—At the Armistice in Nov. 1918, more than 1,350 vessels were flying the white ensign, this number including 42 battleships and battle cruisers, with cruisers, destroyers, submarines and gunboats numbering 786 in all. By 1920 the ships in commission had been reduced to 332 and the numbers of officers and men reduced from 407,000 to 176,000. A reduction of this sort was normal at the conclusion of a war, but on this occasion all previous maxims of naval policy were reversed in the name of economy. The superiority in naval strength upon which governments had previously agreed was now abandoned in order to maintain cheaply an equality with the growing navy of the United States. By the same agreement, reached at the Washington conference of 1921–22, Japan, France and Italy were each restricted to a lower scale of naval strength, while Germany was prevented from having more than a skeleton fleet, lacking submarines and aircraft. This agreement marked the end of British naval predominance. More than that, it left the royal navy inferior in strength to an alliance, say, of Italy and Japan. The alliance with Japan was dropped in 1922 as inconsistent with the unwritten alliance now assumed with the United States. By 1931 Japan was counted as a potential enemy and in 1934 the Japanese declared themselves no longer bound by the Washington treaty. In the following year the Anglo-German treaty revived the German navy and completed the process by which the royal navy was rendered hardly superior to the combined navies of Germany and Japan. Britain was thenceforward unable to maintain an eastern as well as a home fleet. If the royal navy were to be engaged in home waters (against, for example, Germany and Italy), India, Australia and New Zealand would be defenseless against Japan. Without the eastern fleet advocated by Earl Jellicoe in 1919, the Singapore naval base, begun shortly after that date, was a provocation to Japan without providing any protection for the countries which Japan might menace.

The. royal naval air service of 1914–18 had subsequently been merged in the royal air force, but the difficulties inherent in a joint control of carrier-based aircraft led to the creation in 1937 of the fleet air arm under admiralty control. Shore-based aircraft operating over the seas remained under the control, however, of coastal command, R.A.F. A short-service branch was created in 1938 to build up a reserve of officer pilots, and naval ratings were allowed to volunteer for service as observer's mate and gunner. The construction of aircraft carriers was pushed forward on a scale which provided seven in existence and five being built when war broke out in 1939. Much was done to develop the fleet air arm, but few senior officers realized to what extent naval warfare was soon to be revolutionized. The question of whether a battleship could be sunk by aircraft was being hotly argued up to the date on which the first capital ships were in fact so lost. At the London Naval conference in 1930 and the further conference held in London 1935–36 it was still being assumed that naval strength was to be measured only in terms of battleships and cruisers. The same assumption underlay the naval limitation treaties with Germany and the U.S.S.R. in 1937.

Table I.—Comparative Naval Strengths at Outset of World Wars I and II

The Eve of World War II.—Britain was nearly at war with Italy in 1935 over the Ethiopian crisis and the home fleet was dispatched to the Mediterranean. British warships took part in the attempts made in 1937 to prevent the shipment of war materials to either side in the Spanish civil war. Then, at the launching of the German battleship "Bismarck" in 1939, Adolf Hitler declared his intention to build up his submarine fleet to parity with Great Britain. He followed this by announcing his refusal to observe the naval limitation treaty of 1937. By the outbreak of World War II, however, Germany possessed only five capital ships with two under construction, its chief strength consisting of 56 submarines, in which type of warfare it had almost reached the parity with Britain at which Hitler professedly aimed. Had Hitler not been planning a battle fleet, his submarine fleet might have been very much larger. Italy, by comparison, had 105 submarines, but these, like other Italian naval units, were of doubtful quality. The strength of the Japanese navy in 1939–42 was only partly known, and its fighting qualities were difficult to estimate.

World War 11.—When Great Britain declared war on Germany on Sept. 3, 1939, the naval situation was favourable in so far as the Germans were the only opponents. As the German Adm. Karl Donitz confessed in 1945, "Germany was never prepared for a naval war against England. . ." For such a conflict Germany lacked sufficient surface vessels and did not expect submarine warfare. For commerce raiding, it lacked overseas bases, and for warfare in European waters the German navy had no air arm of its own; nor had the *Luftwaffe* been trained for operating against warships. The only area in which the German navy could operate was the Baltic and Scandinavian waters, hedged by various neutralities and well within range of air bases which Germany had or could readily seize.

The royal navy had made preparations for war which included the training of merchant service officers from 1937 and of seamen as well from 1938. On mobilization, 46,000 reservists were called up and large numbers of volunteers (and later, conscripts) accepted for training. Officers were at first taken from the reserves, but in 1940 there was introduced a system of drawing all temporary officers from the lower deck. The women's royal naval service was re-established on lines similar to those of World War I but with wider duties., Women replaced men in small craft and harbour boats and did valuable work as armourers. radio operators. clerks and drivers and as experts in such technical subjects as ciphers, meteorology and aircraft recognition. There was vast expansion of the fleet air arm from its initial strength of 340 first-line sea-borne aircraft, and the far larger numbers of land-based aircraft in coastal command came (in 1940) under the operational control of the admiralty while still part of the R.A.F. for all purposes of administration, training and maintenance.

With surface forces so unequal. operations were at first confined to a strict blockade of the German coast, to which Germany replied by unrestricted (but not at this period very extensive) submarine warfare. One British battleship, the "Royal Oak," was torpedoed and sunk, and several German warships, including the battleship "Deutschland" and the pocket battleship "Admiral Graf Spee," operated against British commerce in the Atlantic.

This phase ended for the time being when the "Graf Spee" was brought to action by three British light cruisers in Dec. 1939 and so damaged that she had to seek shelter in the neutral waters of the river Plate. When ordered by the government of Uruguay to leave, the captain of the "Graf Spee" destroyed his own ship and allowed the crew to be interned. During this phase of the war, with the allied French fleet operating in the Mediterranean, with no open threat in the far east and with the royal navy able, therefore, to concentrate its forces mainly in the North sea and Atlantic, the naval position was satisfactory. It began to deteriorate in April 1940 with the German invasion of Denmark and Norway, and deteriorated more sharply with the adverse results of the war on land. By June the British troops in Europe had been evacuated by means of all the available small craft in southern England, and French resistance had virtually ended in collapse. The immediate results included such heavy losses off Dunkirk and Norway as to reduce the number of British destroyers from 178 to about 100. Almost as immediate was the entry of Italy into the war as Germany's ally. Less immediate, but now inevitable, was the establishment of German bases for aircraft and submarines along the entire coast of Europe from Norway to the Spanish frontier.

The fall of France and the Italian declaration of war deprived Britain of the co-operation of the French navy (9 capital ships, 18 cruisers, 70 destroyers and 100 submarines) while confronting it with a new enemy fleet in the Mediterranean (6 capital ships, 19 cruisers, 49 destroyers and 100 submarines). Worse still was the prospect of the French navy, with its overseas bases, falling into German hands. This had to be prevented. The result was the bombardment of Oran, Algeria, which sank or immobilized four French capital ships in July 1940, followed in September by the damage done to a fourth at Dakar, French West Africa. The other French warships did not, in fact, fall into German hands. Nevertheless, the situation in the Mediterranean, where Britain had no effective naval base between Gibraltar and Alexandria (2,000 mi. apart), was extremely grave. In the Atlantic, meanwhile, a grim war to protect British commerce against submarines and air attack began. With Ireland neutral and its ports closed to the navy, and the eastern British ports under constant air bombardment, the main work of commerce protection had to be divided between Liverpool and the Clyde. Britain itself was threatened, moreover, with invasion and was compelled to deploy naval forces to watch the European coasts from Bremerhaven to Le Havre, which further caused an acute shortage of escort vessels. In fact more than 1,000 British merchantmen had been lost by June 1941, and the situation would have been worse but for the bargain in Aug. 1940 by which the royal navy acquired 50 obsolescent destroyers from the United States in return for the lease of bases in the Caribbean. Apart from this, the navy now made extensive use of two new classes of escort vessel, built more cheaply than destroyers and proving almost as effective for this particular purpose. These were corvettes and frigates, the former very small and slow and not designed—although extensively used—for operating outside coastal waters, the latter more nearly approaching the destroyer in size and armament. These and other escort vessels struggled to protect the convoys in a situation which showed no marked improvement until the autumn of 1942. The later successes against submarines were often the result of action by, or co-operation with, aircraft. Throughout, the royal navy received great help from the royal Canadian navy.

In the Mediterranean the war would have been disastrous had the Italian fleet acted with the enterprise which its strength would have justified. But the Italians did little more than blockade and bomb Malta while trying to intercept British convoys sent to its relief. Their capacity for doing more than this was curtailed in Nov. 1940, when half their capital ships were sunk or disabled by the British fleet air arm at Taranto. Early in 1941 the remainder of the Italian fleet was defeated by Sir Andrew Cunningham (later Viscount Cunningham of Hyndhope). This enabled the Mediterranean fleet to take part in the hunt for the German battleship "Bismarck," which had broken out into the Atlantic. She sank the battle cruiser "Hood" by a hit in the magazine, which blew up, but was disabled by aircraft from the carrier "Ark Royal" and finally sunk by the cruiser "Dorsetshire" after her guns had been silenced "by the greatest concentration of gunfire ever poured into a vessel." Two more German capital ships, the "Scharnhorst" and "Gneisenau," were pinned down at Brest in March 1941 and kept there under air attack for more than ten months. Their escape back to Germany through the English channel in Feb. 1942, though disappointing in itself, reflected the German realization that these ships could achieve nothing in the Atlantic. They had served in the meanwhile to occupy a part of the home fleet and distract British attention from what was happening elsewhere. For while the Mediterranean fleet was cutting the communications of the axis forces in Africa and while the Atlantic fleet was guarding Britain and the western approaches and, after June 1941, escorting convoys which were being sent to assist a new ally in the U.S.S.R., a ne danger had appeared in the far east.

The War Against Japan, 1941–42.—The Japanese entered the war by attacking the United States fleet on Dec. 7, 1941. The effect of Japanese intervention would have been far greater had it taken place before the German and Italian fleets had been largely destroyed. As it was, the mere existence of the remaining German battleship, the "Tirpitz," kept most of the latest British capital ships in the Atlantic. As against that it must be recalled that Japan was to some extent forced info the war by the United States' embargo of July 1941 and the high price demanded by the U.S. for an agreement to cease aiding China and to allow oil to reach Japan. Late as it came, the Japanese attack on southeast Asia fell with terrific force on an area in which no British fleet was stationed. Two capital ships, the "Prince of Wales" and "Repulse," were sent out just before the new war began as the nucleus of a far eastern fleet and "in the hope of steadying the Japanese political situation." It was intended to build up a balanced fleet, based on Singapore, with 7 capital ships and 1 aircraft carrier, 10 cruisers and 24 destroyers. But the Japanese did not allow time for this fleet to assemble. On Dec. 10, 1941, Japanese aircraft sank both British ships and so sealed the eventual fate of Singapore itself in Feb. 1942. The Japanese had 12 capital ships, 43 cruisers, about 6 aircraft carriers, 160 destroyers and 140 submarines. No comparable force could be deployed against them and they were not effectively checked until their aircraft were defeated over Colombo in April. The only other immediate measure was the Allied occupation of Madagascar in May. The operations against Japan in 1942–44 were left almost entirely to the U.S. navy. It was not until late in 1944 that a British Pacific fleet under Adm. Sir Bernard Rawlings (4 carriers, 2 battleships, 6 light cruisers and 17 destroyers) joined the flag of Adm. William F. Halsey (U.S.N.) and took part in air attacks on Japan and Formosa in 1945; and by then the Japanese navy had practically ceased to exist.

Combined Operations, 1942–45.—The temptation in 1942 was to divert British naval effort to the new theatre of war that had been opened in the Pacific and so attempt to protect Australia and India. But the Allied governments wisely decided to finish first what had been so well begun, the destruction (in that order) of the armed forces of Italy and Germany. This would necessarily be a military task in the main but possible only through naval co-operation. Apart from the continued struggle to keep open the Atlantic supply lines, the war was now to comprise a series of enormous combined operations. Efforts began, therefore, to create a vast fleet of landing ships and landing craft, varying in size and design to fulfil many specialized purposes. The Atlantic war had sufficiently progressed to allow of the first great landing operation's taking place in Nov. 1942. This was the invasion of North Africa. It led directly to the axis collapse in Tunisia and the subsequent combined operations which brought Anglo-U.S. forces into Sicily and then into Italy. All these landings in 1943 were supported by the royal navy, and it was under naval protection that the troops landed were afterward supplied. These triumphs of organization and close support were the prelude to examples on a still larger scale of a perfected technique, shown successively on the beaches of Normandy and the south of France. The navy played a vital, if not always spectacular, part in the campaign which liberated Europe. German submarines, deprived of the French ports, made their last efforts from Norway in 1945, but their morale was broken before Germany collapsed.

The War Against Japan, 1944–45.—It is important to remember that whereas Britain entered the war with definite superiority in aircraft carriers, a superiority used with effect against both Italy and Germany, it engaged no navy that was similarly armed. The result was that the royal navy, specializing latterly in anti-submarine warfare and in combined operations, took little part in the decisive campaigns by which the Japanese navy was destroyed. In fact, by Aug. 1945 the Japanese navy had been reduced to a mere fragment, with only four damaged aircraft carriers (and only one battleship) still afloat. The decisive battles of the Pacific war were fought almost solely by carrier-borne aircraft, with opposing fleets which seldom came within range of one another's guns. While it is true (as we have seen) that a detachment from the royal navy served latterly with the U.S. navy, it is also true that during the vital six months and in the battles of the Coral sea and of Midway Island the U.S. navy fought alone. (C. N. P.)

After World War 11.—After the end of hostilities in Europe and the far east the royal navy was reduced in size to meet peace-time needs. In the years 1946 and 1947 not only were the majority of the older vessels discarded, but also some of the units constructed during World War II.

Many ships were broken up or converted to mercantile use, while other ships were acquired by the commonwealth and foreign countries to replace obsolete tonnage. The personnel in May 1945 numbered 778,000. By 1947 this was drastically cut to 150,000. To facilitate this reduction, a great many ships at home and abroad were paid off or greatly reduced in complement, temporarily bringing down the effective strength of the home fleet to one cruiser and four destroyers. By 1955 all battleships were in reserve. There was a maximum strength of 133,000 in April 195j, including complements of royal naval air stations, marine commands and women's royal naval service.

The invasion of Korea in June 1950 caused many ships which had been laid up to be brought forward for service, British ships providing support for United Nations air and land forces.

By 1953 emphasis was concentrated on the construction of mine-sweeping and anti-submarine craft, on aircraft carriers and their jet fighters. The concept of a battle group centred on the

modern aircraft carrier with its multipurpose squadron of aircraft was nearing realization by 1956. New cruisers and destroyers would be defended by anti-aircraft guided weapons. The reserve fleet was being reduced to facilitate rapid mobilization, necessitated by the possibility of thermonuclear warfare.

The work of planning a nuclear power plant for the propulsion of warships had started, nuclear power being first employed in submarines.

A fundamental change in the system of permanent cadet entry into the navy was introduced in 1954, after which all cadets of the permanent entry joined in one age group at about 18 to conform with the general trend of educational policy. They were to be trained for about two years at Dartmouth, partly on shore and partly afloat in a small squadron of frigates and mine sweepers.

As a result of the reduction of seagoing appointments for executive officers of the rank of commander and above it became impossible to provide all such officers with sufficient seagoing experience. It was therefore decided to divide them into two lists, the "posts list" and the "general list." Only officers on the "posts list" would be eligible for seagoing command.

Naval estimates steadily increased from £193,000,000 for the year 1950–51 to £401,670,000 for 1956–57.

DEFENSE: AIR FORCE

British military aviation began with the creation of a balloon section of the royal engineers, which first saw service in Africa in 1884 and took an active part in the South African War of 1899–1902, where balloons were used for scouting and the direction of artillery fire. On April 1, 1911, the balloon section was expanded into the air battalion, with one balloon company and one aeroplane company. About the same time, the navy permitted a few officers to learn to fly at their own expense at civilian schools. On May 13, 1912, the royal flying corps came into being, with naval and military wings, and a joint flying training establishment was established on Salisbury plain. Meanwhile, the balloon factory at Farnborough had been redesignated the Royal Aircraft factory and turned its attention to the design of airframes and aero engines, of which the BE (Bleriot Experimental) series was in production in time to take part in the early stages of World War I. Pioneer British aviators also turned to aircraft design though they made use exclusively of French engines.

World War I.—On the outbreak of World War I, the royal flying corps, possessing a total of 179 aeroplanes and 1,244 officers and men, sent an aircraft park and four squadrons to France on Aug. 13, 1914. The latter were, at first, used only for reconnaissance and spotting for artillery, but the progress of the war led rapidly to the specialization of aircraft types for fighting, bombing, reconnaissance and photography, while technical advances increased speeds from 70 to 150 m.p.h. and engine power from 70 to more than 400 h.p. before the end of the war. On the naval side, the original naval wing of the R.F.C. had very soon became a separate organization under the title royal naval air service, with its own bomber, fighter and reconnaissance squadrons.

The growth of the air forces and the realization that they had an important role to play independently of the other two services led late in the war to the creation of the royal air force as a separate service, controlled by its own secretary of state and air ministry. On April 1, 1918, the royal naval air service and the royal flying corps were absorbed into the new royal air force, which took its place as the junior partner among the three fighting services. In the last months of the war, a bombing force under the command of Maj. Gen. Hugh Trenchard (later Marshal of the Royal Air Force Viscount Trenchard, first chief of the air staff) carried out strategic bombing of targets in France and Germany independently of the army command.

The strength of the royal air force in Nov. 1918 was nearly 291,000 officers and men. It possessed 200 operational squadrons and nearly 200 training squadrons, with a total of 22,647 aeroplanes. In the course of the war it had suffered nearly 17,000 casualties, of whom more than one-third were killed.

Between World Wars I and II.—As soon as peace came, the royal air force, in company with the navy and army, was drastically reduced, and a peacetime pattern was produced for a service consisting of 33 squadrons, of which 12 were to be stationed at home and 21 overseas. The preponderance of overseas strength as compared with that of the air forces at home resulted partly from the fact that another war in Europe was considered to be unlikely and partly from the system that had been evolved by the air staff of making use of air power as a humane and economical means of maintaining order in undeveloped countries. During the next 15 years, relatively small air forces repeatedly crushed incipient revolts and restored peaceful conditions in Somaliland, Aden and the North-West Frontier Province of India. In Iraq, up to 1932, the R.A.F. assumed sole responsibility for the military control of the country with a force consisting of eight squadrons of aircraft and a few armoured car companies.

To train permanent officers for the general duties or flying branch of the service, a college was opened at Cranwell, Lincolnshire, in 1920 and a staff college at Andover, Hampshire, in 1922 to train staff officers for the home and dominions air forces. The need for specialist mechanics, skilled in the many trades peculiar to aviation, was catered for by the establishment of an apprentices' school at Halton, near Aylesbury, at which boys were received at the age of 15½ for a three years' course.

In order to ensure a constant supply of new pilots a short-service commission scheme was introduced in 1919. Young men were recruited for four years, of which one year was spent in flying training. At the conclusion of their active service, they passed to the reserve of air force officers for a minimum period of four years. The period of regular service was subsequently increased to six years. A medium-service scheme under which officers served for ten years' regular service followed by a period on the reserve was also introduced. In 1925 a new part-time organization called the auxiliary air force was formed; its members undertook flying and other training during week ends and at summer camps. By the outbreak of World War II, this force consisted of a number of fully trained fighter squadrons (together with a large number of balloon units) which did such good service during the war that it was awarded the prefix "royal" in its title at the end of hostilities.

By 1923 the political sky had begun to cloud over, and it was therefore decided to increase British air defenses. A new organization, the Air Defence of Great Britain, was set up in 1925, which was to be built up to a strength of 52 squadrons of bombers and fighters. Delays occurred, however, and in 1933, the year of Adolf Hitler's assumption of power, the R.A.F. possessed only 87 squadrons, regular and part-time, at home and overseas. With a rapidly worsening international outlook, a considerable further increase was undertaken, and from 1936 onward the aircraft industry was rapidly expanded. Among other methods employed, special factories were built at government expense as branch establishments of the existing aircraft construction firms, and motorcar builders turned to the making of aircraft. Meanwhile the R.A.F. volunteer reserve and the civil air guard were created to give flying training at civilian flying schools; university air squadrons in which undergraduates learned to fly and which were a fertile field for regular officers for the R.A.F. had been in existence since shortly after World War I. Balloon barrage squadrons for the protection of cities and other vulnerable points began to be formed in 1936; the observer corps. to give early warning of enemy aircraft attack, had been formed on a voluntary basis as early as 1924; the women's auxiliary air force (the descendant of the women's royal air force of World War I) was created in June 1939 from the (women's) auxiliary territorial service, an army-sponsored body established in 1938 which had recruited special air force companies. (In 1949 the W.A.A.F. resumed its World War I title and became the W.R.A.F.) Finally, though this did not occur until 1941, the air training corps replaced the air defense cadet units and school air cadet corps of the immediate prewar years. The A.T.C. was designed to give suitable boys some preliminary air force training, with a view to eventual entry into the R.A.F. The control of R.A.F. units embarked in naval carriers had long been a matter of controversy between navy and air force, and in 1937 the fleet air arm became an admiralty responsibility, shore-based units for operation over the sea remaining under the air ministry.

World War II.—At the outbreak of war at the beginning of Sept. 1939, the first-line strength of the royal air force in the United Kingdom was about 2,000 aircraft, divided among fighter command, mainly concerned with home defense, though a small proportion of it proceeded to France with the British expeditionary force; bomber command, for offensive action against the enemy; coastal command, consisting of all those shore-based aircraft which worked over the sea in the protection of maritime routes and were placed under the operational direction of the navy in 1940, though remaining under R.A.F. command. There were, in addition, balloon, maintenance, reserve and training commands. The progress of the war involved certain changes in the organization of commands, notably the formation of army co-operation command in 1940 and of ferry command (subsequently expanded into transport command) in 1941. Meanwhile great air forces were built up as required in North Africa, Italy, Burma, France and elsewhere as the tide of war ebbed and flowed in one part or another of the world-wide conflict. By the time the war ended, the strength of the royal air force was 963,000, to which must be added 153,000 women in the W.A.A.F. (For the part played by the R.A.F. in defense of Britain and in service overseas *see* WORLD WAR II: *Air Warfare Over Western Europe, Germany, Mediterranean and Italy.*

In order to provide the large number of air crew required to man the rapidly expanding front-line strength, training schemes in many parts of the British empire were started in the early months of the war. Canada, Australia and New Zealand combined to operate the vast empire air training scheme, under which each dominion agreed to recruit and train pilots, observers and radio operators for service with the R.A.F. Canada also undertook the additional commitment of training personnel sent from the United Kingdom. Similar arrangements were made for the training of R.A.F. air-crew pupils in South Africa and Southern Rhodesia. From June 1941 (before the United States entered the war) to the end of hostilities, British airmen also continued to be trained at a number of service and civilian-operated schools in the United States. Indeed, the United Kingdom forming the main base for air operations against the enemy and being itself under constant threat of air attack, virtually all basic training of air crew had to be carried out abroad. As country after country was overrun by axis forces in the early part of the war, numbers of foreign airmen found their way to Britain, and these were reformed into national air forces under the mantle of the R.A.F. volunteer reserve, which had become the main channel of entry into the service for all officers and men. Such national air forces wore royal air force uniform with a shoulder badge bearing the name of their country. Thus Poles, Czechs, Dutch, Belgians and Norwegians served in homogeneous units side by side with royal air force squadrons. Free French units mere also formed for service under R.A.F. command but retained their own uniform and internal organization.

In the course of the war the technique of introducing troops on special missions behind the enemy's lines, either by parachute or glider, was rapidly developed. The royal air force co-operated with the army in training and transporting parachutists and also in towing gliders, the pilots of which were normally soldiers who had been specially trained as glider pilots. Supplying isolated bodies of troops in jungle and other difficult country and the regular transportation of vast quantities of food, ammunition and even vehicles and guns became regular activities of transport aircraft, which were formed into a separate transport command with detachments as far apart as Canada and Burma.

For the protection of aerodromes against enemy attack a royal air force regiment was formed and trained on commando lines. Armed with anti-aircraft weapons, as well as with the ordinary infantry armament, they were normally under the orders of the commander of the aerodrome, but were so organized that they could fit smoothly into the army command pattern in case of a widespread enemy threat.

Development After World War II.—As a result of the general demobilization in 1945, the strength of the royal air force, including all overseas garrisons. fell to 150,000. The international outlook led, however, to an expansion of the services in 1951 and, with minor fluctuations. it remained thereafter round about 250,000. In 1956 the number of men and women in the service was 257,000, of whom approximately three-quarters were at home.

The wartime organization of the commands was retained, as follows: (home commands) bomber, fighter, coastal, transport, flying training, technical training. maintenance and home commands; (overseas) 2nd tactical air force (Germany), middle east air force and far east air force. In 1956 M E A.F. underwent a major reorganization. consequent upon political developments in that area. With its headquarters in Cyprus, it exercised command over two operational groups, one responsible for the "air control" areas in Africa and the Persian gulf, the other forming the axis of reinforcement in the middle east in case of major war, with air units in Iraq, Jordan, Cyprus and Libya.

The royal auxiliary air force, which had been retained as a fighter force during the period 1945–56, was disbanded in 1957 for reasons of economy. The royal air force regiment continued into peacetime, consisting of rifle and light antiaircraft squadrons. The women's royal air force became a regular arm of the service on Feb. 1, 1949, by virtue of the Army and Air Force (Women's Service) act. 1948. The royal observer corps was also perpetuated as a civilian volunteer force under the operational control of fighter command, with an establishment throughout the country of 28,000 part-time observers and a nucleus of permanent officers. Its strength in 1956 was approximately 20.000.

The air training corps for pre-entry training of boys 14–18 years of age was placed on a peacetime basis, the whole being administered by home command. The corps, organized on a territorial basis, with more than 700 squadrons throughout the country, numbered 36,000 in 1956. Glider training was added to the activities of the A.T.C. and, in 1956, the corps operated 21 gliding schools.

Organization and Training.—*In* the peacetime organization of the service, there are five main branches: genera! duties (flying), technical, secretarial, equipment and R.A F. regiment, with other ancillary branches such as airfield construction, education, marine, medical and chaplains. The normal method of appointment to commissions is through the ranks, but cadets of the R.A.F. college and university graduates are commissioned direct and a certain number of short-service commissions are also available. National servicemen are eligible to present themselves for training as pilots or navigators and are granted national service commissions. They may, if they wish, extend their compulsory service to a total of six years. For other air-crew categories, national servicemen are eligible only if they engage for nine years' regular service. In the ground trades, national servicemen may transfer to a regular engagement of 3 to 12 years.

Selection for air crew is made at the air-crew combined selection centre, Hornchurch. Essex, and preliminary training is carried out at an initial training school, after which the candidate receives his practical air training at a flying school in the United Kingdom or Canada, proceeding thence to an operational conversion unit, before being posted to a squadron. Specialist flying training is given at the central flying school (for instructors) and the R.A.F. flying college.

The needs of the service for long-service, highly skilled mechanics and other noncommissioned tradesmen of various kinds are largely supplied by means of five schools of technical training, of which the oldest-established is Halton, near Aylesbury, Buckinghamshire. There, boys are received between the ages of $15\frac{1}{2}$ and 17, undergo 18 months to 3 years' training and then pass into the service, where they engage to serve for no fewer than 12 years and may continue their service to qualify for a pension.

Equipment. — Though in the air World War II was fought almost entirely with aircraft powered by piston engines, the last year of hostilities witnessed the advent of the newly evolved jet engine. From 1945 onward great progress was made with jets, and the greatly improved speeds and climbing powers of jet aircraft pointed immediately to their value as fighters. Thus it was in this field that re-equipment first took place. By 1956 standard fighter equipment consisted of Meteors and Vampires, Venoms, Sabres and Hunters, and the Gloster Javelin (engined by two Armstrong Siddeley Sapphires) was beginning to come into service as an all-weather fighter. The English Electric twin jet (Rolls-Royce Avons) Canberra had shown itself the most versatile aircraft to be produced since the Mosquito, being in first-line service in medium bomber, photographic reconnaissance, long-range night intruder and high-altitude bomber versions. The bomber force was being built up as a "deterrent," designed to strike quickly at distant targets and to move rapidly from base to base with the assistance of transport command. The so-called "V" bombers were to form the backbone of the force, with Vickers Valiants (four Avons), Avro Vulcans (four Bristol Olympus) and Handley Page Victors (four Sapphires). By the temporary conversion of some of the bombers into tanker aircraft, a considerable portion of the bomber force could be refuelled in flight to give exceedingly long range. Plans had been made to station strategic bomber squadrons overseas in order to give better dispersion against atomic attacks and to bring a greater selection of targets within range.

A number of interesting prototypes were under test during 1956 and level speeds exceeding that of sound were clearly indicated for the next generation of fighters. Much progress had been made in the design of guided missiles and bomber development was predominantly directed toward the carriage of atomic weapons.

NATIONAL FINANCE

Origins of the Modern System.—During the middle ages there was no distinction between the revenue of the government and the personal income of the sovereign. The king was expected to live and govern on the income from the royal demesne, the yield of import duties, which were either hereditary or granted by parliament for his life, and the fees derived from the administration of justice and the exercise of feudal rights. Other taxes, such as the Fifteenth and Tenth, were granted by parliament in emergencies. The rise in prices during the 16th and 17th centuries made the traditional sources of revenue quite inadequate, and this was one of the main causes of the constitutional struggles between the Stuarts and their parliaments.

Out of these struggles arose some of the main features of the modern system of national finance. It was finally established that the crown could not levy taxes without the authority of parliament. In the words of the Bill of Rights (1689), "the levying of money for or to the use of the Crown by pretence of prerogative without grant from Parliament for longer time or in other manner than the same is or shall be granted, is illegal." It was also established by convention that the house of lords could not amend, though it might reject, a money bill.

The revolution of 1688 also marked the beginning of a distinction between the royal income and the revenue of the government. An act of 1698 granted to William III, "for the service of his household, and family and for other necessary expenses and occasions," taxes designed to produce £700,000 a year, with the important proviso that, if the yield proved greater than was expected, no more than the £700,000 should be spent without the authority of parliament. From this there grew the distinction between the civil list and the supply services. The former included salaries and pensions of judges and other high officials, and it was not until the accession of George IV (1820) that these were separated from the purely personal income (or privy purse) of the sovereign. Expenditure on services not covered by the civil list came to be voted annually by parliament, with the important consequence that it became necessary for parliament to meet every year.

Linked with the annual voting of supplies was the practice of "appropriating" expenditure to particular purposes. This was one of the issues raised in the impeachment of the earl of Danby (1665), and after 1688 it became regular practice. Supply votes and appropriation regulate the making of expenditure, not the raising of revenue, and so parliament came to have a double control over the national finances.

Finance During the 18th Century. — The chief sources of revenue during the 18th century were a land tax, a tax on houses and a great variety of customs and excise duties. These revenues were not nearly enough to pay for the costly wars of the period and so there grew up a permanent national debt. The king had often borrowed in the past, but only for limited periods. The origin of the permanent debt is usually dated from the raising of £1,000,000 by the sale of life annuities in 1692. In 1694 a group of London merchants lent £1,200,000 to the state in return for a charter of incorporation as the Bank of England. The bank made further loans to the government, assumed the responsibility for the issue of exchequer bills and other loans, and also came to act as banker to the government. At the accession of Queen Anne the debt stood at £16,000,000. In 1715 it was £54,000,000; in 1763, £138,000,000; and at the close of the American Revolution (1781), £249,000,000. A considerable part of the debt (Lord North estimated it at £59,000,000 in 1776) was held by Dutch investors. Several attempts were made to reduce the debt. The ambitious plan of the South Sea company failed with the bursting of the South Sea Bubble (1720). Sir Robert Walpole established a sinking fund of £1,000,000 a year, but it was often raided both by himself and his successors. In 1786 William Pitt the younger provided that £1,000,000 a year was to be paid to commissioners for the reduction of the national debt. They were to buy government stock (bonds), which was not to be cancelled but to be held by them, and the interest was to be used to make further purchases. However, the plan had been in operation only seven years when it was overwhelmed by the immense new borrowings caused by the wars of 1793–1815.

The 18th century brought several important changes in financial administration. After 1714, the office of lord treasurer disappeared and was replaced by a body of lords commissioners. From Walpole's time the first lord of the treasury was the prime minister. The chief responsibility for finance fell to the chancellor of the exchequer. These t o offices were combined, but in later times the amount of work falling upon both made it necessary to keep them separate. The junior lords of the treasury hold minor political appointments unconnected with finance.

Walpole simplified the customs duties and introduced bonded warehouses for tea and coffee, but was prevented from extending the system to other goods by the defeat of his excise bill in 1733. In 1752 Henry Pelham converted a large block of different loans into a single issue, which came to be called the consolidated bank annuities, the first "consols." Among many reforms of the younger Pitt was a similar act of consolidation on the revenue side. Taxes which had previously been paid into a number of separate accounts earmarked for special purposes were, from 1787, all paid into a single consolidated fund. out of which practically the whole of government expenditure was paid. Another of Pitt's reforms was the appointment, in 1785, of a body of five commissioners to audit the public accounts.

The Wars of 1793–1815.—The French wars of 1793–181j were far more costly than any which had preceded them. Annual government expenditure rose from less than £20,000,000 in the early 1790s to more than £100,000,000 in 1813–14. The latter sum probably represented between a quarter and a third of the whole national income. In the first few years of war there was little increase in taxation, but after the financial crisis of 1797 greater efforts were made and the revenue rose steadily until, in 1814–15, it provided nearly £83,000,000 out of an expenditure of slightly less than £100,000,000. A landmark in wartime taxation was Pitt's introduction of income tax in 1799. At first the main responsibility for the collection of the tax lay with the general commissioners, recruited from the landed gentry. Gradually, however, a more centralized administration was built up under the commissioners for affairs of the taxes, with the surveyors of the house tax as their agents in the provinces. Another important development was the introduction, in 1803, of taxation at the source wherever possible. With these improvements in administration the yield of the income tax rose gradually to more than £15,000,000 a year, but very heavy indirect taxation was also necessary.

The failure to grapple with the financial problem in the early years had evil results which persisted until the end of the war. The government borrowed large sums from the Bank of England and the reserve of that institution was reduced to a very low level. In 1797 a rumour of a French invasion caused a run on the bank and it was obliged to suspend the payment of its notes in gold. This suspension was confirmed by parliament and remained in force until 1821. Freed from the obligation to pay its notes in legal tender money, the bank pursued the passive policy of discounting all good bills offered to it at the rate of 5%. This rate, though it was the maximum allowed by the usury laws, was far too low to check inflation. By 1814 general prices had risen to about twice their prewar level, while grain prices rose even more sharply as a result of a series of bad harvests. The wartime inflation was accompanied by controversies over monetary policy which had great importance for the development of banking. A significant result in the field of national finance was the passage, in 1819, of an act forbidding the bank to lend to the government for more than three months without the authority of parliament.

During the war the government was obliged to borrow on very unfavourable terms. Some 4% and 5% loans were issued, but the greater part of the borrowing was by means of 3% stock issued at a price of about £60 per £100 nominal value. From the point of view of annual cost to the government in the immediate future, a 3% stock issued at 60 and a 5% stock issued at par come to the same thing; both cost £5 per £100 borrowed. The 5% stock, however, offers far better opportunities for conversion when. as usually happens after the end of a war, interest rates come down.

Another anomaly was the maintainance of William Pitt's sinking fund, augmented by £400,000 a year plus 1% of all new loans. Genuine debt redemption can, of course, come only from a budget surplus. The process of raising new loans to buy back old ones was not only pointless but actually harmful, for the state usually paid rather more on its new borrowing than it saved on the loans purchased by the fund.

The net result of these operations was that, by 1816, the nominal value of the debt had risen to £846,000,000, involving an annual charge of £32,000,000. In relation to the national income the amount of the debt was as great, and the annual charge considerably greater, than that left by World War II.

Finance During the 19th Century.—The first few years after the end of the war were a period of great financial strain. A sharp fall in prices raised the real value of the debt charge and reduced the yield of taxes, and the difficulty of balancing the budget was increased when parliament insisted on abolishing the unpopular income tax in 1816. Gradually, however, the rapidly increasing wealth of the community made itself felt and the budgetary problem became less important. The growth of revenue and expenditure from 1820 onward is shown in Table III.

Table III.—*U.K. Exchequer Receipts and Issues, 1820–1913 (Decennial Averages)*

Financial years	Receipts	Issues	Expenditure as percentage of national income
1821–30	£55,600,000	£55,300,000	—
1831–40	47,200,000	47,800,000	—
1841–50	51,400,000	51,200,000	12
1851–60*	63,700,000	65,700,000	10
1861–70	70,600,000	69,600,000	8
1871–80	77,300,000	76,900,000	7
1881–90	88,200,000	88,100,000	8
1891–1900*	99,700,000	99,700,000	7
1901–10*	143,800,000	159,400,000	9
1911–13	192,600,000	179,700,000	8

*The expenditure figures for 1851–60 include the cost of the Crimean War; those of 1891–1900 and 1901–10 include the cost of the South African War.

The fourth column of Table III has not been completed for the period before 1840 because of the difficulty of making accurate estimates of the national income, and even the later figures must be regarded only as rough approximations. It will be seen, however, that, although expenditure was growing steadily from 1840 onward, the national income was growing as fast, or even faster, during most of the time.

Not only the amount but also the type of expenditure changed considerably during the century. In 1820 national debt charges took £32,000,000 out of a budget of £58,000,000. The army and navy took more than £16,000,000 so that less than £10,000,000 was left for all other services. The national debt charge was gradually reduced by conversions and repayments so that, in the financial year 1913–14, it amounted to only £24,800,000 out of a budget of £197,500,000. The cost of defense had grown, particularly as a result of the naval building program, and amounted to £77,200,000. The state was also beginning to incur substantial expenditure on the social services. Elementary education had been made compulsory in 1880 and free in 1891. The cost was divided between the central government and local authorities, and the share of the exchequer in 1913–14 amounted to £17,500,000. Other new developments included old-age pensions (1908), employment exchanges (1909) and the beginnings of health and unemployment insurance (1911). These services cost £14,600,000 in 1913–14.

Free Trade and Income Tax.—Sources of revenue also underwent a great change. The immediate aftermath of the Napoleonic wars brought the passage of the Corn law of 181j. placing a prohibitive duty on imports when the home price of wheat was less than 80*s.* a quarter (67*s.* for colonial grain), and the repeal of the income tax in 1816. However, disciples of Adam Smith were already creating a strong public sentiment in favour of free trade, which was expressed in a notable petition, drawn up by Thomas Tooke, on behalf of an influential group of London merchants, in 1820. Only minor changes were made during the next 20 years, but in 1840 a parliamentary committee on import duties reported in favour of drastic changes in the tariff. The first thorough overhaul was undertaken in 1842 by the ministry of Sir Robert Peel; William Ewart Gladstone was vice-president of the board of trade and played a leading part in drafting the legislation. Further reductions in duties were made in 1845, and the Corn laws were repealed in 1846. The free trade movement was continued and virtually completed in two further budgets, of 1853 and 1860, for both of which Gladstone was chancellor. The budget of 1860 was associated with the Cobden-Chevalier treaty with France, which gained some valuable reductions in the French tariff. After 1860 there were only 48 articles subject to import duties, out of many hundreds that had previously been taxed. Even these were mostly for revenue rather than protection, as they fell on things that could not be produced at home, and some of them were repealed later. Thus, from 1860 to 1931 Great Britain was virtually a free trade nation.

To compensate for the loss of revenue caused by the 1842 tariff reform, Peel reintroduced the income tax. The tax was intended to be only temporary, but it was never removed again, though it was reduced to only 2d. in £1 in 1874. The growth of expenditure after 1890 raised new budgetary problems and there was also developing a new climate of opinion about the social function of taxation. The incidence of taxation became a subject of keen discussion, and it was generally agreed that taxation should be progressive (*i.e.*, it should take more from larger incomes than from smaller ones).

This attitude was reflected in several changes. In 1894 Sir William Harcourt repealed a number of old duties on property passing at death and replaced them with the simpler and more productive estate duty and succession duty. The latter was paid by the person receiving a legacy and was graduated according to the degree of kinship. The estate duty was levied on the whole estate and varied (according to its value) from 1% to 8%.

The standard rate of income tax was raised and the tax was brought more into conformity with the new ideas of equity by the taxation of earned incomes at lower rates (1907) and by the granting of rebates to persons of small income and for dependents. In the budget of 1909 David Lloyd George introduced the supertax, on incomes of more than £5,000 a year, and the land taxes, an attempt to tax increases in land rents resulting from economic development. The house of lords,. precluded by convention from amending a money bill, rejected this budget. The government dissolved parliament and was returned to power after a general election. The lords then passed the budget, but the government prevented any repetition of the constitutional deadlock by passing the Parliament act of 1911, limiting to one month the lords' right of veto over a money bill. Incidentally, the land taxes, which had been the chief cause of the storm, never worked satisfactorily, and were eventually repealed in 1920.

The National Debt.—During the 19th century the capital value of the debt was reduced by repayments and the interest upon it by conversions. After several modifications, Pitt's sinking fund was abolished in 1829. In its place was put the simple rule that the surplus accruing in any year should be applied to debt redemption, and the sums thus made available came to be known as the "old sinking fund." By 1853 the debt had been reduced to £769,000,000, but the Crimean War raised it by £39,000,000. In 1875 Sir Stafford Northcote introduced the "new sinking fund." A sum of £28,000,000 (later reduced to £24,500,000) was set aside annually for the service of the debt. This was more than sufficient to meet interest payments, and the balance was applied, together with the old sinking fund, to debt redemption. By these means more than £300,000,000 was repaid. The South African War (1899–1902) brought £159,000,000 of new borrowing but, even so, the debt had been reduced to slightly less than £650,000,000 by 1914.

The interest charge was reduced by conversions in 1822, 1824 and 1829. A much larger operation was carried out by Henry Goulburn in 1844, when about £250,000,000 of $3\frac{1}{2}\%$ stock was converted into a new issue bearing $3\frac{1}{4}\%$ for ten years and then 3%. In 1888 G. J. Goschen was able to convert the three per cents into a stock yielding $2\frac{3}{4}\%$ until 1903 and $2\frac{1}{2}\%$ thereafter. These were the 24% consols which formed by far the greater part of the debt in 1914.

Another change of great future significance was the issue of the first treasury bills in 1878. Issued on the advice of Walter Bagehot, the bills were usually for three months and were modelled on the ordinary commercial bill of exchange, so as to enable the government to take advantage of the facilities of the London discount market. The size of treasury bill issues was small until 1914, but it increased greatly during World War I.

The economic importance of the debt was further diminished by the rapid growth of the national income and property. In 1914 the debt was a little over 5% of the estimated value of private property, but nearly half of it was in the hands of official bodies and public institutions. The annual interest charge was barely 1% of the national income.

FINANCE IN WORLD WAR I

World War I raised government expenditure from less than £200,000,000 to a peak, in 1917–18, of nearly £2,700,000,000.

Table IV.—*National Expenditure* **and** *Revenue, 1914–15 to 1919–20*
(In millions of pounds)

Years ending March 31	1915	1916	1917	1918	1919	1920	Total
Expenditure	560.5	1,559.2	2,198.1	2,696.2	2,579.3	1,665.8	11,259.1
Revenue	226.7	336.8	573.4	707.2	889.0	1,339.6	4,072.7
Deficit	333.8	1,222.4	1,624.7	1,989.0	1,690.3	326.2	7,186.4

The figures shown in Table IV include loans to allies and various other items which do not represent actual expenditure in Great Britain. So far as it can be calculated. government expenditure on British goods and services was somewhat more than £9,000,000,000, and at its peak in 1917–18 it formed nearly half the national income. These figures must not, of course, be taken to indicate the cost of the war. They include normal government expenditure which would have taken place had there been no war, and it is impossible to allow exactly for this or for some other corrections that would have to be made. In fact, there is little point in trying to make exact calculations of the cost of World War I, for prices were changing rapidly and consequently money figures cannot have an exact meaning.

In their search for revenue, wartime chancellors relied very largely on heavy increases in the prewar taxes. Income tax was raised to 2s. 6d. in £1 in the autumn of 1914, 3s. 6d. in 1915, 5s. in 1916 and 6s. in 1918. The rate of supertax was also raised until, in 1918, the highest incomes paid 4s. 6d in £1 over and above the standard rate of income tax. There were also heavy increases in the duties on alcohol, tobacco, tea and sugar. In the budget of Sept. 1915, Reginald McKenna made a minor break with the principle of free trade by introducing import duties on motorcars and motorcycles, clocks, watches and musical instruments. The most important new tax, however, was the excess-profits tax introduced in 1915. A standard rate of profit was fixed and all profits in excess of the standard were taxed. The rate of tax was originally 40%, but it was raised to 60% in 1916 and to 80% in 1917. The rise in prices created very large excess profits, and the tax, though it contained many anomalies, succeeded in bringing a large part of these profits into the treasury.

Table V.—*Yield of the Principal Taxes in 1913–14 and 1918–19*

Source of revenue	1913–14	1918–19
Income tax and supertax	£47,200,000	
Excess-profits tax	—	£285,000,000
Alcohol	38,800,000	50,400,000
Tobacco	18,300,000	46,200,000
Tea	6,500,000	16,100,000
Sugar	3,300,000	27,000,000

In spite of these efforts there was a very large budget deficit in each of the years 1914–15 to 1919–20, and in 1917–18 less than 26% of expenditure was covered by taxes. On the whole the proportion of expenditure financed out of revenue was considerably lower than in World War II and even in the Napoleonic wars.

At first the government tried to meet its needs by a series of long-term loans, tiding over the intervals between issues with treasury bills and ways and means advances from the Bank of England. Three great war loans were issued as follows:

Nov. 1914: a 3% loan (1925–28) at 95. The issue was limited to £350,000,000 and was fully subscribed.

June 1915: a $4\frac{1}{2}\%$ loan (1925–45) at par. The issue was unlimited in amount and yielded £587,000,000 in cash and £313,000,000 in conversions.

Jan. 1917: a 5% loan. (1925–47) at 95 and a 4% tax-free loan (1929–42) at par. The issue raised £998,000,000 in cash (including treasury bills surrendered) and £1,130,000,000 in conversions. All except £52,000,000 was in the 5% loan.

An objectionable feature of the borrowing was the right given to subscribers to the first two loans to convert into subsequent issues. and this explains the very large volume of conversions in the third loan. This form of borrowing was becoming very expensive and there were many technical difficulties in transferring such huge sums to the government in a short time. Hence, in 1917, there was a change of policy and no more large long-term issues were made until after the end of the war. Instead, money was raised by the sale of medium-term exchequer bonds and national war bonds, supplemented by treasury bills and ways and means advances. In April 1915 treasury bills were offered "on tap"; *i.e.*, the market could obtain them at a fixed rate at any time and in any quantity, instead of tendering for the fixed amounts previously offered from time to time by the treasury. Later in the war the same system was applied, with great advantage, to the medium-term issues.

The large ways and means advances from the Bank of England were associated with what is generally known as the "special deposits" scheme. Normally the Bank of England allows no interest on money deposited with it, but from 1916 onward it accepted special deposits which it relent to the government and on which it paid interest. One of the main objects of the scheme was to encourage foreigners to hold money in Britain, and from Nov. 1917 special rates were paid on foreign balances and a considerable reduction was effected in the rates for treasury bills and other short-term domestic loans. Another interesting feature of wartime borrowing was the effort made to encourage small savings. These could, of course, be lent to the government through the post office and trustee savings banks, and the second war loan was offered in small amounts through the post office as well as in the normal manner through the Bank of England. In Feb. 1916 there was made the first issue of savings certificates. The subscriber paid 15*s*. 6d. for a certificate entitling him to £1 after five years, but he could claim repayment at any time by the sacrifice of a small part of the accrued interest.

On March 31, 1919, the internal national debt stood at no less than £6,142,000,000. This scale of borrowing was far greater than the normal savings of the public could provide and was bound to lead to inflation. Moreover, there was no chance of the banking system's exercising any curb on the inflationary forces. The outbreak of war caused a crisis in the City, and one of the relief measures was the issue of government currency notes. These notes were formally convertible into gold, but few of the public knew this and, in fact, gold practically disappeared from circulation during the war. The notes were issued through the Bank of England and, until 1919, there was no limit to their amount. A commercial bank which required notes would draw them out and pay for them by a draft on its account with the bank. This sum would then be credited to the currency notes account, invested in government securities, spent by the government, and so would eventually come back to a commercial bank and be paid back into the Bank of England. Thus the banks, collectively, could always add to their holding of currency notes without causing any permanent decline in their other assets. So long as this was so, there was no possibility of inflation being checked by a shortage of legal tender money and a consequent curtailment of bank lending.

Prices rose sharply during the first two and a half years of the war. During 1917 and 1918 a comprehensive system of government controls was built up and this checked the price rise, but only at the cost of building up reserves of unused purchasing power which caused a further price rise in 1919–20 after most of the controls had been removed. Even so, by the end of World War I prices had doubled as compared with 1913, the volume of bank deposits had nearly doubled and the volume of legal tender money in circulation had more than doubled.

Pegging the Exchange.—Another problem of war finance was that of providing for purchases abroad, both British and Allied. Large loans were made to dominion and Allied governments to help finance their purchases in Great Britain and in neutral countries. The principal borrowers were Russia, France and Italy. Total lending up to March 31, 1919, was £1,741,000,000, of which £1,415,000,000 went to these three countries.

Thus Great Britain had to provide foreign exchange to cover both its own purchases and many of those of its allies in neutral countries. Imports were strictly controlled but, even so, drastic measures were necessary. From the autumn of 1915 the U.S. dollar exchange was pegged at a rate of $4.74 to £1 (as compared with a prewar par of $4.85). In order to maintain this rate, the government had to be prepared to sell dollars whenever private supplies were insufficient to meet demand. To obtain the necessary dollars, gold was shipped to the United States, more than £500,000,000 of British-owned securities were sold in the United States, and a number of loans were floated on the U.S. market. The situation was eased by the entry of the United States into the war in April 1917. British requirements in dollars were met by direct loans from the U.S. government, which also took over responsibility for Allied purchases in the United States. Smaller loans were also floated in other countries. Total foreign borrowing up to March 31, 1919, was £1,365,000,000, of which £841,000,000 was a direct liability to the U.S. government.

THE INTERWAR PERIOD

The finance of the period between World Wars I and II was different in many respects from that of the years before 1914. Before World War I government expenditure had never reached £200,000,000 a year; the lowest figure of the interwar period was £778,000,000 in 1933–34. Prices remained well above their prewar level, but even allowing for this there was a great increase in the scale of government expenditure. In 1913 it amounted to about one-twelfth the national income; during most of the period from 1920 to 1939 it was about one-fifth. The national debt had also become of much greater economic importance. Its nominal value had been raised to nearly ten times that of 1914, and it has been estimated that in 1924 government securities in private hands amounted to about a quarter of the value of all private property, The debt was also held to a much greater extent than formerly by banks and other financial institutions in the City of London, and so government policy with regard to it had a profound effect upon the whole capital market.

This policy was largely determined by the general monetary policy of the country, and this, in turn, was subject to two often-conflicting influences, the demands of the international situation and the needs of domestic industry and trade. The wartime inflation, the dislocation of trade caused by World War I and the loss of foreign investments all created difficulties in balancing international payments and tended to impair the exchange value of sterling. The traditional remedy for these ills was a policy of high interest rates and credit stringency. It was generally agreed, however, that such a policy was discouraging to domestic industry and, with unemployment rates ranging from 10% to more than 20% of the insured labour force, this was a powerful argument against it.

Return to the Gold Standard.—During the war gold had practically disappeared from circulation and in 1919 its export was prohibited. It was generally agreed, however, that national policy should be directed toward a return to the gold standard, with sterling at its prewar value, as soon as possible. The abandonment of many wartime controls in the spring of 1919 was followed by a very sharp rise in prices. The Economist index (1913 = 100) rose from 212 in March 1919 to 314 in March 1920. The bank rate was raised to 6% in Nov. 1919 and to 7% in April 1920, and it was maintained at this penal level for more than a year. In Dec. 1919 a treasury minute fixed a maximum issue of currency notes for 1920 and provided for a gradual reduction of the note issue by declaring that the actual maximum of any one year should be the legal maximum for the next year.

These measures broke the postwar boom, but only at the cost of creating very heavy unemployment. However, during the years 1923–24 there was a gradual improvement both in domestic trade and in the exchange value of sterling, and, in the budget speech of April 1925, Winston Churchill announced the return to a gold standard. Gold coins were not to be issued again, but the export of gold was permitted and the Bank of England was to buy and sell gold bullion at the prewar price. Thus gold was made freely available for international transactions. and this was sufficient to fix the exchange value of the pound at its prewar level. Three years later (1928) the currency note issue was transferred to the bank.

The Bank of England found it far from easy to maintain its gold reserve, and from 1925 to the end of 1929 the bank rate varied from 4% to $6\frac{1}{2}$%. It was reduced in the early stages of the depression of 1930–31, but the financial crisis of 1931 caused a rise to 6% and led to abandonment of the gold standard in September.

Cheap Money.—The end of the gold standard brought the beginning of a long period of "cheap money." The bank rate had fallen to 2% by June 1932 and it remained there, apart from a very short time at the outbreak of World War II in 1939, until Nov. 1951. In order to give some stability to the foreign exchange market. the exchange equalization account was set up in 1932. The account began operations with a capital in treasury bills. When it was desired to check an increase in the exchange value of sterling, the account would acquire sterling by disposing of its treasury bills and would then sell this sterling in the foreign exchange market for gold or foreign currencies. When once a reserve had been built up, the account was in a position to reverse the process and could check an undesired fall in the value of sterling by selling gold and foreign currencies. The proceeds of such sales would again be invested in treasury bills. Bills were issued to the account and to other government departments "on tap," though the tender system had been resumed for other buyers. The account thus made possible large international gold movements without any effect on the reserve of the Bank of England. It insulated the banking system from the effects of fluctuations in that reserve, which would have been felt under a gold standard, but its operations created an important new influence, particularly in the market for government securities.

Management of the Debt.—The big problems of debt management were the payment of the medium-term issues as they matured and the reduction of the floating debt (the very short-term debt consisting of treasury bills and ways and means advances). A victory loan was offered in June 1919, consisting of a 4% funding loan (1960–90) at 80, and 4% victory bonds, repayable at par by annual drawings, at 85. The issue raised £574,000,000 in cash and £192,000,000 in conversions, which was generally regarded as disappointing. The very high interest rates of 1920 made conversion operations impossible, but in 1921 a new $3\frac{1}{2}$% conversion loan (redeemable after 1960) was offered to holders of national war bonds on terms corresponding to a price of 62. The first offer was unsuccessful, but in later years a substantial amount of this loan was issued on terms much less unfavourable to the government. In July 1921 a new medium-term treasury bond was issued and this again was followed by further issues of the same kind. Holders of national war bonds also had the option to convert into 5% war loan (on the terms of the 1917 issue) and during 1923–24 a considerable amount was so converted. Other substantial issues were a $4\frac{1}{2}$% conversion loan (1940–44) in 1924; 4% consols in 1927; and a 5% conversion loan (after 1944) in 1929.

The impact of the cheap money policy was seen at once in the conversion of the 5% war loan into a $3\frac{1}{2}$% loan in 1932. Out of more than £2,000,000,000 only £163,000,000 had to be paid in cash. The money for this and some minor operations was raised by the issue of a 3% conversion loan (1948–53) and by two new treasury bond issues, a 3% bond (1933–42) and a 2% bond (1935–38). The downward trend in rates continued, and during 1935-36 a funding loan (1956–61) at $2\frac{1}{2}$% and a new series of treasury bonds (1939–41) at only 1% were issued. At the end of the interwar period, rearmament led to fresh borrowing, including the issue of $2\frac{1}{2}$% national defense bonds (1944–48) in the financial year 1937–38 and a 3% national defense loan in the following year.

These operations reduced the annual charge on the national debt from nearly £350,000,000 in 1920 to £212,000,000 in 1934. On the other hand, there was little net repayment of debt. The budget of 1923 provided a new sinking fund to replace that of 1875, and to incorporate payments due on the U.S. loan and various special sinking funds created in connection with some of the wartime loans. A budget surplus was still to be applied to debt redemption, but for the period as a whole the net surplus was very small. The nominal value of the debt, influenced by conversions as well as by repayments, was £7,247,000,000 on March 31, 1939.

The general tendency of these operations was to increase the amount of long-term and medium-term debt and to reduce the amount of short-term debt, and this tendency was accentuated by the fact that the exchange account and other official institutions were large holders of treasury bills. The result was an important change in the pattern of interest rates. Short-term rates always fluctuate more than long-term rates, but until 1921 there had been a close correspondence between the yield of long- and short-term loans averaged over a period of several years. About 1921, however, a gap appeared, and it was widened considerably by the cheap money policy. Short-term rates fell much more than those on longer-term loans, and in the years 1932–38 the average yield of consols was 3.3% and the average rate of discount on treasury bills was only 0.8%. The main item in the external debt was the loan, nominally payable on demand, from the U.S. government. By 1923 this amounted, together with accrued interest, to nearly $4,000,000,000. To set against it, Great Britain had nearly double this amount in loans to allies and in its share in German reparations. In 1923 an agreement was made for the repayment of the U.S. loan, with interest, over a period of 62 years by annual instalments of $161,000,000 for the first ten years and $184,000,000 thereafter. The international economic crisis led to a one-year moratorium (the Hoover moratorium) in June 1931. Germany did not resume reparations payments and Great Britain, unable to collect payment from its debtors, made token payments on the U.S. loan until Dec. 1933 and then ceased.

Revenue and Expenditure, 1920–39.—Government expenditure was maintained far above its prewar figures partly by the heavy debt charge and partly by the growth of expenditure on the social services. The unemployment insurance scheme was greatly extended in 1920. The revenue of the insurance fund was derived from contributions by employers, employees and the state, but with the very heavy unemployment from 1921 onward the fund fell increasingly into debt. In 1926 a contributory scheme was started for widows', orphans' and old-age pensions, and in 1934 the unemployment fund was put on a sound financial basis by the limitation of the period for which insurance benefit could be drawn. Those who had been unemployed so long that they had exhausted their benefit rights were transferred to a new body, the Unemployment Assistance board. This board (later simply the Assistance board) drew its revenue entirely from the state. The cost of education also increased, and these services accounted for 15.5% of the budget in 1927–29 and for 24.9% in 1935–37. Comparative figures of the main items for these years and for the years 1947–48 to 1951–52 are shown in Table VI.

This heavy expenditure made it necessary to maintain many taxes at or even above their prewar level. The chief exceptions were the excess-profits tax (abolished in 1921) and the "breakfast table" duties on tea, coffee. cocoa and sugar, which were substantially reduced. The standard rate of income tax never fell below 4*s.* in £1, though considerable relief was given to incomes at the bottom of the taxable range by a new system of allowances introduced as a result of the recommendations of a royal commission in 1920. Surtax was slightly reduced in the lower ranges, but increased in the higher ones, and estate duties were raised on several occasions.

TABLE IX.—Government Expenditure on Goods and Services

tive duties were introduced under the Safeguarding of Industries act, 1921. The main fabric of free trade remained, however, until 1931 when, as a result of the economic crisis, a duty of 50% ad valorem was hurriedly imposed on imports of manufactured and semimanufactured goods. It was still regarded as politically undesirable to tax most basic foods and raw materials, but the import of many of these was curtailed by quota restrictions. The new tariff was intended to be protective rather than revenue-producing, and at first the yield was small. It increased with the revival of trade in the late 1930s and in 1938–39 it amounted to about £35,000,000.

WORLD WAR II

The finance of World War II was greatly influenced by previous experience and by those developments in economic theory particularly associated with the name of J. M. (later Lord) Keynes. Keynes asserted that the dominant influence on the rate of interest aas the supply of and the demand for money in relation to the supply of and the demand for various types of security. Hence, by varying the quantity of money, and by adjusting its borrowing policy to meet changes in the demand for different types of security. the government could, within very wide limits, determine the rate of interest.

The truth of this was demonstrated during the 1930s and. later, by the way in which the vast government loans of 1939–45 were floated at rates very little above those of 1932–38.

Another development intimately associated with Lord Keynes was the use of national income statistics as an aid to budgeting. This led, in 1941, to the publication of the first White Paper, *An Analysis of the Sources of War Finance and an Estimate of the National Income and Expenditure*. The White Paper was continued annually, dropping the first part of its title at the end of the war but otherwise expanding steadily in scope and detail. In his budget speech of 1941 Sir Kingsley Wood used these estimates to calculate the "inflationary gap"; *i.e.*, the gap between the estimated spending, public and private. for the year and the current value of the goods that would be available for purchase. By incurring a budget deficit, the government takes less from private incomes than it spends; unless this difference is made up by normal savings, total spending will exceed the current value of goods coming to market and prices will tend to rise.

TABLE VIII.—Revenue and Expenditure During the Years 1939–40 to 1945–46

(In millions of pounds)

Year ending March 31	1940	9	1942	1943	1944	1945	1946	Total
Expenditure.	1,408.2	3,970.7	4,876.3	5,739.9	5,909.3	6,179.5	5,601.1	33,685.0
Revenue	1,134.7	1,495.3	2,174.6	2,922.4	3,140.2	3,354.7	3,401.2	17,632.1
Deficit	273.5	1,475.4	2,701.7	2,817.5	2,768.1	2,824.8	2,199.9	15,052.9

For government revenue and expenditure *see* Table VIII. Not all that expenditure was met out of current production. Some of it had its counterpart in borrowing abroad, and sale of foreign assets or the postponement of repairs and replacements to domestic capital equipment. The orders of magnitude of these are shown in Table IX, compiled from the national income White Papers.

The figures are for calendar years, not financial years, and government expenditure includes that of local authorities, but takes account only of expenditure on goods and services and not of transfer payments. From these figures it would appear that about 45% of current production was used by the government. It must be remembered, however, that the value of private purchases was swollen by heavy indirect taxation. If this is allowed for, approximately half of current resources was taken by public expenditure. Production was increased by the virtual disappearance of unemployment, by the conscription of married women and others not normally in the labour market, and by longer hours. Even so, a curtailment of personal consumption was necessary, and the real value of personal spending (after allowing for the rise in prices) was about 15% less from 1941 onward than it had been in 1938.

The actual diversion of resources from private use to war purposes was made by direct government controls and, to that extent, finance was reduced to a subordinate role. The main problem of the chancellor was to see that the private sector of the economy was not left with so much income as to create an intolerable pressure on the controls. It was here that the concept, already mentioned, of the inflationary gap assumed its importance.

Wartime Taxation — Taxationwas increased much more drastically and at an earlier stage than in World War I. A supplementary budget in Sept. 1939 raised the standard rate of income tax to 7s. in £1 and that of supertax to 9s. *6d.* in £1, over and above the standard rate on the highest incomes. It also imposed an excess-profits tax of 60% and raised the alcohol and tobacco duties.

The standard rate of income tax was raised to *7s.* 6d. in the first budget of 1940, 8s. 6d. in the second and 10*s.* in the budget of 1941. Together with the surtax of gs. *6d.*, this meant that the highest incomes were paying a marginal rate of 19*s.* 6d. in £1, and there was a virtual income ceiling at about £6,000 a year after tax had been deducted. Allowances were also reduced and this, together with the rise in earnings, meant that many weekly wage earners became liable to tax for the first time. It was possible to collect the tax efficiently by deducting it from wages on the "pay as you earn" principle, adopted in 1940 and extended to salary earners as well as wage earners in 1944.

Excess-profits tax was raised to 100% in 1940, and the taxes on beer and tobacco were raised in each of the years 1940 to 1943. Entertainment duties were also increased sharply. The most important new tax was a purchase tax on a wide variety of luxury and semiluxury goods. It was introduced in the second budget of 1940, at rates varying from $12\frac{1}{2}\%$ to $66\frac{2}{3}\%$ of the wholesale value of the goods, and was later raised to 100% on some articles. The main fabric of wartime taxation had thus been completed by 1941 and, apart from some increases in indirect taxation, later budgets made few changes. On the other hand, the yield of all taxes rose steadily with the rise in prices and money income.

Of a total increase in revenue of £2,400,000,000 between the two

TABLE X.—*Yield of the Major Sources of Revenue in 1938–39 and 1945–46*

Source of revenue	1938–39		1945–46	
	Million pounds	Percentage	Million pounds	Percentage
Income tax and surtax	398.8	39.6	1,442.2	42.2
Estate duties	77.5	7.7	119.6	3.5

Miscellaneous	168.0	16.7	273.0	8.0
Total	1,006.8	100.0	3,411.3	100.0

years shown in Table X, more than £2,200,000,000 came from five main sources: income tax and surtax, excess-profits duty, alcohol, tobacco and purchase tax.

It was generally agreed that one of the main risks of inflation lay in the so-called "vicious spiral" of rising prices leading to increases in wages which caused a further rise in prices, and so on. An extensive system of price control was adopted, and in 1940 the government began the payment of subsidies to offset the rise in import prices of certain basic foodstuffs. In the budget of 1941 the chancellor announced the continuation and extension of this policy in order to keep the cost-of-living index at not more than 25%–30% above the prewar level. In return he appealed to the trade-union movement for moderation in wage claims. The index was stabilized (though the prices of some things not represented in the index rose considerably) and moderation in wage claims was secured, but the cost to the exchequer rose to more than £270,000,000 in 1945. Another novel feature of Sir Kingsley Wood's remarkable 1941 budget was the introduction of a system of forced saving advocated by Keynes. Income-tax payers whose payments had increased because of the reduction of allowances were to have the increase recorded as a "postwar credit" in the post office savings bank. Members of the armed forces were to receive a small part of their pay in a similar credit, and 20% of payments of excess-profits duty (less the appropriate income tax) were credited to the firms concerned for postwar reconstruction.

Wartime Borrowing.—In spite of these heavy increases in taxation, borrowing on an unprecedented scale was necessary. The internal debt rose from £7,247,000,000 on March 31, 1939, to £23,372,000,000 on March 31, 1946. Monetary policy was directed toward enabling the government to borrow on the cheapest possible terms. At the outbreak of war the gold reserve of the Bank of England was transferred to the exchange account and the fiduciary issue was raised to £580,000,000. Further increases followed whenever the reserve reached an inconveniently low level, and by July 1945 the issue had reached no less than £1,350,000,000. Freed from anxiety about its own reserve, the bank proceeded to confer the same freedom on the rest of the banking system and the money market by buying all bills offered to it through its official broker (usually known as the "special buyer"). Thus the banks were able to replenish their reserves at will, just as they had been in World War I, though the mechanism was different.

The treasury did not make the mistake, made in the previous war, of offering large blocks of long-term loans. There was an issue of £300,000,000 of 3% war loan (1955–59) in March 1940, but the other important issues were all "on tap" and were carefully adjusted to meet the needs of all types of investor. During the period from March 1939 to March 1946, treasury bills increased by £3,531,000,000 and ways and means advances by £477,000,000. A large part of this floating debt must have been held by the Bank of England (as cover for the note issue), the exchange account and other official bodies, and by dominion and foreign governments with balances in London, but much of it was also in the hands of the banks and the money market. The treasury also accepted deposits from the banks for six months at $1\frac{1}{8}\%$ for which it gave treasury deposit receipts. The treasury made known the amount it wished to borrow in this way week by week, and the banks arranged to lend on a quota basis in proportion to their deposits. More than £1,500,000,000 treasury deposit receipts were outstanding in March 1946. Medium-term loans included six issues of $2\frac{1}{2}\%$ national war bonds ranging in redemption date from 1945–47 for the first issue, made in 1941, to 1954–56 for the sixth in 1945. The six issues together brought in £3,410,000,000. A longer-term loan was provided by four issues of savings bonds. The first three were at 3%, with redemption dates from 1955–65 to 1965–75. The fourth issue (1965–67) carried only $2\frac{1}{2}\%$, but this was not offered until May 1946. The three wartime issues produced more than £2,700,000,000 and the fourth issue more than £700,000,000.

Great efforts were made to stimulate small savings. Four issues of defense bonds, the first three at 3% and the fourth at $2\frac{1}{2}\%$, were designed chiefly for the small personal investor and yielded more than £1,100,000,000. There was also an increase of more than £1,200,000,000 in the value of savings certificates and of £1,736,000,000in the deposits of the post office and trustee savings banks. These sums represented a far greater contribution from the small saver than had been made in World War I.

Oversea Payments and Lend-Lease.—The finance of purchases abroad was again a major problem, with the supply of U.S. dollars as its focal point. The exchange was pegged at \$4.03 to £1, and securities salable in the U.S. were again requisitioned. Reserves were within sight of exhaustion when, in March 1941, the U.S. congress passed the legislation commonly known as the Lend-Lease act, which authorized the president to transfer supplies without immediate payment to countries whose defense was considered vital to the defense of the United States. Ultimate settlement was to take the form of any benefit, direct or indirect, to the United States which the president might consider satisfactory. With the entry of the United States into the war, the British government reciprocated by providing certain supplies to U.S. forces in Britain and elsewhere, and the same principle was also applied by both countries to their other allies.

Even so, British expenditure in the United States amounted to more than £1,500,000,000, and heavy liabilities were also incurred in other foreign countries. Expenditure in India, Egypt and elsewhere was met out of funds provided by those countries in return for "sterling balances" (*i.e.*, short-term credits) in London. From Sept. 1939 to June 1945, total British disinvestment abroad was officially estimated at £4,198,000,000, made up as follows: sale and repayment of foreign investments, £1,118,000,000; increase in "sterling balances," £2,576,000,000; other foreign borrowing. £303,000,000; reduction in gold and dollar reserves, £152,000,000; unallocated, £49,000,000; total, £4,198,000,000.

FINANCE AFTER WORLD WAR II

The five years after the end of World War II were dominated by the high level of public expenditure, the need to control domestic inflation and to maintain a balance of external receipts and payments, and the desire to continue the cheap money policy. In some ways these were conflicting aims. The attempt to reconcile them involved the continuation of many wartime controls, the drastic restriction of private investment and the reduction of private expenditure by means of large budget surpluses. The latter was, of course, an extension of the principles applied to wartime budgeting. Just as a budget deficit leads to an "inflationary gap" by taking less from private citizens than the government is spending, so a budget surplus reduces inflationary tendencies in other parts of the economy by taking more from private persons than the government is spending.

The great extension of social services involved a heavy increase in government spending. As early as 1942 the government published a report by Sir William (later Lord) Beveridge, *The Social Insurance and Allied Services*. The main recommendations of this report were embodied in the National Insurance act and the National Health Service act of 1946, and the National Assistance act, 1947, though the provisions of these acts did not come into full operation until 1948. The scope of insurance, assistance and health services was considerably extended and a system of family allowances was introduced. The Education act of 1944 led to the raising of the school-leaving age to 15. The cost to the exchequer of the social services in 1953–54 is shown in Table XI. Large

TABLE XI.—Cost to the Exchequer of Social Services, 1953–54

Service	Cost	Service	Cost
National health service	£408,600,000	War pensions	£84,300,000
National insurance and family allowances	182,300,000	Education	241,600,000
National assistance	105,900,000	Other	182,900,000

sums were also spent by the National Insurance funds and by local authorities. The total cost of social services for Great Britain and Northern Ireland in 1953–54 was £1,975,700,000.

The food subsidies were continued, though there were some reductions by R. A. Butler and H. Macmillan after 1951, and the charge on the national debt had been raised by wartime borrowing. Defense expenditure fell immediately after the war, but then rose sharply from £740,700,000 in 1949–50 to £1,405,000,000 in 1955–56. Finally, the budget was, of course, swollen by the general rise in prices. As a result of all these influences, expenditure in the years 1953–54 to 1955–56 averaged £4,610,000,000, more than five times its prewar level.

Taxation. — The need to reduce private expenditure in order to avoid inflation was a dominant feature of taxation policy. Each of the years 1947–48 to 1955–56 showed a large surplus of ordinary revenue over ordinary expenditure. There were, however, substantial "below the line" payments (including repayment of excess-profits tax refunds and postwar credits, compensation for war damage and housing loans to local authorities) which are not included in the ordinary budget.

The need to raise this very large revenue precluded any major remissions of taxation. Excess-profits duty was abandoned from the end of 1946, but was replaced by a profits tax. The standard rate of income tax was reduced from 10*s*. to 9s. in £1 in Oct. 1945, raised to 9*s*.6*d*. in 1951, and again reduced to 9s. in 1953 and to 8*s*.6*d*. in 1955. There were several changes in allowances, in exemption limit and in the amount of income chargeable at less than the standard rate, which tended to reduce the burden of the tax especially on lower incomes. Business investment was also encouraged by changes in depreciation allowances. On the other hand, there was a heavy increase in the tobacco duty in 1947 and it was raised yet again in 1948 and 1956. Alcohol duties were also raised in 1948 and a new tax on betting was imposed. There were a number of other changes, including a tax on dividends and a "once and for all" special contribution on investment income (in 1948), but their yield was small in relation to that of the main sources of revenue. Taxation in 1955–56 is shown in Table XII.

TABLE XII.—*Yield of* Taxation, *1955–56*

Tax	Amount	Percentage
Income tax and surtax	£2,081,500,000	44.9
Estate duties	175,700,000	3.8
Profits tax and excess-profits tax arrears	210,950,000	4.5
Alcohol	408,083,000	8.8
Tobacco	668,175,000	14.4
Oil	324,781,000	7.0
Purchase tax	418,802,000	9.0
Other customs and excise	193,266,000	4.2
Other tax receipts	158,359,000	3.4
Total receipts from taxes	4,639,618,000	100.0

The Internal Debt.—With Hugh Dalton as chancellor of the exchequer in 1945, the cheap money policy was intensified. The new phase began with the curtailment of the rate on treasury deposit receipts from $1\frac{1}{8}\%$ to $\frac{5}{8}\%$ in Oct. 1945, and culminated in the issue of a $2\frac{1}{2}\%$ treasury stock (redeemable after 1975) at par in Oct. 1946. To achieve this reduction the assets of the insurance fund and other official funds were invested heavily in long-term debt, the treasury bill issue was increased and much of the increase was taken up either by the banks or by the money market with resources provided by the banks. The Bank of England, as in wartime. provided the banks with all the reserves they needed, and bank deposits rose by about £800,000,000 during 1946.

There was a change of policy in the spring of 1947, when official support was withdrawn from the long-term market, and the price of these securities was allowed to fall. This phase lasted until Nov. 1951. The Bank of England continued to provide the banks with virtually unlimited credit through the special buyer, and the volume of bank deposits continued to rise, though at a slower rate than in 1946, but there was a gradual decline in the prices of government securities. A further change in policy occurred, under R. A. Butler's chancellorship, in Nov. 1951. The bank rate was raised to $2\frac{1}{2}\%$ in November and to 4% in March 1952, and the activities of the special buyer were curtailed. In Nov. 1951, £1,000,000,000 of treasury bills, about half of them held by the banks, were converted into new short-term funding loan. Treasury deposit receipts, which had been declining in volume for some time, were suspended in March 1952. The general effect of these changes was to reduce the liquidity of the banking system and to bring about a further rise in interest rates. Treasury bill rate rose to about $2\frac{3}{8}\%$, and the yield on long-term government securities to somewhat more than 4%. There was a general fall in rates in 1953–54, but inflation and balance of payments difficulties in 1955–56 brought a renewed rise. The bank rate was raised to $4\frac{1}{2}\%$ in Feb. 1955 and to $5\frac{1}{2}\%$ in Feb. 1956. The yield on consols rose to about $4\frac{3}{4}\%$ and that on some short-dated government bonds to over 5%. This phase may be regarded as completing the reaction against the cheap money policy and establishing again the view that interest rates should be determined by general economic conditions and not by the convenience of the treasury in its debt management.

The External Problem.—At the end of World War II Great Britain was left with a reduced income from foreign investments and shipping and a disorganized export trade. The government, therefore, anticipated an adverse balance of payments during the period of recovery. The lend-lease arrangement came to an end in Sept. 1945, and a settlement with the United States was reached in the Washington agreement in December. Obligations in respect of supplies received during the war were cancelled, and Great Britain agreed to pay $650,000,000 for supplies shipped after the end of the war and for U.S. military installations in Britain. The British government also received a "line of credit" of $3,750,000,000. The combined sum was to be repaid, with interest at 2%, in 50 annual instalments beginning in Dec. 1951. As part of the agreement, Britain undertook to remove exchange restrictions on current transactions by July 1, 1947. A Canadian loan of £281,000,000 in dollars was also negotiated in March 1946.

The promised removal of exchange restrictions was followed by so rapid a drain on reserves that convertibility had to be restricted again after less than two months. There followed a period of fluctuations in the reserves, with gains in 1948, 1950 and 1952–54 and heavy losses in 1949, 1951 and 1955. In 1949 sterling was devalued from $4.03 to $2.80 to £1. The foreign exchange crisis of 1951 brought restrictions on imports and the changes in domestic policy already described. With the recovery in 1952–54 steps were taken to increase the convertibility of sterling, and there was a strong revival in its use as an international currency, though British residents could still not convert sterling into dollars without official permission. The loss of reserves in 1955 was met wholly by internal measures, and without any further restrictions either on imports or the foreign exchanges.

DEVELOPMENT OF GOVERNMENT FINANCE

The first half of the 20th century produced revolutionary changes in the economic significance of government finance. The national debt came to form a major part of private property. At the end of World War II government securities probably formed nearly half of all private property, and the proportion was increased still further by the nationalization of a number of basic industries between 1945 and 1950. The peacetime expenditure of the central government increased from about one-twelfth to about one-third of the national income. Expenditure on national debt interest and on defense declined in relative importance, and a whole new range of government-financed social services came into being. The weight of taxation increased enormously. Among direct taxes there was a great increase in the taxation of higher incomes and of large estates passing at death, while among indirect taxes there was a wide range of new protective duties. It is difficult to estimate how far these changes redistributed income, as it cannot be known exactly how indirect taxes were apportioned between differentincome groups. It is certain, however, that there was a drastic reduction in the real value of the higher incomes and a great alleviation of extreme poverty. The latter was achieved not only by transfers from rich to poor, but also by transfers within each income group; *e.g.*, the taxes of the single man help. to provide family allowances, education and health services for the large family. The growth of government expenditure raised problems with regard to parliamentary control. In theory parliament has a double control through its voting of taxes (in committee of ways and means) and through its authorization of expenditure (in committee of supply). These are both committees of the whole house. The ways and means committee discusses the budget proposals at some length, but supply days are traditionally days for the airing of grievances; the subjects for debate are chosen by the opposition and usually have little connection with finance. Two smaller committees. the select committee on estimates and the public accounts committee, examine estimates and accounts respectively, but it is inevitable that, once parliament has determined the general lines of policy, it should rely very heavily on the treasury for the supervision of details.

Local Government Finance.—Besides the services financed by the central government, there are important economic activities which are in the hands of local authorities. After 1875, a number of these authorities built up trading services, including water supply, gas, electricity and public transport. The nationalization of gas and electricity reduced the scope of these activities, and the National Assistance act of 1947 transferred some of the functions of poor relief from local authorities to the National Assistance board. Their most important remaining functions, other than the trading services, are education, housing, highways, police and fire services and public health. Expenditure (excluding capital expenditure) and revenue for the year 1954 were as shown in Table XIII.

TABLE XIII.—*Local Government Finance, 1954*

Revenue		Expenditure	
Central government grants	£432,000,000	Education and child care	£399,000,000
Rates	460,000,000	Health	56,000,000
Trading income	27,000,000	Roads and lighting	
Rent, interest, etc.	184,000,000	Police and fire services	107,000,000
		Debt interest	127,000,000
		Miscellaneous	208,000,000
		Surplus	109,000,000
Total	1,103,000,000	Total	1,103,000,000

Rates are a tax on land and buildings. In 1929 they were drastically reduced for agricultural land and industrial buildings. and the tax falls mainly on private dwellings and commercial premises. The government grant is paid partly in respect of specific services (*e.g.*, police and education) and partly in the form of a block grant which is not related to any one form of expenditure. The method of paying this grant was changed by the Local Government act of 1948, which provided for a revaluation of property and for the payment of equalization grants to local authorities with less than an average ratable value per head of their population.

An impression of the size of the combined operation of the central government, local authorities and the national insurance fund is given in Table *XIV*, compiled from the national income White Paper for 1955. When these figures are related to the national income, it appears that nearly 20% of all the goods and services produced by the nation were used by public authorities, that the power to purchase another 12½% was transferred from its original recipients to others, that nearly 30% of all private incomes was paid in taxes, rates and national insurance contributions and that more than 12% of all saving was done by public authorities.

TABLE XIV.—*Current Account of the Central Government, Local Authorities and the National Insurance Funds, 1954*

Income		Expenditure	
Taxes and rates	£4,601,000,000	Goods and services	£3,099,000,000
National insurance contributions	532,000,000	Subsidies	426,000,000
Property income	512,000,000	Debt interest	750,000,000
Grants from abroad	50,000,000	Other current transfers	1,021,000,000
		Grants abroad	53,000,000
		Surplus	346,000,000
Total	5,695,000,000	Total	5,695,000,000

ECONOMICS AND TRADE

In the following account of the development of industry and trade, statistics must be understood to include Northern Ireland where applicable, although it should be noted that before World War II only a small proportion of industrial production was located there. No census of production is available for Northern Ireland for 1948. by which time, however, production had begun to increase (*see* IRELAND, NORTHERN). Figures for years before 1921 may also include the rest of Ireland, now the Republic of Ireland.

POWER RESOURCES

Coal.—Coal is by far the most important source of power in the British Isles. The amount of coal reserves has been variously estimated at different dates, and in 1950 coal reserves likely to be developed during the succeeding century were estimated at 21,607,000,000 tons. At rates of consumption in the 1950s the coal known to exist was expected to last for between four and five centuries. If, however, account was taken of probable and possible reserves, there was enough coal to last seven centuries, and there would be a further extension if means were found of using the small coal so largely wasted.

There is no definite evidence of the use of coal in Great Britain till between A.D. 1230 and 1240, when Northumbrian grants are extant of the right to take "sea coal," probably coal eroded and washed up on the shore. Outcrop mining seems to have begun in the northern coal field at the end of the century. In the 14th century elementary shafts began to be sunk, and from the 16th century onward fairly considerable quantities of coal for domestic uses were being brought to London from the northern pits by sea. But by modern standards production was still small; in 1800 it was about 10,000,000 tons a year, and it was not until the development of the steam engine that coal mining rose to its full importance. The coal fields of England are generally arranged in three groups, the southern, midland and northern. The southern includes the south Wales, Forest of Dean. Somersetshire and Gloucestershire and Kentish fields; the midland comprises the Yorkshire. Nottinghamshire. Lancashire, north Wales, Staffordshire, Leicestershire, Warwickshire and some smaller fields; and the northern includes the fields of Northumberland, Durham, Cumberland and Scotland. During the second quarter of the 20th century the south Wales fields declined while the midland group rose in importance.

Water Power.—Hydrometric statistics for Great Britain are given in the *Surface Water Yearbook* of *Great Britain 1945–53* (H.M.S.O., London. 1955). The most important potential sources of water power are in the Highlands of Scotland, north Wales and Cumberland. but throughout the industrial era the rivers, notably those of Lancashire, Yorkshire and north Derbyshire, have been used for industrial power purposes. As the output of coal developed and the scale of manufacture increased, many of the early installations fell into disuse; later, however, no doubt because of the improvement of steam turbines and electrical appliances, the use of these rivers tended to revive. British rivers can never be used as sources of electric power to an extent comparable with those of the Scandinavian countries or Italy; similarly, vast water-power projects are impracticable in Great Britain.

An exhaustive study of the water-power resources of the country was published by the Water-Power Resources committee, appointed by the board of trade in 1921. The committee came to the conclusion that schemes which were economically possible could not generate more than 40% of the electricity then generated by public and transport authorities. Practical development during and after World War II was mainly concentrated in the Scottish Highlands, and in 1943 the North Scotland Hydro-Electric board was authorized. By 1954 total British electricity generated by water power came to 2,237,000,000 kw.hr.

Fuel Oil.—The production of petroleum in Great Britain has been negligible, but supplies do exist which, though small, could probably in some instances be worked remuneratively. In 1918 the government began extensive investigations. Petroleum has been found in Derbyshire, Nottinghamshire, north Staffordshire, Yorkshire (near Rotherham), Cumberland, Lancashire, Shropshire and certain parts of Scotland, but none proved of commercial importance.

Oil shale exists in large quantities in Dorsetshire. Somersetshire, Norfolk, Lincolnshire. Yorkshire, Midlothian. Linlithgowshire and Lanarkshire. The most important fields in England are at Kimmeridge and Corton in Dorsetshire. But the only commercially important deposits of oil shale lie in Midlothian and West Lothian and in Lanarkshire. The reserve position is as follows: Midlothian 163,500,000 tons, Linlithgowshire 416,540,000 tons and Lanarkshire 16,630,000 tons. A group of oil fields in east Nottinghamshire was proved in 1943. In 1954 the total of British production from oil shale was 3,000,000 gal.

Atomic Energy.—The development of the theoretical basis on which the practical application of nuclear physics rests goes back to 1895. During World War II this development was diverted to the design of atomic weapons. The success with nhich this mas effected provided a strong impetus for the further development of less destructive aspects of nuclear physics.

On Oct. 29, 1945, the ministry of supply took over responsibility for further development from the Department of Scientific and Industrial Research. A comprehensive atomic energy research establishment was set up at Harwell, Berkshire. The Atomic Energy bill, empowering the government to control the use and development of atomic energy. became law on Nov. 6, 1946. Immediate control was vested in the minister of supply; but on the recommendation of the Waverley committee (Cmd. 8986) a non-departmental minister, the lord president of the council, was made responsible for the atomic energy program. By the Atomic Energy act, 1954, responsibility for the atomic energy project was transferred to the United Kingdom Atomic Energy authority under the lord president.

By the mid-1950s the following position had been reached. The Harwell establishment (responsible for basic research into nuclear physics and atomic energy) housed two experimental piles. Gleep (graphite low energy experimental pile) and Bepo (British experimental pile). It also housed a zero energy fast reactor (Zephyr) and a pile using heavy water called Dimple (deuterium-moderated pile low energy). Two further heavy-water piles were under construction (E 443 and RE 773). The Radio Chemical centre at Amersham, Buckinghamshire, was a subsidiary to Harwell. Production of fissile material was directed from the headquarters of the industrial group at Risley, Lancashire, and there were production factories at Springfield, Lancashire (for pure uranium), Windscale, Cumberland (for plutonium), and Capenhurst, Cheshire (for separating the uranium isotope U^{235} from the less scarce U^{238}). The Atomic Energy authority was building a nuclear power plant at Calder Hall, Cumberland, and a nuclear power reactor (working on the breeder principle) at Dounreay, Caithness. The Calder Hall station was designed to generate 50,000 kw, of electricity, enough to supply a medium-sized town.

In the early stages of nuclear development private industry was confined to working for the Atomic Energy authority and manufacturing nuclear instruments. Later the scope of private industry began to expand. By the mid-1950s a number of concerns were investigating the application of nuclear energy to the propulsion of ships, aircraft and land vehicles. One aspect of the nuclear development is the production of isotopes. In 1954 the British exports of isotopes were the biggest in the world.

MINERALS AND MINING

Coal Output.—Great Britain's industrial supremacy during the 18th and 19th centuries was founded on the country's coal mines.

TABLE XV.—*Coal* Output

Decennial average or year	Production (tons)	Average number of persons employed*
1873–82	138,087,000	482,000
1883–92	169,922,000	552,000
1893–1902	203,323,000	713,000
1903–12	253,983,000	936,000
1913–22	241,109,000	1,068,000
1923–32	233,126,000	982,000
1933–42	221,155,000	754,000
1943	198,948,000†	708,000
1944	192,765,000	710,000
1945	182,784,000	709,000
1946	190,082,000	697,000
1947	197,464,000	711,000
1948	209,445,000	724,000
1949	215,166,000	720,000
1950	216,324,000	697,000
1955	223,074,000	704,000

'Prior to 1922 clerks and salaried persons are included. In that year they numbered on average about 24,000 and in 1946 about 21,000, inclusive in each case of clerks and salaried persons employed at headquarters Since 1946 the information about clerks and salaried persons at headquarters offices is not comparable. At the end of 1946 there were 13,800 clerks and salaried persons employed at the mines and, in Sept. 1951, 20,000. From 1954 a new method of recording attendance reduced numbers on colliery books by about 4,000. †Figures for coal from 1943 onward include opencast coal.

The output of coal in Great Britain and Ireland and the number of persons employed at the mines since 1873 are given in Table XV. The figures for 1913–22 and for the years after 1922 show that the position of the industry underwent a serious change. After the early 1920s the coal industry was. in fact, one of the sore spots of the British economic system. It had reached its peak of prosperity in the years preceding 1914; during World War I it was under government control, and in the years immediately following the course of international events prevented it from seriously feeling the direct effects of the postwar slump until 1924.

Until 1921 wages and hours of labour in the industry were governed by regulations put into force during the war, but in 1921, after a three months' stoppage, the miners secured a minimum wage, pay increases and the prospect of shorter hours. This agreement was made possible by a government subsidy of £10,000,000 to the mineowners. It lasted till April 1924, and, when a further stoppage became imminent, the government granted further subsidies and appointed a royal commission under Sir Herbert (later Lord) Samuel to survey the position. The commission's report did not prove acceptable to either side, and the miners ceased work on May 1, 1926. They did not return until the following November, by which time the unions' resources were completely exhausted. The miners were forced to accept an increase of hours, with wages to be settled by district agreements.

Meanwhile the position of the industry, both in relation to world trade and the national economy, was becoming clearer. Before 1914 the margin of profit depended largely on the capacity of the industry to export, which in turn depended on the facts that nearly all the important British coal fields were within 25 mi. of the sea and that the output per man-shift was higher in Britain than in any other European coal fields except those of Upper Silesia. After 1918 the European countries began again to compete with British coal mines for the export market, and at the same time considerable advances in methods of production were being made abroad while scarcely any improvements were being made in Great Britain. In 1913 the output per man-shift in Great Britain was 21.5 cwt., and in 1930 it was 21.6, but during the same period it had improved from 18.6 to 26.6 in the Ruhr, from 23.6 to 28.6 in Silesia and from 16.2 to 24.5 in the Netherlands. The stoppage of 1926 also compelled foreign buyers to obtain coal elsewhere, and some of the markets then lost were never fully regained. Table XVI shows the movements of British coal exports to the principal European markets.

The Samuel commission was fully alive to the disadvantages under which the British coal industry laboured because of its methods of production and its lack of proper organization, and its recommendations in large measure determined the course of later parliamentary legislation. The Mining Industry act of 1926 was passed to facilitate amalgamation of mines so that they could be worked on a more economical basis. The Coal Mines act of 1930 attempted to introduce a greater degree of compulsion. In addition, executive boards were set up to determine quotas of production for each coal-mining district, and provisions were made for

TABLE XVI.—*Coal Exports*
(In tons)

Destination	1913	1930	1939	1952	1954	1955

Spain	2,534,000	1,712,000	—	549,315	309,814	81,740
Portugal	1,202,000	1,136,000	771,000	305,093	301,158	349,690

the sale and transfer of quotas within each district. This act was only partially successful in overcoming the opposition of the owners to amalgamation. but the provisions concerning quotas succeeded in maintaining price levels and were extended until 1938, when the Coal act provided for the vesting of all the unworked coal in Great Britain in a coal commission, which was empowered to acquire it from the owners for a sum which had been set by a special tribunal at £66,450,000, and to administer the leases held by the mining companies. At the same time the commission received far wider powers to enforce reorganization and amalgamation. On July 1, 1942, the commission took over its rights in unmined coal, but its plans for organization were suspended in 1939 by the outbreak of war.

World War II virtually enforced the nationalization of the coal industry. Government control was established in June 1942, and by 1945 organization existed for planning production, increasing efficiency and maintaining manpower and welfare. The industry saw that the essential aspect of public ownership (viz.. centralization and concentration on efficient pits) would have to remain. The Foot plan (Jan. 1945) recommended establishment by the industry of a central coal board having authority over the whole of the industry, with powers of integration through the amalgamation, compulsory if necessary. of collieries. This principle mas admitted in different terms in the Technical Advisory committee's report (March 1945), which drew attention to the difficulty of eliminating uneconomic mines and to the industry's chronic financial embarrassment. Under C. R. Attlee's first Labour government, the National Coal board was constituted (July 1946) and the industry was taken over on Jan. 1, 1947. The compensation procedure was protracted over a number of years. The Nationalization act concentrated the responsibility for management with the board and provided no statutory machinery for decentralization. Under the board a number of divisions, and under these a number of areas, were set up. The Burrows committee (Nov. 1948) indicated that the board was not devoting enough time to general questions and that overcentralization existed.

During the decade preceding World War II profits were insufficient for the installation of new machinery. Manpower was not concentrated at the most productive units and mechanization was underdeveloped. The great bulk of British coal (86% in 1949) was won by longwall mining, which does not easily lend itself to mechanization. Capital investment was gradually increased during the early 1950s. Under a plan drawn up in 1950, more coal was to be produced in parts of Scotland, in east Durham, Yorkshire, the east midlands. north Staffordshire and Kent, and less in west Durham, Lancashire, parts of Cannock Chase. the Forest of Dean and Somerset. Little scope was found for developing new coal fields. Coal began to be imported on a growing scale in the mid-1950s. Opencast coal mining was begun in 1942. A peak of 12,440,000 tons was reached in 1949.

Other Minerals.—Table XVII gives the British output of some of the principal minerals since 1913.

Iron Ore.—Iron ore is very much the most important of these minerals, and it will be seen that production declined considerably during the decade 1923–32, though it recovered again in 1934. The quantity of imports is shown in Table XVIII.

The great bulk of British iron ore is produced in England, the most productive counties being Yorkshire. Lincolnshire, Northamptonshire, Cumberland and Staffordshire. The richest ores come from Cumberland, Lancashire and Staffordshire. Output reached a maximum in 1943, after which it declined. Production in 1951 was still above the immediate prewar average, however.

Tin Ore.—Tin ore is obtained almost exclusively from Cornwall. The fall in production (to 2,050 tons in 1935) was accompanied by an increase in retained imports. The capture of Malaya by the Japanese early in 1942 and the consequent cutting off of the principal sources of imports inevitably led to increased home production of tin. By 1950, however, production had fallen to 1,000 tons. In 1953 imports amounted to 62.363 tons.

Lead.—The British output of lead declined between 1919 and 192j, while imports rose. After 1926 this trend was reversed for a time. In 1949 no important reserves existed except for some small deposits at Wanlockhead in Scotland. In 1954 imports came to 197,500 tons.

TABLE XVII.—*British Output of Some of the Principal Minerals*
(In tons)

Year or average of years	Iron ore and ironstone	Tin ore, dressed	Lead ore, dressed	Zinc ore, dressed
1913–22	12,318,000	5,716	16,539	8,419
1923–32	9,843,000	3,511	21,942	1,603
1933–42	13,879,000	2,903	33,670	8,071
1943	18,488,000	2,216	5,323	7,775
1944	15,472,000	2,169	5,104	15,469
1945	14,175,000	1,648	3,588	6,360
1946–49	12,437,500	1,377	3,450	—
1950	12,963,000	1,390	4,193	71
1951	14,777,000	1,790	6,093	353
1952	16,232,000	1,549	7,418	2,777
1953	15,818,000	1,467	10,034	3,388
1954	15,557,000	1,397	11,057	2,475

TABLE XVIII.—*Iron Ore Imports**

Year	Tons	year	Tons
1913	7,442,249	1951	8,747,480
1919	5,200,696	1952	9,693,864
1924	5,917,393	1953	10,981,063
1939	5,308,416	1954	11,611,257
1945–49†	6,988,372	1955	12,896,400

*Including manganiferous ore. †Average.

Copper.—At one time Great Britain supplied almost three-quarters of the world's copper. By 1949 the richer deposits in Cornwall were exhausted and no evidence existed that new deposits were likely to be discovered.

Zinc.—Zinc was formerly mined chiefly in north Wales, the north of England, the Isle of Man and Dumfriesshire. In 1949 no important reserves were known to exist.

China Clay (Kaolin).—This mineral is of great importance in the ceramic, papermaking, bleaching and chemical industries. The whole British supply is derived from Cornwall. A large but varying amount is exported. Output was 776,621 tons in 1913, fell to a wartime minimum of 178,000 tons in 1943 and recovered to 974,000 tons in 1954. Imports are negligible in quantity.

Fluorspar.—This mineral is of considerable importance in the manufacture of steel and in other branches of metallurgy. The British production first became substantial at the beginning of the 20th century. Most of the acid-grade spar comes from Derbyshire. Reserves were estimated at 1,336,750 tons in 1949. Annual output was 69,000 tons in 1954.

Barytes.—This is an extender for paint and filler for linoleum, etc. Production was 66,400 tons in 1938 and 75,000 tons in 1954. The biggest field is in Shropshire and Montgomeryshire.

INDUSTRIES

Industrial Development.—The change from peasant to industrial civilization in Great Britain is thus described by J. L. and Barbara Hammond in The Rise of *Modern* Industry (1926) :

> The wants of the ordinary man were supplied in the early middle ages, as in the days oi Greece and Rome, either by himself and his family, or by his neighbours; in the next stage these wants were supplied by special persons plying a craft, in a village or small town, organised sometimes in guilds; in the third stage the provision of those needs became the business of individual or group production and large scale merchanting ; in the fourth it became the business of large scale production. At that point the world passes to the industrial age; to an age in which commerce and finance are no longer aspects, growing in importance, yet still aspects of its life, but the basis on which a society depends.

Though England was comparatively late in becoming a great commercial power, it was the first to develop the industrial system. Before the discovery of America and of the Cape route to the east, trade centred in the Mediterranean and the Mediterranean nations were the chief European traders. The opening of the Atlantic routes transferred commercial supremacy to the nations possessing coast lines facing them. First came the monopoly of Spain, broken by the defeat of the Armada in 1588; from that time till 1660 the Dutch led, their chief rivals being Great Britain and France. From 1660 till the end of the 18th century the two latter countries fought for commercial supremacy, which then passed to Britain. It was the development of large-scale commerce in Britain that made possible the development of that country's industrial system, since without wide markets the capital required for the development of machine production would not have been forthcoming. All through the 17th and 18th centuries England was developing its overseas trade and its home market side by side. The 18th century was marked by a long period of stable government at home. The development of the road system in the 17th century and of the canals in the 18th made the home market easy of access, while the establishment of a colonial empire stimulated overseas trade.

These were favourable conditions for industrial development, and this was helped forward by the Protestant refugees from Antwerp at the end of the 16th century, by the Huguenot refugees after the revocation of the Edict of Nantes, and by the Dutch immigrants who followed William III. By these were laid the foundations of British cotton, silk and other industries.

More important still was the existence of great coal supplies, which were made mobile by the development of the canal system. It was British coal that made possible the creation of a large iron and steel industry, and the development of machine production and of the steam engine. But this development could not have been brought about without the existence of enterprise and imagination of a high order, and the 18th century was the period which saw the birth of those inventions which made the industrial system a possibility. James Watt's first patent was taken out in 1769, and by the end of the century the steam engine was in use in mines, foundries, cotton mills, etc. The iron industry, dependent during the 17th and early 18th centuries on charcoal, began to languish with the gradual exhaustion of British forests. Coal began to be used effectively in blast furnaces as early as 1709. The use of coal in forges was made effective about 1785, thus altering the whole aspect of the iron industry, and the introduction of the steam engine was the finishing touch. The output of pig iron rose from 25,000 tons in 1720 to 68,000 tons in 1788; to 253,000 tons in 1806; and to 1,347,000 tons in 1839.

The cotton industry had a similar story. In spite of the exceptionally favourable climatic conditions in Lancashire, the English industry consumed only about 2,000,000 lb. of raw cotton annually during the early part of the 18th century. The invention of the flying shuttle for weaving in 1733 and of the spinning jenny less than 30 years later revolutionized the industry. Until 1785, however, the mills had to depend on water power. That year marked the introduction of the steam engine and the creation of the great cotton industry, which was to become the greatest exporting industry of the country, sending no less than 80% of its huge annual production overseas. In 1833 this industry, which 100 years before had used little more than 2,000,000 lb. of raw cotton annually, was importing no less than 300,000,000 lb.

"From the 12th to the 19th centuries the woollen industry was the premier English industry, and as such was largely responsible for the growth of the country's wealth and so for the accumulation of capital which has rendered possible the development of the homeland and the empire" (L. D. Stamp and S. H. Beaver, The British Isles, p. 442 [1933]). Originally the greater part of the wool produced in the country was shipped abroad for manufacture, but weaving gradually increased in importance and by the end of the 15th century England was "largely a nation of sheep-farmers and clothmakers." During the 16th and 17th centuries there were various periods, especially in the first half of the 17th century, when the industry suffered severely from foreign competition, but eventually the English cloth trade surpassed that of Flanders, and by the end of the 17th century woollen manufactures made up two-thirds of England's export trade. Workshops were scattered all over the country wherever the conditions of wool supply and running water for power purposes made the locality convenient. To this day the industry is very much more scattered than the cotton industry, although the great majority of it is now centred in the West Riding of Yorkshire whither it migrated when use of coal for power purposes began to develop. Subject to the above differences, the woollen industry followed very much the same course as cotton.

The story of these great industries was repeated in others, and it may be said that, before the introduction of railway transport during the second quarter of the 19th century, factory production was established in every important branch of industry. The establishment of the railways was the crowning achievement. enormously facilitating as it did the mobility of the working population, the supply of raw material and distribution of the finished commodities. With it the industrial system reached its characteristic form. The only further fundamental change was the introduction of the use of electrical power in the 1880s and, in transport, the introduction of the internal-combustion engine.

As to the general development of British industry, the first three-quarters of the 19th century saw a very rapid increase of production and export. From the middle of the century onward, however, the rate of increase in exports of manufactured goods began to fall, while the rate of increase of imports was accelerated. This tendency was a marked feature of the period after 1919.

1919 to 1939.—The immediate effect of the cessation of hostilities at the end of World War I was to create a boom in industry and trade which lasted for a little more than 18 months. By the end of 1920 there were clear signs of depression, which reached its peak in the winter of 1921–22. This depression was partly the result of currency disturbances abroad, but it was felt most in industries in which foreign competition was severest: coal mining, iron and steel, shipbuilding and cotton. Though 1924 saw a general return to prosperity, the industries just mentioned failed to recover from the depression; unemployment was rife in them, and it gradually became clear that England was becoming divided into two economic units, the prosperous south and the depressed north (with which must be included south Wales), where most of the industries alluded to were concentrated.

Elsewhere, however, the period 1924–29 was one of prosperity; employment remained steady and foreign currencies had been stabilized. New industries sprang up, and some, such as the manufacture of motorcars and electrical goods, made unprecedented progress.

Financial crisis in the United States late in 1929 was the forerunner of a world depression in trade and industry of exceptional severity. Unemployment rose alarmingly, and recovery was unusually slow, since it was not marked until 1937. As in 1924 the newer industries recovered first, and those which were already suffering most continued depressed. Recovery was aided by the abandonment of the gold standard, and the government hoped to stimulate it by the adoption of protective tariffs. The attempt made at the Ottawa conference to weld the empire into an economic unit was not so successful. It seemed in 1938 that another period of depression was approaching, but rearmament produced an improvement in the coal-mining, steel and shipbuilding trades.

There is little doubt that British industry was ill fitted to meet the difficulties with which it was faced between 1918 and 1938. It was only gradually realized that a return to trade conditions as they were in 1913 mould never come, and that the productive capacity of certain industries was greatly in excess of the demand. Equipment was out of date and capital for modernization difficult to obtain; organization and marketing badly needed overhauling. Only the newer industries, such as the motorcar industry, were able to follow the example of the United States and develop mass production. It took many bitter years to convince owners and employers in the depressed industries that the closing down of uneconomical works, amalgamation and reorganization offered them their only hope of salvation. This. however, is not the whole picture, in spite of the fact that problems of industry and unemployment were urgent throughout the period. London and southern England, on the whole, grew and prospered, largely at the expense of the depressed areas, and in certain fields of international trade Great Britain more than held its own.

Some idea of the progress of the principal industries during the 20th century can be formed from the various censuses of production. Before 1907 no such census had been undertaken; another was begun in 1912, but not completed because of World War I. Thereafter they were made in 1924, 1930, 1935 and 1948. In comparing the figures for these years some allowance must be made for variations in the purchasing power of money; for instance, 1907 figures should be increased by about 50% for accurate comparison with 1935. (See Table XIX.)

TABLE XIX.—*Industrial Production in Great Britain*

Product	1907	1935	1954
Coal (thousand tons)	266,558	221,624	224,090
Gas (thousand million cu. ft.)	196.29	303.4	514.8
Electricity (million kw.hr.)	..	17,568	74,706
Iron ore (thousand tons)	8,184	10,920	15,557
Crude steel (thousand tons)	636	9,880	18,520
Pig iron (thousand tons)	6,988	6,448	11,883
Motor vehicles			
Cars	8,800	338,304	769,165
Commercial		85,572	572,970
Locomotives (steam)	..	717	1,270*
Aircraft	..	644	388
Shipbuilding (thousand gross tons)	..	..	1,493
Cotton woven cloth (million linear yd.)	7,076	3,081	1,994
Woven wool fabrics (million sq. yd.)	418.39	261.8†	414.4
Rayon filament yarn (million lb.)	..	107.88	219.6
Rayon staple fibre (million lb.)	..	11.04	228.0

*Including diesel electric. †Linear yards.

Ajter World War II.—Like its predecessor, World War II introduced a drastic change. Inventiveness and investment were directed toward the production of arms and of ancillary products such as electrical equipment. The consumption goods industries, pre-eminently the textile industry, were deliberately restricted. After the war these trends continued to develop. The output of civil aircraft, motor vehicles, agricultural machinery, machine tools and electrical, textile and office machinery strikingly exceeded the prewar level. The output of textiles. on the other hand, though it recovered from the wartime restrictions, failed to rise significantly above the prewar level. One aspect of these changes was the greater output of capital goods and a corresponding vulnerability to the fluctuations of the trade cycle. Another potential weakness was introduced by the Distribution of Industry act, 1945, which sought to assist the former "special areas" (renamed "development areas") by favouring the establishment of industries within them. This was done through the licensing of factory construction by the board of trade. In this way certain industries were brought to the resident population rather than the other way about, and the economic significance of a favourable location was disregarded.

Industrial output was high during the early postwar period. From 1938 to 1954 the index of industrial production rose by 52%, while the number of persons employed in manufacturing industry rose by 20%. Much of the increase in production was the result of very full employment. The number of hours worked reverted to something nearer the prewar figure.

It follows that (if the war years are excluded) productivity increased at a flat rate of about 4.3% a year—a rate well above the prewar normal. This increase probably reflects fairly accurately the net additions of new plant and machinery to the national stock, additions which were kept low by scarcities, heavy taxation and high consumption.

Public Utilities and Power.—In 1954 the amount of coal used in gasworks and for the generation of electricity by public undertakings was 67,000,000 tons, or 33% of the total home consumption. Of this, 27,000,000 tons were used for gas and 40,000,000 for electricity. Domestic consumption accounted for about 32% of electricity generated under the electricity authority.

Gas.—The products of the gas industry for selected years are shown in Table XX. The gas industry was nationalized by the Gas act, 1948. Vesting day was May 1, 1949, when 1.037 undertakings passed into state ownership. For purposes of management

TABLE XX.—*Gas Industry Output*

Product	1935	1948	1951	1954
Total gas made (million cu. ft.)	303,400	448,430	498,135	514,800
Coke and breeze	7,640,000	13,497,000*	15,044,000*	15,163,000*
Tar (tons)	951,000	1,655,000	1,849,000	1,934,000
Sulphate of ammdnia (tons)	75,000	69,000	81,000	84,000

*Excluding that used for heating retorts. †64,000 in 1942. ‡Total of census.

the emphasis rests on the gas boards of the 12 areas into which Great Britain is divided. Above them is the Gas council. which deals with wider tasks. The council advises the minister of fuel and power on general questions, and assists the area boards. The latter deal with the development and supply of gas and coke (except metallurgical) and with the recovery of by-products. A gas consultative council in each area acts as a link between the boards and the public.

Compensation was paid to the former proprietors in 3% guaranteed gas stock, 1990–95, issued and redeemable at par.

Generation *of* Electricity.—Problems of electric supply were the object of considerable parliamentary attention after 1918. In that year a committee, headed by Sir Archibald Williamson, reported that electricity was generated and supplied by more than 600 different concerns, each with a monopoly within its own small district. The committee recommended that generation and distribution should be concentrated in 16 districts, and that a board of electricity commissioners should be set up with full powers. As a result the Electricity (Supply) act of 1919 was passed; the Electricity commission was set up, but provision was made only for voluntary co-ordination. so that it was not until the passage

TABLE XXI.—*Sales of Electricity*

Item	1948		1954	
	Units sold (million kw.hr.)	Total revenue	Units sold (million kw.hr.)	Total revenue
Lighting, beating and cooking	18,045	£107,518,000	27,821	£191,058,000
Power	19,581	75,966,000	32,029	152,283,000
Public lighting	257	1,644,000	576	3,376,000
Traction	1,398	5,432,000	1,451	6,738,000
Total	39,281	£190,560,000	61,877	£353,455,000

of the Electricity (Supply) act of 1926 that real progress was made. This act set up the Central Electricity board. The primary duty of this board was to carry out the work of concentrating energy in certain selected power stations and to erect a high-tension transmission line to interconnect these stations and link the regional systems into a national grid. The board did not own the generating stations and had no control over distribution. Its function was to make production more efficient through concentration and co-ordination. It was given power to obtain land compulsorily for wayleave purposes. By these means, frequencies were standardized and much uneconomical duplication was eliminated. The board derived its revenue from supplying bulk energy to the authorized systems, which supplied to the consumer. The members of the board were nominated by the minister of transport. The economies effected by the grid system are illustrated in Table XXII, which shows the average selling price in pence per unit of electricity over the years 1924, 1935, 1948 and 1954.

TABLE XXII.—*Electricity; Average Selling Price*
(In pence per unit)

Item	1924	1935	1948	1954
Lighting, heating and cooking	4.4	1.9	1.4	1.6
Power	1.2	0.7	0.9	1.1
Public lighting	2.3	1.2	1.5	1.4
Traction	1.1	0.6	0.9	1.1
Average	1.6	1.1	1.2	1.4

In 1937 a committee under Sir H. McGowan reported that it was still possible to establish greater uniformity in supply, voltages and tariffs, and recommended a substantial reduction in the number of systems. The report was accepted in principle by the government, but the pressure of international affairs prevented any legislative action. (This relative decentralization of the system enabled it to withstand the effects of German bombing.)

The British electricity industry mas nationalized on April 1, 1948. About 540 local electricity undertakings were taken over. At the head of the system stands the Central Electricity authority, which enjoys wider powers than the Gas council; under it are 12 area boards in England and Wales. In southern Scotland the South of Scotland Electricity board operates. The authority is responsible for the production of electricity and its supply in bulk to the boards. These, like the authority, are statutory corporations appointed by the minister. For purposes of management, the power stations and grid are divided into 14 generation divisions, which agree approximately with the regions under the area boards and buy electricity from the authority. The system covers Great Britain except for Scotland. where the secretary of state discharges the functions of the minister of fuel and power.

After the end of World War II the electricity industry continued its expansion. From 1938 to 1955 capacity increased from 9,365,000 kw. to 22,572,000 kw.; output from 25,708,000,000 kw hr. to 81,837,000,000 kw.hr.; and utilization of plant from 36.7% to 48.1%. The price of electricity was kept fairly low. Demand continued to exceed supply; the spread of electrification was a striking aspect of the postwar development of Great Britain.

TABLE XXIII.—*Aggregate* Capacity of *Generating* Sets

Table XXIII shows the types and capacity of the various generating plants in Great Britain in 1951. The numbers employed in the generation, transmission and distribution of electricity were 41,000 in 1924; 65,000 in 1930; 87,000 in 1935; 151,000 in 1948; 181,000 in 1951; and 195,000 in 1956.

Iron and Steel.—Table XXIV shows the amount of iron and steel produced (in thousands of tons) over a number of years, classified according to method of production.

The average number of blast furnaces in operation was 99 in 1938, rose to 105 in 1953, but declined to 100 in 1954. Steel furnaces rose from 619 in 1938 to 728 in 1954. While open-hearth furnaces declined from 446 (1938) to 397 (1954), electric furnaces rose from 104 to 232.

In the third quarter of the 19th century Great Britain produced half the world's output of pig iron and was by far the largest steel-manufacturing centre. But though the British output steadily expanded. world production increased on a much faster scale, and by 1913 Britain was producing little more than a tenth of the world total. During World War I the demand for weapons and munitions enforced the modernization of a somewhat lagging industry and brought about a great extension of production capacity, but after the war the industry soon began to encounter difficulties.

Productive capacity had been similarly increased in other parts of the world, and, while Britain maintained its policy of free trade, the iron and steel industry had to face competition from countries which were maintaining their own industries behind tariff barriers and at the same time had free access to the British market. In addition, the industry suffered heavily from the depression during 1931 and 1932, when unemployment was more than 40%.

Improvement began in 1933 with the imposition of a high tariff on imported iron and steel products, and the creation of the British Iron and Steel federation in 1934 was the first step in the reorganization of the industry on a more economic basis.

By 1937 recovery had made considerable progress and the industry was in a position to meet the demands first of rearmament and then of war.

After 1939.—The outbreak of World War II in 1939 found the British iron and steel industry repairing the injuries of the depression. More than £50,000,000 had been spent on modernization in the years immediately before the war, and the annual steelmaking capacity had been raised by about 2,000,000 tons. During the war steel production (about 12,750,000 tons a year) averaged barely 1,000,000 tons more than during the last years of peace. At the same time new steels, especially alloys, were developed. Plants suffered heavy wear and tear.

The industry's £240,000,000 postwar development plan was designed to continue the process of modernization and expansion interrupted by the war, the biggest of many projects being the integrated Abbey works of the Steel Company of Wales. By the end of 1950, £169,000,000 was actually spent. By 1954 pig iron production had been raised from 8,000,000 tons to 11,900,000 tons and steel output from 13,000,000 tons to 18,520,000 tons.

Increased capacity was accompanied by greater integration, more continuous processes, bigger furnaces and higher fuel efficiency, and the introduction of the continuous working week in steel melting shops. These developments had the full support of the trade unions, and between the end of the war and 1954 output per man rose by about 25%. Many new techniques and products were introduced, notably the special alloy steels for high-temperature work, which played an important part in the development of jet-propelled aircraft. The integration of works allowed the spare ores of Lincolnshire and Northamptonshire to play a growing part in the industry. The establishment of integrated works permitted the output of a relatively finished product direct from the raw materials, and it became economically practicable to provide for a continuous flow of certain types of product and hence for the continuous rolling mill. This in turn permitted the establishment of continuous heating furnaces as opposed to in-and-out batch furnaces. These developments had begun in the late 1920s, but continued with increasing vigour after World War II.

Since before the war the industry's central organization, the British Iron and Steel federation, provided common services to supplement the activities of the individual firms under general government supervision. During the war the ministry of supply iron and steel control formed the link between government and industry and ensured that the demands of the war effort were met. Between 1946 and 1949 public supervision was exercised by the Iron and Steel board, representing the employers, the trade unions, the treasury and consumers under an independent chairman. The

Labour government's Iron and Steel act of 1949 transferred about 80 of the largest iron-and-steel-producing companies to public ownership in Feb. 1951, by vesting their securities in the new Iron and Steel Corporation of Great Britain. The Conservative government began to denationalize the industry in 1953.

TABLE XXIX.—*Foreign Trade in Nonferrous Metals and Manufactures Thereof*

Imports and Exports	1939	1955
Imports	£32,717,394	£243,934,000
Exports	£15,658,397	£239,957,000

Increases over the period before 1914 were substantial, especially in the production of aluminum and of tin manufactures. Table XXIX gives the import and export figures.

Engineering. — Since it became possible to manufacture machinery with any degree of precision, engineering has held an important place in the British economy, though one vulnerable to the fluctuations of the trade cycle. A particularly important place was acquired during the 1930s by electrical engineering.

During this period the foreign trade oosition of the electrical industry was very satisfactory, since Great Britain's position as the chief exporting country in the world was challenged only by the United States, Germany (which easily led the world before 1914) having dropped back in the race. In spite of setbacks caused by the depression of the early 1930s, the industry continued to expand.

The average number of persons employed in general engineering establishments in 1938 was 913,000; in 1947 it was 1,261,000.

During World War II the engineering industries naturally expanded. They retained much of their added importance after the war, working partly for the industrial re-equipment of the country and partly for new industries developing abroad. The number of persons employed, including a large proportion of women, was about 49% greater in 1954 than in 1938. During this period exports of engineering products formed a greatly increased proportion of the total of British exports. Tables XXX and XXXI give an idea of the development of machinery output.

TABLE XXX.—*Machinery Output, by Value*
(In thousands of pounds)

Type	1935	1948	1951	1954
Mechanical engineering	103,178	452,864	763,500	1,067,000
Electrical engineering	55,846	225,629	379,000	498,400
Marine engineering	12,434	51,905	68,500	95,600
Locomotive manufacturing	17,878	61,062	70,200	90,700
Textile machinery, parts and accessories	12,000	59,000	76,000	70,000
Machine tools (metalworking)	6,000	33,000	49,000	66,000
Stationary internal-combustion engines	4,000	27,000	43,000	44,000
Mining machinery	3,000	17,000	20,000	20,000
Printing, bookbinding, etc., machines	3,000	11,000	18,000	18,000

TABLE XXXI.—*Agricultural Machinery Output*
(In units)

Type	1938	1946	1950	1954
Tractors	10,679	47,046	150,488	166,791
Plows	12,580	99,947	55,490	36,573
Mowing machines	4,641	9,338	27,076	19,554
Milking machines	...	6,041	19,447	10,238
Harvester-threshers	—	125	4,325	6,120

Motor and Cycle Industries. — Production figures in quantities and values for the motor and cycle trades were as shown in Table XXXII. The number of persons employed in the motor and cycle

TABLE XXXII.—*Motor and Cycle Industry*

Product	1907	1924	1935	1951
Complete motor vehicles, including commercial (number and value)	9,800 £3,323,000	133,400 £34,757,000	377,561 £58,354,000	739,258 £296,443,000
Complete chassis, including commercial (number and value)	£859,000	22,454 £8,113,000	63,697 £13,661,000	
Motorcycles (number and value)	£139,000	120,422 £5,877,000	64,600 £2,624,000	181,990 £17,494,000
Cycles (number and value)	615,300 £3,396,000	704,352 £3,859,000	1,987,000 £6,664,000	3,786,000 £30,380,000
Engines and parts (value)	£1,845,000	£29,366,000	£47,218,000	£231,036,000*

*Excluding motor bodies.

industries increased from 53,639 in 1907 to 169,288 in 1924, to 224,568 in 1935, to 316,150 in 1948 and to 338,000 by the end of Dec. 1955.

Import and export figures are given in Table XXXIII.

The motorcar industry enjoyed a measure of tariff protection, with but one brief interval, from 1915 on, and was enabled to develop while other industries were still feeling all the effects of foreign competition in the home market.

After the outbreak of war in 1939 the industry suffered for a time from declining markets, and it was not until after the fall

TABLE XXXIII.—*Value of Foreign Trade in Motorcars and Chassis*

Year	Imports				Exports			
	Cars		Chassis		Cars		Chassis	
	Number	Value	Number	Value	Number	Value	Number	Value
1913	6,820	£1,700,000	7,958	£1,900,000	7,595	£2,400,000	1,234	£500,000
1924	14,717	3,000,000	12,459	1,800,000	19,315	5,100,000	9,735	2,300,000

1951	2,415	1,134,000	1,308	188,000	309,119	108,200,000	59,618	10,900,000
1955	11,127	4,503,000	1,034	201,803	322,452	112,800,000	50,751	9,700,000

*Including chassis of commercial vehicles.

of France, in June 1940, that it was fully mobilized for war production. An important section of the industry was transferred to the manufacture of aeroplanes, but in 1942 it was producing tanks and other military vehicles at the rate of 257,000 a year. After World War II motorcars became an important export. In order to simplify production the range of models was reduced and much was done to standardize components. This process was accompanied by a structural simplification, and by 1956 only 20 independent car manufacturers remained. Experiments with gas turbines indicated an important technical development.

Aircraft Industry. — Production figures for various years from 1924 onward were as shown in Table XXXIV.

TABLE XXXIV.—*Aircraft Trade*

Item	1924	1930	1935	1951
Value of products .	£4,j54,000	£8,688,000	£13,919,000	£188,757,00c

Number of establishments .	20	A7	52	215

*Excluding military types except those for export. †Figures withheld for security reasons.

The figures in Table XXXIV reflect the very satisfactory progress of a young industry, but the actual number of aeroplanes produced in 193j was still considerably less than the number produced in 1918. Although the production of military aircraft was steadily increased from 1938 onward, it was not until after the middle of 1940 that the full urgency of the need for an air force capable of repelling German attacks became apparent.

Aircraft production was undertaken on a previously unparalleled scale during the last part of the year, and for a time became the most vital part of the British war effort. The rate of production was more than maintained, and by the first quarter of 1942 it was double that of the last quarter of 1940. World War II gave a powerful impetus toward new developments, and this was maintained during the internationally uneasy first decade after the war. The reciprocating engine was strongly challenged by the turbine; pure jet and turbojet engines were used to power bigger and faster aircraft for both military and commercial requirements. Aircraft of unusual shapes were becoming commonplace as new wing shapes (delta and swept-back) and metals were developed in attempts to overcome the thermal barrier.

Cotton. — Cotton Spinning. — No effective comparison can be made between 1907 and 1924 or later years, since no particulars were recorded in 1907 of the output of yarn used for manufacturing purposes by the spinning firms. The figures of output for 1924 and various later years are as shown in Table XXXV.

TABLE XXXV.—*Output of Cotton Yarn and Waste*
(Weight and value in thousands)

Output	1924	1935	1948	1951
Goods made for sale

1955*	93,190	180,130	273,320

*Estimate at end of May.

With 1918 the cotton industry declined seriously and it was unlikely that it would ever regain the position in world trade it once occupied. The causes of this decline were twofold: increased competition abroad and insufficient adaptability within the industry at home. . Improved methods of production rendered obsolete much of the equipment of the Lancashire cotton mills, but replacements were not made, and the industry was unable to organize itself more economically by such means as amalgamation, joint marketing schemes, etc. Countries such as India and China which were formerly customers themselves became producers, and the rapid expansion of the Japanese cotton industry introduced the severest competition in world markets. The Cotton Industry act, designed to reduce the excess capacity of the industry and to increase consumption, was passed in Aug. 1939, but the coming of war prevented it from having the desired immediate effect. During the war many of the cotton factories were taken over and converted for various types of war production.

During World War II the cotton textile industry suffered the penalty for not being directly connected with the prosecution of the war. Raw materials mere rationed, production was concentrated in a restricted number of plants and labour was diverted to other tasks. The labour shortage persisted after the war and prevented the industry from sharing the general industrial expansion which then began. Soon after, the growth of cotton textile industries abroad threatened to provide a more lasting barrier to recovery. The industry continued to suffer from inadequate equipment and from excessive fragmentation. Nevertheless, through the inducement of a re-equipment subsidy, the Labour government did bring about a substantial consolidation of interests in the spinning section. In its search for export markets the industry moved strongly toward the manufacture of finer counts.

Woollen and Worsted Industries. — SemimanufacturedProducts. — The totals of semimanufactured products for 1907 and various later years are given in Table XXXIX.

TABLE XXXIX.—*Woollen and Worsted Production*
(In thousands of pounds)

Product	1907	1924	1930	1948	1955
Tops or slubbing	243,500	285,529	; A	275,929	309,500
Noils	430,000	535,785	385,989	404,336	538,800
Yarns . .					

Woollen and Worsted Fabrics. — The total values of woollen and worsted fabrics for the same years as those shown in Table XXXIX were as follows: (1907) £40,294,000; (1924) £89,578,000; (1930)

£59,960,000; (1948) £137,883,000; (1955, provisional returns) £618,200,000. Foreign trade figures are given in Table XL.

TABLE XL.—*Foreign Trade in Woollen and Worsted Products*
(In thousands)

Product	1913	1924	1930	1948	1951	1954
Yarns (lb.)						
Imports	32,994	17,801	19,058	9,673	6,809	3,145

Exports	168,374*	221,563	113,753	98,035	118,728	99,000

*Linear yards.

The wool textile industry followed roughly the same course as the cotton industry after 1918, though its decline was far less serious. It was, however, subjected to similar foreign competition, losing considerable markets in the far east, and as partial recovery came after the depression years there was growing concern over redundancy of plant, with consequent attention to schemes of control and planning. Other developments affecting the industry were the increased use of synthetic fibres and attempts abroad to find substitutes for wool. Within the industry itself there was an increased demand for woollens at the expense of worsteds and for knitted fabrics at the expense of woven ones. Such factors influenced regional unemployment, since the various branches of the industry were highly localized.

The woollen and worsted industries underwent a contraction during World War II. They also maintained a high degree of specialization. Foreign competition was far less severe, and for a number of years after the war the industries' products were among the country's most valuable manufactured exports. The capital equipment, however, was tending toward obsolescence. The average number employed in the industry was 264,021 in 1907; 274,397 in 1924; 230,342 in 1930; 242,209 in 1935; 183,668 in 1948. It remained fairly steady for the next six years and estimated numbers at the end of May 1955 were 207,000.

Silk and Synthetic Fibres.— Output and employment figures are shown in Table XLI.

TABLE XLI.—*Silk and Synthetic Fibres*

Year	Value of gross output	Average number employed
1907	£5,236,000	32,198
1924	20,299,000	39,932
1935	36,110,000	81,825
1951*	200,800,000	92,200
1954*	198,400,000	84,300

*Provisional census returns.

This industry showed a steady expansion, as a result of the development of synthetic fibres. It is significant that before 1924 there are no statistics of production distinguishing synthetic fibres from silk, but in 1924 the output of natural silk and mixtures was valued at £3,558,000 and that of synthetic fibres and mixtures at £3,308,000. By 1935 the balance of production had changed remarkably; natural silk and mixtures had decreased to £1,579,000, but the value of synthetic fibres and mixtures had reached a total of £17,028,000.

After 1924 exports overtook imports and till 1939 the excess of exports over imports was steadily growing.

The synthetic fibre industry continued to expand after World War II. Unlike the production of other textiles, that of synthetic fibres remained in the hands of a small number of large undertakings. Nylon, first produced in the United States in 1939, assumed importance as a British manufacture after the war. Output of Terylene (known as Dacron in the U.S.) for 1956 was forecast at over 11,000,000 lb.

TABLE XLII.—*Foreign Trade in Synthetic Fibres, Yarn and Fabrics*

Year	Imports	Exports	Year	Imports	Exports
1924	£5,515,178	£4,310,225	1939	£1,957,670	£4,674,993
1930	7,545,626	5,934,853	1948	7,557,467	37,825,308
1935	2,948,759	3,985,781	1955	11,829,855	33,902,954

Forestry and Timber.— Great Britain was once heavily forested, but centuries of timber cutting and clearing have denuded the country of the original forests. In Europe as a whole about 31% of the surface is covered with timber, but in Great Britain, in spite of its well-wooded appearance, barely 4% of the surface is thus covered. It was estimated in 1926 that there were roughly 3,000,000 ac. of woodland of all types in the island.

World War I showed how dependent Great Britain was on imported timber, and stocks of native trees were seriously depleted to meet wartime needs. In 1919 a forestry commission was set up to meet the situation, and it embarked on a scheme for planting 1,777,000 ac. over a period of 80 years. By the end of 1938 it had acquired 1,097,000 ac., of which 340,638 ac. had been planted. A special feature of the activities of the commission from 1936 onward was its attempt to combine reafforestation with relief of the distressed areas in northern England and south Wales.

During World War II felling had to be undertaken on a large scale. Domestic production consequently dwindled and remained on a low level for several years after the war. From the peak of 1943 to 1954 production fell from 216,500,000 to about 87,000,000 cu.ft. Reafforestation was undertaken after the war. Great Britain is dependent on imported timber; exports are negligible. After World War II a reafforestation program began. It aimed at producing 5,000,000 ac. of fully productive forests.

Building Materials.— The production of these materials and the average number of persons employed in certain years are as shown in Table XLIII. It should be noted that the figures for 1930 and 1935 include returns made by certain firms which were assigned to the building and contracting trade for 1924. The number of persons employed in 1930 by these firms was about 2,000.

TABLE XLIII.—*Clay and Building Materials Manufacture*

Year	Value of gross output	Average number of persons employed
1907	£9,599,000	...
1924	9,599,000	20,307
1930	13,930,000	29,731
1935	15,045,000	30,561
1954*	126,600,000	67,000

*Provisional census returns.

Several items of interest are included under these headings. Thus, tar-paving and other road materials in 1930 were valued at £6,360,000 (Great Britain), whereas the total for 1907 was only £308,000, including Ireland. This reflects the increasing wear and tear on the roads through motor traffic. Another symptom is the heading of £1,649,000 for contract and job work on roads in 1924 (including paving materials used) for which no counterpart is to be found in the earlier year. Other items which increased materially as a result of the development of new methods of construction were artificial stone and roofing felts.

TABLE XLIV.—*Building and Contracting Industry*

Year	Value of gross output	Average number employed
1907	£87,967,000	513,993
1924	193,494,000	514,353
1930	194,288,000	453,807
1935	216,000,000	502,300
1954*	1,911,400,000	1,650,300

*Provisional census returns.

TABLE XLV.—*Furniture, Cabinetmaking and Upholstery Manufacture*

Year	Gross output	Average number employed
1907	£12,063,000	76,415
1924	26,108,000	67,555
1930	33,815,000	91,948
1935	33,015,000	91,093
1954*	161,600,000	105,200

*Provisional census returns.

After World War II building materials grew in variety; heavy arrears had to be made good, and standard materials such as timber were hard to get for several years. Innovations which seemed likely to stay comprised the greatly extended use of cement and artificial stone, plasterboard in place of plaster and laths for walls and ceilings, concrete and hollow blocks for floors and bituminous asphalt as a substitute for lead and zinc on roofs.

Chemical and Allied Industries. — The total output of chemical manufactures in 1907 was valued at £24,025,000. The figures for 1935, 1948, 1951 and 1954 were as shown in Table XLVI.

TABLE XLVI.—*Chemical and* Allied Trades
(In millions of pounds)

Product	1935	1948	1951	1954*
Total	194.6	452.4	1,283.3	1,707.9
Mineral oil refining . . .	7.8	42.5	181.3	302.0
Drugs and medicinal products .	19.0	73.0	111.3	125.5
Coke ovens and by-products .	16.5	75.1	93.8	...

Explosives and fireworks . .	7.1	18.6	32.0	...
Toilet preparations and perfumery	6.4	17.1	25.0	...

*Provisional census returns.

The average number of persons employed was as follows: (1907) 52,257; (1924) 66,962; (1930) 70,475; (1935) 77,611; (1948) 165,532; (1955, May 31 est.) 519,490. The dominating position in the British chemical industry is held by Imperial Chemical Industries. Ltd. (*q.v.*).

When war broke out in 1914 British factories were equipped for manufacture of explosives only on a small scale, and the industry had to be expanded rapidly with government assistance. The position with regard to dyes and dyestuffs was even worse, since more than 80% of the world output came from Germany and only 2% from Great Britain. As a result the German patents were revoked, and by 1917 the essential requirements of the country were being met. After the mar the strategic importance of the industry was fully realized, and it was maintained by means of the Dyestuff (Import Regulations) act, which came into force in 1921 and prohibited imports except under licence. Though Germany recaptured the greater part of the export trade that it had formerly had, British output of dyestuffs in 1937 was 31,633 tons as against 63,000 tons in Germany.

The chemical industry expanded rapidly during World War II and was further strengthened by the Patents and Designs act, 1950. The productive capacity was estimated at £350,000,000 in 1948 and continued to expand rapidly for a number of years. Particular attention was given by the government to the refining of crude petroleum. Other new developments included, among chemical fibres, the production of nylon and Terylene and, in the pharmaceutical branch, of antibiotics, in particular of penicillin. Chemicals played a greatly increased part among exports.

The imports and exports of chemical manufactures are given in Table XLVII. It will be seen that British exports considerably exceed the imports.

TABLE XLVII.—*Foreign* Trade in Chemical Manufactures

In spite of vicissitudes corresponding to general trade cycles, the record of the glass industry was one of development and expansion. The manufacture of glass was revolutionized after the beginning of the 20th century through the replacement of old methods by automatic and semiautomatic machines, which enormously increased productive capacity. New uses for glass were found, and many new types of glass were developed. The output of glass containers more than doubled between 1935 and 1952.

Rubber. — In 1938 Great Britain imported 168,200 tons (including synthetic) of crude rubber, of which 132,000 tons were retained for manufacturing; in 1954, 262,900 tons were imported, of which 236,400 tons were retained. In 1950 the gross output of the rubber trade was £162,069,000. Table LIII shows the values of the principal rubber manufactures.

The rubber industry of Great Britain, like that of the United States, suffered severe dislocation early in 1942 when the Japanese, by occupying Malaya and the Netherlands Indies, captured the principal sources of the world's rubber supply. After the war this was reversed. By 1948 imports of rubber exceeded the 1938 level and continued to expand. Tires and tubes remained the most important items of production.

Wartime Organization of Industry.—Comparatively little had been done before Sept. 1939 to put British industry on a war footing, although a certain amount of effective planning had been begun. In the aircraft industry, for instance, "shadow" factories had been organized, and new factories, as well as extensions of existing ones, had been authorized during 1938. But, in spite of many governmental controls, British industry, during the first eight months of war, followed a "business as usual" policy.

The complete reorganization of industry on a wartime basis did not begin until after the fall of France. First the aircraft industry, and gradually every other industry, was brought to the maximum of war production, until only the barest needs of the civilian population were supplied by such factories as were allowed to continue producing their usual products.

Control of Industry.—Until March 1942 production was directed by a production executive under the war cabinet. Under the production executive there were four main committees, and decentralization of the handling of production problems was achieved through the work of 11 regional boards.

Under the Emergency Powers act, the government specified that it should control: (1) the production, storage, distribution and consumption of all articles, and the price at which they might be sold or hired; and (2) charges for any aspect of essential work.

Many steps were taken to ensure the employment of machinery, materials and labour with maximum economy.

After the entry of the United States into the war the national effort was directed primarily toward procuring a maximum of manpower rather than toward the reorganization of industry, and for the rest of the war the severest shortage was that of workers. Censuses were taken of all types of machinery, and the machine tool control of the ministry of supply was strict in removing tools which were not fully employed. The regional boards and capacity clearing centres were active in exposing delays and bottlenecks. Finally the government had the power to appoint a controller to manage any business when it deemed it necessary. In the early stages of the war civilian supplies were cut down by the Limitation of Supplies order, which restricted supplies of certain raw materials to wholesalers working for the domestic market. This method was eventually superseded by a system of direct regulations and prohibitions for a wide range of civilian goods.

Concentration of Industry.—In March 1941 the president of the board of trade initiated a new plan for concentrating production of civilian and export goods in a reduced number of factories. In each industry a number of firms were to select "nucleus" firms to handle all their production. The latter were to work full time and would be guaranteed adequate labour and raw materials. The remaining firms were closed or converted for the duration of the war, their labour, machinery and factory space thus becoming available for the production of war goods. By April 1, 1942, after one year of operation, concentration had released 195,560 workers from 31 industries and it was expected that an additional 30,000 workers would be released. By March 1944 the total number of persons so released came to 290,000. Factory space thus made available was reallocated by the board of trade, and during the first year 52,000,000 sq.ft. of space was thus reallocated, one-third for production, two-thirds for storage.

Control of Labour.—In June 1940 steps were taken to prevent competitive bidding for skilled workers. An order was issued providing that workers in essential industries could be engaged only through the ministry of labour's employment exchanges.

By Oct. 1941, 19,000 undertakings had been scheduled under the various orders, including undertakings in the merchant navy, coal mining, building and civil engineering, iron and steel, dock labour, agriculture, railways, shipbuilding and cotton manufacturing. By June 1942, 8,000,000 workers were covered under the Essential Work orders.

Within industry itself there was a considerable growth of joint (*i.e.*, employers' and employees') machinery for the regulation of wages and working conditions. A further striking development in collaboration was the formation of joint production advisory committees within the factories to stimulate production.

Production.—No specific figures for output were issued, but it was clear that by mid-1942 British production was nearing its peak. Using the production of Jan. 1941 as equivalent to 100, production in June 1942 had reached the equivalent of 244 for aircraft and 289 for "other warlike stores." During the later years of World War II the claims of the fighting services led to a decline in the total volume of production.

Effects of the War.—The final impact of the war on the country's capital equipment was different in different sectors. From the beginning new investment had been strictly controlled and on balance there was a substantial loss in capital equipment. At the end of the war it was estimated that nearly 750,000 extra workers would be needed simply for the maintenance and renewal of plant. Maintenance and equipment were inadequate in transport, docks, gas, electricity, water and drainage and in all the manufacturing industries except metals, engineering and chemicals. The mines were somewhat and agriculture was much more heavily mechanized at the end of the war than they had been at the beginning. This distribution of investment exerted an important influence on the postwar development of industry.

EXTERNAL COMMERCE

British commerce underwent an enormous development after the first quarter of the 19th century. In 1826 the aggregate value of the imports into and exports from the United Kingdom amounted to no more than £88,758,678; the total rose to £110,559,538 in 1836 and to £205,625,831 in 1846. In 1856 the aggregate of imports and exports had risen to £311,764,507, in 1866 to £534,195,956 and in 1876 to £631,931,30j. Thus the commercial transactions of the United Kingdom with foreign states and British colonies increased more than sevenfold in the course of 50 years.

The important fact about the foreign commerce of the United Kingdom during the 20th century is that there was a steady increase in imports but no corresponding steady increase in exports of British produce and manufactures. Many industries, which formerly were mainly in British hands, were developed on the continent of Europe, in America and to some extent in the east. The movement began in 1872. Up to that time the exports of British home produce had kept on increasing with the imports, although at a lesser rate and far inferior aggregate value; but a change took place in the latter year. While the imports continued their upward course, gradually rising from £354,693,624 in 1872 to £375,154,703 in 1876, the exports of British produce fell from £256,257,347 in 1872 to £200,639,204 in 1876. The decline in exports, regular and

steady throughout the period, and with a tendency to become more pronounced every year, affected all the principal articles of British home produce. The external trade of the United Kingdom from 1875 onward is shown in Table LVI, which gives the total values of net imports, exports and re-exports.

The figures in Table LVI show for the earlier period a favourably steady upward movement in both imports, exports and re-exports, subject only to a decline in the five years 1885–89. The figures for 1919 and 1920 reflect the severe inflation of prices in those years, since they exceed by almost 2½ and 3 times, respectively, the average value of the imports for 1910–13, although the actual increases were only about 89.7% and 87.8%, respectively, over the 1913 imports. After 1919 there was a continued decline in the value of some important export commodities (textiles, coal, ships, iron and steel), but between 1924 and 1929 the value of nearly every other class of British exports showed an increase. In 1931, however, at the height of the depression, the disparity between imports and exports became so serious that Great Britain abandoned the gold standard and turned from free trade to protection. It was hoped to build up a system of imperial preference so that empire markets should be held and at the same time to use the tariff as a means of bargaining with other countries; but, while it is true that some industries were undoubtedly stimulated by protection, most economists agree that this change of policy was not the primary cause of Great Brit- [illegible] The plain fact is that "the depreciation of sterling and the adoption of protection left the volume of British exports much lower, and the amount of unemployment appreciably higher, than before the great depression" (F. Benham, *Great Britain Under Protection,* pp. 222–223. In 1933 both exports and imports started on an upward course which continued until 1939.

The excess of imports over exports, which was a feature of British trade balances after 1872 and which rose as high as £463,000,000 in 1926, is counterbalanced by the so-called "invisible" exports. These consist of the earnings of British shipping, insurance, commissions and London financial services. To them must be added the income from overseas investments and from the tourist industry.

While Table LVI does not include capital movements, it suggests reasons why Great Britain was able, as in 1928, to bear an apparently adverse trade balance of £352,000,000. On the other hand, the over-all adverse balance of current items amounting to £100,000,000 in 1931, together with the drain of gold from the country, caused the abandonment of the gold standard and the adoption of protective tariffs. The table also suggests that Great Britain's recovery from the depression was due to internal causes and not to a revival of exports, since in the very prosperous year of 1937 there was nevertheless an adverse over-all foreign balance of about £56,000,000. After 1939 the country had to draw heavily on its capital resources.

Between 1913 and 1930 the percentage of the total British trade with the commonwealth changed little. After the Ottawa conference of 1932, this trade increased. This is shown in Table LVIII.

Table LIX shows the geographical distribution of U.K. trade for certain years. Imports from Europe declined, but re-exports increased. The effects of Japanese competition are visible in the decline of exports to Asia, while the increase in trade with Oceania is largely the result of the Ottawa agreements.

World War II and After.—The outbreak of war in 1939 greatly increased the problem of earning enough by exports to pay for imports, which, of course, included munitions of war. The difficulty did not lie in finding markets—the elimination of German exports and general shortages made it certain that anything exported would be readily bought—but in getting the raw materials and labour needed to produce the goods. In tackling this problem the state directed labour and allotted the raw materials, while production and marketing were left to private enterprise. This arrangement worked fairly well, though the value of exports (1935 prices equalling 100) fell steadily from 94 in 1939 to 56 in 1941, after which the position was altered by the entry of the United States into the war.

The volume of imports decreased as the war went on, partly from shortage of money and partly from shortage of shipping. The weight of imports of food and feeding stuffs fell from an annual

average of about 22,000,000 tons for 1934–38 to one of 10,800,000 tons for the first half of 1944. Imports of raw materials fell even more heavily. The shortage of shipping made necessary some thoroughly uneconomic developments: thus, while imports of iron ore fell by about two-thirds, those of steel ingots, semifinished steel and finished steel more than doubled.

These concomitants of total war destroyed anything approaching a balance of trade. The deficit was financed partly by the realization of foreign securities (these were reduced by fairly equal stages from £3,545,000,000 capital value in 1938 to £2,417,000,000 in 1945 and to £1,960,000,000 in 1948), partly by the accumulation of debts (the so-called sterling balances, which in June 1945 amounted to £3,052,000,000) and partly by lend-lease supplies from the United States amounting to £2,426,000,000 net. The existence of the sterling balances and the loss of foreign investments continued for several years after the war to overhang the British balance of trade. Another legacy of the war was the formation of the sterling area—that is, the large but shrunken region in which the pound sterling continued to be freely convertible.

The distribution of British overseas trade was profoundly affected—and distorted—by the war. After the war the world could be divided into five main areas: (1) the dollar area, a source of vital imports but too nearly self-sufficient to be an easy market for exports; (2) the rest of the western hemisphere, less important but relatively untouched by war; (3) the countries of the Organization for European Economic Cooperation (O.E.E.C.), trying to build up their injured economies by reciprocal action and U.S. aid; (4) other nonsterling countries; and (5) the sterling areas. Of these, the dollar area, the most important, took in 1938 about 10% of British exports and furnished about 22% of British imports. In 1947 the respective figures were 9% and 35%. After this, strong efforts were made to redress the balance, and by 1954 the balance of trade with North America was more satisfactory. The percentages for (2) underwent no great change, but those for (3) and (5) showed a greater orientation of British trade toward the O.E.E.C. and toward the rest of the sterling area. These increases occurred at the expense of (4), the other nonsterling countries, including of course the U.S.S.R. and the countries in its orbit. The structure of British overseas trade also underwent a substantial change. In 1938 imports of food. drink and tobacco made up about half the total, the rest being divided fairly equally between raw materials and manufactured articles. In 1945 this pattern had not greatly changed. But during the following nine years the share of food, drink and tobacco shrank until, in 1954, it made up only about 40% of the total. Raw materials gradually came to predominate, while imports of manufactured articles formed a smaller part of the total than in 1938.

In its main outlines, the structure of exports remained as it was in 1938, with manufactured articles dwarfing all other exports. (The only important raw material to be exported before World War II, coal, could not be spared in large quantities after 1945.) Within the list of manufactured exports some significant changes occurred: those of capital goods (notably electrical goods and machinery) became more important, while textiles, which had been growing less important before the war, fluctuated a good deal: but roughly held their position.

Unbalanced Trade.—From the outbreak of war until the end of 1954 the structure and distribution of British trade were less important than the net balance. This varied widely from year to year and was affected by political as well as by economic factors. The chief causes of the unbalance lay in the difficulties of the U.S. market and in the fluctuating terms of trade. The cost of this unbalance was high: U.S. and Canadian loans worth £1,210,000,000 and European Recovery program aid aggregating $2,694,000,000 were used up in an attempt to maintain the balance.

SHIPPING AND SHIPBUILDING

Shipping.—The movement of British shipping from 1910 is shown by Table LX.

A feature of the situation before 1914 was the steady increase in British tonnage accompanied by a considerably more rapid increase in German, Scandinavian, Dutch and Spanish tonnages. In 1890 British tonnage represented 71% of total entrances and clearances, but the average proportion for 1910–13 was only 57%. From 1919 to 1928 British shipping seemed to be recovering its position, and in 1928 the percentage of entrances and clearances rose to 67%. Later, however, it steadily declined and in 1938 was 57%, a proportion almost identical with that of 1913.

TABLE LX.—*Tonnage of Vessels Entered and Cleared at British Ports*

Year	Entered		Cleared	
	British	Foreign	British	Foreign
1910–13 average	42,828,465	30,712,572	43,075,761	30,934,772
1925	52,020,734	31,997,047	52,839,274	32,450,835
1935	46,840,294	38,699,029	47,286,438	38,829,148
1939	45,353,000	34,845,000	44,832,000	35,061,000
1940	30,746,000	10,914,000	31,163,000	10,335,000

1943	16,754,000	13,847,000	17,333,000	13,706,000
1944	27,305,000	29,632,000	27,506,000	29,608,000
1945	32,801,000	22,840,000	33,104,000	22,651,000
1946	32,945,000	17,427,000	33,499,000	17,979,000
1947	36,753,000	17,605,000	37,128,000	17,572,000
1948	40,646,000	22,750,000	41,484,000	22,907,000
1949	42,771,000	24,363,000	43,115,000	24,537,000
1950	43,529,000	27,680,000	44,274,000	27,973,000
1951	44,905,000	33,355,000	44,886,000	33,614,000
1953	48,108,000	39,224,000	48,276,000	39,344,000
1954	49,884,000	40,668,000	50,280,000	40,736,000

World War I brought about a great change in the relative position of the chief maritime countries. An immense quantity of tonnage was destroyed by combatants, the total being estimated at 14,202,000 tons, of which Great Britain's loss was 5,202,000 tons. On the other hand, the United States added to its fleet no less than 6,729,000 tons. The world net loss of tonnage was, therefore, 7,473,000 tons. The German merchant marine, however, which in 1913 numbered 5,082,061 tons, was in 1921 reduced to 717,450 tons by surrender of reparation tonnage to the Allies.

The war years and those immediately succeeding witnessed a very high rate of construction. The result was that world shipping, which in 1914 aggregated 45,409,000 tons and in 1918 had sunk to less than 39,000,000 tons, had increased to 47,897,000 tons by the middle of 1919 and to 70,131,000 tons by 1931. It sank in 1935 to 64,886,000 tons, but by 1939 it had risen again to 69,440,000 tons. (For shipping losses in World War II *see* **SHIPPING INDUSTRY**: *World Merchant Fleets.*)

After World War II construction went rapidly ahead. World shipping rose to 80,290,000 tons in 1948 and to 100,569,000 tons in 1951. The total number of persons employed on vessels of a gross tonnage of 100 tons or more, engaged in home and foreign trade, was 236,188 in 1930. The number sank to 182,391 in 1935, and in 1952 it was 167,240. The number of persons employed on sea, river and canal transport was estimated at 223,500 in the census of 1951.

Shipbuilding.—The total value of the gross output in the census years of ships and for all classes of work, including repairs, for private shipyards in the United Kingdom, together with the average number employed, is shown in Table LXI.

Table LXII, taken from Lloyd's *Annual Summary of Shipbuilding*, gives the tonnage of merchant vessels launched in the United Kingdom and the total tonnage for the world from 1921 to 1955.

Fluctuations shown in Table LXII were shared fairly equally by British and foreign shipyards, but the table also illustrates the significant decline of shipbuilding in the United Kingdom. In 1913 the output of British yards constituted 58% of the world total, but between 1931 and 1939 it was only about 30%.

In 1946 the British output recovered to 53%, but the recovery of foreign yards brought the British share back to 26% in 1954.

One development in shipbuilding in which British yards had only

TABLE LXI.—*Shipbuilding*

1954*	305,800,000	221,100

*Provisional census results.

a limited share was the construction of motor ships. Their increasing popularity was a result, first, of the disorganization of the world coal industry between 1919 and 1926 and, second, of a growing demand for oil tankers and the enormous increase in the use of fuel oils. A comparison, based on a table given in *Lloyd's* Register, is given in Table LXIII of the numbers of steel motor ships of 100 gross tons and more launched in the United Kingdom and in the rest of the world from 1936 to 1955.

*Nonpropelled craft excluded after 1940 †Excluding the U.S.S.R.

By 1955 Great Britain was producing a large proportion of motor tonnage built, and much pioneering work was done in the development of the high-pressure steam turbine and of the electric drive.

At the outbreak of the war in Sept. 1939, the Germans immediately began a campaign of unrestricted sinking of merchant shipping. The occupation of Norway and the Atlantic coast of France in 1940 gave German submarines a far greater number of ports from which to operate than in World War I. British losses were heavy. The aggregate loss of British merchant shipping, from Sept. 1939 to Aug. 1946, amounted to 11,677,475 tons.

TABLE LXIII.—*Steel Motor Ships of 100 Gross Tons and More Launched*

Year	United Kingdom	Other countries	Year	United Kingdom	Other countries
1936	120	330	1947	187	299
1938	99	499	1948	182	406
1940	70	119	1949	181	407
1941	76	118	1950	151	529
1942	73	125	1951	172	614
1943	86	110	1952	179	650
1944	131	101	1953	135	722
1945	95	247	1954	163	778
1946	143	212	1955	196	992

During the war merchant shipping construction had to compete with the claims of the navy (over which it was at times given priority) and of repairs. The output of new tonnage was never sensational, the highest being 1,270,714 in 1942. A number of important technical improvements were made. After the pact of Munich (1938) it was found that some shipyard equipment was badly out of date, and in 1942 a modernization scheme, to cost £6,900,000, was approved. For the construction of some small craft prefabrication was adopted, and by 1943 some companies were building landing craft in 24 months where they had formerly taken 6 months. But the industry as a whole continued to suffer from obsolete equipment until well into 1943. After the war merchant building expanded steadily, and in 1954 G.K. launchings reached 1,408,874 tons. Large-scale welding had been introduced during the war; later its use was extended, for instance, to boilermaking. In tanker construction (tankers increased rapidly in size and number) the use of longitudinal frames developed. The long-term trend toward the construction of faster vessels generally continued, and the use of motor propulsion expanded rapidly.

See *Lloyd's Register of Shipping* (London, annual); *Shipping World Yearbook and Who's Who* (London, annual); *Fairplay's Annual Summary of British Shipping Finance* (London, annual).

TRANSPORT AND COMMUNICATIONS

Railways. — The first line of railway for regular passenger service, that from Stockton to Darlington. 38 mi. in length, was opened on Sept. 27, 1825. The first really important railway was the line from Manchester to Liverpool, opened on Sept. 15, 1830. The first sod for the London-Birmingham railway was cut at Chalk Farm, London, on June 1, 1834. All the great railway systems of England sprang into existence within less than ten years after the opening of the London-Birmingham line. The railway companies were at first authorized only-to construct and maintain the permanent way, charging tolls to the owners of locomotives and freight cars and coaches which used the lines. The next step was that they became providers of the locomotives which hauled the privately owned freight cars and coaches. Finally the companies became providers also of the freight cars and coaches, except in the case of mineral cars on the London, Midland and Scottish, Southern and Great Western railways.

There were 40 mi. of railway in Great Britain in 1825, 293 by 183j and in 1850 a total of 6,621 mi. The number of passengers carried per mile of railway increased from 4,860 in 1832 to nearly 12,000 in 1842.

At the outbreak of World War I in 1914 the government took complete control of the railways. guaranteeing the companies their prewar revenues. The fact that the war lasted for more than four years, and involved a far-reaching rearrangement and redistribution of the trade and traffic of the country made the strict terms of the agreement practically inapplicable. A large sum of money was required to put the companies back into their prewar condition of repair and efficiency. Rolling stock had been removed to other countries, stations closed, permanent may and other plant allowed to fall into comparative disrepair, staff seriously depleted and the arrangements for routing of traffic widely altered, The costs of operation had also risen enormously.

TABLE LXIV.—*Freight and Passenger Traffic Mileage and Receipts*

Item	1938	1945	1954
Passenger traffic			
Sumber of journeys	1,237,200,000	1,371,800,000	991,200,000
Estimated passenger-miles	18,993,000,000	35,248,000,000	20,712,000,000
Estimated average distance per journey (miles)	15.9	26.9	21.1
Average receipt per passenger journey (pence)	11.38	27.63	27.44
Average receipt per passenger-mile (pence)	0.74	1.03	1.35
Freight traffic			
Freight, mineral and livestock (tons)	265,700,000	266,400,000	274,040,000
Estimated net ton-miles	16,266,000,000	22,023,000,000	22,048,000,000
Average receipt per ton-mile (pence)	1.34	1.81	2.96

The government, foreseeing the difficulties which would arise if control were suddenly removed, passed in 1919 the Ministry of Transport act, which gave the minister powers to control the operation and charges of all existing means of internal transport. Later there was passed the Railways act, 1921, under which:

1. The 120 railways of Great Britain were amalgamated into four large groups, the Southern, the Great Western, the London, Midland and Scottish and the London and North Eastern. (The passenger transport of London and its suburban areas was separately amalgamated and placed under the London Passenger Transport board in 1933.)

2. A new tribunal called the Railway Rates tribunal was set up, its most important function being the regulation of fares and rates and conditions of carriage.

The Railway Rates tribunal was responsible for introducing a new classification of merchandise into 21 classes to determine freight charges, and it drew up a schedule of standard charges to which the companies were obliged to adhere. Somewhat more latitude was allowed the companies in determining passenger fares. The principle by which rates were fixed was defined in the act when it stipulated that they should "yield, with efficient and economical working and management, an annual net revenue equivalent to the aggregate net revenues in the year 1913 of the constituent companies." This was £50,000,000, a figure which actually was not reached until World War II. Under the 1921 act the relations of the companies and their employees were to be governed by an elaborate system of conciliation councils, of which the chief were the Central Wages board and the National Wages board. In addition, the companies received from the government £60,000,000 in final settlement of all war claims—a sum which brought to nearly £150,000,000 the amount thus paid.

The economic condition of the railways after World War I was dominated by their rigid cost structure on the one hand and the emergence of formidable competition from road transport on the other. The railways were badly hit by the world slump of 1929–32, and the companies made a vigorous attempt to cut costs by reducing wages by 10%. A cut of less than 5% was secured, but the companies gave notice of their intention to withdraw from the National Wages board and the Central Wages board. After a temporary breakdown new conciliation machinery was established in 1935, and the railway owners concentrated their attention on the fight against the competition of road transport.

Under the 1921 act the railway companies were not allowed to maintain any road services, and it was not till 1928 that this provision was relaxed. Thereafter they attempted to acquire and maintain some of the services which had been competing against them. But the situation was far from satisfactory.

A royal commission, appointed in 1928, issued its lengthy and inconclusive final report on the co-ordination and development of transport in 1931, and in the following year a conference of rail and road experts, under the chairmanship of Sir Arthur Salter, made a number of more restricted, but more practical, recommendations, some of which were embodied in the Road and Rail Traffic act of 1933. By this act local traffic commissioners were empowered to license vehicles carrying goods, authorize routes and prevent duplication. This system worked fairly well until 1938, when the railway companies began an agitation for freedom from legislative shackles.

On the outbreak of World War II the minister of transport took control of the railway companies and the London Passenger Transport board. The railways were to be paid a sum based on the prewar profits which in 1941 was altered to a fixed annual payment of £43,000,000. During the war the railways' receipts largely exceeded this sum. The number and length of passenger journeys increased, while the number of trains running was reduced. The average load carried by passenger trains was 125% greater than before the war. These special conditions ended soon after the war, while costs continued to rise. By the middle of 1946 they were 70% above the prewar level. From 1947 the railways ran at a loss. In 1955 a 15-year modernization scheme, to cost about £1,200,000,000, was announced.

Nationalization.—A radical change in the entire transport system was introduced by nationalization, which was effected through the Transport bill of 1946 (enacted in 1947 and brought into force on Jan. 1, 1948). The object was to secure "the provision of an efficient, adequate, economical and properly integrated system of public inland transport." The machinery of the act placed the minister of transport at the head. Under him was the Transport commission, with five executives, in charge of railways, road transport. docks and canals, London transport and hotels. Large powers of direction were reserved to and sometimes employed by the minister of transport.

Integration proved a slow and difficult undertaking. The lack of progress toward it, as well as political considerations, caused Winston Churchill's Conservative government to pass the Transport act (May 1953) for denationalizing the road transport services and decentralizing the railways. The act abolished the executives except the London Transport executive. Further changes were effected in Oct. 1953 and Jan. 1955. The British Transport commission was put in charge of major policy and general direction, while a measure of departmental authority was transferred to the six geographical regions into which the railway system was already divided. The Railways Reorganization scheme provided for further decentralization by transferring powers to the area boards, one of which was set up in each region. The boards were given wide powers of initiative and management.

A high level of business activity helped in the optimum utilization of existing resources. The average train load in 1938 was 125 tons; in 1951 it was 162 tons. In British Road services—the nationalized haulage concerns—empty vehicle-miles tended to form a lower percentage of loaded vehicle-miles run. But these indications of efficient and progressive practice were not accompanied by clear proof that the main objective—integration—was being achieved. Co-operative machinery was extended—in 1948 a standing conference for co-operation was set up, and in 1949 liaison conferences between the different executives were established. Under the Transport act of 1947 road transport was nationalized with the exception of vehicles carrying a trader's own goods. A vacillating policy was followed with regard to these services. Under Winston Churchill's government vehicles began to be sold back to private owners, but in 1955 it was decided to retain the larger vehicles. A sort of compromise between integration and competition was thus reached.

Canals.—The majority of the canals in Great Britain were built during the early stages of the Industrial Revolution and before the railway era, so that they fell more and more into disuse with the development of more modern methods of transport.

The British canal system labours under serious disadvantages in comparison with the much greater systems on the continent. British canals are narrow; the frequent locks slow down transport; there is a good deal of duplication; and multiplicity of ownership hinders the most economical working. The amalgamation in 1930 of eight canal companies into the Grand Union Canal company enabled 300 mi. of waterway, linking London and the midlands, to be improved so as to accommodate 100-ton barges.

During World War I the use of canals for transport increased considerably, and with the outbreak of war in 1939 there was a similar increase. A central canal committee was set up in 1941 to co-ordinate six regional committees, and the canals, which before World War II carried an annual total of 15,000,000 tons, were handling much larger quantities, particularly of coal, under government supervision. After the war the canal system was nationalized under the Transport act. Traffic by 1954 had dropped to 12,250,000 tons, mostly fuel in various forms. For an account of proposals in the early 1950s for the reorganization and development of canals *see* INLAND WATER TRANSPORT.

Roads.—"The high road, a hundred years ago, was not the grass-grown desert of the present time; it was alive with traffic and gaiety," wrote William Makepeace Thackeray in The Virginians (1857). His point of view was that of the railway age, but later years saw a return to the conditions of the 18th century on a scale previously undreamed of. The modernization of British roads owed most to the passage of the Development and Road Improvement Funds act of 1909, which based the road improvement fund on the proceeds of a gasoline tax and provided for its nationwide administration.

The enormous increases in expenditure on roads and their upkeep are shown in Table LXV.

There were, by 1954, in Great Britain 187,040 mi, of public highways, of which 95% were hard-surfaced. These were divided into the following classes: (1) trunk roads, 8,250 mi., the direct responsibility of the minister of transport with moneys for their maintenance and improvement provided entirely from central funds; (2) class I roads, 19,533 mi.; (3) class II roads, 17,697 mi.; (4) class III roads, 48,682 mi.

Roads thus classified are maintained by the county and urban highway authorities whose areas they pass through. Apart from county boroughs these highway authorities receive state grants of 75%, 60% or 50%, according to the classification of the roads. The remainder of the roads are unclassified and receive no grants-in-aid.

The great extension in the use of roads is a result, of course, of the development of the internal-combustion engine. There were 17,810 motor vehicles in Great Britain in 1904, 45,020 in 1906

TABLE LXV.—*Expenditure Other Than Loan Charges on Highways and Bridges, Great Britain**

Year	Expenditure	Year	Expenditure
1912–13 . . .	£15,876,057	1938–39 . . .	£58,284,000
1923–24 . . .	50,556,085	1946–47 . . .	60,598,000
1929–30 . . .	65,469,691	1950–51 . . .	72,836,000
1936–37 . . .	58,528,000	1953–54 . . .	90,335,000

*This table gives expenditure on class I, II, III and unclassified roads. Class III roads were adopted as from 1946. Expenditure on trunk roads is included from 1938, when they were introduced.

and 388,860 by 1914. Increases after that time are shown in Table LXVI, which gives the number of licensed vehicles in 1922, 1930, 1938, 1945 and 1955.

After 1918 the more striking developments in road transport were the establishment of rural bus services, which opened up the English countryside. and the growth of public haulage services, which seriously competed with the railways.

To cope with the constantly growing volume of traffic on the roads various measures were adopted. Ribbon development (*i.e.,* the building of houses for miles on either side of main roads leading out of towns, to the detriment of traffic) was restricted

by an act of 1935. More and more bypasses were built so that main-road traffic could skirt the towns on the route. The Trunk Roads act of 1936 put 4,460 mi. of main roads under the direction of the ministry of transport instead of the local authorities to ensure their uniform development.

From Sept. 1939 onward, war conditions greatly affected the use of the roads. In July 1940 the manufacture and sale of new cars was stopped. On June 30, 1942, allowances of gasoline for private cars ceased and private motoring was no longer possible.

After World War II the number of road-using vehicles increased substantially. Between Feb. 1939 and Feb. 1952 they increased from 2,571,000 to 3,820,000 (government-owned vehicles excluded) and to 6,412,000 by Sept. 1955. During the first decade after the war nothing was done to provide a road system to cope with the increased traffic, though a development plan was put forward in 1954.

Tramways.—An act passed in 1870 to facilitate the construction of tramways throughout the country marked the beginning of their modem development, but they did not spread rapidly until after 1890. After 1924 they declined, and in 1931 the royal commission on transport regarded them as obsolescent because they "caused much unnecessary congestion and considerable unnecessary danger to the public." It therefore recommended that they should be gradually eliminated.

The number of tramcars licensed in 1924 was 14.448; in 1938 it was 7,207. After World War II the replacement of trams by trolley buses and motorbuses continued. The number of trams licensed in 1953 was 2,560.

Air Lines.—Air transport first became a commercial reality after World War I, the first commercial passenger plane crossing to Paris in Aug. 1919. The first airmail contract was made by the government in the following November. In 1924 the British air lines merged in the state-aided enterprise of Imperial Airways Ltd., a £1,000,000 company with government representation on the board. In 1939 Imperial Airways and British Airways (Imperial Airways' principal competitor after 1924) became, by act of parliament, the government-controlled British Overseas Airways corporation (B.O.A.C.).

Great Britain is ill suited to internal air communications, since distances are so short that the saving of time made possible by flying is of comparatively little consequence. The early air services between Britain and the various parts of the continent were always regarded as steppingstones to the time when it would be possible to link the whole empire by air. The formation of Imperial Airways was the first step in the development of such services. From 1921 to 1927 the royal air force conducted an airmail service between Cairo and Baghdad, and this was taken over by Imperial Airways as soon as it had established its service to Cairo on a satisfactory basis. At first there were difficulties to contend with in Europe, since various European countries placed restrictions on aircraft flying across their territory, but in 1938 the normal route to Cairo was via Marseilles, Brindisi and Athens.

From Egypt, routes were extended in various directions. The Baghdad service went on first to Basra and then, in 1929, to Karachi. Eventually an agreement was reached with the Indian government and the service was extended to Delhi, Calcutta and Singapore and finally, in 1934, after negotiations with the Australian government, to Sydney. Hong Kong was linked to the service in 1935. Services were also extended southward. first to Nairobi in 1931 and then to Cape Town in 1932. Various branch lines connected the west coast of Africa with the system.

The next step was obviously the development of a transatlantic service, and here Great Britain was behind not only the United States but continental countries such as Germany and Italy as well. During 1937 trials were flown across the Atlantic and a regular service was instituted from Bermuda to New York city.

In the extension of all these services the carrying of mails either preceded or began simultaneously with the carrying of passengers. Airmail rates were steadily lowered until the postmaster general (Sir Kingsley Wood) announced the empire airmail scheme, under which all first-class mail would be carried at the normal rate of $1\frac{1}{2}d.$ an ounce. The service to South and East Africa was inaugurated in 1937, and in 1938 it was extended to India, Malaya, Australia and Hong Kong. Table LXVII furnishes some details of the progress of British commercial aviation.

The coming of war in 1939 brought great changes in civil aviation. The government was already in control of British Overseas Airways, and inland air lines were taken over from 1940 until 1945. The empire airmail scheme had to be suspended. The principal wartime developments in transatlantic flying, however, took place in 1941, 400 crossings being made by British Overseas Airways on the northern route in 18 months. When the service began in Nov. 1940 the journey took 16 hours. but two years later it frequently took no more than 8. New Zealand was linked to the empire services in April 1940, and in June 1940 regular services

TABLE LXVII.—*U.K. Regular Air Services; Totals for All Companies**

Year	Number of flights	Passengers carried	Cargo carried (short tons)		Aircraft mileage
			Mails	Freight	
1928	4,800	27,300	93	818	916,000
1938	95,100	222,200	3,867	2,830	14,331,000
1946	89,556	423,500	3,014	4,572	33,017,000

to Lisbon, which immediately assumed the utmost importance, were inaugurated. In 1942 British Overseas Airways was still flying over routes of more than 50,000 mi. Communications with the middle east were maintained via Lisbon, Bathurst and Freetown, and Khartoum. In the summer of 1940 the "horseshoe" route from South Africa to Sydney via India and Singapore came into operation, and it mas maintained as far as Calcutta after the Japanese occupation of Burma. Malaya and the Netherlands Indies. An agreement with the Brazilian government in Nov. 1941 foreshadowed further links between Africa and the two American continents. From 1939 up to about 1946, practically all new commercial aircraft in operation were of U.S. origin, since British factories were concerned solely with war production.

The end of World War II brought two changes: a release of the pent-up forces toward a wide expansion, and nationalization. By the Civil Aviation act. 1946, side by side with the British Overseas Airways corporation, the British European Airways (B.E.A.) corporation and the British South American Airways corporation (both with fields of operation explained by their names) were set up. The latter, after a chequered career, was absorbed by B.O.A.C. under the Airways Corporations act, 1949. The resulting structure left the great bulk of civil aviation in the hands of the state, a small residue being left to private charter and liner companies. The postwar expansion of civil aviation is shown obviously in Table LXVII. By 1955 the main services operated by B.O.A.C. covered New York city, Chicago, Montreal and the Caribbean; Australia, India. Ceylon, Singapore, Hong Kong, Tokyo and the middle east; and Cairo, Accra, Nairobi and Johannesburg. B.E.A. operated services within Great Britain from London to most of the greater cities, the main network following the north-south axis of the islands. In Europe it ran services which fanned out clockwise from the London-Oslo line to the London-Gibraltar line, the greatest density lying in western Europe.

Communication. — The *Post* Ofice. — The first inland post was established in England in 1635. Early charges were *2d.* per 80 mi., *4d.* for 140 mi., 6d. for greater distances in England, 8d. to Scotland. At first the volume of correspondence was very small, and Sir Walter Scott in The Heart *of Midlothian* mentions that one day in the late 17th century the mail from London to Edinburgh consisted of a single letter. The institution of mail coaches in 1784 marked a great step forward. Mails were first sent by rail in 1830, and the penny post was established in 1840. The sending of telegrams was originally in the hands of various telegraph companies, the transfer to the state taking place in 1870. After 1880 the then novel and undeveloped system of telephony was carried on under licence from the state, being held to be within the state telegraph monopoly.

The National Telephone company gradually absorbed all other licensees and obtained a licence which expired in 1911. The state, however, had control of all trunk lines. The National Telephone company's system was transferred to the post office on Jan. 1, 1912. The number of exchanges increased from 1,566 in 1910 to 3,971 in 192j and 5,951 in 1953; the number of telephone stations increased from 619,399 in 1910 to 1,357,908 in 1925 and 5,843,979 in 1953. The use of automatic exchanges developed after World War I. By the end of 1927 these were working in more than 60 provincial towns, and the first automatic exchange in London was opened at Holborn in that year. The same year witnessed a great extension of telephone connection with foreign countries, and in the succeeding years further extensions of the service gradually made it possible to speak by telephone or radiotelephone to practically any town in the world as well as to passenger ships at sea. A popular innovation which gave an impetus to the use of the telephone was the introduction in 1933 of the shilling trunk call between any two points in Great Britain after 7 P.M.

Tables LXVIII and LXIX give some idea of the magnitude of the business handled by the post office. First are given the numbers of letters, parcels, telegrams and telephone calls handled annually, then the balances in the expenditure and income accounts for each of the services. It should be mentioned in connection with Table LXIX that there was an over-all deficit in the post office accounts for the years 1920, 1921 and 1922, but after that the balance was always favourable.

An interesting development during World War II was the institution in 1941 of the airgraph mail to the forces in the middle east. The letters were written on special forms and then photographed on miniature film. The film was flown to its destination, and the addressee received a print from the negative.

After the war the transport of mail by air expanded largely, both inland and overseas, particularly to the commonwealth and North and South America. In 1951 the first "inland" night-mail service was introduced to Northern Ireland and the Republic of Ireland, and air parcels services were being run to most parts of the world. In 1950 the post office took over the assets of Cable and Wireless, Ltd., though the company continued to operate its overseas services and to own the assets pertaining to them.

Cables and *Wireless* Telegraphy. — The first submarine cable was laid across the channel in 1850, and the Atlantic was conquered in 1866. In 1922, when the Eastern Telegraph company, the group which practically controlled the whole system, celebrated its jubilee, the total mileage of cable in the world had grown from less than 1,000 to 325,000 and the capital invested in this one group alone to £25,000,000, with a total for all companies of about £60,000,000. The system, protected by the royal navy, was of extraordinary importance during World War I, for whereas Germany was at a very early stage completely isolated, the British cables were cut at only two points and these were quickly restored.

For several years after 1918 there was severe competition between the cable and wireless companies. In 1924, for instance, the Marconi company entered into a contract with the government to provide beam stations for communication with Canada, Australia, India and South Africa. In 1928, however, the Imperial Wireless and Cable conference recommended the co-ordination of these services, and as a result Imperial and International Communications, Ltd. (name changed in 1934 to Cable and Wireless, Ltd.), was formed to operate most of the extra-European communications. After 1950 it came under post office ownership.

A later development in the telegraphic service was the transmission of photographs and drawings, particularly of news photographs. As early as 1927 attempts were made to work out plans for a two-way service with the United States for transmitting pictures by television, but experience showed that for long-distance transmission the cable was then far superior to wireless.

Cable and Wireless, Ltd., became national property under an act of 1946. The end of the war found the cable system in need of repair. Arrears were not made good until 1950, and development on the whole favoured the wireless side of the undertaking. Long-distance radiotelephony and radiophototelegraphy expanded. Traffic development followed commonwealth lines, particularly to the middle and far east and to the West Indies. The volume of traffic expanded with a tendency to follow the fluctuations of the trade cycle.

BIBLIOGRAPHY.—Annual reports of British Transport Commission, British Overseas Airways Corporation, British European Airways Corporation and Cable and Wireless, Ltd.

AGRICULTURE AND FISHERIES

Agriculture. — In spite of the rapid growth of manufactures and commerce in Great Britain after the middle 1800s, agriculture remains one of the largest industries of the country. It usually employs about 750,000 persons. The area devoted to it in 1954 was about four-fifths of the country's land—more than 47,900,000 ac. out of the total area of 56,200,000 ac. The agricultural output of Great Britain in 1955 was officially estimated at (gross) £1,500,-000,000. A radical change was introduced into British agriculture by World War II. Emphasis was placed on grain at the expense of livestock; at the same time there was a thoroughgoing mechanization. The agricultural land is classified into three groups: arable, permanent grass and uncultivated rough grazings. Table LXX shows the area of each in 1938 and 1955.

In Scotland more than two-thirds of the land used for agriculture is uncultivated rough grazings, mostly of mountain type, while more than two-thirds of the cultivated area is arable-land; in England and Wales about 36% of the cultivated area is under permanent grass and only one-sixth of the agricultural land is rough grazings. In these circumstances the number of persons employed per acre is much lower in Scotland than in England and Wales.

TABLE LXX.—*Land Use, 1938 and 1955*
(In thousands of acres)

Land and year	England and Wales	Scotland	Total
Arable land			
1938	8,878	2,983	11,861
1955	13,423	3,148	16,571
Permanent grass			
1938 . .	15,833	1,577	17,410
1955 . .	11,045	1,239	12,284
Rough grazings			
1938	5,615	10,448	16,063
1955	5,211	10,953	16,164

Apart from the stringencies of war periods. when special efforts were made to produce as much home-grown grain as possible, economic influences for many years prior to World War II had led to the laying down of arable land to permanent grass. The increased production of grains in America and also Australia caused prices of grain to fall and the production of meat and milk to become relatively more profitable, until World War II stimulated the home production of grain.

The reduction in the arable area was relatively less rapid in Scotland than in England and Wales, possibly because of the fact that much of Scotland's arable land would very quickly revert to rough grazings if left for many years under grass. Changes were, however, much less marked in some parts of England than in others, the eastern counties, where rainfall is small and good permanent

pasture difficult to maintain, showing the smallest decreases in arable land.

Areas Devoted to Chief Crops.—During the period before World War II the three chief grain crops did not share equally in the reduction of the grain area; indeed the area under oats increased, the decrease being confined to wheat and barley. In the 50 years from 1871–75 to 1921–25, the area under wheat was reduced by about one-half and that under barley by more than one-third, while the acreage of oats was increased temporarily by one-eighth. The heavy reduction in the wheat acreage, as compared with other cereals, was no doubt mainly a result of the greater fall in price of this grain, while the increase in the acreage of oats was apparently a result of the substitution of this crop for other cereals, as the bulk of it was used for feeding to stock on farms and its selling value was not the chief consideration.

The relatively low prices for grain crops after 1921, as compared with most other classes of farm produce. led to further reductions in the area of grains. Nearly one-half the total acreage of wheat in Great Britain is ordinarily in the ten eastern counties

TABLE LXXII.—*Acreage of Grain Crops in Great Britain*
(In thousands of acres)

Crop	Average. 1871–75	Average, 1928–37	Average. 1941–50	Average, 1951–55
Wheat . . .	3,527	1,592	2,462	2,156
Barley . . .	2,367	1,022	1,906	2,155
Oats . . .	2,672	2,406	3,155	2,749

w

of England from the East Riding to the Thames as far inland as Bedford and Huntingdon, while more than one-half the barley acreage is in the same ten counties. The acreage of oats, on the other hand, is fairly evenly distributed throughout the country, this being by far the chief grain crop in the west and north, where the total arable area is smallest.

The absolute acreage devoted to the main crops underwent a drastic change under the policies adopted during and after World War II. Bet een 1938 and 1955 the biggest percentual increase among the chief crops was that for barley, potatoes, rye and sugar beets. The area devoted to potatoes did not follow the decline in the arable area but increased, in spite of a slight falling off for several years after 1925. This increase in the potato acreage was necessary to meet the requirements of the increasing population. Potatoes were grown most extensively in Lancashire and Cheshire in the west of England and in the south of Lincoln and the Isle of Ely in the east. After 1880 the acreage of potatoes changed little in Lancashire and Cheshire, but in the eastern counties named above and in the adjoining counties the acreage was trebled between 1880 and 1930. Potatoes are also an important crop in some of the eastern counties of Scotland. During and after World

TABLE LXXIII.—*Acreage of Certain Arable Crops and Bare Fallow in Great Britain*
(In thousands of acres)

Crops and fallow land	Average, 1871–75	Average, 1921–25	Average, 1928–37	Average, 1941–50	Average, 1951–55
Potatoes . . .	550	652	615	1,160	969
Turnips and swedes .	2,129	1,249	930	728	585

Bare fallow . . .	627	441	393	294	309

War II potatoes became a most important crop, the acreage being nearly doubled between 1938 and 1950.

The acreage of mangolds was maintained until 1925 because of the value of this crop as a food for dairy cattle, the numbers of which had increased. On the other hand, turnips and swedes, expensive crops to grow and more liable than mangolds to damage by pests and adverse weather conditions, were grown on rapidly declining areas, so that they came to occupy less than one-half the area of 80 years earlier. After the war the unpopularity of turnips and swedes continued. The acreage of clover and rotation grasses expanded very considerably. With the aid of the sugar subsidy sugar beets became a crop of importance.

Yields.—Crop statistics showed little change in the productivity of the land after produce statistics mere first collected in 1885. Average yields per acre of the chief crops in Great Britain are shown in Table LXXIV.

TABLE LXXIV.—*Average Yields per Acre of the Chief Crops in Great Britain*

Mangolds (tons) . .	17.4	20.0	18.5	20.0	23.1

Livestock. — With the conversion of arable land to grass before World War II, livestock became of increasing importance in the agriculture of Great Britain, but the increase was confined to cattle. Pigs fluctuated about a mean which showed little change for many years, but in the 1950s their numbers began to increase rapidly.

Cattle. — Before World War II cattle occupied a predominating position in British agriculture, accounting for about 40% of the total output from the farms of Great Britain. In the 50 years from 1871–75 to 1921–25 the total number of cattle increased by 20%, while the increase in the dairy herd was even greater, the addition being nearly 40%.

In neither case, however, did the increase keep pace with the increase in population, the number of the dairy herd per 1,000 of population being 10% less and of other cattle about 20% less in the later than in the earlier period. The needs of the increasing population for fresh milk were met by the additions to the dairy herd, but this was not the case as regards butter and cheese, of which more was imported as the years advanced. Similarly more and more beef was imported to supply the increased demand. When imports fell during and after World War II consumption was reduced. Despite the war the cattle herd increased considerably from 1938 to 1954, the increase being particularly noticeable for heifers in calf with first calf.

TABLE LXXV.—*Numbers of Cattle in Great Britain*

Year or average	Cows and heifers in milk or in calf	Other cattle	Total cattle
1871–75	2,204,000	3,609,000	5,813,000
1881–85	2,353,000	3,757,000	6,110,000
1891–95	2,562,000	4,078,000	6,640,000
1901–05	2,627,000	4,147,000	6,774,000
1911–15	2,825,000	4,272,000	7,097,000
1921–25	3,053,000	3,942,000	6,995,000
1926	3,207,000	4,244,000	7,451,000
1938	3,576,000	4,454,000	8,030,000
1946	4,067,000	4,649,000	8,716,000
1955	4,487,000	6,060,000	10,547,000

The check in the increase in the number of cattle in 1921–25 was the result of an extensive slaughter of calves at the end of the war food control, primarily because of the decontrol of veal prices in advance of those of other meat; but after 1921 there were increases each year, and in 1938 the number was the largest ever recorded. The density of cattle on the land is naturally larger in the grass areas of the west of the country than it is in the east.

Sheep. — The number of sheep in Great Britain, though fluctuating to some extent, on the whole declined after about 1870. The ravages of liver fluke and unfavourable weather in the first part of this period caused a sharp fall which was subsequently partially recovered, while the numbers were reduced very sharply toward the end of World War I, and immediately thereafter, after which there was a good recovery. Between 1920 and 1926 the flocks of the country were increased by 4,320,000 or 22%. During World War II the sheep population fell by about a quarter, and the severe winter of 1946–47 caused a further heavy fall, after which a recovery began. Changes in the number of sheep in Great Britain have varied, as will be seen from Table LXXVI.

Until 1938 the numbers of sheep were maintained in Scotland and increased in Wales, the reduction being confined to England. A subdivision of the figures for England, however, shows that there was practically no reduction in the northern counties, while in the eastern counties numbers were less than one-third those of 1871–75,

TABLE LXXVI.—*Number of Sheep in Great Britain*

and in every other part of England except the southwest the decreases were about 50% during the same period. The reduction in the sheep population, therefore. was most drastic in the arable counties, and sheep breeding made headway or at least held its own in those areas where costs were low because of the existence of extensive rough grazings on hill land. As a result of World War II, the sheep populations of Scotland and Wales followed the declining trend previously confined to England.

Pigs. — Since pigs may be bred much more quickly than other farm livestock there are relatively much more rapid changes in the

TABLE LXXVII.—*Number of Pigs in Great Britain*

Year	Number	Year	Number
1871–75	2,485,000	1921–25	2,825,000
1881–85	2,433,000	1926	2,345,000
1891–95	2,483,000	1938	3,821,000
1901–05	2,491,000	1946	1,644,000
1911–15	2,585,000	1955	5,854,000

numbers from year to year, and consequently sharper rises and falls in prices. From 1871–75 to 1951 the numbers moved up and down with fair regularity every five years, with little change in the general level. World War II entailed a very heavy fall in the number of pigs; but by 1954 the 1938 figure was far surpassed.

Pigs are kept rather more in the eastern counties of England than in most other districts. The numbers in Scotland are relatively small.

Poultry. — The number of fowls on the farms of Great Britain continues to increase. The earliest figures available relate to 1908, when there were 32,360,000 fowls in Great Britain; in 1926 there were 41,600,000, and in 1938 there were 59,920,000. World War II led to a heavy culling of flocks, but by 1949 the prewar figure was exceeded.

Value of Agricultural Output. — The ministry of agriculture estimated that the value of the farm produce sold off farms or consumed in farm households in 1938 in England and Wales was £224,500,000, and if comparable figures were available for Scotland it would probably be found that the value of the agricultural output of Great Britain was in the neighbourhood of £270,000,000 to £280,000,000. Of this output. livestock and livestock products accounted for the bulk—at least 70%.

The value of the gross output for 1955 was estimated at £1,500,000,000. Because of the change in the value of money, and the incidence of subsidies, a comparison with the figures before World War II would have little meaning. It should be explained that the sums received from the sale of livestock and livestock products have to cover the cost of growing those grain, root and fodder crops used for feeding to livestock, and it is only those proportions of the crops which are sold off the farms which are valued as crops in the figures quoted above.

Sizes of Agricultural Holdings. — The total number of agricultural holdings in Great Britain in 1955 was 453,995, of which about 290,000 were of less than 50 ac. of cultivated land.

While it is true that many holdings of agricultural land are separately included in the agricultural returns without being economic farm units, since they are small pieces of land attached to residential properties or detached fields separately returned, etc., there is a very large number of separate farm units in the country. From 1895 to 1938 there was a fairly steady reduction in the number of holdings, especially in those of less than 20 ac. After 1895 there was no very marked change in the number of small and medium holdings of from 20 to 300 ac., but the number of holdings of more than 300 ac. increased. After World War II the trend was irregular. There was an increase in the smallest and the largest classes of holding.

Persons Employed. — It is clear, from the population censuses of the 60 years before World War II, that the number of persons employed in agriculture (excluding horticulture) in Great Britain declined considerably, from about 1,500,000 in 1871 to about 1,170,000 in 1931 (about 770,000 in 1952). This reduction had several causes. among which the decrease of arable cultivation and the increased use of machinery are no doubt the most important.

Capital Invested. — The capital invested in agriculture in England and Wales was estimated in 1931 at £925,000,000 of which £645,000,000 was the value of the land, including farmhouses and buildings, and £280,000,000 the working capital of the occupiers of the land. Assuming similar figures per acre for Scotland, for cultivated land and rough grazings, respectively, the total capital invested in the whole of Great Britain in agriculture amounted to nearly £1,176,000,000.

By 1950 the market value of farms in Great Britain was estimated at £1,748,000,000, tenants' capital in the form of crops, livestock and machinery at £1,280,000,000 and tenant-right valuation in the form of cultivations, etc., at £100,000,000.

Agriculture After 1939.—World War II caused radical changes in British agriculture. The effect was to cut off large imports of foodstuffs, and the country had to become as nearly as possible self-sufficient. This meant a far-reaching change from grass to arable, a change which was largely maintained after the war. The shortage of labour led to extensive mechanization.

Under the defense regulations the minister of agriculture was given wide powers to control and direct agricultural production. The war agricultural executive committees were the essential link in the chain of direction between the minister and the industry. The committees gave direct aid to farmers, being in control of machinery pools which enabled them to undertake such work as moorland reclamation, heavy drainage and the plowing out of rough grassland beyond the scope of ordinary farm equipment.

During the war and later, much-needed money was being provided for the industry by extensive subsidies for plowing out, moorland reclamation, liming and the purchase of fertilizers and (under the hill and marginal lands schemes) by the provision of roads and modernization of farm buildings.

The new importance of agriculture was recognized and consolidated in the Agriculture act of 1947, which embodied some of the wartime ideas and machinery. This instrument gave stability to the industry by a system of guaranteed prices and assured markets for the leading agricultural products. It provided measures to encourage efficient farming, giving the minister powers to dispossess offenders. It revised the relationship between landlord and tenant, with the objects of giving the tenant greater security and ensuring good farming. It embodied a small-holdings policy designed to ensure that small holdings went to people fit to run them. Finally, it provided the necessary administrative machinery. The chief instruments were the county agricultural executive committees (successors to the county war agricultural executive committees), which are joint bodies, partly appointed by the minister and partly recruited from the industry. The Agriculture (Scotland) act of 1948 extended the system to Scotland.

During and after the war security with regard to prices was given by an annual price review, when the ministries of agriculture and food and the National Farmers' union agreed in joint consultation on minimum prices for appropriate periods. The differences between farm prices and those charged to the consumer under the policy of keeping down the cost of living was made up by subsidies. The price review was also the machinery for directing agricultural production into the channels desired by the government. Thus the need for economy in the use of cargo space during the war made it essential that the country should produce the maximum of bulky products, such as grain and potatoes, while care for the health of the rising generation, as exemplified in the free milk scheme, made it necessary to increase milk production. The price review was used to attract farmers into this line of production. at the expense principally of meat. By 1949 exchange difficulties and the shrinkage in world meat supplies necessitated increased home production of meat, and again the price review was the main instrument.

Measured in terms of land utilization the wartime concentration on grain reached its culminating point in 1944, when the total of permanent grassland was 11,735,000 ac. as compared with 18,798,000 ac. in 1938. After this the gradually developing difficulty in importing meat led to a slight increase in grassland. But even in 1951 the change in the layout was very pronounced. The total area of agricultural land was virtually unchanged between 1939 and 1954; but whereas in 1939 arable made up about 41% of the total, the proportion of arable in 1954 was 58%.

Under the stimulus of the war and of the postwar shortages of food, a number of new techniques were introduced. The most valuable single instrument in raising the production of milk and of arable crops and, above all, in bringing into arable production a very large area of the country where the dominant tradition for generations had been that of livestock and permanent grass, was that of ley farming; *i.e.*, the introduction of temporary grass into the crop rotation system. This technique had been practised for a considerable time in the Scottish lowlands. but was new to much of England. Great advances were also made in grassland husbandry, in pest control (*e.g.*, by systematic use of insecticides) and in weed control through chemical means and by the use of hormonal weed killers. Stock farms tended to become increasingly self-sufficient. Stock farmers grew more fodder crops, which they were helped to utilize by improvements in the existing methods of grass conservation; *e.g.*, by ensilage and drying.

The advance in technique was accompanied by intense mechanization which continued after the war and made British agriculture among the most highly mechanized in the world. The change in the country's stock of plows gives a good illustration. From 1942 to 1954 the total number of plows mas almost unchanged. So was the arable acreage. But whereas in 1942 there were about three times as many horse-drawn plous as there were tractor-drawn ones, there were in 1954 three times as many tractor-drawn as horse-drawn plows. Much of the farm machinery was owned and hired out by commercial concerns specializing in this work.

Fisheries. — Great Britain's sea-fishing industry is among the most important in the world. The principal kinds of fish caught are herring, cod. haddock, plaice and hake. classed as wet fish, and. among shellfish, oysters, crabs and lobsters. The annual consumption of wet fish is about 18 lb. per head of the population, and with improvements in the methods of preservation (by refrigeration) and transport, consumption should be increased. The principal grounds frequented by British fishermen are the North sea, Iceland, the Faeroe Islands. south of Ireland. west of Scotland, Barents sea, west of Ireland, Irish sea and English channel. A notable event was the opening in 1927 of new halibut fisheries off the Greenland coast. This was made possible by the adoption of new methods of brine freezing.

During World War II fishing grounds and catches were restricted. Fleetwood for a time became the most important fishing port. Immediately after the war, landings and consumption rose rapidly, but by 1950 had relapsed to below the prewar level. The proportion of foreign-caught fish was higher than before the war, and measures were enacted in 1944, 1945 and 1948 to assist the herring, the inshore and the whitefish industries with grants for boats and equipment. The wartime and postwar shortage of meat helped raise the price of fish, and though the weight of British-caught landings in 1950 was one-sixth lower than in 1938, the value was half as high again. After the war efforts were made to modernize the fishing fleet, many of its vessels being then very old. Some new devices were introduced, among them echo sounding for the location of shoals. Table LXXVIII shows the number and total of fishing vessels on the register in Great Britain for certain years from 1913 to 1954. The decrease in total numbers of vessels is to some extent offset by the gradual conversion from sail and steam to motor propulsion.

TABLE LXXVIII.—*Fishing Vessels on the Register in Great Britain*

Year	Total vessels	Net tonnage	Year	Total vessels	Net tonnage
1913	17,465	319,060	1938	11,522	245,404
1924	16,013	288,960	1946	12,935	186,913
1930	13,099	179,127	1951	11,864	199,169
1935	12,583	268,656	1954	8,365	...

The number of fishermen in Great Britain before and after World War II cannot be exactly compared because of a change in the basis of computation, but it certainly diminished.

For 1938 and 1954 the total figures for landings in Great Britain were as shown in Table LXXIX. Despite the decline in numbers of vessels engaged in fishing and in the numbers employed, the amount of fish landed showed a tendency to increase during the 20 years before World War II in spite of the fact that exports

TABLE LXXIX.—*Quantities and Value of Fish* Landed in Great Britain, 1938 and 1954*

Landings	1938		1954	
	Weight (cwt.)	Value	Weight (cwt.)	Value

of fish declined. After the war landings were on a lower level. Exports are shown in Table LXXX.

The most important factor in the export trade is herring, which represents about 68% of the total. The canned fish industry of

TABLE LXXX.—*Exports of Fish of British Taking or Curing*

Year	Quantity (cwt.)	Value	Year	Quantity (cwt.)	Value
1913	10,998,771	£7,503,468	1938	4,381,587	£3,870,262
1924	8,142,816	8,438,243	1946	997,496	2,698,508
1930	7,173,671	7,039,973	1951	1,270,226	5,685,653
1935	4,588,064	3,750,926	1955	5,778,433	986,275

the country is peculiar in that Britain imports the great bulk of the canned fish (principally salmon and sardines) which is consumed and exports most of what is actually canned in the country — herring. Fresh-water fisheries, in spite of serious attempts made between 1914 and 1918, have never contributed substantially to the feeding of the British population.

Considerable attention has been given to research and organization in the fishing industry. A great deal of research has been carried out by the government and under government direction (ministry of agriculture and fisheries). Government vessels have continuously studied the movements, habits and feeding of fish both inshore and at sea. Research has been carried out in hydrography and into methods of capture, into the breeding and cleansing of shellfish, etc.

See *Agriculture* (H.M.S.O., London, monthly); *Scottish Agriculture* (H.M.S.O., Edinburgh, quarterly).

INDUSTRIAL AND SOCIAL CONDITIONS

Population. — The population of Great Britain by mid-20th century was aging and seemed virtually certain to fall during the third quarter of the century. In 1939 young men up to 34 years of age constituted 56.4% of the total male population; in 1954, only 52.3%. For women and girls the corresponding percentage of the total female population fell even more strikingly, from 52.3% to 48%. The prospective burden of age in the welfare state (see below) is obvious.

A later development, a result of the extension of state socialism during and after the war, was the growth in the number of persons employed on national and local government service.

In 1937 a royal commission was appointed to inquire into the distribution of the industrial population. Its report was not published till 1940, but it sharply focused attention on certain well-known tendencies which had been in progress for more than a century. The growth of large cities is not a phenomenon peculiar to Great Britain, but England (as distinct from Scotland) is among the most thickly populated areas in Europe. and it is necessary for the proper utilization of the natural resources of the country that the spread of population be controlled. For details of population by counties, and of urban and rural population, and other vital statistics, see ENGLAND; SCOTLAND; WALES.

Two tables compiled from censuses and mid-year estimates (Tables LXXXI and LXXXII) show first the distribution of the whole population and then the distribution of the occupied population. They are best commented on in the terms of the commission's report:

> These tables illustrate the outstanding feature of the geographical distribution of the industrial population in modern times, namely, its concentration to an increasing extent in particular areas of the country. The seven specified areas constitute only 27% of the total area of Great Britain. In 1801 they contained about 45% and in 1931 (the latest year for which figures are available) 73% of the occupied population. . . .
>
> Over the 19th century the total and occupied population of all the specified areas, except the Midland group of countries, increased both absolutely and proportionately to the country as a whole. Early in the' present century signs of a change began to appear in some areas; both Lancashire and Mid-Scotland lost ground between 1901 and 1911 in relation to the country as a whole. Since the war [of 1914–18] that experience has become more widespread: between 1921 and 1931 the proportion of the total population declined in Lancashire from 12.6 to 12.3, in Northumberland and Durham from 4.6 to 4.4, in Mid-Scotland from 6.2 to 5.8, and in Glamorgan and Monmouth from 3.6 to 3.2. . . . So far as the distribution of industrial population is concerned, those changes are completely overshadowed by the experience of London and the home counties where the occupied population has increased both absolutely and relatively, to a far greater extent than in any other part of Great Britain.

These changes of population reflect economic changes. The continued depression in the special areas. and the decline of coal mining, cotton and shipbuilding, tended to drive workers away from the areas and industries concerned to the southeast where industry was expanding and comparative prosperity was to be found. This general picture per-

TABLE LXXXI.—*Distribution of the Total Population*

sisted during the first five years after World War II. Within the total of persons employed the contribution of London and of the south generally increased from 1939 to 1950; in the midlands and the north (except for the region embracing Durham, Northumberland, Cumberland. Westmorland and the Sorth Riding of Yorkshire) it diminished. The Welsh contribution grew. The exceptions just mentioned relating to the north, and the case of Wales, were partly the outcome of official policy which controlled the location of industry. This was the result of (1) the Distribution of Industry act, 1945; (2) the already existing system of building licences; and (3) the Town and Country Planning acts, 1947. The government thus could foster the industrial development of the former distressed or special areas, now renamed development areas.

Prices and Wages.—Any statistical account of variations in the standard of living must be based on a correlation of prices and wages. The difficulty, however, of carrying such an investigation back for any long period is very great.

Prices.—During the 19th century the course of prices could best be illustrated by index numbers compiled from wholesale prices because retail prices fluctuated so much between different localities and even different retailers that representative data were practically unobtainable. On the other hand, wholesale quotations for the principal commodities could be easily obtained. In the 20th century, however, and especially in the period of continuously rising prices after 1938, this became untrue, as is seen when the rise in wholesale prices between 1938 and 1955, shown in Table LXXXIII, is compared with the much less marked rise in the cost-of-living index shown in Table LXXXV.

TABLE LXXXIII.—*Index* Numbers of Wholesale Prices, *1800–1955*

Year	Index number	Year	Index number	Year	Index number	Year	Index number

Table LXXXIII (which shows the fluctuation of wholesale prices after 1800), based on one compiled by W. T. Layton from W. S. Jevons' index number from 1800 to 1865 and A. Sauerbeck's from 1865, has been continued to 1938 by Sauerbeck's (Statist) index and from 1938 by the board of trade index.

Prices from 1800 to 1820 were abnormally high (the figure of 235 for the year 1800 comparing with 100 of the year 1900) and subject to violent fluctuations as a result of the disturbance caused by the Napoleonic Wars. The years 1820 to 1825 saw a boom in trade because of the rapid development of transatlantic commerce. This was accompanied by an inflation of credit and deflation of banking reserves, ending in a serious crisis. About 25 years of falling prices followed, until after 1850 an upward movement was started by the discoveries of gold in California and Australia. The continued fall throughout the last three decades of the 19th century was related to a steady decline in the gold output and the gradual adoption of the gold standard by various countries, leading to an increased demand for gold, while the rise in prices after 1900 follows an upward movement in the volume of gold production, a result of the development of South African supplies. Intermediate events were the world financial crises of 1856–57 and 1863–64; the Overend Gurney and Co. failure of 1866; the Austrian, U.S. and German crises of 1873, which caused a fall not interrupted till the trade revival of 1879; the French and U.S. crises of 1882 and 1884; the Baring crisis of 1890; followed by a U.S. crisis in 1893, the effects of which were felt till 1897; the South African War of 1900, which interrupted the succeeding revival; and the steady upward movement of trade and prices from 1903 until the outbreak of World War I, interrupted only by the U.S. financial crisis of 1907.

The effects of World War I require separate mention. During the war the gold standard was abandoned and the currency divorced from gold. As a result the high-level record attained during the Napoleonic Wars was surpassed (more than $33\frac{1}{3}\%$) by the figure in July 1920.

Statistics for the course of prices after 1920 show that, apart from seasonal fluctuations. prices fell steadily from the end of 1920 until the middle of 1924. After a slight rise late in 1924 the downward course continued with little interruption until 1935, when prices began rising slowly again. This rise continued from the beginning of World War II in 1939, but Table LXXXIII shows clearly the results of government efforts first to check any rapid rise in prices and then to stabilize as much as possible the cost of living. Food prices in particular were held in check, and in March 1942 were only 25% above those of the month before the war, the index figure for food alone being 60 on April 1, 1942.

Stabilization of prices during World War II was achieved by various means. The board of trade was empowered to fix maximum prices on goods and services and to limit margins of profit. Rents were also stabilized. The food ministry fixed prices on a wide range of foods, and prices paid to farmers for produce were determined by negotiation with the ministry.

By 1941 the cost of living had risen by about 25%. It was then kept steady until June 1947, when a new and more realistic collection of items affecting the cost of living was drawn up, to be followed by a fairly exhaustive one in Jan. 1952. Between 1947 and 1955 the cost of living, on the new definitions, rose by 50%. A further index was introduced in Feb. 1956. It was based on the assumed spending schedules of about 90% of the households in the country and reflected the great improvement in the standard of living since before the war. It included such items as television sets, motorcars and washing machines.

Wages.—Commensurate with the rise in prices during 1914–18, wages rose sharply and continued to do so until 1920, when the average percentage increase over the 1914 level reached 180. From 1921 to 1923 they dropped rapidly and, as Table LXXXIV shows, remained fairly stable between 1926 and 1938, in spite of serious fluctuations in employment. For the prewar years the table is based on the average for 1924, which is reckoned as 100, and this in turn represents a 70% increase over the 1914 figure; for the postwar years the base of 1947=100 has been taken. Table LXXXIV gives half-yearly averages.

TABLE LXXXIV.—*Index Numbers* Showing the General Course of Weekly Rates of Wages*

Year	June	December	Year	June	December

*For years 1926–38, average for 1924=100; for years 1947–55, June 30, 1947=100.

Real Wages.—When prices rise rapidly there is a natural tendency for wages to follow them, but, unless they overtake prices, the wage earner, of course, is no better off for his higher pay. It is worth inquiring in what ways the condition of the British wage earner substantially changed after the late 1800s, and to do this it is necessary to investigate the relationship between prices and wages in order to discover changes in "real" wages.

It is now agreed that statistics from 1850 and 1880 are not sufficiently precise for such an attempt to be made for that period, but it is fairly clear that, subject to fluctuations in 1865–68 and 1874–79 especially, real wages rose by about 33% during the period of 30 years.

In his Wages and Income ***in the United*** Kingdom Since 1860 (1937) A. L. Bowley related changes in retail prices with changes in wage rates in an attempt to measure real wages. His table, for the period 1880–1936, is reproduced in Table LXXXV, with some figures of his (*Journal* of *the Royal Statistical Society,* 1952) interpolated between 1914 and 1924, and it is continued after 1936 by utilizing index numbers of retail prices and rates of wages as shown in the "Bulletin of the London and Cambridge Economic Service," published in *The Times Review* of *Industry.*

*1914=100; discontinued after 1947. New index based on 1947=100 from 1948.

At no time in the period was the rate of increase in real wages rapid, and for 15 or 20 years before World War I no advance at all was recorded. In the early years of World War II prices rose more rapidly than wage rates, but by 1944 real wage rates had recovered to the 1938 level and by 1946 showed an improvement of 11%, near which level they remained. With full employment, opportunities for getting paid more than the minimum, for increasing income by more intensive work at piece rates or from bonus schemes and for overtime mere greater than previously and by 1955 earnings had inereased since 1938 by 38% more than the index of wage rates would lead one to expect. Table LXXXVI gives some information about average earnings per week obtained from wage censuses of the ministry of labour covering most major industries but excluding agriculture, coal mining and rail transport.

The position of wage earners has also been improved by the development of social expenditure on health and education services, on pensions, sickness and unemployment benefits and on family allowances, partly offset by direct contributions of wage earners to national insurance and by their income tax payments.

*Figures relate to October except in 1941 and 1944 (July).

Hours of Work.—Between 1919 and 1955 the hours of labour were reduced in nearly all industries, Table LXXXVII. given in the *Ministry of Labour Gazette,* showing the aggregate amount for the whole country.

By 1939 the working week had been generally fixed by collective agreement at 44–48 hours for adult males, excluding overtime, with a 48-hour maximum for women and young persons. At the outbreak of war extensions were permitted. At the spring crisis of 1940, the ministry of supply ordered contractors to work a full seven-day week. Most munitions plants worked two 12-hour shifts, or 70–75 hours weekly. There were similar long hours in aircraft factories and shipyards. Only where it was possible to organize a three-shift system was the maximum week limited to 56 hours. It was found, however, that in spite of these long hours production began to decrease. The causes were fatigue, ill-health and accidents. The Industrial Health Research board reported that there was little gain, and probably an actual loss, if working hours exceeded 60–65 for men and 55–60 for women. Accordingly, the ministry issued a memorandum stressing the need for maintaining maximum production by adjusting hours of labour. The ministry recommended, wherever machines could be run nonstop, the adoption of three shifts and a 55–56 hour week as soon as sufficient skilled labour could be made available. Where it was not available, a 60-hour week was permitted for men, and the provisions of the Factory act were restored for women and young persons, subject to modification in an emergency.

TABLE LXXXVII.—*Hours of Labour**

Year	Approximate number of workpeople whose normal hours of labour mere		Aggregate net increase (+) or decrease (−) in weekly hours
	Increased	Reduced	
1919	1,150	6,305,000	−40,651,000
1920	2,000	570,000	− 2,114,000

1937	1,500	390,650	− 960,000
1938	1,950	166,650	− 371,100
1939	—	396,000	− 1,412,000
1940	54,000	193,000	− 633,000
1941	16,000	10,000	− 2,500
1942	4 000	10,000	+ 5,000
1943	8,000	141,000	− 256,000
1944	3,000	—	+ 4,400
1945	—	22,000	− 42,000
1946	—	2,128,000	− 5,719,000
1947	—	5,223,000	−18,429,000
1948†	—	616,000	− 1,834,000
1949	3,500	1,017,000	− 1,471,000
1950	108,500	1,500	+ 105,500
1951	1,100	10,000	− 26,000
1952	2,500	56,000	− 164,000
1953	—	300	− 1,000
1954	—	199,000	− 318,400
1955‡	—	179,500	− 249,300

*In addition to the workpeople for whom figures are given in this table, there were 8,000 workpeople in 1939, 214,000 in 1942, 33,000 in 1943, 12,500 in 1945, 48,000 in 1946 and 183,000 in 1947 who were affectedby increases and also by reductions of equal amount within the same year. †The figures for 1948 and later years are not strictly comparable with those for earlier years, since particulars relating to employees in government establishments and shop assistants were introduced for the first time in 1948. ‡Figures preliminary and subject to revision.

By 1954 over-all hours of work in a large range of industries had returned almost exactly to the level of 1938. Within this total the hours worked by women underwent a fairly substantial reduction, while those worked by men slightly increased.

Unemployment **and** Its **Relief.**—Between 1900 and 1914 the percentage of workers unemployed never rose above 8%, and the average for the years 1911 to 1914 was less than 3%. On the other hand, after 1918 unemployment was one of Great Britain's most serious problems. When the Unemployment Insurance act came into operation in Nov. 1920, accurate statistics became available. From 1923 to 1929 the average number of insured persons unemployed was about 10%; at the height of the depression it rose in 1932 to 21.9%, and by 1936 had only fallen to 13%.

Table LXXXVIII, issued by the ministry of labour, shows the actual numbers of workers included in these percentages and brings the figures down to the end of 1955. It will be seen that unemployment reached its apex in 1932, and that from 1934 to the outbreak of World War II there was slow but steady improvement. After World War II prices tended to rise, the result partly of shortages, partly of monetary inflation and partly of a growing will to spend on the part of the public. Very full employment, fuller than theoreticians nould have believed possible, was a by-product of this rising price level.

TABLE LXXXVIII.—*Average Number on the Registers of Employment Exchanges i n Great Britain and Northern Ireland*

Year	Wholly unemployed	Temporarily stopped	Unemployed casual workers

1955	239,200	21,000	4,300

*The 1947 averages exclude the numbers unemployed during the fuel and power crisis early in the pear, who did not register as unemployed at employment exchanges.

Before 1911 assistance to the unemployed had only been given by the poor-law authorities in the form of relief on the ground of destitution. In that year was passed the first Unemployment Insurance act.

It covered only 2,250,000 workpeople, out of about 14,000,000, being confined to the building, woodworking, engineering and shipbuilding trades, which were at that time peculiarly affected by unemployment. The premium under the scheme was contributed compulsorily by the employer. the workman and the state in equal shares! and benefit was at the rate of 7*s.* per week. In 1916 the scope of the act was extended to cover certain trades which had been excessively expanded to meet the war emergency, against the anticipated postwar deflation, and in 1918 an emergency act was passed to provide relief for all persons thrown out of employment by the cessation of the war; this scheme was not covered by premium contributions, and it was ultimately succeeded by a new Unemployment Insurance act of 1920. This act covered about 12,000,000 persons; *i.e.*, speaking generally, all industrial workers with the exception of agricultural and domestic employees.

When the act came into force unemployment was increasing, and for the next ten years there followed a series of amending acts extending the limits of insurance and making various financial adjustments. To enable benefits to be paid it became necessary for the Unemployment Insurance fund to obtain loans from the exchequer. In 1930 a royal commission was appointed to determine whether the fund could become self-supporting, and many of its recommendations were incorporated in the Unemployment act of 1934. A consolidating act mas passed in 1935, and in the following year unemployment insurance was extended to cover agricultural workers. Further minor modifications and extensions in the scheme were made in 1938, 1939 and 1940.

Ministry of labour estimates suggest that the number of persons insured against unemployment increased from 11,000,000 in 1922 to 14,000,000 in 1936. In 1939 the estimate gave 15,157,000 persons in Great Britain and Northern Ireland as insured under the general scheme and 741,000 under the agricultural scheme. The Unemployment Insurance fund. as has already been mentioned, was forced during the depression to obtain advances from the exchequer which by 1934 had totalled £115,000,000. This debt was then funded, and more favourable industrial conditions in succeeding years enabled the fund to show a credit balance. As a result, outstanding debt had been discharged by the end of 1941.

Employment Exchanges.—In connection with the unemployment insurance scheme the ministry of labour and national service established numerous employment exchanges. On becoming unemployed a worker must register at an exchange in order to receive his insurance benefits, and it is the function of the exchange to find him fresh employment as soon as possible. There were about 1.000 employment exchanges by the mid-1950s. Under them were about 200 branch employment offices and local agencies affording limited facilities in remote places

There were some specialized exchanges (*e* g., for women and for the hotel and catering trades) and youth employment offices, about half of them run by local authorities. Benefits were paid on an agency basis on behalf of the ministry of national insurance and of the National Assistance board. Both in 1938 and in 1954 (the first a year with heavy and the second a year with virtually no unemployment) about 2,500,000 vacancies were filled.

Mention should also be made of certain subsidiary services provided by the ministry. Where employment is scarce in a worker's district but available for him elsewhere. he can be granted fares for himself and his family and financial aid to meet the cost of removal and resettlement. In certain circumstances he can also qualify for a lodging allowance. In addition, the exchange can arrange for him to attend a government training centre in order to acquire a new skill. During World War II, the problem of transferring workers from peacetime industries to war nork assumed large proportions; the ministry's training centres proved inadequate for the numbers of workers involved, and arrangements were made. wherever possible, to train skilled workers in the factories in which they would be employed.

Other Remedies for *Unemployment.*—Other methods adopted by the state to deal nith the problem of unemployment after 1920 included the provision and subsidizing of relief nork in various forms. Among the classes of nork thus subsidized were road work, land drainage, water supply, forestry, etc. There were also two schemes designed for the general stimulation of trade, viz., the trade facilities and export credit schemes.

Under the first of these the treasury nas emponered to guarantee the interest and capital of loans raised for expenditure calculated to promote employment. The guarantees mere mainly confined to public utility undertakings between the years 1921 and 1928. The total so guaranteed nas about £75,000,000, and by March 31, 1939, the amount outstanding had been reduced to £27,000,000. The export credit scheme was initiated in 1920 and was amended several times thereafter. The board of trade is authorized to grant exporters credits in connection with exports to foreign countries and to insure risks not otherwise insurable on reasonable terms. After the outbreak of World War II in 1939 the scheme was extended. not to relieve unemployment but to maintain certain trade relations that were felt to be of importance.

Special Areas.—The unrelieved depression over a long period in the regions of Durham and the Tyneside. Cumberland and south Wales caused them in 193j to be designated "special areas." Commissioners were appointed to superintend and organize relief nork, and between 193j and 1939 more than £16,000,000 had been spent on various schemes initiated by the commissioners New industries were brought to the depressed areas under subsidy, and numerous schemes for public works were developed. These areas were later renamed development areas (see above).

Emigration.—It was pointed out by some authorities that the exceedingly high unemployment figures betneen World Wars I and II were due in some measure to the natural increase of population and the decline of emigration. The ministry of labour's statistical survey of 1927 stated that, in spite of increased numbers of unemployed during the previous decade. the actual number of workers in employment was higher than it had ever been before. If there had been emigration on the scale of the years before 1914, the available supply of labour in Great Britain might even have been inadequate for the needs of industry at that time.

The decline of emigration after 1919 was largely due to restrictions on immigration imposed by the United States and the British dominions. The United States Immigration act of 1924 imposed a rigorous quota on the number of immigrants admitted in each year, and the dominions strongly opposed unrestricted immigration on the ground that it would be liable to disturb their internal economies. It is notex\-orthy that from 1931 to 1937 there were more arrivals in than departures from Great Britain. This reversal of a century-old trend was a result of the fact that the depression was world-aide and that emigrants who had been unable to succeed abroad tended to return home.

SETTING UP OF THE WELFARE STATE

World War I1 made manifest the benefits of full employment and, by so doing, impressed on all concerned the moral and political inexpediency of allowing the unemployment of the prewar years to recur. At the same time, war (a great socializing force. as Bernard Shaw had pointed out as long ago as 1916) provided ample experience in the erection and working of administrative machinery permitting the vigorous moulding of people's lives on the largest scale. World War II gave many people a chance to improve their standard of living; at the peak of the war effort the national expenditure (in terms of 1938 prices) on beer, tobacco and entertainment rose. Winston Churchill, the prime minister. laid it down that the standard of living must not be lowered to primitive levels. These factors led to the coinmissioning and rendering of a report by Sir William Beveridge on social security and allied services (Nov. 1942) which "takes freedom from Want as its aim, and sets out a Plan for Social Security to achieve this aim." In Sept. 1944 the coalition government put forward proposals for social insurance and family allowances, and in November the ministry of national insurance was instituted. The great body of social legislation was, however: the work of C. R. Attlee's first Labour administration. Details of this legislation will be found in the article SOCIAL SECURITY.

The institution of the welfare state was accompanied by a far-reaching redistribution of incomes. For this there were a number of causes: (1) the continuing scarcity of labour, with the result that real wages underwent a slight increase, while most other types of income dwindled; (2) the cost of the various schemes described was raised by taxation, the bulk of which fell on the higher-income groups; (3) in a similar way money was raised for

TABLE LXXXIX.—*Distribution of Personal Incomes (Before Tax)*

Income	1938 per cent	1954 per cent
Wages	37.9	42.4
Salaries	17.9	21.3

the cheapening of food (£369,000,000 net in 1950), houses (£65,000,000) and other commodities (grand total £479,000,000). The result is shown in Table LXXXIX.

Social Insurance. — In the 18th and 19th centuries the principal means available to the worker for insuring himself against sickness or other disabilities was to become a member of a friendly society, to which he paid his regular contribution. But friendly societies were only for the better-paid and more thrifty workers; for the less fortunate there was nothing but charity and poor-law relief. Between 1911 and 1936 national health insurance was made compulsory for all workers earning less than £250 a year between the ages of 14 and 65.

The first Old Age Pensions act was passed in 1908, and it provided a pension of js. a week for old persons over jo. In 1925 the first contributory scheme for pensions was introduced, and it was later extended. Pensions of 10s. a week were payable to an insured man when he reached the age of 65 and to his wife when she reached the age of 60; insured unmarried women became eligible for pensions at the age of 60. Pensions were also paid to widows of insured men, with additional allowances for children under the school-leaving age, and to orphans. Supplementary pensions of varying amounts were paid to pensioners requiring additional assistance, providing they could establish their need. In 1938, 20,678.499 persons in Great Britain were contributing to the pensions scheme and 1,945,509 were receiving benefits under it. In the same year the pensions service was costing £48,158,951, of which £17,000,000 came from a parliamentary grant.

Under the National Insurance act, 1946 (amended in 1949 and 1951), in principle all persons over school-leaving age (except persons of pensionable age and married women occupied in their own homes or who elect not to be insured) are insured. They fall into three classes: (1) employed persons; (2) self-employed (persons in business on their own account); and (3) nonemployed. Contributions are payable by the persons insured, by the employers of employed persons and by the state. The benefits cover insurance against unemployment and sickness, maternity grants, industrial injuries. widows' benefits, guardians' allowances, retirement pensions and death grants.

TABLE XC.—*Contributions Payable by Insured Persons, 1956*

Insured persons	Employed	Employer of employed person	Self-employed person	Nonemployed person
Men over 18	6s. 9d.	6s. 11d.	8s. 5d.	6s. 6d.
Women over 18	5s. 6d.	4s. 6d.	7s. 2d.	5s. 2d.
Boys under 18	3s. 11d.	2s. 10d.	4s. 10d.	3s. 9d.
Girls under 18	3s. 3d.	[illegible]	4s. 3d.	3s. 2d.

To finance the system two funds were established: the National Insurance fund and the National Insurance (Reserve) fund. The former receives the income derived from contributory payments, exchequer grants and interest; it pays out the statutory benefits and provides for the costs of administration. It also pays a contribution to the national health service. It is actuarially revised every five years.

In financial 1953–54 the Insurance fund received £594,800,000 (mostly contributions from employers and insured persons) and disbursed £485,400,000, of which £334,100,000 was for retirement pensions. None of these benefits was subject to a means test.

The Industrial Insurance acts replaced the various Workmen's Compensation acts from 1925 to 1945. About 70% of the total contributions are derived from employers and employees and one-sixth from the exchequer. The insurance covers injuries, disablements and death. In the year to March 1954 payments relating to injuries amounted to £11,000,000; and those relating to disablement totalled £12,200,000.

The National Assistance act supplemented the National Insurance act. It was designed to sweep away the poor-law system and to replace it by one more comprehensive and also more liberally worked. The act, administered by the National Assistance board, granted assistance (mainly in cash) to persons without, or with inadequate resources. The board's expenditure in 1954 reached £130,000,000, the great bulk of which was accounted for by national assistance (£104,200,000), and noncontributory old-age pensions (£19,500,000). At the end of 1954 the total number of persons receiving allowances was 1,796,000, over half of these being paid in supplementation of retirement pensions. The average weekly payment was 21s. 11d.

*Payable for 18 weeks. †Payable for 13 weeks. ‡Payable under certain conditions.

The board also administers noncontributory old-age pensions under the Old Age Pensions act, 1936. It further provides reception centres (formerly workhouses) for persons without a settled way of living. Under the Legal Aid and Advice act, 1949, and the Legal Aid and Solicitors' (Scotland) act, 1949, it investigates the resources of certain persons applying for legal aid and determines their maximum contribution.

Health Service.—The ministry of health is responsible for the administration the National Health Service act, 1946. The service was originally entirely free, but certain dental and prescription charges were introduced in June 1952. The act covers England and Wales; Scotland (*q.v.*) is covered by a special enactment of May 1947.

The service works under three main authorities divided on a functional basis.

1. Hospitals. The regional hospital boards administer the hospital and specialist services of a regional area covering three or four counties and are based on their own university centre. Under each board a number of hospital management committees each administers a single hospital or a number or group of adjacent hospitals. Members of the boards are appointed by the minister from nominations submitted by various bodies; members of the committees are appointed by the regional board. Teaching hospitals are administered by separate boards or governors.

2. General practitioner health services, which are administered by local executive councils based on local health authority areas. The councils are divided into professional and lay representatives. Professional representation is made up of seven doctors appointed by the local medical committee, three dentists appointed by local dental committees and two pharmacists appointed by local pharmaceutical committees. Lay representation is made up of eight members appointed by the local health authority and four nominated by the ministry. As the buying and selling of practices was discontinued by the act, local executive councils are responsible for filling vacancies.

3. Public health services, which are administered by the local health authority through its health committees. The local authorities lost their hospital services as a result of the National Health Service act, but they acquired the new responsibility of finding premises for health centres. In addition, there are certain statutory responsibilities under the act; *e.g.*, the care of mothers and young children.

The original form of remuneration for doctors was a capitation fee, paid in respect of each patient on the list, up to a maximum of 4,000, with an additional 2,400 if an assistant was employed. In cases where doctors were starting in practice in unestablished practices, they could claim a basic salary of £300 a year if they could show reasonable prospects of obtaining a list of 500 patients within a specified time, which varied with circumstances; the application had in the first instance to be approved by the local medical committee. Later modifications provided for a practice allowance of up to £600 on condition that the new practitioner started in an area which was not restricted. (The Medical Practice committee had divided the country into restricted, intermediate and open areas.) Doctors were also encouraged to combine in partnerships. Group practices were encouraged by the promise of loan capital for the establishment of joint surgeries and kindred purposes.

A revolutionary change introduced by the act was the setting up of a dental service. During World War II it was found that 80% to 90% of young recruits needed dental treatment; the nation's general dental health mas poor, and the Teviot report (Oct. 1944) found that the number of new entrants into the profession was inadequate. To correct this tendency a scale of fees giving substantially higher incomes was introduced.

The dental service operates under the executive councils (*see* above), with the help of local dental committees. Proposals for major treatment go before the Dental Estimates board, whose statistical material enables it to study trends.

Family Allowances.—The Family Allowances act, 1945, provides for the grant of cash allowances for children other than the first child. It is administered by the ministry of national insurance.

Education.—For an account of the development of education in Great Britain, *see* EDUCATION, HISTORY OF. The pattern of education in Great Britain in the mid-20th century was set by the Education act, 1944, for England and Wales and the Education (Scotland) act, 1946. (Similar legislation for Northern Ireland was contained in the Education act Northern Ireland, 1947.)

These acts organized education in three stages: primary (to age 11; compulsory from 5); secondary (12–18); and further, from the end of full-time compulsory education (15; to be raised to 16 as soon as practicable); and made, at a date to be determined, some part-time education compulsory between the school-leaving age and 18. Furthermore, it was to be the duty of the state, through the local education authority, to provide free education at all three stages, and not only at the elementary (5 to 14) stage as previously.

cation without an organization in three sides (comprehensive).

As well as schools maintained by the local education authorities, there nere some schools which received government grants direct from the education department; these mere known as direct-grant schools. By the 1944 act. independent schools, which received no grant, were also to be inspected and recognized as efficient.

The figures in Tables XCII. XCIII and XCIV refer only to England and Wales, unless otherwise stated. See also the sections on education in the articles SCOTLAND and IRELAND, NORTHERN.

Housing. — Even before 1914 British housing fell sadly short of the ideal standard. The census of 1911 showed a tenth of the population in overcrowded conditions; *i.e.,* more than two to a room (including living rooms). The shortage extended to both town and country, and in addition a number of the working-class houses in occupation were dilapidated and insanitary, large areas in many cities being characterized as slum. At the end of World War I there was estimated to be a shortage of houses of between 300,000 and 400.000, in addition to considerable arrears of work to be done in slum clearance and making good defective dwellings. This deficit had arisen from two causes. There had been a distinct slowing up of the normal rate of building from 1910 to 1914, and during the war very few working-class houses were built. The estimated normal annual requirements to meet the natural increase of the population are 70,000 new houses and 30,000 to replace those which go out of use for various causes.

The position at the conclusion of World War I was further complicated by the great shortage of building materials and building-trade workers, with a concomitant rise in the cost of building. Therefore not only was there a severe shortage of houses, but it seemed impossible that houses to make good this shortage could be supplied by normal methods at rents which would be within the means of the working classes to pay and which would adequately remunerate the capital expended. Therefore it became necessary to take special measures. Local authorities had already under existing legislation (the principal acts being the I-lousing act of 1890 and the Housing and Town Planning act of 1909) considerable powers of providing for the working classes and improving the standard of existing houses. In 1919 a new act transformed the position of those authorities, converting a power into a positive obligation and enabling the state to reimburse them all expenditure exceeding the produce of a penny rate.

Housing policy between 1920 and World War II fell into two periods. In the first; up to about 1930, housing was encouraged by government subsidies not only to local authorities but to private enterprise as nell. By the end of 1928, 826,973 subsidized and 447,127 unsubsidized houses had been built. However, it gradually became apparent that most of the new houses were being let at a rental beyond the means of most labourers.

From 1928 increasing financial stringency was felt. and the subsidies were gradually withdrawn. In 1928 and 1929 they were withdrawn from private enterprise; and in 1930 from the local authorities for all dwellings except class C houses, or cheap houses which could be rented to the poorest classes. Finally. in 1933 all subsidies except those which would make slum clearance possible were stopped.

The advent of World War II brought about an almost complete cessation in new housing. For six years building was limited to the erection of a small number of special houses for particular war workers. Repairs to existing mar-damaged houses did, however, become necessary on an immense scale. According to a White Paper published on Nov. 28, 1944, out of about 13,000,000 houses at the outbreak of war, 202,000 were totally destroyed; 255,000 heavily damaged and unhabitable and 4,073,000 slightly damaged. To meet the cost of repairs and compensation, the government instituted a scheme of compulsory insurance under the War Damage act of 1941. By Sept. 1945 the War Damage commission received notifications of damage to 3,281,953 properties, including 1,400,245 in London. Contributions under the act totalled about £200,000,000, but by Jan. 1949 about £750,000,000 had been absorbed by war damage payments.

At the end of hostilities three serious housing problems emerged. Not only was there a reduction from the 1939 complement of houses. due to losses by bombing. but there was also a great volume of damage arising from enemy action and still awaiting permanent repair under the War Damage act. Second, there was an accretion of ordinary maintenance repairs on almost all houses. Third: an increase in population had taken place for which no housing provision had been made. In 1944 legislation widened local authority housing powers, and empowered the government to build prefabricated bungalows in partnership with the local authorities; 124,970 such bungalows were erected between 1945 and 1948.

The end of hostilities in 1945 made vitally urgent the recommencement of house building on a grand scale by local authorities. The Housing (Financial and Miscellaneous Provisions) act, 1946, authorized the payment of exchequer subsidies and rate contributions sufficient to enable local authorities to build houses to let at reasonable rents. Furthermore. it authorized the minister of health to make special grants to authorities using more expensive, nontraditional materials or forms of construction. A special subsidy was made available for houses built for letting to agricultural workers. Under the 1946 act were built most of the houses completed from 1946 to 1952. By the middle of 1954 about 1,900,000 houses had been built in Great Britain since early 1945. The numbers built and the subsidies granted were atiected by political as well as by economic considerations. In 1954 (as before World War II) special attention was again being given to slum clearance. During the period the lion's share in new construction was assigned to the local authorities. An overriding control over land utilization was provided by the Town and Country Planning act, 1947, and by the Town and Country Planning (Scotland) act, 1947, which coordinated planning throughout the country. Most of the privately on-ned houses were let subject to rent control. Table XCV shows the development of housing before and after World War II.

SAVINGS INSTITUTIONS

Apart from deposits in the joint-stock and other banks and in building and co-operative societies, and investments in securities and property of all kinds, British savings are held in four main forms; namely. deposits at the trustee savings banks. deposits at the post-office savings bank, savings bonds and savings certificates. The establishment of the savings bank in Great Britain dates from the year 1810, when the first private bank was founded. The post-office savings banks were founded in 1861, at which date more than £40,000,000 was invested in the trustee banks. The government institutions gradually overhauled. the other system, and at the end of the century, whereas the trustee banks had only increased their deposits to about £50,000,000, the post-office banks had more than £140,000,000 deposits.

		1955 . . .	1,698,700,000

In 1916 the national savings movement was instituted. The instrument adopted was the "war savings certificate," a government security, registered and nonnegotiable. accumulating compound interest over a fixed period free of income tax. After the end of the mar the War Savings committee and war savings certificate (see *National Finance* above) dropped the word "war" from their titles and became part of a national savings group which now embraces local committees, savings associations, regional advisory committees and a National Savings committee. Certificates are repayable at any time at the option of the holder, but because of the exemption from income tax it was thought necessary to impose an upper limit which has varied from time to time.

During World War II the national savings movement concentrated on the sale of defense bonds. which were introduced in 1939 with certain features designed to attract the small investor. as well as of national savings certificates. This movement continued after the war. The element of personal savings plays a recognized part in balancing the national economy, and chancellors of the exchequer have come to allow for it in framing the budget. In Oct. 19jj national savings certificates outstanding (including interest) came to £2,384,000,000, post-office savings bank balances to £1.722,000,000, trustee savings bank balances to £1,050,300,000 and stock on the post-office register to £968,200,000—total, £6,124.500,000. (W. H. JN.)

GREAT CHAIN OF BEING, a conception of the structure of the universe that had a pervasive influence in western thought in Neoplatonism during the Renaissance and the early modern period. particularly in the 17th and early 18th centuries. The term denotes three general features of the universe: plenitude, continuity and gradation. The principle of plenitude states that the universe is "full." exhibiting the maximal diversity of kinds of existences; everything possible (*i.e.,* not self-contradictory) is actual. The principle of continuity asserts that the universe is composed of an infinite series of forms, each of which shares with its neighbour at least one attribute. According to the principle of linear gradation. this series of forms ranges in hierarchical order from the barest type of existence through all possible grades up to the *ens perfectissimum,* or God.

The idea of the chain of being was first systematized by the Neoplatonist Plotinus. though the component concepts were derived from Plato and Aristotle. Plato's "idea of the good" in the *Republic,* eternal, immutable. ineffable. perfect, the universal object of desire, is fused with the demiurge of the *Timaeus,* who constructed the world of becoming because "he was good, and in one that is good no envy of anything else ever arises." for, "being devoid of envy . . . he desired that everything should be so far as possible like himself." Aristotle introduced a definition of the continuum and pointed out various graded scales of existence. Thus, in the words of Plotinus: "The one is perfect because it seeks for nothing. and possesses nothing, and has need of nothing: and being perfect. it overflows. and thus its superabundance produces an Other." "Whenever anything reaches its own perfection, we see that it cannot endure to remain in itself, but generates and produces some other thing. . . . How then should the most perfect being and the first good remain shut up in itself, as though it were jealous or impotent—itself the potency of all things. . . . Something must therefore be begotten of it" (*Enneads,* v. 2, 1; and v. 4. 1). This generation of the many from the one must continue until all possible varieties of being in the descending series are realized. "The world is a sort of life stretched out to an immense span, in which each of the parts has its own place in the series. all of them different and the whole continuous. and that which precedes never wholly absorbed in that which comes after" (*Enneads,* v. 2, 2).

The scale of being served Plotinus and numerous later writers as an explanation of the existence of evil in the privative sense of lack of some good. It also offered an argument for optimism: since all beings other than the *ens perfectissimum* are to some degree imperfect or evil, and since the goodness of the universe as a whole consists in its fullness, the best possible world will be one which contains the greatest possible variety of beings and consequently all possible evils.

The concept of the chain of being was unorthodox for scholastic theology because it was thought to conflict with the freedom of will of the deity. However! it had been clearly enunciated by Abelard in the 12th century. During the Renaissance and more especially in the 17th and early 18th centuries, it was almost universally accepted. A. O. Lovejoy points out that next to the word "nature." "the Great Chain of Being" was the sacred phrase of the 18th century. In Pope's *Essay on Man* (Epistle i, 1732) it is expressed most clearly. He speaks of the best possible systems (which infinite Wisdom must form)

> Where all must full or not coherent be,
> And all that rises, rise in due degree; (45–46)

And later:

> Vast chain of being! which from God began,
> Satures aethereal, human, angel, man,
> Beast, bird, fish, insect, nhat no eye can see,
> So glass can reach; from Infinite to thee,
> From thee to nothing —On superior pom'rs
> Were we to press, inferior might on ours;
> Or in the full creation leave a void,
> Where, one step broken, the great scale's destroyed:
> From Nature's chain whatever link you strike,
> Tenth, or ten thousandth, breaks the chain alike. (237–246)

The principle of plenitude was really a disguised version of the principle of sufficient reason, fundamental to the systems of Leibniz and Spinoza. This principle required some reason for the existence of every entity; namely its roots in the eternal order. in the necessities belonging to essences and their relations. Thus seen. the principle of plenitude asserts that the universe is completely rational and intelligible.

The main 18th-century critics of these ideas were Voltaire and Samuel Johnson, who conclusively refuted the whole theory of "the scale of being." though their criticisms failed to gain proper recognition at the time. Nevertheless. it became increasingly apparent that the objects of our sensible experience do not constitute an unbroken continuum of forms. The principles of plenitude and continuity could, therefore. be saved only if it were assumed that the forms became actual in the course of a long period of time. The chain of being had to be seen as growing in time and so became a sort of cosmic evolutionism. Already Leibniz had spoken of "a cumulative increase of the beauty and universal perfection of the works of God, a perpetual and unrestricted progress of the universe as a whole."

See A. O. Lovejoy, The *Great Chain of Being (1936)*.

(B. R. Ma.)

GREAT CIRCLE, any circle on .the surface of a' sphere marking the intersection of the sphere with a plane passed through its centre. All meridians of longitude of the earth are great circles. but the only parallel of latitude which can qualify is the equator.

Since the shortest distance between any two points on the surface of a sphere is along the arc of a great circle, it is important for an airplane or ship to follow a great-circle course whenever practical.

See also MAP: *Map* Projections; NAVIGATION. (M. H I.)

GREAT DIVIDING RANGE, Australia: *see* EASTERN HIGHLANDS.

GREAT FALLS, the largest city of Montana, C.S., is 93 mi. N.E. of Helena in central Montana. at an altitude of 3.330 ft., on the Missouri river, 12 mi. above the falls of the Missouri (93 ft. high) from which it derives its name; it is the seat of Cascade county.

The region is noted as a great wheat-growing and grazing area, although Great Falls is primarily an industrial city serving a large area as the manufacturing, commercial, financial and jobbing centre. The main industries include a copper and zinc refinery, which also fabricvtes copper and aluminum wire, power plants and flour mills. The municipal airport and the Malmstrom air force base gained importance as stations on the polar route to Europe and through Alaska to the orient.

In 1805 Lewis and Clark observed the nearby Giant Springs, one of the largest in the world, with a daily flow of 388,800,000 gal. of water, at a temperature of 52° F. the year around. The city was founded in 1883 by Paris Gibson of Minneapolis, Minn., and incorporated in 1888. Gibson planned the wide tree-lined streets and a fine system of parks which were linked later by many boulevards. The Charles M. Russell Memorial Studio and museum is a favourite cultural attraction.

The population of Great Falls increased from 29,928 in 1940 to 35.214 in 1950, and by 1960 had reached 55,357. The Great Falls standard metropolitan statistical area which consists of Cascade county had at its establishment in 1960 a population of 73,418. (For comparative population figures see table in >$OKTANA: *Population.*)

The College of Great Falls. a Roman Catholic school. was established in 1932. The State School for the Deaf and Blind and a rehabilitation centre for crippled children, which serves the state. also ore in Great Falls. A civic centre building contains a large auditorium, exhibit and recreational facilities in addition to city offices. (M. G. Bu.)

GREAT HARWOOD, an urban district in the Clitheroe parliamentary division of Lancashire, Eng., 5 mi. N.E. of Blackburn. Pop. (1961) 10,718. Area 4.5 sq.mi.

Mainly a cotton-manufacturing town, it also has light engineering and the making of leather goods. It is the birthplace of John Mercer (1791–1866), the inventor of the mercerizing process for cotton cloth.

GREATHEAD, JAMES HENRY (1844–1896), British civil engineer, whose name was given to a tunneiing shield. was horn at Grahamstown, South Africa, on Aug. 6. 1843. He came to England in 1859 and was P. W. Barlow's pupil (1864–67). Barlow patented a tunneling shield—an iron ring forced forward by hydraulic jacks against the last erected lining ring of cast-iron segments, while men worked on the earth face ahead. Barlow proposed a subway under the Thames near the Tower to exemplify his method, and Greathead contracted for the work, completed in 1869.

The Grenthead shield was used to bore the City and Southwark and the Waterloo and City railways under his direction, and on all the other railway "tubes" that were bored deep in the London clay after his death.

Greathead first proposed cable traction for tube railways, but changed to electric. Apart from his tunnels he was engaged on numerous railway works and took out a number of patents. He died at Streatham, London, on Oct. 21, 1896.

See memoir in *Proc. Inst. Civil Engineers,* vol. cxxvii (1897).

(S. B. HN.)

GREAT LAKES, THE. The Great Lakes and their connecting waterways of the United States and Canada form the largest group of lakes in the world. The Great Lakes proper are Lakes Superior, Michigan, Huron, Erie and Ontario extending roughly from west to east. Their combined area is 95,170 sq.mi., and they drain a land area of 295,200 sq.mi. The lakes are connected to form a single drainage system which discharges down the St. Lawrence river. This system constitutes a waterway that extends nearly halfway across the North American continent. The distance by water from Duluth, Minn., at the head of Lake Superior, to the open Atlantic ocean is 2,340 mi.

Exploration.— Jacques Cartier ascended the St. Lawrence river as far as Montreal in 1535. Samuel de Champlain, founder of Quebec, traveled up the Ottawa river and explored the Georgian bay area of Lake Huron in 161j. Champlain and Étienne Brulé discovered Lake Ontario later in 161j, and it is probable that Brulé saw Lake Superior in 1622. Jean Nicolet traversed the North channel of Lake Huron and visited Lake Michigan and Green bay in 1634. Pierre Radisson and Médard des Groseilliers traveled extensively on Lake Superior in 1655.

The first white man known to have seen Lake Erie was Louis Jolliet, who returned from the Lake Superior country by way of the St. Clair river, Lake St. Clair, the Detroit river and Lake Erie in 1669. Lake Erie was the last of the Great Lakes to be discovered, partly because the powerful Iroquois Indians, who were unfriendly toward the French and their Indian allies, controlled the two lower lakes, and partly because the system of the Ottawa and Mattawa rivers leading to the upper lakes was a route more suitable to canoe travel than were the' open waters of Lakes Ontario and Erie and the impassable Niagara river with its gorge and falls. By 1671 France had claimed all of the territory of the St. Lawrencc river-Great Lakes region. The explorations of Jolliet and Father Jacques Marquette in 1673–74 added much to knowledge of the region about Lake Michigan. The first sailing vessel: the "Griffin," built under the direction of Robert Cavelier de la Salle, traversed Lakes Erie, Huron and Michigan in 1679, but was lost on the return voyage.

France dominated an extensive fur trade for nearly a century, but the entire French territory embracing the Great Lakes was ceded to England in 1763, at the close of the French and Indian War. After the Revolutionary War a treaty in 1783 fixed a boundary between Canada and the United .States in the Great Lakes region. That boundary was contested but not appreciably altered by the War of 1812. During that war extensive but generally indecisive conflict occurred on Lake Ontario. The battle of Lake Erie, in which a U.S. fleet under Commodore Oliver H. Perry was victorious, secured U.S. claims to the northwestern part of the region.

Physiography.— The lakes, which lie between latitude 41° 22' and 49° 00' N. and longitude 76° 04' and 92" 06' W., occupy elongated, somewhat crescentic basins, the long axes of which are oriented in several directions. Lake Superior, the most northerly and westerly of the group, extends from west to east for 383 mi.

and is 160 mi. from north to south; Lake Michigan extends from north to south for 321 mi. and is 118 mi. from east to west; Lake Huron extends from northwest to southeast for 247 mi. and is 101 mi. from east to west; Lake Erie extends from east to west for 241 mi. and is 57 mi. from north to south; and Lake Ontario extends from east to west for 193 mi. and is 53 mi. from north to south.

The combined shore line of the Great Lakes is more than 8,300 mi. and a water surface of 95,170 sq.mi. is enclosed. Of this, 60,960 sq.mi. are in the United States and 34,210 sq.mi. are in Canada. The drainage basin. including the lake surfaces, is 295,200 sq.mi. Mean annual precipitation in the region ranges from 29 in. at Lake Superior to 34 in. at Lakes Erie and Ontario.

The levels of all of the Great Lakes fluctuate seasonally, reaching their lowest stages in late winter and their highest stages in late summer. The usual range between the winter and summer mean levels, in any one year, has been between one and two feet. In the 100 years from 1860 to 1959 the differences between the lowest and the highest monthly mean stages of the whole period have been between 4.0 and 6.6 ft. in the various lakes. Short-period changes in level. caused by storms, generally do not exceed two feet but a maximum change in lake level of ten feet has occurred within a few hours.

The water of the lakes is fresh and generally clear at all depths, with dissolved solids amounting to between 60 and 400 parts per 1,000,000. The water temperature in all of the lakes. below a depth of about 100 ft., remains close to 39° F. throughout the year. Surface water temperatures range from 32° F. in winter to 60° or 70° F. in summer. There are no appreciable lunar tides in the lakes, and surface currents generally are slight. Waves reach dangerous size, particularly during autumn and winter storms. Shore erosion, caused by storms occurring during years of high-water stages, has destroyed valuable lake-front lands.

Lake Superior, at the head of the system, stands at an average altitude of 602 ft. above mean sea level and it is 1,333 ft. deep. It is the largest of the Great Lakes. with a surface area of 31,820 sq.mi., and it contains over half of the water of the entire system. The largest tributary is the Nipigon river, entering from the north, which drains Lake Nipigon, a body of water with a surface area of 1.870 sq.mi. The St. Marys river is the outlet of Lake Superior, connecting Whitefish bay with Lake Huron 63 mi. to the southeast. The mean annual discharge of the St. Marys river is 73,300 cu.ft. per second. (See SUPERIOR, LAKE.)

Lakes Michigan and Huron, which are connected by the Straits of Mackinac, are similar in many respects. They are at the same level, 581 ft. above mean sea level, and have about the same surface area. Lake Michigan, which lies entirely within the United States, covers 22,400 sq.mi.; Lake Huron covers 23,010 sq.mi. The greatest depth of Lake Michigan is 923 ft.; the greatest depth of Lake Huron, 750 ft. Lake Michigan includes Green bay, a large embayment lying on its western side. Lake Huron includes Georgian bay and the North channel, which lie on the northeastern and northern sides of the main lake. (See GEORGIAN BAY; HURON, LAKE; MACKINAC, STRAITS OF; MICHIGAN, LAKE.)

From the southern end of Lake Huron. the St. Clair river flows directly south for about 40 mi. into Lake St. Clair. which, at an altitude of 575 ft., is 6 ft. lower than Lake Huron. Lake St. Clair, which is 26 mi. from north to south and 24 mi. from east to west, has a surface area of 490 sq.mi. and a maximum natural depth of about 23 ft. An improved channel in the lake bottom connects the mouth of the St. Clair river with the head of the Detroit river. Lake St. Clair is connected with Lake Erie 32 mi. to the southwest through the Detroit river. The mean annual discharge of the Detroit river is 178.000 cu.ft. per second. (See SAINT CLAIR RIVER: ST. CLAIR, LAKE.)

Lake Erie. which is 572 ft. in average altitude, has a surface area of 9.930 sq.mi. Because its maximum depth is only 210 ft., it is the only one of the Great Lakes whose bottom does not extend below sea level. With an average depth of only 58 ft., the lake has a water volume of 109 cu.mi., a little more than one-thirtieth of Lake Superior's volume. (See ERIE, LAKE.)

From the northeastern end of Lake Erie, the Niagara river flows about 34 mi. in a northerly direction. It descends 60 ft. to the brink of Niagara falls, drops 167 ft. in the falls and descends nearly 100 ft. farther in the course of the Niagara gorge. After leaving the gorge, the river traverses a plain for a distance of 7 mi. and enters Lake Ontario. The mean annual discharge of the river is 195,800 cu.ft. per second. (See NIAGARA RIVER AND FALLS.)

Ontario, the most easterly of the Great Lakes, has an average surface altitude of 246 ft. above sea level. The maximum recorded depth, 778 ft., is 532 ft. below sea level. With a surface area of 7,520 sq.mi., Lake Ontario is the smallest of the Great Lakes in area but it ranks third in maximum depth and its volume far exceeds that of Lake Erie. (See ONTARIO, LAKE.)

The St. Lawrence river leaves Lake Ontario at its northeastern end and flows 265 mi. to tidewater (sea level) at Trois Rivières (Three Rivers), Que.; from there to Quebec the distance is 77 mi., and from Quebec to the open Atlantic ocean the distance is about 750 mi. The mean annual discharge of the upper St. Lawrence river is 233.900 cu.ft. per second. The principal tributary to the St. Lawrence is the Ottawa river. (*See* ST. LAWRENCE RIVER; ST. LAWRENCE SEAWAY.)

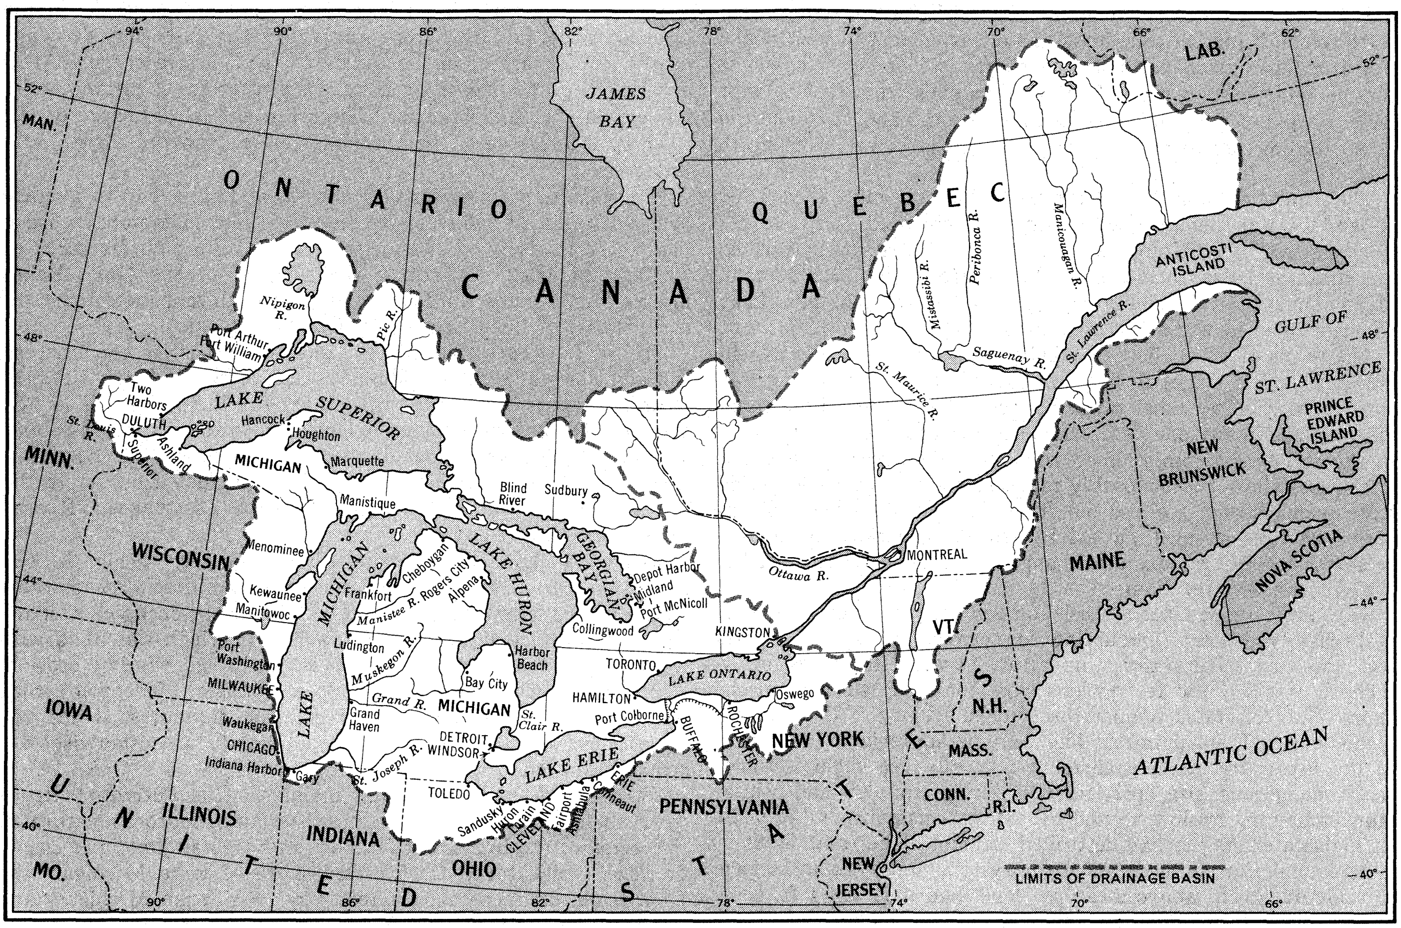
Geology.— Lake Superior lies almost entirely within the Canadian shield, an area of very old (Pre-Cambrian) rocks which generally are hard and dense. The lake basin occupies a structurally downwarped and downfaulted basin which was filled with weaker rocks and then reopened in later geologic time by erosion. The other four Great Lakes lie in a younger (Paleozoic) rock province mainly consisting of limestones, dolomites, shales and sandstones which have been consolidated but otherwise not strongly altered or deformed.

The lake basins are situated mainly in the outcrop belts of weak shale formatidns. The most striking bedrock feature in the region of the four lower lakes is the Niagaran Dolomite cuesta or ridge. which forms the western shore of Lake Michigan, the Door peninsula, separating Green bay from Lake Michigan, and the northern shore of Lake Michigan; extends eastward. forming the islands which separate Lake Huron from the North channel and Georgian bay; curves southeastward to form the Saugeen peninsula between Lake Huron and southern Georgian bay; and, farther southeast, swings eastward south of Lake Ontario. where it forms the escarpment over which the Niagara river drops at Niagara falls. The region, in general, is a lowland of gently rolling hills and ridges separated by plains, swamps and lakes.

There is ample evidence that the Great Lakes did not exist before the Pleistocene (glacial) epoch. The deep lake basins were once broad valleys of trunk streams and their many tributaries, eroded generally in the belts of weaker rock. Several advances of the great continental ice sheets covered the region and further deepened many of the preglacial valleys. When the margin of the last major glacier retreated northward into the lake basins, only about 18,000 years ago, the first known lakes were formed. These were narrow ice-margin lakes which spilled southward over the divides and drained down the Wabash, Ohio, Illinois, Wisconsin and blississippi rivers.

As the ice margin retreated the lakes expanded and coalesced; some of them then drained through new, lower outlets. Re-advances of the ice margin caused several modifications of the glacial lakes. including temporary return of their outflow to the older southern outlets. Further retreat of the ice reopened northern outlets and permitted further enlargement of the lakes. As the ice disappeared from the region, the land. which had been depressed under the weight of the ice. rose slowly and this caused further shifting of outlet channels. Uplift of the land in the northern parts of the region is still in progress, amounting to more than a foot per 100 years. (See PLEISTOCENE EPOCH.)

While bedrock formations constitute the framework of the Great Lakes region and form some of the higher lands, the rocks generally are covered by unconsolidated deposits left by the Pleistocene glaciers. These deposits include gravel, sand and clay of commercial value, and many of the rich soils of this agriculturally important region were formed on some of these deposits. The principal mineral resources which provide the basis for steel pro-



MAP OF THE GREAT LAKES-ST. LAWRENCE REGION

duction in the region are iron ore in the Lake Superior district, coal in Pennsylvania. Ohio and Illinois and limestone suitable for flux, quarried mainly on the shore of Lake Huron near Rogers City, Mich. Limestones and shales, produced in many areas, are the ram materials for the manufacture of cement. Other valuable mineral products of the region are copper irom the Keweenaw peninsula of Lake Superior; nickel, cobalt and uranium from the district north of Lake Huron: and salt irom New York. Pennsylvania, eastern Ohio and Michigan.

Commerce. — Because of the position of the Great Lakes deep in the North American continent and on the boundary between the United States and Canada, their utilization is of great importance. Towns and cities line the shore, no small part of whose gronth and importance is directly associated nith the abundant supply of fresh water available to them. Two of the five cities of the United States with populations of 1.000.000 or more, Chicago and Detroit. and the two largest cities of Canada. Toronto and Montreal, are on the Great Lakes and the St Lawrence river.

Since the international boundary follows the long axes of four of the five Great Lakes, a boundary waters treaty was signed in 1909 which guaranteed the Great Lakes to be free and open to inhabitants of both countries on equal terms and established the principles concerning the use of boundary waters. An international commission of three members from Canada and three from the United States was established, and it is a source of great pride in international relations that there are neither fortifications nor warships along the Great Lakes boundary.

Transportation. — The Great Lakes and their connecting waterways constitute the most important system of inland water transportation in the world. Because of their situation in the interior of a continent which is a producer of heavy commodities, the Great Lakes provide the transportation system for enormous quantities of bulk freight hauled at a rate considerably lower than for other comparable inland systems.

Not far distant from the western and southern shores of Lake Superior, in Minnesota, Wisconsin and the upper peninsula of Michigan: are iron mines which furnish an enormous amount of bulk freight which moves to the iron and steel centres at the southern end of Lake Michigan and south of Lake Erie. Coal from the Appalachian fields southeast of the lakes is an important return commodity from Lake Erie. Wheat from the spring-wheat region of the United States and Canada west of Lake Superior moves down the lakes to the cities on the southern and eastern shores. Stone moves down the lakes from Michigan, and pulp wood and petroleum move up the St. Lawrence.

Lake Michigan, the only lake to interrupt east-west railway and highway traffic; has a well-developed year-around railroad car. automobile and passenger ferry traffic. Eastbound, the railroad cars are loaded with iron and steel goods, wines and liquors and flour. grain. sart-mill and fabricated paper products. Westward. the cars are loaded with coal, building cement, rock, newsprint and steel ingots. blooms, billets, slabs, sheets and bars. (See also INLAND WATER TRANSPORT.)

Carriers. — Since most of the traffic on the Great Lakes consists of heavy, bulky, nonperishable commodities, special boats were designed to carry maximum loads under the specific conditions of the lakes, especialiy the length and depth of the locks in the canals. The characteristic lake bulk carrier, except on Ontario. is long and narrow, with machinery in the stern, the navigating bridge forward and crew quarters both forward and aft, and it has a cargo capacity of about 15,000 tons.

Special port facilities have been developed to accommodate the bulk carriers. At the ore docks on Lake Superior, boats are loaded in a matter of minutes, and special unloaders at the steel mills on Lake Erie and southern Lake Michigan remove the cargo in a few hours.

Overseas Trade. — Chicago, Toronto, Detroit, Cleveland, Milwaukee and Green Bay are leading ports engaged in overseas trade. In dollar value the principal exports are machinery and machine parts, edible animal oils and fats, hides and skins, motor vehicles and vehicle parts, chemicals and tobacco; the principal imports are alcoholic beverages, steel-mill products, electrical and other machinery, motor vehicles, glass and glass products, wood pulp and tools.

Navigation Improvements. — The relatively regular shore lines of the Great Lakes limited the number of harbours. Private interests as well as the governments of the United States and Canada built docks and harbours, dredged channels, dug canals: installed locks and otherwise improved the lakes for navigation. Most of the major lake ports developed at the mouths of the short rivers which flow into the Great Lakes. These ports usually had an inner harbour on the dredged portion of the river and an outer harbour protected by extensive breakwaters constructed of piling, rock and concrete. Coast guard stations and storm warnings, as well as radio communication, protect traffic over the entire Great Lakes.

Although there are about 200 harbours of all types, the important ones are the commercial and industrial cities of the southern Great Lakes and the ore and grain ports of Lake Superior.

Connecting Waterways.—Of critical significance to Great Lakes traffic are the connecting waterways. especially those in which there is a notable change in level irom lake to lake. At Sault Ste. Marie (the "Soo"), passage around the rapids of the St. Marys river, between Lakes Superior and Huron, is provided by canals and locks constructed on both the U.S. and Canadian sides of the river. Lake Michigan, which is connected with Lake Huron by the broad and deep natural channel of the Straits of Mackinac, is also connected with the Illinois and Jlississippi rivers by the Chicago Sanitary and Ship canal, which has a minimum depth of nine feet (see MICHIGAN, LAKE).

In the St. Clair-Detroit river system, connecting Lakes Huron and Erie, improved channels provide a minimum of 25 ft. for downbound vessels and 21 ft. for upbound vessels (*see* SAINT CLAIR RIVER; ST. CLAIR, LAKE). The Welland Ship canal, extending about 27 mi. from Port Colborne, Ont., on Lake Erie, to Port Weller, Ont., on Lake Ontario, provides for transit of vessels between the two lakes. The minimum depth in the canal is 23.5 ft. (see WELLAND SHIP CANAL). A system of canals operated by the state of New York, with federal support, provides free waterway communication between Lake Erie and the Hudson river. Branches of the system connect, with Lake Ontario and Lake Champlain. The minimum depth in the waterway is 12 ft.

From Lake Ontario to the Gulf of St. Lawrence, the St. Lawrence river consists of three segments. The first extends to the mouth of the Ottawa river, a distance of 175 mi., and includes the Thousand Islands, shoals and rapids. The middle segment extends from the mouth of the Ottawa river 95 mi. to the estuary, and the broad estuary is the third segment. Through navigation in the St. Lawrence river is provided by the St. Lawrence seaway development, which was completed in 1959, with a minimum depth of 27 ft. (see ST. LAWRENCE SEAWAY). The canals and channels connecting Lakes Ontario, Erie, Huron and Superior, which had been maintained for several years with a minimum depth of 21 ft. for upbound traffic and aj ft. for downbound traffic, were dredged to 27 ft. following the opening of the seaway.

Timber Resources. — Magnificent stands of timber, principally pine, once covered the upper lakes region, but the virgin forests were destroyed by exploitative cutting between 1870 and 1910. Timber growth is considered the best use for much of the land, and nearly half of the forested area is held in federal and state forests.

Fisheries. — Commercial fishing for iake trout, whitefish, perch, suckers and chub, once an important industry on the lakes. declined seriously after about 1945. The decline was coincident with an invasion of a species of sea lamprey (eel), and measures for control of the lamprey were being undertaken by government agencies in an effort to restore the fish populations of the lakes. (See also FISH CULTURE.)

Pollution. — The use of the lakes for domestic and industrial water supply and for recreational purposes was adversely affected by pollution in some areas. The discharge of sewage, either untreated or inadequately treated, into tributary streams as well as directly into the lakes mas a principal cause of pollution in the more densely populated parts of the region. Various organic and inorganic industrial wastes also were important factors in some areas. Lake Erie. because of its relatively shallow depth and small volume and because of the concentration of population and industrial plants in its watershed, was most heavily polluted. A program of remedial measures, including removal of settleable solids, oxidation of organic matter and reduction of pathogenic bacteria, which was required by law, resulted in a slight decrease in pollution in years of high or normal rainfall. Southern Lake Michigan and some other areas were polluted to a lesser extent, but increasingly effective programs of pollution abatement were needed.

Tourism. — Recreation has developed as an industry of major importance in the region. Cool pleasant summers and numerous lakes in a wilderness setting have attracted tourists and sportsmen. Thousands of vacation cottages have been built along the shores of the Great Lakes and around inland lakes in the region. Vacationists make use of public campgrounds and tourist cabins in the summer, thousands of hunters visit the region during the autumn hunting seasons, and the cold snowy winters attract increasing numbers of winter sports enthusiasts.

For further iniormation on the Great Lakes region, see articles on the various states and provinces bordering the lakes.

Garland (ed.), *The North American Midwest* (1955); Harlan Hatcher, *The Great Lakes* (1944); Jack L. Hough, *Geology of the Great Lakes* (1958). (*J. L. H*H.)

GREAT MOTHER OF THE GODS, the ancient oriental-Greek-Roman deity commonly known as Cybele in Greek and Latin literature from the time of Pindar. She was also known under many other names, some of which were derived from famous places of her worship, for example, Dindymene from Mt. Dindymon.

Cybele is her favourite name in ancient and modern literature, while Great Mother of the Gods, or Great Idaean Mother of the Gods (Muter *Deum* Magna, *Mater* Deum *Magna* Idaea), the most frequently recurring epigraphical title, was her ordinary official designation.

The legends agree in locating the rise of the worship of the Great Mother in Asia Minor, in the region of loosely defined geographical limits which comprised the Phrygian empire of prehistoric times and was more extensive than the Roman province of Phrygia. Her best-known early seats of worship were Mt. Ida, Mt. Sipylus, Cyzicus, Sardis and Pessinus, the last-named city, in Galatia near the borders of Roman. Phrygia, finally becoming the strongest centre of the cult. But the existence of numerous very similar non-Phrygian deities indicates that she was merely the Phrygian form of the nature deity of all Asia Minor. From Asia Minor the cult of the Great Mother spread first to Greek territory. It found its way into Thrace at an early date, was known in Boeotia by Pindar in the 6th century, and entered Attica near the beginning of the 4th century. At Peiraeus, where it probably arrived by way of the Aegean islands, it existed privately .in a fully developed state (that is, accompanied by the worship of Attis [*q.v.*]) at the beginning of the 4th century, and publicly two centuries later. The Greeks irom the first saw in the Great Mother a resemblance to their own Khea, and finally identified the two completely. though the Asiatic peculiarities of the cult were never universally popular with them. In her less Asiatic aspect (*i.e.*, without Attis) she was sometimes identified with Ge and Demeter. It was in this phase that she was worshipped in the Metroon at Athens.

In 204 B.C., in obedience to the Sibylline prophecy which said that whenever an enemy from abroad should make war on Italy he could be expelled and conquered if the Idaean Mother were brought to Rome from Pessinus, the cult of the Great Mother, together with her sacred symbol, a small meteoric stone reputed to have fallen from the heavens, was transferred to Rome and established in a temple on the Palatine (Livy, xxix, 10–14). Her identification by the Romans with Maia, Ops, Rhea, Tellus, and Ceres contributed to the establishment of her worship on a firm footing. By the end of the republic it had attained prominence, and under the empire it became one of the three most important cults in the Roman world, the other two being those of Mithras and Isis. Epigraphic and numismatic evidence prove it to have penetrated from Rome as a centre to the remotest' provinces. During the brief revival of paganism under Eugenius in A.D. 394 occurred the last appearance of the cult in history. Besides the temple on the Palatine, there also existed minor shrines of the Great Mother in the present Piazza S. Pietro, on the Sacra Via on the north slope of the Palatine, near the junction of the Almo and the Tiber rivers, south of the city *(ibid.,* 311–314).

In all her aspects, Roman, Greek and oriental, the Great Mother was characterized by essentially the same qualities. Most prominent among them was her universal motherhood. She mas the great parent of gods and men as well as of the lower orders of creation. Especial emphasis was placed upon her maternity over wild nature. She was called the Mountain Mother; her sanctuaries were almost invariably upon mountains and frequently in caves; lions were her faithful companions. Her especial affinity with wild nature was manifested by the orgiastic character of her worship. Her attendants, the Corybantes, were wild, half-demonic beings. Her priests, the Galli, were eunuchs attired in female garb, with long hair fragrant with ointment. Together with priestesses, they celebrated her rites with wild music and dancing until their frenzied excitement found its culmination in self-scourging, self-laceration or exhaustion. Self-emasculation sometimes accompanied this delirium of worship on the part of candidates for the priesthood.

Though her cult sometimes existed by itself, in its fully developed state the worship of the Great Mother was accompanied by that of Attis (*q.v.*). The cult of Attis never existed independently. There is no positive evidence to prove the existence of the cult publicly in this phase in Greece before the 2nd century B.C., nor in Rome before the empire, though it may have existed in private. The philosophers of the late Roman empire interpreted the Attis legend as symbolizing the relations of Mother Earth to her children the fruits. In this interpretation they were not far wrong, for Cybele and all her kind are embodiments of the earth's fertility.

At Rome the immediate direction of the cult of the Great Mother devolved upon the high priest, Archigallus, called Attis, a high priestess, Sacerdos Maxima, and its support was derived, at least in part, from a popular contribution, the *slips*. Besides other priests, priestesses and minor officials, such as musicians, curator, etc., there were certain colleges connected with the administration of the cult, called *cannophori* (reed bearers) and *dendrophori* (branch bearers). The quindecimvirs exercised a general supervision over this as over all other authorized foreign cults. Roman citizens were at first forbidden to take part in its ceremonies, and the ban was not removed until the time of the empire.

The main public event in the worship of the Great Mother was the annual festival, which took place originally April 4, and was followed next day by the *megalesia*, games instituted in her honour on the introduction of the cult. Under the empire, from Claudius on, the *megalesia* lasted six days, April 4 to 10. and the original one day of the religious festival became an annual cycle of festivals extending from March 15 to 27, in the following order: (1) March 15, *Canna intrat,* the sacrifice of a six-year-old bull, the high priest, a priestess and the *cannophori* officiating, the last named carrying reeds in procession in commemoration of the exposure of the infant Attis on the reedy banks of the stream Gallus in Phrygia. (2) March 22. *Arbor intrat*, the bearing in procession of the sacred pine, emblem of Attis' self-mutilation, death and immortality, to the temple on the Palatine, the symbol of the Mother's cave, by the *dendrophori*, a guild of workmen who made the Mother. among other deities. a patron. (3) March 24, *Dies sanguinis*, a day of mourning. fasting and abstinence, especially sexual. commemorating the sorrow of the Mother for Attis. The frenzied dance and self-laceration of the priests and the self-mutilation of neophytes were special features of the day. The *taurobolium* (*q.v.*) was often performed on this day, on which probably took place the initiation of mystics. (See also CRIOBOLIUM.) (4) March 25, *Hilaria*. All mourning was put off. and good cheer reigned in token of the return of the sun and spring, which was symbolized by the renewal of Attis' life. (5) March 26, *Requietio*, a day of rest and quiet. (6) March 27, *Lavatia*, the crowning ceremony of the cycle. The silver statue of the goddess, with the sacred meteoric stone, the *acus,* set in its head, was borne in gorgeous procession and bathed in the Almo, the remainder of the day being given up to rejoicing and entertainment, especially dramatic representation of the legend of the deities of the day.

The Great Mother is especially prominent in the art of the empire. No work of the first class, however, was inspired by her. She appears usually with mural crown and veil, well draped, seated on a throne and accompanied by two lions. Other attributes which often appear are the patera, tympanum, cymbals, sceptre, garlands and fruits. Attis and his attributes, the pine, Phrygian cap, pedum, syrinx and torch, also appear. In literature she is the subject of frequent mention, but no surviving work of importance, with the exception of Catullus lxiii, is attributable to her inspiration. Her importance in the history of religion is very great, for her cult, like the other mystic worships, at once formed a rival to Christianity and acted as a steppingstone to it. *(See* MYSTERY.)

GREAT PLAINS. A major flattish land-form area in North America extending from the Mackenzie river lowlands in northern Canada to the Rio Grande in the Big Bend section of Texas, the Great Plains lie directly east of the Rocky mountains and, in New Mexico, of the Basin and Range province. In general, they are about 375 mi. wide and slope gently to the east, where they merge with the central lowlands and the coastal plains.

The eastern border of the Great Plains is readily discernible in only a few places. In Texas the Balcones escarpment, west of Austin, rising to heights of 300 to 1,000 ft., provides a clear break between the Great Plains (there also referred to as High Plains and Edward's plateau) and the coastal plains. A somewhat more subdued escarpment is found in the Coteau du Missouri in North Dakota. Between these two escarpments the eastern border is usually associated with either the 1,500- or the 2,000-ft. contour line. In the United States, these lines lie close to the 97th to 100th meridians, which are also frequently mentioned as border lines.

Below the mountain front on the west the Great Plains have an elevation of 5,000 to 6,000 ft. All major rivers have west-east axes and an average gradient of about ten feet per mile. Prominent streams are the North and South Saskatchewan, Milk. Missouri, Yellowstone, Powder, Little Missouri, Cheyenne, White, Niobrara, Platte, Republican, Kansas, Cimarron, Arkansas, Canadian, Red, Brazos and Colorado rivers.

Much of the plains area consists of gently tilted shale, limestone and sandstone discontinuously mantled by glacial deposits (in the north), loess and alluvial deposits. Although the plains are generally pictured as flat to rolling, conspicuous land forms characterize some of their parts. Among these are the Black hills of South Dakota and Wyoming, the badlands of South Dakota, the sand hills of Nebraska and a series of mountain outliers in Montana and elsewhere. Locally, cuestas, hogbacks, breaks and mesas are sculptured in the sedimentary bedrocks.

Because of limited precipitation, ranging from 10 to about 20 in. a year, grass is the prevailing natural vegetation. Short grass or steppe prevails in the southern plains whereas the cooler temperatures and more effective precipitation in the northern plains support intermediate and tail grasses. In central Alberta and

Saskatchewan the limited but effective moisture also supports broadleaf and mixed broadleaf coniferous forests. Moderate precipitation has meant limited leaching and the soils are usually of superior productivity when supplied with moisture.

Population in the plains area is relatively sparse. It is supported largely by grazing of livestock, dry farming of wheat and the production of sorghums and cotton. Farming under irrigation is expanding. Parts of the plains are well endowed with coal and lignite, petroleum and natural gas.

GREAT RIFT VALLEY, a part of the most extensive rift on the earth's surface extending over 50 degrees of latitude from the Jordan valley in southwest Asia to the Shiré tributary of the Zambezi in east Africa. In Africa it is marked by a line of narrow, deep and steep-sided lakes, including Rudolf, Magadi, Natron and Nyasa, by associated volcanic outpourings such as mounts Kilimanjaro (19,340 ft.) and Kenya (17,058 ft.), and in places by steep edges like the Mau and Kikuyu escarpments. A western branch of the Rift valley. extending in a great arc from the northern end of Lake Nyasa, is occupied by Lakes Tanganyika, Rivu, Edward and Albert. See also the Physical Geography sections of AFRICA; KENYA; TANGANYIKA. (R. W. SL.)

GREAT SALT LAKE, in northwestern Utah, U.S.a large body of shallow, briny water, is the most extensive lake of its kind in the western hemisphere and the largest remnant of a Pleistocene lake which overspread the eastern part of the Great Basin (see UTAH). About 83 mi. long and 51 mi. wide, the lake has varied in area—from about 2,200 sq.mi. at a high level in 1873 to 1,500 sq.mi. at a low level in 1940. With an average depth of 10 ft., it had a maximum depth at mid-20th century of 35 ft. and a mean elevation of 4,199 ft. above sea level; it was then a foot lower than at mid-19th century and 12 ft. under the level of 1873.

The salts held in solution are principally sodium chloride and sodium sulfate; after mid-20th century the salinity remained close to 25%, slightly under the point at which salts begin to precipitate.

Few things can live in this saturated salt solution (maintained by evaporation in the face of continued inflow from the Bear, Weber and Jordan rivers). There are some algae, a few flagellates. protozoans and invertebrates, a small brine shrimp and two brine flies. Thousands of tons of salt have been harvested without perceptibly reducing the supply. Stansbury, Antelope arid Fremont islands are used for grazing purposes, the first two being connected with the mainland when the lake is low. Smaller islands and islets are used as nesting sites by white pelicans, great blue herons, cormorants, terns and gulls. A federal migratory bird refuge was established in 1928 at the mouth of the Bear river. Father Silvestre Vélez de Escalante and Francisco Dominguez referred to the Great Salt Lake as early as 1776, though they had not seen it, and for many decades it was reflected on maps of America as a half-legendary body of water, usually named Timpanogos or Buenaventura.

The lake seemingly mas independently discovered in 1824–25 by two trappers, James Bridger and Étienne Provost, and by 1826 other hunters had circumnavigated it. The first formal exploration. by John Charles Frémont in 1843 and 1845, was followed by Howard Stansbury's survey in 1850. The Lucin Cutoff (30 mi. of railway trestlework and fill), constructed across the lake by the Southern Pacific railroad, 1902–03, was replaced in 1957–60 by a dike built at an estimated expense of $49,000,000. There is a yacht harbour at the southeastern shore of the lake, with popular beaches nearby.

See James *E.* Talmage, *The Great Salt Lake, Present and Past* (1900) and Dale L. Morgan, *The Great Salt Lake* (1947). (D. L. M.)

GREAT SLAVE LAKE (ATHAPUSCOW), in Mackenzie district, Northwest Territories, Can., between latitude 60° 50′ and 63° 10′ N. and longitude 108° 50′ and 117° W. and j16 ft. above the sea, is about 298 mi. long, 62 mi. wide and 11,170 sq.mi. in area; it drains by the Mackenzie river into the Arctic ocean. The water is very clear and deep. The shore is indented by large bays, often with rocky slopes that form rugged cliffs fronting East Arm. The western shores are well wooded; the northern and eastern shores are largely barren.

The navigation season is from about mid-June to mid-October, the lake freezing over in winter.

The English explorer Samuel Hearne discovered the lake in 1771. Gold is produced in the Yellowknife and Rae areas. An inland fishing industry (whitefish, trout) was established in 1945 with packing plants at Gros Cap and Hay River. (J. R. M.)

GREAT SMOKY MOUNTAINS. In western North Carolina and eastern Tennessee, U.S., between Asheville and Knoxville, the Great Smoky mountains are the western segment of the high crystalline Appalachians and blend into the Blue Ridge escarpment on the east. The blue smoky haze that covers the region gave the mountains their name.

Originally the domain of the Cherokees, the Smoky mountains were explored in the mid-19th century by the geologists Thomas L. Clingman and Arnold Guyot. The highest segment of the mountains is occupied by the Great Smoky Mountains National park (*q.v.*), which extends 54 mi. between the Little Tennessee river on the southwest and the Pigeon river on the northeast, and is zpproximately 20 mi. wide. Highest peaks in the park area are Clingmans Dome (6.642 ft.), Mt. Guyot (6,621 ft.), Mt. Chapman (6,430 ft.), Mt. Collins (6,188 ft.), Mt. LeConte (6,593 ft.) and Mt. Kephart (6,150 ft.). The mountains are covered by forests, about 40% of which is virgin growth. There is an abundance of rhododendron, mountain laurel, wild flowers and animal life. Gatlinburg. Tenn., serves as park headquarters and offers a wide range of accommodations and services for tourists. A transmountain highway runs from Gatlinburg through Newfound Gap (5,048 ft.) to Cherokee, N.C., which is the site of a Cherokee Indian reservation. (M. C. P.)

GREAT SMOKY MOUNTAINS NATIONAL PARK, in eastern Tennessee and western North Carolina, was established in 1940 to preserve the last remaining sizable area of southern primeval hardwood forest in the United States. The park, 511.678 ac. in extent, contains some of the highest mountains east of the Mississippi river, with Clingmans Dome (6,642 ft.) the tallest in the park.

Summits and ridges are crowned with a forest of red spruce except where open areas—balds—occur. Some of these are grown with rhododendrons (R. catawbiense), which display large purple-pink blooms in the early summer. The forests on lower slopes, traversed by rushing streams, are composed of such trees as hemlocks, silver bell, black cherry, buckeye, yellow birch and tulip tree, the latter sometimes attaining trunk diameters of six feet and larger. Understory trees on lower slopes and in the valleys are flowering dognood, redbud and serviceberry; dense stands of mountain laurel, several species of brilliant-flowered azalea and the white-blossomed rhododendron (R. maximum) form almost impenetrable thickets. Wild flowers of many kinds are abundant in the spring and summer.

A few of the park's more important species of wildlife are black bears, white-tailed deer, foxes, bobcats, raccoons, ruffed grouse, turkeys and many colourful songbirds and insectivorous birds, the latter occurring in greatest numbers while migrating northward in spring.

During pioneer times, many families settled in the sheltered coves and valleys of the area, and a number of their picturesque, primitive farmhouses, barns and a mill are preserved in the park. Cades Cove contains such an exhibit, and there a number of families remain and continue to farm in harmony with certain National Park service regulations. (Dx. B.)

GREAT TREK is the name given to a migration of the Boers from British jurisdiction in south Africa (*see* SOUTH AFRICA, UNION OF: *History*). About 12,000 voortrekkers and their families left Cape Colony between 1835 and 1843.

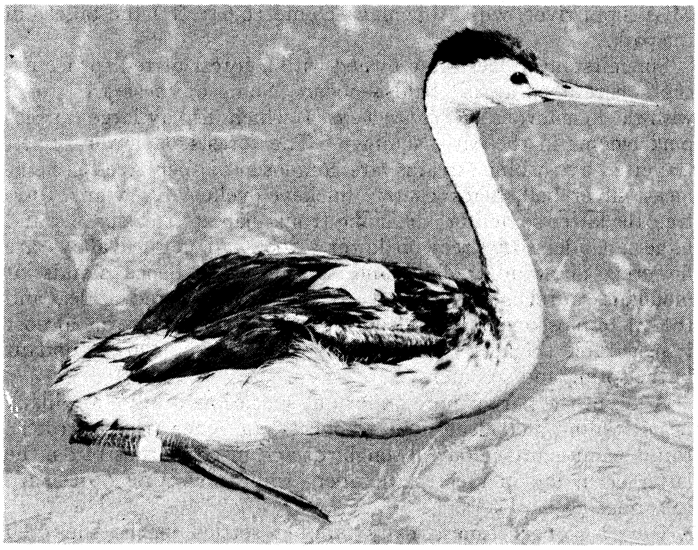
Most of them settled in Natal, but when it was annexed by Great Britain in 1843 many moved across the Orange river and founded the Orange Free State (see ORANGE FREE STATE: *History*) and the Transvaal (see TRANSVAAL: *History*). Both oi these later became Boer republics.

GREAT WALL OF CHINA, a defensive fortification extending about 1,500 mi. from the Gulf of Chihli of the Yellow sea to the gates of central Asia, is the greatest building enterprise ever undertaken by man. Walled frontiers between kingdoms in China date from at least the 4th century B.C., developing from the siege warfare of a people who lived in walled cities. In the 3rd century B.C. the "first emperor of Ch'in"—Ch'in Shih Huang Ti—after uniting China, linked up some already existing walls and built new sections to create the Great Wall, defending China from the Hsiung-nu or Huns on the north. It was built of earth and stone, and its eastern sections were faced with bricks. The Great Wall was frequently modified in later centuries. The sections built in the 15th and 16th centuries—which took in less territory than the "original" Great Wall—were about 30 ft. high and wide enough on top ior a column of troops. Towers about 40 it. high were built at intervals of 200 yd. Not all the outlying walls in Mongolia have been fully traced, mapped and identified as to date. See also CHINESE ARCHITECTURE. (O. L.)

GREAT WAR, THE, 1914–1918: see WORLD WAR I.

GREBE, an aquatic diving bird of the family Podicipedidae, order Podicipediformes, containing several genera including *Podiceps* and *Aechmophorus*. The grebes are generally considered to be among the most primitive living families of birds. As a rule they are weak though fairly rapid fliers. Grebes are distinguished by the rudimentary tail. legs placed far back on the body, flattened shank and elongated toes furnished with broad lobes of skin in lieu of webs, bodily characteristics of adaptive importance to these divers. Although grebes are excellent swimmers. found on coastal and inland waters throughout the world, they are almost helpless on land and take to wing reluctantly. All species have short and close plumage usually some shade of brownish gray above. often reddish markings, white and glossy below.

Most species develop special nuptial adornments in the spring in both sexes, in the form of crests or tufts. and very remarkable mutual courtship ceremonies have been described (*see* COURTSHIP, ANIMAL). In some species, as the great crested grebes (Podiceps



A. WETMORE, U.S. FISH AND WILDLIFE SERVICE

FEMALE WESTERN GREBE (AECHMOPHORUS OCCIDENTALIS) WITH CHICK ON HER BACK

cristatus), this involves the partners facing each other, standing practically erect on the surface of the water. bowing, then dropping to a more horizontal position, and occasionally skittering over the water as if they were walking on the surface.

The nest, usually built among tangled vegetation in shallow waters, consists of a mass of water weeds, in a shallow tray on which the chalky white eggs are laid. The parent covers the eggs before leaving the nest, so that the moist covering, besides screening the eggs from view, provides warmth as a result of its decay. The downy youth, striped black, white and bronn, are often carried about on the parent's back, and if danger threatens, the adult tucks the young under its wings and dives with them.

Of the five European species, P. *ruficollis* is the well-known little grebe or dabchick (*q.v.*), with a wide range over the old world. The great crested grebe (Podiceps *cristatus*) is also a wide-ranging species. The subarctic red-necked grebe (P. *grisegena*) inhabits Europe and America, as does the horned or Slavonian grebe (P. *auritus*). Various other species inhabit North America, among which may be mentioned the western grebe (*Aechmophorus occidentalis*), with a long slender neck and black and white plumage; and the pied-billed grebe (*Podilymbus* podiceps), the best-known grebe in America.

Several more are found in South America, of which the most remarkable is the flightless *Centropelma micropterum* of Lake Titicaca. The common-eared grebe (Podiceps *nigricollis*) breeds over Africa, Europe, northern Asia and western parts of Canada and the United States; four other species of Podiceps occur from Peru to the Falklands and Straits of Magellan. The Mexican grebe (*Podiceps dominicus*), of tropical South and Central America, is a small bird reaching the West Indies and southern Texas; four other species occur in Australia, New Zealand, Malaya and Madagascar. *Podilymbus gigas* is confined to Lake Xtitlan. Guatemala. while *A. major* ranges from Peru and northern Brazil to the Straits of Magellan. (G. F. SS.; HT. FN.)

GREBEL, CONRAD (1498?–1526), Swiss religious leader, the chief founder of Swiss-South German Anabaptism and thus of the Free Church type of Protestantism, was born in Zurich, the son of Junker Jakob Grebel of a prominent patrician family. He received a good humanist education at the universities of Basel, Vienna and Paris, but completed no degree. Returning to Zurich in 1520, he soon became an ardent supporter and associate of Huldreich Zwingli (*q.v.*) in the Swiss Reformation, only to break with him in late 1524 on the issue of the establishment of a free church, separated from the state.

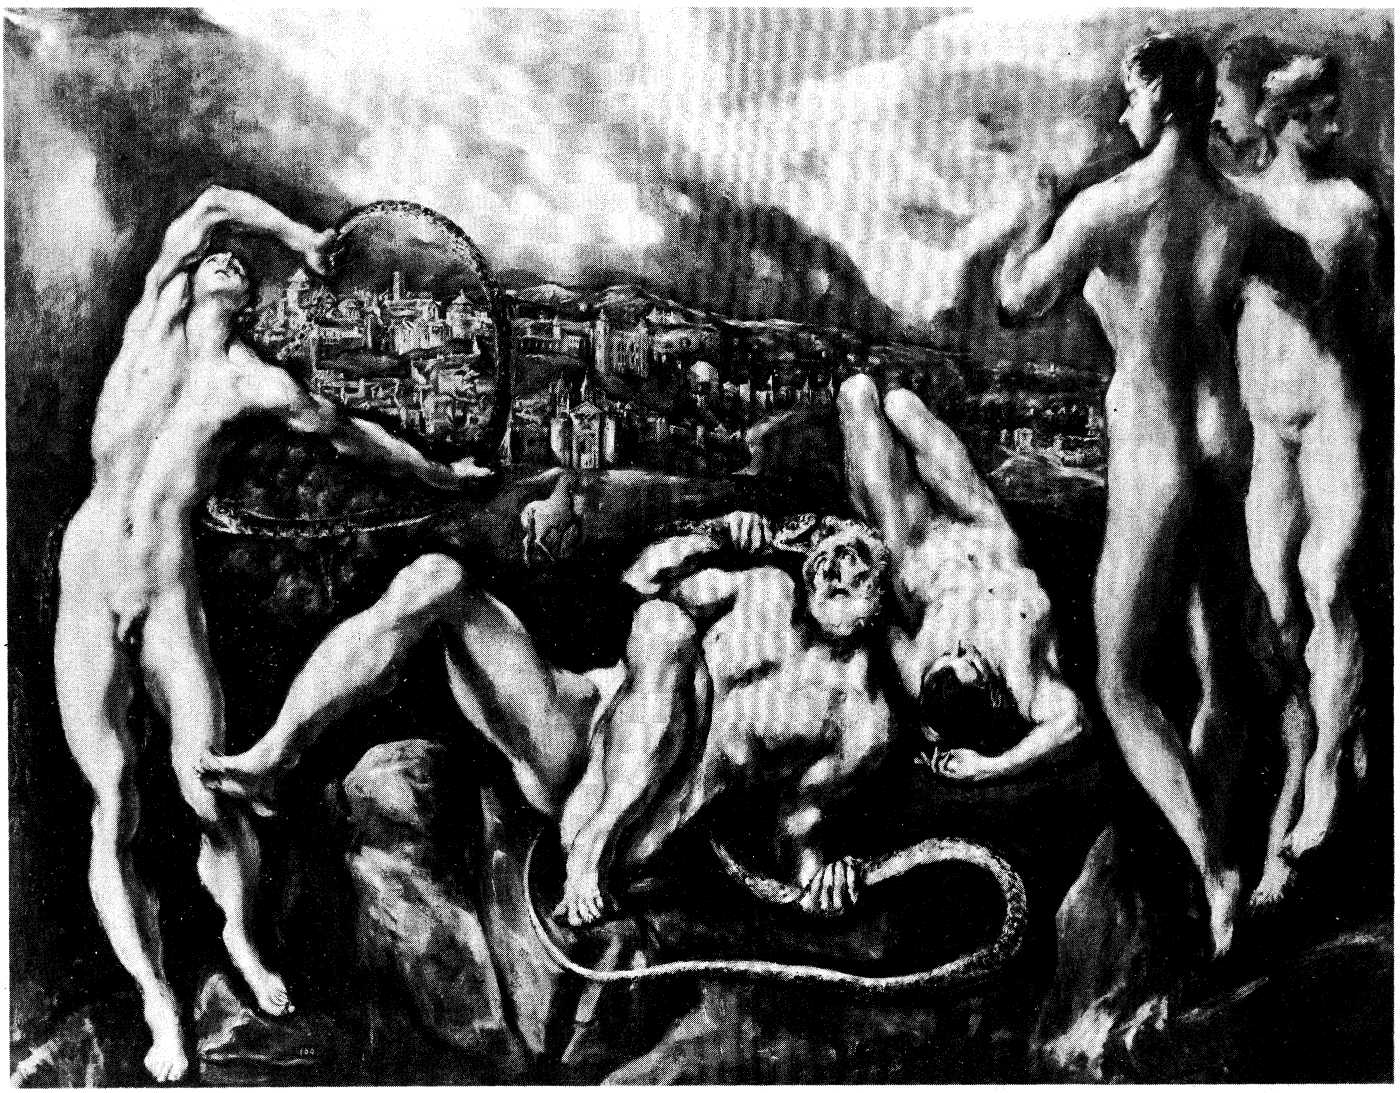
In association with Felix Manz and George Blaurock, Grebel started such a church on Jan. 21, 1525, by performing the first adult baptism in modern history. The group was immediately plunged Into persecution, and Grebel lived a harried life until his death of the plague in 1526 in Maienfeld, Grisons canton. He was imprisoned twice in Zurich for a total of at least six months. He left no writings, but 69 of his letters are preserved in St. Gall. Grebel's major emphases were on the voluntary believers' church, Christian discipleship and holy living, and an ethic of love which included rejection of all warfare. See also ANABAPTISTS.

See Harold S. Bender, *Conrad Grebel ca. 1498–1526, The Founder of the Swiss Brethren, sometimes called Anabaptists* (1950). (HD. S. B.)

GRECHANINOV, ALEKSANDR TIKHONOVICH (1864–1956), Russian composer notable for his religious music and music for children, was born in Moscow on Oct. 25, 1864. From 1881 to 1890 he studied the piano with V. I. Safonov and composition with S. I. Taneev and A. S. Arensky at the Moscow conservatory; from 1890 to 1893 he worked at composition and orchestration at St. Petersburg with Rimski-Korsakov. He soon became known by his songs, his first string quartet (1893) and the first of his five symphonies (1894). His opera Dobrinya *Nikitich* was produced in Moscow in 1903. (The later Soeur Beatrice was produced in 1912 but had to be withdrawn at once on religious grounds.) He composed in all media, producing a great quantity of piano music, songs and choruses, but his music lacks any strong personal stamp. His church music brought him an imperial pension, though his later religious music (from 1912 onward) introduces instruments and cannot be used in the Orthodox liturgy. With the 1917 Revolution he lost his pension and, after several visits to the west, he settled in Paris in 1925. There he published an autobiography. In 1940 he fled to New York, where he died—a U.S. citizen—on Jan. 3, 1956.

See A. Grechaninov, *My Life,* trans. by Nicolas Slonimsky (1952). (G. AB.)

GRECO, EL (1541–1614), properly called DOMENIKOS THEOTOKOPOULOS, one of the greatest and most individual masters of Spanish painting, was born in Crete and trained in Italy. He spent



BY COURTESY OF THE NATIONAL GALLERY OF ART WASHINGTON, D C

"LAOCOÖN" BY EL GRECO. IN THE SAMUEL KRESS COLLECTION, NATIONAL GALLERY OF ART, WASHINGTON, D.C.

the second half of his life in Spain and is known as a Spanish painter. In Italy he was called Il Greco, in Spain Domenico Greco or El Griego, but he is now generally referred to as El Greco. Nothing is known of his early life in Crete, then under Venetian domination, but some of his works suggest that his first schooling was in the Byzantine style of icon painting. The form of the small signed polyptich (Modena gallery, Italy), the vivid colours and the scene of "Moses on Mount Sinai" are of Byzantine origin, while most of the other compositions are derived from Venetian models. There is no evidence of when El Greco went from Crete to Italy but it can be assumed that he was in Venice studying under the aged Titian some time before 1570, when he moved to Rome; for there can be no doubt that he is the artist recommended by the miniature painter Giulio Clovio in a letter of 1570 to Cardinal Alessandro Farnese: "There has arrived in Rome a young man from Candia, a pupil of Titian, who seems to my judgment to have a rare gift for painting. . . ." There is a signed portrait of Clovio by El Greco (Naples museum); he introduced this portrait together with those of Titian, Michelangelo and Raphael, three of the masters to whom he was indebted, in one of his paintings of the "Purification of the Temple" (Minneapolis, Minn.). These and other works executed in Italy are mainly Venetian in style and colour but show a variety of sources. He was influenced by Tintoretto, Paolo Veronese and Jacopo Bassano as well as Titian; in Rome he borrowed from Raphael and Michelangelo and was also affected by the prevailing Mannerist styles.

It is not known why or when El Greco left Italy for Spain; when questioned later in Toledo he refused to reply. Mancini, writing a few years after his death, relates that when it was proposed to repaint some of the nude figures in Michelangelo's "Last Judgment," El Greco's announcement that if the whole painting were demolished he could replace it with one that mould be "decorous and seemly and no worse as a work of art" caused such indignation that he was obliged to leave Rome and retire to Spain. It is. however, probable that he went there with the prospect or hope of employment by Philip II in the decoration of his new palace monastery of the Escorial.

He was first recorded in Spain in Aug. 1577, the date of his contract for altarpieces in S. Domingo el Antiguo, Toledo; there is evidence that he had already been in Madrid. He seems to have made only two paintings for the king, one of which may have been painted before he went to Toledo. The "Adoration of the Name of Jesus" (Escorial; model in the National gallery, London), traditionally called the "Dream of Philip II," has been identified as an allegory of the Holy league, with portraits of Philip II, the pope and the doge of Venice; and though on a much larger scale, this painting is not far removed in style from his later Italian paintings.

The "St. Maurice and the Theban Legion" (Escorial) was commissioned in 1580 for the church of the Escorial, but was rejected for the altar for which it mas painted because it did not please the king.

El Greco appears to have made no further attempt to obtain royal patronage and settled for the rest of his life in Toledo. He was extremely active as a religious artist, whose paintings were much sought by churches and convents. He also painted a number of portraits of church dignitaries and other distinguished persons; his few landscapes and genre compositions and one surviving mythological representation are among the first examples of these subjects in Spanish painting.

In Spain he was known as an architect and sculptor as well as a painter and he designed, if he did not execute, some of the carved altarpieces and their sculptures for which he made the paintings.

It was only after his move to Spain that El Greco developed that highly individual style for which he is famous. Most of his paintings produced in Italy have later been attributed to Tintoretto, Veronese and other Italian artists but his Spanish paintings have never been ascribed to anyone else. Though the transformation of his Italian sources was a gradual process, his early works in Toledo were already distinctive in character. In the "Espolio," which he painted for the cathedral soon after his arrival (1577–79), the elimination of space and dramatic concentration on the figures create a new, highly emotional effect. This painting involved him in a lawsuit concerning the price, in which he was ordered to correct certain "improprieties" in his treatment of the subject, though this was never done.

The "Burial of Count Orgaz," executed in 1586 for the church of S. Tomé, his first entirely independent work, established his fame in Toledo and is still his most celebrated painting. Here all the elements of his Spanish style appear in a composition for which there is no Italian iconographic precedent. The subject is the legend of a local Toledan nobleman of the 14th century who was rewarded for his pious deeds by the miraculous appearance of SS. Stephen and Lawrence to carry his body to burial, in the presence of all the noblemen of the city. The miracle itself is represented in the lower half of the picture in comparatively realistic terms. The frieze of noblemen which forms the background to the burial, the saints and other attendants, have the appearance of individual though stylized portraits, their faces expressing various emotions from contemplation to rapture. Above, the scene in heaven, to which the count's soul is borne by an angel, is in an entirely different language. The elongated figures with floating draperies, grouped in exaggerated postures amid fantastic clouds, the violently contrasting colours and dramatic lighting emphasize the visionary character of the spiritual world.

Later El Greco was to adopt this language for his representations of holy persons on earth as well as in heaven.

His portraiture shows a gradual development from the formal likenesses of his Italian period to an increasingly subjective interpretation. In a number of simple busts and half-length figures (many in the Prado, Madrid), the facial expressions give vivid impressions of personality and temperament. This etiect is in no way diminished by increasing disregard for natural form and conventional modeling. On the contrary, in his late portraits of Cardinal Fernando Niño de Guevara (*c.* 1600, Metropolitan museum, New York) and Fray Hortensio Félix Paravicino (*c.* 1606, Boston)—seated figures in the Renaissance tradition—he achieves his most remarkable effects of likeness with hardly any indication of the structure of the bodies and with a free impressionistic technique that eliminates detailed description.

For his devotional subjects El Greco created types that he hardly ever varied, but his interpretation changed with the development of his style. Thus, several examples of the "Purification of the Temple" (*e.g.,* National gallery, London), based on his Italian compositions of the subject, illustrate the transition from narrative description to symbolical interpretation. His representations of saints, St. Francis in meditation and ecstasy, the repentant St. Peter, St. Mary Magdalene and St. Jerome—like the "Purification" themes of special doctrinal importance to the Counter-Reformation church—become transformed into visionary figures. Rocks, caves or clouds provide mysterious settings and the exaggeration of postures, gestures and facial expressions accentuates the spiritual meaning of the image. The number of replicas of these subjects that exist from his own hand and from his studio shows that they must have enjoyed great popularity.

The painter Francisco Pacheco, who represented the orthodoxy of his time in matters of decorum and aesthetics, proclaimed El Greco to be the best painter of St. Francis of his age.

Among the major accomplishments of his late years was the decoration of the Capilla Mayor of the Hospital de la Caridad at Illescas, dedicated to a miraculous image of the Virgin, for which he designed the altars and probably executed the sculptures as well as the paintings (1603–04, no longer intact). The co-ordination of architecture, sculpture and painting and the unity of subject matter in a composition intended to be seen from a single viewpoint foreshadow principles of Baroque design. In his last paintings, the complete harmony of form and content creates an emotional impact hardly surpassed by later Baroque artists. The distorted bodies in twisted, strained attitudes, seen against the spectral background of Toledo, give direct expression to the physical and mental torment of "Laocoön" (National gallery, Washington, D.C.). The long attenuated figures, whose upward swirling movement is directed by the arbitrary and dramatic lighting, create an impression of a miraculous apparition of the "Assumption of the Virgin" (S. Vicente, Toledo); and the "Opening of the Fifth Seal" (Zumaya, Sp.), in similarly unrealistic language, powerfully evokes the mystic spirit of the ecstatic figure of St. John and of his apocalyptic vision.

The extraordinary originality of El Greco's Spanish style made his paintings a subject of dispute from the beginning. He failed to satisfy the conventional taste of Philip II, whose court painters were mediocre and moderate followers of Italian Mannerism. Yet he won considerable renown in Toledo both as an artist and as a remarkable if strange personality. At the same time he was involved in several lawsuits concerning the orthodoxy of his paintings, and the prices that he demanded. The conventional Pacheco, who visited him in Toledo a few years before his death, described him as "singular in everything as he was in his painting." Shocked by El Greco's opinions on art, particularly his statement that "Michelangelo was a good man who did not know how to paint," Pacheco had to admit that El Greco could not be excluded from the ranks of the great artists. Since his death various legends have been invoked to explain the so-called extravagance of El Greco's style, including a popular local legend that he was mad; in modern times attempts have even been made to prove that he suffered from astigmatism. But this extravagance had its roots in his Greek origin and Italian training, and his development from a minor Greco-Italian painter into one of the greatest artists that Spain has ever known must be attributed to the impact on him of his new environment. The exotic atmosphere of Toledo: a centre of intellectual and religious life, must have been particularly congenial to his own eccentric personality, and his "View of Toledo" (Metropolitan museum, New York) in his late "visionary" style hardly exaggerates the extraordinary appearance of the city. His isolation there from the artistic activities at the court and from modern trends in Italy must also have contributed to his highly original formal development, and the lack of new models as well as Byzantine traditionalism would account for his frequent repetitions of compositions; figures and rhetorical gestures.

Above all, however, his Spanish paintings reflect the atmosphere of fanatical religious zeal in his adopted country and they are particularly close in spirit and expression to the writings of the great Spanish mystics like St. John of the Cross, who was in Toledo when El Greco settled there.

El Greco had a few pupils and assistants, but his style was too personal to be communicated to followers and he remained an isolated figure. Until the end of the 19th century his paintings were practically unknown outside Spain. Since then they have provided a stimulus to many modern painters and El Greco is recognized as one of the world's great artists.

(E. Hs.)

GRECO-TURKISH WAR (1921–22). The origin of the Greco-Turkish War of 1921–22 was the treaty of Sèvres (Aug. 10, 1920), by which among other provisions the Allied powers awarded to Greece eastern Thrace up to the Catalca (Chatalja) line and including Gallipoli, together with the district of Smyrna (Izmir).

On May 12, 1919, the Greeks had already been authorized by the Allied Supreme council to land at Smyrna. In June 1920 the Greeks occupied Bursa and Bandirma on the Sea of Marmara; in October they mere at Yenisehir and Inegol, east of Bursa. Turkey, however, refused to ratify the treaty of Sèvres and from the opposition to it emerged the national revival under Mustafa Kemal Pasha (see MUSTAFA KEMAL ATATÜRK). The situation was complicated by the fact that the Greek elections of Nov 14, 1920. which followed the death of King Alexander returned a royalist majority and led to the withdrawal of Eleutherios Venizelos from politics. On Dec. 20, King Alexander's father, Ring Constantine, who had been forced to vacate his throne by the Allies on June 12, 1917, on account of his pro-German policy, was restored as the result of a plebiscite. His advent to power brought about some disorganization in the Greek army on account of the dismissal of Venizelist officers: the Greek commanders in Turkey, Gen. Anastasios Papoulas and his successor, Gen. Georgios Hadjanestis, owed their positions to their political allegiance rather than to their military capacity. In Jan. 1921 a poorly equipped Greek army started an offensive into Anatolia and took the two railway junctions of Afyon (Afyonkarahisar) and Eskisehir, but was forced to withdraw in April as a result of a Turkish victory.

In July 1921 the Greeks resumed their offensive in order to forestall a Turkish attack. Afyon and Eskisehir were retaken and the Greek advance pressed forward in the direction of Ankara, but it was severely checked by Kemal in September on the Sakarya river, from which the Greeks were obliged to withdraw.

Great Britain and France, meanwhile, showed little unity of policy. The British prime minister, David Lloyd George, favoured the Greeks; but he was greatly hampered by the danger of repercussions in Muslim countries nhere British interests could be affected if too great a measure of support were given to the Greeks. France. on the other hand, was in favour of a compromise with the Turks. On Oct. 20, 1921, France gave up the intention of occupying Cilicia, retaining only the sanjak of Alexandretta (Iskenderun). France. moreover, undertook to supply Turkey with arms. Such sympathy as France had for Greece was weakened when in Jan. 1922 Aristide Briand's government fell and mas succeeded by that of Raymond Poincaré.

The Paris inter-Allied conference recommended on March 24, 1922, an armistice between the two parties. but the Turks under Kemal demanded the total evacuation of Anatolia On Aug 26. 1922, the Turks achieved a great victory at Afyon which compelled the Greek army to withdraw in disorder On Sept. 9, 1922, the Turkish army recaptured Smyrna, where a large part of the Greek population was massacred The Kemalist army was then free to march to the Bosporus, where the French authorities refused to offer resistance to their entry into Istanbul and the British authorities were compelled to follow the French example The armistice of Mudanya, concluded on Oct. 11, 1922, admitted Turkish troops into Istanbul and made provision for renewed peace discussions at Lausanne betneen Turkey and the Allies

The results of the campaign mere important for Greece. A body of officers on the island of Chios led by Col. Nikolaos Plastiras, demanded that Constantine abdicate. Ironically Constantine, forced to abdicate in 1917 under Allied pressure, was now compelied to give nay to his son, George II for having undertaken action with the encouragement of the Allies. On Nov. 28, 1922, the responsible Greek ministers, Dimitrios Gounaris, Petros Protopapadakis, Nikolaos Stratos, Georgios Baliatzis, Nikolaos Theotokis and Hadjanestis, were sentenced to death and executed despite British and French warnings. For Turkey the campaign ended more happily. After protracted negotiations the treaty of Lausanne was signed on July 24. 1923. Greece had to give up eastern Thrace and accept the Maritsa (Evros) river as its eastern frontier, while Turkey obtained Imbros and Tenedos. To some extent future causes of Greco-Turkish friction were removed by the transference of Greek and Turkish minorities to their respective homelands. The sultanate having been abolished on Nov. 1, 1922, Kemal's regime began with the prestige of a great military victory. In Great Britain, Lloyd George's anti-Turkish policy produced a crisis, since it was likely to have repercussions in Muslim areas of the empire and to be criticized by the self-governing dominions, uhom he had not consulted. On Oct. 19, 1922. the Conservative party decided to break the coalition formed in 1918.

GREECE (Greek Ἑλλάς), a country of southern Europe, comprising the southern peninsular projection of the Balkans, the northern foreshore of the Aegean as far east as the Maritsa river and, except for Imbros and Tenedos, all the main islands of the Aegean, including Crete and (from 1947) the Dodecanese.

PHYSICAL FEATURES

Geology.—Structurally, Greece forms part of the system of folded mountains, thrown up in the Tertiary period, which crosses the old world from the western Mediterranean to the East Indies. In the Balkans these fold ranges consist mainly of sedimentary limestones which were crushed against a resistant central nucleus of hard crystalline rocks, the Rhodope massif. detached fragments of which are seen in the coastlands of Macedonia and Thrace.

The backbone range of central Greece is that of Pindus, which preserves the general north-northwest to south-southeast trend of the Dinaric ranges of Yugoslavia, of which it forms a projection. The Pindus range has a hard core of granites and serpentines, flanked with Cretaceous limestones. From it there diverges eastward, in broad arcs, a series of ranges which form the various promontories of the east coast, and whose lines can be followed out into the several archipelagos of the Aegean. South of the Gulf of Corinth, the general Dinaric grain of the Pindus can be traced again in the promontories of the southern Peloponnesus (Morea), but beyond there these folds make a broad curve. the undrowned fragments of which can be seen in Crete and Rhodes.

After the folding of the mountains. which began in the late Cretaceous period and continued into the Miocene, the topography of the country was vastly modified by rifting and subsidence, processes which still continue on a minor scale and result in earth tremors like those which caused havoc in the Ionian Islands in 1953. This fracture and collapse had various results. In the first place, the rivers of Greece often follow rift valleys, as in the case of the Vardar (Axios) and Struma (Strimon). Second, deep enclosed depressions were formed, which were occupied by lakes. Throughout the Pliocene period these gradually filled with sediment to form wide flat plains, like those of Larissa and Trikkala, often imperfectly drained through a single narrow outlet. Third, the main outline of the coasts was shaped at this time. Where the cleavage ran parallel to the general trend of the mountains, the resulting coast was straight and harbourless, as in Elis. Where, however. the rifting ran across the grain of the folded ranges, long sheltered bays, like the Gulfs of Corinth and Aegina, were the result. Last. the origin of the Aegean sea and its islands must be attributed to the fall of a whole major section of the fold mountains, betneen the eastern shore of the Greek mainland and the west coast of Asia Minor. In the Aegean the depth of the subsidence was greater in the south than in the north. Much of the sea between Lemnos and Thrace is less than 1,200 ft. deep; off the Northern Sporades the sea is at most 5,000 ft. deep; while between the Cyclades and Crete maximum depths of about 8,000 ft. are recorded. The present sea level of the Aegean, therefore, stands approximately halfway between the deepest part of the sea bed and the summit of the highest crests on the mainland. South of Crete, the Aegean "platform" ends abruptly and the sea bed falls to depths of 20,000 ft. or more.

A countereffect of the earth fracture of the Tertiary period was the volcanic eruption that produced the now extinct craters of Patmos, Nisyros and Melos, and that which is still from time to time active on Thera (Santorin). On the mainland, occasional deposits of tuff and lava, as at the cone of Methana, as well as hot springs like those of Lutraki and Thermia, are further signs of vulcanism.

Finally. many details of the coast have been modified. even since classical times. by silting, especially in the deltas of Thessaly.

The peculiar beauty of Greece is found not in the grandeur of its mountains and rivers, but rather in the infinite variety of its scenery and in the intimate juxtaposition of harsh white limestone crags, piedmont terraces with deep-green orchards of olive and fig, dusty plains of sparse thorny pasture and limpid sea of cerulean blue.

Climate. — Summer is hot and dry almost everywhere in Greece, and the mean July temperature at sea level is usually very close to 80° F. The extreme heat is tempered to a small extent in the immediate vicinity of the coast. where a regular sea breeze blows in every afternoon. Temperatures are lower also in the higher mountains of northern Greece which, because of their elevation, enjoy an appreciable rainfall in summer and autumn. Elsewhere! the summer drought is unbroken, and the etesian winds. becoming steadily warmer in their movement southward, parch the earth they pass over. These winds. which belong to the same system as the trades, are gentle. regular and reliable, and summer is the traditional sailing season in the Aegean.

With the break of the rains in late September, conditions change immediately. In winter the belt of eastward-moving cyclonic storms of temperate latitudes shifts southward to include Greece and the other Mediterranean lands. The winds at sea become squally and turbulent, changing direction as each cyclone passes by, and they may make sailing conditions as hazardous as those described by St. Luke in his account of the shipwreck of St. Paul. In Macedonia the north wind from the heavy, cold air mass of the central Balkans is liable to blow with particular force when it is drawn as an indraft down the valleys of the Vardar and Struma into one of the cyclones over the Aegean. At one such time a thermometer reading as low as 14° F. was observed at Salonika. and the nearby gulf had a thin coating of ice. This cold north wind is known as the *bora* and has its counterpart in the *shilok* or warm wind from the south, which on the west coast in the intermediate seasons may quickly heat the local atmosphere as much as 12° F. The difference of temperature between northern and southern Greece is much greater in winter than in summer, and while Athens has a mean January temperature of 46.4" F., the corresponding figure at Salonika is 40.6° F. The west coast. where most of the winter winds blow onshore. has the mildest winters, and Corfu records a mean temperature for January of 50.4° F.

'The amount of rainfall varies markedly over very small distances, according to elevation and exposure. The driest parts are the plains of the east, especially those of Thessaly, where the total annual rainfall is usually less than 15 in. Athens has an average annual fall of 15.4 in.. almost all of which comes between October and March. Salonika, where the summer drought is less extreme, has an average annual total of 21.5 in. The west coast is the wettest part of Greece, for there the winter cyclones strike the mountains squarely after collecting moisture in their passage over the Ionian sea; Corfu has an average annual rainfall of jo.4 in. The winter rains of Greece, being of cyclonic origin, fall in downpours, often divided by long periods of clear days. Much of this torrential rain is lost by immediate seepage and runoff.

Drainage. — Since the rainfall of Greece is very unevenly distributed throughout the year, the flow of its rivers is extremely seasonal, and even in the winter period of high water the flow is irregular and rises with the bursting of each cyclonic storm. In addition, the beds of the rivers are very uneven, as is usual in youthful and little-eroded mountain country; there is a clear contrast between the precipitous upper stretches of streams like the Xliakmon and their lower courses that meander lazily over the old alluvium-filled lake basins or ill-drained deltaic swamps. For all these reasons. the rivers of Greece are of little value for navigation. and they are also very difficult to control for irrigation. The most copious and perennial of them are the Vardar and Struma, which have large catchment basins in the central Balkans, but whose lower sections alone lie in Greece. In addition to these, the chief rivers that enter the Aegean from this country are the Mesta (Nestos), the Aliakmon, the Peneus (Salami-ria) and the Spercheios: the Eurotas of Laconia is the largest stream of the Peloponnesus while Acarnania and Epirus are drained principally by the Achelous. the Arta (Arachthos) and the Kalamas (Thyamis).

An individual feature of the drainage of the limestone districts is the *katavothras* or swallow holes. These are enclosed depressions, formed by subsidence or solution. where the drainage sometimes disappears straight underground and sometimes. when the inflow is heavy. accumulates to form a temporary lake.

The **Peloponnesus (Morea)**.—The Peloponnesus was joined naturally to central Greece by a 4-mi.-wide isthmus. which is now cut by the Corinth canal, linking the gulfs of Corinth and Aegina. The most fertile part of this peninsula is the coastal plain of Pliocene marls and conglomerates in the north and west, the districts of Achaea and Elis where the bulk of the Greek currant crop is grown. The two great alluvial depressions of Laconia and Messenia are oases of fertility on either side of the dry, barren limestone wilderness of Mt. Taygetus (7,897 ft), one of the least peopled parts of Greece. But even in these lowlands the cultivated area is only that which has access to springs of irrigation water from the mountain slopes. Beyond this lies, according to the season, malarial swamp or dusty plain, a type of scenery which occurs throughout all the central part of the third great alluvial lowland of the Peloponnesus. that of Argolis.

The limestone plateau of Arcadia. in the heart of the Peloponnesus is one of the most inaccessible parts of all Greece, and there in ancient times a unique archaic dialect lingered. The open hills carry a very mean pasture, but among them lie occasional tectonic basins that contain some of the best cultivated land of the peninsula. Some, like the basin of Megalopolis. drain outward, in this case to the Alpheus. Others, like the plain of Tripolis (Tripolitsa), are true katavothrus of underground drainage.

The east coast of the Peloponnesus is deeply indented, and has numerous small natural harbours. The coast of Elis, on the other hand. was formed by a straight fault and has been further smoothed by the deposition of strand flats, through longshore silting. Katakolon is the only good harbour there.

Central Greece.—The central range of Pindus throws off four spurs to the east. The most northerly of these, the Kamvounia range—which some geologists regard not as a fold range but as fragments of the old crust block—runs parallel to the straight faulted coast from Salonika to the Gulf of Volos. It is a discontinuous chain, whose trend can be traced through Olympus (9,550 ft), Ossa and Pelion out into the islands of the Northern Sporades. Skiathos, Skopelos and Skyros. Between this range and the next, that of Othrys, whose line is continued in the Kandelion mountains of northern Euboea. lie the three plains of Halmyros, Trikkala and Larissa. each marking the site of a lake basin of Tertiary times, since filled in with detritus. These last two plains are both drained by the Peneus, which leaves each through a constricted gorge, the lower one being the famous Vale of Tempe, embowered within the forests of Ossa and Olympus.

Passing southward, the third range to leave the Pindus is that of Oeta (7.080 ft.), which is continuous with Mt. Oche (Ocha) in central Euboea and which, together with the Othrys range, encloses the alluvium-filled tectonic trough drained by the Spercheios river. The pass of Thermopylae Iies between the eastern tip of the Oeta range and the sea.

Finally, the fourth and most southerly of these subsidiary chains is that linking Parnassus (8,061 ft.), Helicon, Cithaeron, Parnes and Hymettus. Between this range and that of Oeta lie the lowlands of Phocis and Boeotia, drained by the Cephisus and Asopos rivers, These plains, being exposed to the north. have a more continental and extreme climate than Attica, and the olive does not thrive. But thanks to careful drainage the lowland about Thebes has always been good wheat country, and since 1886, when the seasonally fluctuating Lake Copais was drained by the canal of Talenti. much extra fertile farmland has been reclaimed in the plain of Phocis.

The depressions of Attica are among the least fertile basins

SCENES AND PEOPLE OF GREECE

Top left: Soldier of the royal army on guard duty

Top right: Fishermen of Thasos, an island off the Macedonian coast, bringing in their nets

Centre right: Corinth ship canal, 4 mi. long, joining the Gulf of Corinth and the Saronic gulf

Bottom left: Two-tiered Roman aqueduct at Kavalla, Macedonia. The ancient structure was still used in the 20th century to supply the town with water from Mt. Pangeus

Bottom right: Shepherds of the Peloponnesus grazing their sheep and goats by a stream of central Greece. Their summers are excessively hot, their winter rainfall small and precarious. Athens, however, in the plain of the Attic Cephisus, has the great advantage of a central position easy access to harbours in the Gulf of Aegina and the command of rich and varied resources of timber, pasture. and olive- and vine-groning country, the silver mines of Laurion (Laurium) and the marble quarries of Pentelikon (Pentelicus).

Western Greece and the Ionian Islands.—The southern extremity of the Pindus about Mt Kiona (8,240 ft.) divides Attics and Phocis on the east from Xcarnania and Aetolia on the west, just as the northern Pindus in the region of Mt. Smolikas (8 640 ft.) separates Thessaly irom Epirus The provinces to the west of the main watershed have far fewer fertile basins than those to the east Epirus consists of four parallel limestone ranges, separated by narrow valleys of softer sandstones from which the rivers escape through constricted gorges, like that of the Acheron (Mavropotamos) at Suli. The most extensive fertile plain is the *polje* or basin of inland drainage at Janina (Ioannina) in the mountains, whence a difficult road leads down the Arta valley to the sea. Eastern Aetolia has some eroded Pliocene strata which make fair agricultural country, but the limestone heights of Xcarnania and western Xetolia near the Gulf of Arta are very barren.

The main difference between the provinces on either side of the Pindus range, however. is climatic. On the western side. Epirus in particular is well watered and snow lies on its higher mountains until mid-June. Unlike the rest of Greece, but in common with the central Balkans. the interior of this province enjoys an appreciable rainfall in late surnmer and early autumn, and the olive. which only thrives where there is summer drought, is not found more than about 25 mi. inland from the west coast.

Like the mainland opposite, the Ionian Islands consist of heights of Cretaceous limestone and depressions of softer Pliocene strata, particularly of sandstone. Corfu is fortunate in that, except for the limestone block of Pantokrator in the north, it is composed entirely of these fertile Pliocene deposits and also enjoys a high rainfall. The southern islands are much drier. Cephalonia and Ithaca are almost entirely limestone and have a very broken relief. Leukas (Santa Maura) and Zante (Zacynthus) have steep cliffs to the west, but more gentle slopes leading to the eastern coastal plains.

Macedonia and **Thrace.**—The faults or lines of breakage between the mountain blocks of the coastlands of northern Greece mostly trend northwest and southeast and give their direction. for example, to the lower Vardar, Struma and Mesta; but there are other series of faults. like those that run east and west to form Lakes Koroneia (Langada) and Bessikion. which separate the peninsula of Chalcidice from the rest of Thessaly.

Between the crystalline massifs deep lake basins were left, that became encumbered with detritus in the Tertiary and Quaternary periods. Subsequent drainage and erosion have left a series of terraces. but malarial swamps in the lowest parts of these piains show that the process of drainage is still not complete. These marshes are particularly extensive wherever the main stream leaves the basin through a constricted exit, as in the plain of Serrai on the lower Struma. and in that of Drama, on a tributary. The largest swamps of all, however. are in the Campania, the coastal flats which are being built forward into the Gulf of Salonika by the combined deltas of the Vardar and the Aliakmon.

The three promontories of Chalcidice were islands in the Tertiary period, as is shown by the Pliocene deposits at their roots. These Tertiary deposits also overlie much of the limestone of the Kassandra promontory. the lowest of the three. Those of Longos (Sithonia) and Athos (Akrathos) consist largely of wooded hills of schistose rocks, though there is a steep block of limestone at the tip of Athos.

In western Macedonia. beyond the forested hills of Vermion, lie the high enclosed lake basins of Tertiary deposits of Eordaia, and of Kastoria on the upper Aliakmon. Both these vales are dry and barren. by contrast with the higher valleys of Epirus on the other side of the watershed of Pindus.

The Islands of the Aegean.—The islands of the Thracian sea are all Greek, except Imbros and Tenedos (Bozcaada) which lie in Turkey. Thasos is an ancient mineraliferous massif. like those of the Thracian mainland. Samothrace is of volcanic origin, and its coasts are smooth and harbourless. by contrast with Lemnos which possesses the large strategic anchorage of Moudros.

Lesbos. Chios and Samos are detached fragments. respectively, of the Troad (Troas), the Erythraean peninsula and Mt. Messogis on the mainland of Asia Minor. All are favoured with a mild and temperate climate and palms can be grown in sheltered corners of Chios. But the land surface in all three is rocky, the only extensive areas of fertile soil being in the southern part (Catomeria) of Chios, which consists of limestones of relatively recent formation. In Lesbos, Mytilene, originally an island colony, is the first port, but the deep Gulf of Kallone is the finest natural harbour. The port of Chios is on the east side of the island of that name, opposite the small harbour of Cesme on the mainland.

The Northern Sporades (the "Scattered Islands") continue the structural trend of Olympus, Ossa and Pelion and, like the mainland range, consist largely of crystalline rocks.

Euboea, though a single island. includes projections of two of the mainland ranges, those of Othrys and Oeta, and its rocks range from the fertile Eocene sands and clays of the north through the barren limestone ranges of the centre to the ancient Primary crystalline formations of its southeastern extremity.

The Cyclades (the "Central Islands") were anciently considered to be disposed in a circle about Delos. They are the extreme summits of drowned mountains, in which two main ranges can be followed. The first leads from Euboea through Andros, Tenos, Mykonos, Icaria and Samos to the Mycale promontory of Caria. The second may be traced from Cape Sounion (Sunium) through Kea (Ceos). Kythnos. Seriphos, Siphnos, Kimolos and Amorgos as far as Levitha. Between these two main ranges are Paros and Naxos, which consist of very ancient metamorphic rocks, yielding the marble of the one and the emery of the other. Syros (Syra) and Delos lie slightly south of the main northern arc of islands.

The **Dodecanese.**—This group includes islands of varied geological structure. Kalymnos, Syme and Chalke consist almost entirely of hard gray limestone, which weathers into very poor, thin soil. In Leros, by contrast, fertile Tertiary marls overlie much of the limestone. The southern half of Patmos is the collapsed western rim of an extinct volcano. consisting of purple porphyry, and Nisyros is a complete volcanic cone whose lavas have weathered into a very rich soil Rhodes is the largest of the 12 islands. Its core of hard rocks rises more than 4,000 ft. above sea level and captures a considerable rainfall, while the lower slopes are constructed of weathered marls and sandstones which make good farmland. The remaining islands of the 12 are Kos, Astypalaia, Telos, Karpathos and Kasos. (See DODECANESE.)

Crete.—This island is an extension of the arc of the Dinaric fold mountains. which have here been eroded, invaded by the sea in Tertiary times and later raised again. The landscape is mountainous, most of the island's area of flat land being concentrated in the central plain of Mesara.

In the extreme west. the schistose rocks have weathered into rounded slopes, but the limestone heights of the Lefka Ori ("White Mountains") and Mt. Ida (8,058 ft.) have a more precipitous outline. The north coast, with its alluvial bays, is very different from the south coast, which falls to the sea in steep faulted cliffs. (See CRETE.) (WM. C. B.)

Flora and Fauna.—The vegetation in the different parts of Greece is determined by the climatic and edaphic conditions. In the southern and central regions it is of the Mediterranean type which, to the north and on the higher slopes of the mountains, merges into a central European flora. The main kinds of plant cover are deciduous and evergreen forest and brushwood or scrub. More than half the land surface is under scrub and four distinct types of scrub community can be recognized—maquis, found largely in the Peloponnesus; pseudomaquis, in Macedonia and other northern parts; phrygana in the hills of Attica, the Ionian Islands and the Cyclades; and shiblyak at high altitudes.

The chief plants of the maquis are Spanish broom, strawberry tree, oleander, bay, kermes oak, olive, myrtle and chaste tree

(*Vitex agnus-castus*), whose supple stems are used for making baskets. The tree heath is common except on limestone. Plants of the pseudomaquis include oaks, box, terebinth, juniper, jasmine and cherry laurel. Phrygana consists of scattered bushes, often thorny with gray-green leaves and a resinous aromatic sap, such as *Poterium spinosum, Thymus capitatus,* marjoram, *Cistus,* lavender and *Genista.* Shiblyak is mainly composed of *Paliurus spina-Christi,* smoke tree (*Rhus cotinus*), sumac (*R. coriaria*) and barberry. There is only a very small area in Greece above the tree limit and there juniper and *Daphne oleoides* are the chief plants found. In the lowlands, up to about 650 ft., the flora is of the Mediterranean type consisting of trees, evergreen shrubs and herbaceous plants. A feature of the stony ground in the south and in the islands in spring, and to a lesser extent in autumn, is the brilliant patches of grape hyacinth, star of Bethlehem, asphodel, crocus, fritillary, narcissus, iris, tulip and gladiolus, with annuals, such as anemones and poppies, that make their growth during the winter and die down in the summer. They are succeeded in summer by composites, labiates and other hardier plants.

On the higher slopes bloom *Dianthus, Silene, Verbascum, Thymus* and *Centaurea,* while among the rocks are campanulas, saxifrages, violas, *Potentilla, Sedum, Achillea, Draba,* etc. The river courses are usually stony and bear planes, poplars, willows, chaste trees, oleanders and terebinth. Aleppo and stone pines are characteristic of the northern and western coastal plains.

In the southern and central highlands. and at lower altitudes in the north, where the summer rain and winter cold are greater, deciduous trees (oaks and chestnut in particular) are found on the middle slopes with an undergrowth of sumac, Judas tree, *Ostrya carpinifolia,* wild pear and bay. Above are coniferous forests dominated by the Greek fir (*Abies cephalonica*) and silver fir (*A. alba*) with little or no undergrowth except in the clearings where it is mostly of juniper, hawthorn and small-leaved lime. The clearings and ravines in woods and forests are bright in the spring and summer with crocuses, irises, tulips, fritillaries, asphodels, gentians, etc.

Above 6jo ft. most of the surface is covered by forest and scrub. The woods are of the Mediterranean evergreen type on the lower slopes, mixed deciduous above and coniferous higher still. The Pindus ranges carry oaks and chestnuts and, above them, firs and pines; on Othrys are extensive oak woods; in Attica many of the Aleppo pine forests have been cut down; the higher slopes in the Peloponnesus bear Greek fir and black pine (*Pinus nigra*); beech grows on the higher slopes in the north and chestnuts in southern Macedonia and on the middle slopes of Olympus, Ossa and Pelion. Black pine forms the high forest of Olympus and is common on siliceous soils from about 2,000 to 4,500 ft.

Though by 1954 the fauna of Greece had not been completely studied, many mammals were known to be rare and others very rare. Among the latter are the European brown bear, chamois and red and fallow deer. There is a great variety of birds; and reptiles are common, especially in the Peloponnesus and the Cyclades, but only two of the snakes are poisonous. *See* BALKAN PENINSULA.

HISTORY: INTRODUCTION

The finer arts and crafts of civilized man, invented in Mesopotamia and in Egypt, were adopted and developed first in Europe by the Minoans of Crete and by the Mycenaeans of Greece during the Bronze Age. The civilizations of these peoples attained a high level before each in turn was overwhelmed. A dark age ensued in Europe. But memories of Bronze Age civilization survived in the rich saga and in the epic poems of which some were finally attached to the names of Homer and Hesiod. These memories played an important part in the Greek renaissance of the 9th century B.C. But a new political, intellectual and social spirit came to birth with the city-state. This spirit was carried to the European shores of the Mediterranean sea and of the Black sea by Greek colonists from the 8th century B.C. onward and to Asia as far as the Indus valley by Greeks and Macedonians in the 4th century B.C. Even when Rome replaced Macedon as the leading imperial power and later fell in turn to barbarian invasions in the 5th century A.D., the Greek civilization which had been a unifying factor in the Greco–Macedonian and the Greco–Roman world lived on for 1,000 years in the dwindling empire of the Byzantines. Once again there was a dark age in Europe. It was enlightened by that rediscovery of the Greek outlook vital to the Renaissance that heralded the end of the middle ages and laid the foundations of modern western civilization. Thus Greek history has a wide scope. It is the keystone of the arch which united east and west, it cast a bridge over two dark ages and has given continuity to man's development in Europe from the Bronze Age to modern times. It is essentially universal and not parochial in interest.

This article covers Greek history in the following three main sections:

(1) *Ancient History,* which includes the Minoan and Mycenaean civilizations of the Bronze Age; the early migrations and colonizing movement of the Dark Age and the Greek Renaissance; the Graeco–Persian wars; the great wars in Greece (the First Peloponnesian War, 460–445, the age of Pericles, the Great Peloponnesian War, 431–404); the city states, 404–354; the Macedonian period; and a summary of authorities on classical Greek history.

(2) *Postclassical and Medieval History,* covering Greece under the Roman republic and Roman imperial rule and the Byzantine periods.

(3) *Modern History,* which traces the history of Greece from its conquest by the Turks in the 15th century to modern times. Sections on the population, government and economy of modern Greece follow.

ANCIENT HISTORY

THE BRONZE AGE

The Minoan Civilization. — The civilization of Ur in Mesopotamia was already mature when the first waves of settlers came by sea from Asia to Greece not later than 3000 B.C. They occupied Cyprus. Crete, some of the Cyclades and the eastern areas of the Greek peninsula, which are warmer and drier than the western. When they arrived, they were familiar with agriculture and seafaring as well as with pastoral life. They were still in the Neolithic stage, for their tools were made of stone and obsidian, a vitreous lava found mainly on the island of Melos. At the beginning of the Bronze Age in Greece, *c.* 2600 B.C. (some scholars subdivide the Bronze Age into a Copper Age and a Bronze Age proper, and date its beginning earlier, *c.* 2900 B.C.), these sparse settlements were reinforced by further waves of settlers, conversant with the use of copper, who probably came from Asia and were similar in race to their predecessors. They were a comparatively peaceful and unwarlike people, for they lived in unfortified villages or hamlets and had more tools than weapons. They developed local variations of culture, but had in common the use or worship of stumpy statuettes which represented a female deity.

In the Neolithic period Cnossus (Knossos) in Crete was an important centre. It controlled the main routes within the island, its port at Amnisus faced the Aegean sea, and its houses soon became considerable in size, with a main room in the centre and a cluster of smaller rooms round it. When the Cretans were reinforced by new settlers at the beginning of the Bronze Age, the skeletons which have been discovered in their two-roomed tombs show them to have had long, narrow skulls and to have been short men and women who averaged just over and under five feet respectively. Quite a different people appeared *c.* 2300 B.C. at Phaestus (Phaistos) in the plain south of Cnossus; they were soon absorbed or eliminated, but they left their memorial in the huge circular buildings where they laid the bones of their dead. Apart from this short-lived intrusion the Bronze Age inhabitants of Crete developed their own culture continuously down to 1450 B.C.

After 2000 B.C. political power was wielded by dynasts at Cnossus, Phaestus and Mallia and finally became concentrated in the hands of the ruler of Cnossus. The central figure of Cretan religion was a female deity, represented in human form, clothed in Cretan dress and attended by priestesses and animal-headed humans. Her cult was associated particularly with sacred trees and with the snake. bull and dove. The furniture of ritual included a three-legged altar. a double axe and twin horns of consecration. There is a temple-tomb near the palace at Cnossus which suggests that the dead rulers received worship as deities. whereas the graves of the commoners are too humble to have been the object of any cult. The Cretans were gifted in painting, gem cutting, metalworking and architecture. Their frescoes reveal a fresh joy in the beauty of the natural world and a love of dancing, boxing and a sport in which boys and girls somersaulted over the backs of charging bulls. Their well-built houses were of masonry usually bonded with timber. and the towns were often laid out on terraced slopes with paved streets and tiers of houses. The great palace at Cnossus was a fine example of monumental architecture with spacious state rooms and numerous storerooms. where the wealth of the realm was hoarded.

Although the palaces and the towns were unfortified and peaceful scenes predominated in the frescoes. the Cretans made excellent daggers. spearheads and rapiers first of copper and then of bronze. and the roads which linked the countryside to the palaces were protected by guard posts. The great wealth of the palaces and the widespread prosperity in the island were due to the profits of trade. protected or exploited by Cretan naval vessels in which a prolonged keel beam served as a ram. In the 16th century *B.C.* Cretan colonies were planted on Cythera. Calymnos and Rhodes. a chain of islands controlling the southern Aegean, and at Miletus on the coast of Asia Minor. Articles of Cretan origin were exported to Egypt. Syria. Asia Minor, the Cyclades and Greece and. further westward. to Lipara and Ischia. The 15th century B.C. brought the greatest prosperity to Crete. Metals, textiles, manufactured goods and natural products were traded between the continents. Egypt. Syria and Troy grew rich as centres of exchange on the mainland. Crete controlled the sea routes toward southern Europe and the west, which were beginning to emerge from barbarism.

The art of pictographic writing had been practised for centuries in the east before it was adopted about the end of the 3rd millennium by Crete. Soon after 1700 B.C. the Cretans invented a linear script with signs for syllables and for numerals on the decimal system. This script has not yet been deciphered. As the people and culture of Crete owed their origins and developments predominantly to the east, it is probable that the Cretan language belonged to an Asian group distinct from the Indo-European group. Philologists see survivals of this Asiatic group in place-names ending in *-ssos* and, *-inthos*, which are commonest in Crete and Asia Minor. Some aspects of Cretan culture, such as the palaces of the dynasts. the worship of deified rulers. the female deity, animal-headed humans and the predominance of peaceful pursuits. are also found in contemporary civilizations of the east; but so many features are peculiar to Crete that the first great civilization on European soil should be regarded as an independent entity. The ancient name of the island and of its people is unknown. Some have identified the island with "Keftiu," whence envoys came to Egypt in the first half of the 15th century B.C. Others have accepted the names which were recorded centuries later by Homer: "Crete. where the race of Minos is" *(Odyssey,* xvii. 523) and its great city "Cnossus where hfinos ruled. holding converse with great Zeus every ninth year" *(Odyssey,* xix. 178). Following Homer. we speak of "Minoan" civilization, and we attribute the legends of the Minotaur, Theseus and Ariadne to the great age of Crete.

After 1450 B.C., when Cnossus had a monopoly of political power in the island and developed a distinct culture of its own in which there are signs of a more militaristic spirit. a new linear script is found at Cnossus and also on the mainland of Greece. This script. unlike the earlier Minoan script. has been deciphered. The language it expresses is Greek. It is therefore certain that at least in the period 1450–1400 B.C. the rulers of Cnossus spoke Greek and presumably were Greeks nho had come from the mainland. They called the place "Ko-no-so" in their new script. which may be called the "Mycenaean" script after the name of Mycenae. which was the chief centre of Greek culture on the mainland. The intrusion of the Greeks marked the beginning of the end of Cretan ascendancy. About 1400 B.C. Cnossus was sacked, and other leading cities of Crete were destroyed within a few decades of that date. The sackers of Cnossus are unknown, but their action opened the way to peoples from the north who were pressing toward the riches of Crete and the near east.

The Mycenaean Civilization.— The early settlers in some of the Cyclades and in the warmer parts of the Greek mainland were reinforced *c.* 2600 *B.C.* by further settlers from Asia and developed their own distinctive cultures. The seafaring peoples of the Cyclades made little models of their ships in lead. They produced beautiful pottery and exported marble vases and figurines. They grew prosperous by carrying the trade of Minoan Crete, whose influence was particularly strong at Melos. Toward the end of the Bronze Age they engaged in raids on Egypt, where they were described, with others. as "the peoples of the sea." Centuries later the Greeks called them Carians. Leleges and Phoenicians — peoples whose affinities were with the coasts of Asia whence the settlers of the early Bronze Age had come (Herodotus. i. 171; Thucydides, i. 8); the most common later name for them. however, was Pelasgians. By virtue of their geographical position they acted throughout the Bronze Age as intermediaries between the Greek mainland and Troy. Asia Minor and Crete. On the mainland the Bronze Age settlers were interested primarily in agriculture. Their largest settlements were made in the plains of eastern Greece south of Rlt. Othrys, but they spread gradually into the western areas. The flat-roofed, rectangular houses of their unfortified villages were built close together and contained reserves of grain stored in large jars. By the beginning of the 2nd millennium the eastern areas had developed separate cultures north and south of the Isthmus of Corinth. Of these, the northern areas traded principally with Troy and with northwestern Asia Minor, the southern area (the eastern Peloponnese) with the Cyclades. While both areas produced fine pottery. the eastern Peloponnese was more advanced in the arts. At Lerna. for instance, a large house was built on a complex plan suitable for a royal residence. and a stone statuette of exquisite workmanship has been found in its debris. It is clear from this and other statuettes that religion was centred on a female deity. If they had been left in peace, the inhabitants of central and southern Greece might have continued to develop a civilization which was similar in many ways to those of the Cyclades and Crete. but in the years after 1900 B.C. they became the victims of aggression.

The districts of northern Greece which lie beyond Mt. Othrys mere not occupied by the settlers who came from Asia at the beginning of the Bronze Age, c. 2600 B.C. The earliest wave of settlers remained in undisturbed possession of Thessaly and continued in the Neolithic stage of civilization until c. 2200 B.C. Their isolation may have been partly an effect of the climate. The Thessalian climate is intermediate between the warm Mediterranean climate of the south and the cold continental climate of upper Rlacedonia. Nor did the Neolithic people of Thessaly penetrate northward in the direction of Macedonia except at Servia (in a low-lying bend of the Haliacmon river): where they founded a small settlement. This settlement was destroyed c. 2500 B.C. by a much cruder people who were evidently nomadic hunters, the first of many groups who soon spread into central Macedonia and Chalcidice and some time later forced their way into Thessaly and occupied the sites of Dimini and Sesklo. These newcomers were quite unlike the earlier settlers of Greece. Their pottery mas roughly made and incised with spiral decorations. They wielded stone battle-axes and they fortified their villages at Dimini and Sesklo with a ringwall. When they adopted a settled life, they built long narrow houses with pitched roofs. entry porches and sometimes apsidal ends. which were suitable for a cold damp climate. Archaeologists have called this type of house megaron, after the Greek word for a long hall. Although the archaeological evidence in northwestern Greece is scanty, it suggests that groups of these newcomers entered Epirus and gradually moved down the western side of Greece as nomad hunters and shepherds. At Servia and at some sites in Thessaly. where they settled among the earlier inhabitants, their worship of the masculine aspect of life is indicated by the use of phallic emblems and male statuettes.

The ultimate origin of these newcomers is uncertain. Their way of life and the climate of the areas in which they settled suggest that they had come through the Balkans, and this suggestion is supported by the appearance of similar houses of an early megaron type in areas near Troy at the time of the first settlement there (c. 2600–2400 B.c.). The most probable hypothesis is that the settlers of Macedonia and of Troy were Indo-European — perhaps the first Indo-Europeans to reach the vicinity of the Mediterranean sea. Another branch, ancestor to the Illyrians, probably reached the Adriatic sea in the same period.

Newcomers disturbed the peace of the Greek peninsula during the middle Bronze Age (c. 1900–1600 B.c.) by irruption and infiltration. They probably entered from the western side of Greece. Early examples of megaron houses have been found at Eutresis in Roeotia, at Lerna and Tiryns in Xrgolis, at Korakou near Lechaeum in Corinthia and at Thermum and Olympia in n-estern Greece. Although they lowered the standard of civilization at first, they brought with them (or coincided with the arrival of) the potter's wheel, on which a fine pottery called hlinyan ware, imitating metal shapes, was made; and they introduced the horse, bones of which have been found in Macedonia in contexts dating to c. 2100 B.C. Similar phenomena occurred at Troy, where new settlers founded the sixth city (c. 1900–1300 B.C.), made Minyan pottery and introduced the horse into Asia Minor.

It is generally agreed that the newcomers of the middle Bronze Age were the first Greek-speaking peoples to reach central Greece and the Peloponnese. Their antecedents are a matter of dispute, but it is probable that they were descended from the Neolithic settlers of Macedonia, of whom a part occupied Dimini and Sesklo in Thessaly. Centuries later Hesiod gave a localized genealogy of the founders of the Greek race which supports this probability. He declared that Thessaly was ruled by Deucalion's descendants. "Hellen the war-loving king and his sons Dorus, Xuthus and Aeolus, delighting in horses." and that their cousins "Magnes and hlacedon, delighting in horses, lived in the area of Olympus and Pieria." The Greek or "Hellenic" race was divided by dialect into three main groups in Hesiod's time—Ionians, Xeolians and Dorians—of which the ancestors were held to be Ion (son of Xuthus), Aeolus and Dorus. The division certainly existed early in the Bronze Age, and it may have begun in Macedonia. Epirus and adjacent areas in the period 2500–1900 B.c., because the Ionians and Aeolians entered central and southern Greece during the Bronze Age but the Dorians in general after the Bronze Age.

When conditions became less troubled in the peninsula, the fusion of the Greeks and their predecessors produced a much more vigorous and artistic civilization than that of the early Bronze Age. This civilization, called Mycenaean, because it was first found by excavators at Mycenae in Argolis, lasted with fluctuating fortunes from c. 16jo to *c.* 1125 B.C. Rule was exercised by dynasties of kings who accumulated wealth on their citadels. At Mycenae the dynasties (Shaft Grave I, Shaft Grave II, Tholos Tomb I, Tholos Tomb II) are numbered by the excavators in accordance with their styles of burial, which were practised at other capitals of the time; and the objects buried with the first two dynasties show that they were Greek. The rulers of the first Shaft Grave dynasty (c. 1650–1600 B.C.) were buried with their weapons and with jewelry of gold, silver, electrum and ivory in tombs at the foot of deep vertical shafts, which were then filled up and marked by upright stone stelai engraved with scenes of war and hunting. The second group of shaft graves (c. 1600–1500 B.C.) was richer still in weapons, jewelry (including amber) and cups of precious metal; horse-drawn chariots were represented on the stelai; and remains were found of a boar's tusk helmet (*i.e.,* a leather cap on which slivers of tusk were sewn for greater protection). Death masks of gold and electrum show that the rulers wore moustaches, and the skeletons are those of a race of men between 5 ft. 6 in. and 6 ft. tall. The first group of tholos (beehive) tombs (*c.* 1500–1400 B.C.) and the second group (c. 1400–1300 B.c.) are examples of skillful architecture. A large circular tomb was excavated in a hillside and roofed over with a great dome (tholos) of conical shape, constructed of masonry blocks carefully wedged and counterweighted, and the whole was then covered with earth and a waterproof layer of clay. The tomb was entered by a walled passage which led to a massive doorway set in the side of the tholos. In the so-called Tomb of Atreus, built *c.* 1330 B.C., the dome is 40 ft. high. The period of the tholos tombs was even more prosperous than its predecessors, but it was followed by a gradual decline during which the rock-cut chamber tomb was in vogue.

At first the more advanced art of hlinoan Crete inspired the Greek peoples, who soon traded direct with Crete and became rulers of Cnossus c. 1450 B.C. The Mycenaean script, designed to express the Greek language by syllabic signs, was probably invented at Cnossus in the 15th century B.C. and taken to the mainland. Greek settlements were planted in Rhodes *c.* 1450 B.c., and Greek traders and exports appeared beside those of Crete at Miletus, in Syria, in Egypt and in the west at Lipara. When Cnossus and other cities of Crete were sacked c. 1400 B.c., the Greeks of the mainland replaced them as the leading naval power in the southern Aegean. They planted settlements in Crete, Cyprus and Cilicia and had trading stations at Ugarit and Poseidium in Syria. Mycenaean pottery, which combined Minoan taste in decoration with greater technical skill and formal design, was exported in large quantities to Syria, Palestine and Egypt. Trade relations were also close with Troy, and Thessaly and lower Macedonia were influenced by Mycenaean culture as they offered ports of call on the sea route to Troy. The absence of hfycenaean imports suggests that the Cyclades (apart from Melos, Thera and Delos) probably preserved a hostile independence. Greeks also settled in the west at Acragas and Syracuse in Sicily and at Oria and Taras in southern Italy. Thus the Greeks became to an even greater extent than the hlinoans of Crete the intermediaries of seaborne trade between Europe and Asia, and a general uniformity of Mycenaean culture prevailed by 1300 B.C. throughout the Ionian Islands (except Corcyra), the Greek peninsula (except Epirus and upper Macedonia) and the islands of the southern Aegean.

After 1300 B.C. Greek trade with Sicily, Troy, Syria and Egypt began to decline. Mycenaean culture lost its uniformity and developed local peculiarities. On the mainland men expected war and violence. Immense fortifications were built to enclose the citadels at Mycenae, Tiryns, Athens and elsewhere, and the slashing sword took the place of the rapier sword. The great palaces, built round a central megaron (of which the finest examples have been excavated at Mycenae, Tiryns and Pylos), were still wealthy, but their subjects in the open suburbs were exposed to attack and arson and declined in prosperity. As conditions worsened, the Greeks turned to piratical raids on Egypt: Cyprus and Caria and finally attacked and destroyed the fortified city of Troy c. 1200 B.C. The Trojan War opened the door to disaster. Barbarians broke into Asia Minor, overthrew the Hittite empire and set in motion a series of great raids by land and sea which destroyed the prosperity of the states in the eastern Mediterranean and brought the great civilizations of the Bronze Age to an end.

Our knowledge of Greek history in the Bronze Age is due mainly to archaeology, which constantly provides new evidence and new problems of interpretation. But we have also two kinds of literary evidence: Greek epic poetry composed from traditional sources before or after 800 B.c.; and contemporary Bronze Age texts in Greece, Asia and Egypt. The literary qualities of the *Iliad* and of the Odyssey are described elsewhere (see HOMER). We are concerned here with the extent to which they represent accurately the setting of the tenth year of the Trojan War and its aftermath. The Iliad (ii. 816–875) gives a "catalogue" of Troy's allies. As they were overwhelmed after the fall of Troy, the source of the catalogue, if historical, was composed in the Bronze Age; otherwise its contents would be fictitious and incorrect. In fact, the names of many allies in the catalogue occur in Bronze Age texts, both Hittite and Egyptian, and this is true also of Troy and its inhabitants (Greek *Troia*=Hittite *Taroisha; Dardanoi*=Egyptian *Dardenui; Ilioi*=Egyptian *Iliunna*). The catalogue of Greek allies (Iliad ii, 485–768) draws a map of political power in Greece and in the islands which mas no longer existing after the Bronze Age but has been fully borne out by excavation. The Greeks as a whole were called *Akhaioi* (Achaeans) and *Danaoi* in the *Iliad;* and these names in the forms *Akaiwasha* (cf. also Hittite *Ahhiyava* for the country of the *Akhaioi)* and *Danauna* or *Denyen* occur in Egyptian documents of the Bronze Age but were not in vogue later in Greece. The *Odyssey* too describes a political situation in western Greece which disappeared at the end of the Bronze Age, and its stories of piracy and raids are typical of the great raids on Egypt in 1192 and 1187 B.C., mhich were recorded in Egyptian documents. The paraphernalia of daily life described in both poems—bronze weapons, boar's tusk helmets, equipment, drinking cups, furniture, metal inlay, etc.—are paralleled by Bronze Age objects and not by those of a later period. The very language of the poems contains dialectal forms which probably derive from a time when Arcadian and Xeolic dialects of Greek were widely spoken, that is, in the late Bronze Age. These and other considerations lead us to believe that not only the *Iliad* and the *Odyssey* but also the great body of saga on which Hesiod and other poets drew were derived in subject matter from the poetry and beliefs of the late Bronze Age. Archaeology has produced parallels for such survival from other parts of the Bronze Age world; for the Babylonian Epic of *Gilgamesh* persisted in Mesopotamia for more than 2,000 years, and some traditions recorded in the Hebrew book of Genesis are found to rest upon historical facts of the Bronze Age.

Contemporary Greek records in the Mycenaean script (the decipherment was still imperfect in the middle of the 20th century A.D.) prove that Greek was the language of the rulers of the palaces at Cnossus and on the mainland c. 1450 B.C. and later; that some at least of the Olympian gods named by Homer were worshipped in Bronze Age Greece; and that some parts of Homer's picture of a feudal society are true to the conditions of the late Bronze Age. The script is mainly scratched on clay tablets, which served as inventory labels for stores. and the tablets have only survived when baked in a great conflagration, Fuller knowledge of this great period of history must depend on further archaeological discoveries and on a progressive decipherment of the scripts. *(See* also AEGEAN CIVILIZATION; CRETE; and GREEK ARCHAEOLOGY.)

THE DARK AGE AND THE RENAISSANCE

The Migrations.—The collapse of Bronze Age civilization was followed by migrations which affected the Mediterranean world and lowered the standard of life for several centuries. Invading bands who probably came from the Danube valley destroyed the settlements in central Macedonia: and the impact of this assault started a great movement of peoples from upper Macedonia and Epirus, areas remote from Mycenaean civilization. It was led by a clan, the Heraclidae, who claimed descent from Heracles and called themselves Achaeans. Their chief followers were Dorians, speaking a broad dialect of Greek, who were brigaded in three tribes, Hylleis, Dymanes and Pamphyli. Many other tribes were associated with them; they too spoke dialects of Greek, grouped by scholars under the title "Northwest Greek." The first invasions in the second half of the 12th century were sufficiently well organized to break down the resistance of the strongest Mycenaean powers. Thessali, led by Heraclidae, forced their way from southern Epirus into southwestern Thessaly, displacing Boeoti who invaded Boeotia (then called Cadmeis). Dorians, led by Heraclidae, migrated from Doris between the Pindus range and Mt. Parnassus, crossed the Gulf of Corinth and broke into the Peloponnese; peoples who spoke the Northwest Greek dialect crossed the western end of the gulf and invaded the western Peloponnese. Once they had overcome resistance, other migrants followed in their wake. Thereafter, as Thucydides wrote (i. 2, 1), "migrations mere of frequent occurrence, the several tribes readily abandoning their homes under the pressure of superior numbers." For when they had pillaged the Mycenaean cities and burned the palaces, the migrating hordes broke up into groups which roamed far and wide and did not accept the unfamiliar conditions of settled life.

Chaos and turmoil continued for two centuries in the Greek peninsula. Only Arcadia, in the mountainous centre of the Peloponnese, and Attica. lying on a peninsula off the main lines of invasion, succeeded in maintaining their independence. Elsewhere the earlier inhabitants mere made subject to the invaders or driven out as refugees. In pursuit of loot, Dorian bands crossed the sea, occupied the southernmost islands of the Aegean and established themselves on the southern part of western Asia Minor. Aeolic-speaking refugees from Thessaly and central Greece ended their wanderings by settling in the northern part of Asia Minor and on the islands of Tenedos and Lesbos. Ionic-speaking refugees fled first to mountainous Achaea and then to Attica, which the Dorians failed to enter by attack from the south. The last of the great migrations from Greece began c. 1000 B.C. when the Athenians launched the so-called Ionian migration, and ended c. 900 B.C. with the occupation of the Cyclades, the central sector of western Asia Minor and the adjacent islands. Meanwhile these and other migrating bands in Asia and Europe had enlarged the area of chaos to include Italy, Sicily and North Africa.

Excavation has exposed the poverty of the dark age in Greece. Men lived in scattered hamlets of hovels. having few material possessions and waging war against one another with the iron weapons which marked the transition from the Bronze Age to the Iron Age. Attica was an exception for a time. Formed into a unified state by Theseus in the late Bronze Age, the people of Attica preserved their Mycenaean traditions as well as their political independence. The city of Athens was strengthened too by the influx of refugees, capable and courageous men. who led the Ionian migration overseas and spread the use of the fine protogeometric pottery which had been evolved in Attica. But, when the migration was finished: the general paralysis of communications on the mainland and in the Aegean affected Athens too, and the city became impoverished by isolation. Conditions were no less difficult overseas in the islands and on the coast of Asia Minor, where the Greeks had established themselves in isolated pockets on narrow coastal strips of land and had to fight for existence against the native peoples and against one another.

The 9th and the 8th Centuries **B.C.**—An oasis of civilization in the near east survived the dark age. Its centre was Phoenicia, Palestine, Syria and Cyprus, where kingdoms such as Solomon's Israel flourished. The Phoenicians maintained their skill as seafarers, traders and artists; they planted Carthage and other colonies in the western Mediterranean; they developed the Phoenician alphabet, in which a separate sign or letter stood not for a syllable but for a consonantal or vowel sound; and they produced finely worked ivories and embroidered textiles. In the 9th century contacts were renewed by Phoenicia and Cyprus with the southern islands of the Aegean, the eastern Peloponnese and Athens. Phoenician ivories were imported and Phoenician letters were adapted to express the Greek language. Several Greek alphabets were in existence by 800 B.C., and intercourse gradually increased among the small communities of the mainland. Another legacy of the Bronze Age was epic poetry orally transmitted by those who still lived in such conditions as obtained during the breakdown of the late Bronze Age. The strongest school of epic poetry was in Ionia, the traditional birthplace of Homer, whose lifetime was put in the second half of the 9th century by Herodotus (ii, 53). Of the works ascribed in antiquity to Homer the *Iliad* is the oldest; some scholars agree with Herodotus' date and others place the poem in the 8th century. The *Odyssey* is clearly later and was probably composed by a diiferent author; even so, it should be dated before 750 B.C., to a time when the western Mediterranean was still unexplored by the Greeks. These great poems and many others, now lost to us, soon became known to the mainland and revealed the religious beliefs, personal ideals and material glories of the Mycenaean world to a population which was slowly emerging from the darkness of the Dorian invasion and its aftermath.

The renaissance of the Greek spirit in the 9th and 8th centuries was a gradual process, and it took place in conditions far different from those of the Bronze Age. Religion played a prominent part. Centres famous in Mycenaean times revived: Apollo again received worship at Delphi from the mainlanders, and Apollo's shrine at Delos attracted the Ionians of the islands. Religious leagues of a regional character, called amphictyonies (or amphictionies), were formed: the northern tribes worshipped at Anthela, the Boeotians at Coronea. some states near the Saronic gulf at Calauria and the Ionians of Asia Minor at the Panionium on the peninsula of

Mycale. Poetic competitions and athletic games were held at such religious festivals, and Olympic games were instituted in honour of Zeus at Olympia in the western Peloponnese. Temples were built between 850 and 750 B.C. at Sparta. Perachora and at Drerus in Crete; and continuity in religion and in architecture was preserved from Mycenaean times at Thermum in Aetolia. where a Mycenaean megaron was superseded by a 10th- or 9th-century temple of megaron type with an apsidal peristyle and this in turn by a classical temple.

A school of religious epic poetry grew up in central Greece. Its leading poet, Hesiod, whom Herodotus regarded as a contemporary of Homer. incorporated many Bronze Age legends in his Works *and* Days but added a strong sense of moral purpose which was characteristic of the mainland in his own day. The Tlzeogony, which was composed considerably later, drew upon Bronze Age traditions and set the Greek pantheon in order.

The political traditions of the Mycenaean world were preserved on the mainland in Attica, where all the citizens belonged to four Ionian tribes and paid a rather loose allegiance to a central government, headed at first by a king and then by magistrates. The refugees from the mainland organized their small states on similar lines when they settled on the islands and the coast of Asia Minor. As the defensible centre in each case was a citadel or polis, these states were called *poleis* or city-states. The Dorians, however, developed a different kind of state in Crete and in Laconia. At the time of the conquest the Dorians reduced the local inhabitants to serfdom and generally did not marry outside their onn circle. During the dark age the Dorian masters split up into small villages (komaz). which tended to fight with one another and nere themselves split by family and tribal feuds (for each district contained members of the three Dorian tribes). Under such conditions the masters might well be overthronn by their serfs. The Dorians of Crete put an end to the internal feuds in their villages by instituting a system of state education Boys were taken from their homes at an early age and trained together until they entered rival troops at the age of 1 j; if they qualified after two years of rigorous discipline, they were admitted to a men's club or mess (andueion) and thereby received the full franchise. Members of a mess fed together and fought side by side during their active life. The troops and messes were maintained by the state, and the members were trained exclusively to serve the state in politics and war; for they formed the "warrior class" in contrast to the "land-\\orking class" of serfs.

Kingship, which was appropriate to large tribal groups. declined in Crete during the dark age, and the villages elected ten executive magistrates to hold office for a year and to supervise the system of state education. A council, which had consisted of heads of clans in the tribal state, was now recruited from former magistrates to form a council of 30 elders, who held office for life. The assembly of citizens elected the magistrates and the elders but had little voice in policy, unless the council was divided in its views.

In Crete there were more than 100 states with such institutions, which agreed never to liberate the serfs in the frequent aars which they waged against one another. As Crete mas geographically self-contained, the energies of their centralized city-states were absorbed within the island, but it proved otherwise on the mainland when Sparta followed the example of the Cretans. In the plain of the Eurotas five Dorian villages combined politically to form the united state of Sparta and to impose much the same system of state education. Under the reform associated with the name of Lycurgus, those who were elected to the messes became full citizens, or Spartiates, at the age of 30 and were called "equals," those who failed to graduate in the state system became "inferiors" with lesser rights. The agricultural land was divided into equal lots, allocated to Spartiate families and worked by state-owned serfs, called helots. Kingship in the form of two royal houses had survived in Laconia, the tno kings claiming suzerainty over all Lacedaemonians (inhabitants of Laconia). In the constitution of the new state the two kings were the military and religious heads, but they had equal powers in the council with 28 elders. who were elected from equals of 60 or more years of age and held office for life. Five magistrates, called ephors, who supervised the state education and the messes, were elected from the equals and held officefor a year; at first they had little importance in the constitution. The assembly of Spartiates elected the elders and the ephors by acclamation. voted on proposals submitted by the council (for it could not initiate proposals itself) and passed decisions which were binding. The Dorian tribal system was replaced for military and political purposes. by five new tribes, each containing the residents of one of the five constituent villages at the time of the reform and thereafter their descendants.

The Spartan state was the first example on the mainland of the famous definition of Xristotle (Politics, 1252^b 28): "the partnership of several villages is the full-grown polis, which already possesses the dimensions of virtually complete self-sufficiency." Its formation was dated by Thucydides (i, 18, 1) toward the end of the 9th century, and it rapidly showed its superiority over its neighbours. (The date and to some extent the character of the reform associated with the name of Lycurgus are much disputed; for the view given here see *Journal* of *Hellenic Studies,* lxx, pp. 42–64 [London, 1950].) The warrior class of Sparta enforced the kings' suzerainty by reducing all Lacedaemonians to dependent status: the Perioeci (people of the vicinity), as they were called, henceforth obeyed the dictates of Sparta and served in the army, retaining only limited powers of internal self-government. The Lacedaemonian army then annexed Nessenia after 20 years of war (c. 740–720 B.C.) ; the best land was allocated to Spartiates and worked by Messenian serfs, and the hill people became Perioeci. Two other Dorian states grew, as did Sparta, out of constituent villages in the 8th century, namely Corinth and Megara. They conducted an indecisive war with one another for control of the Corinthian isthmus. But a new outlet was found for their energies in colonization.

The Colonizing Movement **and** Its Effects.—The pioneers of Greek colonization were the Ionians of Asia Minor. When life became more peaceful, they soon felt the pinch of over-population; for they held only a small foothold on the coast and could not overcome the vigorous peoples of the interior. Led by the Milesians. they sailed into the Black sea and planted their first colonies on its coasts m the first half of the 8th century. The Ionians of Chalcis and Eretria in Euboea opened up the west by planting colonies on the island of Ischia in the bay of Naples and at Cumae on the mainland opposite in the middle years of the 8th century. They were the first also to colonize Sicily. The Ionians of the islands were among the early colonists on the northern coast of the Aegean and on the island of Thasos. Although the Dorian states of the mainland came later, they founded the strongest colonies: for example, Syracuse, Corcyra, Apollonia Illyrica, Ambracia, Leucas and Potidaea founded by Corinth; Byzantium and Chalcedon founded by Megara; Taras (Tarentum) founded by Sparta; and Cyrene founded by Thera. The spate of colonization continued until c. 550 B.C., by which date hundreds of colonies were planted on the northern Mediterranean coast and islands from Spain to the Hellespont (except in the inner Adriatic), on all shores of the Black sea and on the African coast between Egypt and Carthage. The limits to the areas of colonization were set by the rival sea powers Etruria, Phoenicia and Egypt.

The Greek colony was a small independent unit, a replica and not a servant of its founder's original city; it was a polis in its own right, an apoikia or "settlement far from home." Thus the great variety of city-state institutions! alphabets, calendars! festivals and so on was perpetuated overseas in innumerable small states. Because the colonists aimed to establish a self-sufficient community, they went out in search of fertile land; but they chose sites in most cases which were suitably placed for trade. They were able to establish themselves at the expense of less civilized and less well-organized peoples by virtue of intelligence and fighting power; for they came usually in longboats of 50 oars, seized and fortified a small island or strong point and used their superiority of weapons and defensive armour to win good land. The Greeks adopted little from the natives of the sites that they colonized. Their colonies were rather outposts of a Greek civilization which was racially and culturally exclusive, but from them spread those hellenizing influences which transformed Europe during the Greek and Roman periods.

The Greek states of the homeland sent out their colonists for a variety of reasons. Sometimes they wished to rid themselves of surplus population or political malcontents, but they usually had their own positive interests in mind. The earliest colonies were planted to tap the trade in metals: and others were set up in areas rich in wheat, tunny fish or animal products. The colonies could thus trade with the homeland and particularly with the founding city. The commercial character of Greek colonization was so marked that the agricultural states of the homeland (the central Greek states. including Attica and the bulk of the Peloponnese) sent out no colonies, whereas the leading commercial states; such as Miletus. Chalcis. Eretria and Corinth. founded the largest number of flourishing colonies.

As the colonies were planted, Greek trade increased steadily. The traffic by sea, ranging from the shores of the Caucasus to Spain. had its centre of exchange at the Isthmus of Corinth. The merchantmen. being unable to tack against the mind, sailed along the coasts and islands, taking advantage of the onshore and offshore winds rather than venturing across the open seas. The Corinthians. c. 600 B.C., constructed a roadway (diolkos) for hauling vessels and cargoes across the four-mile span of the isthmus; Corinthian shipwrights invented the go-oared longboat; and the strategic position of its colonies, combined with its own wealth and naval power, gave the city of Corinth a strong hold on the western trade. The expansion of Greek trade within the colonial areas coincided with a period of close relations with Syria, Phoenicia and Egypt, The traffic which began in the 9th century revolutionized Greek ceramic art in 750–700 B.C., when the formal but austere dignity of geometric pottery gave way to the orientalizing style of polychrome painting and imaginative decoration. The new style was developed first in Crete, Corinth and Laconia and later in Athens and Ionia, but it spread rapidly throughout the Greek world, the potters of Corinth holding the lead until 550 B.C. Greek traders were active in the eastern Mediterranean, where stations were established at Naucratis in the Nile delta and at Poseidium near the mouth of the Orontes in Syria. Greek troops were employed as mercenaries by the kings of the east.

The Tyrannies.—Prosperity brought political troubles in its train. The traditional loyalties of the tribal state with its constituents — tribe (phyle), brotherhood (phratry) and clan (genos) —were centred in the racial units and were based upon the agricultural landowning system. The claims of birth were now upset by the claims of wealth. The first effects were seen among the aristocratic leaders. whose solidarity of interest was disrupted. At Corinth. where the Racchiadae were the ruling clan. Cypselus, the son of a Bacchiad woman. seized power and set up a "tyranny" which mas maintained by him and his descendants from *c.* 657 to c. 582 B.C. His example was followed at Sicyon, where tyranny lasted for a century, and at Megara, where it was short-lived. The tyrants were not social revolutionaries but self-seeking aristocrats. who increased their own revenues by keeping the citizens at work and promoted the trade and prestige of their states with remarkable success. When they fell, they left a legacy of political bitterness. from which oligarchy emerged once more triumphant. In these Dorian states the existence of the serf class also acted as a brake against social revolution. In the Ionian states. where all men were citizens. the tyrants at Ephesus and at Miletus. for example, overthrew the aristocratic order but failed to establish a stable government; and on their fall a period of faction ensued between oligarchs and democrats.

Solon. — The troubles which attended sudden prosperity were sometimes solved by "law-givers" or arbitrators. The most famous of these. Solon of Athens. was appointed in 594 B.C., at a time when the wealthy were entitled under the laws of debt (1) to tie bankrupt debtors to the land and exact one-sixth of the produce and (2) to sell off a second category of debtors as slaves. The explanation of these two categories of debtors is disputed: the first probably comprised members of Athenian clans. who were prohibited by law from alienating land owned by the clan: the second was probably composed of *orgeones* (that is to say, members of guilds), who were Athenians originally by naturalization and not by blood and owned alienable goods. Solon liberated both categories. forbade the tying or selling of bankrupts and made new laws of debt. He then carried a constitutional reform to safeguard the poor from oppression. He instituted a people's court of appeal in the Heliaea; there anyone could initiate a case. and the appeal from the ruling of a magistrate or the verdict of a phratry or clan court was judged by a panel drawn by lot from all citizens, however poor. He divided the people into four classes according to income and ruled that candidates for state offices should belong to this or that class; he thus eliminated the aristocratic principle of birth, which had hitherto been important in candidature for office. He left the constitution much as he found it (annual magistrates elected by the people; the council of the Areopagus, the members of which nere elected for life from the former magistrates; and an assembly or ecclesia), but he nominated 400 members to serve for ten years on a new council or boule, which was to act as a steering committee for the assembly. Solon was a true arbitrator: he gave to each section of the state those powers which he considered it fit to wield He enunciated for all citizens freedom of the person, equality before the law and a say in election and government, but he left the mass of real power in the hands of the Areopagus council and the wealthy class in the state. which was in the main the aristocracy of birth. He also took an important step to widen the economic basis of a country which was mainly agricultural and had stood aside from the colonizing movement: he invited craftsmen from other states to settle in Athens and to receive the franchise. Further, he reformed the standard of the currency so that Athens could enter the commercial orbit of Corinth on favourable terms.

Currency and Coinage. — During the expansion of the Greek states, 750–550 B.C., commercial exchange was lubricated by the adoption of currency from Lydia in Asia Minor, where a lump of electrum (a natural alloy of gold and silver, in which the proportion of gold is variable) was guaranteed at a definite price by the king of Lydia and stamped with his emblem of state. a lion's head. Most of the Greek states which engaged in commerce were coining in silver before 600 B.C., and the circulation of fractional currency in place of barter made it possible to accumulate mobile wealth more rapidly. Credit, usury and banking soon followed. and the foundations were laid of an active capitalism which has distinguished Europe from the east for many centuries.

The Conflict Between Greece and Persia

The Persian Advance and the Growth of Sparta and Athens. — The expansion of the Greek states was favoured by external circumstances. No great power overshadowed the Mediterranean area in the period 750–550 B.C. The civilized states of Asia Minor, Syria. Egypt, Carthage and Etruria were less aggressive and less capable than the Greeks, and no really great wars broke out between the Greek states theinselves (the conflict that involved the largest belligerent coalitions was the Lelantine War between Chalcis and Eretria and their several allies). The situation changed when Cyrus the Great incorporated Lydia in the Persian empire c. 546 B C.; and his successors reduced every state from the Mediterranean coast of Asia to the Indus valley and Egypt also. In 514–513 Darius I led the forces of the Persian empire across the Bosporus into Europe, marched north against the Scythians beyond the Danube and withdrew discomfited; but he retained control of the northern Aegean coast. conquered some Greek islands off Asia Minor and the Hellespont and received the submission of the king of Macedon In 500 the Persians were preparing to advance into the Aegean, where they were invited to intervene at Naxos in the Cyclades.

The Peloponnesian League. — The Greek states of the mainland took no steps to help the Greeks of the Asian coast and the islands when they were overrun by Persia. The Spartan government uttered diplomatic threats. but remained. no less than the others. immersed in its own affairs. By j46 B.C. Sparta had become the strongest power in Greece. a Messenian revolt (*c.* 640–620) had been put down; the rival military power of Xrgos had been defeated; and a military coalition known as the Peloponnesian league or, more accurately. the Spartan alliance, had been formed. As leader of a coalition Sparta had many attractions to offer, including a stable constitution, a superb standing army and a sound agricultural economy—(having banned the introduction of coinage, the Spartans had very little commercial interest, and they had no hunger for land). The Spartans' record moreover was good, in that they had deposed tyrants in some states and supported conservative government in general. Any state which joined the military coalition contracted a defensive alliance with Sparta, agreed to serve under Spartan command in time of war and undertook to provide help against the seris; and the contracting state received in exchange the protection of the leading military state against any aggressor. Having initiated this policy *c.* 550 B.C., Sparta brought almost all the Peloponnesian states, apart from Argos, into this coalition before j10.

Peisistratus and the *Peisistratids*.—Athens grew in power under a tyranny. When Solon retired, there was a long period of party striie which ended finally in the seizure of power by Peisistratus about j46 B.C. He and his sons ruled Athens until 510 with a firm and consistent policy which brought the prosperity envisaged by Solon. Athenian pottery outstripped Corinthian and established a long-lasting supremacy for black-figure and red-figure wares. Under Peisistratus, Athens became one of the leading centres of commercial exchange, had very close relations with the Ionians, planted settlers on the Thracian Chersonese, on Lemnos and Imbros and held Sigeum in the Troad, thus securing some grip on the approaches to the Hellespont. After Peisistratus died in 528 or 527, the advance of Persia weakened the Athenian position. Two friendly tyrants. Polycrates of Samos and Lygdamis of Naxos, fell from power. and Darius annexed the Chersonese and threatened Lemnos and Imbros. Athens moreover became embroiled in 519 with Boeotia. where a league of city-states had grown up under the leadership of Thebes and was trying to force Plataea into membership. When Athens made an alliance with Plataea. Thebes and Athens came to blows, and Athens was victorious. This success caused alarm to the other Greek states. In 514 Hipparchus, one of Peisistratus' sons. n-as assassinated by two Athenians, Harmodius and Aristogeiton. In 510 Sparta, aided by Athenian exiles. used force to expel from Athens the leader of the Peisistratids, Hippias, who fled to Persia. Athens was now enrolled in the Peloponnesian league: which included Boeotia and other states in central Greece.

Cleisthenes.—Liberation did not bring peace to Athens. The aristocrats who had been ousted from authority or banished by the tyrants now struggled with one another for power. But the common people and especially the town dwellers, to whom the tyrants had brought prosperity. were a new factor in the situation; for they had gained some political experience in working the constitution and the laws of Solon under the tyrants. who kept the real control in their own strong hands. A returned exile, the aristocrat Cleisthenes of the Alcmaeonid clan, who was losing the struggle against his peers, espoused the cause of the commons. His rivals called in a Spartan garrison to occupy the acropolis in 508 B.C. The Athenians rose in disgust, forced the garrison (commanded by a Spartan king. Cleomenes I) to withdraw from Attica and authorized Cleisthenes to set up a constitution.

Cleisthenes' aim was to cut away the political power of the clans which made the rivalry of the aristocrats so dangerous and to give the guildsmen a part in the administration of the state. He therefore made residence instead of race the basis of the electoral system and replaced the four racial tribes with ten new tribes of residents in "demcs" (about 170 areas similar in size to small parishes). As he wanted the new tribes to cut across (1) the local influence of the clans which owned big estates and (2) the sectional interest of the town as opposed to the country, he constructed each new tribe out of demes usually not contiguous one with another and drawn in equal proportion irom town, coast and inland. Having broken the racial principle (as the Spartans had done in their reformj. Cleisthenes made tribal membership hereditary after 507 B.C. Each new tribe provided a military contingent; elected a general (strategus) and lesser officials annually; and for a council of state provided 50 members annually: selected by lot irom candidates elected by its own demes in proportion to the population of each deme. The new council or boule of 500 members, inheriting the powers of Solon's council of 400, prepared all business for the assembly, carried out routine administration and was divided by tribe into ten committees of which there mas always one, elected by lot, in permanent session for a tenth part of the year. Although Cleisthenes ensured the electoral and political rights of the commons, he left the constitution in the hands of the experienced class. The council of the Areopagus, as guardian of the constitution and the laws, had the right to veto a decree of the assembly and tried cases of treason. The chief magistrates (the nine archons) were still elected by the people en masse from members of the two richest classes, and the 500 councilors had to be members of the top three classes, who had passed a scrutiny (*dokimasia*) by the outgoing council. There were thus sufficient checks on the assembly's sovereignty to make the constitution a balanced one, "admirably adapted to promote unanimity and preserve the state" (Plutarch, *Life* of Pericles, 3).

Athens and the Peloponnesian League, *506–500*.—The constitution was soon tested. In j06 B.C. the Spartans advanced to Eleusis with their Peloponnesian allies, while Boeotian and Chalcidian armies invaded northern Attica at two points. The Athenians concentrated their army at Eleusis. But the Corinthians, who disapproved of an attack on Athens, left the Peloponnesian ranks, and this precipitated a quarrel between the two Spartan kings, who had equal powers of command. A deadlock resulted, and the whole Peloponnesian army went home. Athens then trounced the forces of Boeotia and Chalcis separately. annexed the best land of Chalcis and planted 4.000 Athenian settlers on it. Aegina then made an alliance with Boeotia and sent a strong fleet to ravage the coast of Attica. The Athenians approached Persia for help. but, when they were ordered to accept Hippias as tyrant, broke off negotiations. Meanwhile Sparta was dealing with the problems raised by the fiasco of the recent invasion of Attica. A law was enacted whereby the two Spartan kings were forbidden to serve together, except in Laconia. Next, anxious to deprive Persia of a gambit for entering Greece, the Spartans brought Hippias over from Asia and promised to restore him as tyrant. They then asked their allies to send delegates to a conference at Sparta and explained their plan; but the Corinthian delegate protested, the others followed suit and Sparta acquiesced in the decision.

This conference not only saved Athens but also crystallized the organization of the Peloponnesian league. Thereafter, whenever a defensive alliance with Sparta was invoked. Sparta convened the delegates of the allies and explained the position. The delegates then voted: each state having one vote, whether the body of allies was to go to war; the decision of the majority, being binding on the minority, was reported to Sparta, which voted separately in the state's own assembly. If the two equal bodies—the congress of allies and the Spartan state—concurred, a common policy was adopted; otherwise no action was taken by the Peloponnesian league as a whole. 'This was a realistic procedure. which recognized that the agreement of Sparta was indispensable to the league.

The Ionian Revolt.—The Greek states of the mainland thus were iar from united in 500 B.C. when Persia accepted an invitation to intervene at Naxos. A member of the Persian royal house and a Greek called Aristagoras, who had been appointed tyrant of Miletus by Persia, tried to take Naxos by surprise in 499 and failed. Afraid of Persian resentment at this failure, Aristagoras made plans to raise the Ionian states in revolt. He resigned his tyranny at Miletus and persuaded the other states to depose their pro-Persian tyrants. Then he applied to Sparta for help. Sparta was already committed to enmity with Persia, but saw that the Spartan army, which counted 10,000 men at full strength, could do little or nothing to hold the narrow coastal fringe of Asia Minor against the vast resources of Persia. Sparta therefore refused. Aristagoras, however. went on to Athens, and the Athenian assembly gave him a squadron of 20 ships. thus earning the gratitude of the Ionians and the hostility of Persia. The only other help was five ships sent by Eretria.

The Ionian states that had deposed their tyrants decided in 498 to tight ior their independence against Persia. It was a remarkably courageous decision; for the resources of Persia were vast and individually the Ionian states were puny by comparison. At first they held the initiative; for the Persians had to muster the fleets of their subjects in Cyprus, Phoenicia and Egypt. But the Ionians started by marching inland. n-here they burned Sardis but failed to capture the citadel. The Greek cities of the Bosporus and of the Hellespont rose in sympathy, thereby cutting off the Persian forces in Europe and opening the way for supplies from the northern coast of the Black sea. Most of the Carians. who were good soldiers. joined the revolt. Finally the Greek states in Cyprus attacked the Phoenicians in the island. Instead of co-ordinating their allies and sailing to Cyprus. the Ionians allowed Persia to take the initiative in 497. At this stage the Athenians sailed home. Two Persian army groups operated in Asia Minor, and a third was transported by the Phoenician fleet to Cyprus. where the Ionians brought them to battle on land and at sea. Although the Ionians were victorious at sea, the Persians kept the initiative by land and recovered the whole of Cyprus in 496 B.C. In Asia Minor one Persian army group reduced some Greek states in the area of the Hellespont. but the other group was finally annihilated by the Carians late in 496. During the winter of 496–495 the Ionian states sent deputies to a conference at the Panionium to make an agreed plan. They decided to raise no army but manned 353 ships. each contingent serving under its own captain. When the captains entrusted the command of the fleet to one of their number, the seamen mutinied. Meanwhile Persia raised a larger fleet. which moved up the coast with an army in support and offered a free pardon. if the Ionians would capitulate; but the offer was refused. In midsummer of 495 a naval battle was fought at Lade. in which some Ionian squadrons fought well but others fled without engaging. The Persian fleet was decisively victorious, and by the summer of 493 the last of the rebels was reduced. (The chronology is disputed; for this account see Historia, iv. p. 385 [1955])

The Ionian revolt was not in vain. It showed the Greeks of the homeland that resistance to Persia was not hopeless and that co-ordinated policy, unified command and sea poner nere of the first importance. The Persians too learned a lesson. When the) had meted out punishments. they permitted democratic government in the Ionian states, ordered them to keep the peace nith one another and demanded tribute in accordance nith a just assessment. This politic settlement was successful. The Ionians stayed quiet while the Persians re-established their authority in Europe as far as Macedonia in 492 and raised forces in 491 to punish Xthens and Eretria

The policy of Athens had fluctuated during the revolt. When it ended in failure. the Athenians began to fortify their naval base at the Peiraeus on the advice of Themistocles. who advocated resistance to Persia ; and they sought a *rapprochement* with Sparta In 491, Persian agents visited the Greek states and demanded earth and water. the tokens of submission Several states medized (*i* e , joined the Medes and Persians). One of them. Aegina nas still at nar with Athens. At the request of Xthens. Sparta compelled Aegina to re\ oke this submission to Persia in 491, but Aegina attacked Athens in the following year and was only held in check by Athens with the aid of Corinth. (The chronolog} is disputed: for this account see *Historia,* iv. p. 385 [1955].) Nevertheless, Athens could now count on the help of Sparta

The Persian Wars in Greece.—A strong Persian expeditionary force sailed across the Aegean in 490 B C All the islands in its path submitted except Euboea \ here Carystus and Eretria resisted but were quickly reduced. The Persian commanders, taking the advice of Hippias, landed unopposed at Marathon; supplies were ferried over from Euboea, and the plain was suitable for their cavalry, which was far superior to any Greek cavalry When the Athenians learned of the landing, they sent a runner Philippides (or Pheidippides), to inform Sparta (he reached Sparta. 140 mi. away, on the next day) and met in assembly to discuss strategy. On the proposal of Miltiades. nho was general of a tribal contingent. they sent their heavy infantry to Marathon There the Athenian commander. Callimachus. pitched his camp on the foothills where the Persian cavalry could not deliver an attack. and watched the Persian infantry drawn up along the shore. For a few days neither side moved. The Athenians numbered about 10,000 men and were reinforced by 1,000 Plataeans. The Spartans promised to send an army when they had completed the festival of Apollo, but that would not be for a week or more.

Marathon.—Miltiades had had considerable experience of Persian warfare. As ruler of the Thracian Chersonese. he had seen the army of Darius in 513 and followed the events of the Ionian revolt from close quarters. He therefore appreciated the fighting qualities of both sides at Marathon. The Greek heavy infantryman. the hoplite. wore defensive armour of bronze (helmet. breastplate and greaves). whereas the Persian infantryman more a bonnet. a padded or scale-clad tunic and close-fitting trousers. The Greek weapons were a bronze shield, a six-foot spear and a sword, whereas the Persian had a wicker shield, a shorter spear and a sword. Miltiades knew that despite inferior numbers the Greek infantry would have a chance of defeating the Persian infantry at close quarters. Infantry tactics were similar on both sides; for the men fought in a solid line, several ranks deep. The Greeks, however: were more experienced : hoplite warfare had been practised since 700 B.C.. and the Athenians and Plataeans were seasoned soldiers. The Persians were a picked but composite force with far less tradition of infantry fighting. Miltiades, therefore, advised his fellow generals to attack as soon as opportunity offered. The votes of the ten generals were equally divided. and the casting vote lay with Callimachus, a civil magistrate (archon polemarch). He sided with Miltiades. Even so, each general had one day of operational command in turn. Those who had sided with Miltiades gave him their days, and it so happened that Miltiades commanded on the day of the attack. The circumstances which made the attack possible are not explained by Herodotus, the historian of the Persian Wars. and the following account is a reconstruction which is controversial.

While the armies waited. Miltiades advanced his position into the plain by felling trees and making stockades at night. until he was only a little more than a mile from the Persian infantry lines. The large force of Persian cavalry, perhaps 5,000 strong, maneuvered in the plain by day but needed water and pasture at night; these were best found at that time of year (September) in the springs and marshes at the far end of the Marathon plain. One night near dawn some Ionians serving with the Persians came to the stockades and said, "The cavalry are away." Miltiades drew up his men, strengthening the wings and thinning out the centre of the line, hurried across the plain in the dawn and charged the Persians at the double. Bitter fighting ensued. The Athenian centre was pushed back. but the weight and superior armour of the wings prevailed and both wings then turned inward and attacked the Persian centre from both sides. Once the melee of the infantry battle had started, the Persian cavalry could not intervene effectively. and the Greeks drove the enemy down to the sea, where their fleet took them off.

As the Persian fleet stood out toward Euboea, the Athenians on the battlefield saw flashes from a shield inland. The flashes were evidently a signal; for the fleet changed course and headed for Athens. Suspecting that the supporters of Hippias intended to surrender the city, the Athenians managed by a forced march to reach Xthens just before the fleet entered the bay of Phalerum. A landing was now impossible. The Persian fleet sailed for Asia. Next day the Spartan vanguard arrived and marched to Marathon to study the arms and tactics of the Persians. The Athenian dead, 192 in number. were buried where most of them had fallen. The burial mound still marks the spot. The Persians had lost 6,400 men and much of their prestige.

Preparations for War, 490–480.—Darius was now determined to invade Greece in force. But a revolt by Egypt: Darius' death in 486 B.C. and the reduction of Egypt by Xerxes, his successor, delayed the offensive until 480. Although the Greek states had ample warning, most of them made no preparations until the last moment. Athens showed more foresight. Rliltiades led a fleet of 70 ships into the Aegean to secure the Cyclades against Persia. He was wounded in an unsuccessful attack on Paros and was later condemned on a charge of misconduct. He died of his wound soon afterward. The offensive was then abandoned, but the Athenians made political preparations for the future. The aristocratic leaders. who were related to Hippias, and perhaps also other leaders favoured appeasement or collusion. Even the advocates of resistance differed in their strategy, because some trusted in their victorious army and others in their comparatively inexperienced and small navy. The decision lay with the assembly from meeting to meeting, but there was a grave danger that the mood and, therefore, the policy of the assembly might fluctuate if it were to be exposed to the oratory of rival leaders. It was essential to make a lasting choice in good time. The means were found in ostracism —a procedure which may have been devised by Cleisthenes but was used now for the first time. If the assembly decided without debate to hold an ostracism, each citizen scratched the name of the man he wished to expel on a piece of pottery (ostrakon) and returned it at a later meeting. If the pieces of pottery exceeded 6,000, the man whose name headed the poll was banished for ten years but retained his property and citizenship. Between 488 and 482 ostracism was used frequently (thousands of ostraka have been found in the excavation of the Agora in Athens). Victims were Peisistratid and Alcmaeonid leaders and finally Xanthippus, son-in-law of Cleisthenes, and Aristeides. a colleague of Miltiades at Marathon. By this effective method the assembly selected Themistocles, the advocate of a naval strategy, as its leader for the war against Persia and authorized him in 483-482 to devote an unexpected yield from the state-owned silver mines to the building of warships. In 480 the victims of ostracism were recalled. The fleet then stood at zoo vessels and Themistocles mas in charge.

Another problem at Athens was the machinery of command in the field. The preliminaries at Marathon had made this obvious. In 487 the assembly deprived the civil magistrate of his military functions and changed the procedure for appointing the nine chief magistrates. The demes now elected 500 candidates, of whom nine were selected by lot, scrutinized by the council and appointed. The ten generals were the only officials still appointed by direct election. They became the most important figures in Athens at a time when a war for survival was imminent. (See STRATEGUS.)

Effective resistance depended less on Athens than on Sparta. Whereas Athens was hemmed in by enemies (Thebes and Aegina), Sparta led a powerful military coalition and had shown prowess by inflicting a severe defeat on Argos *c.* 495 B.C. When Xerxes sent envoys to ask all Greek states except Athens and Sparta for earth and water, Sparta held a Greek congress late in 481, at which delegates of about 30 states agreed to enter into alliance against Persia and to terminate all wars with one another. Argos, Crete and Syracuse were invited to join the alliance. Their refusal was reported when the delegates met in the spring of 480 at the Isthmus of Corinth. The problem of co-ordinating 30 states was solved by the statesmanship of the Spartans and their allies. who formed the bulk of the coalition. Each state. Sparta included. cast a single vote at a congress of delegates and agreed to obey a majority decision. The congress entrusted the command by land and sea to Sparta, decided the general lines of allied strategy, raised and allocated men and money, conducted diplomatic negotiations and threatened medizing states and persons. The member states of the congress entitled themselves "the Greeks" (Hellenes). Thus for purposes of defense a Greek league came into existence and evolved an efficient machinery of allied co-operation.

Artemisium and Thermopylae.—In the spring of 480 B.C., Xerxes entered Europe with a vast army, supported by a large fleet. His chief problems were supply and transport. He had laid some dumps in advance but depended mainly on the fleet; which was therefore tied to the army. The means of transport in a country without roads were pack horse and oxcart. Indeed the army advanced at so sluggish a rate that Xerxes brought the Greeks to battle on land only once in 480, and that was on ground chosen by them. The congress of the Greek league wanted to inflict a defeat on the Persian fleet, which would halt Xerxes' advance. They therefore posted the Greek fleet at Artemisium in northern Euboea and a holding force of 6,000 or 7,000 hoplites at the pass of Thermopylae on the mainland farther down the Euboic channel. The fleets fought indecisively on three successive days. The Greeks had sufficient success to encourage them in view of their inferior numbers, but their base on the island became unsafe when the Persian army turned the position at Thermopylae. There the hoplites proved far superior in hand-to-hand combat, and the Spartan king Leonidas and his 300 Spartiates showed the spirit of free men by fighting to the death.

Salamis.—The congress of the Greek league chose the island of Salamis, off the Bay of Eleusis, as its next naval base and fortified the neck of the Isthmus of Corinth. Central Greece was left defenseless. Thebes joined the Persian forces, as Thessaly had already done, but the Athenians took to their ships on the advice of Themistocles, abandoned Athens to fire and pillage and let the council of the Areopagus represent the state during the emergency, while the people were dispersed as refugees. The political decision of the Greek congress was unpopular from the outset with some of the captains who had to put it into effect. The Greek fleet of 380 warships was faced by a Persian fleet which had replaced its heavy losses in storms off Thessaly and Euboea and now mustered about 1,400 ships (for the numbers of ships involved. as well as for other controversial matters connected with the battle of Salamis, see the full discussion in the *Journal* of Hellenic *Studies,* lxxvi, p. 32 ff. [1956]). When the Persian fleet conducted a reconnaissance off the eastern exit of the Straits of Salamis, the division of opinion flared up on the council of captains over which the Spartan commander, Eurybiades, presided. Many captains wished to withdraw their national contingents and defend their homes in the Peloponnese, for they were afraid of being bottled up and annihilated in the Straits of Salamis and the Bay of Eleusis. The decision lay with Eurybiades, but Themistocles did not wish the future of the Greek navy to hang on the Spartan's judgment. He sent a message that evening to Xerxes, saying the Greeks were divided and about to disperse and that he, Themistocles, was friendly to the Persian cause. The advisers of Xerxes, remembering the Greek dissensions at the battle of Lade, thought the message credible. and Xerxes acted upon it. He sent 200 ships that night to close the western exit from the Bay of Eleusis, off Megara, landed picked troops secretly on an island at the eastern end of the straits and kept the main fleet under oar all night, patrolling the open water outside the eastern exit. Meanwhile the Greek captains wrangled into the small hours, until Aristeides brought a report that the western exit was being closed by the enemy. Withdrawal was now impossible. The Greek command made its plans, aided by the captain of a ship from Tenos who deserted and gave details of the Persian dispositions.

The Greeks were experienced in naval warfare. Their ships were vessels of a uniform type, the trireme, driven in battle by 170 oars and designed for ramming. They were more stoutly built and therefore lower and slower than the Phoenician galleys. which were designed for boarding tactics and carried more marines. The first problem for the Greek command mas to offset their smaller numbers by drawing the Persian fleet into the straits. As dawn broke, the Greeks embarked at their bases halfway up the straits and rowed off northward out of sight. The Persian fleet, seeing them disappear, thought they were in flight and rowed into the straits. Then the Greeks returned in battle order to the narrowest part of the waters, maneuvered under oar to create favourable circumstances for ramming and went into the attack at the crucial moment. The Phoenician squadron. in the van, suffered heavy losses, and the leading files were driven back onto those which were still advancing. Then the Greek ships, encircling the scene of confusion, rammed repeatedly with a sure aim, until the Persian ships capsized and the sea was covered with wreckage and corpses (Aeschylus, *Persae,* lines 417–421). As a west mind rose, the Persians hoisted sail and fled to Phalerum. having lost the pick of their fleet. Next day Xerxes, who had watched the battle from the mainland, did not renew the engagement; for although his fleet was still far superior in number, he saw no hope of prising the Greek fleet out of its strong position.

Plataea and Mycale.—The Greek victory at Salamis halted the Persian advance in September, the end of the campaigning season.

Xerxes himself returned to Asia with his fleet and part of his huge army, but his general Mardonius wintered in central Greece with a formidable army. Despite Athenian, Plataean and Megarian pressure, the Greek congress at first kept its army at the Isthmus of Corinth and its fleet at Aegina to conduct a co-ordinated defense; if necessary; but it passed to the offensive on both land and sea in late summer, 479 B.C. Mardonius, having tried in vain to detach the Athenians from the Greek cause by diplomacy and then by ravaging Attica, withdrew his army of perhaps 150,000 men as the Greeks advanced. He chose his ground in the Boeotian plain below Plataea. There the Persian cavalry dominated the plain and the Greeks stayed on the foothills. where they soon ran short of supplies and water; for nearly 40.000 hoplites and 70,000 light-armed troops were dependent on pack horses traversing Mt. Cithaeron. One night in August the Spartan regent Pausanias ordered a general withdrawal, which was disrupted by the obstinacy of a Spartan officer who stayed at his post. Dawn found the Greek units scattered. Mardonius advanced at once, concentrating his best infantry against 10.000 hoplites of Sparta and 1,500 hoplites of Tegea. who were isolated from the main Greek army.

Pausanias kept his troops in hand, until he judged the moment ripe. Then he led his Spartans and Tegeans downhill at the charge. They overwhelmed the Persians with their superior weight, longer weapons and disciplined array, killed Mardonius and pursued the fugitives to their stockaded camp so closely that the cavalry could not intervene. The Greek centre was driven back from the plain; but the Athenians. 8.000 strong under Aristeides, defeated the Thebans. joined Pausanias and stormed the camp. By nightfall the bulk of the Persian army was destroyed. Meanwhile the Greek fleet. commanded by the Spartan king Leotychidas. drove the Persian fleet to the Asian mainland at Mpcale. Leotychidas landed his sailors and marines farther up the coast. destroyed the Persian fleet and inflicted very heavy casualties on a supporting army. The Ionians and Aeolians at once rose in revolt. The Persian invasion thus met with final disaster.

The Greek Offensive.—As Persia had vast resources. Xerxes was likely to attack again. The best method of hindering him was to punish the medizing states, to cut the communications between Europe and Asia and to keep the Phoenician fleet out of the Xegean. Late in 478 B.C. this was almost achieved; for Thebes had been punished and Thessaly invaded, and the navy under Pausanias had captured most of Cyprus and occupied Byzantium. But the revolt of the Ionians and Aeolians raised a difficult problem. Sparta and the other Peloponnesians still thought (as in 498) that Ionia could not be defended and therefore advised the Ionians and Aeolians to leave Asia. Athens. however. appreciating the nature of sea power, believed that Ionia could be protected and could help to protect the Aegean from the Phoenician fleet. The divergence of opinion between Sparta and Xthens was also based on self-interest. Having lost a considerable proportion of their best troops at Thermopylae and Plataea, the Spartans wished to husband their manpower for the suppression of the helots and the strengthening of the Peloponnesian league. The chief asset of Athens was the fleet; for Attica was ruined, and the walls, of Xthens were being rebuilt against the wishes of Sparta. If Athens could win the leadership of the Ionians of the islands and of Asia Minor, a mass of power comparable to that of the Spartan alliance would be created. Xthens then played a skillful hand. In 479, after the victory at Mycale, the Athenian squadron under Xanthippus joined the Ionians in capturing Sestos in the Hellespont. In 478, when the Spartan Pausanias became unpopular and mas recalled. the Ionians offered the command of the Greek navy to the Athenian captain. Aristeides. Athens accepted and Sparta acquiesced. They had combined to defeat Persia in the past and were both under oath to maintain the principles of the Greek league.

The Confederacy of Delos.—An offensive and defensive alliance was contracted by Athens with each of a number of Ionian states separately in the winter of 478–477; these Ionian states did not necessarily make alliances with one another. Xthens (with a fleet of 200 triremes) was thus the centre and leader of the coalition, but undertook to respect the autonomy of the other members. The allies met regularly at Delos in a synod, where each state had one vote and a majority vote was binding; the Athenian state took its own decisions separately. If the synod and Athens agreed, a joint policy was formed by the coalition. which was known in Greek as "Athens and the allies" and goes now under the loose title of the Confederacy of Delos. It resembled the Peloponnesian league closely? except that the alliance was offensive. The allies accorded to Athens the command at sea, a half-share of any booty and important executive powers: *e.g.*, Athens decided which states should contribute money and which states ships and assessed the amount in each case. Athenian officials kept the accounts of the allied fund, which was placed in the temple of Apollo and Artemis at Delos. and Athenian commanders had disciplinary powers over the troops which each state had to supply in addition to money or ships. The coalition won a series of successes against the Persians in Europe and Asia, which culminated in an attack on a Persian army and a navy of 350 ships mustering at the Eurymedon river in Pamphylia *c.* 466 B.C. Under the command of Cimon. the Athenian fleet of zoo ships, carrying about 5,000 hoplites. and the allied squadrons, amounting to 100 'ships and carrying parties of marines and archers, sank 200 enemy vessels. forced a landing and defeated the Persian army. The policy of Athens was triumphantly vindicated.

Cimon and Sparta.—During these years Athens had to watch its relations with Sparta. Themistocles, who had deceived Sparta while the walls of Athens were being rebuilt, and Aristeides and Xanthippus, who brought the Confederacy of Delos into being, were in favour of democracy and hostile to Sparta. but the people put their trust in Cimon, a friend of Sparta. and in the council of the Areopagus, which had proved its excellence during the year of emergency. Themistocles was ostracized and then banished; he died in the pay of Persia. The Areopagus maintained friendly relations with Sparta. Athens was also careful to have the allies' agreement on matters of external policy and was probably supported by a majority vote of the Delian synod in forcing Carystus to join the coalition and in compelling Naxos, which had seceded, to rejoin on less favourable terms. But Cimon's victory of the Eurymedon created a new situation, because the allies were now safe from Persian attack and the last Persians in Europe were about to be expelled. In 46j B.C. Athens demanded from Thasos a share in certain possessions on the Thracian coast. As this demand infringed their autonomy. the Thasians seceded from the Confederacy of Delos. Xthens attacked Thasos. which was reduced by 462 B.C. and forced to rejoin the confederacy as a dependent state: the Thasians were compelled to surrender their fleet, dismantle their walls. give up their mainland possessions and, thenceforward. contribute money to the allied fund.

The policy of Athens alarmed the Spartans, who secretly promised help to Thasos. But a terrible earthquake in 464 killed many Spartiates, and the helots rose in revolt. Sparta obtained help from its allies, including Athens. but in 462–461, while the Athenian army was in Messenia. the democratic leaders. Ephialtes and Pericles, carried a reform at Athens which ended the ascendancy of the Areopagus and installed a democratic constitution. Sparta dismissed the Athenian army with ill-concealed mistrust. In 461 the Athenian assembly ostracized Cimon and entered into alliance with Argos and Thessaly, the medizing states, which were the enemies of Sparta on the mainland. The period of co-operation between Sparta and .Athens, which had led Greece to success against Persia. was now at an end.

Greek Civilization during the Persian Wars.—Greek beliefs, as expressed by Homer and Hesiod, had much in common with the Bronze Age. The physical universe. for instance. was held to be a sphere, the upper half airy and light and the lower dank and dark. with the earth a flat disk floating midway between the two halves on the waters of the "underworld" and rimmed all around by the great river of Ocean. Matter was original. at first chaotic and confused but then of its own volition orderly and arranged The gods were secondary in time, resident some in the heavens, some in the underworld, but unable to change the conditions of material existence. Men. created by the gods. were subject not only to the material world but also to the caprice of gods who were at odds among themselves. These beliefs formed the background of the Babylonian epics (especially the Epic of *Gilgamesh*) and of early Egyptian religion, but they led to a state of fatalistic despair and superstitious terror, in which men became subservient to the magical incantations of an authoritative priesthood. The Greeks, however, retained a faith in man's free will, moral purpose and independent judgment: the legendary hero Achilles chooses to. fight because he has his own standards of conduct and accepts the prospect of an early death. Likewise, they attributed the same qualities to the superhuman beings of their mythology: Prometheus chooses to give fire to man and accepts eternal suffering. But the consequences of such acts of free will do not lie solely within man's or god's control: they are subject to the immutable laws of physical life—heredity, disease, death and so forth. When Orestes murders his mother to avenge her assassination of his father, no man or god can prevent the onset of insanity.

Faith in free will, in moral purpose and in independent judgment had important political consequences. The Greeks despised the oriental subjects of the Persian monarchy. They defended the free city-state to the death. Solon told the Athenians that they were individually responsible for the internal relations of their society and that Athena, the goddess of their state, would be their guardian in the external fortunes of international and material life. Therefore he laid down a plan for social justice which the Athenians might implement of their own free will but which he would not enforce by seizing power. The colonizing movement and the wars against Persia and Carthage (see SICILY) made the Greek states more conscious of their common heritage and strengthened their belief in the benignity and power of their gods, over whom Zeus presided. Religious faith was strong; Olympia, Delphi and Delos became international centres which influenced the far-flung world of small city-states. Pindar expressed the orthodox piety, moral principles and personal ideals of the Greek world at the time of the struggle with Persia and Carthage. Aeschylus, who fought in the Persian Wars, saw Zeus as the governor of the nations who regulated the consequences of man's free will in accordance with his divine justice. He wrestled with the problem of God's relations with the physical laws of matter—with death, disaster and insanity. In his last trilogy, the *Oresteia* (458 B.C.), he brought the gods of light and the gods of darkness into harmonious agreement to use the immutable laws of physical life for the advancement and well-being of the human race.

The remarkable achievements of the city-state were due to a solidarity of feeling among the citizens, which sprang from the qualities that we associate with family life. Religion played a very important part in it. The gods of the state presided over the festivals of tribe. brotherhood and clan and required the full loyalty of all their members. The citizens expressed their gratitude in temples and in statues of the gods, and the plays of Aeschylus were enacted at a religious festival in honour of Dionysus. The common sense of obligation which united so many states in resistance to Persia was strengthened by the religious sanctions of the Panhellenic oath taken at the Isthmus of Corinth and Plataea. Yet this solidarity was beginning to split by 461 B.C. Sparta and Athens were on the verge of a war which might divide the Greek world. There were outbreaks of party strife within individual states, where the conflict of rich and poor weakened the traditional loyalties of tribe and clan. A new philosophy of life was growing up in the more sophisticated society of Ionia, where the individual man advanced the claims of individualism and denied the divine right of moral and religious restraints in society. The very independence of the Greek spirit was in danger of losing its sense of purpose and undermining its own achievements.

(*See* also GRAECO-PERSIAN WARS.)

THE GREAT WARS IN GREECE

The First Peloponnesian War, 460–445.—In Athens. after the political power of the Areopagus was overthrown, the council of 500 and the assembly controlled all legislation and enacted all decrees of state without let or hindrance. The constitution became a full democracy, a direct government by the majority of the people (*demokratia*). The council prepared the agenda for the assembly, directed the magistrates and heard charges of treason. The people's courts gave a final decision, except in such matters of religious observance as were left to the Areopagus. The assembly had an unrestricted competence, except that any proposal which conflicted with the established laws could be impugned by any citizen and held up until a people's court gave a ruling. The limits set on candidature for office by Solon and Cleisthenes were swept away in 457 B.C., so that the poorest citizen became eligible for all magistracies, except those which carried religious or financial responsibilities. The ordinary man was directly involved in all aspects of political life to an extent unthinkable in a modern European state, and the majority had a deep devotion and enduring loyalty to the tenets of the revolution.

Democracy at Athens was confident and aggressive from the outset. The people engaged in war on two fronts in 460 B.C., endeavouring to break up the Peloponnesian league and to detach Egypt from the Persian empire. As Sparta was weakened by the helots' revolt and the Egyptians fought well against Persia, Athenian energy and courage achieved remarkable success in the first years of the so-called First Peloponnesian War. The navies of Athens and the confederates defeated the Peloponnesian navies, captured Aegina and controlled the Gulf of Corinth from bases set up at Naupactus and Pegae. At the same time they protected the long lines of communication to Egypt and maintained an expeditionary force, which held the Persian garrison of Egypt under siege. Even when the Spartans operated in Boeotia, the Athenians and their allies, who included Thessaly, Argos and Megara on the mainland, raised an army of 14,000 hoplites and held the enemy to an indecisive battle at Tanagra, with heavy losses on both sides, in 457. In the same year Athenian forces overran Boeotia and took civilian hostages from Phocis and Opuntian Locris. Athens established, or favoured the establishment of, democratic governments in these mainland states, in the hope that they mould remain loyal. The city of Athens itself was made almost impregnable—so long as Athenian sea power lasted—by long walls of thick masonry linking it to the Peiraeus.

The Rise of *Pericles*.—The tide of Athenian success turned when Persia invaded Egypt with huge forces and made a separate peace with the majority of the Egyptians. Confident in their sea power, Athens and the allies continued to operate on the Nile, until the Persians diverted its waters, captured the fleet and annihilated a relieving squadron in 454. The sea power of the Delian confederacy was suddenly crippled. The confederate states. already disgruntled by Athens' self-seeking policy: resented their losses in Egypt, and many of them in the southeastern Aegean rebelled from the confederacy. At this time the leading statesmen in Xthens were Pericles, author of the democratic reform and enemy of Sparta, and Cimon, victor of the battle of the Eurymedon and friend of Sparta, who had been recalled from ostracism. Their policies were diametrically opposed except in regard to Persia. The people wisely used Cimon to negotiate a truce with Sparta for five years (451–446) and appointed him to command a fleet of zoo ships. which won several decisive victories over the Persians in the eastern Mediterranean in 450 and 449. Cimon, however, died during the campaign. For other purposes the people put their trust in Pericles. His policy was to complete a process which had already begun, the conversion of the confederacy into an empire and the application of democratic principles at Athens.

In the winter of 454–453 B.C. the fund of the confederacy was transferred from Delos to Athens. The vast sum of 8,000 talents, accumulated mainly from booty, passed technically into the keeping of Athens but effectively into the possession of the Athenians, who appointed Pericles to supervise the monies. Then, while the Persian fleet was being held in Cyprus and Cilicia, the rebels in the Aegean were quickly reduced; for. having been ordered in the past to contribute money, instead of ships, they had no fleet. They were given harsh treatment. Xthens installed a garrison, set up a "democratic" council appointed in the first instance by Athenian commissioners (episkopoi) and exacted an oath of loyalty from each councilor and sometimes from each citizen, which ensured that anyone violating his oath could be summarily executed. Athenian cleruchies were also planted to picket the confederacy.

(A cleruchy was a settlement in which each settler had an allocation or kleros of land and retained his Athenian citizenship.) Before 478 B.C. cleruchies had already been established on Lemnos, Imbros. the Thracian Chersonese, at Sigeum and Salamis; and soon afterward Scyros had been conquered and a cleruchy placed there. Now, between 450 and 446, the Athenians made their imperial purpose clear. They confiscated the best land of some of the "confederates" (*e.g.*, Andros and Naxos) and gave it to cleruchs, who acted as a deterrent against revolt and provided bases for naval operations. In addition Athens made the use of Athenian currency, weights and measures obligatory for all confederates.

On seizing the fund of the confederacy Athens became rich overnight and so could afford a more extravagant democracy. Pericles instituted state pay for those who rendered political and other services. Jurors, councilors, officials and troops—20,-ooo men in all, according to Aristotle—mere soon in receipt of modest payments. Pericles asserted that the poorest citizen should thus be enabled to serve the democracy. His rivals accused him of political jobbery; for they believed he mas buying votes with stolen money. In 451 B.C., on the proposal of Pericles, Athenian citizenship was resrricted to those who were of Athenian parentage on both sides. Thus Athens became racially exclusive, at the expense mainly of the confederates. By closing the citizenship during the very process of empire building the Athenians showed themselves less wise than the Romans were later to prove.

While the truce held with Sparta, Athens made peace with Persia, probably in 448 B.C. The treaty, known as the peace of Callias, marked the successful conclusion of the Greek war against Persia. Under its terms the freedom of the Greeks in Asia was recognized, and the contracting parties—the Athenians and their allies and "the Great King"—agreed not to intervene in one another's territory and waters. Athens tried to represent this treaty as a Panhellenic triumph and invited all states which had been in the ambit of the Persian invasion to attend a conference at Athens, to restore the temples burned by Persia and to plan a general peace throughout the Greek world. Yet the offer of peace talks came strangely from the aggressors in the First Peloponnesian War, who were busily converting the Confederacy of Delos into an empire for themselves. When the Spartans and their allies made no response, the other invitations were canceled.

Pericles had at least extricated his country from war on two fronts. After 448 B.C. the Athenians could concentrate their efforts against Sparta. On the surface they were strong. They had complete control of Aegean resources, as well as great wealth and an unrivaled fleet; they had Megara, Boeotia and Locris in subjection. Phocis as an ally and Achaea. Naupactus and Troezen on their side; and they had alliances with Leontini in Sicily and with Rhegium in southern Italy. Only goodwill was lacking. Puppet governments euphemistically called "democracies," Xthenian garrison troops and Athenian monopoly of policy deceived no one who had experienced them. Early in 446. when the truce was about to expire. refugees from Boeotia, Locris and Euboea defeated Athenian troops in Boeotia and forced Athens to evacuate that country. Then the states in Euboea revolted. As soon as Pericles crossed to Euboea with an army. Megara revolted. The Peloponnesian league's army was already on the road to Attica. Pericles brought the Xthenian army back to Attica. while the Boeotians and the Peloponnesians combined their forces near Eleusis. Then, at the very moment when the superior strength of Sparta was about to be applied, the Spartan king in the field, Pleistoanax. withdrew his army and went home. He was fined on a charge of having taken bribes from Pericles. Meanwhile Pericles reduced the whole of Euboea in a rapid campaign. In the winter of 446–445 a treaty of peace "for 30 years" was concluded between Athens on the one side and the Spartans and their allies on the other.

The terms of the Thirty Years' treaty recognized the Xthenian empire and the Peloponnesian league. Sparta left Aegina and Naupactus under Athenian control. and Athens abandoned Achaea, Troezen and Megara to the Peloponnesian league. The beneficiaries of the treaty were the two coalitions, and the prospects of its duration rested on the balance of power between them. Therefore Argos, as a strong military power, was to be kept neutral; but any other state could join either group at any time and enjoy the terms of the Thirty Years' treaty. It was a statesmanlike attempt to secure a lasting peace. There were provisions for the freedom of the seas and for arbitration in case of disputes. Peace and prosperity reigned for 15 years thereafter throughout the eastern Mediterranean. Yet these were years of preparation for war; for the peace between Sparta and Athens rested not on goodwill but on a balance of power which was becoming more and more precarious. The Spartans indeed, having no capital for new enterprises, had little hope of expansion and were content to husband their military strength within the bastion of the Peloponnese and to maintain the freedom of the western seas across which corn and goods were imported. Athens, on the other hand. had the capital and the spirit to expand; and Sparta felt that Athens was only waiting for a suitable opportunity to return to the attack.

Periclean Democracy and Imperialism, 445–431.—In the years of peace Athens decided future policy. The choice was between Cimon's successor, Thucydides son of Melesias, and Pericles. Thucydides stood for a qualified democracy, for co-operation with Sparta and for alliances with the Aegean Greeks; Pericles stood for a full democracy, for enmity with Sparta and for imperialism in the Aegean. Thucydides was ostracized in 443 B.C. Those who shared his views lay dormant until the revolution of 411.

The full democracy had such faith in Pericles that it acknowledged him to be the first citizen in the state, elected him annually as senior general and made him responsible for the great reserve fund on the acropolis. He owed his position to financial honesty, intellectual vision and force of character, not to any cabal or party. Indeed the policies of the democracy knew 'no party organization. He made the city of Athens beautiful by building the Parthenon and the Propylaea on the acropolis from public funds. He brought prosperity to the citizens by increasing sea-borne trade. by annexing land for cleruchs and by granting pay for service at home and in the empire. He claimed that the democracy was a model to all men. It gave to its citizens equality and freedom in speech, in law, in politics and in education; it provided full employment. good economic conditions and also humane treatment for resident aliens and slaves; and it combined these blessings with a constitution under which the individual citizen was directly involved in forming policy and in managing all aspects of administration. The Periclean democracy engendered an ardent loyalty in which idealistic principles and material interests frequently coincided.

Pericles consolidated the empire. Civilian hostages were deported from unruly subject states to Athens. Cleruchies were planted, for instance, at Chalcis and at Histiaea in Euboea and colonies of Athenians and their subjects at Amphipolis in Thrace and on the coasts of the Black sea. Between 445 and 431 there was only one incident which threatened the stability of the empire. Ordered to accept Athenian arbitration in a dispute with Miletus. the Samians stood on their rights as voluntary members of the "alliance"; for they still had their own fleet. Pericles then occupied Samos and administered the usual punishment: a '.democracy" supervised by a garrison and commissioners, the surrender of civilian hostages and a fine for disobedience The Samians revolted, hoping for help from Persia and Sparta; but their hopes proved vain. and they capitulated after a lengthy siege in 439. Athens made them surrender their fleet. demolish their fortifications, give hostages and pay the cost of the war (1,276 talents) in installments over a number of years. The only state which revolted in sympathy. Byzantium, capitulated after the fall of Samos. The empire was securely held. But, as Pericles said later, it was held under a tyrannical rule which Athens could not remit without danger (Thucydides ii, 63).

Sparta and Persia were prepared to tolerate the Athenian empire so long as their onn interests were not affected. But domination of the Aegean and the Black seas had not satisfied Athenian ambitions or apprehensions. Athens gained a strategic base in the west by helping Xcarnania to defeat Ambracia. a colony of Corinth, and then contracting a close alliance with Acarnania and Amphilochia (c. 437 B.C.). The appearance of an Athenian fleet in the

Ionian sea alarmed the Peloponnesians and especially Corinth. But Corinth mas not deterred on that account from quarreling with Corcyra, originally a Corinthian colony and now a considerable naval power. Sparta tried in vain to persuade Corinth and Corcyra to accept arbitration. They went to war in 435. The Corcyraean fleet of 120 triremes was victorious; but Corinth and some friendly states. many of which were members of the Peloponnesian league, mustered a fleet of 150 triremes in 433. At this stage Corcyra asked Athens for an alliance. The issue for the Athenians was clear: if they wished to preserve the general peace under the Thirty Years' treaty, they would refuse to help Corcyra; if they wanted to fish in troubled waters, they would grant an alliance at the risk of endangering the general peace. The assembly hesitated. On the first day of debate the majority was against an alliance. but on the second day it voted an alliance on the advice of Pericles. Corcyra seemed a prize worth having: the accession of its fleet would alter the balance of naval power decisively, and the Corcyraeans controlled the coasting route from the west to the Peloponnese. The Athenians combined audacity with cleverness. They granted Corcyra a defensive alliance, which was not a breach of the Thirty Years' treaty, and sent *only* ten ships. hoping perhaps that the prestige of Athens would halt Corinth and that the smallness of the force would not frighten the Peloponnesians as a whole. When the ten ships were already on the way to Corcyra, they sent 20 more; they may have learned that Corinth was about to attack and hoped that the 30 Xthenian ships would by their superior seamanship give the Corcyraean fleet an advantage. But the Athenian commanders were given orders to engage only if the Corinthians were about to force a landing on Corcyra.

In Sept. 433 B.C. the Corinthians and their allies defeated the Corcyraeans in the sputhern channel. but broke off the action when the ten Xthenian ships engaged to prevent a landing. The Corinthian fleet returned to the attack in the evening; but the fortuitous appearance of the other 20 Athenian ships from the south at this crucial moment caused the Corinthian fleet to withdraw and sail homeward. Athens now had bases on Corcyra, in Acarnania and at Naupactus and the assistance of the battered Corcyraean navy and. in the winter of 433–432, began to put pressure on Corinth and on Megara as an ally of Corinth. Potidaea, an old Corinthian colony in Chalcidice, was ordered to break off relations with Corinth and to dismantle its sea walls. Economic sanctions were imposed against Megara, whose commerce was excluded from all ports of the Athenian empire. Potidaea revolted. and the Corinthians and their Peloponnesian friends placed "volunteers" in the city before it was invested by Athens. Sparta, reluctant to engage in war against a naval power or to terminate the Thirty Years' treaty without legitimate grounds, was playing a waiting game; but Corinth. Megara and other states made a *démarche* to Sparta, claiming that Athens' aggression had violated the treaty and invoking the defensive alliance on which the Peloponnesian league was based. The Spartan assembly then held a debate. The decision mas taken by a large majority that Athens had violated the treaty. The Spartans reported this decision to the congress of allies which met and concurred. Thus the two organs of the Peloponnesian league decided to go to war unless Athens was prepared to retract. Abortive negotiations ensued. Then Sparta delivered an ultimatum: peace would continue only if Athens recognized the independence of the Greek states. Pericles spoke in the decisive debate at Athens. He advocated war and the assembly supported him. Their decision was that Athens would accept an offer of arbitration but not any ultimatum from Sparta. Negotiations ceased in the winter of 432, and Thebes. a member of the Peloponnesian league, committed the first act of war by delivering a treacherous attack on Plataea, an ally of Athens: in the following spring. The historian Thucydides saw the fundamental cause of this war in the growing power of Athens together with the growing apprehension of Sparta. He appreciated at the outset that it would be a great war, because it was likely to end in the destruction of one party or the other.

The Great Peloponnesian War, 431–404.—The course of the war is described elsewhere (*see* PELOPONNESIAN WAR, THE). In the Archidamian War (431–421) each side began with superior strength on its own element, and ten years of fighting increased the margin of superiority. Vet neither side could apply its superiority with decisive effect. Sparta could not force Athens to battle, or breach the impregnable walls; and the Peloponnesians, unable to campaign far afield or for long periods because they lived on their own agricultural produce, failed to exploit the advantage which the Spartan commander Brasidas gained in Chalcidice by raising Athens' subjects in revolt. The Xthenians held the seas with their navy. but their warships could not impose a complete blockade on Peloponnesian merchantmen; and their sea-borne raids, effective though they were, did not serve as a prelude to an invasion of the Peloponnese. All this, according to Thucydides. was foreseen by Pericles, who expected a long war of attrition and thought that Athens would prove more buoyant than Sparta. On the whole he was correct. The Athenians lost more than one-third of their manpower in the plague and in action, they had to demand three times as much tribute from their subjects and they spent more of the financial reserve than they had expected; but in 421, when the peace of Nicias (so named after the general who guided Athenian policy) was made, they had complete control of almost the whole empire, a great navy and the means of recouping their finances rapidly. Sparta suffered less loss of life than Athens, but was shaken internally by the revolts of the helots; and the allies, especially Megara and Corinth, were impoverished and embittered. Sparta's control of the Peloponnesian league was very shaky in 421, and Argos seemed after a generation of neutrality to be a strong rival in military and political matters. The peace terms of 421 included the restoration of all places (except Plataea, Nisaea and some Corinthian possessions in the northwest) and of all prisoners captured in the mar and an undertaking to submit to arbitration all disputes between the Athenians and their allies on the one hand and the Spartans and their allies on the other.

Pericles had originally gone to war in order to break the Peloponnesian league, the basis of Sparta's power in international affairs. The peace of Nicias provided a great opportunity for doing so by diplomacy, operating from strength. But Pericles had died in 429 and Athens was disunited. A worthy successor might have united Athens. created a block round Athens and Argos and used the Athenian army to lead a coalition against an isolated Sparta. Alcibiades tried but failed. The failure was the fault not so much of one man as of the Xthenians collectively. They did not make a decisive choice between Alcibiades and Nicias. and their indecision lost them the chance of winning the peace. When war broke out again, the same indecision brought the Sicilian expedition to disaster (415–413) and crippled Athens' recovery later. On the other hand the Spartans kept their unity and their power of decision. The victory over Argos and Athens at blantinea in 418, the re-formation of the Peloponnesian league and the winning of the war at sea by Persian money and Peloponnesian manpower were due to Sparta's tenacity and leadership. The hard necessities of war broke the political front at Athens, ruined the state's finances and brought the navy and the empire to an end in 404 B.C. They also strained the strength and warped the judgment of Sparta and undermined the loyalty of the Peloponnesian allies. Moreover the naval position in which the Spartans found themsell-es at the end of the war was one which they could not afford to maintain. The Greek states from the Aegean area to Sicily were torn and weakened by war and dissension. Persia and Carthage were the gainers. Without striking a blow they extended their field of political influence. while the Greeks were wearing one another down.

Greek Civilization, 458–404.—As fear of Persia receded, the city-state became the centre of existence. Whereas Aeschylus (525–456) had studied the relations between God and man in human history, Sophocles (*c.* 496–406) was concerned with relations between man and the city-state. in which God's purpose for man was revealed: the ideal qualities of the characters Oedipus and Antigone in his tragedies were seen in relation to their obligations to the state. Devotion to the state reached its highest level at Athens in the period between the wars. when prosperity and confidence reigned. The Parthenon and Propylaea were built by a people who felt an undivided affection for the city and for the goddess of the city, the maiden Athena. The principles of the democracy were expressed in an ideal form by Pericles. whose vision captured the imagination of his contemporaries and inspired the leading writers of the period—Sophocles, Thucydides and Aristophanes—even on occasions when they criticized the real Athens of the Peloponnesian War. It was an age of great intellectual and emotional power. Men carried principles to their logical conclusion in architecture. sculpture, drama and politics. At the same time they respected "the unwritten laws" of moral and religious restraint which gave a true balance and proportion to their art and to society. Athena and the gods of the family were not abstractions but demanded of their worshippers the highest standards in loyalty and nobility. The Periclean period at Athens was the acme of the Greek city-state. The light of the Greek genius was focused with brilliant intensity on the life of the polis—but only for a short time; for the lens was soon starred by disaster.

The Peloponnesian War broke the strands of traditional religion in Athens. The centres of family worship were lost when the Peloponnesians ravaged the countryside and refugees poured into the city. The horrors of the plague, the disaster at Syracuse and the final shock of utter defeat broke men's faith in the favour of the gods. The state was split by revolution. Citizens killed one another in civil war. and party loyalties took precedence over patriotism. Alcibiades was typical of many young Athenians whose intellectual ability was devoid of any religious scruple or moral principle, and their conflict with the older generation who remembered the days of Pericles is vividly portrayed in the comedies of Aristophanes.

The effects of the war on Athenian society were heightened by the teaching of the sophists, who came from other parts of the Greek world and spread new ideas in the crowded city. Their lectures were stimulating and exciting. They covered the whole range of human thought with remarkable versatility and originality. Although individual sophists laid new foundations for philosophy and conduct. the general trend of their teaching mas rationalist in method and agnostic in conclusion. Traditional religion in their view was the child of convention. and natural law indicated that might is right and that the individual pursues his own interest. Speculation in physics seemed to support this view. for Democritus reduced the operations of the universe to an interaction of atoms which were governed by some impersonal "necessity" or natural law. if not by random "chance." hfedicine. too, emancipated itself from religion. "This disease." wrote Hippocrates of epilepsy (the so-called "sacred disease"). "is no more sacred than other diseases. . . . Its origin is in heredity . . . and its cause lies in the brain, as is the case with all the most serious diseases."

The divine right of the city-state mas severely shaken not only in Xthens but throughout the Greek world, of which Xthens was the cultural capital. The centre of interest was shifting toward the individual. Euripides portrayed the transition in his plays. They show the tragic consequences for the individual of war, tradition and conventional religion. His Hecuba, *Medea*, *Orestes* and *Hippolytus* are psychdlogical studies of the individual woman or man who is not confined within the limits of the city-state. His dramas, therefore, have a modern quality. Aristophanes represented both sides of the conflict. He made fun of the diehard traditionalists and challenged Athens' right to empire and men's justification of war; but he also pilloried the sophists and those who accepted the worst side of their teaching. He deno'unced the self-seeking individualists and the psychologists who rated human desires above moral restraint. In the end he gave his allegiance to his ideal picture of Athens and to the service of the city as it was despite its faults. Socrates was the only Athenian among the sophists. He questioned the assumptions of his pupils in all matters of religion. ethics and belief and professed to know only that he knew nothing. This stage of his teaching created many agnostics, who lost their traditional bearings and found refuge in individualism. But Socrates carried others forward to a new belief in the ultimate verities of goodness, truth and understanding; and his own life of humility in the service of philosophy inspired them to follow his example. R'hen Athens had fallen, Socrates was put on trial "for not worshipping the gods whom the state worships, for introducing religious innovations and for corrupting the young men." He was found guilty of the charge. When he was sentenced to death. he refused to ask for mitigation of sentence. He died because city-state tradition was strong. but his martyrdom proclaimed the individual's right to free thought and belief. Thus a rift was opening between political life and personal philosophy, which Plato later described so simply: "A man who really fights for nhat is right must lead a private. not a public. life, if he hopes to survive. even for a short time" (Apology, 32a).

The City States, 404–354: Independence or Combination?

The Spartans and their allies had fought for the independence of the Greek states R'hen they won, it was expected that several hundred independent states would emerge from the dismembered Athenian empire. But independence mas not necessarily the panacea for international troubles. Its effect was seen in Sicily where victory over Athens in 413 B.C. had left the Greek states free to engage in party strife and to fight against one another and the resulting chaos was exploited by the Carthaginians, who had added most of the Greek states to their empire by 404. The states of Greece and the Aegean area were already torn by civil strife and harboured strong animosities toward one another; and the Persians were more dangerous neighbours than they had been since the battle of the Eurymedon. It was clear to a few political thinkers, such as Isocrates, that Greek civilization could be preserved not by the untrammeled independence but by the co-operation and combination of the Greek states. On the other hand the politicians and the electorates were concerned primarily with the narrower issue of their own survival and expansion, often at the expense of neighbouring Greek states, and they were reluctant to enter any combination which limited their own freedom of action. Many wars were waged in the 4th century B.C. to decide whether independence (*autonomia*) or co-operation (*symmachia*) in various forms should be the guiding principle of Greek international affairs.

Sparta and the Movements for Independence, 404–371.—During the last stage of the Peloponnesian War the Spartans were liberating the small states in the Aegean. They naturally supported pro-Spartan parties. which were oligarchical rather than democratic in outlook; and Spartan troops were left to assist their parties in maintaining power. The Spartans moreover were winning the naval war on Persian subsidies and had agreed in return to surrender the Greek states of Asia Minor to Persia; and they saw that they would be able to break this agreement safely only if the small states of the Aegean were kept firmly in the Spartan bloc. Nor was their position easy on the Greek mainland. The allies had been critical of Spartan leadership and resentful of Spartan demands, and they had their own ideas about the fate of Athens. Corinth, Thebes and others wanted to annihilate Athens as the aggressor in two great wars. but Sparta managed to obtain a majority vote in the congress of allies for the policy of preserving Xthens as a satellite in the Spartan bloc. An oligarchic government (the government of "the 30," commonly known as the Thirty Tyrants) was therefore installed in the presence of Spartan forces. Thus the end of the war in 404 saw Sparta fully launched on an attempt to hold the "liberated" states and Xthens under a system of combination which showed many familiar features of imperialism. The wartime allies of Sparta. who were members of the Peloponnesian league, naturally felt alarmed for their own liberties when they saw the policy of Sparta in the Aegean.

The first reaction came at Xthens. The oligarchs were particularly ruthless in killing and exiling their enemies (for instance, the men who had overthrown the oligarchy of "the 400" set up by the revolution of 411), and they soon had to call in a Spartan garrison. The leaders of the exiles obtained help from disgruntled members of the Peloponnesian league (especially Thebes. Megara and Elis), established themselves in a frontier fortress on Mt. Parnes and went on to capture the Peiraeus. where the democratic element was strongest. They defeated'the oligarchic forces and the Spartan garrison troops in a pitched battle at Munychia in

May 403 and made preparations to attack the walls of Athens. Late in the summer Sparta intervened. There mere by then three factions in Attica: the extreme oligarchs held Eleusis, the moderate party was defending Athens and the extreme democrats were attacking Athens from the Peiraeus. The arrival of a Peloponnesian army ended the fighting and Sparta made a new settlement: Attica was split into two states, one centred on Eleusis and the other on Athens. The Spartans counted on the animosity between oligarchs and democrats to keep the states separate, but the democratic tradition of Athens soon asserted itself. In 401 Xthens swallowed Eleusis, and Attica was unified under a democratic regime, which had the good sense to carry out all its formal obligations to Sparta.

Cyrus the Younger and Agesilaus.—Meanwhile there was a similar reaction to Spartan policy in the Aegean. Sparta broadened the basis of the oligarchical governments in the Aegean states, but insisted that they should follow Sparta in foreign policy and pay tribute to maintain a Spartan navy. The issue with Persia was still undecided, because Cyrus, the Persian viceroy in Asia Minor, was friendly with Sparta and did not take over the Greek states. In the spring of 401 B.C. Cyrus mustered a large army of local peoples and hired 14,000 Greek mercenaries: told Sparta of his plan to seize the Persian throne from his brother. Artaxerxes II Mnemon, and asked for Spartan aid. The Spartans in the past had always refused to commit themselves to war against Persia in Asia Minor, but now decided to give naval support to Cyrus and thereby accepted the risk of war with Persia. It was a bold decision, because Sparta's control of the Aegean states and of the Greek mainland was far from strong. Cyrus was defeated and killed at Cunaxa in Mesopotamia. and Sparta made an alliance with Egypt (which was in revolt) and sent out an expeditionary force in 400 B.C. to defend the liberty of the Greek states in Asia Minor. The adventures of the Greek mercenaries whom Cyrus had engaged gave Sparta some encouragement; for they proved themselves far superior to Persian infantry in battle and in skirmishing and they fought their way from Mesopotamia to the Black sea (the retreat is the subject of Xenophon's *Anabasis*). Sparta held the initiative for five years. The Spartan infantry raided far and wide inland and collected much booty. but it failed to capture strongholds and was harassed by the Persian cavalry. The navy was at first under separate command and operated independently. Then, in 396, the Spartan king Agesilaus went out with reinforcements and was given command of the army and navy. Agesilaus; however. raided inland and did not emulate the strategy of Cimon, who had shown that it was essential to hold the southern corner of Asia Minor and to defeat or contain the Phoenician fleet.

The Corinthian War and the King's Pence.—The Greek states had little sympathy for Sparta in the war against Persia. Even those in Asia Minor which had supported the naval operations of Athens in the 5th century were alienated by Sparta's method of conscripting and requisitioning and by the use of mercenary soldiers, freed helots and Peloponnesian troops whose chief interest seemed to be booty. The islanders disliked the oligarchical governments which Sparta supported and lacked confidence in the Spartan admirals. The mainland states were more afraid of Sparta than of I'ersia. For the Spartans had also abused their position in the Peloponnesian league by launching attacks on Elis in 400 and 399 and by treating the country as Athens had treated Thasos in 462. When Agesilaus went out in 396, Corinth. Thebes and Athens sent no contingents. and it was known that Athenians were entering Persian service in the fleet which an Athenian naval officer. Conon, was commanding. In the summer of 395 the Boeotian league broke away from the Peloponnesian league, attacked Phocis in contravention of Sparta's orders and made an alliance with Athens. At this time a Persian agent toured the dissentient states of the mainland and gave subsidies to anti-Spartan leaders at Thebes, Corinth and Argos. The first attack by Sparta on Boeotia failed. Corinth. Argos and many of the states of central Greece joined the insurgents in 394, and Sparta recalled Agesilaus and his expeditionary force from Asia, because major operations on two fronts were impossible. The Persian navy then launched its offensive, defeated the Spartan navy decisively at Cnidus in Aug. 394 and sailed into the Aegean sea, expelling pro-Spartan oligarchs and tyrants from the islands.

This war of independence, called the Corinthian War, was inconclusive on land. The insurgent states failed to evolve a centralized system of command. and the Spartan army defeated all its rivals. Agesilaus fought his way from central Greece through Boeotia and brought his army into the Peloponnese. A stalemate ensued with heavy fighting at the isthmus. where Corinth and Argos held a strong defensive position. At first these two states formed a union under which each had reciprocal rights in the other's territory; later Argos annexed Corinth. The decision in the war lay with the Persians. At first, in 393, they let Conon help Athens to rebuild the long walls (which had been demolished under the peace terms of 404) and to form a small fleet, but after 390 their attitude changed as the Athenians tried to regain some of their Aegean empire and to assist Cyprus. then in revolt from Persia. Sparta held on to the Hellespont and even attacked the Persians and the small Athenian fleet with some success. Persia's support was then switched to Sparta, and Athens was soon blockaded by a Spartan fleet operating from Aegina (387). In 386 all Greek states accepted the terms of a peace which was guaranteed by Sparta and Persia and called either the peace of Antalcidas (from the name of the Spartan negotiator) or the Icing's peace. The Greek states in Asia Minor. Clazomenae and Cyprus were to be subject to Persia, and all other Greek states were to enjoy independence, except Lemnos, Imbros and Scyros which were to be Athenian possessions. Persia undertook to attack any Greek state which refused to accept the peace "by land and sea; with ships and money."

Confident in the support of Persia, the Spartans interpreted "independence" in their own interest. They broke up every example of combination to which they could apply force. The Boeotian league was dissolved. so that each state there should be "independent." and Corinth was separated from Argos. Mantinea was forcibly split up into five "independent" villages in 384 B.C. The strong Chalcidian league was dissolved by Sparta in 379 after three years of fighting. The Spartans also interpreted independence in the sphere of internal government in each state as the rule of an oligarchic regime. They captured Thebes by treachery and replaced the democrats with pro-Spartan oligarchs; and they forced Phlius to capitulate after a long siege and gave the oligarchs a free hand. Sparta pursued a policy of "divide and rule" under the empty mask of independence. The members of the Peloponnesian league were controlled by intimidation; Sparta's own subjects were held down by oligarchic governments and by garrisons where they were needed; and Persia, Macedonia and Dionysius I, tyrant of Syracuse. were Sparta's allies. Those who suffered under this rule learned the truth of the Spartan saying: "We cheat boys with dice and men with oaths." Rut the basis of Spartan power was dangerously small. The Spartiates were a very small minority in the Spartan state itself, and the oligarchic parties in other states were a minority in each state. Sparta relied ultimately on the force of arms wielded by several thousand men in order to hold down most of the Greek states.

The War *of Independence, 379–371: Leuctra.*—The fight for independence began in 379 B.C. Seven exiles returned to Thebes at night and led a successful revolt. Sparta promptly isolated the area of trouble, but a Spartan officer made a foolish and unsuccessful attack on Athens, which caused such indignation that Athens made an alliance with Thebes. Two years of fighting ensued, and then the allies captured the passes over Mt. Cithaeron and kept the Spartan army out of Boeotia. Sparta then took the offensive by sea against Athens. which was building up a naval coalition. The Spartans suffered a series of defeats, but fought on at sea until a split developed between Athens and Thebes. At this stage Persia appeared again on the diplomatic scene. In 371 the representatives of Persia. Sparta and Athens, together with those of their allies, agreed to make peace on the principle of "independence." under which garrisons were to be withdrawn and general disarmament was to be carried out. The Spartans took the oath on behalf of their own city and its "allies,!' but the delegates of Athens and those of the allies of Athens, including Thebes, took the oath individually. The Theban delegates then asked to be recognized as acting for the Boeotian league, but Sparta refused to permit this. Thebes uithdrew from the peace. The Spartan army entered Boeotia before the Thebans could muster their allies in Boeotia and forced a decisive battle at Leuctra. The Thebans uere outnumbered. but they had a general of genius in Epaminondas, who appreciated the Importance of striking at the enemy's strongest point. He therefore massed his men 50 deep against the Spartan right wing, where the Spartan king Cleombrotus and the Spartiate troops were stationed, and charged at the double. The massed Thebans killed 400 Spartiates and routed all the rest of the enemy before the Theban centre and right wing came into action. The military reputation on which Sparta's supremacy had been founded was broken irretrievably, and the Spartan empire was destined to collapse rapidly and completely.

The Second Athenian Confederacy and the Boeotian League — During the war of independence from 379 to 371, Athens and Thebes developed new and important ideas in the field of combined action by a number of states. Athens published the charter of a confederacy in March 377. In this, Athens undertook to respect the independence of any ally which entered the confederacy under a defensive alliance: specifically, Athens promised not to exact tribute, not to introduce a garrison, not to meddle with internal government and not to revive any territorial claims against an ally. The constitution of the new confederacy resembled that of the Delian one. Each allied state cast one vote at the congress of allies, and a majority decision was binding on them all; the Athenian state, however. stood outside the congress as a separate entity and took its own decision on any matter of mutual interest. If both bodies reached the same decision, the confederacy as a whole acted upon it. In such an event Athens was entrusted with full executive command and disciplinary powers in the field; but an ally could seek redress through the congress of allies sitting as a deliberative or judicial body. The allies also controlled their own treasury recruited by contributions from members on an assessment by the congress. and Athens made grants in money and ships from the state treasury. Athens and the allies formed a joint court to pass judgment on any person who broke the charter of the confederacy. Thus machinery was created uhereby a group of states could combine in a common policy of defense and each state had precise safeguards for its own independence. In 376 Athens defeated Sparta in a naval battle off Naxos, and in the next few years the confederacy attracted about jo states which revolted from Spartan rule in the Aegean and the Ionian seas. The Athenians set them a fine example by taxing their own resources heavily and providing the bulk of the fleet.

Thebes had alnays been the leading spirit of the Boeotian league. The numerous states of Boeotia had been grouped in the past into 11 wards, each of which had returned 60 councilors to form a strong central government, sitting at Thebes, and had contributed its quota of money, troops and generals (boeotarchs). Thus the federal state of Boeotia had adopted a system of proportional representation, such as is common in modern Europe. But the Thebans of 379 B.C. regarded indirect government as oligarchical. When they liberated the states of Boeotia from Spartan rule, they created a democratic assembly of Boeotians. meeting at Thebes, in which policy was determined by direct vote. The executive officials-councilors. magistrates. army commanders, etc — were elected by the wards, reduced in number from 11 to 7. Thebes and its dependencies. nhich together formed three of the seven wards. played a predominant part in the league and supplied the ablest boeotarchs and the best hoplites in the war of liberation. The Boeotian league was particularly well designed for small states in an agricultural area of limited extent and its success in overthrowing Sparta led many other states to emulate its constitution.

The second Athenian confederacy and the Boeotian league, as associations of free states, contrasted themselves with the imperial systems of Sparta and Syracuse under Dionysius I. The pressure of Carthage on Sicily had created a situation in which Dionysius had succeeded in establishing himself as tyrant or dictator at Syracuse in 405, and his subsequent achievements made a great impression on the Greek world. He enlarged Syracuse far beyond the normal size of a city-state by destroying other states and deporting their population into his territory, and he amassed great armaments by ruthless confiscation of capital resources and by hiring mercenary troops in large numbers. His cosmopolitan forces conquered those Greek states of Sicily which lay outside the Carthaginian zone and also many Greek states in southern Italy, and he planted colonies on the Adriatic coasts and islands. Syracuse became the capital of an empire which was bound to the mill of Dionysius and enjoyed commercial supremacy in the Greek west. In 371, when the Spartans were defeated at Leuctra. the dictator mas at the height of his power. Men admired his success but did not reckon the cost in terms of political morale and human degradation. The example of Dionysius may well have inspired Jason of Pherae in Thessaly. Jason had made himself tyrant of his own city-state and, by the end of 373, had forced the other Thessalian states to obey the commands which he issued as "ruler of Thessaly" or *tagos*—a title that had been in abeyance for many generations. In 371 Jason had the finest cavalry force and the largest mercenary army in Greece and was drawing substantial revenues from the peoples of Thessaly. These examples of the voluntary and the forced association of states into a powerful group aroused interest and alarm. They were studied by Isocrates, who preferred the voluntary association (as he argued in his *Panegyricus)* but believed that some sort of forced association might be better than internecine wars between individual states.

The Attrition of the Leading Powers, 371–355.—Although Athens and Thebes proclaimed similar principles, they were separated by a dislike born of many frontier disputes and two great wars. More recently, Athens had seized Oropus, a frontier post, and Thebes had destroyed Plataea and subjugated Thespiae. Therefore when the Thebans asked their Athenian ally for help after the battle of Leuctra. Athens made no answer but invited all Greek states to a conference. Athens' proposal was that the Greek states should ally themselves individually with the second Athenian confederacy as a whole and maintain the terms of the peace of 371 with the backing of Persia. This proposal was accepted by almost all the Greek states. But the diplomatic triumph of Athens did not arrest the revolt of the Peloponnesian states from the rule of Sparta. Democrats seized power in many states. Those in Mantinea and Tegea founded an Arcadian league in the spring of 370 and invited the Boeotian league to assist it in the autumn. Meanwhile Thebes had been watching Jason, who had come south to help Thebes immediately after the battle of Leuctra but had taken the opportunity to seize Thermopylae on his return and to strengthen his net of alliances. Fortunately for Thebes, Jason was assassinated in the summer of 370. The Boeotian league then formed a strong coalition of central Greek states which included Euboea and Acarnania, hitherto members of the Athenian confederacy. The forces of this coalition, led by two boeotarchs, Epaminondas and Pelopidas, and those of their allies. the Arcadian league. Elis and Argos, ravaged the whole of Laconia and liquidated the Peloponnesian league forever. In 368 Epaminondas returned to strengthen his allies. In the course of his two Peloponnesian campaigns. Messene was fortified as the capital of the liberated Messenians and Megalopolis was built as the federal capital of Arcadia. These successes alarmed Athens, who took the radical step of making an alliance with Sparta and later with Sparta's ally Dionysius of Syracuse and tried in vain to halt the progress of Boeotia by defending the isthmus. where Corinth and other states which were afraid of Argos sided with Sparta and Athens.

The Boeotian Ascendancy, to 362.—Boeotia was the leading land power for a decade. This state's democratic federalism was widely imitated. Leagues with sovereign assemblies and federal magistrates on a cantonal basis were formed in Thessaly and Aetolia, as uell as in Arcadia; and other federal states—Phocis, Acarnania and Achaea—nere brought into alliance with Boeotia. Epaminondas advocated a liberal attitude toward the federal states and accepted the oligarchic governments of the member states of the Achaean league in 366 B.C., but the Boeotian assembly replaced them with democratic governments and installed garrisons to keep them in office. Pelopidas extended Boeotia's influence in the north, intervening successfully against Athenian interests in Thessaly and Macedonia. When Athens and Sparta sent envoys to Persia for help, Pelopidas won the favour of Artaxerxes II and tried to impose a "King's peace" on the Greek states in 366. The terms were "independence" for all states, and Athens was ordered to withdraw her fleet from the Aegean sea.

The confidence of the Athenians had been shaken by Boeotia's victories, and they knew that their confederates disliked the alliance with Sparta and Dionysius. There was now the further danger that Boeotia and Persia might launch a naval offensive. The Athenians therefore began in 366 to convert the confederacy into an empire. They captured Samos off Asia Minor, Sestos and Crithote in the Chersonese, Pydna and Methone in Macedonia and Potidaea, Torone and other cities in Chalcidice. They did not admit these cities to the confederacy but occupied most of them with cleruchies and used them as naval bases. They also made a treacherous and unsuccessful attack on Corinth and allied themselves with Alexander, tyrant of Pherae, in Thessaly and with Arcadia in the Peloponnese. The Boeotians pressed their advantage, defeated Alexander (they lost Pelopidas in the process) and then launched a naval offensive, probably in 363, under the command of Epaminondas. His fleet of 100 triremes sailed unchallenged to the Bosporus, where Byzantium and other members of the Athenian confederacy joined him in attacking Athenian corn ships sailing for the Peiraeus. But continuous warfare from 378 had exhausted the finances of Boeotia, and Epaminondas returned home without exploiting his success. Affairs in the Peloponnese demanded his attention. The Arcadian league had broken away from the Boeotian coalition, attacked Elis, seized Olympia and appropriated the funds of the temple of Zeus. This act of sacrilege split the Arcadian league, and a Boeotian force became involved in a fracas between Tegea and Mantinea. Epaminondas invaded the Peloponnese in 362 with forces drawn from Boeotia, Thessaly, Euboea. Locris and Aeniania. He was joined at Tegea by troops from Argos. Sicyon, Messenia and part of Arcadia. The decisive battle took place near Mantinea, where the armies of Mantinea, Sparta, Athens. Elis and Achaea held a defensive position. Epaminondas outmaneuvered his opponents, overwhelmed the Mantineans and Spartans and was mortally wounded at a critical moment. The Boeotians and their allies halted. Soon after peace was concluded on the *status quo*.

The League of States. — The Greek states were exhausted by war after war and by the vicissitudes of party strife. In the winter of 362–361 all mainland states except Sparta formed a league. They promised to maintain a general peace among themselves, to settle disputes by negotiation and to protect members of the league against aggression by "a general alliance," that is, by collective security. Their aims for all member states were strength, prosperity and peace. They probably set up a federal congress, a court of justice and a central treasury; and they passed a resolution as "the Greeks" in which they refused to join a group of satraps who were in revolt from Persia. The attempt to form a league of Greek states was short-lived, because the leading states continued to form military coalitions among the members. Athens made alliances with Arcadia, Achaea, Elis, Phlius and the Thessalian league, and Boeotia sent troops into Arcadia in 361. The Athenians moreover pursued their imperialistic policy by punishing those "confederates" who had joined Epaminondas in 363 and by undertaking operations of war in Euboea, Thessaly, Macedonia, Corcyra. Thrace and the Hellespont.

The Social War and the Sacred War to 354. — Athens was strained to the utmost in 357, when Mausolus, satrap of Caria, supported the revolt of Chios, Rhodes. Cos and Byzantium from the confederacy. In the Social War (*i.e.*, "War of the Allies"), as it was called. the Athenian fleet was defeated in 356, and threats by Persia caused Athens to make a peace in 355, under which the independence of the rebels was recognized. Meanwhile a so-called Sacred War had broken out in central Greece: provoked by menaces from Boeotia against Phocis, the Phocians under the leadership of Philomelus confiscated the treasure of the temple of Apollo at Delphi, hired thousands of mercenary soldiers and defeated the citizen levies of Boeotia, Locris and Thessaly early in 354. The collapse of the great powers on the mainland was almost complete. Xenophon wrote with justice that after the battle of Mantinea "even greater confusion and indecision" descended upon the Greek states. In the west. too, there was anarchy and chaos The empire of Dionysius I collapsed when exiles returned to attack his son and successor Dionysius II and drove him off to Italy. The leader of the liberators. Dion. was murdered in 354 B.C., and civil war raged in Syracuse.

Political and Economic Troubles. — Although the first half of the 4th century B.C. was racked by war, it was a period of widespread prosperity. Trade flowed in increasing volume from the outer parts of the Greek world — Spain and Massilia, the Adriatic coasts. Thrace and the Crimea, the eastern Mediterranean and Cyrenaica. At the same time Carthage and Persia accumulated large capital reserves. Athens was the leader of Greek commerce, but was rivaled in the 4th century by many states which engaged in sea-borne trade and acquired capital resources Culture, too, was widely diffused. The Attic dialect and alphabet, Attic commercial law and Attic town planning were becoming characteristic of many parts of the Greek world. Any considerable city had its theatre, civic centre and gymnasium. whether in Sicily, Italy, Greece, Asia or Cyrenaica. Trade in books was beginning, and Greek manners were spreading into the hinterlands of the continents. Banking, marine insurance, commercial treaties, mortgaging and so on were fully developed. Isocrates spoke of a "Greek" culture, as we may speak of a European culture and it was based on a prosperity which was expanding in spite of the spasms of war.

Prosperity made the states feel more constricted than ever by the narroa confines of their territories. They fought with their neighbours, to defend or extend their lands — Sparta with Arcadia, Arcadia with Elis, Corinth with Argos, Athens with Boeotia — and they fought to secure the seaways along which their exports and imports traveled. The distribution of wealth within the states was an even more potent cause of war. Capital accumulated rapidly in the hands of the wealthy. Because direct taxation was imposed only in times of emergency, the gap between rich and poor tended to increase apace. unless a revolution led to a redistribution of property. In a moderate democracy the poorer classes, which usually were in the majority, viewed the rich with suspicion and laid on them many "liturgies" or voluntary offices which were costly to discharge. A dividing line existed too between those who had some capital and those who had none, the *aporoi*. As Aristotle pointed out, the granting of doles to the poor at Athens, for instance, was a palliative and not a solution; he advocated the making of capital grants which would raise a poor man above the line and start him in some business (*Politics*, 1320a 35), but few states had the resources and none the will to do so. The antagonism between rich and poor was reflected in the swing from oligarchy to democracy. which was given additional impetus by the imperialistic or "liberating" po ers who exploited the internal situation in another state for their own advantage. It was made more dangerous in some states by the presence of large slave or serf populations and of foreign mercenary soldiers, as well as by the proximity of aggressive neighbours. The situation in Sicily as described in a Platonic letter is an extreme case: "There is never any end. What seems to be an end always links on to a new beginning. The circle of strife is likely to destroy both factions utterly. the faction of tyranny and the faction of democracy, and the Greek language will almost die out in Sicily as it becomes a province of Carthage or of Italy."

The stresses and strains which beset the city-state from within and from without weakened the solidarity and loyalty of the citizen body and favoured the growth of individualism. Life mas becoming more specialized. Lawyers. financiers, philosophers, merchants and farmers, for instance, concentrated their energies on one pursuit and played less part in public life than they had done in the 5th century. War was often conducted by mercenary soldiers and mercenary rowers; leading generals of city-states, such as Chabrias. Iphicrates and even Agesilaus, hired themselves out to serve Persia, Cyprus or Egypt. Finance was becoming more and more the sinews of uar, and citizen levies diminished in importance and to some extent in quality. Corporate religion began to decline. Great temples were still built, but more attention was given to secular and civic buildings. Tragedy lost its religious inspiration and followed the lead given by Euripides toward psychological drama. Political comedy was changing gradually into a comedy of social manners. where chance placed individuals in ridiculous situations! and prose developed at the expense of poetry. Sculpture lost something of its idealism and gained in sensual beauty, in sentiment and in realistic portraiture. Philosophy was concerned with the soul or mind of man rather than with his conduct in the state. When Plato envisaged the ideal city, he appreciated that the philosopher would be reluctant to become a ruler.

Although the Greek world was troubled by so many rapid changes. it remained immensely vigorous in action and fertile in ideas. Greece was unrivaled in commercial capitalism. in the understanding of agriculture and of finance and in the skillful practice of the art of war. The greatest philosophies and the noblest prose of antiquity were created in this period, and sculpture and painting reached a high level of perfection. But the political problem remained unsolved. Greek thought was still conditioned by the nationalism of the city-state. Plato and Aristotle analyzed the defects of contemporary politics with remarkable insight. They believed that a more enlightened education and the intelligence which it would produce might reform the city-state from within, and they both gave a picture of an ideal city-state in which the effects of capitalism would be controlled by the authority of state laws. But each state was envisaged as a separate entity and divorced, as far as possible, from contacts with its neighbours. Isocrates had a more practical outlook. He also believed in the value of education. but he saw that interdependence was more important than independence in the crowded world of the city-states. Practical politicians and the electorates behind them devised many forms of association which met some of the new needs of interdependence: complete merging of city-states by force or by agreement, the growth of federal systems with a common citizenship (sympolity) or with an exchange of citizenships (isopolity); sharing of monetary or commercial advantages; organization of large and efficient coalitions based on collective security; and even the formation of a league of states. But at the same time each city-state pursued an independent policy and often an imperialistic policy. as soon as it had reaped the temporary advantages of membership in an association. The liberal principles of the second Athenian confederacy and the Boeotian league did not withstand the temptations of success. The Greek world was exhausted and leaderless in 354 B.C., when a new power was growing in the north.

THE MACEDONIAN PERIOD

The area which we now call Macedonia was inhabited in the 4th century B.C. by peoples of Greek, Illyrian and Thracian stock. The Macedonians proper held the coastal plain at the head of the Thermaic gulf and had more Greek blood than their neighbours of upper Macedonia. Their royal house claimed descent from Heracles, son of Zeus, and the kings were recognized as Greek by the presidents of the Olympic games early in the 5th century. They claimed suzerainty over the cantons of upper Macedonia which had their own royal houses, but they were seldom able to exercise an effective suzerainty. Kingship in Macedonia proper and in the cantons of upper Macedonia, like that of the Heroic age in the Homeric poems, was hereditary within one family and constitutional. The king owned all land and conducted all affairs of state in war and peace at his own discretion. He chose his own "companions" from the nobles of the land to advise him and serve with him in battle. They had a personal "kinship" with the king which enhanced his claim on their loyalty. The Macedonian people elected the king. tried cases of treason in which the king was a litigant and had power to depose him by their vote. They derived their land and citizenship from the king and owed him personal service. taxes and dues. They had no substratum of serfs or slaves, and as freemen they consorted on easy terms with the king and his companions. The feudal institutions of Macedonia proper and of upper Macedonia were unlike those of the city-state and were regarded as barbaric by the Greeks.

As Greek manners spread inland, they were canalized by the royal house. Greek culture was adopted by the court and Macedonia traded with the sea po ers of the Aegean, but the march of Greek political ideas which led to the growth of city-states in Thessaly was successfully resisted by the Macedonian kings.

The Rise and Triumph of Macedonia. — Although Macedonia proper and the cantons of upper Macedonia were not closely united *c.* 360 B.C., they had a common interest in contending with their aggressive neighbours in Illyria. Paeonia and Thrace and with the Greeks who attacked them from Chalcidice or Thessaly or from the Aegean sea. In 359 the Illyrians killed the king. Perdiccas III. and 4,000 Macedonians in battle and annexed the western part of upper Macedonia. Athens, then still very powerful. Paeonia and Thrace were ready to invade and divide the country. The infant son of Perdiccas was elected king; and Philip, a brother of Perdiccas. was appointed regent Having lived as a hostage at Thebes in the period of Epaminondas and Pelopidas. Philip at the age of 22 had a thorough knowledge of Greek warfare and diplomacy as well as of the methods of the Balkan peoples. He bribed his enemies in Paeonia and Thrace to keep the peace and concentrated his troops against a pretender, Argaeus, who landed with the support of 3,000 mercenary soldiers. sent by Athens, late in 359. Philip defeated the pretender. He let the mercenaries go free and made peace with Athens, which was then at war with the revived Chalcidian league and desired to capture Amphipolis. In 358 he subjugated the Paeonians, defeated the Illyrians decisively and won the support of Illyria's southern neighbour, Epirus, nhere he married Olympias, daughter of the Molossian king. These remarkable successes led the Macedonians to elect him king as Philip II. He now exercised effective suzerainty over upper Macedonia and began to incorporate the leaders of the cantonal royal houses into the ranks of his companions.

Philip's Alliance with the Chalcidian League.—The chief threat to Macedonia came from the Greek states. Fortunately for Philip, the Chalcidian league, in which the principal state was Olynthus, was at war with Athens over Amphipolis, an independent state supported by the league. In the spring of 357 B.C., Philip boldly laid siege to Amphipolis. When Athens was asked by Amphipolis to send a garrison to its aid, Philip made a secret pact to give Amphipolis to Athens, if Athens gave him Pydna, a city on the Macedonian coast which was an ally of Athens. The Athenian bases at Potidaea and Torone in Chalcidice kept the Chalcidian league occupied, while Philip prosecuted the siege and captured Amphipolis. He pronounced Amphipolis independent, attacked and took Pydna and negotiated with the Chalcidian league for a defensive alliance; for Athens was now engaged in the Social War, and the Chalcidian league became the strongest power in the northwestern areas of the Aegean. The alliance was consummated with the cession of a rich territory called Anthemus to the league; and Philip captured Potidaea and gave it to the league as well. As both powers mere at war nith Athens, they agreed under the terms of their alliance not to treat separately with the common enemy. But Philip was anxious not to embitter Athens and therefore let the Athenians depart from Potidaea without ransom. In 356 he advanced from Amphipolis to help Crenides, a Thasian settlement, against the Thracians. Crenides received Macedonian settlers and gave Philip access to the gold and silver mines of Mt. Pangaeum, from which he later derived a revenue of 1,000 talents a year. Athens organized a coalition of the kings of western Thrace, Paeonia and Illyria. Philip attacked them one by one. In Aug. 356 the Illyrians mere defeated. Philip's horse won a race at the Olympic games, and Olympias gave birth to his first son, Alexander.

Philip advanced his power along the Thracian coast and captured the last Athenian base on Macedonian territory. Methone, in 354 But his main task in these years mas to consolidate and develop his kingdom. He absorbed the royal houses of upper Macedonia into his entourage and chose young nobles to act as royal pages He increased the prosperity of Macedonia by a trade pact with the Chalcidian league and by building roads and founding colonies in the interior. Pella, the capital, was a thriving inland port; and Crenides, renamed Philippi. brought him gold and silver from which he minted coins on the Thracian and Attic standards. The Macedonian cavalry, headed by the companions, was the traditional arm of the country, and Philip raised the Macedonian infantrymen or "foot companions" to a high pitch of efficiency by regular training. As he advanced his frontiers he annexed some territories and created new Macedonian citizens—some of them of Greek extraction—by granting them land in his enlarged realm. He was forming a national territorial state, capable of expanding its territory and citizenship in a way unknown to the Greek city-state. At the same time he represented himself to the city-states as an upholder of Greek ideas. He placed the heads of Heracles and of Zeus on his coins. He set up a copy of the treaty with the Chalcidian league at Delphi. He entered Thessaly to help the free states against the tyrant Lycophron of Pherae and he captured Pagasae for them in 354 before Athens was able to come to its relief. When the opportunity came to intervene in the Sacred War, he was careful to represent himself as the champion of Apollo.

Onomarchus and Philip in *Thessaly*.—In central Greece Boeotia defeated the Phocians under Philomelus in the latter part of the year 354 B.C., but a new Phocian leader, Onomarchus, rallied his countrymen, hired more mercenaries and made alliances with the tyrants in Thessaly against the free states, which invoked Philip's aid. Onomarchus defeated Philip and his Thessalian allies twice in 353 and then turned to inflict heavy losses on Boeotia, which was the natural but probably not the formal ally of Philip. Onomarchus now ruled from Mt. Olympus to the Corinthian gulf, and was the ally of Athens, Sparta, Corinth, Megara, Achaea and other states. Nevertheless Philip attacked him in Thessaly in 352, defeated his army of 500 cavalry and 20,000 infantry and inflicted almost 10,000 casualties; Onomarchus himself was killed; the remainder escaped to an Athenian fleet which lay offshore in support. This resounding victory caused the tyrants to capitulate. Philip allowed them to withdraw, reorganized the Thessalian league to include all Thessalian cities and accepted election as its president with command of its forces and some claim on its revenues. In the summer of 352 he led the Macedonian and Thessalian forces to Thermopylae, but he found the pass defended by the Phocians and their Athenian, Spartan and Achaean allies. He withdrew at once and switched his attack to Thrace. In 351 his eastern frontier was at the Hebrus river, and he was on good terms with Byzantium and with Cardia. enemies of Athens.

Eubulus and Demosthenes in Athens.—During these years there had been considerable fighting in the Peloponnese and unrest among the island states in the Aegean. Athens had recovered steadily from the effects of defeat in the Social War, thanks to a policy of refusing invitations to join in adventures in the Peloponnese or to intervene in party struggles in the Aegean. The democracy had become more extreme after 404, the council losing many of its pou-ers to the assembly and to the people's courts and the orators gaining greater influence in the assembly. The process was checked in 354 when a conservative politician, Eubulus, was elected chief commissioner of the theoric fund (money reserved for the relief of the poor) for four years and the commissioners were authorized to control general expenditure. During his tenure a law was passed whereby surplus revenue went into the theoric fund and could only be diverted into the military fund by a decision of the assembly. As the poor commanded a majority, they now had a financial interest in preserving the peace so as not to divert money from the theoric fund and were less ready to engage in adventurous wars than in the past. But Eubulus and the assembly were not pacifist: they sent expeditionary forces to counter Philip at Methone, Pagasae and Thermopylae; and they acquired the Chersonese and sent cleruchs to Sestos in 353–352. The chief opponent of Eubulus was Demosthenes, a brilliant orator, who advocated an adventurous policy in the Peloponnese. Rhodes and Thrace but did not denounce Philip as the chief enemy of Athens until he delivered the speech known as the First Philippic, probably in 350 B.C.

The Fall of *Olynthus*.—Chalcidice was the key to any offensive against Macedonia. Eubulus negotiated unsuccessfully with the Chalcidian league late in 352 B C.. and Philip forced the issue in 349 by asking the league as his ally to surrender two pretenders to his throne. The Chalcidians refused and treated separately with Athens, which was a breach of their alliance with Macedonia. Athens granted an alliance and sent 2,000 mercenaries and 38 triremes. Philip remained inactive until the sailing season ended. Then he took a number of Chalcidian cities by storm or negotiation and started a rising against the pro-Athenian governments in Euboea in Jan. 348. As Euboea lay on the sea route to Chalcidice, Athenian forces were sent there rather than to Chalcidice; but these forces suffered such reverses that Athens recognized the independence of Euboea and paid a large sum to ransom prisoners in July. Meanwhile Philip reduced all Chalcidice except Olynthus, to which Athens had sent a further force of 4,000 mercenaries and 18 triremes. A third force of 2,300 citizen troops and 18 triremes was held up by northerly winds. It arrived to find Olynthus in Philip's hands. Philip razed the city to the ground and incorporated Chalcidice in his realm.

The End of the Sacred War.—Before the Athenians had recovered from the shock of defeat in Euboea and in Chalcidice, Philip offered peace and alliance. Athens was in a weak position, because Phocis was now failing in the Sacred War. and Thessaly, Boeotia and Euboea formed a strong group. Even Demosthenes, who had criticized Eubulus and denounced Philip in the Olynthiac speeches, supported negotiations with Philip as a necessary step in extricating Athens from the Sacred War. An interruption occurred in the winter of 347–346, when Sparta and Athens tried to seize Thermopylae, but the plan miscarried. Peace and alliance were concluded between Macedonia and Athens in July 346 (the peace of Philocrates) ; but opinion in the Athenian assembly was divided, Eubulus and Aeschines proposing to implement the alliance and Demosthenes trying to prevent its implementation. Philip and his allies, with the exception of Athens which refused to send a contingent. invaded Phocis and received the capitulation of the Phocians. The Amphictyonic council, guided by Philip, made a settlement which was merciful by Greek standards: the Phocians were disarmed, their towns were split into villages and they had to pay an indemnity to Apollo. The two votes of Phocis on the council were transferred to Philip, and he was elected president for the Pythian games in Sept. 346. Athens refused at first to acknowledge Philip's position. But the Amphictyonic council demanded an apology, and Athens apologized after a debate in which Aeschines was shouted down and Demosthenes emphasized Athens' isolation and the need to avoid a rupture with Philip and his allies.

Demosthenes' Policy of Resistance.—Between 346 and 340 Philip increased his control of the Balkan area by a series of campaigns and negotiations. He controlled Illyria as far north as Scodra (the modern Shkoder or Scutari in Albania), Epirus. Thessaly through the Thessalian league (of which he was elected president for life) and Paeonia and Thrace through vassal kings. His alliances reached as far as the Getae on the lower Danube. the Greek cities on the Black sea and the lesser states in the Peloponnese. The Aetolian league allied itself with him *c*. 343. The kingdom of Macedonia was becoming unified by economic prosperity and military success. and the subject peoples in the Balkan area were secured by military colonies, economic development and the prestige of the king himself. The very strength of Macedonia forced the Athenians to decide between Aeschines and Demosthenes in the assembly and in the people's courts. They chose the policy of Demosthenes and won the alliance of other states which were apprehensive of Macedonia: Corcyra, Ambracia, Leucas, Corinth. Achaea, Messenia, Byzantium, Abydos, Chios, Rhodes and Euboea, which sent delegates to a conference at Athens in March 340 B.C. and agreed in principle to participate in a war against Philip. Demosthenes was crowned for his services to the state.

Philip had hoped to win the Greek states by diplomacy. But the triumph of Demosthenes ended those hopes, and there was now a danger that Athens would find an ally in Persia, which had put down a series of revolts and held the Asian side of the Bosporus. Philip laid siege to Perinthus in the summer of 340 B.C. and then to Byzantium, as these cities had refused to implement their alliance with him; and he sent a letter of complaint to Athens which rescinded the treaty of alliance with Macedonia. Help was sent to Perinthus and Byzantium by Persia and Athens, which contracted an alliance, and by Athens' other allies. Philip raised the siege, conducted a campaign as far as the mouth of the Danube and fought his way through the Triballi in northern Thrace. In 339 his friends on the Amphictyonic council offered Philip the command of their forces in a new Sacred War against the Locrians of Amphissa. Philip accepted. When his Macedonian and Thessalian forces reached Cytinium in Doris, he sent envoys to ask the Boeotian league to join him in accordance with the alliance. Demosthenes led Athenian envoys to Thebes and offered a favourable alliance to the Boeotian league, under which Athens would pay two-thirds of the expenses of war and serve under Boeotia's command in the field. The assembly of the Boeotian league voted for alliance with Athens and denounced the existing alliance nith Philip. The allies occupied strong defensive positions. They refused all overtures for peace which Philip made, and it was clear that Philip could only overcome their opposition by force.

Philip's *Victory at Chaeronea, 338* B.C.—The Macedonian army was an unknown quantity to the citizen levies of Boeotia and Athens; for it had fought on Greek soil only in Thessaly and then against the mercenary troops of Onomarchus. The Macedonian cavalry was far superior to that of the allies: the heavy cavalry, wearing protective armour and equipped with shield, s ord and lance, operated in wedge-shaped formations for close fighting; the light cavalry, armed like Greek cavalry with javelin and sword, was designed for skirmishing. The infantry carried a pike twice as long as the Greek hoplite's spear, fought in less close order and were more flexible in maneuver. and the phalanx or line of battle was supported by units of specialized light infantry. In the summer of 338 B.C. Philip broke through the allies' position north of Amphissa, which was held by 10.000 mercenary troops. He offered in vain to negotiate with the citizen forces of Boeotia and Athens. A decisive battle mas fought at Chaeronea between about 35,000 Greek hoplites and about 30.000 Macedonian infantry. Philip, commanding the right wing of the phalanx, made a bold maneuver of withdrawal which drew the Athenians opposite him out of their position. As the Greek line moved to its left to maintain contact, a gap opened near the right wing, into which the young prince Alexander charged at the head of the companion cavalry. At the same time Philip delivered his attack. Both wings of the allied army were destroyed or captured; the centre broke and fled. Philip did not launch his cavalry in pursuit, as he had done with deadly effect in other battles. Boeotia capitulated and was treated as a treacherous ally; the league was disbanded and oligarchic government mas installed at Thebes, where a Macedonian garrison occupied the acropolis. The Athenians accepted terms, under which they lost what had been left of the second Athenian confederacy, but kept Lemnos, Imbros. Scyros. Delos and Samos and entered into alliance with Macedonia. Philip entered the Peloponnese and was honoured by every state except Sparta, which proudly refused him entry but could not prevent his marching to Gythium in southern Laconia. The military might of Macedonia was triumphantly demonstrated with a minimum of bloodshed.

Greece under Philip and Alexander. — The enemies of Philip had always claimed that he would follow the path of Greek imperialism and destroy or enslave the city-states which he conquered. Isocrates, who was now 98 years old. wrote a letter to Philip in which he urged him to end the period of mad imperialism. to bring the Greek states into an association of goodwill and to declare war on Persia. Nor was this an old man's fantasy. Isocrates had seen the ceaseless wars for hegemony in Greece and the consequences of social unrest, and he had observed Philip's ability to win the support of Thessaly and his enlightened generosity in victory. Demosthenes, on the other hand, found that generosity inexplicable. He distrusted Philip and Macedonia at the moment and for the future. because he was the advocate of untrammeled independence for his city-state. Athens.

Philip chose the way of co-operation. At his suggestion the Greek states of the mainland (except Sparta). together with many island states. formed a Greek league, which was ratified in 337 B.C. at Corinth and is now called the League of Corinth. The states undertook to keep the peace among themselves and to use military sanctions against any aggressor; to respect the constitution and liberty of one another and to unite in suppressing piracy and brigandage; and to refrain each in its own state from any executions or revolutionary procedures uhich were contrary to the existing laws. Each state elected a number of delegates, proportionate to its military and naval strength, who sat on the federal organ of government, "the council of the Greeks." All states were bound by the council's decisions. which were taken on a majority vote and covered all matters of federal government, including issues of foreign policy. At its first meeting the council entered into an offensive and defensive alliance for all time with "Philip and his descendants." decided to conduct a war against Persia and elected Philip to be commander of its armed forces and chairman of the council during the war, citing him as "a benefactor of Greece" The council then approved the presence of Macedonian garrisons in Thebes. Chalcis. Ambracia and Corinth and called up contingents for the war against Persia.

The settlement of Greece was certainly statesmanlike. It went much further than the league of 362 B.C. had gone to arrest the endemic troubles of the Greek states; and war with Persia would provide an outlet for their energies and surplus populations. Alliance with Macedonia did not amount to incorporation in a Macedonian empire. Philip avoided that step. It is uncertain whether he acted as a Greek with an interest in Greek affairs, as an enlightened statesman who wanted a strong union of powers against Persia, or as a hypocrite who preferred to dominate by appearing to unite his potential enemies in a Greek league. In any event the league held firm until Philip was assassinated in 336 B.C. It then elected his son and successor, Alexander III, to command its forces. The same year saw the completion of a federal system in Sicily, where Timoleon had defeated the Carthaginians and established a moderate form ot government in the Greek states.

The conquest of Persia by Alexander the Great and the army of the Greek league is described elsewhere (*see* ALEXANDER III, *THE* GREAT). We are here concerned with events in Greece. Before the expedition set out, Thebes rose in revolt, in 336 B.C. and again in 335. Alexander pardoned the first offense and gave Thebes an opportunity to retract from the second revolt. But Thebes remained obstinate. Alexander then stormed the city with his own troops and with those of the Boeotian states which were hostile to Thebes. The punishment of the rebels was referred to the council of the Greek league, which condemned the population to slavery and allotted its lands to neighbouring states. Alexander executed the sentence. He could and should have prevented the council from passing such a sentence; for the liquidation of Thebes was interpreted as an act of Macedonian imperialism. He showed generosity toward Athens and other states which had helped to instigate the revolts of Thebes and also toward Demosthenes and other statesmen who had received subsidies from Persia. but the confidence which Philip had hoped to create between Macedon and Greece was destroyed almost irretrievably.

In the opening years of the campaign against Persia (334 *et seq.* B.C.) Alexander respected the position of the Greek league. Island states were enrolled as members of the league, and a check was imposed on party strife and on revolutionary procedure. On the other hand the Greek states in Asia Minor were probably treated as part of Alexander's kingdom; for each nas given a treaty by Alexander, and Greek and barbarian alike were governed by his regulations. So long as the Persian fleet stayed at sea. Sparta acted openly as the enemy of Macedon. and Athens not only instituted conscription for young men but also intrigued with Persia. When the Persian fleet aas disbanded, Sparta used Persian money to hire a large mercenary army, raised Elis. Achaea and part of Arcadia in revolt and invited Athens to join in the fight for independence. But Athens refused. The coalition nith 2.000 cavalry and 20,000 infantry, defeated one Macedonian army and attacked Megalopolis but was broken up in the autumn of 331 by Xntipater. Alexander's deputy in Macedonia, who reinforced his army with contingents from the Greek league. The fate of Sparta and the rebellious states was entrusted by the council of the Greek league to Alexander. He forced Sparta to enter the league and made the rebels pay an indemnity to Megalopolis.

During the rest of Alexander's lifetime the Greek states made no move. The central issue in their party politics was the attitude to be shown toward him. In 330 B.C. Demosthenes won his case in Athens with his speech "On the Crown" in defense of Ctesiphon, whom Aeschines was prosecuting for having proposed that a crown should be given to Demosthenes after the battle of Chaeronea; and Aeschines left the country. A steady stream of exiles flowed from the Greek states to Asia. until Alexander decreed in 324, probably with the agreement of the Greek league, that all exiles should be reinstated. The states even granted Alexander "godlike honours" at his own request—some with gratitude and some with mockery. Greek envoys, wearing crowns in his honour, waited upon him at Babylon just before he died in 323 B.C., at the age of 32.

Macedonia and the Greek States, 323–224.—The conquests of Alexander in Asia brought great prosperity to the eastern Mediterranean. The accumulation of capital reserves enabled Athens to equip a large fleet and to improve the city's defenses, and other states on the mainland of Greece benefited from the years of peace. The wealthy class in most states favoured good relations with Macedon. The democratic leaders were afraid of a coup *d'état* by the wealthy and resented the restrictions on foreign policy which had been imposed by the League of Corinth. So long as Alexander lived and conquered, they complied reluctantly with his wishes. But the news of his death and of the quarrels between his generals gave the democratic leaders some hope of throwing off the alliance with Macedon. Large forces of Greek mercenaries were under arms: 8,000 men, commanded by an Athenian, Leosthenes, were at Taenarum in Laconia and 23,000 men were marching homeward from the east. The Athenian people decided to go to war. They engaged Leosthenes and his mercenaries and formed an alliance with the Aetolian league, but most of the Greek states—especially those which had reason to fear Athenian ambitions—opposed this policy or at least refused to co-operate. The allies began the Greek War, as they called it, (it is alternatively called the Lamian War) with an army of about 30,000 men. They seized Thermopylae in Oct. 323 B.C. and blockaded a Macedonian army under Antipater in Lamia throughout the winter. Meanwhile an Athenian fleet of 170 ships sailed to the Hellespont but gained no allies. In 322 three Macedonian armies were operating in Thessaly and two Macedonian fleets held the northern Aegean. Superior numbers enabled Antipater to defeat and split the Greek allies. Athens surrendered unconditionally in Sept. 322. A year later the Aetolian league accepted moderate terms from Antipater, who was anxious to settle affairs and to intervene in Asia.

The lessons of the Greek War were clear. Athens was unable to unite the Greek states because of their mistrust and the forces of Athens and Aetolia alone were far inferior to the massive armies of the Macedonians. Antipater abandoned the policy of co-operation. Treating Athens as a traitor, he exacted an indemnity for the war, placed a garrison in Munychia to control the Peiraeus and Athens and disfranchised the poorer class, so as to leave only 9,000 citizens as the electorate for an oligarchic government. The assembly passed sentence of death on the democratic leaders who had instigated the war. Demosthenes committed suicide. Antipater set up pro-Macedonian oligarchies in the Peloponnesian states and installed Deinarchus, a politician from Athens, to act as Macedonian governor of the Peloponnese. The freedom of Athens and of the Peloponnesian states was at an end. They were now subject to a Macedonian protectorate, which dictated their form of government and made them keep the peace.

From 320 to 275 B.C. the states of the mainland were involved in the wars of the Diadochi ("successors") of Alexander, who fought for power and ended by dividing the Macedonian empire into a number of fairly stable monarchies. During these troubled years the Greek states were important to the rival kings and generals because they were able to provide troops and taxes. The policy of co-operation was applied for the last time in 303 by Demetrius Poliorcetes, who revived the League of Corinth and treated the Greek states as allies. Otherwise the Macedonians kept control, whatever their protestations may have been, by setting up puppet governments and imposing garrisons. In Athens, for instance, Antipater's son Cassander in 317 placed Demetrius of Phalerum at the head of an oligarchic government under the protection of a Macedonian garrison; and this situation lasted till 307. The council of the Areopagus received many of its traditional powers, the rich were freed from the liturgies (public duties) imposed by the democracy and a strong control was set on all legislation; but behind this façade Demetrius of Phalerum was a tyrant who ruled with Macedonian support. The state which made the boldest bid for independence was Sparta, whose successful revolt, in 280, was joined by Elis and by some states in Arcadia and Achaea but not by rivals of Sparta in the Peloponnese. But the very success of this revolt made Sparta's allies suspicious and uneasy and they fell away when Sparta attacked the Aetolian league and suffered heavy losses. In 275 the Antigonid dynasty was finally established on the Macedonian throne.

Between 275 and 224 the strength of the Macedonian kingdom in Europe was weakened by the attacks of Pyrrhus of Epirus (d. 272) and by the intrigues of Ptolemy II of Egypt and other Hellenistic monarchs. The Greek states obtained a greater measure of independence. The most vigorous peoples were those of the hill country who developed the federal system. The Aetolian league had been organized as a league of cantons with a democratic assembly on the model of the Boeotian league since 370, and it had never been subjugated by Macedon. Now it expanded its territory by incorporating other states, which retained their own citizenship but assumed Aetolian citizenship under an act of sympolity, and it granted an exchange of citizenships with more distant states under an act of isopolity. The Aetolian assembly, which met twice a year, decided on policy and elected for the year a general who presided over the assembly and commanded its armed forces; and routine administration was carried out by a council, of which the members were elected by the cantons in numbers proportionate to their military strength. The general and his advisers, acting as a committee, were entrusted with wide powers, because the assembly met so rarely; and a man could be re-elected to the generalship only after an interval of some years, lest he become too powerful and autocratic. By 224 the Aetolian league, having defeated its rival, the Boeotian league, included within its sympolity the core of central Greece from coast to coast and counted among its close allies by isopolity such states as Cephallenia and Chios. Just as the democratic city-states of the previous century had been, the Aetolian league was aggressive and warlike.

The Achaean league had been disbanded in the period of Macedonian domination. It formed again on a democratic basis c. 280 B.C., with an assembly of citizens over 30 years of age and a representative council of deputies. From c. 200 B.C the assembly's powers declined. It met jointly with the council at irregular intervals to decide major issues. The predominance of the council made the policy of the Achaean league less adventurous than that of the Aetolian, and the member states had a greater degree of independence, rarely exchanging their citizenship by an act of isopolity. The number of annual generals of the league was reduced from two to one in 255. Then the general acted as president of the assembly and commander of its forces and shared with a small committee of officials the exercise of a strong executive authority; and the same man could be elected general in alternate years. This feature in the league's democratic constitution enabled Aratus of Sicyon to hold office every other year and gain a strong position of leadership. Aratus had a fanatical hatred of the tyrants whom Macedon supported, and he drove them out of city after city until by 228 the Achaean league comprised almost all states in the Peloponnese except Elis, Messenia and Sparta.

The greatest city-states of the past led a rising against Macedon in 267 or 266 B.C. This was the Chremonidean War (so named after the Athenian leader), in which Athens and Sparta, in alliance with Ptolemy II of Egypt, proclaimed themselves champions of the liberty of the Greek states. But few of the states joined them. The Athenians fought gallantly, but were starved into surrender by the superior forces of Macedon in 262. They did not become independent again until 229; after this, they preserved their freedom by a policy of neutrality.

The Spartans lost their allies and remained a second-rate power, without Macedonian intervention, until 227 B.C., when they saw themselves threatened by the expanding Achaean league. Sparta indeed had been crippled, ever since the battle of Leuctra, by the small number of Spartiates, or full citizens, who ouned sufficient land to pay their contributions to the messes. In 227, however, a Spartan king. Cleomepes III. changed the situation by revolutionary methods: he abolished debts and confiscated all land, which he redistributed in lots to increase the citizen body. Having thus enlarged his army and announcing a program of social revolution, Cleomenes attacked the Achaean league and detached so many of its member states that its general. Aratus, called on Antigonus Doson. king of Macedon, for help in 224.

The Coming of the Romans.—Between 224 and 205 B.C. Macedon struggled to regain a dominant position in Greece. As the price of help to Aratus, Antigonus Doson took over Corinth and founded another Greek league. This was similar to Philip II's League of Corinth and included the leagues of Thessaly, Phocis, Boeotia, Euboea, Epirus, Acarnania and Achaea. As the elected commander of the league's forces, Antigonus cornered and defeated the Spartans at Sellasia in 222, entered Sparta and canceled the measures of Cleomenes. When Xntigonus died, in 221. Philip V succeeded to the throne of Macedon. He helped the members of the new Greek league against the Aetolian league, Elis and Sparta in another so-called Social War (220–217). which was indecisive. At the peace conference the Aetolian delegate spoke of "the cloud rising in the west," namely Rome, nhich had gained control of a part of the Illyrian coast and Corcyra in 229 and sent envoys to the Isthmian games at Corinth's invitation in 228. When the outbreak of the Second Punic War was followed by a series of Roman defeats, Philip allied himself with Carthage (21j) and tried in vain to oust Rome from the Illyrian coast. Rome raised Philip's Greek enemies—the Aetolian league, Elis. Sparta and Messenia—against him in 21 2; the Romans were about to invade Africa when fighting ended in Greece in 20j without any clear gain for either side.

The period from 20j to 146 was marked by the advance of Rome. Some Greek states called upon Rome for help, as they had called upon Persia and Macedon, but they learned to their cost that the Romans had neither gratitude nor scruple where their desire for power was involved. The Romans' first step was to defeat Philip V (battle of Cynoscephalae, 197 B.C.) and to confine him to Macedonia; they were helped in this by the Aetolian and Achaean leagues, Athens, Rhodes and Pergamum. It was now the Romans, not the Macedonians, who proclaimed that the Greek states were to be independent. They used Greek and Roman troops to enforce the transfer of Argos from Sparta to the Achaean league. Also, Rome gave the Aetolian league less territory than it claimed. The Roman army left Greek soil in 194, but the Aetolian league countered by inviting the Seleucid king Antiochus III into Greece. Antiochus came, in 192, but the Romans and Philip V of Macedon drove him out and reduced the Aetolian league to impotence. The Romans then defeated Antiochus at Magnesia, on the other side of the Aegean, in 189, deprived him of Asia Minor west of the Taurus mountains and announced the freedom of the Greek cities there in 188.

Meanwhile Rome's ally, the Achaean league led by Philopoemen, was extending its territory; Sparta, which had been brought into the league in 192, tried to secede; but Philopoemen was able to enforce the annexation of the state in 188. after a number of leading citizens had been massacred. A few years of uneasy peace were marked by complaints which the Greek states made to Rome against one another and against Macedon. Then, in 171 the Romans ordered Perseus, the successor of Philip V of Macedon, to disband his forces. Perseus refused and Rome attacked. The Greek states played little part in the war. They watched the almost complete annihilation of the Macedonian army (battle of Pydna, 168 B.C.) and the dismemberment into four republics of the kingdom which had towered over them for two centuries. The Greeks too were given a taste of Roman methods: in Epirus, where sympathy with Macedon had been shown in two wars, the Roman army destroyed 70 towns and deported 150,000 men as slaves; although the Achaean league had declared for Rome, 1,000 leading citizens were deported to Italy; and Aetolia was weakened by Roman troops which helped the pro-Roman party in a civil strife. Even so, the authority of Rome was flouted. Then, in 148 a Roman army annexed Macedonia as a province; and in 146 another army defeated the forces of the Achaean league—Boeotia, Euboea, Phocis and Locris. This time the consul L. Mummius made an example of Corinth: the men were massacred, the women and children were enslaved and the city was razed. Rome ordered the disbanding of all leagues and the replacement of democracy by oligarchy in a number of states and announced that any breach of the Roman regulations would be punished by death. Thus the liberties of the Greek states mere finally and completely abrogated.

During the period of Macedon's supremacy the centre of economic prosperity shifted to Asia Minor and Egypt, but the Greek states remained prosperous, especially those north of the Isthmus. War was more humane until Rome entered the field, and it caused little disruption of trade. The instability of Greek politics was due to the widening gap between rich and poor and to the growth of slave populations, which reduced the unskilled free worker to the minimum level of subsistence. The danger of social revolution was always present. It caused the rich to band together and to lean on the support of Macedon or Rome. whereas the democrats sought to overthrow the rich and to gain new territories. The leagues grew in response to the challenge of the greater states of the Macedonian world, but they pursued their policy as rivals and not as unifiers of Greece, until disaster engulfed them and the weaker single city-states. Greek culture became more uniform, but Athens was still the centre of sophistication and philosophy. It was in Athens that Menander wrote his comedies, which depicted social life in a city with kindly wit and perfect style. The schools of Plato and Aristotle were rivaled by four sects which concentrated on the problems of individual happiness—the Sceptics, the Cynics. the Epicureans and the Stoics Individualism was now fully emancipated from the strands of city-state religion. Greek culture made great strides in medicine. mathematics, astronomy. botany, hydrostatics and technical subjects; it excelled in scholarship and in those varieties of prose and poetry which depend on the precise and imaginative mind of the scholar; and it was magnificently portrayed in sculpture and painting. But Greek culture was gradually losing the distinction that it had derived from the city-state and was fitting itself for the long life that it was to enjoy as the culture of educated men in an urban setting within the framework of the Roman empire.

Authorities for Classical Greek History

Our knowledge of the Bronze Age is derived from archaeological excavation (see AEGEAN CIVILIZATION) and from the poems attributed to Homer (*q.v.*). For the period of the Greek renaissance from the 9th century onward we rely on archaeology and on the remains of epic (see HESIOD), lyric and elegiac poetry. Political and military history begins with the works of Herodotus and Thucydides (*qq.v.*), who painted some of the background of the great wars which they described so brilliantly. Contemporary inscriptions and coinage have survived from the 6th century B.C. onward in increasing quantity; they check the accuracy of ancient historians and supplement their accounts in an infinity of ways. For the 4th century the contemporary history of Xenophon (*q.v.*) is filled out by the fragments of Ephorus and Theopompus, who were themselves the ultimate source of later works composed under the Roman empire—the Lives of Plutarch (*q.v.*) and the Library of Diodorus Siculus (*q.v.*). The whole body of classical literature, architecture and art provides the rich background against which the historical data are marshaled, and understanding of Greek politics owes most to the 4th-century orators and philosophers—Isocrates and Demosthenes, Plato and Xristotle.

For the Hellenistic period the scholar draws on a mass of contemporary inscriptions, coins and material remains, but with the outstanding exception of Polybius (*q.v.*) the works of contemporary historians have survived only in fragments. The career of Alexander has been preserved for us by a Roman governor, Arrian (*q.v.*), whose account rests on sources contemporary with Alexander and is supplemented by Diodorus Siculus and by Quintus Curtius Rufus. Our information about the Greek mainland from 323 to 146 B.C. is drawn mainly from Diodorus Siculus, Polybius, Plutarch's *Lives* and Livy; and an insight into social manners is afforded by the comedies of Menander (*q.v.*).

POSTCLASSICAL AND MEDIEVAL HISTORY

Greece under the Roman Republic.— After the collapse of the Achaean league the Roman senate appointed a commission to reorganize Greece as a dependency of Rome. Corinth, the chief centre of resistance. was destroyed; the national and cantonal federations were dissolved, commercial intercourse between cities was restricted. and the government was transferred from the democracies to the propertied classes, whose interests were bound up with Roman supremacy. Some favoured states like Athens and Sparta retained their rights as *civitates liberae,* the other cities continued to enjoy local self-government but probably were subjected to payment of tribute. General powers of supervision were entrusted to the governor of Macedonia. The internal disorder which remained over from the previous political revolutions was checked by the historian Polybius, whom the senate deputed to mediate between the litigants.

Greece was seriously disturbed during the first Mithradatic War (88–84 B.C.). Many of its cities sided with Mithradates, whose success in detaching the Greeks from Rome is to be explained partly by the way in which his agents incited the imperialistic ambitions of cities like Athens, partly by his promises of support to the democratic parties. The result of the war was disastrous to Greece. Apart from the confiscations and exactions by which the Roman general L. Cornelius Sulla punished the disloyal communities, the extensive and protracted campaigns left central Greece in a ruinous condition.

During the last decades of the Roman republic oppressive exactions by officials were not unknown. Still greater was the suffering produced by the rapacity of Roman traders and capitalists. Sicyon had to sell its most cherished art treasures in order to satisfy its creditors. A further hindrance to Greek prosperity was the diversion of trade which followed upon the establishment of direct communication between Italy and the Levant The coastal districts and islands suffered considerably from swarms of pirates who freely plundered the chief trading places and sanctuaries; *e.g.* Delos in 69 B.C. This evil came to an end with the suppression of piracy in the Mediterranean by Pompey (67 B.C.), who settled some of his captives on the desolated coast of Achaea.

In the conflict between Julius Caesar and Pompey the Greeks provided the latter with a part of his excellent fleet. In 48 B C. the decisive campaign was fought on Greek soil, and the resources of the land were severely taxed by the requisitions of both armies. Though Caesar treated the country quite leniently after his victory at Pharsalus. the Greeks supported the cause of Brutus after Caesar's assassination; but they were too weak to render much service. They subsequently passed into the hands of Marcus Antonius, who imposed further exactions to defray the cost of his wars. The levies and requisitions which Antonius made in 31 B.C. for his campaign against Octavian (the future Augustus) exhausted the country so completely that, after the battle of Actium, Octavian had to take prompt measures to avert a general famine. The depopulation which resulted from the civil wars was partly remedied by the settlement of colonists at Corinth and Patrae by Julius Caesar and Octavian; on the other hand, the foundation of Nicopolis by the latter merely had the effect of transferring the people from the country to the city.

Roman Imperial Rule; **Augustus** to Diodetian.— In his reorganization of the provinces of the Roman empire Augustus incorporated Thessaly with Macedonia and converted the rest of Greece into the province of Achaea under the control of a senatorial proconsul resident at Corinth Several states, including Athens and Sparta, retained their rights as free cities. The provincials were encouraged to send delegates to a synod at Argos to consider the general interests of the country and to uphold national sentiment. The Delphic amphictyony was revived and extended so as to represent in a similar fashion northern and central Greece.

Economic conditions did not greatly improve under the empire. Although new industries sprang up to meet the needs of Roman luxury and Greek marble, textiles and table delicacies were in demand, the only cities which regained a flourishing trade were the partly Italian communities of Corinth and Patrae. Commerce languished in general, and the soil was mainly abandoned to pasturage. Such wealth as remained was amassed in the hands of a few great landowners and capitalists; the middle class continued to dwindle; and many persons became dependent on doles and largesses.

Seeing no future before them, the European Greeks were content to dwell in contemplation amid the glories of the past; and national pride was fostered by the undisguised respect with which the leading Romans treated Hellenic culture. To perpetuate this culture, the Greeks continued to set great store by classical education, and in Athens they possessed one of the chief universities in the Roman empire. At the same time the Greeks had so far lost their warlike qualities that they supplied scarcely any recruits to the army; and they retained too much local patriotism to crowd into the official careers of senators or imperial servants. Although in the 1st century A.D. the astute Greek man of affairs and the *Graeculus esuriens* ("hungry little Greek") of Juvenal abounded in Rome, both these types were mainly derived from the less pure-blooded population beyond the Aegean. The influx of Greek rhetoricians and professors into Italy during the 2nd and 3rd centuries A.D. was balanced by the large number of tourists who came to Greece.

In A.D. 15 the Greeks petitioned Tiberius to transfer the administration to an imperial legate. This new arrangement was sanctioned, but lasted only till A.D. 44, when Claudius restored the province to the senate. The years 66 and 67 were marked by the long visit of the emperor Nero, who wanted to display his artistic accomplishments at the various festivals: in return for the flattering reception accorded to him he besto ed freedom and exemption from tribute upon the country (this favour was speedily revoked by the emperor Vespasian). Important material benefits were conferred by Hadrian, who made a lengthy visit to Greece: besides erecting public works in many cities. he relieved Achaea of arrears of tribute and exempted it from various imposts; and he fostered national sentiment by establishing a new pan-Hellenic congress at Athens.

In the 3rd century Greece again experienced danger from foreign invasions. Already in 170 the Costoboci from beyond the Danube had penetrated into central Greece and sacked Eleusis before being broken up by the local militia. In 253 a Gothic army unsuccessfully besieged Thessalonica. In 268 the province was overrun by Gothic bands in collusion with a Herulian navy; these captured Athens and advanced as far south as Sparta; but a new landing in the north was defeated by the emperor Gallienus, and the victories of the emperor Claudius II in 269 put an end to the immediate danger. (W M.; X.)

The Early Byzantine Period.— After the reorganization of the empire by Diocletian at the end of the 3rd century, Achaea occupied a prominent position in the diocese of Moesia. Under Constantine the Great, Macedonia was a diocese of the prefecture of Illyricum and was subdivided into the eparchies of Thessaly, Achaea (including some of the Ionian and Aegean Islands), Epirus

Vetus (including Corfu and Ithaca) and Crete while the other Greek islands formed an eparchy of the diocese of Asia. A complex hierarchy of imperial officials was introduced and the system of taxation elaborated so as to yield a steady revenue. The levying of the land tax was imposed upon the *dekaprotoi* ("ten leading men") who, like the Latin *decuriones*, were entrusted henceforth with the administration in most cities. The tendency to reduce all constitutions to the Roman municipal pattern became prevalent.

Although the elevation of Constantinople to the rank of capital in 330 was prejudicial to Greece, which felt the competition of the new centre of culture and learning and had to part with numerous works of art to embellish it, the general level of prosperity in the 4th century was rising. Commercial stagnation was checked by a renewed expansion of trade consequent upon the diversion of the trade routes to the east from Egypt to the Euxine and Aegean seas. Agriculture remained depressed, and many small proprietors were reduced to serfdom; but the fiscal interests of the government called for the good treatment of this class, whose growth at the expense of the slaves was a step in the gradual equalization of the entire population under the central despotism. This prosperity received a sharp setback in a series of unusually severe earthquakes in 37j.

The emperors of the 4th century attempted to stamp out by edict the old pagan religion, but except for the decree of Theodosius I by which the Olympic games were interdicted (394). these measures had no great effect and indeed were not rigorously enforced. Paganism was long to survive in Greece—particularly in the Laconian mountains. The sure footing gained by the Christian Church in Greece in the course of the 4th century was strengthened by the judicious manner in which the clergy, unsupported by official patronage and often out of sympathy with the Arian emperors, identified itself with the interests of the people.

The schools of Athens in the 4th century still retained much of their prestige, and the Cappadocian fathers. for instance Basil of Caesarea. went there for their classical studies. In the 6th century Justinian forbade pagans to teach philosophy in Athens; and there appears to be no evidence that this work was taken over in Athens by Christian scholars. who seem at this time to have been attracted to the more flourishing schools of Gaza and Alexandria. But even if the schools of Athens declined in the early middle ages, there is ample evidence that the Byzantines prized their Hellenic tradition. Although they called themselves *Rhomaioi* ("Romans") and were proud of their Christian orthodoxy, they never forgot their ancient Greek culture. Greece itself, however, was for a long time an obscure and neglected province, with no interests beyond its church and its commercial operations, and its culture declined rapidly.

Barbarian invasions, meanwhile, continued. The incursion of the Visigoths under Alaric (395–396) was accompanied by a systematic devastation that crippled Greece for decades (the arrears of taxation that resulted were remitted by the emperor Theodosius II in 428). Vandal pirates raided the country in 466 and in 47j. The Ostrogoths under Theodoric were in Thessaly in 482. The Huns reached the Isthmus of Corinth in their invasion of j40 and Thermopylae in that of jj8. The early part of the 7th century saw Greece invaded by hordes of Avars and Slavs; and numbers of Slavs settled in parts of Greece (though the country was never completely slavicized, as J. P. Fallmerayer maintained).

From the **Isaurians** to the **Angeli,** 717–1204.—The emperors of the Isaurian dynasty in the 8th century continued the reorganization of the provinces into themes which appears to have been initiated by the 7th-century Heraclian emperors and subsequently extended to the rest of the empire. By the end of the 10th century Greece was divided among the themes of Hellas, the Peloponnese, Nicopolis, Dyrrachiuin. Cephalonia and Thessalonica, with the maritime themes of Samos and of the Aegean Sea. (Crete had its own governor, but from the early part of the 9th century to 961 it was in Moslem hands.) During the iconoclast controversy which raged intermittently from 726 to 843 Greece showed itself to be a strong supporter of the traditional use of icons—notably in 727 and in 823, when revolts broke out.

After the final renunciation of iconoclasm by the imperial government (843) and the establishment of the strong Macedonian dynasty (867), the Greek themes shared in the prosperity of the rest of the empire and had a flourishing economic life—particularly through the silk industry centred in Corinth and Thebes. In spite of imperial restrictions, the landed magnates (*e.g.*, the Sgouri of Nauplia and the Cantacuzini of Messenia) built up large family estates in Greece as elsewhere. Northern Greece was open to attack from the Bulgars late in the 9th and early in the 10th centuries, but by 1018 the Bulgarian empire had been conquered by the Byzantines. Thessaly was occupied by nomad Vlachs at the end of the 11th century and became known as Great Walachia. Greece was also attacked from time to time by the ambitious Normans of southern Italy. Robert Guiscard took Durazzo in 1082, whence his army advanced into Thessaly before it was driven out by Alexius Comnenus. In 1147 the army of Roger II of Sicily sacked Thebes and Corinth and took back to Palermo spme of the Byzantine silkweavers from these flourishing centres of the industry.

The **Late Byzantine** Period.—With the crusaders' conquest of Constantinople in 1204 (*see* CRUSADES) and the subsequent establishment of a Latin empire, Greece was split between Latin conquerors and Byzantine aspirants to the imperial throne. In the north the Greek despot Michael Angelus Comnenus set up an independent kingdom consisting of Epirus, Aetolia and Acarnania; and the Epirote rulers for a time enlarged their territory and hoped to regain Constantinople. But when Constantinople fell to the rulers of Nicaea, Epirote territory and authority d indled; and by 1340 what remained had either become part of the restored Byzantine empire of the Palaeologi or fallen to the Angevins of Naples or to the Serbs. In the middle of the 15th century. after being overrun by Serbs and Italians, this territory was conquered by the Ottoman Turks Thessalonica, Thessaly. with central and southern Greece and the islands were divided among the Latin conquerors after the Fourth Crusade, and a number of feudal principalities uere set up. In the north the kingdom of Thessalonica was granted to Boniface of Montferrat. but it soon fell, first to Theodore. despot of Epirus, uho took the title of emperor in 1223, then to the Byzantine emperor of Nicaea. John III Vatatzes, in 1246. After changing hands several times in the 14th and early 15th centuries Thessalonica was captured by the Turks in 1430.

The duchy of Athens (Attica and Boeotia) was granted as a fief by Boniface of Montferrat to the Burgundian Otto de La Roche, whose family kept it until 1308. It fell to the Almogávares (*q.v.*) in 1311. These Almogávares, otherwise known as the Grand Catalan company had entered Byzantine service as mercenaries on the conclusion of peace between the French and the Aragonese in Sicily (1302). They soon quarreled with the Byzantines, however, and moved southward. Walter of Brienne, who had become duke of Athens on the extinction of the house of La Roche. engaged their services next. but quarreled with them in turn; whereupon they defeated him in battle. Settling on his lands, they set up their own form of government in the duchies of Athens and Neopatras, with Aragonese princes from Sicily as their dukes. This Catalan–Aragonese domination lasted until 1388. when it gave way to the Florentine lord of Corinth Nerio Acciajuoli, nho in 1391 acknowledged Amadeo of Savoy as prince of Achaia and called himself "lord of Corinth and the duchy of Athens and Neopatras." The duchy of Athens mas ruled by the Acciajuoli family (apart from a period of Venetian domination, 1395–1402) until it was conquered by the Ottomans in 1456–58.

The most flourishing Frankish principality in Greece was that of Achaia, or the Morea (the Peloponnese), under the Villehardouin family. It was originally a fief of Boniface of Montferrat and was granted to William of Champlitte, whom in 1205 Pope Innocent III called "prince of the whole province of Achaia"; but by 1209 it was held direct from the Latin emperor by Geoffrey of Villehardouin with the title of prince. The Frankish rulers found the Byzantine system of granting land in *pronoia* (*i.e.*, to the care of someone) not dissimilar from their own grants in fee and came to terms with the natives. who were allowed to hold their lands in return for military service to the conquerors Toward the end of the 13th century, the splendid Frankish civilization of the Morea began to deteriorate William of Villehardouin prince of Achaia, had already been decisively defeated by Michael VIII (Palaeologus) at the battle of Pelagonia (1259) and been forced after three years' captivity, to cede the Moreot strongholds of Mistra, Old Maina and Monemvasia (1262). The Palaeologi subsequently regained much more of the territory, which was reorganized in the 14th century as the Byzantine theme of the Peloponnese and governed by despots, usually members of the imperial family, with their centre at Mistra (still famous for its buildings and frescoes, the last flowering of Byzantine civilization). In 1381, hon ever. another band of mercenaries, the Navarrese company, took possession of a considerable area in the west in the name of Jacques de Baux, a claimant to the Frankish principality; and from 1383, when Jacques died, the Navarrese themselves ruled there till 1430, when they were overthrown by the Palaeologi. In the 15th century. however, there were renewed Turkish attacks. which the new Byzantine fortification, the Hexamilion across the Isthmus of Corinth, failed to stem, and Thomas and Demetrius Palaeologi were finally conquered by the sultan Mohammed II in 1458–60.

Venice long retained its Greek conquests. The partition of 1204 and subsequent acquisitions had given it a number of scattered possessions of strategic and economic value, ruled directly or by nominees or by special arrangement. The more important of these were: the Ionian Islands (*q.v.*); Modon (1206), Coron (1206), Argos (1388). Nauplia (1388) and Monemvasia (1464) in the Morea; Crete (1204); and interests in the island of Euboea (shared with the Veroneae family Dalle Carceri), as well as in numerous other islands and in the duchy of the archipelago. This last was organized under the leadership of the Venetian Marco Sanudo, who captured Naxos as early as 1204–05. By 1207 more than two dozen islands were held either by him or as fiefs from him, and henceforth the Latin archipelago was dominated by Venetian families such as the Sanudi and the Ghisi, the Barozzi and the Crispi. Venice held Nauplia and Monemvasia until 1540, Crete until 1669 (two strongholds there till 1715) and the Ionian Islands until 1797.

The Frankish conquest brought the establishment of a Latin ecclesiastical hierarchy, though the native Greek priests were left undisturbed and the higher Byzantine clerics continued to exist side by side with the Latins, though they often resided in Constantinople. It vigorously stimulated economic and cultural life in Greece and, on the whole. was accepted by the indigenous majority. It also evoked a revival of Hellenic patriotism among Greek leaders and thinkers in the Byzantine despotate of the Peloponnese. In particular, the humanist Georgius Gemistus Pletho (*q.v.*) put forward utopian plans for the new constitution based on Plato's republic, but such attempts to revive Greek political life could not stave off the Ottoman conquest.

MODERN HISTORY

Greece Under the Turks (1453–1821).—The Turkish conquest of Greece (Tourkokratia) is conventionally dated from 1453, when Constantinople was captured by the sultan Mohammed II and the last Byzantine emperor, Constantine XI, fell with his capital. In fact this date is no more than a symbol and a convenient average, for the greater part of the territory of the empire was already in the hands of the Ottoman Turks, and of the remainder, some parts remained outside Ottóman control for generations and even centuries longer.

At Trebizond, on the Black sea, a so-called Greek empire survived till 1461; on the mainland, the despotat of Epirus outlived Constantinople in independence for a generation; and many of the islands fell to the Ottomans only in the following centuries—Rhodes in 1523, Cyprus in 1571, Crete in 1669 and Tenos in 1715. The Ionian Islands almost entirely escaped Turkish occupation But even those parts of Greek territory which escaped or delayed Turkish occupation were scarcely ever independent. The alternative was generally subjugation to the power of Venice, which proved generally more unpopular than that of the sultan. When Venice gained control of the Peloponnesus by the peace of Karlowitz (1699), the Turks were able to recover it within 20 years with the ready acquiescence of the Greek population.

The comparative popularity of Turkish rule during the first centuries of the occupation was due to a number of contributory causes. In the first place, the rule of the early sultans was able and strong; at least it kept at bay the predatory powers of the west. collectively known to the Greeks as Franks. who had shown, by diverting the fourth crusade to Constantinople in 1203. that their fellow feeling for Christendom was barely skin-deep. In the second place, the doctrinal schism of Christendom had reached a degree of bitterness in the 15th century sufficient to make Mohammedans actually more welcome to Orthodox Greeks than the Catholics of Rome: and there were those who held that the fall of Constantinople was no more than the just due of the emperor and of the patriarch who had accepted reunion with Rome, on humiliating terms. at the council of Florence in 1439. Mohammed II therefore astutely appointed Gennadius, the surviving leader of the party that had opposed reunion with Rome. to be patriarch under his rule. with full confirmation of his rights over the Orthodox community in return for their political obedience; and such tolerance toward Christians, who were, like the Ottomans. "people of the book," was in perfect accord with Mohammedan principle.

In the third place. Ottoman rule was not initially oppressive in its incidence on the subject communities, at least in the golden age of the empire (whose apogee is generally identified with the reign of Soliman the Magnificent, in the middle of the 16th century). The Greeks in particular enjoyed freedom in two important spheres, apart from the practice of their religion. and these were interconnected, both in preserving the continuity of their national consciousness and in leading eventually to the struggle for independence.

One of these was freedom of trade, an occupation which the Turks traditionally looked down upon in comparison with the profession of arms and which enabled the Greek mercantile class to build up simultaneously contacts abroad, wealth. a tradition of independence and a merchant fleet which could in the event be readily converted to warlike purposes. The second great freedom was that of education in the Greek language. which went hand in hand with the freedom of the church. The importance of this factor in the conservation of Greek individuality needs no emphasis; the schoolmaster, the priest and the poet were the makers of the Greek revolution.

Next among the reasons why the Greeks acquiesced so readily for so many generations in the Turkish occupation was the nature of the Ottoman political system; but since it was this also which led ultimately to the struggle for independence, it is the least simple element in the story. The system was based on the traditions of the Turkish tribes' nomadic past, adapted to more settled conditions, but the system never fully assimilated the conception of fixed geographical frontiers or that of the nation-state. The one constant factor was the centralization of all power in the hands of the sultan, from whom alone all rights emanated. His empire was divided for administrative purposes into provinces under governors of his own nomination, of which Greece was distributed among six; but all the land remained the property of the sultan, who could dispose of it as he wished in fiefs allotted to Turkish settlers (usually loyal military adherents), or permit his non-hfoslem subjects to live on it on payment of a land tax. There grew up piecemeal exceptions to the system. however. Some important garrison towns were subordinated directly to Constantinople instead of to the provincial governor; some areas achieved a special status (Chios, for instance, becoming a private appanage of the empress-mother of the sultan); and other areas, because of their inaccessibility, were left virtually to their own devices (*e.g*, parts of Crete and of the Pindus mountains and some of the smaller islands). A varying measure of local autonomy in the administration of justice was also tolerated, especially in the Peloponnesus.

At the height of its power. Ottoman rule was not inhumanly oppressive. Its defect was that it was arbitrary and unpredictable, being too dependent on the character of individuals, especially on that of the sultan at the top. The Greeks' principal obligations were to pay the capitation tax (kharaj), which simply entitled them to remain alive in the sultan's dominions, the land tax, the tax on commerce and occasional special levies according to their circumstances and way of life; and to contribute male children (about one out of five on average) to the sultan's private service, to be brought up as janissaries (*q.v.*). The last was a cruel practice (though not always to the worldly disadvantage of the Greek children, who might rise through it to great heights), and it was abolished beiore the end of the 17th century. The taxes, however, were not in themselves exorbitant by modern standards. The vice of the system was that the Greeks received no rights—not even the 'elementary rights of justice and security—in return. The result was, on the one hand, that they turned increasingly to their own resources to manage their own affairs (especially to the priests and to the leaders of their own communities. known as prokritoi or primates); and. on the other. that in many areas lawlessness became endemic. in the form of the *klephtai* (brigands) and the scarcely more law-abiding *armatoloi* (men-at-arms or *gendarmes*) whom the Turkish government indiscriminately licensed to put down the brigands. Finally, the Greeks had one other course open to them in the ramshackle system which Ottoman administration became when the days of the great sultans were over; this was to penetrate and to usurp the system themselves, by climbing the rungs of power which the corps of janissaries and other opportunities opened to them. By the 18th century they had done this so successfully that four of the great offices of state (dragoman of the Porte. dragoman of the fleet and voivode or governor of each of the two Transdanuhian provinces, Moldavia and Wallachia) had become virtually Greek preserves. The Greeks who infiltrated the administration system in this way formed a distinct colony at Constantinople. known as the Phanariotes (from the Phanar, the quarter in which they lived).

All these factors contributed in different ways to the state of affairs which eventually made the liberation of Greece possible. But they took long to work in this direction. partly because the system was not generally felt to be sufficiently oppressive except in passing spasms. and partly because the contributory factors were to some extent contradictory in their operation. There was little common sentiment between the sophisticated Phanariotes of Constantinople and the priests and peasants of central Greece or the brigands in the mountains.

Such manifestations of opposition to Turkish rule as occurred up to the 18th century were as spasmodic and unpurposeful as Turkish oppression. Greek uprisings were generally in response to deliberate and unscrupulous provocation by external powers in the course of great wars fought for no interest of the Greeks, and the latter were then generally the victims of both sides. At the naval battle of Lepanto in 1571, for instance, between the Turks and the forces of Don John of Austria, Greek islanders were by force of circumstances serving in both fleets; and mainland Greeks who rose in revolt at the instigation of Don John were simply put down without mercy by the Turks and without help from their allies. In the following century, the invasion of the Peloponnesus by the Venetian general Francesco Morosini (whose guns were responsible for the destruction of the Parthenon at Athens in 1687) aroused not a spark of enthusiasm among the Greeks; and the return of the Turks to the Peloponnesus in the following generation was accepted as the lesser evil.

It was not until the intervention of the Russians in the 18th century that a serious revolt was promoted on Greek territory; and again the motives were unconnected with any real demand for national independence. Meanwhile, the influential Greeks of Constantinople were in effect pursuing quite a different policy of their own, which was not to disrupt the Ottoman empire but to take it over as a going concern.

The Rising of *1770* and *the* Beginnings of Nationalism.—The rising in the Peloponnesus in 1770 is virtually the beginning of modern Greek history. It was precipitated by the empress Catherine the Great of Russia as a diversion in one of the recurrent Russo-Turkish wars; but for the first time it struck a spontaneous response from the Greeks (especially the Peloponnesians) and thus came near to success.

The Russian claim to interfere in Greek affairs rested ostensibly on the possession of a common religion, which the tsars regarded themselves as entitled to protect, and on the inheritance of the Byzantine tradition as a result of the 15th-century marriage between the niece of the last emperor of Constantinople and the grand duke Ivan III of Muscovy, the first Russian to call himself tsar. In practice. the real motive lay in the advantage that a Russian liberation (which meant annexation) of Greece would give the tsars over the Ottoman rulers, by opening a backdoor to Constantinople.

The Greeks. however, welcomed the approaches of the tsar's agents for reasons of their own. In the Peloponnesus society was relatively advanced and ripe for self-rule and, being relatively well populated, that area suffered more than most from the land hunger which resulted from the rule that no land could pass from Turkish into Greek possession. The conjunction of a politically conscious and aggrieved upper class with a landless and therefore lawless lower class led naturally to a revolutionary mood.

The revolt of 1770, prepared and incited by Russian agents, took the Turks by surprise and was at first successful. But Russian help was late and inadequate (having to come by sea round Europe and through the Mediterranean); and, with the help of a bloodthirsty army of Albanians, the Turks eventually suppressed the rising in the Peloponnesus, the only area in which it reached serious proportions. The Russians quickly abandoned the Greeks in order to pursue the war with Turkey elsewhere and brought it to a relatively successful conclusion in the treaty of Kuchuk Kainarji (1774). An ambiguous clause in this treaty gave the Russians a right "to make representations" on behalf of the sultan's Christian subjects at Constantinople, and this provided the excuse for all future Russian interventions in Greek affairs.

After about nine years of barbarous repression by the Albanian forces of the sultan. the Peloponnesus recovered a normal level of existence and prosperity. But when Catherine the Great tried again in 1786 to provoke a similar rising against the Turks, the Peloponnesians had naturally learned their lesson too well to respond. The only response came from elsewhere. The inhabitants of Suli (Souli), in the province of Southern Albania, rose against the sultan and were savagely suppressed by the provincial governor. Ali Pasha, from his capital at Janina. The Russians again abandoned their allies, but this time the consequences were more pregnant for the future. Ali Pasha's appetite was whetted by success, and within 30 years he carved out for himself a large semi-independent slice of the sultan's empire, seriously weakening the strength and cohesion of the whole. This remarkable figure unwittingly played a large part in making possible the Greek revolution of 1821 (see Ali [called the Lion of Janina]).

Between the risings of 1770 and of 1821 history underwent a great change which decisively shifted the balance in favour of the Greeks. The American and French Revolutions, the rise and fall of Napoleon, the conflict of the great powers in the near east, the outbreak of nationalist revolutions as far away as South America and as near as Serbia, the weakness of the Ottoman empire as revealed by the virtual secession of Ali Pasha, the incitements of European liberals and poets, not only foreign (such as Lord Byron) but also native (such as Rhigas Pheraios). and the awakening of a national consciousness by native scholars (such as Adamantios Korais) as well as by merchants, politicians and priests all contributed to the outburst of 1821. The one factor that played relatively little part in bringing about the revolution was immediate Turkish oppression. It was rather the enfeeblement and relaxation of tyranny that fed the appetite for liberty, as it was the apparently imminent dissolution of the Ottoman empire that offered the opportunity of escape.

But the positive motives at work among the Greeks were dangerously confused. The aspirations of the different classes and regions were unreconciled. The Greek aristocrats of Constantinople. of the Transdanubian provinces and of the tsar's court had little in common with the peasants, priests and brigands of central Greece or with the wealthy merchant families of the islands; and no reconciliation had been attempted, or was possible, between those who looked to Russia, to England. to France or even elsewhere for patrons of Greek independence. The result was much confusion in the years of war (1821–29).

All the great powers had a more or less definite interest in Greek affairs by 1821. In Russia there mere considerable Greek colonies, including that at Odessa which in 1814 founded the Friendly society (Philiki *Etaireia*) with the express object of promoting a Greek revolution; and there were also highly placed Greek officials. including the tsar's foreign secretary Count Ioannis Capodistrias and his aide-de-camp Prince Alexandros Ypsilantis. The Austrian empire was hoping to encroach eastward and southward as the Ottoman empire disintegrated and was seeking to play the same role in the northern Balkans that Russia sought to play in Greece. England and France alternated in intrigue throughout the near east during the Napoleonic Wars. wooing Ali Pasha, the sultan and the dissident Greek leaders with arms, money and promises by turns. The fate of the Ionian Islands was typical of the whole complex of forces at work. They were taken by the French from Venice in 1797 and then occupied in turn by the Russians (1799), by the Turks (1800), by the French again (1807) and by the British (1814) in the space of 20 years; and one of their dependencies. the mainland port of Parga, mas even ceded to Ali Pasha by the British in 1817. From all such manoeuvres of power politics, the Greeks were simply the sufferers; but experience was teaching them how to take advantage of these rivalries. The Ionian Islands. under British control, were a haven where armed irregulars from the mainland could take refuge under pressure. Russia provided a base from which the Philikz *Etaireia* could mature its plans, as well as a school of statecraft where Greeks could learn their political trade Vienna was another haven of refuge and intrigue for Greek *émigrés*. The French were still reckoned the greatest soldiers of Europe even after Waterloo; and the fall of Napoleon released many military adventurers from whom the Greeks (as well as the Turks and Egyptians) could learn the art of war. Added to this was the newborn European liberal prejudice in favour of freedom. which provided the Greeks with money, arms, propaganda and philhellenes to fight at their side. Only the opportunity of revolt was needed. and this was finally provided by the open rebellion of Ali Pasha against the sultan Mahmud II in 1820. While the Turks were preoccupied with this dangerous threat, the Greeks in their turn rose in March 1821.

For the events of the ensuing seven years see GREEK INDEPENDENCE, WAR OF; NAVARINO, BATTLE OF.

The First Phase of Independence (1829–64).—Although Navarino made the independence of Greece a certainty. another two years pdssed before the fighting ended and nearly five before the new state took shape. Among the great powers, Navarino was not the end of a war but in effect the beginning of a new one. The sultan proclaimed a holy war (jihad) in Dec. 1827, and Russia declared war on Turkey in April 1828. France and Great Britain, who had striven for six years to avert this climax, reluctantly withdrew their ambassadors from Constantinople. It was not until the Russian armies had almost reached Constantinople that, by the treaty of Adrianople (Sept. 1829), the sultan formally accepted the independence of Greece as prescribed by the treaty of London (July 1827). which the battle of Navarino had been fought to enforce. From this date all the great powers and other contestants finally resigned themselves to the two complementary facts that Greek independence could not be reversed and that it did not entail the general dissolution of the Ottoman empire. Europe settled down with a new equilibrium of the near east.

Neither the boundaries nor the constitution of the new Greek state were yet settled. however. During the Russo-Turkish War of 1828–29 desultory fighting continued on the Greek mainland, almost neglected by the preoccupied powers, and even the army of Ibrahim Pasha remained at large in the Peloponnesus until a French expeditionary force was sent there in 1828 to ensure its withdrawal. While the conference of London debated at its leisure what should be the limits of the new state (varying from a minimum area, the Peloponnesus alone, to a maximum area bounded on the north by a line drawn from Volos to the Aspropotamos [Achelous]), the Greeks set about enlarging their territory uell beyond both the minimum and the maximum and lobbying to secure the addition of important islands such as Samos and Crete. They were helped by the military skill of British free lances, such as Sir Richard Church and Frank Abney Hastings (*qq.v*), as well as by the sympathetic connivance of French regulars, to install themselves well to the north of the Gulf and Isthmus of Corinth on both the western and eastern flanks of the Greek mainland during 1828–29, though they could not recover strongly held fortresses such as Athens. Foreign-born Greek leaders, such as Alexandros Mavrocordatos and Dimitrios Ypsilantis, also now played a notable part in consolidating Greek expansion, as well as popularizing Greek ambitions in terms familiar to the European courts; and above all, Count Ioannis Capodistrias (see KAPODISTRIAS IOANNES ANTONIOS, Count), formerly the tsar's foreign secretary, who had been elected provisional president of Greece by the third national assembly (April 1827) and arrived to assume office in Jan. 1828. conducted Greece's foreign affairs with the utmost skill and devotion

Capodistrias and His Successors—In his personal aspirations Capodistrias was less successful. He had a clear but autocratic idea of the way to run his new country, a strong, centralized government aith the last traces of local self-government suppressed; and without actually suggesting that his position should be made permanent. he clearly regarded himself as irreplaceable. Meanwhile the great powers, represented by the conference of London, cautiously sought a more orthodox settlement.

At the time of Navarino. they still had in mind a ruler of Greece who would remain the sultan's vassal. The treaty of Adrianople, by confirming Greece's unqualified independence, made this impossible and early in 1830 the throne of Greece was offered to Prince Leopold of Saxe-Coburg (the futute king of the Belgians, uncle of the future Queen Victoria), who at first accepted. Capodistrias, however, subtly hinted to him that the terms of the offer mere inadequate to ensure Greece's viability, and he withdrew his acceptance. Capodistrias continued his presidency while another candidate was sought, and he grew steadily more unpopular. not with the ordinary people, who benefited by his firm rule. but with the "primate" families (such as Koundouriotis of Ydra [Hydra] and Mavromikhalis of Maina) who had expected to inherit the Turkish feudal system under their own mastership, with the liberal-minded constitutionalists (led by Mavrocordatos, who refused to take office under the president) and with most of the irregular leaders of the war (except Theodoros Kolokotronis, who loyally supported Capodistrias and became his licensed tax gatherer, on characteristically unorthodox principles). To the natural dissensions of the Greeks were added the intrigues of the three official resrdents. Russian, British and French, who mere appointed to look after their countries' interests in Greece from 1828.

The end of Capodistrias' unequal struggle with confusion came on Oct. 9, 1831. when he was assassinated at Nauplia (the first capital of Greece) by two members of the Mavromikhalis clan. He was succeeded by a triumvirate consisting of his brother Agostino (Avgoustinos) with two of the wartime leaders, Ioannis Kolettis and Kolokotronis; but anarchy soon supervened. Agostino fled the country in April 1832, and Kolettis and Kolokotronis each tried to establish a government of his own (the former supported by Mavrocordatos, and each supported by a private army of irregulars). The chaos was mitigated only by the continued presence of a reduced French force to keep order in the Peloponnesus, until at last the conference of London reached its final decision, which was embodied in a convention signed on May 11, 1832 (but dated May 7, because the British government had meanwhile fallen in the crisis of the Reform bill). By this convention Greece was established as an independent kingdom, under the protection of Great Britain. France and Russia with its northern boundary from the Gulf of Volos to the Gulf of Ambracia. and including some of the Aegean Islands (but not Crete or Samos, for which

Capodistrias had fought in vain). Louis I of Bavaria, who was also a party to the convention, accepted the Greek throne on behalf of his 17-year-old son Otto (*q.v.*) who arrived at Nauplia on Feb. 6, 1833, and endeared himself by at once adopting the Greek national costume and the Greek spelling of his name, Othon. He was accompanied by three Bavarian advisers, as well as by a garrison of Bavarian troops to replace the French; and for the next ten years the government of Greece was virtually a Bavarian monopoly.

Otho.—The accession of King Otho (as he is usually called in English), backed by a generous loan from the protecting powers, was looked upon as the beginning of a new golden age for Greece. There were certainly agreeable episodes to record in the immediately following years: the transfer of the capital from Nauplia to Athens (1834); Otho's coming of age (1835) and marriage to Amalia of Oldenburg (1836); the foundation of the University of Athens (1837); and the establishment of diplomatic relations with Turkey (1839). But they were no more than episodes, and the political background was more ominous.

There were constant disorders in different parts of the kingdom, chiefly the result of discontentment of the wartime leaders who had been set aside in favour of Otho's new Bavarian administrators. There were major outbreaks of brigandage on the mainland in 1834–36 and again in 1839, and in the latter year conscription was first instituted. There was a revolt in Crete in 1841, a year after the island had been restored from the Egyptian province of Mohammed Ali to the direct rule of the sultan Abd ul-Mejid; and although this was juridically no business of the new Greek kingdom, it was one of many incidents that helped to remind the Greeks that only a small part of their racial and religious kinship was under independent rule.

Above all, there was resentment of the alien and untactful rule of the Bavarian clique led by Josef Ludwig, Count Armansperg, who was in effect absolute ruler of Greece from 1834 to 1837, though his title mas changed from "president of the regency" to "archchancellor" when Otho came of age. It was not until Dec. 20, 1837, that a Greek. Konstantinos Zographos, was first appointed as the king's chief minister, and even thereafter the Bsvarians continued to hold the ministry of war and to penetrate the administration effectively at many levels.

Resentment came to a head in 1843. On the night of Sept. 2–3 the royal palace was surrounded by a rebel force led by veterans of the War of Independence, whose chief demands were the removal of the Bavarians and the establishment of a constitution. It was a typically Greek revolution, conducted almost without bloodshed, with much ebullient good humour and almost no bitterness (except against the Bavarians) and with a strong streak of conservatism and personal affection for the king. As soon as Otho had given way he became a national hero and the occasion a national holiday. A national assembly was convened (attended significantly by representatives from the unliberated areas of Thessaly, Macedonia and Epirus) which drew up a constitution providing for a lower house (*vouli*) and a senate (yerousia) This constitution, to which the king took his 'oath in March 1844, remained in force for 20 years.

There followed a period of domestic quiescence, marred only by disagreeable episodes in Greece's foreign relations. With Great Britain there were a number of points of friction which did little credit to the protecting power. The British government was entitled to claim, as it vigorously did, the payment of interest on the international loan in 1847, as well as compensation for losses arbitrarily inflicted on British subjects (including the philhellene historian George Finlay and the Gibraltar Jew Don Pacifico); but hardly to enforce the claims, as Lord Palmerston insisted on doing in Jan. 1850, by ordering the Mediterranean fleet to blockade Piraeus (Peiraeeus) and openly hinting an intention to annex two minor islets alleged to have formed part of the Ionian Islands. Palmerston's undignified conduct nearly brought down the government in which he was foreign secretary; he narrowly averted a vote of censure by one of the most celebrated speeches of his career. The British claims were reduced and met, but Otho came out of the episode with greatly enhanced prestige for his courageous refusal to be bullied. Unfortunately this success led him into a more foolhardy act of defiance four years later and to a passionate devotion to the cause of Greek irredentism known as the "Great Idea" (Megali Idea).

In the Crimean War the British and French sided with Turkey against Russia. Imprudently, but for obvious reasons, the Greeks sided with Russia, and Otho took the lead with strong popular support in an attempt to enlarge Greece's territory. There had been no major breach of the peace between Greece and Turkey for 25 years, though brigandage and frontier incidents had led to a brief rupture of diplomatic relations in 1847. Now the Greeks seriously set about trying to conquer Thessaly and Epirus. In Jan. 1854 they entered Epirus and defeated the Turks at Peta; in Thessaly they had little success. The Turks sent an ultimatum to Greece in March and began to expel Greeks from Smyrna and Constantinople in reprisal. In May British and French troops were landed at Piraeus to enforce Greek neutrality, and the occupation lasted until 1857. Greece's frontiers thus remained unchanged and its appetite unappeased. Otho, too, as the leader of Greek irredentism and the victim of the great powers' disciplinary action. reached the height of his popularity.

At the same time Greece's relations with Great Britain were exacerbated by the question of the Ionian Islands. which had been left under British protection by the treaty of Nov. 5, 1815. The national feeling of the Greek inhabitants of the islands had reached a dangerous intensity, which produced a serious rising on Cephalonia in 1849. Their future now became fortuitously connected with the unhappy end of Otho's reign. Otho misused his popularity to behave autocratically at home, while distracting his subjects with the prospects of fresh acquisitions of territory abroad. Despite a succession of patriotic Greek prime ministers, including several heroes of the War of Independence (Mavrocordatos. Kolettis, Kitsos Tzavelas, Georgios Koundouriotis, Konstantinos Kanaris), the king never fully accepted the role of a constitutional monarch. Opposition to him grew, first breaking out in a mutiny in the garrison of Kauplia in Feb. 1862.

This was suppressed, but by October trouble was again brewing. While Otho and Queen Amalia were on a tour of the Peloponnesus, the revolt began in Aetolo-Acarnania on Oct. 19 and spread to Athens on Oct. 22. Otho arrived back in his naval frigate on the following day to find a provisional government in power under Dimitrios Voulgaris, which had proclaimed his deposition and also its intention to maintain the monarchy. Otho never set foot in his capital again. The protecting powers recognized that the Greeks were acting within their rights in deposing their monarch and set about the search for a successor. More than a year passed before the right man was chosen.

It was at this point that the future of the Ionian Islands became bound up with the question of the Greek monarchy. For nearly half a century the British government had argued that its protectorate over the islands was essential to its security in the Mediterranean, though they had played no strategic role in events since the Napoleonic Wars. As recently as May 7, 1861. the chancellor of the exchequer, W. E. Gladstone (who had served briefly in the islands as lord high commissioner extraordinary in 1858–59) had stated that "it would be nothing less than a crime against the safety of Europe" to cede the islands to Greece. Yet exactly 18 months later. on Dec. 8, 1862. the British cabinet decided to renounce the protectorate in favour of Greece, and by the end of the year the decision was widely known to have been taken. (It has even been contended that the prime minister, Lord Palmerston, had personally reached this decision before the fall of Otho, that he offered the islands to Otho on condition that he would refrain from all provocation of Turkey, but that Otho refused.) In Greece the widespread knowledge of this new intention contributed to a characteristic revulsion of feeling in favour of Great Britain, which startlingly expressed itself in a plebiscite on the succession conducted in Dec. 1862. Out of 244,202 votes, 230.016 were given to Queen Victoria's second son. Prince Alfred, whom the British government had already officially declared ineligible, as being a member of the ruling family of one of the three protecting powers.

Various candidates of other powers were similarly ruled out.

Finally the search ended with the choice of the 17-year-old William, second son of the heir to the throne of Denmark. On June 5, 1863. representatives of the three powers and Denmark signed a protocol in London recognizing his election (which the Greek assembly had enthusiastically carried two months earlier) to the vacant throne on the explicit understanding that the Ionian Islands would be ceded to Greece.

The treaty of cession was signed in London on Nov. 14, 1863, by representatives of Great Britain, France. Austria. Prussia and Russia (the powers which had established the protectorate) and confirmed by a further treaty between Greece and the three protecting powers (Great Britain. France and Russia) on March 29, 1864. The new king. who took the title "George I of the Hellenes" (his predecessor had been "king of Greece"), had arrived in Athens on Oct. 30, 1863. and the British evacuation of the Ionian Islands was completed by the following June.

The New Monarchy (1863–1924).—The half century of King George I's reign (1863–1913) was an epoch in itself in modern Greek history. an epoch in which Greece grew to the status of a power in its own right (even if still a minor one) instead of a semi-dependent ward of other powers (though the "protectorate" of Great Britain. France and Russia nominally lasted till 1919). The period was notable for the most considerable (but not the last) increases of Greek territory. Thessaly, most of Greek-inhabited Epirus and Macedonia, Crete and the majority of the Aegean Islands (except the Dodecanese) were added to the kingdom of the Hellenes. These advances were not achieved without setbacks, which mere chiefly due to political instability at home; and the seeds were sown of troubles that were to bedevil the future—notably those of the constitutional dispute between supporters and opponents of the monarchy and those of mutual hostility between Greece and other successor states of the Ottoman empire (chiefly Bulgaria and Albania), which previously had either not existed or been separated from Greece by the surviving extension of Turkey in Europe. Nevertheless, it was also in this period that Greece produced its first two statesmen of recognized European eminence: Kharilaos Trikoupis (1832–96) and Elevtherios Venizelos (1864–1936). These two men differed from their numerous rivals not in the fervour of their support for Greece's expansionist claims, which were the main political issue of the period, but in the wisdom with which they recognized that the country needed sound administration in support of them.

On his accession, the new king inherited a legacy of political confusion bordering on anarchy and even violence. A succession of ministries came and went during his first year. But a clean break with the past came with the inauguration of the new constitution. to which he took his oath in Nov. 1864. It was highly democratic. It abolished the senate, replacing it with a council of state appointed by the crown (abolished in its turn a year later); it established elective local government; and it defined the position of the king, which was in effect that of a passive instrument of the will of the people.

This system came to be described, by an inversion of the usual term, as a "monarchical democracy" (*vasilevomeni* dimokratia); and there is a happy irony in the phrase, since dimokratia is also the Greek for "republic." King George I operated this constitution conscientiously and successfully for 47 years, until it was revised in 1911. He was also luckier than his predecessor in not being accompanied by a foreign garrison; and although he had Danish advisers in his train, the most unpopular of them, Wilhelm Carl, Count Sponneck, left Athens in 1865. Greece was at last truly free—free to becomegreat.

The Cretan Rising, 1866.—Though relative tranquillity was restored at home. the new reign's troubles abroad began soon. In 1866 the Cretans rose in revolt against Turkish rule, which in its decline had become truly oppressive. The sultan. Abd ul-Aziz, sought not only to suppress the revolt but to transfer Crete back to Egyptian rule. A self-constituted Cretan assembly retorted by proclaiming its union with Greece, and although the king and government could not afford the risk of accepting the decision, many volunteers went from the mainland to support the islanders in arms.

The Cretans appealed to the great powers, of whom Great Britain alone was opposed to the solution of a plebiscite. In particular. European opinion was stirred by the heroic end of the monastery of Arkadi. whose abbot blew it up with the garrison and its attackers together rather than surrender alive. Though the revolt was crushed, the intervention of the powers obliged the sultan to grant administrative reforms, which mere embodied in the organic statute of 1868.

The Cretan problem, which was to be virtually coextensive with George I's reign, was thus shelved again. The sultan took his revenge on the Greeks two years later by creating in 1870 the Bulgarian exarchate, a separate ecclesiastical organization for Bulgaria, independent of the Greek Orthodox patriarchate which had been for so many centuries the unifying force of the Ottoman empire's Christian subjects.

The Russo-Turkish War, 1877–78.—The second crisis of the new reign mas precipitated by the Russo-Turkish War of 1877–78. As in the Crimean War, many Greeks saw in it an opportunity to acquire Thessaly, if not Epirus and Crete as well. But a coalition government, in which Trikoupis was foreign secretary, held them in restraint, in the well-grounded expectation that the great powers would sympathetically consider Greek claims at the peace settlement.

Russian victories. however, swept aside these restraints. The government fell. and its successor was only withheld from armed intervention by British mediation and by the collapse of Turkish resistance in Jan. 1878. In the treaty of San Stefano (March 3, 1878) between Russia and Turkey. Greece's territorial claims were ignored in the interests of creating "Greater Bulgaria" as a Russian satellite, with access to the Mediterranean and practically the whole of Macedonia incorporated in it.

The other powers refused to accept this settlement, which was upset by the Conference of Berlin (June 1878); but still Greece received no satisfaction, beyond an injunction to the sultan Abd ul-Hamid II to reach an agreement with King George for the modification of their common frontier. The fulfilment of this injunction was dragged out until 1881, when a conference at Constantinople finally defined a new frontier between Greece and Turkey from the southern slopes of Mt. Olympus in the east to the Arachthos river in the west, giving Greece the greater part of Thessaly and a small corner of Epirus. It was in 1878, after the rejection of the treaty of San Stefano, that Great Britain secured the right to occupy Cyprus (which it did not formally annex until 1914), in return for a guarantee given to Turkey that its Asiatic provinces should be untouched.

Trikoupis.—Between the acquisition of Thessaly in 1881 and the next great foreign crisis in 1896, the domestic scene in Greece was dominated by Trikoupis. He became prime minister early in the '80s and remained in power, with brief and generally unfortunate intervals, until his final resignation in Jan. 1895. During this period great advances were made in Greece's domestic administration. Roads and railways were extended. the merchant navy was expanded, brigandage was virtually suppressed and the financial administration was put on a sound basis which attracted the confidence of foreign investors. But this progress was subject to abrupt setbacks whenever Trikoupis' chief rival, Theodoros Diliyiannis. a crafty but hotheaded parliamentarian, succeeded in replacing him.

One such damaging occasion was shortly before the crisis provoked in Sept. 1885 by the Bulgarian annexation of Eastern Rumelia (part of the territorial expansion which in 1878 Bulgaria had briefly gained at San Stefano and lost again at Berlin). Public opinion in Greece demanded compensating gains at Turkish expense. and Diliyiannis mobilized the army and navy. A brief war broke out between Bulgaria and Serbia, but the great powers intervened before Greece could begin hostilities against Turkey, and by the familiar method of a naval blockade Great Britain compelled the Greek government to abstain and to demobilize in May 1886. Diliyiannis' government fell, and Trikoupis returned to power. He dealt competently with the financial setback caused by Diliyiannis' militant policy and retained the confidence of the king and people for nearly seven years. Even after Trikoupis' party had been defeated in a general election in 1890 (largely for having adopted a pacific policy in one of the recurrent Cretan crises in 1889). the king reappointed him prime minister in 1892, after dismissing Diliyiannis for incompetence. This was the boldest constitutional step of George I's reign.

***Crete** and Macedonia,* 1896–1912.—It was after Trikoupis' death (in April 1896), when Diliyiannis was again prime minister, that the next major crisis in Greece's foreign affairs occurred, again over Crete. The chronic bitterness between Cretans and Turks broke out in violence and bloodshed at Canea, the administrative capital, in May 1896.

This time it was Diliyiannis' turn to exercise restraint and to accept Turkish promises of reform. But these were not carried out, and the deteriorating situation culminated in a further outbreak of violence at Canea in Feb. 1897. Diliyiannis announced that Greece could no longer remain indifferent and sent an armed force to annex the island. Thereupon Great Britain, France, Russia, Italy. Germany and Austria proclaimed an international protectorate and also landed troops. The familiar intervention of the great powers exasperated Greek public opinion to the point of demanding general war on Turkey; and in March 1897, while the expedition to Crete was still indecisive, the crown prince Constantine put himself at the head of the Greek forces in Thessaly in readiness for war. Hostilities were at first limited to skirmishing by irregular bands; but Turkey declared war on April 17, and Greece was defeated in a brief and humiliating campaign ***(see*** GRAECO-TURKISH WAR, 1897). Peace was eventually signed in Dec. 1897. on milder terms than at first seemed probable. Greece naturally had to withdraw from Crete. which remained under the occupation and protection of the great powers, and minor modifications were made to the northern frontier in Turkey's interest, but the indemnity originally demanded was reduced from £T10,000.000 to £T4,000,000. The prestige of the royal family suffered severely, until a characteristic reaction set in after an attempt to assassinate the king in Feb. 1898.

The repulse of Greek claims to Crete and Macedonia was looked upon as no more than temporary, and the two territories largely occupied political attention in Greece for the next 15 years, until the chance of a final settlement came. In Crete the disturbances of 1896–97 even represented a slight immediate advance for the Greek cause. The protecting powers (reduced to four by the withdrawal of Germany and Austria) proclaimed the administrative autonomy of the island; and after a further outbreak of violence in Sept. 1898 (in which the British vice-consul at Herakleion [Iraklion] and a number of British soldiers were killed) they insisted that all Turkish troops should leave the island and invited Prince George of Greece (the king's second son) to become high commissioner under the nominal suzerainty of the sultan. Prince George arrived in Crete in Dec. 1898, originally for a term of three years which was eventually prolonged till 1906. His tenure was unfortunately marred and. finally, terminated by a dispute with a group of Cretan politicians, led by Elevtherios Venizelos, who seceded in March 1905 to set up a "provisional government" of the island at Therison.

Prince George was replaced in 1906 by Alexandros Zaimis, a former prime minister and one of the most eminent, popular and respected statesmen of modem Greece, under whose auspices Venizelos became the leading figure in the Cretan administration. Tranquillity and order were so effectively restored that in July 1908 the great powers felt justified in beginning the withdrawal of their forces from the island.

At almost the same date, an event took place at the other end of the Greek world which entirely upset the powers' calculations. This was the Young Turks' revolution, which set up the Committee of Union and Progress at Salonika, the principal town in Macedonia. Having first compelled the sultan Abd ul-Hamid to restore the lapsed constitution of Turkey, the committee then deposed him in 1909 and effectively ruled the Ottoman empire in the name of his successor Mohammed V; but toward the Christian minorities it pursued a forceful and hostile policy that resurrected all the Greeks' latent fears for the future of Macedonia. Since the end of the 19th century a state of undeclared civil war between Greek, Bulgarian and Turkish irregulars had prevailed in Macedonia. somewhat like the situation in southern Greece before the War of Independence. The Young Turks' revolution now worked a widespread transformation in the whole Balkan scene. It brought together Greeks, Bulgars and Serbs in the common interest of frustrating the "Ottomanization" of Macedonia; it provoked the Cretans yet again to declare the union of Crete with Greece in Oct. 1908 and to send a delegation (including Venizelos) to Athens to give effect to their decision; and it led to the formation in the Greek army of the Military league (May 1909) in imitation of the Committee of Union and Progress. Although the Greek government pursued the juridically correct course of disowning the Cretan proclamation of union. the Military league succeeded in forcing many of its wishes on the king, including the dismissal of his sons from military and naval commands and the summoning of Venizelos to Athens in an official capacity in Jan. 1910.

From March 1910, when the Military league dissolved itself on the completion of its task, Greece moved swiftly to the climax of the Balkan Wars. A national assembly was elected in August. at Venizelos' instigation, to revise the constitution, but when it proved unamenable to his wishes, Venizelos, having become prime minister for the first time on Oct. 18, dissolved the assembly and held a second election'in December. From this election, which gave him a large majority, dated his extraordinary ascendancy over the Greek political scene.

His revised constitution was promulgated in June 1911; his peace was made with the royal family (the crown prince Constantine being restored to high command by the creation of the new post of inspector general of the army); the election of a chamber of deputies under the constitution of 1911 gave Venizelos a majority of five to one in March 1912; and he was ready to set about the creation of the Balkan league, which was to destroy the Ottoman empire in Europe. Still, however, he would not admit the Cretan representatives to the new chamber until he was ready and strong enough to face the consequences.

The Balkan Wars, 1912–13.—During the summer of 1912 treaties were concluded between Bulgaria and Serbia and between Bulgaria and Greece; Serbia and Greece had no conflicting interests and no formal alliance as yet. In October the three govemments presented joint demands to Turkey for reforms in Macedonia, which were unacceptable. Turkey declared war on Bulgaria and Serbia on Oct. 17. Venizelos at last admitted the Cretan representatives to the chamber and declared war on Turkey on Oct. 18. The First Balkan War ***(see*** BALKAN WARS, 1912–13) lasted seven months, interrupted by an armistice (December-January) for peace negotiations in London, in which Greece participated without formally accepting the armistice. The war was a tremendous success for the Balkan allies, not least for Greece, whose armies captured Salonika, Preveza, Parga and Janina in succession, besides the acquisition of Crete, Samos and other islands. Constantine, who fully redeemed his reputation as a commander, succeeded to the throne on March 18, 1913, when King George I was assassinated in Salonika.

Salonika was the point of friction between the allies, of whom the Bulgars at least also hoped to acquire it. Even before the defeat of the Turks was complete, Greece and Serbia began to negotiate a treaty of alliance specifically against the danger of attack on either by their ally, Bulgaria. The First Balkan War was terminated on May 30, 1913, by the treaty of London, which virtually abolished the Turkish empire in Europe. Among other dispositions, it ceded Macedonia to the Balkan league as a whole and left the disposition of the Aegean Islands to the powers. Two days later, the Graeco-Serbian treaty was signed, and within a month the Second Balkan War had begun with a Bulgarian attack on the two allies on June 30.

The Second Balkan War, in which Rumania joined Greece and Serbia, ended in a rapid defeat of the Bulgars and a considerable recovery of lost ground by the Turks. It was ended by the peace of Bucharest on Aug. 10, 1913. Bulgaria was treated generously and still. retained part of Macedonia and an outlet to the Aegean sea in western Thrace.

The fate of other areas liberated from Turkish rule by the upheaval of the two Balkan Wars was still not completely settled even when World War I broke out a year later. For instance, the Greeks continued to claim northern Epirus, part of the newly created state of Albania; the Turks refused to withdraw from several of the Aegean Islands; and the Italians remained in the Dodecanese, which they had occupied on an ostensibly temporary basis in 1912. Relations between Greece and Turkey remained bad, and the Balkans seemed to be again on the brink of another convulsion when the outbreak of World War I in Aug. 1914 merged their parochial problems in the great upheaval of Europe.

World War I and Asia *Minor*.—World War I opened up a bitter difference between the king and Venizelos that lasted beyond their lifetimes and divided Greeks for a generation into royalists and republicans. The cause was that the two men and their advisers disagreed on the likely course of the war and consequently on the interpretation to be put on the Graeco-Serbian treaty in the event of Bulgaria's joining the Central Powers in hostilities against Serbia (who was from the first an ally of the Entente). Venizelos believed in and hoped for a victory of the Entente. Constantine was more uncertain of the outcome and therefore preferred neutrality, with a sympathy toward the Central Powers. The Greek general staff, especially the chief of staff, Col. Ioannis Metaxas (later prime minister). in the main supported the king with their military judgment. Though the crisis was not reached until Sept. 1915, when Bulgaria mobilized to attack Serbia, the two attitudes were clear from the start, when in Aug. 1914 the king assured the German emperor William II (whose sister Sophia he had married) that he. though officially neutral, was on Germany's side in sympathy; and two weeks later Venizelos gave the Entente to understand that his sympathies were wholly with them and that Greece would enter the war on their side if Turkey did so against them. Turkey in fact entered the war against the Entente in Nov. 1914, which was also the occasion of the British annexation of Cyprus.

At this juncture the king's will prevailed, supported as he was by his chief of staff, and he was able both to keep Greece neutral and to retain Venizelos as his prime minister. The struggle between Venizelos and the general staff came to a head in March 1915, when the king dismissed his prime minister rather than accept the resignation of Metaxas. In Venizelos' place the king nominated Dimitrios Gounaris, who unfortunately chose to represent Venizelos as motivated by spite against the royal family. Gounaris retained power even after a general election in June had given Venizelos' party (the Liberals) a small majority. Venizelos was recalled to office only in August and dismissed again in October, but in the interval there had occurred the decisive events of Bulgaria's mobilization to attack Serbia, Greece's countermobilization and the arrival at Salonika of Allied forces on Venizelos' invitation. To restore the situation the king appointed Zaimis prime minister, with instructions to repudiate Greece's obligations under the Graeco-Serbian treaty on the grounds that they applied only to "a war between one of the allied states and a single other power," not to a general European war. Even Great Britain's offer to cede Cyprus to Greece did not sway the new government, and it was soon withdrawn. Greece remained neutral; the king dissolved the pro-Venizelist chamber; and the Liberals abstained from the new elections of Dec. 1915 in protest.

Neither Venizelos nor the Allies took further drastic measures against the king's government until after the discreditable surrender of Ft. Rupel, on the Bulgarian frontier, to the Germans and Bulgars in May 1916. There then followed a series of increasingly strong Anglo-French ultimatums and, in September, Venizelos' secession from Athens to Crete, whence he proceeded to Salonika to set up a rival government. Although the Allies' terms were repeatedly met by King Constantine's successive governments on paper, they grew steadily stiffer (especially after Dec. 1, 1916, when Allied troops landing at Piraeus were fired on by the king's troops as they approached Athens); and they culminated on June 11, 1917, in a demand that Constantine should leave the country, which he did the next day. His second son Alexander succeeded him (the crown prince George being both unwilling and unacceptable to the Allies). On June 26 Venizelos returned to Athens from Salonika as prime minister, and on June 29 Greece declared war on the Central Powers. Greek troops were not in action on the Macedonian front until May 1918, but they played a distinguished part in the final offensive in September and contributed an army corps to the French expedition into the Ukraine in December. Venizelos' subsequent triumph at the conference of Paris (*q.v.*) was the climax of his achievement.

As early as Jan. 1915 the Entente had tried to tempt Greece into the war with the promise of territorial gains on the coast of Asia Minor. Venizelos exacted fulfilment of this promise, and the Allied supreme council in Paris authorized the landing of Greek troops at Smyrna in May 1919. This was the beginning of disaster both for Venizelos and for Greece. He himself spent too long for his own good away from Athens, achieving diplomatic triumphs; securing, for instance, the treaties of Neuilly and Shvres (*qq.v.*), terminating the war with Bulgaria and with Turkey respectively; the agreement with the Italian foreign minister T. Tittoni (July 1919) on the terms of cession of the Dodecanese (*q.v.*) to Greece; an extension of the Greek area of occupation in Turkey (July 1919), almost an agreement on the cession to Greece of northern Epirus (which only Pres. Woodrow Wilson opposed); and, not least, the admiration of all the Allied representatives. But within two years the greater part of this edifice had collapsed. In Sept. 1920, on returning to Athens, Venizelos dissolved the chamber; in October King Alexander died; in November Venizelos was defeated at the polls; in December Constantine was restored to his throne on the crest of a wave of emotion; and in the following year the occupation of Smyrna developed into a catastrophic war with the resurgent power of Turkey under Mustafa Kemal. The Greeks, ill-advised or imperfectly restrained by imprudent western politicians, launched a general offensive in Asia Minor in March 1921, which was defeated and then, in July, obstinately renewed. By September they were in full retreat.

In October the prime minister, Gounaris, appealed to the British government to intervene, while at the same time the French government entered into an accord with Mustafa Kemal. The British government, being itself disunited on policy in the near east, was unable to rally its allies to a common policy, and by 1922 Greece's position was desperate. In Aug. 1922 the Turks launched a final devastating offensive, which drove the Greeks out of Asia Minor and almost totally destroyed Smyrna in September. The remnants of the Greek army rallied on the island of Chios under Gen. Nikolaos Plastiras, who put himself at the head of an antiroyalist revolution. Constantine, blamed for the disaster, left the throne to the crown prince George, and six of his principal ministers and generals (including Gounaris) were court-martialled and shot under Plastiras' orders.

There followed one of the most erratic and unhappy periods in modern Greek history. The war with Turkey was finally liquidated by the treaty of Lausanne (July 24, 1923), which superseded the unratified treaty of Shvres. An agreement for the compulsory exchange of Moslem and Orthodox populations between Greece and Turkey under the supervision of a commission of the League of Nations, following the similar Graeco-Bulgarian agreement of 1919 (which, however, was on a voluntary basis), left Greece with a more homogeneous population, but also with nearly 1,500,000 refugees to assimilate. The country's troubles were aggravated by an incident on the Graeco-Albanian frontier in Aug. 1923, which led to an Italian bombardment of Corfu and to the imposition of a heavy indemnity by the League of Nations, and by an abortive military rising in Macedonia in October, the promotion of which was attributed to the retired chief of staff, General Metaxas, and other royalist officers.

General Plastiras' revolutionary committee accordingly asked the young king, George II, to leave the country (which he did in Dec. 1923) while the future of the monarchy was decided. Anxious to restore constitutional government, the committee held elections on Dec. 16, which were won by the Liberals. The committee then resigned, in Jan. 1924, and after a brief tenure of office by Venizelos (who resigned in February) a republic was proclaimed on March 25 and confirmed retrospectively by a plebiscite on April 13. Adm. Pavlos Koundouriotis, scion of a family famous in the War of Independence and himself a hero of the First Balkan War, became first president.

The Republic (1924–35).—The new republic made an uneasy start, marred by friction with all its immediate neighbours to the north and also with the great powers. The British minister had actually been withdrawn after the execution of the six royalist leaders. Little more than a year after the republic's proclamation, and before it had a constitution, power was seized on June 26, 1925, by Gen. Theodoros Pangalos, one of the few soldiers who had been successful in the recent war with Turkey; and on Jan. 3, 1926, he assumed dictatorial powers. Koundouriotis resigned and was replaced by the dictator himself after a travestied election. Pangalos was an eccentric though not a brutal ruler, but his methods were dangerous and had virtually precipitated a war with Bulgaria in Oct. 1925, which only the intervention of the League of Nations forestalled. He held power only until Aug. 22, 1926, when he was deposed by another military coup d'état, led by Gen. Georgios Kondylis with the support of Col. Napoleon Zervas at the head of a semiautonomous force called the Republican guard. Kondylis hastened to restore normal government. He dissolved the Republican guard with some bloodshed in September; he restored Koundouriotis to the presidency; he organized elections in November; and after a coalition government had taken office under Zaimis, he retired from the scene. With some reconstructions, the same government held office until May 1928, and in the meantime a new constitution (which re-established the senate) was promulgated on June 3, 1927. The occasion of the government's fall was a crisis precipitated by the return from abroad of Venizelos, after several years' absence, in March 1928. He became prime minister on July 3, dissolved the chamber a week later and won a large majority at the general election in August.

Venizelos then held office for nearly four years (until May 1932), during which time he was largely successful in restoring normal relations with all Greece's Balkan neighbours. In Oct. 1928 an agreement was signed with Yugoslavia (which had denounced the Graeco-Serbian alliance of 1913 in Nov. 1924) to negotiate all outstanding differences; in November a convention was signed with Albania; and in the same month a Greek minister was sent to Sofia for the first time since the war. There followed negotiations with Bulgaria on compensation for the property of exchanged populations in Jan. 1929; a treaty of friendship with Yugoslavia in March 1929; treaties of conciliation and arbitration with Hungary and with Austria in 1930; and a final settlement of outstanding differences with Turkey in June 1930. At the end of Oct. 1930 Venizelos paid an official visit to Ankara (Angora). Meanwhile the League of Nations' Refugee Settlement commission had wound up its work at the end of 1930. The republic (of which Zaimis had been elected president in succession to Koundouriotis in Dec. 1929) had begun to appear stable and accepted. But beneath the surface there were still hostile currents.

A financial crisis in 1932 weakened Venizelos' position. His government finally fell over two measures which showed that the constitutional quarrel was not dead. One was to change the electoral system to that of proportional representation, the other to restrict the freedom of the press, which the royalists, under the leader of the so-called Popular party, Panayiotis Tsaldaris, were alleged to be abusing. After two short-lived governments (the second again under Venizelos), a dissolution and a general election followed in September, under the system of proportional representation.

The result was to elect many small groups (including the Communists) with no clear majority for any party. Tsaldaris formed a precarious coalition which fell in Jan. 1933. Another general election in March 1933 (by majority voting) gave Tsaldaris a sufficient lead to form a stable government, and it was this government which crowned Venizelos' work by signing a Balkan defense pact with Rumania, Turkey and Yugoslavia in Feb. 1934. But by the following year a state of near deadlock had been reached between the two principal parties, Tsaldaris' Populists and Venizelos' Liberals, the latter of which controlled the senate while the former controlled the chamber. A bitter battle was fought before the two agreed on the re-election of Zaimis as president in April 1934. The real issue was becoming increasingly plain: it was the Populists' intention to restore the monarchy.

The Monarchy Restored.—In March 1935 an abortive coup d'état was staged with the object of putting Venizelos in power and frustrating the royalists. Its failure was the end of Venizelos' career and made the restoration of King George II a certainty. Kondylis, who put down the rising, was made deputy premier; and after a general election in June, he took part in a coalition government of the right wing under Tsaldaris. After internal disputes about the restoration of the monarchy (which were procedural rather than substantive) Kondylis himself became first prime minister and then regent. He organized a plebiscite on Nov. 3, which approved the restoration of the monarchy; and King George was back in Athens by the end of the month. The constitution of 1911 was restored in place of that of 1927.

But the settlement was still uneasy. At a general election in Jan. 1936 the balance rested almost evenly between a Liberal and Republican group led by Themistoklis Sophoulis in succession to Venizelos and a right-wing coalition of the parties of Tsaldaris and Kondylis and the tiny group led by Metaxas, the former chief of staff. Between these two coalitions the balance was held by 15 Communists. A succession of deaths in the first half of 1936 left Metaxas the only possible prime minister, and on Aug. 4, 1936, he converted his position into that of a dictatorship, with the king's consent, in order to forestall the threat of a Communist coup d'état under cover of a general strike, which had been fixed for the following day.

Metaxas' blow to the constitution and, especially, the king's acquiescence in it reopened bitter feelings between royalists and republicans, but probably saved Greece from anarchy. There followed four years of severe but efficient government, leading up to Greece's entry into World War II in Oct. 1940.

World War II.—The Fourth of August, as Metaxas' regime was called, produced administrative efficiency, a sound currency and adequate defenses, at the expense of some constitutional liberties and of the whole parliamentary system. It was ferociously hostile to the Communists (and to others arbitrarily designated as such) but otherwise benevolent and not unpopular. Metaxas had been expected by many to side with Germany and Italy in the world struggle which was already developing. His military training was German, and so was the sense of discipline which he tried to impose on his individualistic people; and his judgment in World War I had set him at variance with the western Entente. In fact, however, he sought first to strengthen the Balkan pact inherited from Venizelos, which was extended by a nonaggression treaty with Bulgaria in July 1938; and second, to avoid provoking any power, especially Germany. He was anything but timid toward Italy, against whom Greece had joined in voting sanctions in 1935. He accepted a British guarantee of Greece's frontiers in April 1939, after Italy's annexation of Albania, but he remained neutral on the outbreak of World War II and continued so even after an Italian submarine had sunk a Greek cruiser at Tenos in Aug. 1940. On Oct. 28, 1940, however, the Italians forced Greece into the war by invading the country from Albania.

The Greek army under Metaxas' chief of staff, Alexandros Papagos, drove back the invaders with astonishing success and had occupied about a quarter of Albania before the Germans joined in the attack on Greece (*via* Bulgaria and Yugoslavia in April 1941). The country was then rapidly overrun; and a small British expeditionary force, which had reached Greece in March 1941 in fulfilment of the guarantee of 1939, was driven off the mainland by the end of April and off Crete a month later.

By this time Metaxas had died (Jan. 29), his successor had committed suicide and King George II and his new government (under Emmanouil Tsouderos) had gone into enforced exile. Tsouderos' government in exile lasted three years (till April

1944), but had no real power.

The German-Italian occupation of Greece lasted until Oct. 1944, though for the ,final year it was exclusively German. It was marked by appalling suffering and great heroism. The Germans found three successive traitors or dupes to make prime minister, but few others like them among the people. Resistance began with passive nonco-operation, which developed into sabotage and the formation of guerrilla bands in 1941–42 and culminated on Nov. 25, 1942, with the capture and destruction of the Gorgopotamos railway viaduct by a force of Greek guerrillas and British parachutists. This was the only occasion on which the two principal guerrilla forces, the Communist-controlled E.A.M.-E.L.A.S. (National Liberation Front and National Popular Liberation army) and Gen. Napoleon Zervas' E.D.E.S. (National Republican Greek league), effectively co-operated in action. At other times they frequently fought each other, though not without undertaking independent actions against the common enemy.

In a major series of civil conflicts lasting from Sept. 1943 (immediately after the surrender of Italy to the Allies) to the summer of 1944, E.A.M.-E.L.A.S. eliminated all its political and guerrilla rivals except Zervas and set up a provisional government in the Greek mountains which by implication disowned both the king and his government in exile. A mutiny in sympathy occurred among the Greek troops outside Greece in April 1944 (when Tsouderos resigned); but after this had been suppressed and a precarious peace had been restored among the guerrillas in Greece, the two rival governments were brought together in a coalition under Georgios Papandreou, a former Venizelist Liberal. Accompanied by a small British force. his government returned to Athens as the Germans withdrew from Greece in Oct. 1944, but disintegrated a few weeks later when the Communist members of the coalition refused to accept its orders to disband their guerrilla force. A bitter civil war broke out in Athens on Dec. 3, which the British liberating forces intervened to suppress with great difficulty, after E.A.M.-E.L.A.S. had overrun virtually the whole of Greece except a few square miles of Athens and Salonika.

The Communist Rebellion.—The Communists accepted defeat and the disbandment of their forces at the conference of Varkiza in Feb. 1945. Apart from casual brigandage and clandestine subversion, they respected the Varkiza agreement for nearly two years. Meanwhile a period of political reconstruction followed, under the regency of the archbishop of Athens. Damaskinos, in place of the king, who had reluctantly agreed not to return to Greece until a plebiscite had been held on the monarchy. Many governments succeeded each other rapidly before elections (under British, French and U.S. supervision) were held in March 1946. The Communists abstained, and a strongly royalist majority was returned. A plebiscite followed in September and duly restored George II (who survived only until April 1, 1947, when his brother Paul succeeded on his death). But Greece's postwar troubles were once more only beginning. There were now three Communist-controlled countries on the northern frontier, and the U.S.S.R. evidently still hoped to annex Greece to its orbit. The presence of British troops in Greece was unsuccessfully challenged as a threat to peace by the Soviet delegate at the first meeting of the United Nations Security council in Feb. 1946; and Greece's relations with the neighbouring states were constantly on the Security council's agenda thereafter. The climax was the appointment of a United Nations' commission in Dec. 1946 to investigate border incidents.

Within the following months full-scale guerrilla war was reopened by the Communists, who had gone underground in 1946. The commitment of defending Greece became too much for the British troops and the British taxpayer, and it was taken on by the U.S. government, with the announcement of the so-called Truman doctrine on March 12, 1947. Massive financial and material help from the U.S. came only just in time. for by the end of 1947 large areas of Greece were in Communist hands again, and on Dec. 24 the Communist leader Markos Vafiades proclaimed a provisional government in the northern mountains.

Reconstruction and Recovery.—The rebellion dragged on throughout 1948. The Communists gained control of large areas, and carried off thousands of families (including children) behind the "iron curtain." The war was not ended until 1949, when the defection of Yugoslavia from the Soviet bloc closed an important stretch of Greece's northern frontier to the rebels. On Oct. 16, 1949, the Greek Communist broadcasting station announced the end of open hostilities (though subversion and espionage continued). The task of reconstruction was put in hand largely with U.S. funds and under U.S. guidance, but the continual change of governments inhibited progress. The election of March 1950 reversed the trend to the right of 1946 and resulted in a coalition of the Liberals and the left centre under N. Plastiras. The coalition was unstable, and after frequent reshuffling of cabinets, another election was held in Sept. 1951.

A few weeks earlier a new phenomenon had entered the political field. Field Marshal Papagos (the first Greek ever to hold that rank). who had led the Greek army against the Italians in 1940 and against the Communist rebels in 1949, resigned as commander in chief and formed a new political group, the Rally (*Synagermos*). It won the largest number of votes, but not enough to enable Papagos to govern alone, and he refused to enter a coalition. The result was another year of unstable government under his opponents until in Nov. 1952 another election was held, this time under the system of majority voting (last used in 1935). The Rally was overwhelmingly successful, so that at last Greece was able to dispense with a coalition government. Papagos became prime minister and set about accelerating the reconstruction of the country with characteristic thoroughness but without proceeding to the nonparliamentary methods of his dictatorial predecessor Metaxas. By the end of 1955, though still in need of U.S. assistance and in spite of a disastrous series of earthquakes in 1953–54. Greece was well advanced in its postwar recovery.

The Greeks could now at last assume a more considerable role in world affairs. The Dodecanese were finally ceded to Greece by Italy under the peace treaty of Feb. 1947. The admission of Greece into the Council of Europe in 1949 and into the North Atlantic Treaty organization in 1951 (formal entry, Feb. 1952) confirmed that it was now a European power. Papagos was welcomed on his visits to Italy. Germany. France and Spain, as were King Paul and his queen in the United States. A Greek contingent took part in the Korean war (1950–53). On Aug. 9, 1954, at Bled, Yugos., Greece signed a treaty of alliance with its ancient enemy Turkey and with Communist Yugoslavia.

Only one serious point of friction remained, with Great Britain over the sovereignty of the British colony of Cyprus. The campaign of the Cypriote Greeks for union (*enosis*) with Greece mas adopted by Papagos' government in 1954. The Greek claim soon spoiled the harmony between Turkey and Greece. The Turkish government took the view that, in the event of Britain's withdrawal, the island should return to Turkey. A British-Greek-Turkish conference, which gathered in London to find a solution to the dispute, ended in deadlock on Sept. 7, 1955. (*See* CYPRUS.)

The death of Papagos (1883–1955), which occurred on Oct. 4, deprived the country of its outstanding personality, and soon revealed disintegrating tendencies within the Greek Rally. Konstantinos Karamanlis (1907–   ), who as minister of public works had earned himself wide popularity, formed a new government. A new election was held on Feb. 19, 1956. Karamanlis' National Radical union, a new government party, won 161 of 300 seats in the chamber of deputies, the opposition being divided into seven different groups, including a crypto-Communist one.

(C. M. WE.)

POPULATION

The population of Greece. less than 1,000,000 in 1829, steadily increased, by territorial expansion, the influx of refugees from other countries and natural causes. (See Table I.)

TABLE I.—Area and Population

Year of census	Area in square miles	Population	Difference: in numbers	Difference: Per cent	Density per square mile
1821*	18,341	938,765	—	—	51.18
1828	18,341	753,400	−185,365†	−19.75	41.07
1870	19,381‡	1,457,894	+704,194	+194.38	75.22
1879	19,381‡	1,679,470	+221,576	+15.20	86.66
1889	24,552§	2,187,208	+507,738	+30.23	89.08
1896	24,552§	2,433,806	+246,598	+11 27	99.13
1907	24,399‖	2,631,952	+198,146	+ 8.11	107.87
1920	58,222¶	5,531,474	+2,899,522	+110.17	95.01
1928	50,133♀	6,204,684	+673,210	+12.17	123.76
1940	50,133♀	7,344,860	+1,140,176♁	+18.37	146.51
1951	51,182□	7,630,587	+285,727	+ 3.89	149.09
1961◇	50,547	8,357,526	+726,939	+ 9.53	165.34

*Population calculated restrospectively on the basis of the census of 1828. †The drop in population reflects the loss of life during the War of Independence (1821–28). ‡The Ionian Islands were annexed in 1864. §Thessaly and Arta were annexed in 1881. ‖A small strip of territory in Thessaly was ceded to Turkey in 1897. ¶Macedonia, Epirus, Crete and the eastern Aegean Islands were annexed in 1912–13; and Thrace, Imbros and Tenedos in 1919–20. ♀Eastern Thrace, Imbros and Tenedos were ceded to Turkey in 1922. ♁The increase in population between 1920 and 1940 reflects the influx of refugees from Asia Minor and subsequent exchanges of population. □The Dodecanese mere annexed in 1947. ◇Preliminary.

By mid-20th century the average birth rate was 25 per 1,000 and the average death rate 10 per 1.000; during the German occupation of 1941–44, however, the death rate rose to 26 per 1,000.

The distribution of population by geographic regions, according to the census of 1961, is shown in Table II.

TABLE 11.—Population by Geographic Regions, 1961

Regions	Area in square miles	Population
Mainland:		
Central Greece (with Euboea)	9,508	2,805,875
Peloponnesus	8,132	1,090,822
Thessaly	5,395	694,461
Macedonia	13,109	1,887,650
Epirus	3,511	351,167
Thrace	3,295	356,708
Total, mainland	42,950	7,186,683
Islands:		
Ionian Islands	873	212,277
Crete	3,218	482,021
Aegean Islands	3,506	476,545
Total, islands	7,597	1,170,843

The population of the municipal district of the capital, Athens, was 621,741 according to the census of 1961, but greater Athens, which includes the suburbs of the capital as well as its port of Piraeus, had a total population of 1.837.041. Other large towns (1961 pop.) are Salonika (Thessalonike) with 377,026: Patras with 94,758; Volos with 67,314 (mun.); Kavalla with 44.406; Iraklion (Candia) with 64,492; Larissa with 55.733; Kalamata with 38,077; Serrai (Seres) with 39.804; Drama with 32,328; Canea with 38.268; Ioannina with 36,295; Komotine with 29,731 (1951 pop.); and Corfu with 27.431 (1951 pop.). The urban population was 36.8% of the total in 1951, the rural population 63.2%.

Languages.—Although there are small groups of Turkish-speaking Moslems in western Thrace and Slavonic-speaking pockets in Greek Macedonia, 96% of the population speaks the Greek language (*q.v.*), which is the mother tongue of 93% of the population (some being bilingual persons who, in addition to their mother tongue spoken in the home, habitually use Greek). The largest foreign-language group is the Turkish, which numbered about 130,000 in 1951.

Religion.—The Eastern Orthodox faith is the established religion in Greece, 96.5% of the population belonging to that church. Of the remainder, the largest single group is Moslem. The Church of Greece is administered by the Holy synod, which consists of the archbishop of Athens and primate of all Greece as chairman and 12 metropolitans assisting him.

There are 71 dioceses throughout the country, each presided over by a metropolitan. Although inseparably united from the point of view of dogma with the Church of Constantinople (where the ecumenical patriarchate has its seat), the Church of Greece is completely autocephalous. Religious toleration and freedom of worship are guaranteed by the constitution, but proselytism is forbidden and punishable by law.

Education.—Primary education is free and compulsory for all children bet een the ages of 6 and 14 years; in the year 1953–54 there were 9,939 primary schools (public or private), attended by 980,036 children and staffed by 20,442 teachers. Secondary education is provided at gymnasia, which are separate for boys and girls in the big towns but mixed in the smaller towns and villages. Children who have a school-leaving certificate from a primary school may enter a *gymnasium* after passing an entrance examination. Tuition is for six years and is completed by a school-leaving examination. There are also commercial and technical schools in the category of secondary education. In 1953–54 public and private secondary schools together numbered 661, with 218,929 pupils and 6,815 teachers.

For higher studies there are two universities, one in Athens (founded in 1837), with 4,397 students in 1952–53; and one in Salonika (founded in 1925), with 2,261 students. Athens also has the National Technical university ("Polytechnic"; 1,348 students in 1952–53), the High School of Economic and Commercial Studies (2,144; *cf.* 1,108 in 1951–52) and the High School of Political Sciences (1,561). Teachers are trained at 14 training colleges, which had an average annual, attendance of 3,000 in the 1950s.

The ministry of education is also responsible for the preservation and upkeep of ancient monuments of all periods. for the upkeep and functioning of museums and for the supervision of excavations. It has a department of arts, responsible for music and the graphic arts; a department of letters, responsible for theatres, motion pictures. libraries and public records; and a department of churches, responsible for ecclesiastical and religious matters. Great Britain, the United States and France maintain schools of archaeology in Athens. The British council maintains an institute and library, as do Italy, the German Federal Republic and Sweden.

GOVERNMENT, ADMINISTRATION AND DEFENSE

Constitution.—Greece has a written constitution. in the drafting of which the French and U.S. constitutions, as well as British constitutional practice, were largely drawn upon.

During the struggle for independence (1821–32) the representatives of the Greek people, in their national assemblies. made various attempts to evolve a constitution and to organize a state; but all these efforts were of an ephemeral nature. as the persons who framed the constitutions were theorists trying to copy the U.S. and French models while at the same time imposing elaborate checks on the executive without taking realities into account.

From the establishment of the monarchy in 1832, Otho I as "king of Greece" ruled for ten years without a constitution at all but with the assistance of a regency council and of a senate. There was a growing opposition to this "absolutist" regime, however, and a bloodless revolution led by General Demetrios Kallergis in 1843 forced King Otho to agree to the convocation of a national assembly mandated to draw up a liberal constitution.

The constitution of 1844 provided for an elected chamber of deputies and a senate nominated by the crown. The king still retained wide powers, including the right to veto legislation, to appoint and to dismiss ministers and to dissolve the chamber.

In 1862 King Otho was dethroned by another bloodless revolution. and a fresh national assembly was convened to draw up a new and more liberal constitution. This assembly offered the crown to Prince William of Denmark, who became "George I, king of the Hellenes" in 1863 and established a lasting dynasty.

The constitution of 1864 abolished the senate, leaving the chamber of deputies as the sole legislative body. It also laid down that "all powers are derived from the nation and are exercised in the manner prescribed by the Constitution," thus establishing the principle of a popular monarchy (or "crowned democracy" as it is known in Greek legal parlance). It remained in force until 1911, when it was revised to form what is known as the constitution of 1911. Under this new constitution, the main prerogatives of the crown were left intact, so that the king still had the right to appoint and to dismiss ministers and to dissolve parliament; but constitutional practice demanded that after an election the king should entrust the leader of the majority with the formation of a government and that in the event of the government's being defeated by a vote in the chamber and resigning, the king should entrust the leader of the next strongest party in the chamber with the formation of a government.

After the abolition of the monarchy and the establishment of a republic in 1924, a new republican constitution was promulgated in 1927. This remained in force until the restoration of the monarchy in 1935, when the constitution of 1911 was brought back into force.

Greece's first parliament after World War II (elected on March 31, 1946) had a mandate to revise certain "nonfundamental" provisions of the constitution. A constitution drawn up by an all-party parliamentary commission was ratified by the chamber on Dec. 22, 1951, and was promulgated on Jan. 1, 1952. The main provisions of this constitution, which consists of 112 articles, are as follows:

Articles 1 and 2 prescribe that the Eastern Orthodox Church is the established religion of Greece; that the exercise of all other religions is tolerated, with the limitation that there shall be no proselytism directed against the established church; and that the Church of Greece is autocephalous.

Articles 3–20 constitute what may he termed the Greek "Bill of Rights." They prescribe equality before the law, immunity irom arbitrary arrest, habeas corpus, ireedom of assembly and of association, the inviolability oi the home, the freedom of the press, compulsory free state primary education, etc. As revised in 1951, article 11 of the constitution of 1911 was amended by the addition of a clause making it illegal for civilservants to strike. Article 14 was also amended so as to give judicial authorities the right to confiscate a newspaper if it openly incites to sedition.

Articles 21–28 relate to the form of government and to the prerogatives of parliament.

Articles 29–44 define the authority of the crown, the most important of the royal prerogatives being that the king appoints and dismisses his ministers, is supreme commander of the armed forces and has the right to dissolve parliament (but must simultaneously order the holding of elections within 45 days of the dissolution of parliament and the reconvening of parliament within 90 days of its dissolution).

Articles 45–53 relate to the succession and to regency and prescribe that the Greek crown and its constitutional rights are hereditary and vested in the dynasty of King George I, males having priority in the order oi succession; that the heir to the throne must belong to the established church; and that in the king's absence abroad the duties of regent are exercised by the crown prince (if of age) or, in the event of there being no crown prince or of his not being of age, by the queen.

Articles 54–76 prescribe parliamentary procedure and the prerogatives of parliament, including immunity, qualifications and disabilities of deputies.

Articles 77–81 relate to ministerial responsibility and provide for the impeachment of ministers by the chamber.

Articles 82–86 lay down that the council of state (*symvoulion* epikrateias) is the supreme court in matters of administrative law and has the power to examine the legality of ministerial decrees, acting as a court of justice in cases of administrative law and hearing the appeals of private citizens against the validity of acts by ministers or other public authorities.

Articles 87–98 relate to the judiciary and make provisions for its independence, judges of the higher courts being appointed for life and other members of the judiciary being irremovable unless convicted of a criminal offense. They also lay down that courts oi law shall sit in public and that the jury system shall be maintained

Articles 99–112 are of a general nature and provide for the permanency of civil servants, for the election of municipal councils by universal suffrage and for all able-bodied Greek citizens being liable ior military service; they also specify certain constitutional guarantees for foreign capital invested in Greece.

The chamber of deputies meets in Athens and is elected every four years. There is universal suffrage, women having been given the vote in 1952. Voting is obligatory and secret. The electoral system is not prescribed by the constitution, but is regulated by statute.

Local Government. — The Greek administrative system is very largely modelled on the French system. For administrative purposes the country is divided into 9 departments and 51 nomoi or prefectures. There is a governor general (who is a full cabinet ministerj of Northern Greece with headquarters in Salonika and governors general of Epirus, of Thrace, of Crete and of the Dodecanese. Governors general and nomarchs (prefects) are appointed by the government.

The peninsula of Mt. Athos (*q.v.*) in Khalkidiki (Macedonia) forms a self-governing community and enjoys a privileged status. Though administratively forming a part of the Greek state, it is subject to the spiritual jurisdiction of the ecumenical patriarchate in Constantinople and is governed by the Holy Community, which consists of representatives of the 20 monasteries situated in the peninsula.

Municipal government, with elected mayors and urban and rural councils, was established in Greece in the middle of the 19th century and is indeed part of the constitution. Municipalities and communes have the right to raise certain taxation subject to the approval of the ministry of the interior, but the general expenses of the provincial services are defrayed by the state budget. Municipal elections are held every four years.

Civil Service. — The civil service is composed of established permanent officials, who are irremovable except by decision of a ministerial disciplinary council, and unestablished officials who are removable by decision of the minister. There are no permament undersecretaries at the ministries, their place being filled by secretaries-general who change with the government. The secretary-general is the senior official after the minister, some of whose authority is delegated to him.

Justice and Police. — Article 87 of the constitution laid down that "justice is administered by judges appointed by the King according to the law." The supreme court is the Areios Pagos, which consists of two divisions, civil and criminal. There are 11 courts of appeal, which can hear both civil and criminal cases, and 58 courts of first instance. with a criminal court at the seat of each. There are also 350 courts of the justice of the peace and 47 magistrates' courts. Each court (with the exception of the last two categories) has its district attorney. In addition there is the council of state (*symvoulion epikrateias*), whose function has already been described.

The administration of justice is supervised by the minister of justice. Procedure follows the French model; *i.e.*, the investigating officer examines the evidence and interrogates witnesses and, if he decides that there is a prima facie case, sends the file to the district attorney, who then decides whether a charge shall be formulated. If a charge is made, the case is heard in open court, the district attorney representing the crown and the accused being represented by counsel.

There are two bodies of police, the town police (*astynomia poleon*) and the gendarmerie (chorophylaki). Both come under the administrative control of the ministry of the interior. The police were reorganized by a British police mission after World War II.

Labour and Social Legislation. — Greece ratified and put into effect the Washington convention on the 8-hour day and the 40-hour week; and the right to annual holidays with pay was established in 1945 throughout industrial, commercial and public-utility concerns. Engagements and dismissals are regulated by law, and industrial health and safety are also regulated by legislation.

Social insurance is highly developed, and there are a large number of mutual benefit institutions established by the various trades and professions. In 1939 the state established an autonomous central fund (Idryma Koinonikon Asphaliseon or I.K.A.) to provide relief in case of sickness, old age and unemployment, to which other funds have gradually been affiliated. Contributions to the funds vary; for example, to I.K.A. the worker pays 1% of his salary to cover sickness benefit and another 1% to cover his pension, while the employer contributes 5% and 3% respectively.

The Greek trade-union movement numbers more than 2,000 different unions, with a total membership of about 250,000. Largely thanks to the mediating efforts of the British T.U.C. immediately after World War II, the Greek General Confederation of Labour was reconstituted and affiliated to the I.C.F.T.U.

Defense. — The guerrilla operations of 1946–49 necessitated the maintenance of a much larger army than the normal peacetime establishment, and the international defense obligations subsequently assumed by Greece (which adhered to the North Atlantic treaty in Feb. 1952 and signed the tripartite alliance with Turkey and Yugoslavia at Bled on Aug. 9, 1954) did not allow any substantial reduction.

A large proportion of the cost involved was undertaken by the United States and by Great Britain. but defense expenditure still accounted for more than 40% of the Greek budget in 1954–55.

The ultimate responsibility for defense matters rests with the ministry of national defense, which has its own general staff. In addition to the minister of national defense, who exercises over-all supervision and control of defense matters, there is an under-secretary of national defense and an over-all general staff of national defense.

Military service is compulsory. liability beginning in the 21st year of age and lasting until the 50th. The normal term of service is 24 months, followed by 19 years in the first reserve and 10 years in the second.

Effectives of the armed forces totalled 140,000, including 11,000 for the navy and 12,000 for the air force. The land forces are organized in three army corps, in addition to a separate command known as A.S.D.A.N. (higher military command of Attica and the Islands) which has the same status as an army corps and is based at Athens. In 1954 the army comprised ten divisions, with an independent commando brigade.

The navy, in 1954, comprised the cruiser "Elli" (8,856 tons, formerly the Italian "Eugenio di Savoia"), 3 fleet destroyers, 14 frigates, 4 submarines. 7 gunboats, 4 mine sweepers. 1 training ship, 14 motor mine sweepers, 2 mine layers, 16 launches, 8 oilers, 2 repair ships, 10 landing ships, 21 landing craft, 1 salvage vessel, 6 transports, 3 lighthouse tenders, 5 water carriers and 10 fleet tugs. The main base is at Salamis and the main dockyard at Skaramanga.

The air force consisted of fighter squadrons, light bomber squadrons, transport squadrons and reconnaissance squadrons. The main bases are at Therme (formerly Sedes, near Salonika), Larissa, Eleusis and Dekeleia (formerly Tatoi, near Athens).

ECONOMY

Agriculture. — Although only 25% of the land is suitable for cultivation — 15% is forest or woodland and the remaining 60% barren or rocky — Greece is essentially an agricultural country, with more than 55% of the population directly engaged on the land. The country is far from self-sufficient in food, however, as only about one-half of the wheat and one-quarter of the other cereals consumed are home-grown.

The paucity of arable land inevitably resulted in the intensive cultivation of what may be termed luxury products, such as tobacco, currants, etc., which bring relatively high prices on the international market. Tobacco alone normally accounts for about 40% of the total value of the country's exports.

Tobacco is grown mainly in Macedonia, in Thrace and in the Agrinion district of central Greece. The cultivation of the vine is mainly concentrated in the Peloponnesus (especially in the narrow belt of lowland along its northern and northwestern coast line) and in some of the islands (notably Crete). The chief areas for wheat are Thessaly, Macedonia and Thrace, maize being grown mainly in Epirus. After grain, the olive is the most important crop (Greece is the third largest producer in the world); it is grown mostly in the low-lying coastal areas and in the islands, especially Corfu.

The problem of providing a means of livelihood for 1,500,000 destitute refugees from Asia Minor after the disastrous campaign of 1922 and the subsequent exchanges of populations was partly solved by the agrarian reform of 1924, when large estates were expropriated and broken up for settlement by the refugees. The second stage of this redistribution of land came in 1952, when provision was made in article 104 of the revised constitution for the compulsory expropriation of all estates exceeding 65 ac. for settlement as small holdings by landless peasantry. The average holding is very small, amounting to about $1\frac{1}{2}$ ac. of arable land to each peasant. Table 111 shows the yield of the principal grain and other food crops.

TABLE 111. — Agricultural Production
(in metric tons)

Crop	1935–38	1950–53	1954	1955
Wheat	768,000	1,057,500	1,218,500	1,336,000
Barley	197,000	225,250	231,350	224,000
Oats	116,000	135,750	149,290	156,000
Rye	55,000	54,500	50,770	54,000
Maize	255,000	246,000	258,480	288,000
Rice, paddy	2,000	57,000	89,660	61,000
Olive oil	112,700	101,625	108,780	115,000
Olives	...	559,000	553,000	496,000
Currants	158,200	78,725	75,500	...
Sultanas	28,600	33,900	38,000	...
Wine	372,700	399,400	455,020	371,000
Fresh grapes	79,500	122,000	122,410	...
Citrus fruit	53,100	147,275	194,000	...
Dried figs	28,600	23,700	27,000	...
Potatoes	148,200	414,925	452,210	438,000

For the period 1935–38 the average annual volume of exports of tobacco amounted to 45,300 metric tons out of a total crop of 61,000. Figures for annual exports of tobacco for the period 1951–54 were 43,600 tons, against a total crop of 59,800 tons. Greece's main tobacco market is Germany, which before World War II absorbed most of the annual crop. The decline in exports in the immediate postwar years was due to the partition of Germany and to a change in taste toward Virginia blend; hut by 1953 the exports were almost as large as before the war, and the annual crop was also restored to its prewar quantity.

Livestock. — Although the German and Italian occupation of 1941–44 and the guerrilla war of 1946–49 played havoc with the livestock of the country, the animal population was almost restored to its prewar level by 1953, as shown in Table IV.

TABLE IV. — *Livestock*

Type	1938	1951	1952	1953
Horses	363,183	292,222	305,000	315,000
Mules	183,609	174,524	193,000	200,000
Asses	404,379	466,947	475,000	492,000
Cattle	1,041,487	915,067	945,000	976,000
Sheep	8,138,772	7,325,997	7,784,000	8,254,000
Goats	4,356,120	4,003,492	4,139,000	4,510,000
Pigs	429,748	635,791	587,000	603,000
Chickens	11,944,551	10,010,546	10,506,000	10,615,000

Fisheries. — Greek waters abound in fish, and there tvas considerable expansion of the fishing industry between World Wars I and II as a result of the refugee influx of many experienced fishermen from Asia Minor. In World War II the industry was shattered when most of the fishing craft were requisitioned or otherwise lost; but most of the losses were later made good with Marshall plan aid, and the introduction of more efficient methods of fishing and a modern refrigeration plant caused production to rise from 35,000 tons in 1938 to 45,000 in 1951 and then (after falling to 43,000 in 1952) to 52,000 tons in 1953.

The acquisition of the Dodecanese Islands in 1947 doubled Greece's sponge-fishing fleet and led to a considerably increased sponge harvest (63,836 kg. in 1953).

Mining. — Greece has a wide variety of mineral deposits, although all of them are not fully exploited. These deposits include iron ore (of high content), iron pyrites (in Argolis), emery (in Naxos), copper, zinc, lead and silver (at Laurion), manganese, aluminum, antimony, magnesite ore (Euboea), lignite (reserves estimated at 10,000,000 tons), sulphur, bauxite (around Delphi), etc. (See Table V.)

TABLE V.—*Mineral Production*
(in thousands of metric tons of ores or concentrates)

Mineral	1929	1938	1948	1951	1952	1953
Iron	253.0	338.6	—	52.8	158.3	88.3
Lead.	44.8	14.9	1.9	4.9	5.6	6.5
Zinc.	29.0	10.3	5.7	8.4	9.0	11.2

Bauxite	6.3	179.9	44.3	163.7	284.9	328.2
Iron pyrites . . .	133.4	244.0	19.3	181.3	194.7	237.3
Magnesite. . . .	84.0	168.2	11.1	60.9	79.4	107.0
Lignite	156.5	108.0	125.4	191.9	251.1	444.5

Manufacturing Industries.—As it has few raw materials (with the exception of cotton) and is obliged to import almost all its fuel, the country does not lend itself greatly to large-scale industrialization. On the other hand, the availability of cheap skilled labour (especially after the exchanges of populations) made possible a rapid expansion of such industries as there were, notably in the textile branch. Industry is concentrated in Attica, where there is a relatively cheap supply of electric power and where Piraeus offers excellent port facilities. With the exception of a small number of big concerns. the average industrial enterprise is usually a family affair employing a very small number of persons. In April 1951 there were in all 82.674 manufacturing and handicraft establishments employing 318,686 persons, including only 272 establishments with 100 persons or more.

Electricity.—The installed capacity rose between 1950 and 1954 from 236,000 kw. to 397,000 kw. (including 58,000 kw. from hydroelectric power stations). Production rose between 1929 and 1954 from 102,000,000·kw.hr. to 1,176,000,000 kw.hr.

Communications.—There are two main railway networks in the country: the Greek State railways (S.E.K.), which connects Athens with Salonika and the main towns in continental Greece; and the Piraeus-Athens-Peloponnesus railway (S.P.A P.), which connects the capital with the main towns in the Peloponnesus across the Corinth canal.

Widespread damage was caused to the roads, railways, bridges, ports and telegraphs during World War II and the guerrilla war that followed. At the end of World War II the Corinth canal—which connects the Ionian and the Aegean seas—was blocked by the retreating German forces. Largely because of U.S. and British economic aid, most of the damage mas made good by 1954. The Corinth canal had been reopened to shipping in 1948; about 14,500 mi. of road mere back in use; more than 1,600 mi. of railway had been fully restored (only 41j mi. were usable in Oct. 1944); and 1,384 destroyed or damaged bridges had been completely rebuilt or repaired. In 1954 there were 12,892 motor cars, 19,171 trucks

Western Germany . .	41,986	39,830	4,652	35,944	32,002	37,108
Switzerland . . .	2,855	3,123	51,276	2,389	1,933	2,289
Italy	40,903	46,988	10,830	7,558	11,619	19,497
Netherlands . . .	8,861	7,366	2,172	2,235	2,805	3,809
Turkey	4,883	8,559	13,415	3,013	2,886	1,246
Sweden	13,405	10,435	11,763	2,849	1,810	1,371
Austria	6,793	6,545	15,942	4,302	5,052	4,694
Belgium	20,220	13,379	5,503	766	676	862
Yugoslavia . . .	2,643	6,211	2,941	850	5,507	2,298
Finland	3,446	3,609	...	4,182	2,418	3,205

and 5.446 buses. The national air line (T.A.E.), which links Athens with the principal towns and islands, transported in 1953, in 8,072 flights, 43,718,944 passenger-km. and 1,198,119 ton-km. of freight and mail.

Merchant Shipping.—Since ancient times the Greeks have been a seafaring people. The mainland has a long coast line and the islands are widely scattered. so that the most practical means of communication is by sea. The Greeks have thus come to assume a pre-eminent position as sea carriers, and their economy has benefited considerably from this.

The Greek merchant fleet numbered 335 ships (494,000 tons in all) in 1920; 577 (1,837,31j) in 1939; 121 (508,000) in 1945, after losses in World War II; 138 (501,593) in 1946; and 309 (1,242,075) in 1954. In addition to ships registered under the Greek flag, a considerable volume of Greek-owned tonnage is registered under foreign flags, mainly Panaman, U.S., Liberian and British. The total number of Greek-owned ships under Greek and foreign flags in Dec. 1953 was 1,162, with a total tonnage exceeding 7,000,000. In 1953 goods loaded in Greek ports amounted to 770,000 metric tons and goods unloaded to 2,983,000 tons.

Foreign Trade.—The volume and the distribution of foreign trade are shown in Tables VI and VII.

National Finance.—During the first half of the 20th century Greece had to contend with a series of events and circumstances that completely disrupted its economy, placed gigantic burdens on the people and necessitated considerable aid from abroad to keep the country from collapse. The influx of nearly 1.500,000 destitute refugees in the 1920s created vast economic problems. The successful strides made toward restoring the economy to a healthier state were halted by World War II and the guerrilla war of 1946–49, which once again shattered the country's economy and caused widespread destruction of its natural resources and brought about the grossest inflation that Greece had ever known, with the gold sovereign changing hands at dr. 170,000,000,000,000 in 1944.

TABLE VIII.—*Budgets*
(in new dr. 000,000; year endina June 30)

Item	1950–51	1951–52	1952–53	1953–54*	1954–55*
Revenue	4,863.5	5,740.4	7,929.9	10,231.1	12,069.0
Expenditure . . .	6,072.5	6,612.0	6,632.0	9,200.0	10,361.9

*Estimates.

The introduction of a new drachma in Nov. 1944 with a value of 50,000,000,000 old drachmas to 1 new drachma meant in effect the wiping out of the drachma savings of the whole nation. The rate of exchange in relation to the pound sterling went through a series of readjustments (dr. 600 to £1 in Nov. 1944; dr. 2.000 in June 1945; dr. 20,000 in Jan. 1946: dr. 32,000 in Sept. 1948; dr. 42,000 in Sept. 1949; dr. 84,000 in April 1953) until the three zeros were dropped in May 1954 and the rate was fixed at dr. 84 to £1 and dr. 30 to the U.S. dollar.

With a prewar foreign debt of about £75,000,000 still outstanding, the country found itself completely destitute at the end of World War II. The United States and Great Britain were quick to appreciate that only immediate and extensive economic aid could keep Greece from utter collapse, especially as the Communist guerrilla war made necessary the maintenance of a large army on a war footing and the expenditure of large sums of money on defense. When the British government announced in March 1947 that its own economic difficulties made it necessary to terminate its commitments in Greece, the United States took over financial responsibility for the country with the pronouncement of the Truman doctrine on March 12, 1947; and by June 1953, Greece had received more than $2,500,000,000 in foreign aid. This aid enabled the Greeks to persevere in their efforts toward restoring the country's economy. These efforts culminated in a budget surplus for 1953–54. (See Table VIII.)

See Kingdom of Greece, *Statistical Summary of Greece* (Athens, 1954). (S. L. H.)

GREEK ARCHAEOLOGY. The liberation of Greece (1821–29) made the scientific and thorough exploration of her ancient remains possible to many such scholars as Böckh and

Foucart, the epigraphists; Newton, the discoverer of the Mausoleum; Penrose and Dorpfeld who revealed the wonders of Athenian architecture; Brunn and Furtwangler, Ross and Beulé. To-day a well organized Greek archaeological service is actively engaged in preserving and conserving antiquities, and there are American, Austrian, British, French, German and Italian archaeological schools in Athens devoted to the same object in collaboration with the Greek authorities.

Use of Subject. — The genius of the Greek people laid down for the whole western world the foundations of the study of literature, art, philosophy and science, including geometry, astronomy and mathematics, and such subjects as zoology and botany. The Greek histories we possess, both those of Greek writers themselves and those produced by modern scholars based on wider sources of information, deal in the main with political affairs, and hardly touch on the culture of this gifted people from whom our civilization is derived. Political history is apt to describe exclusively political manoeuvres, diplomatic and internal, the personalities of statesmen and generals, and the progress of campaigns and battles. The material circumstances of life, public and private, are rarely discussed and the general tendency of culture at any given period and the various influences which affected it are seldom taken into consideration. Yet the trend of thought in all forms of art, the fashion for a particular type of beauty, the popular style of the age, are essential factors in building up the moral character of a people. The basic information for most of the elements necessary for this study is to be obtained from a proper use of archaeological evidence. The sources for Greek archaeology lie in two spheres, the literary and the material. From the literature of ancient Greece we derive information about the social, political and economic life of the Greeks and some also about the material surroundings of their life. But literature, except a few authors such as Pausanias who travelled in Greece about the time of Hadrian, did not consciously aim at describing this life for us. The descriptions and allusions given were meant for a public already well familiar with such life from personal experience, and therefore are of comparatively little value unless they can be checked by comparison with the actual objects. It is the function of archaeology to supply the material objects so far as they can be found and identified, and to interpret them.

Excavations. — Except in certain cases where temples such as the Parthenon or the Temple of Apollo at Bassae have, though sadly damaged, stood erect from those days to the present, or fortifications such as those of Messene or Aegosthena have similarly survived the assaults of man and time, the materials for Greek archaeology have to be recovered by excavation from the earth which has covered and so preserved them. Objects may be found by casual excavation by farmers tilling their lands, or by deliberate excavation intent on recovering the treasures of the past. Many important objects have been revealed accidentally by the builder or even by the fisherman's net as in the case of the bronze youth from Marathon. Most has been revealed by deliberate excavation, the only correct method, but it must be scientific, because all excavation is in a sense destruction. The very act of digging and of removing objects from the ground destroys their context. For instance a group of vases and jewellery found together in a tomb tell its story; they date each other, and give a picture of the culture of their age. If, however, the jewellery be removed without keeping the pottery with it or at least taking proper note of it, that jewellery like the Aegina treasure in the British Museum can tell us hardly half its story. Similarly a nest of vases found under the foundations of a temple gives a terminus post quem for its building, but if the vases are removed and no observations made as to their position and relationship their value as historical evidence is lost. Thus many of the objects exhibited in museums are archaeologically dumb because they have been found either in the operations, usually illicit, of a professional excavator who digs for plunder to supply the cabinets of collectors or museums, or in the excavations of irresponsible archaeologists. Never was the urgent need of patience, accuracy, and detailed observation more conspicuously demonstrated than in the case of the excavation of the sanctuary of Artemis Orthia at Sparta where thousands of small objects of all periods were found around the ruins of a temple and its altar. It was only the skilled restraint of the archaeologists, who slowly removed the earth almost inch by inch, that unravelled the complicated stratification, and gave us not only the history of one of the most important Spartan temples, but also an invaluable record of the culture of Sparta through 600 of the most momentous years of its existence. The change of soil, the various materials used in building, and all apparently minute points must be constantly watched and this record of the stratification if not made by the excavator can never be made by another and so irretrievable damage may be done. A carelessly conducted excavation is even more disastrous than the burning of a library, for the archaeological evidence it has destroyed can never be replaced.

Objects Found.--Objects from excavations may be found in the ruins of ancient temples and sanctuaries, or in those of public buildings such as theatres or colonnaded market-places, or fortifications, or in those of private houses, or in tombs, perhaps the most fruitful source of all. Tombs are more apt to yield complete objects, temples and public buildings yield inscriptions, and both they and houses produce quantities of fragmentary small objects of everyday use which give us the stratification of culture on any particular site. In this way the evidence obtained from tombs and that from temples or inhabited sites supplement each other.

HISTORY OF EXCAVATION

Scientific archaeological exploration of ancient Greek remains was rather long delayed, though a French expedition had undertaken some researches at Olympia in 1829. Some of the earliest archaeological expeditions worked on the coast of Asia Minor among the Greek colonies rather than on the sites of the motherland. Thus Newton's work at Halicarnassus and Cnidus which enriched the British Museum with the remains of the Mausoleum and the Demeter of Cnidus and Wood's patient search for the Artemisium at Ephesus, though among the earliest excavations carried out with definite scholarly aims, belong rather to Asia Minor than to Greece.

German. — Not till 1875, however, were the great German excavations at Olympia begun, under a special treaty with the Greek Government. This expedition under the leadership of Curtius, Adler and Treu, after six arduous campaigns, revealed what was left of the temples and other buildings of the Panhellenie sanctuary of Olympia. Rich finds rewarded the efforts of the excavators, the pedimental sculptures of the great temple of Zeus, the Winged Victory by Paeonius, and greatest treasure of all, the Hermes of Praxiteles, the only undoubted original by one of the greatest masters of Greek sculpture. These sculptures, whose date is indisputable, are of unrivalled value for the history of Greek art. Since then German expeditions have done important work at several other sites. At Thera the ancient town has been cleared and gives an excellent picture of an island community in the latter part of the classical age, while rich tombs of the early iron age were also found. At Athens the theatre of Dionysus was excavated and also a large part of the Dipylon cemetery, providing much fresh information about Athenian funeral customs. After preliminary campaigns in the early cemeteries of Samos, most useful for the light thrown on early Ionian art, especially the vases, the famous temple of Hera there has been laid bare and the history of another of the sacred sites of Greece is being made known. This and similar work on the temples of Aphrodite and Aphaea at Aegina has yielded valuable facts towards the study of architecture, and the results of the complete excavation of the Aphaea temple now enable us to study in their right context the famous sculptures from it at Munich.

Greek. — Greece has taken a foremost part in the rediscovery and preservation of her treasures, and apart from many minor researches has carried out several major excdvations — the Acropolis at Athens, at Eleusis, the Amphiaraeum by Oropus and at Epidaurus. The history of the Acropolis was entirely rewritten by the results of excavation. The successive stages of the Parthenon and the temples planned to precede it on the same site, the earlier Propylaea, and the old Athena temple all show

how closely the architectural monuments of the prime of Athens are to be co-ordlnated with the history of the city herself. Fresh fragments of the sculptures of the Parthenon were found, but the most surprising artistic find was the hoard of statues damaged and overthrown in the Persian invasion of 480 B.C., which had been subsequently used to fill up a hollow during rebuilding. These, though damaged are at least unrestored originals, and show by the plentiful traces of bright painting still extant on them how the Greeks intended their sculptures to appear. A fundamental date for the history of Greek vase painting was another of the more important facts determined. At Eleusis the Hall of Mysteries was discovered and the progressive enlargement of this and of the sacred enclosure indicate both the gradual increase of culture and prosperity in Greece during the 6th and 5th centuries B.C., and the growth of the importance of the shrine itself. Many important sculptures and inscriptions were found. The Amphiaraeum and Epidaurus were the centres of cults connected with healing, but the latter is the more important as the central shrine of Asclepius himself. Here the whole sanctuary has been cleared with the theatre and all the subsidiary buildings. Valuable architectural results were obtained, and sculptures illustrating the style of Timotheus, a leading artist of the 4th century, with many historical inscriptions, and others giving interesting details about visitors to the shrine and their cures. This whole group of buildings with the theatre, accommodation for patients, gymnasium and music-hall gives a vivid picture of the life of a Greek spa during the first two centuries after Christ. The central sanctuary of the Aetolians at Thermon has been cleared and valuable material for the history of the development of architecture was unearthed and many important inscriptions. At Lycosura in the ruins of the temple were found the greater part of a colossal group by Damophon, a leading sculptor of the 2nd century B.C.

French. — The French school has excavated Delphi, the seat of the famous oracle of Apollo, which has produced sculptures of the first rank, such as the bronze charioteer, a masterpiece from the hand of an artist still unknown, and the marble frieze of the Cnidian treasury, a gem of archaic art. Besides these, the innumerable "treasuries" and shrines, the theatre and other buildings have added much fresh material for the study of architecture, and an immense harvest of inscriptions. At Delos the French have cleared the sanctuary of Apollo with its many temples and colonnades, but the complicated nature of the site makes the unravelling of its history rather difficult. A large part of the Hellenistic town has been cleared with its streets, houses, warehouses, port and theatre, and this combined with the sacred associations of the site, gives a panorama of the active life and trade of this town, a sanctuary of Panhellenic renown and a free port, the great entrepôt of the Aegean, especially for slaves. As the island itself produces little or nothing to sustain the life of even a small population and water is scarce, provisions of all kinds must have been extensively imported. Among other sites where French explorers have worked is Tegea, where the temple of Athena Alea has been excavated and some heads and other fragments of the pedimental sculptures have been recovered. These, though battered, are originals from the hand of Scopas, a master of the 4th century, a contemporary and rival of Praxiteles.

American. — The Americans, now about to undertake the arduous project of excavating the agora of Athens and the other buildings sacred and profane around it, have previously concentrated their efforts on Corinth, the most flourishing commercial city on the Greek mainland next to Athens itself. In 146 B.C. Mummius overthrew all its buildings except the temple of Apollo, some columns of which still stand. The Americans have cleared a large part of the Agora and a short length of the road leading to the port of Lechaeum, and have identified the theatre and other public buildings. The excavations show how complete was the rebuilding that took place when Caesar sent a colony to the site and how thorough was the destruction by Mummius. The elaborate arrangements for the water supply of the city have been revealed in the fountains of Peirene and Glauke. The former which dates back to the 6th century emphasizes the importance attached by the tyrants to making proper provision for this essential for the well-being of their subjects. The ruins of Corinth indicate that this too was a prosperous city, and that the site was eminently adapted by nature for a trading centre. An American expedition also excavated the Heraeum, the national sanctuary of Argos. This site was continuously occupied from the early bronze age till late classical times, and was especially rich in finds of the archaic period of art that illustrate the varied influence notably those from the east, affecting Greece at that date. The architecture of the temple rebuilt after a fire in 423 B.C. and of the other buildings in the precinct forms an interesting contrast to Attic work of the same date; in addition a few interesting sculptures were discovered.

British. — The first British excavation was that of Megalopolis, and apart from the problems involved in the architecture of the theatre and the Thersilion, the council chamber of the Arcadian confederacy, the results hardly came up to expectations. Otherwise apart from valuable contributions to Aegean archaeology by excavations in Crete, at Mycenae, in Melos and in Thessaly, the great excavations of the British school have been at Sparta. Here the classic sanctuaries of Artemis Orthia and Athena Chalcioecus and of Helen and Menelaus have been discovered, and entirely new light has been thrown on Spartan art which now appears to have been extremely flourishing in the archaic period when oriental and Ionian influence were much in evidence. In later times only the growth of a narrow military policy stifled the natural Hellenic tendency towards artistic expression in all the accompaniments of life. The tracing of the walls has determined the size of the city and the excavation of the theatre and the innumerable inscriptions of the early imperial period show that Sparta flourished under the Pax Romana as a provincial capital.

Other nations have taken an active part in excavations in Greece. The Austrians have been at work in Elis, the Dutch at Argos, the Danes at Lindos, the Czechs at Samothrace and the Swedes at Calaureia, while the latter and the Italians have specially distinguished themselves in Aegean archaeology.

SEVEN BRANCHES OF ARCHAEOLOGY

Greek archaeology subdivides naturally into seven branches. These are: —

I. Topography. — This is naturally linked with geography and consists in the exploration of Greek lands and the noting of the ancient ruins they contain, the observation of their natural resources, and finally the co-ordination of the results of such research with the knowledge of the country to be derived from ancient writers. This sifting of the evidence forms the basis of our knowledge of the political and historical geography of Greece. A full understanding of the physical aspects of the country and its natural products, mineral or other, coupled with as full a survey as is possible of the ruins of ancient towns and hamlets, is essential to enable us to picture the land where the drama of Greek history was played, and art and literature had their birth. A classic example of topographical work is Leake's *Travels* in *Northern Greece* and a modern work of the same type is Stahlin's *Das Hellenische Thessalien,* while Frazer's monumental *Commentary on Pausanias* is the outstanding instance of an attempt to stabilize our knowledge of Greece by the correlation of archaeological and literary material and of ancient and modern topography:

II. Epigraphy.-The study of ancient inscriptions which may vary from a grave inscription of a few words to lengthy laws or decrees and fall into two large groups: (A) Inscriptions proper, by which we mean words inscribed on monuments or objects to denote their purpose, often mentioning the name of the deity or person concerned. These subdivide into: (1) Epitaphs, perhaps the largest class of all; these can be of historical importance, as, for instance, the epitaph of Dexileos, an Athenian cavalryman who fell in the Corinthian War about 395 B.C.; (2) Dedications, varying from the official dedication of a building to a word or two scratched on a small bronze offered to a god. The serpent column from Delphi (now in the Hippodrome at Constantinople) recording the names of the Greek cities that won the battle of Plataea against the Persians, and the bronze Etruscan helmet dedicated by Hieron, king of Syracuse, at Olympia after the battle of Cumae (now in the British Museum) show the historical value of such inscriptions. The fragments of the metrical dedication of the Athenians celebrating their victories over Boeotia and Chalcis in 506 B.C. is a useful check on the accuracy of Herodotus who quotes it. Most of the inscriptions celebrating victories at games, such as the famous inscription of Damonon of Sparta, who boasted that he and his son had won more races than anyone else, fall into this class. (3) Honorary inscriptions, such as the lines inscribed on the bases of statues erected to persons like Alexander and Hadrian, or those recording honours granted by a State to citizens or to natives of other States, when the honours usually consisted of the right to a front seat at festivals and *proxenia* and certain exemptions and immunities. (See INSCRIPTIONS.) (B) Documents both public and private or, on another classification, sacred and profane. These subdivide into: (1) Treaties and alliances, such as the treaty between Athens, Mantinea and Argos, which corrects the text quoted by Thucydides; (2) Laws such as the famous laws of Gortyn, which from their archaic language and their legal contents rank high in importance; (3) Decrees of the State or letters from kings, Roman emperors, or some other authority, regulating the affairs of subordinate States, such as the decrees of Eressos about tyrants which were confirmed by letters of Philip Arrhidaeus and Antigonus; (4) Financial records such as the famous tribute lists which form the basis for the study of Athenian finance in the 5th century, or the records of the treasures of the temple at Delos; (5) Building inscriptions such as those of the Erechtheum at Athens which give important architectural details; (6) Lists of names such as those recording the manumission of slaves, some of which from Athens give interesting information about trades, and lists of soldiers killed in battle or of ephebi; (7) Boundary stones recording political boundaries, the limits of sacred areas and the bounds of private property, the last including mortgage stones which give the name of the mortgagee and the amount of the mortgage. Among miscellaneous inscriptions come the potsherds scratched with the names of politicians which were used in voting at an ostracism in Athens. Several of these bear the name of Themistocles himself, others that of Xanthippus, the father of Pericles, and yet others the name of the great political opponent of Pericles, Thucydides the son of Melesias, whose ostracism in 444 B.C. left Pericles free to carry out his policy.

III. **Numismatics,** the study of Greek coins, which includes complicated subjects such as metrology, weight standards, the ratio of the metals to one another as well as the classification of the coins themselves and their study as original objects of art.

IV. **Architecture,** the study of Greek construction which has had a profound influence on subsequent building. Apart from the great temples such as the Parthenon at Athens and all the smaller shrines, there are hundreds of ancient buildings of more secular use, such as the Propylaea or gateway to the Acropolis at Athens, the Stoa of Attalus in the market of Athens, and the theatres, colonnades, and other buildings to be found on every important Greek site. With them can be grouped fortifications and private houses. The study of the gradual development of Greek architecture, and the methods by which the ancients overcame the problems confronting them, provide lessons of the greatest value to modern architects. True, of many Greek buildings little more than the foundations exist, but a study of these and of the fallen blocks of the superstructure enables us to reconstruct the building on paper even if only in part, and the evidence of a single stone when observed by the trained eye may lead to important results. Thus the discovery of the foundations of a building is of the greatest assistance in visualizing it.

V. Ceramics, the study of ancient pottery, which has in recent years been highly developed. Broken pottery is the commonest of all objects found on an ancient site, and is intrinsically the most worthless, and therefore for the archaeologist in many ways the most valuable, for it is unlikely to be stolen or to be forged. Whole vases found in tombs have of course a market value, but these may have no archaeological value if removed from the ground by illicit or irresponsible excavators. Thus on the excavation of an ancient site it is a *priori* probable that the latest pottery will be found near the surface and the oldest deepest down, and so on. (See STRATIGRAPHY and SEQUENCE DATING.) Thus by careful excavation stratum by stratum the archaeologist can obtain a stratified sequence of the potsherds from any given site. These can be dated by the evidence of inscriptions or by that previously obtained from other sites, and thus provide a ceramic history of the site in question and a test by which buildings and other objects can be dated in their turn, and they even serve to correct false impressions or ideas that have hitherto held the field. A classic instance of stratification is the "Persian Stratum" on the Acropolis of Athens which consists of damaged objects used as filling on the restoration of the buildings on the Acropolis after the destruction of Athens in 480 B.C. The study, too, of the pottery that prevails in a given stratum shows the commercial and cultural influences prevailing at that period and throws light on the economic or political orientation of the city where it is found, and on the social customs and the prosperity of its citizens. There are of course pitfalls for the unwary or the inexperienced. The strata are not always laid down on mathematically level ground, but may slope down the side of a mound. The earlier strata may be dug into in laying the foundations of a later building and so be partially disturbed, but proper observation of this enables the later building to be more nearly dated. Again, when the accumulation of debris over a long period of years has made a mound, the site may be levelled for later constructions by cutting off the top and throwing down to the sides as was done at Troy by the builders of the gth, or Graeco-Roman city. Further, when in early days a particular type of pottery has been very commonly used on a site the soil becomes so full of fragments of it that every later stratum can hardly help containing a few pieces. This sometimes leads to error, as occasionally attempts are made to date a building by the earliest objects found in it. As a rule unless there are special circumstances to be taken into account a building, tomb or whatever it is should be dated by the latest object found.

Greek pottery divides into the following groups: —

Neolithic. — This in turn subdivides into that found on the mainland and that found in Crete. (See AEGEAN CIVILIZATION.)

Bronze Age, which has three divisions: Early, about 3,500–2,200 B.C.; Middle 2,200–1,600 B.C.; Late 1,600–1,100 B.C.; and the pottery of these three periods is further subdivided according to the regions where it is found as Minoan, Cycladic or Helladic. Under Middle Minoan comes the pottery formerly called Kamares ware, under Early Helladic Urfirnis ware, under Middle Helladic Minyan ware and Matt-painted ware, and the pottery called Mycenaean is to be classified according to its provenance as Late Minoan, Late Cycladic or Late Helladic. Each of the three divisions of the Bronze age has further chronological subdivisions. (See AEGEAN CIVILIZATION.)

Early *Iron* Age. — The pottery of this period is still far from well known and is marked by the gradual predominance of geometric ornament, by the introduction of new shapes, by a different quality of paint, and in general by an artistic decadence which so often coincides with an improvement in the material concomitants of life.

Geometric Pottery. — By goo B.C. the Iron Age was well established in Greece and the geometric style of ornament predominated. This is sometimes known as Dipylon pottery, because it first became known from vases found in the cemetery outside the Dipylon gate at Athens. About 800–750 B.C. the geometric style began to modify under the influence of oriental motives derived through the Greek colonies on the coast of Asia Minor and Cyprus, and probably, too, through contact with Phoenician traders. This modification is known as Phaleron ware from the site of its first discovery. Then about 750 B.C. what is known as Proto-Corinthian pottery had a great vogue. This consists of small vases delicately made with fine linear ornamentation carefully designed and often combined with friezes of animals and warriors, well and minutely drawn. These vases are called Sicyonian, from the view recently advanced that they were manufactured there. They are, however, the forerunners in many respects of the next great phase of Greek pottery.

Orientalizing.—Towards the end of the 8th century B.C. oriental influence which had gradually permeated the geometric style became the chief characteristic of Greek pottery. Just as the geometric style, though uniform, had many local variations all over Greece according to the circumstances of the place of manufacture and of the quality of the clay employed, so now the orientalizing style throughout the Greek world produced a great number of local styles, and many of these have not yet been definitely placed. The style flourished more in the islands and along the Asiatic littoral where we find Aeolic, Clazomenian, Milesian, Samian, Rhodian, Delian and Melian wares. Even Naucratis had a special fabric of its own, and on the mainland we have Corinthian, Chalcidian, Boeotian, Attic and Laconian wares. Many of these local wares, like the Boeotian and the Laconian developed on their own lines in the succeeding periods, but never attained to any great importance, for Attic pottery eclipsed the rest of the Greek fabrics and became the great standard. It seems to have been extensively exported, especially to Etruria, where its products found a ready market among the Etruscan nobles. Thus Attic pottery from the 6th century onwards is the great centre of Greek ceramics, and we have two main styles: (1) Black-figured ware in which the designs are painted in black on the red ground of the vase and picked out with incisions and with added purple or white paint. This ware flourished during the 6th century, and shortly before 500 B.C. gave way to another style which was practically its converse; (2) Red-figured ware, in which the ground is painted black and the designs are reserved in the red colour of the vase, while details are rendered with black lines. These last two classes of pottery, from the elegance and beauty of their drawing, rank more as paintings than as pottery. With them must be grouped a contemporary ware in which the designs were painted on a white ground. Particularly noticeable are the white *lekythoi* which were made specially to be placed in graves and decorated with unfixed paint. These provide us with some of the best Greek paintings and drawings known.

With the degeneration of the red-figured style in Attica at the close of the 5th century the Greek colonies in Italy took the lead and produced quantities of large vases decorated in a florid and over elaborate style. In Greece itself the red-figured wares gave place to less pretentious vases intended more for use than as works of art. Good pottery covered with the excellent black glaze which was the secret of the Attic potters, was produced in great quantities, but the ornament was limited to incisions assisted by simple patterns in white paint laid on the black surface. Certain simple forms of white grounded ware were still made, but ordinary designs of flowers, fruit, musical instruments and the like were the sole decoration. The principal decorated ware from the 4th century onwards was moulded pottery which includes a large class of vases usually known as Megarian bowls. These are often covered with a uniform black glaze which is seldom of good quality and in later examples tends to be thin and grey. The decoration at first consisted of figure subjects as on the earlier black and red-figured wares, and Homeric subjects were specially popular. Designs based on the acanthus, shells, scales and other motives popular in Greek decorative art are common and figures of Erotes are often added. With these comes a class of black pottery ornamented with moulded medallions or figures applied to the surface. Here the motives employed are usually figures of maenads, satyrs, and other Dionysiac subjects, amazons and gods and goddesses. Moulded wares became popular in Italy as Arretine pottery and so spread throughout the Roman world as "Samian Ware" (now usually called terra *sigillata*) which was the characteristic tableware of the first two centuries of the Christian era. Two probable reasons may be assigned for the decay of Greek pottery after the 5th century. The general increase of wealth and luxury due to the renewed intercourse with the riches of Asia especially after the campaigns of Agesilaus and Alexander, inspired the upper classes, the patrons of the vase painters, with the fashion of using silver plate for their tables. At the same time the new age of adventure beginning in the 4th century caused a change in art which was henceforward practised more for its own sake than as the means of ennobling objects of ordinary domestic and social use.

VI. Sculpture, which properly comes under art and embraces all forms of plastic and toreutic, and can be subdivided into the following groups: (1) Sculpture proper, which is limited to figures carved in the round or in relief by the artist direct from the stone or marble. A minor branch is gem engraving in which subjects are carved either in intaglio or in cameo directly on the stone; (2) Modelling, which applies to figures small or large modelled in clay intended as independent works of art or else as models for large figures to be executed in marble or bronze. The votive terra-cotta statuettes which are found in such numbers in excavating Greek sanctuaries and tombs, though usually cast in moulds, fall into this class and so do the well-known Tanagra and similar figurines which were made in moulds for funeral furniture; (3) Metal casting especially bronze, the favourite material for many of the greatest Greek sculptors. Polyclitus for instance worked principally in this technique. A subdivision of this group is jewellery made by casting in gold and silver small objects which were then fitted together to make earrings, necklaces, and other ornaments; (4) Metal chasing, which is practically confined to the precious metals; (5) Carving in materials other than stone or marble, which is usually restricted to small objects such as statuettes of ivory, but in the earlier days of Greek art according to the literary evidence there were statues of wood which have not been preserved.

VII. Painting.— We have nothing left of the frescoes or easel pictures of the great masters of Greek painting like Polygnotus or Apelles and a history of Greek painting has to be constructed mainly from the literary sources. The vase paintings, however, of the Attic black and red-figured styles and of the white grounded vases supply much beautiful and valuable material for estimating the style and manner of the Greek painters. The painted grave stones from Pagasae which are not earlier than the 4th century represent industry rather than art, but still provide-useful evidence as to methods and technique.

None of the seven branches of Greek archaeology are absolutely independent for they often over-lap each other. Inscriptions may be found on buildings, on statues, on vases and on coins. Coins themselves, being struck from engraved dies in intaglio approach one of the subdivisions of sculpture, and ceramics and vase-painting are also closely connected. Famous statues, too, were often imitated in coin types. Then topography and study of the ancient remains from the geographical point of view take into account practically all the other branches. Thus a hoard of coins containing a large number of bronze coins of a city, the site of which is doubtful may solve its identification. Still every Greek archaeologist, though he naturally specializes in one or two branches only, should have a sound working knowledge of the others.

CHRONOLOGICAL DIVISIONS

In addition to the seven great branches which divide Greek archaeology according to subject, there are two chronological divisions, the pre-historic and the historic. It is hard to say where the first ends and the second begins, but for practical purposes the division may be put at 776 B.C., the Greeks' own traditional date for the first Olympiad and the beginning of their chronology.

Prehistoric.— The prehistoric age subdivides into the usual periods: Palaeolithic, Neolithic, Bronze Age, Early Iron Age. The Palaeolithic Age is not yet established for Greece, though a few isolated palaeoliths are reported. The Neolithic and Bronze Ages are described under AEGEAN CIVILIZATION. The Early Iron Age is a natural evolution from the last phase of the Bronze Age affected by the infiltration of external elements, probably northern, which the Greeks described as the Dorian Invasion or the Return of the Heracleidae. It is characterized by the use of the "geometric" pottery mentioned above, iron swords of a Danubian type, bronze safety-pin brooches often with spiral ornaments, bronze figurines of animals, long bronze pins and sometimes ivory plaques and figurines. This culture is not that of a particular

tribe or people, but of a phase in the evolution of Greek art, for in the civilization of a people community of inspiration is more important than community of race. Early in the 8th century a great increase in oriental influence due partly to Phoenicians and Etruscans and partly to the Greek colonies in Asia Minor inaugurated the orientalizing period of Greek art and here the historic age begins.

Historic.—With this, the classical age, our outlook is different. In the time of unwritten history or legend archaeology itself is history, because the incidents of a people's life are reflected in its material remains. In other words prehistoric archaeology is a manuscript from which history can be deciphered. On the other hand in the classical age history is written. Archaeology then becomes an illuminator and interpreter of history and is best studied under its separate branches described above. (See GREEK ARCHITECTURE; GREEK ART; POTTERY AND PORCELAIN; INSCRIPTIONS; NUMISMATICS; PALAEOGRAPHY.)

RELATIONS TO OTHER COUNTRIES

Greek archaeology is not complete in itself, because inevitably it impinges upon the archaeology of the countries that are the neighbours of Greece. Man is a social animal and lives by contact with his own kind. Archaeology is one way of studying the material results of the contact of man and man. Similarly no race can live for long in a state of complete isolation and the result of the contact between one race and another is reflected in their archaeology which thus provides a means of gauging the extent of the influence of one race upon another. For pre-historic times there is archaeological evidence that Greece was in contact with surrounding races. The marked influence which Egypt and Crete exerted upon each other is well known. So we find connections between the Aegean civilization and Palestine, Cyprus and Asia Minor, where Troy is the classic example. Northwards there are clear evidences of intercourse between prehistoric Greece and Macedonia and the Danubian and Carpathian areas. Westwards there are hints of relations with Italy, and the Aegean civilization (*q.v.*) touched Sicily and Sardinia. So no true student of the Aegean civilization can appreciate its full value without considering its neighbours and in chronology the Egyptian connections are of vital importance. With the beginning of the classical period and the dawn of history the relations of Greek archaeology naturally became more intricate. The connection with Egypt and Asia Minor still remains and there is great uncertainty as to the amount of the debt of Greece to Phoenicia during the orientalizing age. These contacts are of the utmost value for chronological questions. Northwards again Macedonia, Thrace, and the Danubian and Euxine districts become of genuine historical importance through their contacts with Greek archaeology. The dating of the monuments in those regions is due in large part to our knowledge of Greece. For the Adriatic the same holds true and further west in Italy the case is far stronger. Sicily and southern Italy were studded with Greek colonies and their relations with the indigenous cultures provide a reflex of their relative importance and also most useful chronological comparisons, and Etruscan archaeology is throughout illuminated by our knowledge of Greece. Sardinia, the east coast of Spain and the south coast of France were fringed with Greek colonies, and so Greek archaeology illustrates these with great profit to history. These instances show how important it is not to allow the detailed study of Greek archaeology to exclude all view of any other. Two further points of the utmost importance for study of human development occur for note. When Alexander overran the Persian empire and through Macedonia made Greece mistress of the Near East he spread Greek culture which is illustrated by hundreds of monuments throughout the East as far as the borders of India. The influence of Greece on Asia is revealed by Greek archaeology and it was upon this union of East and West that the foundations of Christianity were laid. Secondly, when Rome became mistress of the Mediterranean the culture she adopted was that of Hellenistic Greece, the very culture which Alexander and his successors had propagated. Greek archaeology reveals this to us in the houses of Rome and Pompeii and the adoption by Rome of Hellenistic culture, which Greek archaeology verifies, assisted the rapid growth of Christianity under the Roman empire. Constantine's official adoption of Christianity was one of the greatest landmarks in world history and Greek archaeology helps in no small measure to appreciate why and how this change was inevitable.

MUSEUMS

The materials for the study of Greek archaeology are housed in various museums all over Europe and in America. The museums of Greece take precedence because their contents are mainly the product of scientific excavations and have not lost their contexts and the sculptures they contain have not suffered from restoration. The National museum at Athens is famous for its sculptures, vases, bronzes, the Acropolis museum for archaic sculptures, the Epigraphical museum for inscriptions. The museums of Olympia, Delphi and Delos house the great finds from the excavations of those sites and that of Candia contains the finds from Cnossus and Crete in general. Other important museums in Greece are those at Thebes, Volos (for paintings), Samos (for sculptures), Nauplia and Corinth (both for prehistoric pottery), Sparta (for Spartan art), Thera, Corfu, Chalcis, Thermon and several others. In Italy Rome leads the way with the Museo delle Terme for sculpture, the Vatican for sculpture and vases, the Capitoline museums for sculpture and the Villa Giulia for vases. At Naples the National museum has unrivalled sculptures, as also has the Uffizi at Florence, where in the Museo Archeologico are Greek objects found in Etruria. The museums of Palermo for sculpture, Syracuse for vases, Taranto for vases and terra-cottas are important, and there are many other museums with Greek objects all over Italy. In France the Louvre is the principal museum with great treasures of Greek art. In Germany there are many museums. Berlin has in the State museums fine sculptures and vases and in the Ethnological museum Schliemann's finds from Troy. At Munich the Glyptothek contains the Aegina pedimental figures and other sculptures and the Museum für Antike Kleinkunst contains valuable vases. Dresden (Albertinum), Cassel, Heidelberg, Hildesheim and other German towns have good collections. In Great Britain the British Museum in London has the Elgin Marbles and a fine series of vases, the Fitzwilliam museum in Cambridge and the Ashmolean at Oxford have vase collections, too, and the latter a fine prehistoric collection as well. In Turkey the Constantinople museum has good sculptures and some of the finds from Troy, and in Egypt the Alexandria museum has a good collection of objects illustrating the later stages of Greek art. In Denmark at Copenhagen the Ny-Carlsberg Glyptothek has sculptures and the National museum vases. In Holland the Scheurleer museum at The Hague and the Leyden museum, and in Belgium the Musée du Cinquantenaire at Brussels have good vases and terra-cottas. In Russia the Hermitage museum at Leningrad has sculptures and vases, and several of the south Russian towns such as Odessa have good collections from the Greek colonies on the Black Sea. In America the Metropolitan museum in New York and the Museum of Fine Arts in Boston both have good collections of sculpture and vases, while the university museums at Baltimore, Philadelphia, and Harvard have useful collections.

BIBLIOGRAPHY.—The publication of the results of research in all seven branches of Greek archaeology and of the material yielded by excavations is catered for by a large number of periodicals in the principal countries of Europe and in America and by the issue by specialists and others of learned monographs treating some particular section of the whole field. The principal periodicals are: in Greece the *Ephemeris Archaiologike,* and the *Archaiologikon Deltion;* in Austria the *Jahreshefte* of the Austrian Archaeological institute, in France the *Revue Archdologique* and the *Bulletin de Correspondance Hellénique;* in Germany by the *Jahrbuch* of the German Archaeological institute, the *Athenische Mitteilungen,* and many others; in Great Britain by the *Journal of Hellenic Studies* and the *Annual of the British School at Athens;* in Italy by the *Monumenti Antichi* of the Accademia dei Lincei and the *Annual* of the Italian school at Athens; and in the United States by the *American Journal of Archaeology.* The monographs dealing with special aspects of Greek archaeology fall into three classes: (1) Monumental collections or catalogues of a particular class of object, such as the great Corpus of Greek inscriptions *(Inscriptiones Graecae)* issued by the Berlin academy or the *Corpus Vasorum Antiquorum* published under the auspices of the *Union Académique Internationale* and scientific catalogues of famous museums such as the German catalogue of the Vatican sculptures and the British catalogue of the Capitoline collections and the British Museum catalogue of Greek coins. (2) Comprehensive publications of the objects found in great excavations with full and scientific commentaries such as the German pubhcations of the excavations at Olympia, Thera and Aegina; the French publications dealing with Delphi and Delos which are still in progress; and the Greek publications dealing with Epidaurus and the Acropolis at Athens. (3) Monographs on particular topics which range from handbooks of the usual type for students, such as the histories of Greek sculpture by E. Gardner, Overbeck, Collignon, and Picard, to scientific monographs of the first class which lay the foundations for the study of a particular subject. Here we can class in topography Woodhouse's *Aetolza;* in epigraphy Cavaignac's treatise on the *Trésor d'Athènes;* in numismatics Svoronos' *Nomtsmata ton Ptolemaion;* in architecture Penrose's *Principles of Athenian Architecture,* and the American monograph on the Erechtheum; in Ceramics Beazley's books on Attic black and red-figured vases; in sculpture Joubin's *Sculpture Archazque,* or Furtwangler's *Masterpzeces* and in painting Pfuhl's *Meisterwerke Griechischer Zeichnung und Malerei,* and the great portfolios of plates of sculpture and of portraits published by Bruckmann of Munich. *See* also A Michaelis, *Anczent Marbles in Great Britain* (1882), and *A Century of Archaeologzcal Discoveries* (1908); J. P. Droop, *Archaeological Excavation* (1915). (A. J. B. W.)

GREEK ARCHITECTURE, in this article, refers to the architecture of Greece from approximately 1100 B.C to A D. 300. The historic periods, conventionally known as Greek, during and after the dark ages of invasions, displaced populations and colonization, through the Graeco-Roman period, will be covered here. The earliest prehistoric phase of Greek civilization in the later part of the Aegean period continued the earlier non-Greek phase and therefore will not be discussed *(see* PREHELLENIC ARCHITECTURE). Furthermore, only the historical evolution of Greek architecture as a whole will be traced, leaving the analysis of the orders for discussion elsewhere (see ORDER)

To the Greeks fell the role of inventing the grammar of conventional forms on which all subsequent European architecture was based. The materials at their disposal, wood and stone as well as mud, induced them to adopt a post-and-lintel system, as in Egypt (see EGYPTIAN ARCHITECTURE), instead of massive walls and vaults, as in Mesopotamia. However, for molding their supports they chose conventional rather than naturalistic forms, therein resembling their Aegean predecessors; particularly Greek mas the patient genius with which they perfected every element, rarely deviating from the forward path to invent new forms or new solutions of old problems. This conservative adherence to older types led to such masterpieces as the Parthenon (*q.v.*) and Erechtheum (*q.v.*).

This article is divided into the following sections:

1. Primitive Period (1100–600 B.C.)
2. Archaic Period (600–500 B.C.)
3. Transitional Period (500–450 B.C.)
4. The Culmination at Athens (450–400 B.C.)
5. Fourth Century (400–300 B.C.)
6. Hellenistic Period (300–100 B.C.)
7. Graeco-Roman Period (100 B.C.–A.D. 300)

1. Primitive Period (1100–600 B.C.).—While Greek domestic architecture began with the Dorian invasion, monumental religious architecture first appeared in the 9th century. Mere open areas with altars (Aegina, Sparta, Ephesus) no longer sufficed when gods were represented in large images, requiring special temples. The houses of men furnished the patterns: from the circular nomadic hut developed the horseshoe or apsidal plan (Eretria, Gonnoi), the oblong plan with curved walls (Thermon) and eventually the normal straight-sided oblong, the axis running east and west. and the entrance always at one end. A porch

EXAMPLES OF DORIC TEMPLES

1. Temples at Paestum; at the right the so-called Basilica, really an archaic temple (c. 540 B.C.). At the left the so-called Temple of Poseidon (c. 460 B.C.), showing heavy transitional proportions relieved by numerous flutes; one of the best preserved of Greek temples (for interior see fig. 5)
2. Temple of Apollo at Corinth (c. 540 B.C.), showing the seven standing columns, with sturdy archaic proportions, monolithic shafts, and high architrave (frieze and cornice missing). View from interior, with Acrocorinth in background
3. Temple of Zeus at Olympia (c. 465–457 B.C.); Libon of Elis, architect. East front (restored), showing heavy proportions as at Paestum because of its transitional date and colossal scale, the effect being relieved by pediment sculpture (the shields are Roman additions). Overthrown by earthquakes, little now existing above the platform level
4. The Parthenon on the Acropolis at Athens (447–432 B.C.); Ictinus and Callicrates, architects. The masterpiece of the Doric style, with the lighter proportions of the culminating period. This west front is nearly intact apart from the loss of the pediment sculptures; the flank colonnades were partly demolished by bombardment in 1687 (for interior see fig. 7)
5. Interior of the Temple of Poseidon at Paestum (see fig. 1), showing the usual Doric treatment with superposed tiers of heavy Doric columns to support the ceiling
6. Interior of the Temple of Apollo at Bassae (c. 450–420 B.C.); Ictinus, architect. This shows the later scheme of employing single tiers of slender Ionic columns to support the ceiling, even though the temple is Doric externally
7. Interior of the Parthenon (see fig. 4) from the west, with the internal colonnades (in two tiers as at Paestum) and walls and parts of the flank colonnades blown out by the explosion. The dark patch of pavement in the distance is the site of the gold-and-ivory statue

IONIC AND CORINTHIAN TEMPLES

1. The Erechtheum on the Acropolis at Athens (*c.* 421–405 B.C.); Mnesicles probably the original architect. View from the southwest, showing the irregular plan resulting from the limitations imposed on the architect by religion. There are three different Ionic orders (the east porch of six columns, one visible at extreme right; the north tetrastyle porch at extreme left, compare fig. 4; the sham portico of four engaged columns at the west) and at the south is the Caryatid porch. Rebuilt by the Greek authorities, 1903–1908. 2. Temple of Athena Niké (Niké Apteros) at Athens (*c.* 426 B.C.) as seen from the northeast; Callicrates, architect. An Ionic temple of miniature size, designed with special regard for its situation on a bastion of the Acropolis. 3. Temple of Apollo at Didyma near Miletus (332 B.C.–A.D. 41), Paeonius and Daphnis, architeots. Detail of colossal east façade, showing special stairway in the centre, adapted to human requirements, and varied column bases. 4. North porch of the Erechtheum (see fig. 1), the open proportions and elaborate decoration contrasting with the solidity and simplicity of the neighbouring Parthenon. 5. The Olympieum at Athens (174 B.C.–A.D. 131); Cossutius, architect. The only colossal Corinthian temple of the Greek period, with heavily proportioned columns; the frieze and cornice exist only in fragments. In the background appears the Acropolis

GREEK RELIGIOUS PRECINCTS

1. Athenian Treasury at Delphi (*c.* 515 B.C.), in the form of a small Doric temple, executed wholly in marble, originally with elaborate sculptured decoration (of which only casts of the metopes are in place). Rebuilt by the French authorities 1903–06, by fitting together the scattered fragments
2. The Propylaea of the Acropolis at Athens (437–432 B.C.); Mnesicles, architect. Inner or east front, showing the form of the Doric central porticoes, and the middle intercolumniation widened for processions. The parts above the columns were overthrown by an explosion about 1645, and rebuilt by the Greek authorities 1909–17. At the right appears the unfinished wall of the proposed northeast hall
3. The Propylaea at Athens (cf. fig. 2), showing outer or west front (injured by bombardment in 1687) and steeply sloping approach, with enframing wings at north and south (the latter not shown) terminating in pedestals which were to have enframed gateways to lower precincts. Upon the frustration of the latter portion of the scheme, the Temple of Athena Niké was built on the south (426 B.C.. see Plate II., fig. 2). and the great pedestal of Agrippa on the north (174 B.C.), at extreme left
4. The Great Altar of Zeus at Pergamum, built for Eumenes II. (197–159 B.C.). Detail of the reconstruotion in Berlin, showing podium decorated with colossal frieze, interrupted by stairs which ascend to a colonnaded court enclosing the altar. Only the foundations remain on the actual site

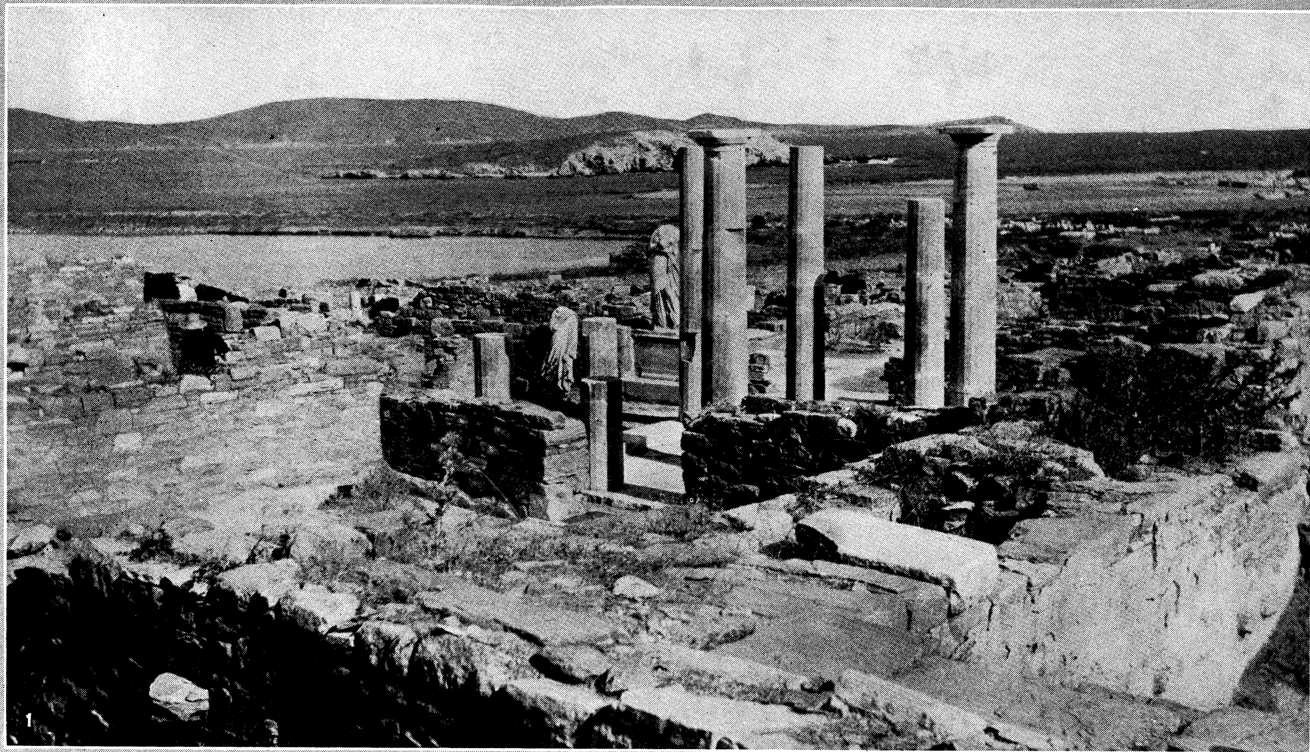
GREEK MONUMENTS AND SECULAR BUILDINGS

1. Tower of the Winds at Athens (*c.* **100** B.C.), designed by the astronomer Andronicus Cyrrhestes; view showing one of the two porches, each of which was composed of two Corinthian columns. Sundials on each of the eight sides, an allegorical frieze of the eight winds at the top, a conical roof surmounted by an octagonal capital and a bronze Triton as weather-vane, completed the design. 2. Grave stele of Hegeso (soon after 400 B.C.), tombstone of wide pedimental type from the Ceramicus cemetery at Athens; slightly projecting lateral antae enclosing scene of parting in relief. 3. Choragic Monument of Lysicrates at Athens (334 B.C.), showing the earliest external use of Corinthian columns, the six intervals filled with thin walls, and the conical roof and trefoil finial originally supporting a bronze tripod. 4. Grave stele of Bion (4th century B.C.), tombstone of narrow type from the Ceramicus cemetery at Athens, with palmette acroterion embellished with acanthus leaves, and two rosettes above the relief. 5. Theatre of Dionysus at Athens (c. 350-325 B.C.), on the south slope of the Acropolis, showing the marble thrones forming the lowest tier, and the ordinary limestone seats rising behind (cf. Plate V., fig. 2). 6. Grave stele of a maiden (4th century B.C.), tombstone of narrow type from the Ceramicus cemetery at Athens, with funeral vase (loutrophoros) in relief and mourning Siren as acroterion



PHOTOGRAPHS, (1) PROF. C. H. YOUNG, (2) EWING GALLOWAY

GREEK SECULAR BUILDINGS

1. "House of Cleopatra" at Delos (138 B.C.), a private house with **peristyle** court, the slender marble columns supporting a wooden **entablature,** and surrounding an **impluvium** with a mosaic floor and a cistern beneath
2. Theatre at Epidaurus (*c.* 325 B.C.); **Polycleitus** the Younger, architect.

View showing the circular orchestra 66% **ft.** in diameter, with the foundation for the central altar, the surrounding auditorium occupying three-fifths **of** the circumference, the left entrance **(parodos)** gateway. The scene building, of which only the foundations remain, is of later **construction**

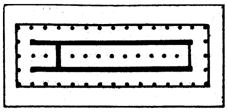
PLAN OF THE ACROPOLIS AT ATHENS

AFTER D'ESPOUY, "MONUMENTS ANTIQUES"

The name given to the citadel in cities of Greece and Asia Minor was Acropolis. It was generally built upon a hill or rock, was fortified and commanded the city and surrounding territory. The Acropolis contained important buildings; in Athens the weights connected with the coinage were kept in the Acropolis (pronaos) might be added in front, a sanctuary (adytum) at the rear, repeating the Mycenaean megaron plan. Walls were of mud-brick resting on stone socles, their free ends (antae and door jambs) encased in wooden sheathing. Simultaneously the roof developed from the nomadic thatched beehive, through the long ogival mud-brick vault (thatched in a model from Perachora), to the sloping hipped roof with wooden rafters, supported by girders resting on the side walls, and so, eventually, to gables at one or both of the narrow ends.



FROM DINSMOOR THE ARCHITECTURE OF ANCIENT GREECE (BATSFORD)

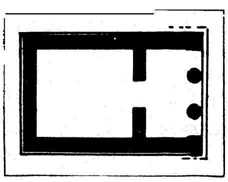
FIG 2 —TEMPLE AT THERMON

In wider temples these cross girders had to be reinforced by columns placed in single file along the main axis (Selinus. Prinias, Locri, Sparta, Neandria. Samos). Thus came into Greek architecture the characteristic post-and-lintel system. At first mere wooden posts, these internal supports were gradually molded on opposite sides of the Aegean sea, into two different types. proto-Doric and proto-Ionic. The former, with its circular molded capital and square abacus, was copied in wood from such surviving Aegean works as the Lion gate at Mycenae. The proto-Ionic type, originated as an elongated capital, early transformed into stone; slender unfluted shafts (sometimes with special bases) were capped by gariands of drooping leaves from which sprang vertical volutes (Lesbos, Neandria, Larisa).

In an open pronaos, a central column repeated the axial colonnade (Locri, Prinias); next, because central columns obscured the cult image, the axis was opened by using two internal colonnades and so two columns *in-antis* on the front. Thus the column first appeared on the exterior and introduced a new problem, the creation of an entablature. The transverse girder formed the architrave, a single solid beam in the Doric, compounded of superposed planks (fascias) in the Ionic; upon this rested the ends of ceiling beams, heavy and widely spaced (triglyphs) in the Doric, light and closely spaced (dentils) in the Ionic. Mutular eaves formed by overhanging rafters characterized the Doric cornice; the Ionic was merely hollowed to shed rain water. The light wooden Ionic entablature is best known through imitations in native rock-cut tombs of Asia Minor; the Doric forms are revealed through the survival of terra cottas which protected the bulky timbers, black or blue triglyphs, gaily painted terra-cotta metopes and facings with conventional patterns on the cornice. The hipped roof was still retained in the earlier temple of Hera on the Silaris (near Paestum). The ridge of the hipped roof was soon prolonged to the front. forming a gable (pediment). the rear end sometimes remaining hipped (Thermon, model at Sparta). The gutter (sima) which had hitherto crowned the cornice on all four sides was retained even under the pediment in the western colonies (Syracuse. Geloan treasury at Olympia); but the mutules, equally anachronistic symbols of rafters under a pediment, remained even on the facade. Semicircular terra-cotta tiles covered the joints between the concave pantiles, terminating at the eaves in semicircular antefixes.

The emergence of the column and the development of the orders inspired Dorian architects to further embellishments. The pronaos might be repeated in a rear porch jopisthodomus), or the whole temple surrounded by a peristyle. From the five lines of the flank walls and the axial and flank colonnades resulted pentastyle facades (Thermon), two internal colonnades required hexastyle facades (Heraeum at Olympia); the flanks were long in proportion, with 15 or 16 columns.

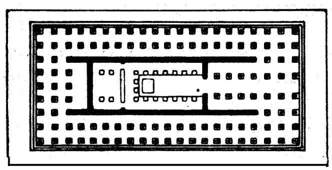
2. Archaic Period (600-500 B.C.).— The new-rich western colonies transformed the peripteral temple into limestone; the Ionian east soon followed with the greater splendour of marble. But the motherland of Greece remained conservative; during eight centuries the wooden columns of the Olympian Heraeum were gradually replaced in stone; as late as 513 B.C. marble was limited to one ostentatious temple façade (Delphi). Limestone, however, was coated with fine marble stucco; sandstone was often used in the west for carved members; terra-cotta cornice revetments were gradually eliminated and the terra-cotta gutters and even roof tiles replaced in more important temples by stone or marble.



FROM DINSMOOR, "THE ARCHITECTURE OF ANCIENT GREECE" (BATSFORD)

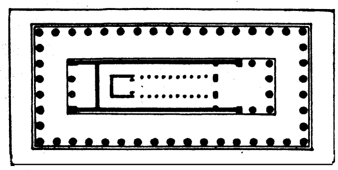
FIG. 3.— TEMPLE AT RHAMNUS

A few primitive types of plans survived, either apsidal (Delphi, Athens, Corinth, Olympia) or with axial colonnades (Olympia, Delos, Paestum, Metapontum). The simple diastyle *in-antis* plan long prevailed in Greece; the "hundred-foot" temple on the Athenian Acropolis was apparently tristyle *in antis* at both ends. But the most favoured temple plan was the hexastyle peripteral, sometimes (in Sicily) with the façade doubled for greater magnificence. The opisthodomus (rear porch) was customary in Greece, the closed adytum (secret chamber) in the west; the interior of the cella might have two rows of columns (in Greece) or none at all (in Sicily). The east outdid the west by doubling the colonnade on all sides, giving the octastyle dipteral plan (Ephesus, Samos, Magnesia), imitated also at Athens (Olympieum); at Corcyra and Selinus ("GT") the inner lines of columns were omitted, becoming pseudodipteral; at Acragas (Olympieum), while retaining the same vast total dimensions as at Selinus. the number of columns was reduced and the scale thereby so enlarged that the intervals were filled with walls, becoming pseudoperipteral. Employment of colossal dimensions, with stylobates measuring up to 180 by 365 ft., column diameters up to 13¼ ft. (Acragas), column spacings up to 28¾ ft. (Ephesus), afforded the tyrants of this period opportunities for lavish display. The entrance was usually toward the east (orientation), but in Asia Minor sometimes toward the west, as at Ephesus.



FROM DINSMOOR, "THE ARCHITECTURE OF ANCIENT GREECE" (BATSFORD)

FIG. 4.— TEMPLE AT EPHESUS (RESTORED)



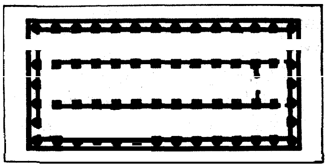
FROM DINSMOOR 'THE ARCHITECTURE OF ANCIENT GREECE' (BATSFORD)

FIG. 5.— TEMPLE "GT" AT SELINUS

The geographical cleavage between the styles continued. The western temples at Syracuse, Selinus, Acragas. Paestum. Pompeii, Tarentum. Metapontum and Corcyra, and those in Greece at Athens, Delphi, Eretria and Corinth, all were Doric. In the east, Naucratis, Ephesus, Samos. Naxos, Paros, Chios. Miletus and Magnesia furnish important landmarks of the archaic Ionic development. The Doric temple invaded the east. at Assos, suffering the intrusion of the Ionic frieze; reciprocally the Ionic temple penetrated the west, at Locri and Hipponium.

In the Doric order the sudden change of material, and timidity as to the strength of stone, caused violent changes. Not only were column shafts often constructed as monoliths, but proportions were at first extremely heavy, with intervals so close that the spreading capitals were nearly contiguous. With growing confidence, larger columns were eventually raised to 5 or even 5⅝ diameters, with intervals up to 1⅔ diameters. Spacings and diameters were often enlarged on the façades in Greece; uniform diameters but different spacings characterize most of the western peristyles. Triglyphs at first appeared only above columns, leaving horizontal oblong metopes between; interpolated triglyphs next reduced the metopes to vertical oblongs, which gradually approached squareness. the half mutules above the narrow metopes then becoming of full width. Relief sculpture succeeded painting in the metopes and pediments, changing in the latter to free statues; human and animal forms replaced the semicircular acroteria. and the antefixes changed from semicircles to prismatic forms, surmounted by palmettes.

The Ionic column, carrying a lighter entablature and longer habituated to stone, was more slender from the very beginning (about 8 diameters), with greater intervals (1½ to 2⅓ diameters); particularly noteworthy were the enormous intervals at the centres of the façades. Though the entablature was friezeless, broad bands of relief sculpture were inserted wherever possible, as on the sima at Ephesus. But in Greece a new type of Ionic entablature was created to vie with Doric proportions; the fascias of the architrave were suppressed, the dentils omitted and a high frieze inserted between architrave and cornice (Ionic treasuries at Delphi).

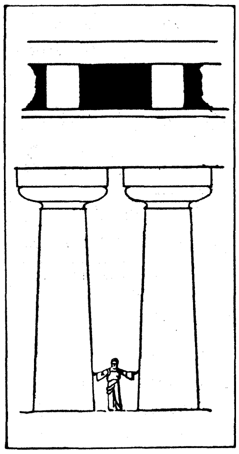


FROM DINSMOOR THE ARCHITECTURE OF ANCIENT GREECE (BATSFORD)

FIG. 6.—OLYMPIEUM AT ACRAGAS

Both orders were awkward at the corners of peristyles. In the Doric, the difficulty lay in reconciling triglyph and column spacings. while bringing a triglyph out to the corner of the entablature; in the west it was met by widening the angle triglyph and the adjacent metope, in Greece by contracting the end columnar interval; finally, metope expansion was combined with column contraction. In the Ionic, the bracket capital seemed incapable of turning the corner, until at Ephesus was devised an awkward L-shaped capital with an angle volute.

Other forms displaying the versatility of the archaic designers were the hybrid Doric-Ionic capitals of Amyclae, the bell capitals of Delphi and the use of human figures as supports, both male (atlantes of Acragas) and female (caryatids of Delphi). Other types of buildings yielded new opportunities — simple templelike treasuries (Olympia, Delphi), the square hypostyle hall (telesterion) at Eleusis, the archaic circular tholos at Delphi, the apsidal senate house at Olympia, altars as at Miletus and Delphi, the throne at Xmyclae and elaborate fountains built by the tyrants (Athens, Megara, Corinth, Samos). And in some of these minor works as in votive columns and grave monuments, migratory architects mingled the styles.

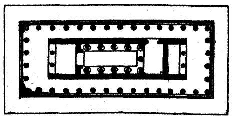


FROM DINSMOOR THE ARCHITECTURE OF ANCIENT GREECE (BATSFORD)

FIG 7 —EARLY ARCHAIC DORIC PROPORTIONS

3. Transitional Period (500–450 B.C.).—The grammar of forms and the types of buildings having been largely determined, the next step was that of refinement. The problem was all the more concentrated because the political subjection of the east to Persia now restricted architectural initiative to the Doric style of Greece and the west, which, furthermore. received fresh impetus from the victories over Persia and Carthage. And in particular at Athens the discovery of copious marble quarries contributed to the refinement of design.

Freedom was now abandoned in favour of strict canonization, resulting almost in monotony. Hexastyle peripteral Doric temples became universal: in Greece at Sunium, Athens (the unfinished older Parthenon), Aegina and Olympia; in the west at Syracuse, Himera, Gela. Caulonia, Acragas, Croton and Paestum. Work was continued on the never-finished colossi at Selinus and Acragas, with distinct changes of details. In the west, columns tended to be of uniform diameter and (except at Himera and Paestum) uniformly spaced on front and flank, apart from the contracted end intervals; and here appeared an innovation, double contraction at the corners. But in Greece some emphasis of the front, either with heavier columns or with wider spacing, was still prevalent; or the corner columns alone might be enlarged. The west adopted the opisthodomus of Greece, sometimes in addition to the adytum; but cella colonnades appeared in the west only at Paestum, apart from the huge octastyle at Selinus. Such internal colonnades were two (at Selinus three) stories in height, separated by architraves and carrying only ceiling and roof; the few known galleries (Aegina, Olympia) were later insertions; and stone staircases (Selinus, Himera, Paestum) ascended merely to storerooms above the ceilings.



FROM BORRMANN, GESCHICHTE DER BAUKUNST (ALFRED KRONER VERLAG)

FIG. 8.—TEMPLE AT BASSAE

In this period the Ionic temple first appeared in Greece (Sunium), with the peristyle strangely confined to one front and one flank, and with the typical mainland form of entablature nithout fascias or dentils. A larger but unfinished Ionic temple was begun at Delos.

Among other types of buildings, additional treasuries at Olympia, the reconstructed oblong telesterion at Eleusis and the similar Cnidian lesche (clubhouse) at Delphi, the old Propylon of the Athenian Acropolis. the colonnade of the Athenians at Delphi. the royal and painted stoas and the tholos at Athens, the Athenian theatre orchestra with wooden scene buildings and the imitation of the oriental gridiron city plan at Miletus, all paved the way for the masterpieces of the following period.

4. The Culmination at Athens (450–400 B.C.).—The middle period of the evolution centred at Athens, which signed peace with Persia in 449 B.C., and in the absence of military requirements nas free to use the wealth of the Athenian confederacy in rebuilding the temples ruined by the Persians. Under the personal initiative of Pericles, and in the hands of architects like Ictinus, Callicrates and Mnesicles, and the sculptors Phidias and Callimachus, Greek architecture reached its zenith.

The Doric style of Greece naturally retained the leading place, and was employed not only in hexastyle temples at Bassae, Rhamnus, Sunium and Athens (Hephaesteum and temple of Ares). but also in the octastyle Parthenon on the Acropolis; besides these erected by Athenian architects, we find hexastyles near Argos (Heraeum), at Acragas (temple of Concord), Segesta and Delos (the last prostyle). Most of those structures were comparatively small, owing their effect to perfection of design and execution, and, in the case of those in Attica, to the beauty of marble, and more slender proportions. Only Bassae retained the older system with heavier columns on the main façade and reduced spacing on both flanks; elsewhere uniformity prevailed. except at the corners. Cella colonnades were omitted except in the works of Ictinus, also in the Hephaesteum and at the Argive Heraeum; Ictinus obtained a new effect by returning the colonnade across the back, at Bassae separating adytum from cella (the lateral columns being engaged to the flank walls), in the Parthenon forming an ambulatory around the statue. The false gallery with two stories of Doric columns appeared for the last times in the Parthenon, Hephaesteum, and Argive Heraeum; a single Ionic order was preferred at Bassae (with three Corinthian capitals across the rear) and in the rear chamber of the Parthenon. The coalescence of the styles was marked by the inclusion of other Ionic elements, moldings and continuous friezes (Parthenon, Hephaesteum, Sunium). Sculptured reliefs in friezes and metopes. pediments filled with statues and crowned by great floral acroteria, these and the fine moldings and the marble ceilings enhanced by colour and gilding, broad masses of colour on triglyphs and in shadowed cornice soffits, further relieved the simplicity of Doric forms.

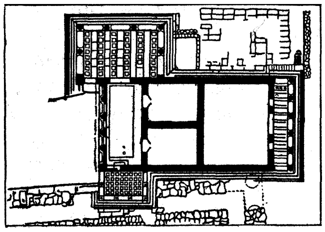


FIG 9 —ERECHTHEUM, DRAWN BY GORHAM P. STEVENS

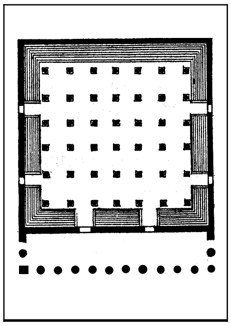
The Ionic style was also employed independently in three nonperipteral temples at Athens (on the Ilissus river, the Nike temple and Erechtheum on the Acropolis); its foothold in Greece was now assured. The amphiprostyle tetrastyle plan was preferred, though in the Erechtheum (*q.v.*) the rising ground at the east so elevated the stylobate that in the final plan six columns were required in the width; and the tetrastyle portico originally planned for the west end was revolved to the north flank to respect the sacred olive tree, balanced by the miniature caryatid portico on the south, and replaced on the west by a sham portico of engaged columns, producing an irregular T-shaped plan. Rampant antefixes above the sima of the Erechtheum, and its elaborately carved moldings, exceptional in the 5th century, foreshadowed the elaboration of the following period.

Another symptom of change was the creation of a third style, the Corinthian, first appearing inside the temple at Bassae. Like the Ionic capitals in the same colonnade, the Corinthian capitals represent an attempt to invent a form symmetrical on all sides,



FROM BORRMANN, "GESCHICHTE DER BAUKUNST" (ALFRED KRONER VERLAG)

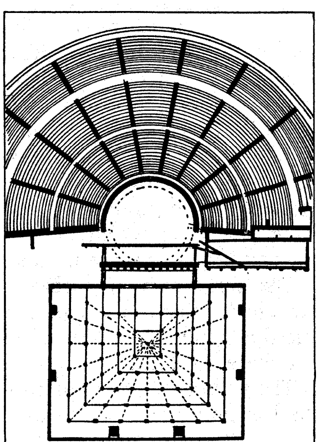
FIG. 10.—TELESTERION AT ELEUSIS

the bell capitals of Delphi being further elaborated with acanthus leaves, scrolls and palmettes.

Among buildings other than temples, the Propylaea (*q.v.*) at Athens take first rank in brilliance of conception. A cruciform plan 224 ft. in length (about equal to the Parthenon) would have formed a frontispiece across the west end of the Acropolis, with wings projecting westward to enframe the ascent; by war and priestly conservatism the design was curtailed until it resembled a lopsided T, only 154 ft. in length. The central building, with its Doric hexastyles and pediments dominating the low hipped roofed north and south arms and west wings (without columns except on the return faces of the wings), formed the entrance, the central intercolumniation widened 6 ft. to allow the passage of festal processions, and the five doorways graded in width like the intercolumniations, with heights varying in proportion. The west ceiling was supported by six Ionic columns in immediate juxtaposition with the Doric. Hardly less notable were the redesigned telesterion at Eleusis, a great square at first with seven rows each of seven columns within, then with four rows of five (these two projects never completed), and finally with six rows each of seven, and the odeum at Athens with internal columns arranged in nine rows of nine; both had clerestory lanterns above the roofs. Corresponding advances in city planning were the importation of the gridiron system to Greece (Peiraeeus) and the west (Thurii).

In these buildings, beauty of proportion was enhanced by "optical refinements," almost a speciality of the culmination. The curve of the platform, rising $\frac{3}{4}$ to 44 in. in a circular arc with a radius as great as $3\frac{1}{2}$ miles, gave vitality and corrected any sagging illusion in the colonnade. The entasis or swelling outline of the column shaft, preventing any sensation of concavity, attained its maximum ($\frac{1}{4}$ to $\frac{3}{4}$ in.) at half of the height, though in earlier and later periods it was much more pronounced. The inward inclination of the column axes (from $\frac{3}{8}$ to 34 in.) gave a pyramidal illusion of greater stability, the axes of the flank colonnades of the Parthenon meeting more than a mile above the pavement; walls, antae and other supposedly vertical surfaces might show similar inclinations. And the manner in which the various members were adjusted to each other, preserving these delicate relations and yet keeping the joints invisible, represents a triumph of calculation and stonecutting.

5. Fourth Century (400–300 **B.C.**).—The displacement of the political centre from Athens successively to Sparta, Thebes, Macedonia and Asia Minor was accompanied by unmistakable evidence of a decline from aesthetic perfection. The service of the gods began to be subordinated to that of men, and from the temple attention was diverted to a great variety of structures corresponding to the varied requirements of a more complex civilization. Even in religious architecture the striving for diversity and innovation is manifest in the increase of excessive ornament.



FROM BORRMANN, "GESCHICHTE DER BAUKUNST" (ALFRED KRONER VERLAG)

FIG. 11.—THEATRE AND THERSILION AT MEGALOPOLIS

In Greece the Doric style was still preferred for temples, but, incapable of further perfection, was now modified. Hexastyle plans (Delphi, Epidaurus, Tegea, Nemea, Stratos, Ptoon and Olympia) were often shortened by omitting the opisthodomus; temples at Delphi and Epidaurus were hexastyle prostyle. Columns were more slender ($5\frac{7}{8}$ to 64 diameters) and entablatures correspondingly lower (one-quarter of the column height), the reduction occurring in architrave and cornice while the frieze remained high to preserve the squareness of metopes. The enrichment of the sima by carved rinceaux and rampant antefixes was counterbalanced by the loss of such delicacies as the hyperbolic echinus profile. Following the example of Bassae, Corinthian internal columns were employed at Tegea, Stratos and Nemea, Ionic at Epidaurus; an inner row of Ionic columns lined a Doric facade at Delphi.

FIG. 12.—GYMNASIUM AT EPIDAURUS

More important was the Ionic Renaissance in Asia Minor. Not only hexastyle plans as at Priene, but colossal octastyles again became the fashion, at Ephesus repeating the archaic plan, at Sardis omitting the inner flank colonnades and becoming semi-pseudodipteral. Even the decastyle plan with 120 external columns appeared at Didyma near Miletus, with the cella unroofed (hypaethral). Column proportions continued to be slender, though because of the enormous dimensions the intervals were contracted; some facades (Sardis, Ephesus) show, however, enormous central spacings. Such abnormal embellishments as sculptured pedestals, bases, drums and capitals were confined to the larger temples. The entablature always lacks the frieze (except at Didyma where the work was protracted into Roman times). Only in Greece (tholos at Olympia) or in nonreligious and hence less conservative Asiatic structures, executed with collaborators from Greece (mausoleum at Halicarnassus), did the frieze penetrate the entablature, now always in combination with dentils.

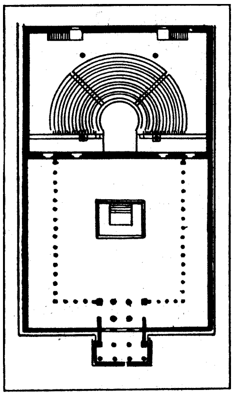
Important buildings other than temples were erected in both styles. In the Doric, treasuries at Delphi, choragic monuments at Athens, tholoi at Delphi and' Epidaurus, the huge dodecastyle facade of the telesterion at Eleusis and the analogous assembly hall (Thersilion) at Megalopolis, porticoes up to 550 ft. in length as at Corinth, the arsenal of 430 ft. at the Piraeus, the Lion tomb at Cnidus (another Doric intrusion in the east), all testify to the vitality of the style. The tholos was reproduced in the Ionic style at Olympia; monumental Ionic tombs in Asia Minor, the Nereid monument at Xanthus (a temple raised on a lofty pedestal) and the mausoleum at Halicarnassus (with a pyramid in turn elevated above a peristyle of 36 columns, attaining a height of 136 ft.), have remained unsurpassed in their field.

The Corinthian capital was developed as a secondary feature inside temples at Tegea, Nemea, Stratos and Didyma, inside tholoi at Delphi, Epidaurus and Olympia; but not until 334 B.C. was the style used independently and externally in a choragic monument at Athens, with an entablature devised by combining Attic frieze with Asiatic dentils.

A few noncolumnar designs require special mention. The Attic tomb stele with its ever-deepening frame of miniature antae and entablature, or with an elaborate floral acroterion, became extinct as the century ended. But the theatre, now provided with a stone auditorium encircling more than half of the orchestra (Athens, Epidaurus, Eretria), its one-storied scene building (also in stone) containing several great openings and flanked by projecting pavilions (parascenia) and sometimes faced by removable wooden proscenium porticoes, was yet in its infancy. The stadium, either round-ended or rectangular, repeated the theatre form. The market place (agora) became, if not strictly rectangular, at least more formal; and the newly founded or rebuilt cities of the period followed the gridiron plan (Priene and Cnidus).

6. Hellenistic Period (300–100 **B.C.**).—The even balance between east and west which had characterized the preceding century was overthrown by the transference of the political centres to the oriental kingdoms of Alexander's successors, resulting in the domination of the oriental elements in Greek architecture. The Doric style, now on the downward path, appeared chiefly in small temples, either ***in antis*** (Selinus, Acragas, Taormina) or prostyle (Pergamum, Lycosura, Samothrace, Gortyna, Oropos); belated peripteral hexastyles occurred at Troy, Pergamum, Cos, Delos and Lebadea — the last symbolic, the abandoned scheme of an eastern monarch. (174 B.C.). A proposal to erect a Doric temple of Dionysus was actually countermanded in favour of the Ionic style; architects frankly wrote that "sacred buildings ought not to be constructed of the Doric order" because of the difficulty of spacing triglyphs and columns. The few who adhered to the style sought new methods of appeal: engaged columns, lighter proportions with slender columns and thin entablatures requiring the interpolation of extra triglyphs; columns with Ionic fluting or even bases. Wall surfaces were modeled. with emphasized joints and belt courses. The cella might even have an internal apse (Lebadea, Samothrace), or projecting aisles at the sides (Lusoi).

The Ionic style, now the successor rather than rival of the Doric, is best exemplified in three beautiful pseudodipteral octastyles (Messa, Smintheum, Magnesia); less successful are smaller examples at Teos, Magnesia and Pergamum. Bases changed from the Asiatic to the Attic form, with plinths; capitals contracted in length; the rising echinus eliminated the downward droop of the cushion, and rinceaux filled the cushion and baluster. The entablature included the Attic frieze, and the dentils became small and meaningless, being used as decoration even in the raking cornice. These forms, and this moment of the Ionic supremacy, are reflected in the volume wherein Vitruvius interpreted Greek architecture to the Romans, using the Ionic as the typical order.



FROM BORRMANN "GESCHICHTE DER BAUKUNST (ALFRED KRONER VERLAG)

FIG 13 —BOULEUTERION AT MILETUS

Now, however, the Ionic supremacy began to be threatened by the Corinthian style, best exemplified at Diocaesarea and in the dipteral octastyle Olympieum at Athens (174 B.C.). Its merits were most obvious in peristyles, the capital being symmetrical on all sides and the entablature unhampered by triglyphs; but its popularity extended even to distyle porches (Messene).

Even more important than temples, however, were numerous other types of buildings. Monumental sacrificial altars rose at Syracuse (74 by 653 ft.). Pergamum (the "Seat of Satan," 112 by 120 ft.), Priene, and Magnesia. Doric porticoes surrounding the temple precincts (Ephesus, Priene. Magnesia); vast stoas built by Hellenistic kings for the cities of Asia (Pergamum, Assos, Priene) and Greece (Delos, Delphi, Athens, Megalopolis, Olympia), or, with slight modifications, used as market halls (Aegae, Alinda, Assos) and libraries (Pergamum); monumental propylaea (Samothrace, Delos, Lindos, Epidaurus, Olympia and Selinus), the tholos at Samothrace, the hypostyle hall at Delos and gymnasia (Epidaurus, Priene); all repeated earlier forms with slight variation. The long "Hall of the Bulls" at Delos surmounted at one end by a tower, the soaring lighthouse of 400 ft. at Alexandria and small senate houses with semicircular or rectangular auditoria imitated from the theatre (Miletus, Priene) were innovations. The theatre itself received a colonnaded stone proscenium before the scene building, of which the great openings were elevated to an upper story (Oropos, Epidaurus, Priene, Ephesus). Commemorative monuments were more lofty, high pedestals (Delphi, Athens) or pairs of columns supporting entablature (Delphi), forerunners of the Roman triumphal arch.. Private houses changed from the megaron type to the peristyle court (Priene, Delos), and in their likeness were designed great hotels with central courts (Epfdaurus, Olympia). The market place became a formally enclosed rectangle (Magnesia) rather than a picturesque group of colonnades and public buildings. The roads outside the city gates were lined with an ever-increasing variety of sepulchral monuments, including the mausoleum type (Acragas, Mylasa) and tumuli with vaulted chambers (Pergamum).

The conquest of the orient had brought Greece into contact with the arch and vault, now freely used in supporting great masses over openings, as in city gates, retaining walls, corridors, staircases and sepulchral chambers. Sloping or intersecting barrel vaults were not uncommon.

The post-and-lintel system was by no means supplanted, but the vaulting system of the orient was being perfected, ready for the Romans to assimilate with their Etruscan traditions. See ROMAN ARCHITECTURE.

7. Graeco-Roman Period (100 B.C.–A.D. 300).—Many of the buildings erected in Greek lands during the Roman domination were still characteristically Greek. Doric was used in propylaea at Athens and Eleusis, and in temples at Eleusis and Kourno. Greek Ionic appears in the circular temple on the Athenian Acropolis, in a propylon at Priene, and particularly in a series of octastyle pseudodipteral temples in Asia Minor (Aezani, Ancyra, Aphrodisias). A hybrid Corinthian style with mixed Doric-Ionic entablatures occurs at Eleusis and Paestum. A simple type of Corinthian capital was used in the clock tower ("Tower of the Winds") at Athens. But the developed Corinthian orders of temples at Sagalassus, Euromus, Cnidus and Pergamum are hardly to be differentiated from those of imperial Rome.

Even though the decorative orders might be those of Rome, some buildings were still distinctive in type. Side by side with true Roman theatres, with wide, low stages and semicircular orchestras (Aspendus), were erected theatres of a compromise type, with equally wide but lofty stages and three-quarter circular orchestras (Termessus); both types had lofty scene buildings incrusted with columns, sometimes connecting with colonnades at the top of the auditorium. The stadium likewise remained characteristically Greek, with further elaboration, such as semicircles at both ends and colonnades at the top.

However, the basilicas, baths, triumphal arches and other forms which flourished everywhere in Greece and Asia Minor at this epoch can with more propriety be considered as part of the purely Roman development.

GREEK ART. It is proposed in the present article to give a brief account of the history of Greek art and of the principles embodied in that history. The products of the various arts practised by a people constitute an objective and most important record of the spirit of that people. But all nations have not excelled in the same way: some have found their best expression in architecture, some in music, some in poetry. The Greeks most fully embodied their ideas in two ways. first in their splendid literature, both prose and verse, and secondly, in their plastic and pictorial art, in which matter they have remained to our days among the greatest instructors of mankind.

The three arts of architecture, sculpture and painting were brought by them into a focus; and by their aid the Greeks produced a visible splendour of public life such as has seldom been elsewhere attained.

The volume of the remains of Greek civilization is so vast, and the learning with which these have been discussed is so ample, that it is hopeless to attempt to find in a work like the present any complete account of either. Rather we shall be frankly eclectic, choosing for consideration such results of Greek art as are most noteworthy and most characteristic. In some cases it will be possible to give a reference to a more detailed treatment of particular monuments in these volumes under the heading of their authors or the places to ahich they belong. Architectural detail is relegated to GREEK ARCHITECTURE and allied articles. Coins and gems *(see* GEM: *Gems in Art)* are treated apart, as are vases (POTTERY AND PORCELAIN); in the article GREEK ARCHAEOLOGY will be found many references bearing on the rediscovery of Greek art and on the discovery of individual monuments and sites; *see* also the bibliography which closes this article.

THE GENERAL PRINCIPLES OF GREEK ART

The study of Greek art is one which is eminently progressive. It has over the study of Greek literature the immense advantage that its materials increase far more rapidly. And it may well be maintained that a sound and methodic study of Greek art is as indispensable as a foundation for an artistic and archaeological education as the study of Greek poets and orators is as a basis of literary education. The extreme simplicity and thorough rationality of Greek art make it an unrivalled field for the training and exercise of the faculties which go to the making of the art critic and art historian.

Before proceeding to sketch the history of its rise and decline, it is desirable briefly to set forth the principles which underlie it *(see* also P. Gardner's *Principles* of *Greek Art)*.

As the literature of Greece is composed in a particular language, the grammar and syntax of which have to be studied before the works in poetry and prose can be read, so Greek works of art are composed in what may be called an artistic language. To the accidence of a grammar may be compared the mere technique of sculpture and painting; to the syntax of a grammar correspond the principles of composition and grouping of individual figures into a relief or picture By means of the rules of this grammar the Greek artist threw into form the ideas which belonged to him as a personal or a racial possession.

No nation is in its works wholly free from the domination of climate and geographical position; least of all a people so keenly alive to the influence of the outer world as the Greeks. They lived in a land where the soil was dry and rocky, far less hospitable to vegetation than that of western Europe, while the land horizon was on all sides bounded by hard and jagged lines of mountain. The sky was extremely clear and bright, sunshine for a great part of the year almost perpetual, and storms, which are more than passing gales, rare. It was in accordance with these natural features that temples and other buildings should be simple in form and bounded by clear lines. Such forms as the cube, the oblong, the cylinder, the triangle, the pyramid abound in their constructions. Just as in Switzerland the gables of the chalets match the pine-clad slopes and lofty summits of the mountains, so in Greece, amid barer hills of less elevation. the Greek temple looks thoroughly in place. But its construction is related not only to the surface of the land, but also to the character of the race. Émile Boutmy, in his interesting *Philosophie de l'architecture en Grèce*, has shown how the temple is a triumph of the senses and the intellect, not primarily emotional, but showing in every part definite purpose and design. It also exhibits in a remarkable degree the love of balance, of symmetry, of a mathematical proportion of parts and correctness of curvature which belong to the Greek artist.

Here, however, our concern is not with the purposes or arrangements of a temple, but with its sculptural decoration, and we would note that elaborate decoration is reserved for those parts of the temple which have, or at least appear to have, no strain laid upon them. It is true that in the archaic age experiments were made in carving reliefs on the lower drums of columns (as at Ephesus) and on the line of the architrave (as at Assus). But such examples were not followed. Nearly always the spaces reserved for mythological reliefs or groups are the tops of walls, the spaces between the triglyphs. and particularly the pediments surmounting the two fronts, which might be left hollow without danger to the stability of the edifice. Detached figures in the round are in fact found only in the pediments, or standing upon the tops of the pediments. And metopes are sculptured in higher relief than friezes.

"When we examine in detail even the simplest architectural decoration, we discover a combination of care, sense of proportion, and reason. The flutings of an Ionic column are not in section mere arcs of a circle, but made up of a combination of curves which produce a beautiful optical effect; the lines of decoration, as may be best seen in the case of the Erechtheum, are cut with a marvellous delicacy. Instead of trying to invent new schemes, the mason contents himself with improving the regular patterns until they approach perfection, and he takes everything into consideration. Mouldings on the outside of a temple, in the full light of the sun, are differently planned from those in the diffused light of the interior. Mouldings executed in soft stone are less fine than those in marble. The mason thinks before he works and ahile he works, and thinks in entire correspondence with his surroundings." (*Principles of Greek Art,* p. 44.)

Greek architecture, however, is treated under GREEK ARCHITECTURE; we will therefore proceed to speak briefly on the principles exemplified in sculpture Existing works of Greek sculpture fall into tno classes The first comprises what may be called works of substantive art, statues or groups made for their own sake and to be judged by themselves. Such are cult-statues of deities from temple and shrine, honorary portraits of rulers or of athletes, dedicated groups and the like. The second comprises decorative sculptures. such as were made, usually in relief, for the decoration of temples and tombs and other buildings, and were intended to be subordinate to architectural effect

Speaking broadly, it may be said that the works of substantive sculpture in our museums are in the great majority of cases copies of doubtful exactness and verv various merit.

The Hermes of Praxiteles is almost the only marble statue which can be assigned positively to one of the great sculptors; we have to work back towards the productions of the peers of Praxiteles through works of poor execution, often so much restored in modern times as to be scarcely recognizable. Decorative works, on the other hand, are very commonly originals. and their date can often be accurately fixed, as they belong to known buildings. They are thus infinitely more trustworthy and more easy to deal with than the copies of statues of which the museums of Europe, and more especially those of Italy. are full. They are also more commonly unrestored But yet there are certain disadvantages attaching to them Decorative works, even when carried out under the supervision of a great sculptor, were but seldom executed by him. Usually they were the productions of his pupils or masons Thus they are not on the same level of art as substantive sculpture And they vary in merit to an extraordinary extent, according to the capacity of the man who happened to have them in hand, and who was probably but little controlled. Every one knous how noble are the pedimental sculptures of the Parthenon. But there is no reason why they should be so vastly superior to the frieze from Phigalia: nor why the heads from the temple at Tegea should be so fine, while those from the contemporary temple at Epidaurus should be comparatively insignificant From the records of payments made to the sculptors who worked on the Erechtheum at Athens it appears that they were ordinary masons, some of them not even citizens, and paid at the rate of 60 drachms (about 60 francs) for each figure, whether of man or horse, which they produced. Such piece-work would not, in our days, produce a very satisfactory result

1. Works of substantive sculpture may be divided into two classes, the statues of human beings and those of the gods. The line between the tuo is not. however. very easy to draw, or very definite For in representing men the Greek sculptor had an irresistible inclination to idealize, to represent what was generic and typical rather than what was individual, and the essential rather than the accidental And in representing deities he so fully anthropomorphized them that they became men and women, only raised above the level of everyday life and endowed with a superhuman stateliness. Moreover, there was a class of heroes represented largely in art who covered the transition from men to gods. For example, if one regards Heracles as a deity and Achilles as a

man of the heroic age and of heroic mould, the line between the two will be found to be very narrow.

Nevertheless one may for convenience speak first of human and afterwards of divine figures. It was the custom from the 6th century onwards to honour those who had done any great achievement by setting up their statues in conspicuous positions. The earliest example we have is the portraits of the twins Cleobis and Biton from Delphi mentioned by Herodotus.

Another of the earliest examples is that of the tyrannicides, Harmodius and Xristogiton, a group, a copy of which has come down to us. Again, people who had not won any distinction were in the habit of dedicating to the deities portraits of themselves or of a priest or priestess, thus bringing themselves, as it were, constantly under the notice of a divine patron. The rows of statues before the temples at Miletus, Athens and elsewhere came thus into being. But from the point of view of art, by far the most important class of portraits consisted of athletes who had won victories at some of the great games of Greece, at Olympia, Delphi or elsewhere. Early in the 6th century the custom arose of setting up portraits of athletic victors in the great sacred places. We have records of numberless such statues executed by all the greatest sculptors. When Pausanias visited Greece he found them everywhere far too numerous for complete mention.

It is the custom of studying and copying the forms of the finest of the young athletes, combined with the Greek habit of complete nudity during the sports, which lies at the basis of Greek excellence in sculpture. Every sculptor had unlimited opportunities for observing young vigorous bodies in every pose and in every variety of strain. The natural sense of beauty which was an endowment of the Greek race impelled him to copy and preserve what was excellent, and to omit what was ungainly or poor. Thus there existed, and in fact there was constantly accumulating, a vast series of types of male beauty, and the public taste was cultivated to an extreme delicacy. And of course this taste, though it took its start from athletic customs, and was mainly nurtured by them, spread to all branches of portraiture, so that elderly men, women, and at last even children, were represented in art with a mixture of ideality and fidelity to nature such as has seldom been reached by the sculpture of any other people.

The statues of the gods began with stiff and ungainly figures cut out of the trunk of a tree. In the Greece of late times there were still standing rude pillars, with the tops sometimes cut into a rough likeness to the human form And in early decoration of vases and vessels one may find Greek deities represented with wings, carrying in their hands lions or griffins, bearing on their heads lofty crowns. Rut as Greek art progressed it grew out of this crude symbolism. In the language of Brunn, the Greek artists borrowed from Oriental or Mycenaean sources the letters used in their works, but with these letters they spelled out the ideas of their oun nation. What the artists of Babylon and Egypt express in the character of the gods by added attribute or symbol, swiftness by wings, control of storms by the thunderbolt, traits of character by animal heads, the artists of Greece work more and more fully into the sculptural type; modifying the human subject by the constant addition of something which is above the ordinary level of humanity, until we reach the Zeus of Pheidias or the Demeter of Cnidus. When the decay of the high ethical art of Greece sets in, the gods become more and more warped to the merely human level They lose their dignity, but they never lose their charm.

2. The decorative sculpture of Greece consists not of single figures, but of groups; and in the arrangement of these groups the strict Greek laws of symmetry, of rhythm, and of balance, come in. We will take the three most usual forms, the pediment, the metope and the frieze, all of which belong properly to the temple, but are characteristic of all decoration, whether of tomb, trophy or other monument.

The form of the pediment is triangular'; the height of the triangle in proportion to its length being about 1:8. The conditions of space are here strict and dominant; lo comply with them requires some ingenuity. To a modern sculptor the problem thus presented is almost insoluble; but it was allowable in ancient art to represent figures in a single composition as of various sizes, in correspondence not to actual physical measurement but to importance. As the more important figures naturally occupy the midmost place in a pediment, their greater size comes in conveniently. And by placing some of the persons of the group in a standing, some in a seated, some in a reclining position, it can be so contrived that their heads are equidistant from the upper line of the pediment.

The statues in a Greek pediment, which are after quite an early period usually executed in the round, fall into three, five or seven groups, according to the size of the whole. As examples to illustrate this exposition we take the two pediments of the temple at Olympia, the most complete which have come down to us, which are represented in figs. 13 and 14.

The metopes were the long series of square spaces which ran along the outer walls of temples between the upright triglyphs and the cornice. Originally they may have been left open and served as windows; but the custom came in as early as the 7th century, first of filling them in with painted boards or slabs of stone, and next of adorning them with sculpture. The metopes of the Treasury of Sicyon at Delphi are as early as the first half of the 6th century. This recurrence of a long series of square fields for occupation well suited the genius and the habits of the sculptor. As subjects he took the successive exploits of some hero such as Heracles or Theseus, or the contemporary groups of a battle. His number of figures was limited to tno or three, and these figures had to be worked into a group or scheme, the main features of which were determined by artistic tradition, but which could be varied in a hundred ways so as to produce a pleasing and in some degree novel result.

With metopes, as regards shape, may be compared the reliefs of Greek tombs, which also usually occupy a space roughly square, and which also comprise but a few figures arranged in a scheme generally traditional. A figure standing, giving his hand to one seated, two men standing hand in hand, or a single figure in some vigorous pose, is sufficient to satisfy the simple and severe taste of the Greeks.

In regard to friezes, which are long reliefs containing figures ranged between parallel lines, there is more variety of custom. In temples the height of the relief from the background varies according to the light in which it was to stand, whether direct or diffused. Almost all Greek friezes, however, are of great simplicity in arrangement and perspective. Locality is at most hinted at by a few stones or trees, never actually portrayed There is seldom more than one line of figures, in combat or procession, their heads all equidistant from the top line of the frieze. They are often broken up into groups; and when this is the case, figure will often balance figure on either side of a central point almost as rigidly as in a pediment.

Some of the friezes executed by Greek artists for semi-Greek peoples, such as those adorning the tomb at Trysa in Lycia, have two planes, the figures in the background being at a higher level.

The rules of balance and symmetry in composition which are followed in Greek decorative art are still more clearly to be discerned in the paintings of vases, which must serve, in the absence of more dignified compositions, to enlighten us as to the methods of Greek painters. Great painters would not, of course, be bound by architectonic rule in the same degree as the mere workmen. But in any case the fact must never be lost sight of that Greek painting of the earlier ages was of extreme simplicity. It did not represent localities, save by some slight hint; it had next to no perspective; the colours used were but very few even down to the days of Apelles. Most of the great pictures of which we hear consisted of but one or two figures; and when several figures were introduced they were kept apart and separately treated, though, of course, not without relation to one another. Idealism and ethical purpose must have predominated in painting as in sculpture and in the drama and in the writing of history. The laws of balance and symmetry in Greek drawing are perhaps best shown in the decoration of vases (see POTTERY AND PORCELAIN).

HISTORIC SKETCH

To begin with, there was a rise of national art, after the destruction of the Minoan and Mycenaean civilizations by the irruption of tribes from the north (see ARCHAEOLOGY: Greek *and Roman* Orient [Including *Egypt-Indus*]), and then the Roman age of Greece, after which the Greek art works in the service of the conquerors (see ROMAN ART). The period (roughly 800–?50 B.C.) is divided into four sections: (1) to the Persian Wars, 480 B.C.; (2) the period of the early schools of art, 480–400 B.C.; (3) that of the later great schools, 400–300 B.C.; (4) that of Hellenistic art, 300–50 B.C. In dealing with these periods this article is confined to sculpture and painting, which in Greece are closely connected. The arts — pottery. gem-engraving and the like — are treated under their separate headings, and the reader is also referred to the biographical accounts of the chief artists (PHIDIAS, PRAXITELES, APELLES, etc.).

PERIOD I. 800–480 B.C.

The Aegean or Mycenaean civilization was for the most part destroyed by what appears to have been a gradual invasion from the north; its racial character is much in dispute, though archaeological evidence abundantly proves that it was the conquest of a more by a less rich and civilized race. In the graves of the period (900–600 B.C.) is found none of the wealthy spoil which has made celebrated the tombs of Mycenae and Vaphio (*q.v.*). The

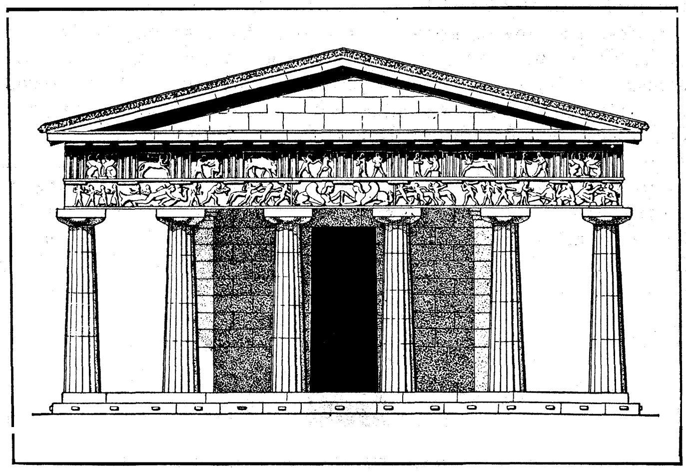
FIG. I. — RESTORATION OF THE TREASURY OF CNIDUS. IONIC STYLE

character of the pottery and the bronze-work which is found in these later graves reminds one of the funerary art of Hallstatt and other sites belonging to what is called the bronze age of North Europe. Its predominant characteristic is the use of geometrical forms, the lozenge, the triangle, the maeander, the circle with tangents, in place of the elaborate spirals and plant-forms which mark Mycenaean ware. For this reason the period from the 9th to the 7th century in Greece passes by the name of "the Geometric Age." It is commonly held that in the remains of the geometric age is traced the influence of the Dorians, who, coming in as a hardy but uncultivated race, probably of purer Aryan blood than the previous inhabitants of Greece, not only brought to an end the wealth and the luxury which marked the Mycenaean age, but also replaced an art which was in character essentially southern by one which belonged rather to the north and the west. The great difficulty inherent in this view, a difficulty which has yet to be



FROM PERROT AND CHIPIEZ, "HISTOIRE DE L ART" (CHAPMAN AND HALL, AND HACHETTE & CO.)

FIG. 2. — RESTORATION OF THE TEMPLE AT ASSUS, SHOWING THE FRIEZE OF ARCHAIC DECORATIVE SCULPTURES ALONG THE ENTABLATURE

met, lies in the fact that some of the most abundant and characteristic remains of the geometric age which we possess come, not from Peloponnesus, but from Athens and Boeotia, which were never conquered by the Dorians. For the early history of Greek work in gold and bronze refer to the articles METALWORK, DECORATIVE, and SILVERSMITHS' AND GOLDSMITHS' WORK.

Architecture **and** Sculpture. — The Greek temple in its character and form gives the clue to the whole character of Greek art. It is the abode of the deity, who is represented by his sacred image: and the flat surfaces of the temple offer a great field to the sculptor for the depicting of sacred legend. The process of discovery has emphasized the line which divides Ionian from Dorian architecture and art. The Ionians were a people more susceptible than were the Dorians to oriental influences. The dress, the art, the luxury of western Asia attracted them with irresistible force. We may suspect, as Brunn has suggested that Ionian artists worked in the great Assyrian and Persian palaces (and that the wall reliefs of those palaces were in part their handiwork). Some of the great temples of Ionia have been excavated in recent times notably those of Apollo at Miletus, of Hera at Samos, and of Artemis at Ephesus. Very little, however, of the architecture of the 6th century temples of those sites has been recovered,' though the French, who have been excavating at Delphi more or less continuously since 1892, have successfully restored the treasury of the people of Cnidus.(fig. 1), which is quite a gem of Ionic style, the entablature is supported in front not by pillars but by two maidens or Corae. and a frieze runs all round the building above. But though this building is of Ionic type, it is scarcely in the technical sense of Ionic style since the columns have not Ionic capitals, but are carved with curious reliefs. The Ionic capital proper is developed in Asia by degrees (see GREEK ARCHITECTURE; ORDER; CAPITAL; also Perrot and Chipiez, *Hist.* de *l'art,* vii, 4).

The Doric temple is not wholly of European origin, yet it was developed mainly in Hellas and the west. The most ancient example is the Heraeum at Olympia, next to which come the fragmentary temples of Corinth and of Selinus in Sicily. With the early Doric temple we are familiar from examples which have survived in fair preservation to our own days at Agrigentum in Sicily, Paestum in Italy, and other sites.

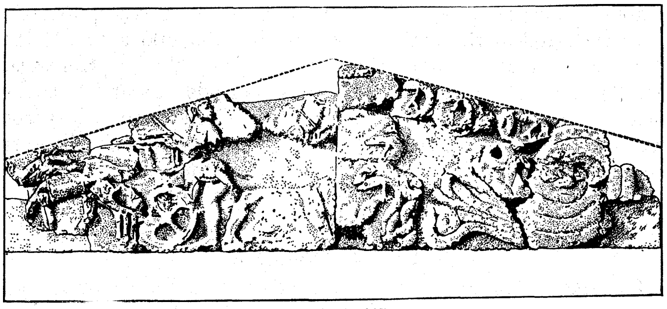
Of the decorative sculpture which adorned these early temples we have more extensive remains than we have of actual construction. It will be best to speak of them under their districts. On the coast of Asia Minor, the most extensive series of archaic decorative sculptures which has come down to us is that which adorned the temple of Assus (fig. 2). These were placed in a unique position on the temple, a long frieze running along the entablature, with representations of wild animals, of centaurs, of Heracles seizing Achelous, and of men feasting, scene succeeding scene without much order or method. The only figures from Miletus which can be considered as belonging to the original temple destroyed by Darius, are the dedicated seated statues, some of which, brought away by Sir Charles Newton in the middle of the 19th century, are now preserved at the British Museum. At Ephesus J. T. Wood was more successful (1869–74) and recovered considerable fragments of the temple of Artemis, to which, as Herodotus tells us, Croesus presented many columns. The lower part of one of these columns, bearing figures in relief of early Ionian style, has been put together at the British Museum; and remains of inscriptions recording the presentation by Croesus are still to be traced. Reliefs from a cornice of somewhat later date are also to be found at the British Museum. Among the Aegean islands, Delos has furnished us with the most important remains of early

FROM COLLIGNON, ('SCULPTURE GRECQUE"

FIG. 3.— STATUE OF NIKE OR VICTORY OF DELOS (RESTORED)

art. French excavators have there found a very early statue of a woman dedicated by one Nicandra to Artemis, a figure which may be instructively compared with another from Samos, dedicated to Hera by Cheramues. The Delian statue is in shape like a flat beam; the Samian, which is headless, is like a round tree. The arms of the Delian figure are rigid to the sides; the Samian lady has one arm clasped to her breast. A great improvement on these inexpressive figures is marked by another figure found at Delos, and connected, though perhaps incorrectly, with a bases recording the execution of a statue by Archermus and Micciades, two sculptors who stood, in the middle of the 6th century, at the head of a sculptural school at Chios. The representation (fig. 3) is of a running or flying figure, having six wings, like the seraphim in the vision of Isaiah, and clad in long drapery. It may be a statue of Nike or Victory, who is said to have been represented in winged form by Archermus. The figure, with its neatness and precision of work, its expressive face and strong outlines, certainly marks great progress in the art of sculpture. When the early sculpture of Athens is examined, reason is found to think that the Chian school had great influence in that city in the days of Peisistratus.

Athenian Sculpture. At Athens, in the age 650–480, may be traced two quite distinct periods of architecture and sculpture. In the earlier of the two periods, a rough limestone was used alike for the walls and the sculptural decoration of temples; in the later period it was superseded by marble, whether native or imported. Every visitor to the museum of the Athenian Acropolis stands astonished at the groups which decorated the pediments of Athenian temples before the age of Peisistratus — groups of large size, rudely cut in soft stone, of primitive workmanship, and painted with bright red, blue and green, in a fashion which makes no attempt to follow nature, but only to produce a vivid result. The two largest in scale of these groups seem to have belonged to the pediments of the early 6th century temple of Athena. On



FROM "ATHEN. MITTEIL. DEUTSCH. ARCH." INST. X. 237

FIG. 4.— ATHENIAN PEDIMENT REPRESENTING HERACLES SLAYING THE LERNAEAN HYDRA WHILE IOLAUS HOLDS THE REINS OF THE CHARIOT

other smaller pediments, perhaps belonging to shrines of Heracles and Dionysus, there are conflicts of Heracles with Triton or with other monstrous foes. It is notable how fond the Athenian artists of this early time are of exaggerated muscles and of monstrous forms, which combine the limbs of men and of animals; the measure and moderation which mark developed Greek art are as completely absent as are skill in execution or power of grouping. Fig. 4 shows a small pediment in which appears in relief the slaying of the Lernaean hydra by Heracles. The hero strikes at the many-headed water-snake, somewhat inappropriately, with his club. Iolaus, his usual companion, holds the reins of the chariot which awaits Heracles after his victory. On the extreme left a huge crab comes to the aid of the hydra.

There can be little doubt that Athens owed its great start in art to the influence of the court of Peisistratus, at which artists of

FROM "ATHEN. MITTEIL. DEUTSCH. ARCH "

FIG. 5.— ATHENA STRIKING AT A PROSTRATE FOE. FROM A MARBLE PEDIMENT ON THE TEMPLE OF ATHENA

all kinds were welcome. There was a gradual transformation in sculpture, in which the influence of the Chian and other progressive schools of sculpture was visible, not only in the substitution of island marble for native stone, but in increased grace and truth to nature, in the toning down of glaring colour, and the appearance of taste in composition. A transition between the older and the newer is furnished by the well-known statue of the calf-bearer, an Athenian preparing to sacrifice a calf to the deities, which is made of marble of Hymettus, and in robust clumsiness of forms is not far removed from the limestone pediments. The sacrificer has been commonly spoken of as Hermes or Theseus, but he seems rather to be an ordinary human votary.

In the time of Peisistratus or his sons a peristyle of columns was added to the old temple of Athena; and this necessitated the preparation of fresh pediments. These were of marble. In one of them was represented the battle between gods and giants; in the midst Athena herself striking at a prostrate foe (fig. S). In these figures no eye can fail to trace remarkable progress. On about the same level of art are the charming statues dedicated to Athena, which were set up in the latter half of the 6th century on the Acropolis, whose graceful though conventional forms and delicate colouring make them one of the great attractions of the Acropolis museum. We show a figure (fig. 6) which is the work of the sculptor Antenor, who was also author of a celebrated group representing the tyrant-slayers, Harmodius and Aristogiton. To the same age belong many other votive reliefs of the Acropolis, representing horsemen, scribes and other votaries of Athena.

FIG. 6.— FIGURE BY ANTENOR, UNRESTORED

Dorian Sculpture. From Athens we pass to the seats of Dorian art. And in doing so we find a complete change of character. In place of draped goddesses and female figures, there are nude male forms. In place of Ionian softness and elegance, hard, rigid outlines, strong muscular development, a greater love of and faithfulness to the actual human form—the influence of the palaestra rather than of religion. To the known series of archaic male figures modern exploration has added many examples. More especially may be mentioned figures from the temple of Apollo Ptoos in Boeotia, probably representing the god himself. Still more noteworthy are two colossal nude figures of Cleobis and Biton remarkable both for force and for rudeness, found at Delphi, the inscriptions of which prove them to be the work of an Argive sculptor. In the island of Crete was found the upper part of a draped figure, whether male or female is not certain, which should be an example of the early Daedalid school, whence the art of Peloponnesus was derived; it is hardly a characteristic product of that school; rather the likeness to the dedication of Nicandra is striking.

Another remarkable piece of Athenian sculpture, of the time of the Persian Wars, is the group of the tyrannicides Harmodius and Aristogiton, set up by the people of Athens, and made by the sculptors Critius and Nesiotes. These figures were hard and rigid in outline, but showing some progress in the treatment of the nude. Copies are preserved in the museum of Naples.

Olympia, Sparta, Selinus. Next in importance to Athens, as a find-spot for works of early Greek art, ranks Olympia. Olympia, however, did not suffer like Athens from sudden violence, and the explorations there have brought to light a continuous series of remains, beginning with bronze tripods of the geometric age and ending at the barbarian invasions of the 4th century A.D. Notable among the 6th century stone-sculpture of Olympia are the pediment of the treasury of the people of Megara, in which is represented a battle of gods and giants, and a huge rude head of Hera which seems to be part of the image worshipped in the Heraeum. Its flatness and want of style should be noted.

Among the temples of Greece proper the Heraeum of Olympia stands almost alone for antiquity and interest, its chief rival, besides the temples of Athens, being the other temple of Hera at Argos. It appears to have been originally constructed of wood, for which stone was by slow degrees, part by part, substituted. In the time of Pausanias one of the pillars was still of oak, and at the present day the varying diameter of the columns and other structural irregularities bear witness to the process of constant renewal which must have taken place. The early small bronzes of Olympia form an important series, figures of deities standing or striding, warriors in their armour, athletes with exaggerated muscles, and women draped in the Ionian fashion, which did not become unpopular in Greece until after the Persian Wars.

Excavations at Sparta have revealed interesting monuments belonging to the worship of ancestors, which seems in the conse ative Dorian states of Greece to have been more strongly developed than elsewhere On some of these stones, which doubtless belonged to the family cults of Sparta, are shown the ancestor seated holding a wine-cup, accompanied by his faithful horse or dog; on some we see the ancestor and ancestress seated side by side (fig 7), ready to receive the gifts of their descendants, who appear in the corner of the relief on a much smaller scale. The male figure holds a wine-cup, in allusion to the libations of wine made at the tomb. The female figure holds her veil and the pomegranate, the recognized food of the dead. A huge serpent stands erect behind the pair The style of these sculptures is as striking as the subject.—lean, rigid forms with severe outline, carved in a very low relief, the surface of which is not rounded but flat. The name of Selinus in Sicily, an early Megarian colony, has long been associated with some of the most curious of early sculptures, the metopes of ancient temples, representing the exploits of Heracles and of Perseus Even more archaic metopes have in recent years been brought to light, one representing a seated sphinx, one the journey of Europa over the sea on the back of the amorous bull, a pair of dolphins swimming beside her. In simplicity and rudeness of work these reliefs remind us of the limestone pediments of Athens (fig 4), but they are of another and a severer style; the Ionian laxity is wanting.

Delphi. The French excavations at Delphi add a new and important chapter to the history of 6th century art. Of the archaic temple of Apollo, built as Herodotus tells us by the Alcmaeonidae of Athens, the only sculptural remains which have come down to us are some fragments of the pedimental figures. Of the treasuries which contained the offerings of the pious at Delphi, the most archaic of which there are remains is that belonging to the people of Sicyon. To it appertains a set of exceedingly primitive metopes. One depicts Idas and the Dioscuri driving off cattle; another, the ship Argo; another. Europa on the bull, others merely animals. a ram or a hoar. The treasury of the people of Cnidus (or perhaps Siphnos) is in style some half a century later

FIG. 8.— EAST AND WEST PEDIMENTS OF THE TEMPLE AT AEGINA AS RESTORED BY FURTWÄNGLER

(*see* fig. 1). To it belongs a long frieze representing a variety of curious subjects: a battle, perhaps between Greeks and Trojans, with gods and goddesses looking on; a gigantomachy in which the figures of Poseidon, Athena, Wera, Apollo, Artemis and Cybele

FIG. 9.— METOPE FROM SELINUS. EUROPA ON BULL. NOW AT PALERMO

can be made out, with their opponents, who are armed like Greek hoplites; Athena and Heracles in a chariot; the carrying off of the daughters of Leucippus by Castor and Pollux; Hephaestus with his fire. The treasury of the Athenians, erected at the time of the Persian Wars, was adorned with metopes of singularly clear-cut and beautiful style, but very fragmentary, representing the deeds of Heracles and Theseus.

The most interesting and important of all Greek archaic sculptures are the pediments of the temple at Aegina (q *v*). These groups of nude athletes fighting over the corpses of their comrades are preserved at Munich, and are familiar to artists and students. But the very fruitful excavations of Prof Furtwangler put them in quite a new light. Furtwangler (*Aegina: Heiligtum* der *Aphaia*) entirely rearranged these pediments, in a way which removed the extreme simplicity and rigour of the composition, and introduced far greater variety of attitudes and motive. R e repeat here these new arrangements (fig. 8), the reasons for which must be sought in Furtwängler's great publication The individual figures are not much altered, as the restorations of Thorwaldsen, even when incorrect, have now a prescriptive right of which It is not easy to deprive them. Beside the pediments of Aegina must be set the remains of the pediments of the temple of Apollo at Eretria in Euboea, the chief group of which. Theseus carrying off an Amazon, is one of the most finely executed works of early Greek art.

PERIOD II. 480–400 B.C.

The most marvellous phenomenon in the whole history of art is the rapid progress made by Greece in painting and sculpture during the 5th century B C As in literature the jth century takes us from the rude peasant plays of Thespis to the drama of Sophocles and Euripides; a5 in philosophy it takes us from Pythagoras to Socrates; so in sculpture it covers the space from the primitive works made for the Peisistratidae to some of the most perfect productions of the chisel

In architecture the 5th century is ennobled by the Theseum, the Parthenon and the Erechtheum, the temples of Zeus at Olympia, ot Apollo at Phigalia, and many other central shrines, as well as by the Hall of the Mystae at Eleusis and the Propylaea of the Acropolis Some of the most important of the Greek temples of Italy and Sicily, such as those of Segesta and Selinus, date from the same age. It is, however, only or' their sculptural decorations, carried out by the greatest masters in Greece, that we need here treat in any detail.

Painting.— It is the rule in the history of art that innovations and technical progress are shown earlier in the case of painting than in that of sculpture, a fact easily explained by the greater ease and rapidity of the brush compared with the chisel. That this was the order of development in Greek art cannot be doubted. But our means for judging of the painting of the 5th century are very slight. The noble paintings of such masters as Eolygnotus, Micon and Panaenus, which once adorned the walls of the great porticos of Athens and Delphi, have disappeared. There remain only the designs drawn rather than painted on the beautiful vases of the age, which in some degree help us to realize, not the colour-

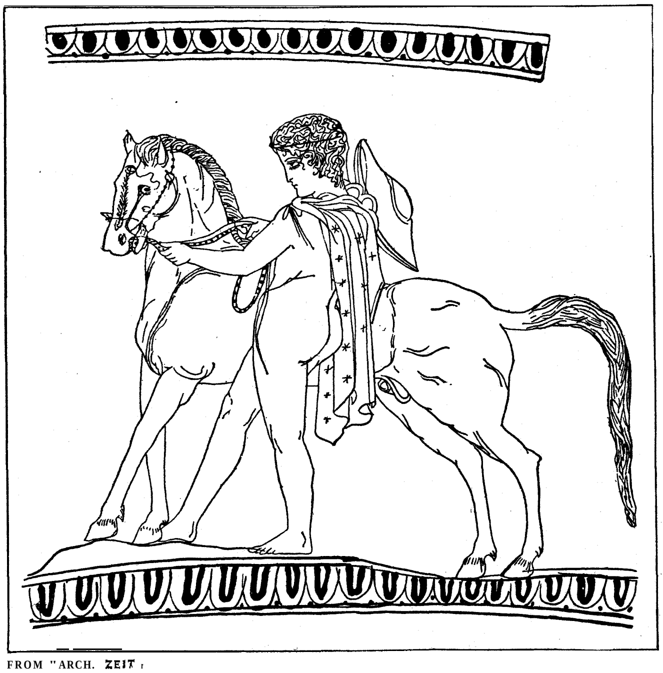
ing or the charm of contemporary paintings, but the principles of their composition and the accuracy of their drawing.

Polygnotus of Thasos was regarded by his compatriots as a great ethical painter. His colouring and composition were alike very simple, his figures quiet and statuesque, his drawing careful and precise. He won his fame largely by incorporating in his works the best current ideas as to mythology, religion and morals. In particular his painting of Hades with its rewards and punishments, which was on the walls of the building of the people of Cnidus at Delphi, might be considered as a great religious work, parallel to the paintings of the Campo Santo at Pisa or to the



FROM "ARCH. ZEIT.

FIG. 11.— VASE PAINTING. 5TH CENTURY B.C.

painted windows of such churches as that at Fairford. But he also introduced improvements in perspective and greater freedom in grouping.

It is fortunate for us that the Greek traveller Pausanias has left very careful and detailed descriptions of some of the most important of the frescoes of Polygnotus, notably of the Taking of Troy and the Visit to Hades, which were at Delphi. A comparison of these descriptions with vase paintings of the middle of the 5th century has enabled us to discern with great probability the principles of Polygnotan drawing and perspective. Prof. Robert has even ventured to restore the paintings on the evidence of vases. There is represented one of the scenes depicted on a vase found at Orvieto (fig. 10), which is certainly Polygnotan in character. It represents the slaying of the children of Niobe by Apollo and Artemis. Here may be observed a remarkable perspective. The different heights of the rocky background are represented by lines traversing the picture on which the figures stand;

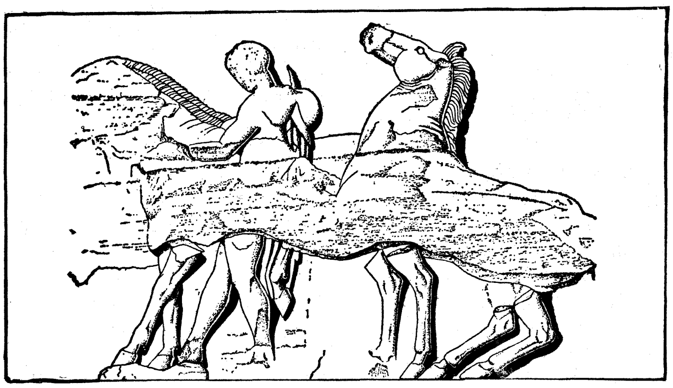


FIG. 12.—A GROUP FROM THE PANATHENAIC FRIEZE OF THE PARTHENON

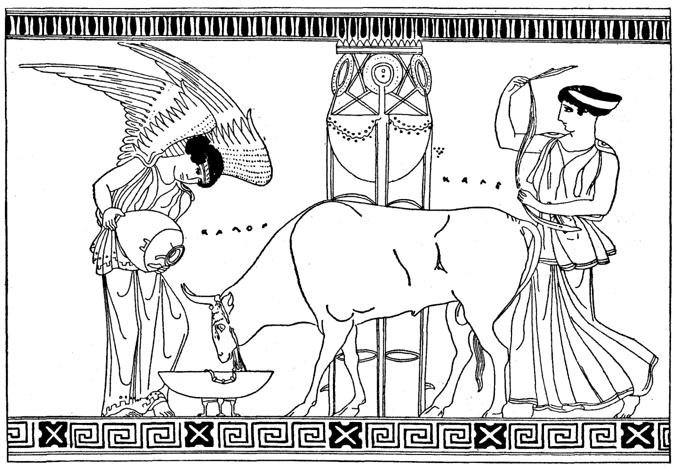
but the more distant figures are no smaller than the nearer. The forests of Mount Sipylus are represented by a single conventional tree. The figures are beautifully drawn, and full of charm; but there is a want of energy in the action.

There can be little doubt that the school of Polygnotus exercised great influence on contemporary sculpture. Panaenus, brother of Pheidias, worked with Polygnotus, and many of the groupings found in the sculptures of the Parthenon remind us of those usual with the Thasian master. At this simple and early stage of art there was no essential difference between fresco-painting and coloured relief, light and shade and aerial perspective being unknown. Two vase-paintings are shown, one (fig. 11), a group of man and horse which closely resembles figures in the Panathenaic frieze of the Parthenon (fig. 12); the other (fig. 13), representing Victory pouring water for a sacrificial ox to drink, which reminds us of the balustrade of the shrine of Wingless Victory at Athens.

Most writers on Greek painting have supposed that after the middle of the 5th century the technique of painting rapidly im-



FROM GERHARD, "AUSERLESENE VASENBILDER"

FIG. 13.—VASE PAINTING OF NIKE AND BULL, 5TH CENTURY B.C.

proved. This may well have been the case; but there is little means of testing the question. Such improvements would soon raise such a barrier between fresco-painting and vase-painting—which by its very nature must be simple and architectonic—that vases can no longer be used with confidence as evidence for contemporary painting. The stories told us by Pliny of the lives of

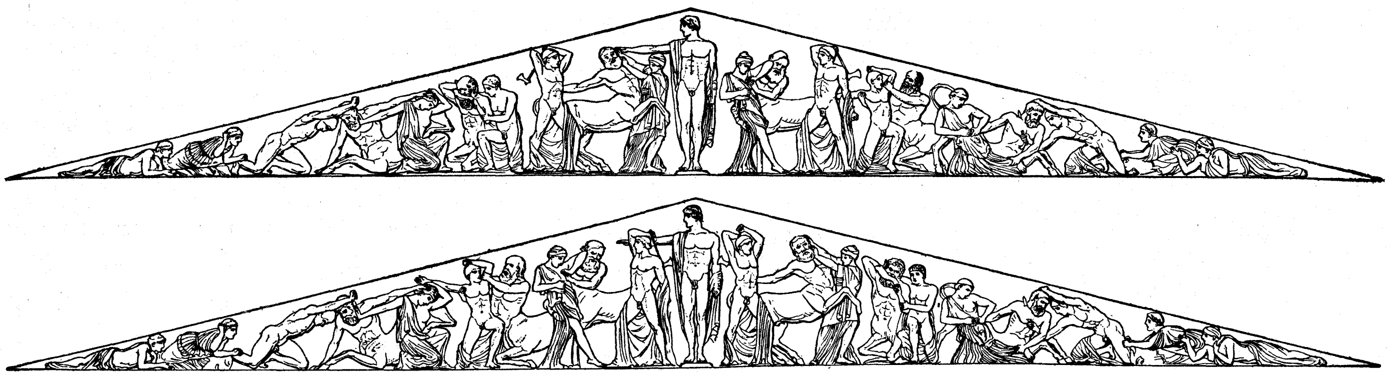


FIG. 14.—TWO CONJECTURAL RESTORATIONS OF THE WESTERN PEDIMENT OF THE GREAT TEMPLE OF ZEUS AT OLYMPIA

Greek painters are mostly of a trivial and untrustworthy character, and in them there are discernible only a few general facts. Of Agatharchus of Athens we learn that he painted, under compulsion, the interior of the house of Alcibiades, and we are told that he painted a scene for the tragedies of Aeschylus or Sophocles, thus leading some to suppose that he attempted illusive landscape. But this is contrary to the possibilities of the time, and it is fairly certain that what he really did was to paint the wooden front of the stage building in imitation of architecture; in fact he painted a permanent architectural background, and not one suited to any particular play Of other painters who flourished at the md of the century, such as Zeuxis and Aristides, it will be best to speak under the next period

It is now genrrally held, in consequence of evidence furnished by tombs that the 5th century saw the end of the making of vases on a great scale at Athens for export to Italy and Sicily. And, in fact, few things in the history of art are more remarkable than the rapidity with which vase-painting at Athens reached its highest point and passed it on the downward road. At the beginning of the century black-figured ware was scarcely out of fashion, and the masters of the severe red-figured style, Pamphaeus, Epictetus and their contemporaries, were in vogue. The schools of Euphronius Hiero and Duris belong to the age of the Persian wars. With the middle of the century the works of these makers are succeeded by unsigned vases of most beautiful design, some of them showing the influence of Polygnotus In the later years of the century, when the empire of Athena was approaching its fall, drawing becomes laxer and more careless, and in the treatment of drapery we frequently note the over-elaboration of folds, the want of simplicity, which begin to mark contemporary sculpture.

Olympia: Temple of **Zeus.**—Among the sculptural works of this period the first place may be given to the great temple of Zeus at Olympia. The statue by Pheidias, which once occupied the place of honour in that temple, and was regarded as the noblest monument of Greek religion, has of course disappeared, nor are we able with confidence to restore it. But the plan of the temple, its pavement, some of its architectural ornaments, remain The marbles which occupied the pediments and the metopes of the temple have been in large part recovered, having been probably thrown down by earthquakes and gradually buried in the alluvial soil. The utmost ingenuity and science of the German archaeologists have been employed in the recovery of the composition of these groups; and, although doubt remains as to the places of some figures, and their precise attitudes, we may fairly say that we know more about the sculpture of the Olympian temple of Zeus than about that of any other great Greek temple. The exact date of these sculptures is not certain, but with some confidence they may be placed between 470–460 B.C. (In speaking of them the opinion of Dr. Treu is followed, whose masterly work in vol. iii. of the great German publication on Olympia is a model of patience and of science.) In the eastern pediment (fig. I j), as Pausanias tells us, were represented the preparations for the chariot-race between Oenomaiis and Pelops, the result of which was to determine whether Pelops should find death or a bride and a kingdom. In the midst, invisible to the contending heroes, stood Zeus the supreme arbiter. On one side of him stood Oenomaiis with his wife Sterope, on the other Pelops and Hippodameia, the daughter of Oenomaus, whose position at once indicates that she is on the side of the newcomer, whatever her parents may feel. Next on either side are the four-horse chariots of the two competitors, that of Oenomaus in the charge of his perfidious groom Myrtilus, who contrived that it should break down in the running, that of Pelops tended by his grooms. At either end, where the pediment narrows to a point, reclines a river god, at one end Alpheus, the chief stream of Olympia, at the other his tributary Cladeus. Only one figure remains, not noticed in the careful description of Paussnias, the figure of a handmaid kneeling, perhaps one of the attendants of Sterope. The illustration gives two conjectural restorations of the pediment, that of Treu and that of Kekulé, which differ principally in the arrangement of the corners of the composition; that of the central figures and of the chariots can scarcely be called in question. The moment chosen is one, not of action, but of expectancy, perhaps of preparation for sacrifice. The arrangement is undeniably stiff and formal, and in the figures we note none of the trained perfection of style which belongs to the sculptures of the Parihenon, an almost contemporary temple. Faults abound, alike in the rendering of drapery and in the representation of the human forms, and the sculptor has evidently trusted to the painter who was afterwards to colour his work, to remedy some of his clumsiness, or to make clear the ambiguous.

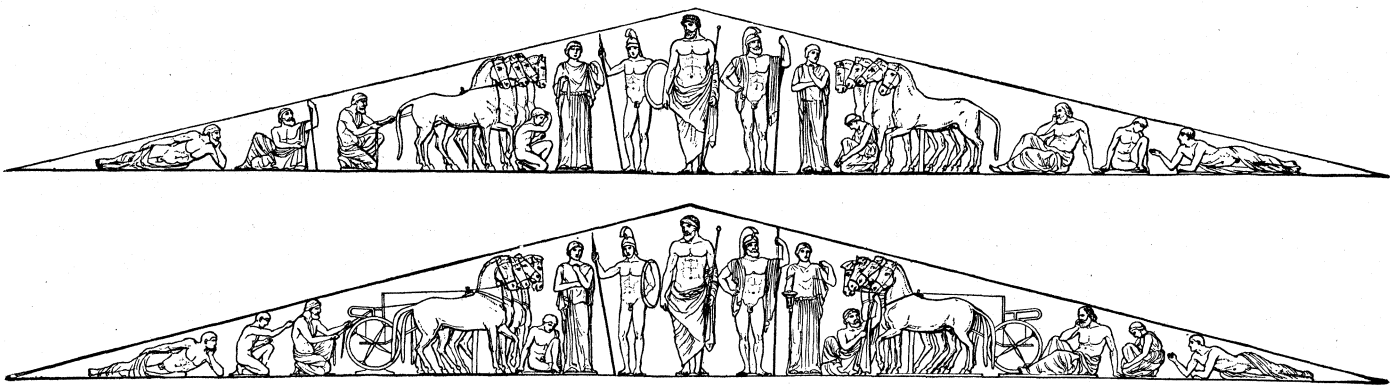

FIG. 15.—TWO CONJECTURAL RESTORATIONS OF THE EASTERN PEDIMENT OF THE GREAT *TEWPLE* OF ZEUS AT OLYMPIA

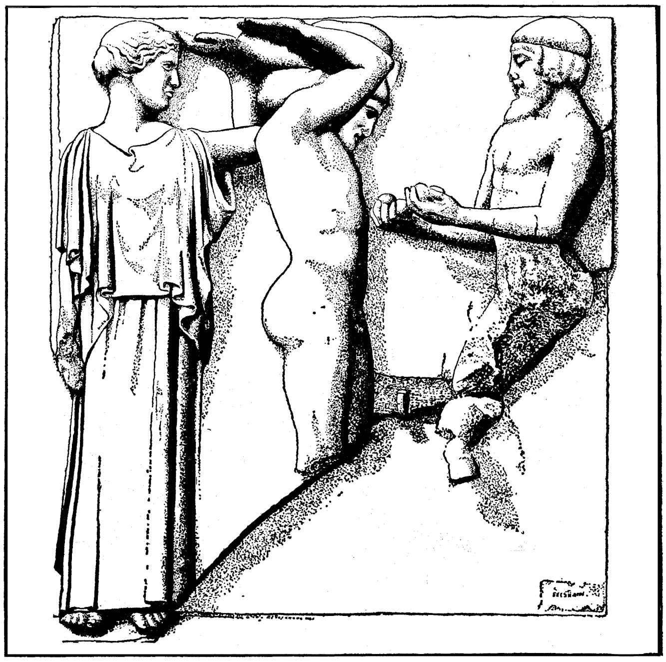
Nevertheless there is in the whole a dignity, a sobriety and a simplicity, which indicates that this pediment was certainly regarded in antiquity as a noble work. fit to adorn even the palace of Zeus. In the western pediment (fig. 14), the subject is the riot of the centaurs when they attended the wedding of Peirithous in Thessaly, and, attempting to carry off the bride and her comrades,



FROM "OLYMPIA," VOL. III., E. TREU, EDITOR

FIG. 16.— METOPE FROM THE TEMPLE OF ZEUS AT OLYMPIA REPRESENTING ONE OF THE 12 LABOURS OF HERACLES (UNRESTORED)

were slain by Peirithous and Theseus. In the midst of the pediment, invisible like Zeus in the eastern pediment, stands Apollo, while on either side of him Theseus and Peirithous attack the centaurs with weapons hastily snatched. The illustration gives two possible arrangements. The monsters are in various attitudes of attempted violence, of combat and defeat; with each grapples one of the Lapith heroes in the endeavour to rob them of their prey. In the corners of the pediment recline female figures, perhaps attendant slaves, though the farthest pair may best be identified as local Thessalian nymphs, looking on with the calmness of divine superiority, yet not wholly unconcerned in what is going forward. Though the composition of the two pediments differs notably, the one bearing the impress of a paradelike repose, the other of an overstrained activity, the style and execution are the same in both, and the shortcomings must be attributed to the inferior skill of a local school of sculptors compared with those of Athens or of Aegina. It even appears likely that the designs also belong to a local school. Pausanias, it is true, said that the pediments were the work of Alcamenes, the pupil of Pheidias, and of Paeonius. a sculptor of Thrace, respectively; but it is almost certain that he was misled by the local guides, who would naturally be anxious to connect the sculptures of their great temple with well-known names.

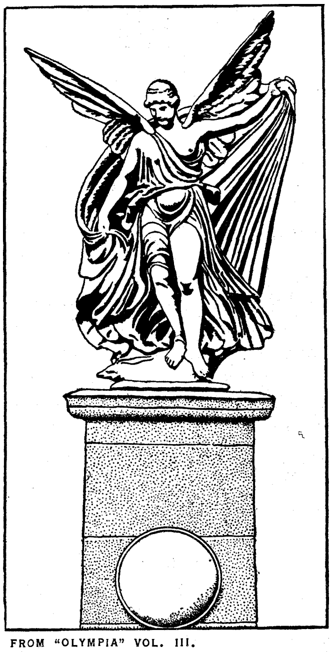
The metopes of the temple are in the same style of art as the pediments, but the defects of awkwardness and want of mastery are less conspicuous, because the narrow limits of the metope exclude any elaborate grouping. The subjects are provided by the 12 labours of Heracles; the figures introduced in each metope are but two or at most three; and the action is simplified.

The example shown (fig. 16), represents Heracles holding up the sky on a cushion, with the friendly aid of a Hesperid nymph, while Atlas, whom he has relieved of his usual burden, approaches bringing the apples which it was the task of Heracles to procure.

Another of the fruits of the excavations of Olympia is the Floating Victory by Paeonius, unfortunately faceless (fig. 17), which was set up in all probability in memory of the victory of the Athenians and their Messenian allies at Sphacteria in 425 B.C. The inscription states that it was dedicated by the Messenians and people of Naupactus from the spoils of their enemies, but the name of the enemy is not mentioned in the inscription. The statue of Paeonius, which comes floating down through the air with drapery borne backward, is of a bold and innovating type, and its influence may be traced in many works of the next age.

Delphic **Charioteer.**—Among the discoveries at Delphi none is so striking and valuable as the life-size statue in bronze of a charioteer holding in his hand the reins. Théophile Homolle maintained this to be part of a chariot group set up by Polyzalus, brother of Gelo and Hiero of Syracuse, in honour of a victory won in the chariot race at the Pythian games at Delphi (fig. 18). The charioteer is evidently a high-born youth, and is clad in the long chiton which was necessary to protect a driver of a chariot from the rush of air. The date would be about 480–470 B.C. Bronze groups representing victorious chariots with their drivers were among the noblest and most costly dedications of antiquity; the present figure is the only satisfactory representative of them. In style the figure is very notable, tall and slight beyond all contemporary examples. The contrast between the conventional decorousness of face and drapery and the lifelike accuracy of hands and feet is very striking, and indicates the clashing of various tendencies in art at the time when the great style was formed in Greece.

Myron. — The three great masters of the 5th century, Myron, Pheidias and Polyclitus are all in some degree known from their works. These are copies of two works by Myron, the Marsyas with Athena and the Discobolus. The Marsyas (a copy in the Lateran museum) represents the satyr so named in the grasp of conflicting emotions, eager to pick up the flutes which Athena has thrown down, but at the same time dreading her displeasure if he does so. More recently the Athena also was identified. The Discobolus was usually judged from the examples in the Vatican and the British Museum, in which the anatomy was modernized and the head wrongly attached. However, photographs of the superior replica in the Lancelotti gallery at Rome show a pose which is much nearer to the original.



FROM "OLYMPIA" VOL. III.

FIG. 17.— FLOATING VICTORY BY PAEONIUS. C. 425 B.C. (RESTORED)

A restoration was made at Munich by combining the Lancelotti head with the Vatican body.

Pheidias.—Of the works of Pheidias there is unfortunately no certain copy, excepting the small replicas at Athens of his Athena Parthenos. The larger of these was found in 1880: it is very clumsy, and the wretched device by which a pillar is introduced to support the Victory in the hand of Athena can scarcely be supposed to have belonged to the great original. Tempting theories were published by Adolf Furtwangler (*Masterpieces of Greek Sculpture)* and other archaeologists, which identify copies of the Athena Lemnia of Pheidias, his Pantarces, his Aphrodite Urania and other statues; but doubt hangs over all these attributions.

A more pertinent and more promising question is how far one may take the decorative sculpture of the Parthenon, since Lord Elgin's time the pride of the British Museum, as the actual work of Pheidias or as done from his designs. Again there is no conclusive evidence; but it appears from the testimony of inscriptions that the pediments at all events were not executed until after Pheidias's death.

Of course, the pediments and frieze of the Parthenon (*q.v.*)

whose work soever they may be, stand at the head of all Greek decorative sculpture. Whether we regard the grace of the composition, the exquisite finish of the statues in the round, or the delightful atmosphere of poetry and religion which surrounds these sculptures, they rank among the masterpieces of the world. The Greeks esteemed them far below the statue which the temple was made to shelter; but to us, who have lost the great figure in ivory and gold, the carvings of the casket which once contained it are a perpetual source of instruction and delight. The whole is reproduced by photography in A. S. Murray's Sculptures *of* the *Parthenon.*

An abundant literature has sprung up in regard to these sculptures, but it will suffice here to mention the discussions in Furtwangler's Masterpieces, and the very ingenious attempts of Sauer to determine by a careful examination of the bases and backgrounds of the pediments as they now stand how the figures must have been arranged in them. The two ends of the eastern pediment are the' only fairly well-preserved parts of the pediments.

FIG. 18.— BRONZE CHARIOTEER FROM DELPHI. 480–470 B.C.

Among the pupils of Pheidias who may naturally be supposed to have worked on the sculptures of the Parthenon, the most notable were Alcamenes and Agoracritus.

Some fragments remain of the great statue of Nemesis at Rhamnus by Agoracritus, and an interesting light has been thrown on Alcamenes by the discovery at Pergamum of a professed copy of his Hermes set up at the entrance to the Acropolis at Athens. This, however, is conventional and archaistic in style, and we can scarcely regard it as typical of the master. Another noted contemporary who was celebrated mainly for his portraits was Cresilas, a Cretan. Several copies of his portrait of Pericles exist, and testify to the lofty and idealizing style of portraiture in this great age.

There have been found also admirable sculpture belonging to the other important temples of the Acropolis, the Erechtheum and the temple of Nike. The temple of Nike is the earlier, being possibly a memorial of the Spartan defeat at Sphacteria. The Erechtheum belongs to the end of our period, and embodies the delicacy and finish of the conservative school of sculpture at Athens just as the Parthenon illustrates the ideas of the more progressive school.

The reconstruction of the Erechtheum has been a task which has long occupied the attention of archaeologists (see the paper by Stevens in the American Journal of Archaeology, 1906). Maidens, called both Corae and Caryatides, support the entablature of the south porch of the building. This use of the female figure in place of a pillar is based on old Ionian precedent (*see* fig. 1), and is not altogether happy; but the idea is carried out with remarkable skill, the perfect repose and solid strength of the maiden being emphasized.

Polyclitus.—Beside Pheidias of Athens must be placed the greatest of early Argive sculptors, Polyclitus. His two typical athletes, the Doryphorus or spear-bearer, and the Diadumenus, have long been identified, and though the copies are not first-rate, they rec er the principles of the master's art. Among the bases discovered at Olympia, whence the statues had been removed, are three or four which bear the name of Polyclitus, and the definite evidence furnished by these bases as to the position of the feet of the statues which they once bore has enabled archaeologists, especially Furtwangler, to identify copies of those statues among known works. Copies of Polyclitan works have also been discovered, and at Delos was found a copy of the Diadumenus, which is of much finer work than the statue in the British Museum from Vaison. The Boston Museum of fine arts has a very beautiful statue of a young Hermes, who but for the wings on the temples might easily pass as a boy athlete of Polyclitan style. In fact, as regards the manner of Polyclitus besides Roman copies of the Doryphorus and Diadumenus, there is quite a gallery of athletes, boys and men, who all claim relationship, nearer or more remote, to the school of the great Argive master, and in the Ashmolean museum is a very beautiful bronze head of the Polyclitan school. It might have been hoped that the excavations, made under the leadership of Prof. Waldstein (Walston) at the Argive Heraeum, would have brought enlightenment to us as to the style of Polyclitus. Just as the sculptures of the Parthenon are the best monument of Pheidias, so it might seem likely that the sculptural decoration of the great temple which contained the Hera of Polyclitus would show us at large how his school worked in marble, but unfortunately the fragments of sculpture from the Heraeum are few. The most remarkable is a female head, which may perhaps come from a pediment (fig. 19). But archaeologists are not in agreement whether it is Polyclitan in style or whether it rather resembles in style Attic works. Other heads and some highly-finished

FIG. 19.— MARBLE FEMALE HEAD EXCAVATED AT THE ARGIVE HERAEUM

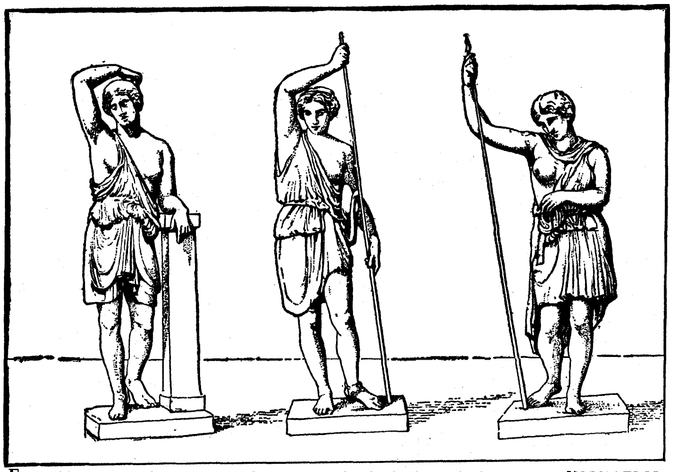


FIG. 20.— TYPES OF 5TH CENTURY AMAZONS RESTORED BY MICHAELIS

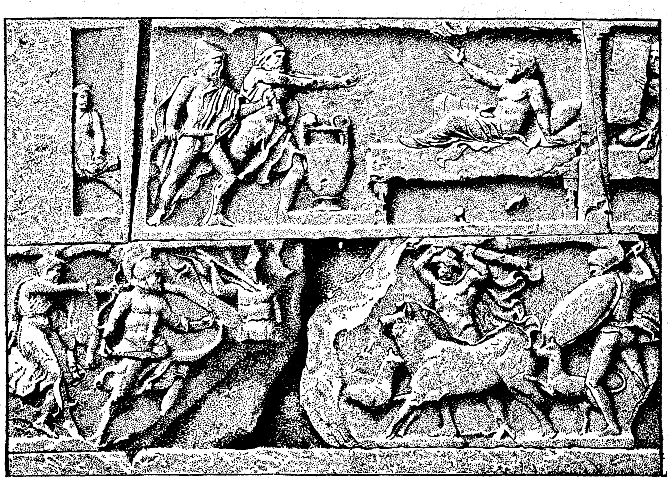
fragments of bodies come apparently from the metopes of the same temple. (See also ARGOS.)

Another work of Polyclitus was his Amazon, made it is said in competition with his great contemporaries, Pheidias, Cresilas and Phradmon, all of whose Amazons were preserved in the great temple of Artemis at Ephesus. In the museums are many statues of Amazons representing 5th century originals. These have usually been largely restored, and it is no easy matter to discover their original type. Prof. Michaelis has recovered successfully three types (fig. 20). The attribution of these is a matter of controversy. The first has been given to Polyclitus; the second seems to represent the Wounded Amazon of Cresilas; the third has by some archaeologists been assigned to Pheidias. It does not represent a wounded Amazon, bur one alert, about to leap upon her horse with the help of a spear as a leaping pole



PROM "HEROON OF GYEUL BASHI TRYSA"

FIG. 21.---FRAGMENT OF A FRIEZE OF THE VIENNA TOMB. ABOVE: ULYSSES SHOOTING SUITORS: BELOW: BOAR HUNTING

Lycia.—It is impossible to devote little more than a passing mention to the sculpture of other temples and shrines of the later 5th century, which nevertheless deserve careful study. The frieze from the temple of Apollo at Phigalia, representing Centaur and Amazon battles, is familiar to visitors of the British Museum. where, however, its proximiry to the remains of the Parthenon lays stress upon the faults of grouping and execution which this frieze presents It seems to be the work of local Arcadian artists. More pleasing is the sculpture of the Ionic tomb called the Nereid monument, brought by Sir Charles Fellows from Lycia Here we have not only a series of bands of relief which ran round the tomb, but also detached female figures. whence the name which it bears is derived, though these women with their fluttering drapery may be not nymphs of the sea, but personifications of sea-breezes.

Lycian sculpture is well represented by the friezes, now in the Vienna Museum, which adorned a heroon near Gyeul Bashi and date from not much later than the middle of the 5th century. In the midst of the enclosure was a tomb. and the walls of the enclosure itself were adorned within and without with a great series of reliefs, mostly of mythologic purport Many subjects which but rarely occur in early Greek art, the siege of Troy, the adventure of the Seven against Thebes, the carrying off of the daughters of Leucippus, Ulysses shooting down the Suitors, are here represented in detail. Prof Benndorf, who has published these sculptures in an admirable volume. is disposed to see in them the influence of the Thasian painter Polygnotus. Anyone can see their kinship to painting, and their subjects recur in some of the great frescoes painted by Polygnotus, Micon and others for the Athenians. Like other Lycian sculptures, they contain non-Hellenic elements; in fact Lycia forms a link of the chain which extends from the wall-reliefs of Assyria to works like the columns of Trajan and of Antoninus. but is not embodied in the more purely idealistic works of the highest Greek art. A small part of the frieze of the Vienna tomb is shown in fig, 21; in this fragment are two scenes, one directly above the other; in the upper Ulysses, accompanied by his son Telemachus, is in the act of shooting the suitors, who are reclining at table in the midst of a feast; a cup-bearer, possibly Melanthius, is escaping by a door behind Ulysses; and in the lower is the central group of a frieze representing the hunting of the Calydonian boar, the boar being shown—as is usual in the best period of Greek art—as an ordinary animal and no monster.

Portraits.— Archaeoloeists formerly paid little attention to an interesting branch of Greek art, that of sculptured portraits, but the known portraits of the 5th century now include Pericles, Herodotus, Thucydides, Anacreon, Sophocles Euripides, Socrates and others. As might be expected in a time when style in sculpture was so strongly pronounced, these portraits. as we may see from later copies, are notably ideal. They represent the great men whom they portray not in the spirit of realism Details are neglected. expression is not elaborated; the sculptor tries to represent what is permanent in his subject rather than what is temporary. Hence these portraits do not seem to belong to a particular time of life; they only represent a man in the perfection of physical force and mental energy. And the race or type is clearly shown through individual traits. In some cases it is still disputed whether statues of this age represent deities or mortals, so notable are the repose and dignity which even human figures acquire under the hands of 5th century masters. The Pericles after Cresilas in the British Museum and the athlete-portraits of Polyclitus, are good examples.

PERIOD III. 400–300 B.C.

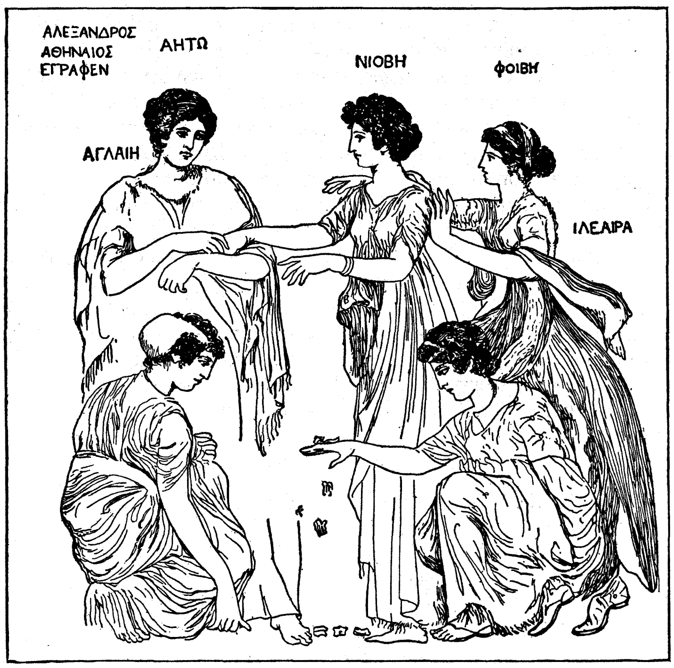
The high ideal level attained by Greek art at the end of the 5th century is maintained in the 4th There cannot be any question of decay in it save at Athens. where undoubtedly the loss of religion and the decrease of national prosperity acted prejudicially. But in Peloponnesus the time was one of expansion, several new and important cities. such as Messene, Megalopolis and Mantinea, arose under the protection of Epaminondas. And in Asia the Greek cities were still prosperous and artistic, as were the cities of Italy and Sicily which kept their independence On the whole there is during this age some diminution of the freshness and simplicity of art; it works less in the service of the gods and more in that of private patrons; it becomes less ethical and more sentimental and emotional On the other hand, there can be no doubt that technique both in painting and sculpture advanced with rapid strides; artists had a greater mastery of their materials, and ventured on a wider range of subject

In the 4th century no new temples of importance rose at Athens; the Acropolis had taken its final form; but at Messene, Tegea, Epidaurus and elsewhere. very admirable buildings arose. The remains of the temple at Tegea are of wonderful beauty and finish; as are those of the theatre and the so-called *Tholus* of Epidaurus. In Asia Minor vast temples of the Ionic order arose, especially at Miletus and Ephesus. The colossal pillars of Miletus astonish the visitors to the Louvre; while the sculptured columns of Ephesus in the British museum show a high level of artistic skill. The Mausoleum erected about 350 B.C at Halicarnassus in memory of Mausolus, king of Caria, and adorned nith sculpture by the most noted artists of the day, was reckoned one of the wonders of the world It has been in part restored in the British museum, where also are models of various conjectural restorations. A small part of the sculptural decoration representing a battle between Greeks and Amazons is shown, wherein the energy of the action and the careful balance of figure against figure are remarkable. We possess also the fine portraits of Mausolus himself and his aife Xrtemisia, nhich stood in or on the building, as well as part of a gigantic chariot with four horses which surmounted it.

Another architectural work of the 4th century, in its way a gem, is the structure set up at Athens by Lysicrates, in memory of a choragic victory. This still survives, though the reliefs with which it is adorned have suffered severely from the weather.

The 4th century is the brilliant period of ancient painting. It opens with the painters of the Asiatic school, Zeuxis and Parrhasius and Protogenes, with their contemporaries Nicias and Apollodorus of Athens, Timanthes of Sicyon or Cythnus, and Euphranor of Corinth. It witnesses the rise of a great school at

Sicyon, under Eupompus and Pamphilus, which was noted for its scientific character and the fineness of its drawing, and which culminated in Apelles, the painter of Alexander the Great. and probably the greatest master of the art in antiquity. To each of these painters a separate article is given, fixing their place in the history of the art. Of their paintings, unfortunately, only a very inadequate notion can be formed. Vase-paintings, which in the 5th century give us some notion at least of contemporary drawing, are less careful in the 4th century. Now and then are found on them figures admirably designed, or successfully foreshortened; but these are rare occurrences. The art of the vase decorator has ceased to follow the methods and improvements of contemporary fresco painters, and is pursued as a mere branch of commerce.



BY COURTESY OF THE NATIONAL MUSEUM, NAPLES

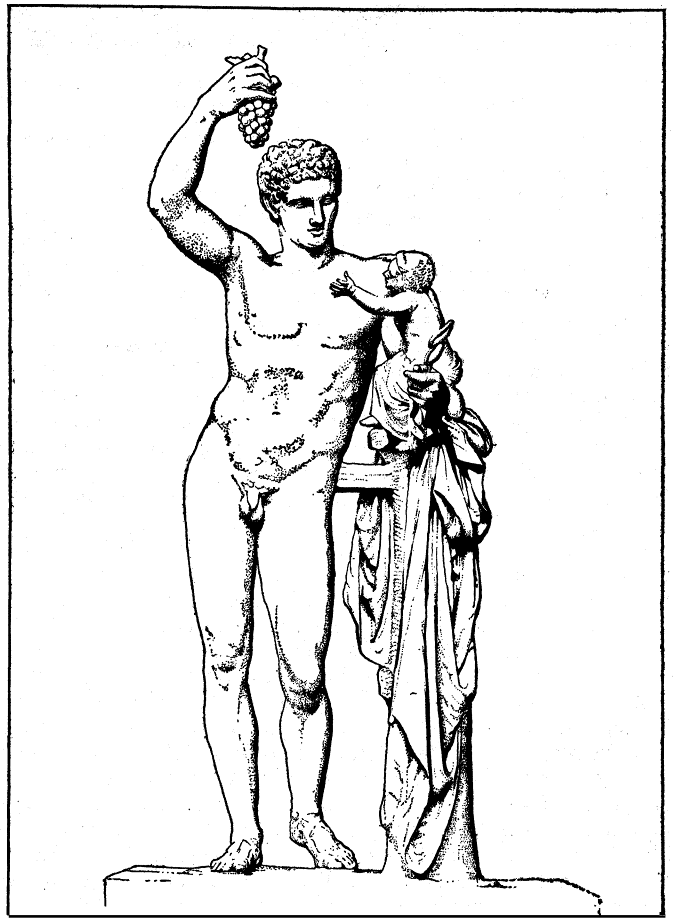
FIG. 22.— DRAWING OF WOMEN PLAYING AT KNUCKLEBONES. 400 B.C.

But few actual paintings of the age survive, and even these fragmentary remains have with time lost the freshness of their colouring; nor are they in any case the work of a noteworthy hand. The illustration (fig. 22) represents the remains of a drawing on marble. showing a group of women playing knucklebones. It was found at Herculaneum. Though signed by one Alexander of Athens. who was probably a worker of the Roman age, Prof Robert correctly maintained that Alexander only copied a design of the age of Zeuxis and Parrhasius. In fact the drawing and grouping is so closely like that of reliefs of about 400 B.C. that the drawing is of great historic value, though there is no colouring. Several other drawings of the same class were found at Herculaneum, and on the walls of the Transtiberine Villa at Rome.

Praxiteles.—Until about 1880 the knowledge of the great Greek sculptors of the 4th century was derived mostly from the statements of ancient writers and from Roman copies, or what were supposed to be copies, of their works. but there is now at least one undoubted original work of Praxiteles as well as sculptures executed under the immediate direction of, if not from the hand of, other great sculptors of that age—Scopas, Timotheus and others. Among all the discoveries made at Olympia in 1877 none became so familiar to the artistic world as that of the Hermes of Praxiteles, a first-rate Greek original by one of the greatest of sculptors. Before its discovery almost all the statues in the museums were either late copies of Greek works of art or else the mere decorative sculpture of temples and tombs, but the Hermes can be submitted to the strictest examination, and it can be seen in every line and touch that it is the work of a great artist This is more than can be said of any of the literary remains of antiquity—poem, play or oration. Hermes is represented by the sculptor in the act of carrying the young child Dionysus to the nymphs who were charged with his rearing. On the journey he pauses and amuses himself by holding out to the child-god a bunch of grapes, and watching his eagerness to grasp them. To the modern eye the child is not a success; only the latest art of Greece is at home in dealing with children. But the Hermes, strong without excessive muscular development, and graceful without leanness, is a model of physical formation, and his face expresses the perfection of health, natural endowment and sweet nature. The statue can scarcely be called a work of religious art in the modern or Christian sense of the word but from the Greek point of view it is religious, as embodying the result of the harmonious development of all human faculties and life in accordance with nature.

The Hermes not only added to the knowledge of Praxiteles, but also confirmed the received views in regard to him. Already many works in galleries of sculpture had been identified as copies of statues of his school.

Noteworthy among these were: the group at Munich representing Peace nursing the infant Wealth, from an original by Cephisodotus, father of Praxiteles; copies of the Cnidian Aphrodite of Praxiteles, especially one in the Vatican, and a torso in the British Museum; copies of the Apollo slaying a lizard (Sauroctonus), of a Satyr (in the Capitol museum), and others. These works, which are noted for their softness and charm, make understandable the saying of ancient critics that Praxiteles and Scopas were noted for the pathos of their works, as Pheidias and Polyclitus for the ethical quality of those they produced. But the pathos of Praxiteles is of a soft and dreamy character; there is no action, or next to none; and the emotions which he rouses are sentimental rather than passionate. Scopas was of another mood The discovery of the Hermes naturally set archaeologists searching in the museums of Europe for other works, which may from their likeness to it in various respects be



FROM "OLYMPIA"

FIG. 23.— THEHERMES OF PRAXITELES FROM OLYMPIA (RESTORED)

set down as Praxitelean in character. In the case of many of the great sculptors of Greece—Strongylion, Silanion, Calamis and others—it is of little use to search for copies of their works, since there is little trustworthy evidence on which to base our enquiries; but in the case of Praxiteles one really stands on a safe level.

Naturally it is impossible in these pages to give any sketch of the results, some almost certain, some very doubtful, of the researches of archaeologists in quest of Praxitelean works. But we may mention a few works which have been claimed by good judges as coming from the master himself Professor Brunn claimed as work of Praxiteles a torso of a satyr in the Louvre, in scheme identical with the well-known satyr of the Capitol. Professor Furtwangler puts in the same category a delicately beautiful head of Aphrodite at Petworth. And his translator, Mrs. Strong, regards the Aberdeen head of a young man in the British Museum as the actual work of Praxiteles Certainly this last head does not suffer when placed beside the Olympian head of Hermes.

At Mantinea (*q v.)* there was found a basis whereon stood a group of Latona and her two children, Apollo and Artemis, made supposedly by Praxiteles. This base bears reliefs representing the musical contest of Apollo and Marsyas, with the Muses as spectators, reliefs very pleasing in style, and quite in the manner of Attic artists of the 4th century. But of course they cannot be ascribed to the hand of the master himself; great sculptors did not themselves execute the reliefs which adorned temples and other monuments, but reserved them for their pupils. Yet the graceful figures of the Muses of Mantinea suggest how much was due to Praxiteles in determining the tone and character of Athenian art in relief in the 4th century. Exactly the same style which marks them belongs also to a mass of sepulchral monuments at Athens, and such works as the Sidonian sarcophagus of the Mourning Women, to be presently mentioned

Scopas.—Excavation on the site of the temple of Athena Alea at Tegea (*q.v.*) in 1883 and later resulted in the recovery of works of the school of Scopas. Pausanias tells that Scopas was the architect of the temple, and so important in the case of a Greek temple is the sculptural decoration, that it can scarcely be doubted that the sculpture also of the temple at Tegea was under the supervision of Scopas, especially as he was more noted as a sculptor than as an architect. In the pediments of the temple were represented two scenes from mythology, the hunting of the Calydonian boar and the combat between Achilles and Telephus. To one or other of these scenes belong several heads of local marble discovered on the spot, which are very striking because of their extraordinary life and animation. Unfortunately they are so much injured that they can scarcely be made intelligible except by the help of restoration; one, the head of a warrior from Tegea, Scopas, 4th century B.C , as restored by a German sculptor, has a strong bony frame and depth from front to back no less noteworthy than the parted lips and deeply set and strongly shaded eye. The latter features impart to the head a vividness of expression such as has been found in no previous work of Greek art, but which sets the key to the developments of art which take place in the Hellenistic age. A draped torso of Atalanta from the same pediment has been fitted to one of these heads. Hitherto Scopas was known, setting aside literary records, only as one of the sculptors who had worked at the Mausoleum. Ancient critics and travellers, however, bear ample testimony to his fame, and the wide range of his activity, which extended to northern Greece, Peloponnese and Asia Minor His Maenads and his Tritons and other beings of the sea were much copied in antiquity. But perhaps he reached his highest level in statues such as that of Apollo as leader of the Muses, clad in long drapery; a head of Apollo found in the Mausoleum, now in the British Museum, is almost certainly a work of Scopas.

Timotheus, Bryaxis, **Leochares.**—In the interesting precinct of Aesculapius at Epidaurus have been found specimens of the style of an Athenian contemporary of Scopas, who worked with him on the Mausoleum An inscription which records the sums spent on the temple of the Physician-god, tells that the models for the sculptures of the pediments, and one set of acroteria or roof adornments, were the work of Timotheus. Of the pedimental figures and the acroteria considerable fragments have been recovered, and it may be assumed with confidence that at all events the models for these were by Timotheus. It is strange that the unsatisfactory arrangement whereby a noted sculptor makes models and some local workman the figures enlarged from those models, should have been tolerated by so artistic a people as the Greeks. The subjects of the pediments appear to have been the common ones of battles between Greek and Amazon and between Lapith and Centaur. There are fragments of some of the Amazon figures, one of which striking downwards at the enemy, is here shown (fig. 27). Their attitudes are vigorous and alert; but the work shows little delicacy of detail. Figures of Nereids riding on horses, which were found on the same site, may very probably be roof ornaments (acroteria) of the temple. There are also several figures of Victory, which probably were acroteria on some smaller temple, perhaps that of Artemis. A base found at Athens, sculptured with figures of horsemen in relief, bears the name of Bryaxis, and was probably made by a pupil of his. Probable conjecture assigns to Eeochares the originals copied in the Ganymede of the Vatican, borne aloft by an eagle, and the noble statue of Alexander the Great at Munich (see LEOCHARES).

Thus it may fairly be said that students are now acquainted with the work of all the great sculptors who worked on the Mausoleum—Scopas, Bryaxis, Leochares and Timotheus; and are in a far more advantageous position than were the archaeologists of 1880 for determining the artistic problems connected with that noblest of ancient tombs.

The School of Argos and Sicyon.—This was contemporary with the Athenian school of Praxiteles; and of it Lysippus was the most distinguished member. Lysippus continued the academic traditions of Polyclitus, but he was far bolder in his choice of subjects and more innovating in style. Gods, heroes and mortals alike found in him a sculptor who knew how to combine fine ideality with a vigorous actuality. He was at the height of his fame during Alexander's life, and the grandiose ambition of the great Macedonian found him ample employment, especially in the frequent representation of himself and his marshals.

There have been discovered none of the actual works of Lysippus; but the best evidence for his style will be found in the statue of Agias, an athlete, found at Delphi, and shown by an inscription to be a marble copy of a bronze original by Lysippus.

The Apoxyomenus of the Vatican (man scraping himself with a strigil) has hitherto been regarded as a copy from Lysippus; but of this there is no evidence, and the style of that statue belongs rather to the 3rd century than the 4th. The Agias, on the other hand, is in style contemporary with the works of 4th century sculptors.

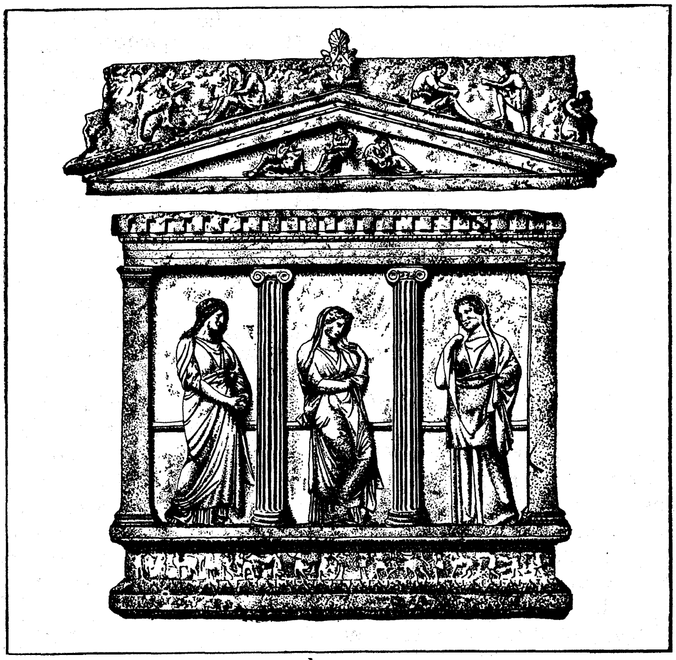
Of the elaborate groups of combatants with which Lysippus enriched such centres as Olympia and Delphi, or of the huge bronze statues which he erected in temples and shrines, no adequate notion can be formed. The recent excavations at Cyrene have produced a figure of Alexander of which the head is of remarkable style, and probably Lysippic in type; a pupil of Lysippus, Eutychides, made a very original and charming statue of the city of Antioch, seated above the river Orontes. The type was widely copied in later sculpture.

Many noted extant statues may be attributed with probability to the latter part of the 4th or the earlier part of the 3rd century. The celebrated group at Florence representing Niobe and her children falling before the arrons of Apollo and Artemis is certainlv a work of the pathetic school, and may be by a pupil of Praxiteles. Niobe, in an agony of grief. which is in the marble tempered and idealized, tries to protect her youngest daughter from destruction. Whether the group can have originally been fitted into the gable of a temple is a matter of dispute.

Two great works preserved in the Louvre are so noted that it is but necessary to mention them, the Aphrodite of Melos, in which archaeologists are now disposed to see the influence of Scopas, and the Victory of Samothrace, an original set up by Demetrius Poliorcetes after a naval victory won at Salamis in Cyprus in 306 B.C. over the fleet of Ptolemy, king of Egypt.

Nor can two works so celebrated as the Apollo of the Belvedere in the Vatican and the Artemis of Versailles be passed over without notice. The Apollo is now by most archaeologists regarded as probably a copy of a work of Leochares, to whose Ganymede it bears a superficial resemblance. The Artemis is regarded as possibly due to some artist of the same age. But it is by no means clear that either of these figures can be removed from among the statues of the Hellenistic age. The old theory of Preller, which saw in them copies from a trophy set up to commemorate the repulse of the Gauls at Delphi in 278 B.C., retained its plausibility.

Sarcophagi of **Sidon.**—This may be the most appropriate place for mentioning the remarkable find made at Sidon in 1886 of a number of sarcophagi, which once doubtless contained the remains of kings of Sidon. They were placed in the museum of Constantinople, and were admirably published by Hamdy Bey and T. Reinach (*Une Nécropole royale à Sidon*, 1892–96). The sarcophagi in date cover a considerable period. The earlier are made on Egyptian models, the covers shaped roughly in the form of a human body or mummy. The later, however, are Greek in form, and are clearly the work of skilled Greek sculptors, who seem to have been employed by the grandees of Phoenicia in the adornment of their last resting places. Four of these sarcophagi in particular claim attention, and in fact present examples of Greek art of the 5th and 4th centuries in several of its aspects. To the 5th century belong the tomb of the Satrap, the reliefs of which bring to light the activities and glories of some unknown king, and the Lycian sarcophagus, so-called from its form, which resembles that of tombs found in Lycia, and which is also adorned with reliefs which have reference to the past deeds of the hero buried in the tomb, though these deeds are represented, not in



FROM HAMDY AND REINACH, "NÉCROPOLE À SIDON"

FIG. 24.— TOMB OF MOURNING WOMEN AT SIDON. 4TH CENTURY B.C.

the oriental manner directly, but in the Greek manner, clad in mythological forms. To the 4th century belong two other sarcophagi. One of these is called the Tomb of Mourning Women. On all sides of it alike are ranged a series of beautiful female figures, separated by Ionic pillars, each in a somewhat different attitude, though all attitudes denote grief (fig. 24). The pediments at the ends of the cover are also closely connected with the mourning for the loss of a friend and protector, which is the theme of the whole decoration of the sarcophagus. Depicted in them are the telling of the news of the death, with the results in the mournful attitude of the two seated figures. The mourning women must be taken, not as the representation of any persons in particular, but generally as the expression of the feeling of a city. Such figures are familiar to us in the art of the second Attic school; there are parallels to the sarcophagus among the 4th century sepulchral reliefs of Athens. The attribution of the workmanship of this beautiful sarcophagus to some sculptor trained in the school of Praxiteles cannot be mistaken. And it is a conjecture full of probability that it once contained the body of Strato, king of Sidon, who ruled about 380 B.C., and who was *proxenos* or public friend of the Athenians.

More celebrated is the astonishing tomb called that of Alexander, though there can be no doubt that, although it commemorates the victories and exploits of Alexander, it was made to hold not his remains but those of some ruler of Sidon who was high in his favour. Among all the monuments of antiquity which have come down to us, none is more admirable than this, and none more characteristic of the Greek genius. The illustration shows, in two lines, the composition which adorned one of the sides of this sarcophagus. It represents a victory of Alexander, probably that of the Granicus (fig. 25). On the left can be seen the Macedonian king charging the Persian horse, on the right his general Parmenio, and in the midst a younger officer, perhaps Cleitus. Mingled with the chiefs are foot soldiers, Greek and Macedonian, with whom the Persians are mingled in unequal fray. What most strikes the modern eye is the remarkable freshness and force of the action and the attitudes. Those, however, who have seen the originals have been specially impressed with the colouring, whereof, of course, our reproduction gives no hint, but which is applied to the whole surface of the relief with equal skill and delicacy. There are other features in the relief on which a Greek eye would have dwelt with special pleasure—the exceedingly careful symmetry of the whole, the balancing of figure against figure, the skill with which the result of the battle is hinted rather than depicted. The composition is one in which the most careful planning and the most precise calculation are mingled with freedom of hand and expressiveness in detail. The faces in particular show more expression than would be expected in art of the previous century. Authorities were unable to assign an author or even a school to the sculptor of this sarcophagus, which comes to us as a new and striking phenomenon in the history of ancient art. The reliefs which adorn the other sides of the sarcophagus are almost equally interesting. On one side is Alexander again, in the company of a Persian noble, hunting a lion. The short sides also show scenes of fighting and hunting. In fact it can scarcely be doubted that if there was but a clue to the interpretation of the reliefs they would be found to embody historic events of the end of the 4th century. There are only a few other works of art, such as the Bayeux tapestry and the Column of Trajan, which bring contemporary history so vividly before our eyes. The battles with the Persians represented in some of the sculpture of the Parthenon and the temple of Nike at Athens are treated conventionally and with no attempt at realism; but here the ideal and the actual are blended into a work of consummate art. which is at the same time, to those who can read the language of Greek art, a historic record. The portraits of Alexander the Great which appear on this sarcophagus are almost contemporary, and the most authentic likenesses of him. The great Macedonian exercised so strong an influence on contemporary art that a multitude of heads of the age, both of gods and men, and even the portraits of his successors, show traces of his type.

There are yet to be mentioned what are among the most charming and the most characteristic products of the Greek chisel, the beautiful tombs, adorned with seated or standing portraits or with reliefs, which were erected in great numbers on all the main roads of Greece. A great number of these from the Dipylon cemetery were preserved in the Central museum at Athens; they impress visitors by the gentle sentiment and the charm of grouping which they display.

PERIOD IV. 300-50 B.C.

There can be no question but that the period which followed the death of Alexander, commonly called the age of Hellenism,

FROM HAMDY AND REINACH. "NÉCROPOLE À SIDON"

FIG. 25.—PAINTED RELIEF ADORNING ONE SIDE OF A SARCOPHAGUS CALLED THE TOMB OF ALEXANDER. PROBABLY REPRESENTING THE VICTORY AT GRANICUS. SIDON. 4TH CENTURY B.C.

was one of great activity and expansion in architecture. The number of cities founded by himself and his immediate successors in Asia and Egypt was enormous. The remains of these cities have in a few cases (Ephesus, Pergamum, Assus, Priene, Alexandria) been partially excavated. But the adaptation of Greek architecture to the needs of the semi-Greek peoples included in the dominions of the kings of Egypt, Syria and Pergamum is too vast a subject to be entered upon here.

Painting during this age ceased to be religious. It was no longer for temples and public stoae that artists worked, but for private persons; especially they made frescoes for the decoration of the walls of houses, and panel pictures for galleries set up by rich patrons. The names of very few painters of the Hellenistic age have come down to us. There can be no doubt that the character of the art declined, and there were no longer produced great uorks to be the pride of cities, or to form an embodiment for all future time of the qualities of a deity or the circumstances of scenes mythical or historic. But at the same time the mural paintings of Pompeii and other works of the Roman age, which are usually more or less nearly derived from Hellenistic models, prove that in technical matters painting continued to progress. Colouring became more varied, groups more elaborate, perspective was worked out with greater accuracy, and imagination shook itself free from many of the conventions of early art. Pompeian painting, however, must be treated of under Roman, not under Greek art. There is shown a single example, to depict the elaboration of painting at Alexandria and elsewhere, the wonderful Pompeian mosaic (fig. 28), which represents the victory of Alexander at Issus This work being in stone has preserved its colouring; and it stands at a far higher level of art than ordinary Pompeian paintings. This, on the contrary, is certainly copied from the work of a great master. It is instructive to compare it with the sarcophagus illustrated in fig. 25, which it excels in perspective and in the freedom of individual figures, though the composition is much less careful and precise. Alexander charges from the left (his portrait being the least successful part of the picture), and bears down a young Persian; Darius in his chariot flees towards the right; in the foreground a young knight is trying to manage a restive horse. It will be observed how very simple is the indication of locality: a few stones and a broken tree stand for rocks and woods.

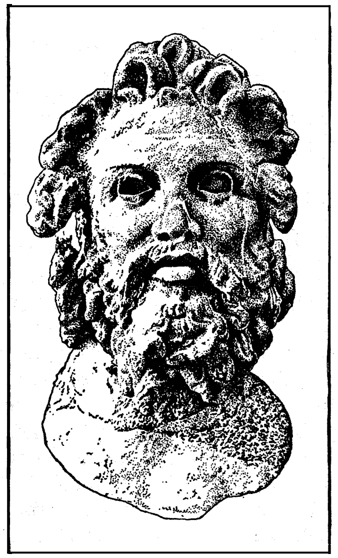


FIG. 26.—THE HEAD OF THE TITAN ANYTUS. ONE OF THE COLOSSAL HEADS FOUND AT LYCOSURA

Among the original sculptural creations of the early Hellenistic age, a prominent place is claimed by the statue of Fortune, typifying the city of Antioch, a work of Eutychides, a pupil of Lysippus.

Of this we possess a small copy, which is sufficient to show how worthy of admiration was the original. We have a beautiful embodiment of the personality of the city, seated on a rock, holding ears of corn. while the river Orontes, embodied in a young male figure, springs forth at her feet.

Almost the only remaining work of the early 3rd century which shows imagination is the above-mentioned statue typifying the city of Antioch by Eutychides, a pupil of Lysippus. Sculptors often worked on a colossal scale, producing such monsters as the colossal Apollo at Rhodes, the work of Chares of Lindus, which was more than 100ft. in height; but they did not show freshness or invention, and for the most part contented themselves with varying the types produced in the great schools of the 4th century. The wealthy kings of Syria, Egypt and Asia Minor formed art galleries, and were lavish in their payments; but it has often been proved in the history of art that originality cannot be produced by mere expenditure.

A great artist, whose date has been disputed, but who is now assigned to the Hellenistic age, Damophon of Messene, is known from his actual works. He set up in the shrine of the *Mistress* (Despoena) at Lycosura in Arcadia a great group of figures consisting of Despoena, Demeter, Artemis and the Titan Anytus. Three colossal heads found on the spot probably belong to the three last-mentioned deities. The illustration is of the head of Anytus, with wild disordered hair and turbulent expression (fig. 26). Dr. Dorpfeld argued, on architectural grounds, that shrine and images alike must be given to a later time than the 4th century; and this judgment is now confirmed by inscriptional and other evidence.

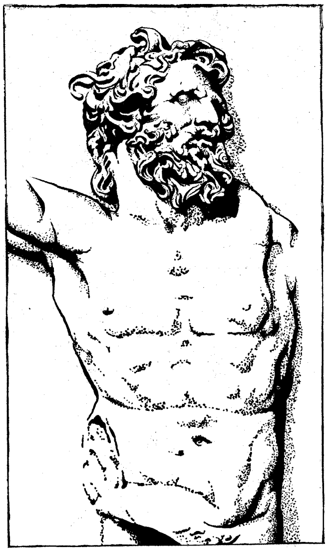

FIG. 27.—GIANT FROM THE GREAT ALTAR OF PERGAMUM; SHAGGY HAIR, FIERCE EXPRESSION, AND HUGE MUSCLES PROBABLY DERIVED FROM THE GALATIANS

In one important direction sculpture certainly made progress. Hitherto Greek sculptors had contented themselves with studying the human body whether in rest or motion, from outside. The dissection of the human body, with a consequent increase in knowledge of anatomy, became usual at Alexandria in the medical school which flourished under the Ptolemies. This improved anatomical knowledge soon reacted upon the art of sculpture. Works such as the Fighter of Agasias in the Louvre, and in a less degree the Apoxyomenus, display a remarkable internal knowledge of the human frame, such as could only come from the habit of dissection. Whether this was really productive of improvement in sculpture may be doubted. But it is impossible to withhold one's admiration from works which show an astonishing knowledge of the body of man down to its bony framework, and a power and mastery of execution which have never since been surpassed.

With accuracy in the portrayal of men's bodies goes of necessity a more naturalistic tendency in portraiture. The art of portraiture was at a high ideal level in the Pheidian age; and even in the age of Alexander the Great, notable men were rendered rather according to the idea than the fact. To a base and mechanical naturalism Greek art never at any time descended. But from 300 B.C. onwards there is a marvellous series of portraits which may be termed rather characteristic than ideal, which are very minute in their execution, and delight in laying emphasis on the havoc wrought by time and life on the faces of noteworthy men. Such are the portraits of Demosthenes, of Antisthenes, of Zeno and others, which exist in our galleries. And it was no long step from these actual portraits to the invention of characteristic types to represent the great men of a past generation, such as Homer and Lycurgus, or to form generic images to represent weather-beaten fishermen or toothless old women.

Altar **of Pergamum.**—The knowledge of the art of the later Hellenistic age is greatly indebted to the German Archaeological institute, the systematic labours of which since 1875 have resulted in recovering the remains of Pergamum, the fortress-city which was the capital of the dynasty of the Philetaeri. Among the ancient buildings of Pergamum none was more ambitious in scale and striking in execution than the great altar used for sacrifices to Zeus, a monument supposed to be referred to in the phrase of the Apocalypse "where Satan's throne is." This altar, like many great sacrificial altars of later Greece, was a vast erection to which one mounted by many steps, and its outside was adorned with a frieze which represented on a gigantic scale, in the style of the 2nd century B.C., the battle between the gods and the giants. This enormous frieze (*see* PERGAMUM) is now one of the treasures of Berlin, and it cannot fail to impress visitors by the size of the figures, the energy of the action, and the strong vein of sentiment which pervades the whole, giving it a certain air of modernity, though the subject is strange to the Christian world. In early Greek art the giants where they oppose the gods are represented as men armed in full panoply, "in shining armour, holding long spears in their hands," to use the phrase in which Hesiod describes them. But in the Pergamene frieze the giants are strange compounds, having the heads and bodies of wild and fierce barbarians, sometimes also human legs, but sometimes in the place of legs two long serpents, the heads of which take with the giants themselves a share in the battle. Sometimes also they are winged. The gods appear in the forms which had been gradually made for them in the course of Greek history, but they are usually accompanied by the animals sacred to them in *cultus,* between which and the serpent-feet of the giants a weird combat goes on. We can conjecture the source whence the Pergamene artist derived the shaggy hair, the fierce expressions, the huge muscles of his giants (fig. 27); probably these features came originally from the Galatians, who at the time had settled in Asia Minor, and were spreading the terror of their name and the report of their savage devastations through all Asia Minor. The victory over the giants clearly stands for the victory of Greek civilization over Gallic barbarism; and this meaning is made more emphatic because the gods are obviously inferior in physical force to their opponents, indeed, a large proportion of the divine combatants are goddesses. Yet everywhere the giants are overthrown, writhing in pain on the ground, or transfixed by the weapons of their opponents; everywhere the gods are victorious, yet in the victory retain much of their divine calm.

The piecing together of the frieze at Berlin has been a labour of many years; it is now complete, and there is a special museum devoted to it. Some of the groups have become familiar to students from photographs, especially the group which represents Zeus slaying his enemies with thunderbolts, and the group wherein Athena seizes by the hair an overthrown opponent, who is winged, while Victory runs to crown her, and beneath is seen Gaia, the earth-goddess who is the mother of the giants, rising out of the ground, and mourning over her vanquished and tortured children.

Another and smaller frieze which also decorated the altar-place gives us scenes from the history of Telephus, who opposed the landing of the army of Agamemnon in Asia Minor and was overthrown by Achilles; it is quite fragmentary, but was pieced together by Dr. Schneider in the *Jahrbuch* of the German Archaeological institute for 1900.

Since the Renaissance Rome has produced a continual crop of works of Greek art of all periods, partly originals brought from Greece by conquering generals, partly copies, such as the group at Rome formerly known as Paetus and Arria, and the overthrown giants and barbarians which came from the elaborate trophy set up by Attalus at Athens, of which copies exist in many museums.

A noted work of kindred school is the group of Laocoön and his sons, signed by Rhodian sculptors of the 1st century B.C., which has been perhaps more discussed than any work of the Greek chisel, and served as a peg for the aesthetic theories of Lessing and Goethe. In our days the histrionic and strained character of the group is regarded as greatly diminishing its interest, in spite of the astounding skill and knowledge of the human body shown by the artists. To the same school belong the late representations of Marsyas being flayed by the victorious Apollo, a somewhat repulsive subject, chosen by the artists of this age as a means for displaying their accurate knowledge of anatomy.

On what a scale some of the artists of Asia Minor would work

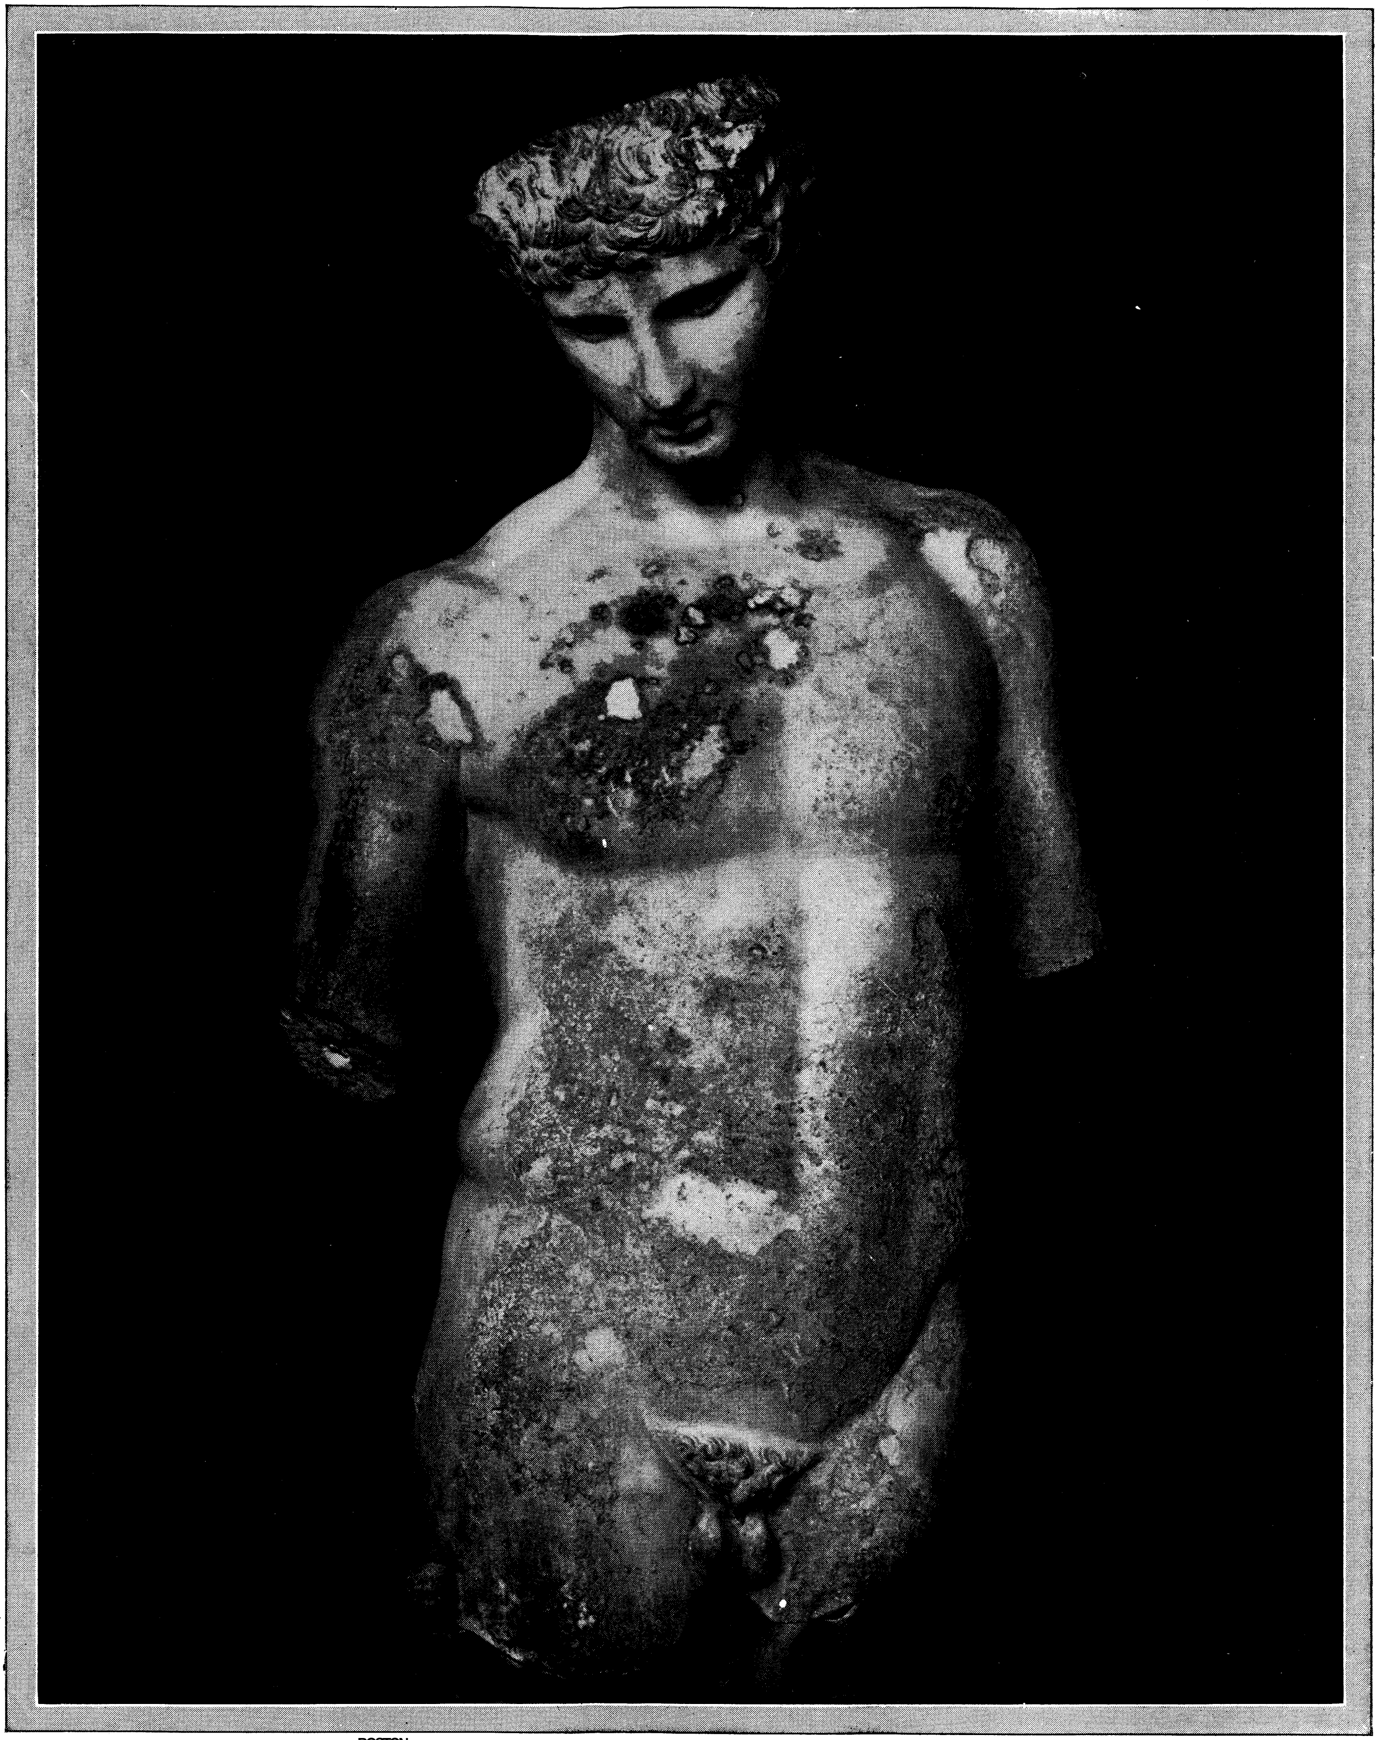
GREEK SCULPTURE OF THE VI. AND V. CENTURIES B.C.

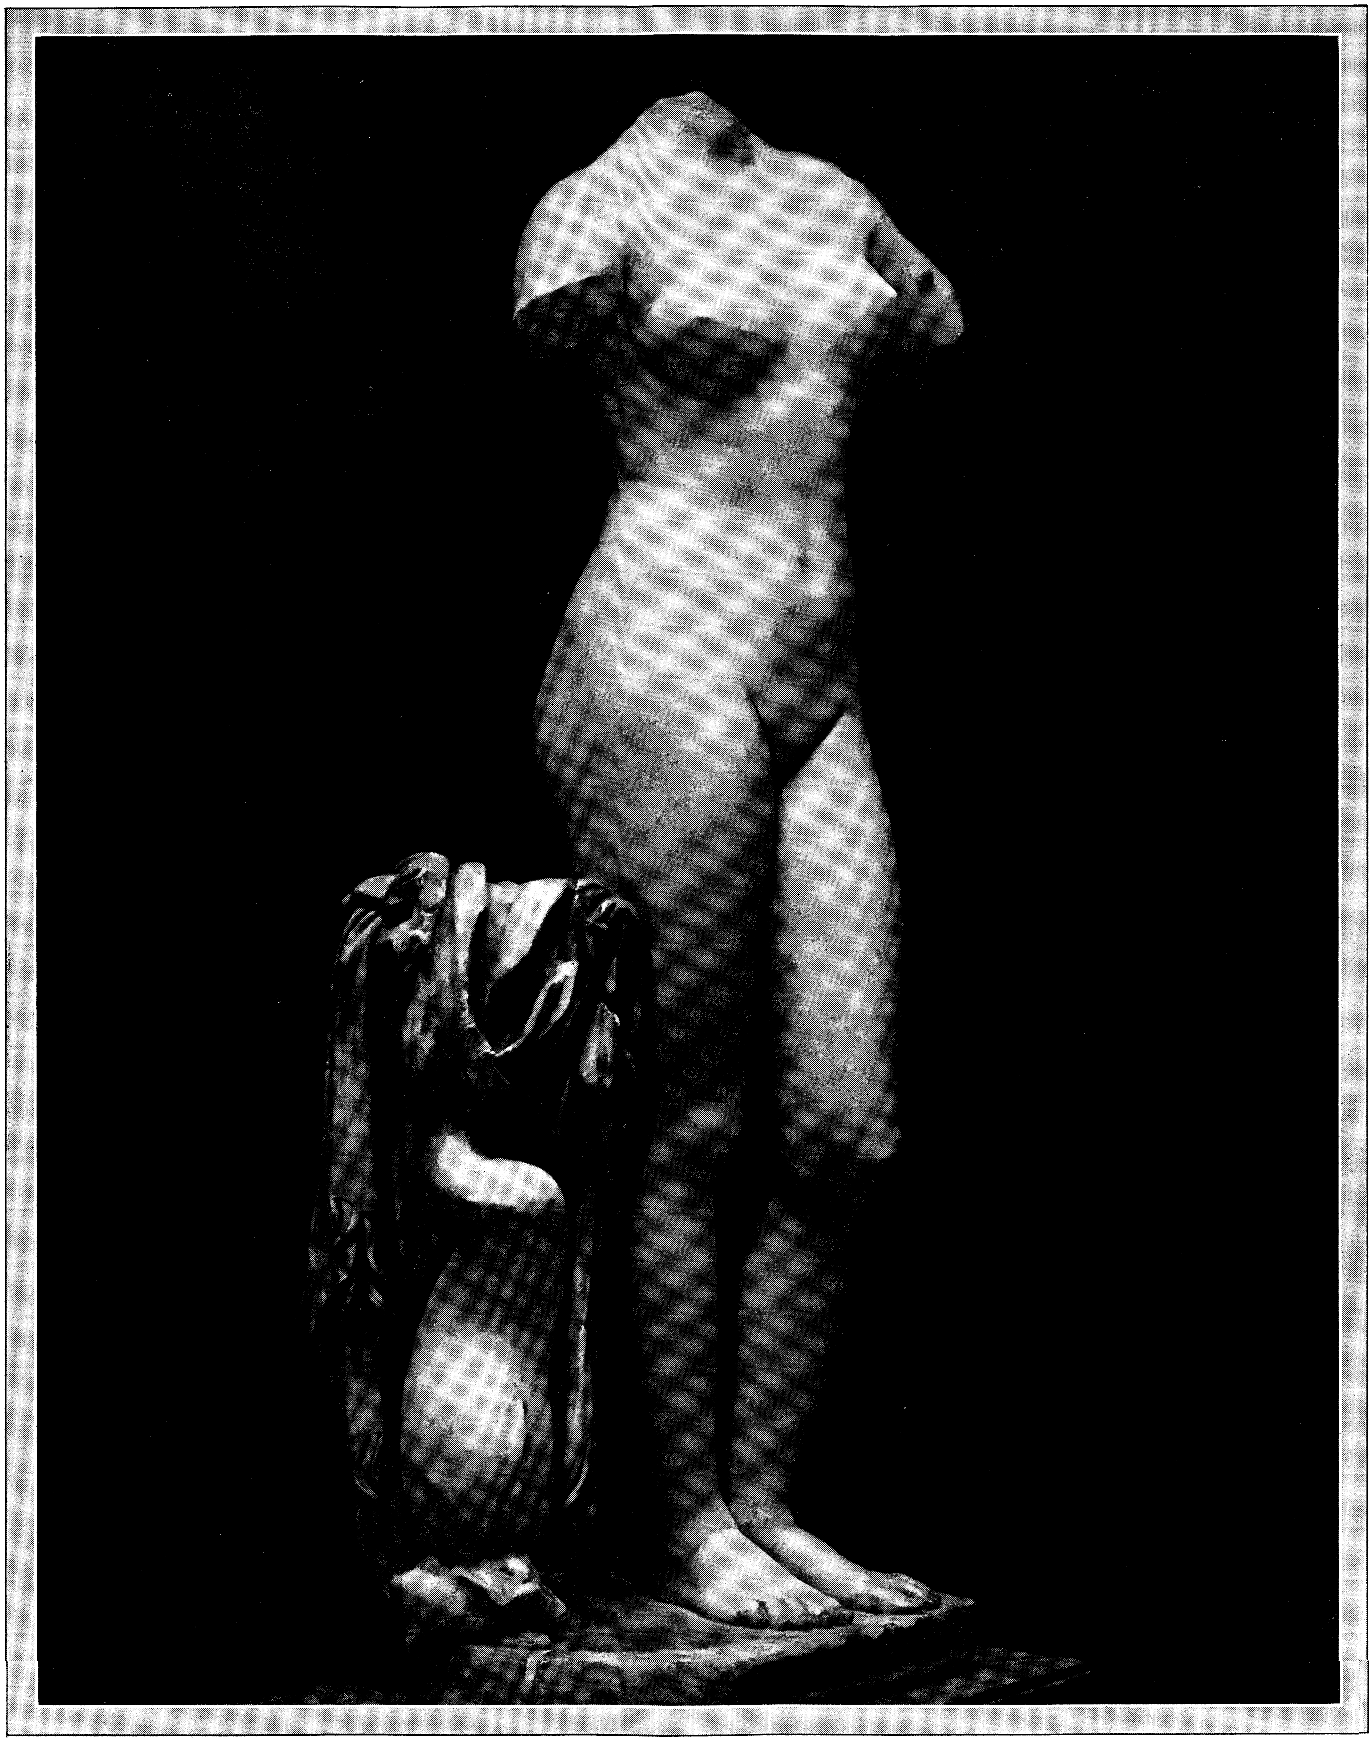
1 and 2. Reliefs from statue bases found in the ruins of the wall of Themistocles, Athens, in 1922. 3. Cleobis, at Delphi, by an Argive sculptor, 6th century; earliest example of Greek portrait sculpture. 4. Standing maiden Museum, Berlin. 5. Statuette of girl running, early 5th century: a cast. original in Museum of Eleusis. 6. Discobolus, by Myron. 5th century: restored by Prof. A. Furtwangler. 7. Harmodius and Aristogiton, probably Roman copies of Greek works of 477-76 B.C. National Museum, Naples. 8. Marsyas. by Myron, 5th century; copy. Lateran Museum, Rome



BY COURTESY OF THE MUSEUM OF FINE ARTS, BOSTON

YOUNG HERMES

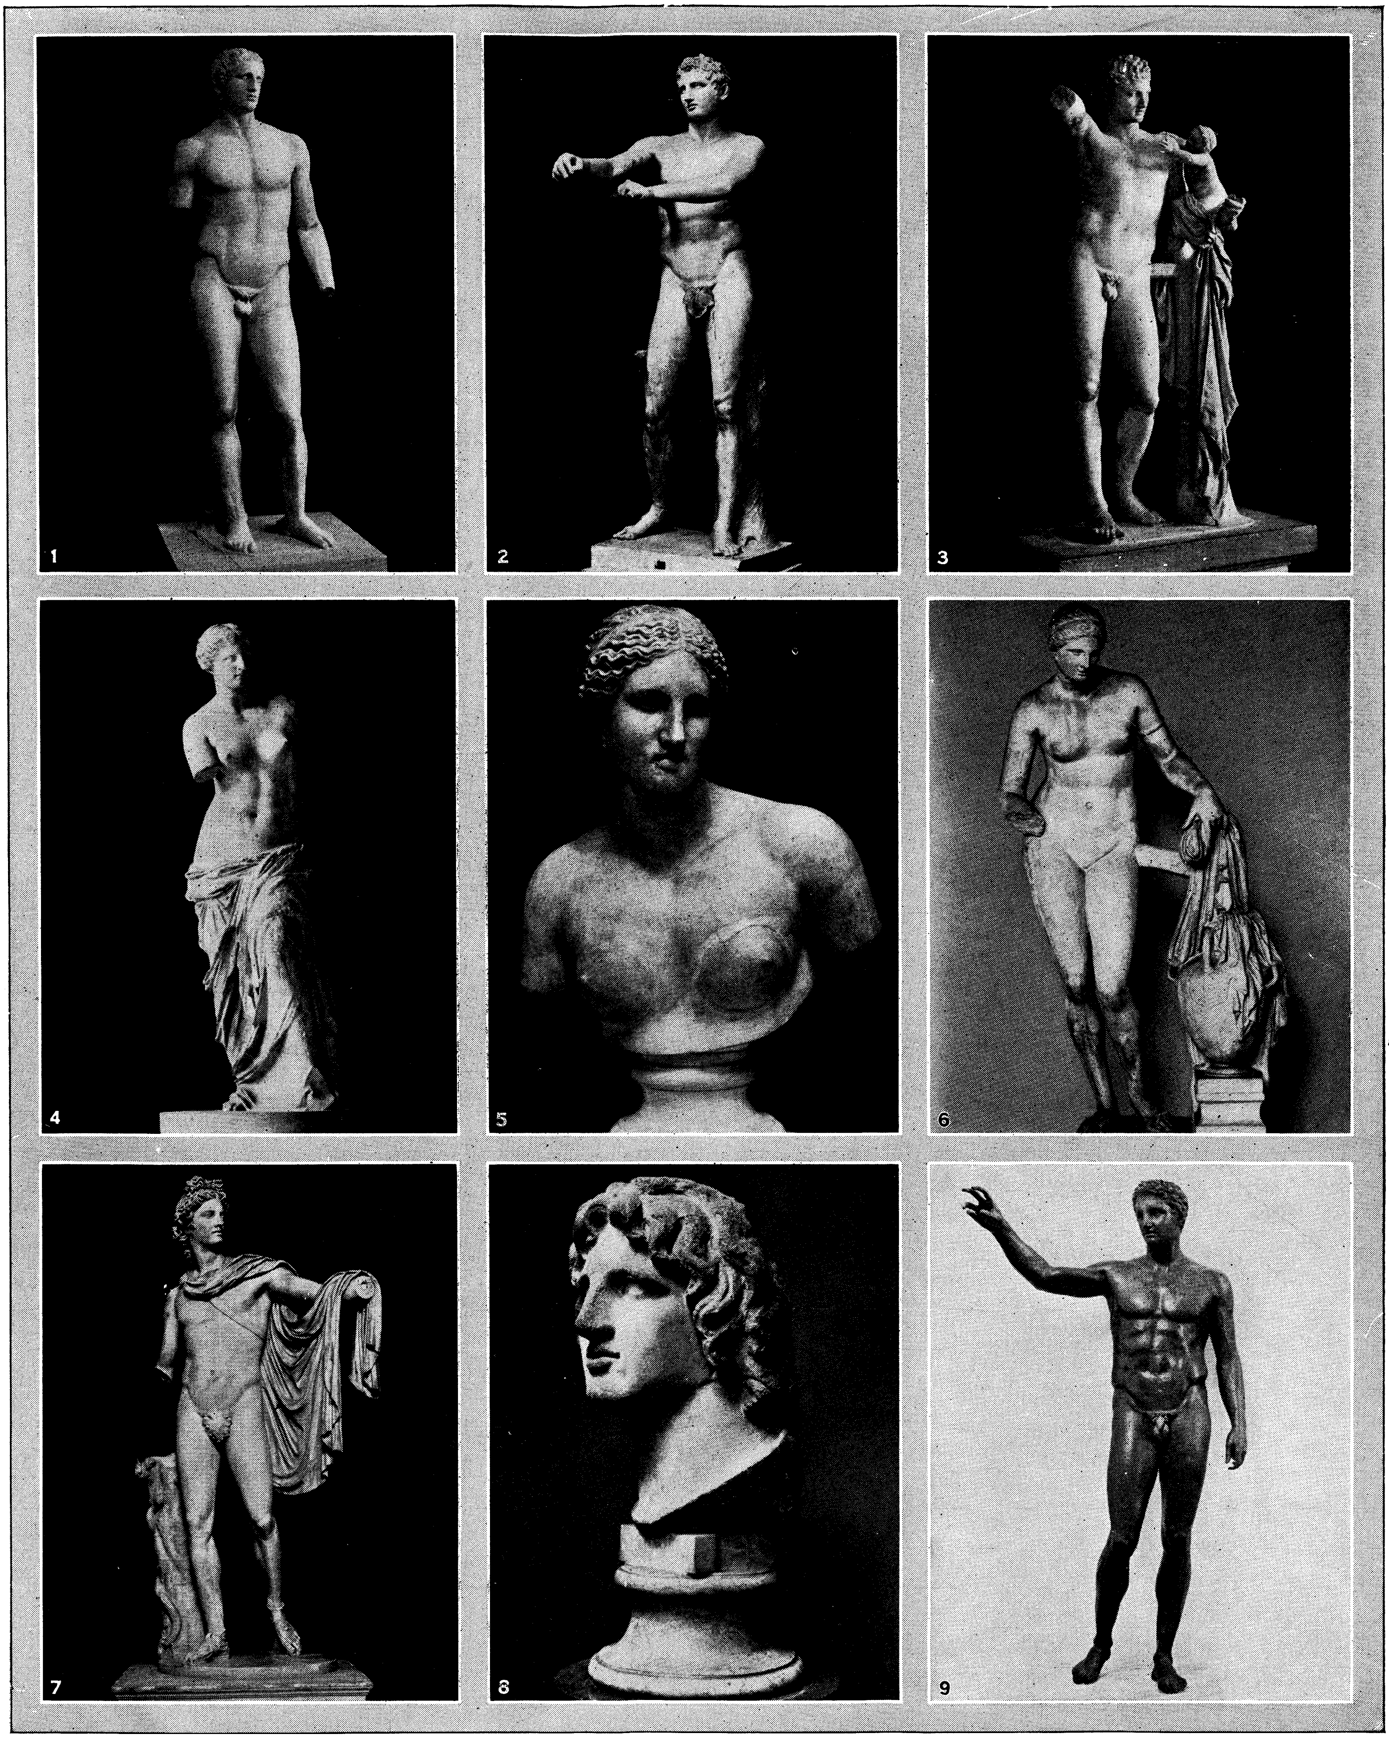
In the Polyclitan style. It may represent Hermes Psychopompos, the Conductor of Souls, and was found near Capua. Roman copy, Graeco-Roman period, 100 B.C.–A.D. 200



PHOTOGRAPH, ALINARI

APHRODITE OF CYRENE

This Venus, found in the Thermae at Cyrene in December 1913, represented the goddess just risen from the sea and wringing out her hair. The support at the side represents a dolphin. The statue may be early Hellenistic, of the Alexandrine school, or possibly a Roman copy. Terme Museum, Rome



GREEK SCULPTURE, IV. TO II. CENTURY B.C.

1. Agias, athlete, Delphi, 4th c. 2. Copy of Apoxyomenos, Lysippus, late 4th c. Vatican. 3. Hermes with the infant Dionysus, Praxiteles, 4th c. Olympia. Original found in 1877. 4. Aphrodite of Melos (Venus de Milo), 2nd c. Louvre. 5. Bust of Aphrodite of Praxiteles, 4th c. copy. British Museum. 6. Aphrodite of Cnidus, 4th c. copy, from a cast. Original in the Vatican. 7. Apollo of the Belvedere, 4th (?) c. Vatican. 8. Head of young Alexander from Cyrene, about 4th c. British Museum. 9. Bronze. athlete, found in the sea near Cythera, style of 4th c. Athens

GREEK SCULPTURE

1. Niobe and her youngest daughter, 4th–3rd c. B.C.; copies. Uffizi Gallery, Florence. 2. Winged Victory of Samothrace; original, 4th c. B.C. Louvre. 3. Niobid, probably an original of the 5th c. B.C. Terme Museum, Rome. 4. Seated boxer, bronze, late Hellenistic. Terme Museum, Rome. 5. Laocoon group, first c. B.C. Vatican. 6. Flaying of Marsyas, Rhodian school. Villa Albani, Rome. 7. Fighter, of Agasias. Louvre. 8. "Marathon boy." Found in the bay of Marathon; 4th c. B.C. 9. Symbolic figure of the city of Antioch, seated above the river Orontes; 3rd c. B.C. Vatican

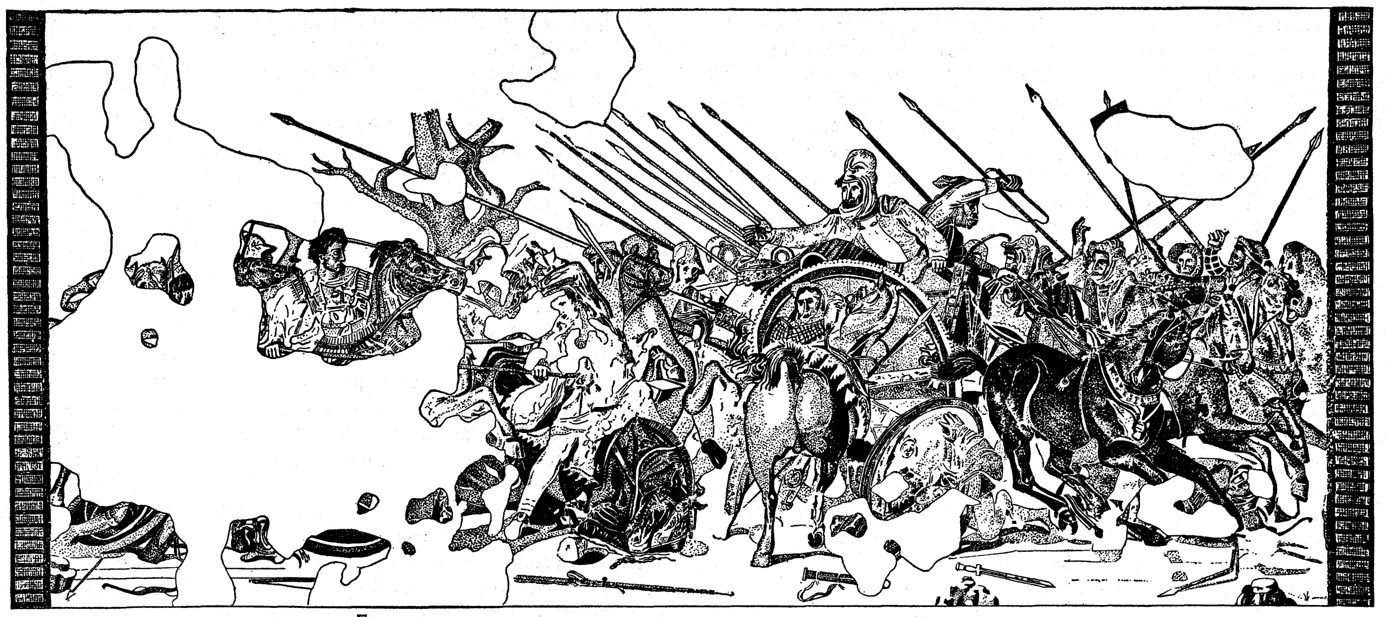

FIG. 28.—BATTLE OF ISSUS AFTER THE MOSAIC IN THE NAPLES MUSEUM

is shown us by the enormous group, by Apollonius and Tauriscus of Tralles, which is called the Farnese Bull, and which represents how Dirce was tied to a wild bull by her stepsons Zethus and Amphion.

Rome. — The extensive excavations and alterations which have taken place at Rome in recent years have been very fruitful; the results may be found partly in the palace of the Conservatori on the Capitol, partly in the Museo delle Terme. Among statues found in our own days none excel in interest some bronzes of large size dating from the Hellenistic age. In the figure of a seated boxer, in scale somewhat exceeding life, attitude and gesture are expressive. Evidently the boxer has fought already, and is awaiting a further conflict. His face is cut and swollen; on his hands are the terrible caestus, here made of leather, and not loaded with iron, like the caestus described by Virgil. The figure is of astounding force; but though the face is brutal and the expression savage, in the sweep of the limbs there is nobility. even ideal beauty. To the last the Greek artist could not set aside his admiration for physical perfection. Another bronze figure of more than life-size is that of a king of the Hellenistic age standing leaning on a spear. He is absolutely nude, like the athletes of Polyclitus. Another large bronze presents us with a Hellenistic type of Dionysus.

Beside the bronzes found in Rome we may set those retrieved from the sea on the coast of Cythera, the contents of a ship lost on the way from Greece to Rome. The date of these statues has been disputed, but, even if executed in the Roman age, they go back to originals of the 5th and 4th centuries The most noteworthy among them is a beautiful athlete, standing mith hand upraised, which reflects the style of the Attic school of the 4th century.

After 146 B.C. when Corinth was destroyed and Greece became one of the Roman provinces, Greek art, though by no means extinct, worked mainly in the employ of the Roman conquerors *(see* ROMAN ART).

GREEK FIRE, the name applied to inflammable and destructive compositions used in warfare during the middle ages and particularly by the Byzantine Greeks at the sieges of Constantinople. The employment of liquid fire is represented on Assyrian bas-reliefs. At the siege of Plataea (429 B.C.) the Spartans attempted to burn the town by piling up against the walls wood saturated with pitch and sulphur and setting it on fire (Thuc. ii. 77), and at the siege of Delium (424 B.C.) a cauldron containing pitch, sulphur and burning charcoal, was placed against the walls and urged into flame by the aid of a bellows, the blast from which was conveyed through a hollow tree-trunk (Thuc. iv. 100). Aeneas Tacticus in the following century mentions a mixture of sulphur, pitch, charcoal, incense and tow, which was packed in wooden vessels and thrown lighted upon the decks of the enemy's ships. Later, as in receipts given by Vegetius (*c.* A.D. 350), naphtha or petroleum is added, and some nine centuries afterwards the same substances are found forming part of mixtures described in the later receipts (which probably date from the beginning of the 13th century) of the collection known as the *Liber ignium* of Marcus Graecus. In subsequent receipts saltpetre and turpentine make their appearance, and the modern "carcass composition," containing sulphur, tallow, rosin, turpentine, saltpetre and crude antimony, is a representative of the same class of mixtures, which became known to the Crusaders as Greek fire but were more usually called wildtire. Greek fire, properly so-called, was, however, of a somewhat different character. It is said that in the reign of Constantine Pogonatus (648–685) an architect named Callinicus, who had fled from Heliopolis in Syria to Constantinople, prepared a wet fire which was thrown out from siphons (*τὸ διὰ τῶν σιφώνων ἐκφερόμενον πῦρ ὑγρόν*), and that by its aid the ships of the Saracens were set on fire at Cyzicus and their defeat assured. The art of compounding this mixture, which is also referred to as *πῦρ θαλάσσιον*, or sea fire, was jealously guarded at Constantinople, and the possession of the secret on several occasions proved of great advantage to the city. The nature of the compound is somewhat obscure. It has been supposed that the novelty introduced by Callinicus was saltpetre, but this view involves the difficulty that that substance was apparently not known till the 13th century, even if it were capable of accounting for the properties attributed to the wet fire. Lieut.-Col. H. W. L. Hime, after a close examination of the available evidence, concludes that what distinguished Greek fire from the other incendiaries of the period was the presence of quicklime, which was well known to give rise to a large development of heat when brought into contact with water. The mixture, then, was composed of such materials as sulphur and naphtha with quicklime, and took fire spontaneously when wetted—whence the name of wet fire or sea fire; and portions of it were "projected and at the same time ignited by applying the hose of a water engine to the breech" of the siphon, which was a wooden tube, cased with bronze. A revival of the idea, if transformed in character by modern chemistry. was seen in the flame throwers (*q.v.*) of World War I and World War II.

See H. W. L. Hime, Gunpowder and Ammunition, their Origin and Progress (London, 1904).

GREEK INDEPENDENCE, WAR OF, the name given to the great rising of the Greek subjects of the sultan against the Ottoman domination, which began in 1821 and ended in 1833 with the establishment of the independent kingdom of Greece. The circumstances that led to the insurrection and the general diplomatic situation by which its fortunes were from time to time atiected are described elsewhere (see GREECE: Modern History; TURKEY: History). If we exclude the abortive invasion of the Danubian principalities by Prince Alexander Ypsilanti (March 1821), which collapsed ignominiously as soon as it was disavowed by the tsar. the theatre of the war was confined to continental Greece, the Morea and the adjacent narrow seas. Its history may, broadly speaking, be divided into three periods: the first (1821–24), during which the Greeks, aided by numerous volunteers from Europe, were successfully pitted against the sultan's forces alone; the second, from 1824, when the disciplined troops of Mehemet Ali, pasha of Egypt, turned the tide against the insurgents; the third, from the intervention of the European powers in the autumn of 1827 to the end.

When, on April 2, 1821, Archbishop Germanos, head of the *Hetaeria* in the Morea, raised the standard of the cross at Ralavryta as the signal for a general rising of the Christian population, the circumstances were highly favourable. In the Morea itself, in spite of plentiful warning, the Turks were wholly unprepared; while the bulk of the Ottoman army, under Kurshid Pasha, was engaged in the long task of reducing Ali, pasha of Iannina (see ALI [called the Lion of Janina]) Another factor, and that the determining one, soon came to the aid of the Greeks. In warfare carried on in such a country as Greece, sea-girt and with a coast deeply indented, inland without roads and intersected aith rugged mountains, victory—as Wellington was quick to observe—must rest with the side that has command of the sea. This was assured to the insurgents at the outset by the revolt of the maritime communities of the Greek archipelago. The Greeks of the islands had been accustomed from time immemorial to seafaring; their ships were well armed. to guard against the Barbary pirates and rovers of their own kin; lastly, they had furnished the bulk of the sailors to the Ottoman navy which, now that this recruiting ground was closed, had to be manned hastily with impressed crews of dock-labourers and peasants. The Turkish fleet, "adrift in the Archipelago"—as the British seamen put it—though greatly superior in tonnage and weight of metal, could never be a match for the Greek brigs, manned as these were by trained. if not disciplined. crews.

Outbreak **of the** Insurrection.—The war was begun by the Greeks without definite plan and without any generally recognized leadership The force with which Germanos marched from Kalavryta against Patras was composed of peasants armed with scythes, clubs and slings, among whom the "primates" exercised a somewhat honorary authority. The town itself was destroyed, but the citadel remained in the hands of the Turks till 1828. Meanwhile, in the south, leaders of another stamp had appeared: Petros, bey of the Maina (*q.v*) chief of the Mavromichales, who at the head of his clan attacked Ralamata and put the Mussulman inhabitants to the sword; and Kolokotrones, a notable brigand once in the service of the Ionian government, who—fortified by a vision of the Virgin—captured Karytaena and slaughtered its infidel population. Encouraged by these successes the revolt spread rapidly; within three weeks there was not a Mussulman left in the open country. The flames of revolt now spread across the Isthmus of Corinth: early in April the Christians of Dervenokhoria rose, and the whole of Boeotia and Attica quickly followed suit; at the beginning of May the Mussulman inhabitants of Athens were blockaded in the Acropolis. In the Morea, meanwhile, a few Mussulman fortresses still held out. One by one they fell, and everywhere were repeated the same scenes of butchery. The horrors culminated in the capture of Tripolitsa, the capital of the vilayet. In September this was taken by storm; Kolokotrones rode in triumph to the citadel over streets carpeted with the dead; and the crowning triumph of the Cross was celebrated by a cold-blooded massacre of 2,000 prisoners of all ages and both sexes. This completed the success of the insurrection in the Morea, where only Patras, Nauplia, and one or two lesser fortresses remained to the Turks.

Meanwhile, north of the Isthmus, the fortunes of war had been less one-sided. In the west Khurshid's lieutenant. Omar Vrioni (a Mussulman Greek of the race of the Palaeologi), had inflicted a series of defeats on the insurgents, and relieved the Acropolis; but the rout of Mohammed Pasha, who was coming to his aid in the defile of Mount Oeta, forced him to retreat and the campaign of 1821 ended with the retirement of the Turks into Thessaly. The month of April had witnessed the revolt of the principal Greek islands, Spetsae, Psara, Hydra and Samos. Their fleets were divided into squadrons, of which one, under Tombazes, was deputed to watch for the entrance of the Ottomans into the archipelago, while the other under Andreas Miaoulis (*q.v.*) sailed to blockade Patras and watch the coasts of Epirus. At sea, as on land the Greeks opened the campaign with hideous atrocities.

General Character of **the** War.—These inauspicious beginnings, indeed, set the whole tone of the war, which was frankly one of mutual extermination. On both sides the combatants were barbarians, without discipline or competent organization. At sea the Greeks rapidly developed into mere pirates, and even Miaoulis, for all his high character and courage, was often unable to prevent his captains from sailing home at critical moments, when pay or booty failed. On land the presence of a few educated Phanariots, such as Demetrios Ypsilanti or Alexander Mavrocordato, was powerless to inspire the rude hordes with any sense of order or of humanity in warfare; while every lull in the fighting was the signal for internecine conflicts due to the rivalry of the leaders. Their cause, indeed, was helped more by the impolitic reprisals of the Turks than by the heroism of the insurgents. All Europe stood aghast at the news of the execution of the Patriarch Gregorios of Constantinople (April 22, 1821) and the wholesale massacres that followed. The cause of Greece was now that of Christendom, of the Catholic and Protestant west, as of the Orthodox east. European Liberalism, too, gagged and fettered under Metternich's "system," recognized in the Greeks the champions of its own cause; while even conservative statesmen, schooled in the memories of ancient Hellas, saw in the struggle a fight of civilization against barbarism. This latter belief, which was flattering to their vanity, the Greek leaders were astute enough to foster; the propaganda of Adamantios Coraës had done its work: and wily brigands, like Odysseus of Ithaka, assuming the style and trappings of antiquity, posed as the champions of classic culture against the barbarian. All Europe hailed with joy the exploit of Constantine Kanaris, who on the night of June 18–19, succeeding in steering a fireship among the Turkish squadron off Scio, burned its flagship with 3.000 on board.

Expedition of Dramali, **1822.**—Meanwhile Sultan Mahmud, now wide awake to the danger, had been preparing for a systematic effort to suppress the rising. The threatened breach with Russia had been avoided by Metternich's influence on the tsar Alexander; the death of Ali of Iannina had set free the army of Khurshid Pasha, who was charged with the task of reducing the hforea. In the spring of 1822 two Turkish armies advanced southwards: one, under Omar Vrioni, along the coast of western Hellas, the other, under Ali, pasha of Drama (Dramali): through Boeotia and Attica. Omar was held in check by the mud ramparts of Missolonghi; but Dramali crossed the Isthmus and with the over-confidence of a conquering barbarian advanced to the relief of the hard-pressed garrison of Nauplia. He crossed the perilous defile of Dervenaki unopposed; and at the news of his approach most of the members of the Greek Government assembled at Argos fled in panic. Demetrios Ypsilanti, however, with a few hundred men joined the Mainote Karayanni in the castle of Larissa, which crowns the acropolis of ancient Argos. This held Dramali in check, and gave Kolokotrones time to collect an army. The Turks, in the absence of the fleet which was to have brought them supplies, were forced to retreat (Aug. 6); the Greeks, inspired with new courage, awaited them in the pass of Dervenaki. where the undisciplined Ottoman host. thrown into confusion by an avalanche of boulders hurled upon them, was annihilated. In western Greece Omar Vrioni opposed and was forced to abandon the siege of Missolonghi and retire northwards.

Civil War Among the Greeks.—The victorious outcome of the year's fighting had a disastrous effect upon the Greeks. Their victories had been due mainly to the guerilla leaders; Mavrocordato, whose character and antecedents had marked him out as the natural head of the new Greek state, in spite of his successful defense of Rlissolonghi, had been discredited by failures elsewhere, and the Greeks thus learned to despise their civilized advisers and to underrate the importance of discipline. The temporary removal of the common peril let loose all the sectional and personal jealousies and the year 1823 witnessed the first civil war between the Greek parties. These internecine feuds might easily have proved fatal to the cause of Greece. All semblance of discipline and cohesion had vanished from the Creek fleet. Had Khosrev, the new Ottoman admiral, been a man of enterprise, he might have regained the command of the sea and, with it, that of the whole situation. But the fate of his predecessor had filled him with a lively terror of Kanaris and his fireships; he contented himself with a cruise around the coasts of Greece, throwing supplies and troops into Coron, Modon and Petras. On land the Turks gained some initial successes, but in the end the harassing tactics of the guerilla bands forced them back northwards. At the end of the year the Greeks were once more free to renew their internecine feuds. Just when these feuds were at their height, in Jan., 1824, the most famous of the Philhellenes uho sacrificed themselves for the cause of Greece. Lord Byron, arrived at Missolonghi. The year was destined to be a fateful one for the Greek cause. The large loans raised in Europe, while providing the Greeks with the sinews of war, provided them also with fresh material for strife. To the struggle for power was added a struggle for a share of this booty, and a second civil war broke out, Kolokotrones leading the attark on the forces of the Government. Early in 1825 the Government was victorious and Kolokotrones was in prison.

Intervention of **Mehemet Ali.—A** new and more terrible danger now threatened Greece. Sultan Mahmud, despairing of suppressing the insurrection by his own power, had reluctantly summoned to his aid Mehemet Ali, pasha of Egypt, whose well equipped fleet and disciplined army were now thrown into the scale against the Greeks. Crete, subdued a year previously, now became the base of operations against the Greeks. On June 19, the Egyptian fleet, under Ibrahim Pasha, sailed from Alexandria. Khosrev, too, emboldened by this new sense of support, ventured to sea, and although his attack on Samos was frustrated by Miaoulis's fireships, he succeeded in joining Ibrahim off Budrun; two indecisive engagements followed with the united Greek fleet on Aug. 5 and 10. The object of Ibrahim was to reach Suda Bay with his transports, which the Greeks should at all costs have prevented. A first attempt was defeated by Miaoulis on November 16, but the Greek admiral was unable to keep his fleet together, thus leaving the sea unguarded. Ibrahim again set sail, and reached Suda without striking a blow. Here he completed his preparations and, on February 24, 1825, landed at Modon in the Morea with a force of 4.000 regular infantry and 500 cavalry. The rest followed, without the Greeks making any effort to intercept them. The conditions of the war were now completely changed. The Greeks. who had been squandering the money provided by the loans, affected to despise the Egyptian invaders, but they were soon undeceived. Ibrahim had laid siege to **Navarino,** and after some delay a Greek force of some 7,000 very mixed men was sent to its relief. On April 19 they were met by Ibrahim at Krommydi with 2,000 regular infantry, 400 cavalry and four guns. The Greek entrenchments were stormed at the point of the bayonet by Ibrahim's fellahin at the first onset and the defenders broke and fled. The news of this disaster, and of the fall of Pylos and Navarino that followed, struck terror into the Greek Government; and in answer to popular clamour Kolokotrones was taken from prison and placed at the head of the army. But his guerrilla tactics were powerless against Ibrahim, who marched northward, seized Tripolitsa and made this the base from which his columns marched to devastate the country far and wide.

Reshid "Kutahia" Besieges **Missolonghi.**—Meanwhile from the north the Ottomans were making another supreme effort. The command of the army that was to operate in west Hellas had been given to Reshid "Kutahia," pasha of Iannina, an able general and a man of determined character. On April 6, after bribing the Albanian clansmen to neutrality, he passed the defile of Makrynoros, which the Greeks had left undefended, and May 7 opened the second siege of Missolonghi. For twelve months the population held out, repulsing the attacks of the enemy, refusing every offer of honourable capitulation. This resistance was rendered possible by the Greek command of the sea, Miaoulis from time to time entering the lagoons with supplies; it came to an end when this command was lost. In Sept. 1825 Ibrahim, at the order of the sultan, had joined Reshid before the town; piecemeal the outlying forts and defences now fell, until the garrison staked all on a final sortie. This took place on the night of April 22, 1826; but a mistaken order threw the ranks of the Greeks into disorder. The Turks entered the town pell-mell with the retreating crowd.

Karaiskakis.—The fall of Missolonghi, followed as this was by the submission of many of the more notable chiefs, left Reshid free to turn his attention to east Hellas, where Gouras had been ruling as a practically independent chief and in the spirit of a brigand. The peasants of the open country welcomed the Turks as deliverers and Reshid's conciliatory policy facilitated his march to Athens, which fell at the first assault on Aug. 25, siege being at once laid to the Acropolis, where Gouras and his troops had taken refuge. Round this the war now centered; for all recognized that its fall would involve that of the cause of Greece. In these straits the Greek Government entrusted the supreme command of the troops to Karaiskakis, an old retainer of Ali of Iannina, a master of the art of guerilla war, and, above all, a man of dauntless courage and devoted patriotism. A first attempt to relieve the Acropolis, with the assistance of some disciplined troops under the French Col. Fabvier, was defeated at Chaidari by the Turks. The garrison of the Acropolis was hard pressed and the death of Gouras (October 13) would have ended all, had not his heroic wife taken over the command and inspired the defenders with new courage. For months the siege dragged on, while Karaiskakis fought with varying success in the mountains, a final victory at Distomo (February 1827) over Omar Vrioni securing the restoration to the Greek cause of all continental Greece, except he towns which were actually held by the Turks.

Cochrane and Church.—It was at this juncture that the Greek Government, reinforced by a fresh loan from Europe. handed over the chief command at sea to Lord Cochrane (earl of Dundonald [*q.v.*]) and that of the land forces to General Church, both Miaoulis and Karaiskakis consenting to serve under them. Cochrane and Church at once concentrated their energies on the task of relieving the Acropolis. Already, on February 5, Gen. Gordon had landed and entrenched himself on the hill of Munychia, near the ancient Piraeus. When Church and Cochrane arrived, a general assault on the Ottoman camp was decided on. This was preceded, on April 25, by an attack, headed by Cochrane, on the Turkish troops established near the monastery of St. Spiridion, the result of which was to establish communication between the Greeks at Munychia and Phalerum. The monastery held out for two days longer, when the Albanian garrison surrendered on terms, but were massacred by the Greeks as they were marching away under escort. For this miserable crime Church has, by some historians, been held responsible by default; it is clear, however, from his own account that no blame rests upon him (see his MS. Narrative, vol. i. chap. ii. p. 34). The assault on the Turkish main camp was fixed for May 4; but, unfortunately, a chance skirmish brought on an engagement the day before, in the course of which Karaiskakis was killed, an irreparable loss in view of his prestige with the wild armatoli. The assault on the following day was a disastrous failure. The Greeks, advancing prematurely over broken ground and in no sort of order, were fallen upon in flank by Reshid's horsemen and fled in panic. Church held Munychia till the 27th, when he sent instructions for the garrison of the Acropolis to surrender. On June 5 the remnant of the defenders marched out with the honours of war, and continental Greece was once more in the power of the Turks. Had Reshid at once advanced over the Isthmus, the Morea also must have been subdued; but he was jealous of Ibrahim and preferred to return to Iannina to consolidate his conquests.

Renewed Anarchy.—The fate of Greece was now in the hands of the Powers, who after years of diplomatic wrangling had at last realized that intervention was necessary if Greece was to be saved for European civilization. The worst enemy of the Greeks was their own incurable spirit of faction, and a third civil war had only been prevented by the arrival of Cochrane and Church. Under their influence a new National Assembly met at Troezene in March 1827 and elected as president Count Kapodistrias (*q.v.*), formerly Russian minister for foreign affairs; at the same time a new constitution was promulgated which. when the very life of the insurrection seemed on the point of flickering out, set forth the full ideal of Pan-Hellenic dreams. Anarchy followed; war of Rumeliotes against Moreotes, of chief against chief; rival factions bombarded each other from the two forts at Nauplia over the stricken town, and in derision of the impotent government. Finally, after months of inaction, Ibrahim began once more his systematic devastation of the country. To put a stop to this the Powers decided to intervene by means of a joint demonstration of their fleets, in order to enforce an armistice and compel Ibrahim to evacuate the Morea (Treaty of London, July 6, 1827). The refusal of Ibrahim to obey, without special instruction from the sultan, led to the entrance of the allied British, French and Russian fleet into the harbour of Navarino and the battle of October 20, 1827 (see NAVARINO, BATTLE OF). This, and the two campaigns of the Russo-Turkish War of 1828–29, decided the issue.

BIBLIOGRAPHY.—There is no trustwoithy history of the war, based on all the material now available, and all the existing works must be read with caution, especially those by eye-witnesses, who were too often prejudiced or the dupes of the Greek factions. The best-known works are: G. Finlay, *Hist. of the Greek Revolution* (2 vols., London. 1861); T. Gordon, *Hist. of the Greek Revolution* (London, 1833); C. W. P. Mendelssohn-Bartholdy, *Geschichte Griechenlands,* etc. (*Staatengeschichte der neuesten Zeit*) (2 vols., Leipzig, 1870–74); F. C. H. L. Pouqueville, *Histoire de la régénération de la Grèce,* etc. (4 vols., Paris, 1824),—the author was French resident at the court of Ali of Iannina and aiterwards consul at Patras; Count A. Prokesch-Osten, *Geschichte des Abfalls der Griecken vom türkischen Reich,* etc. (6 vols., Vienna, 1867), the last four volumes consisting of *pièces justificatives* of much value. *See* also W. Alison Phillips, *The War of Greek Independence* (London and New York, 1897), a sketch compiled mainly from the above-mentioned works. Of great value also are the 29 volumes of Correspondence and Papers of Sir Richard Church, now in the British Museum (Add. mss. 36,543–36,571). For further references *see* the bibliography appended to W. Alison Phillips's chapter on "Greece and the Balkan Peninsula" in the *Cambridge Modern Hislory,* x. 803. (W. A. P.)

GREEK LANGUAGE. This term is commonly applied to the tongues of both ancient and modern Greece. These, however, differ so much that it is necessary to deal with them in separate sections.

Of both the alphabet is as follows:

Name	Sign	Conventional equivalent	Kame	Sign	Conventional equivalent
Alpha	Α α	A	Nu	Ν ν	N
Beta.	Β β	B	Xi	Ξ ξ	X
Gamma	Γ γ	G	Omicron	Ο ο	short O
Delta	Δ δ	D	Pi	Π π	P
Epsilon	Ε ϵ	Short E	Rho	Ρ ρ	R
Zēta	Ζ ζ	Z (DZ)	Sigma	Σ(C) σς	S
Ēta	Η η	long E	Tau	Τ τ	T
Theta	Θ θ	TH	Upsilon	Υ υ	U
Iōta	Ι ι	I	Phi	Φ ϕ	PH
Kappa	Κ κ	K	Chi	Χ χ	CH
Lambda	Λ λ	L	Psi	Ψ ψ	PS
Mu	Μ μ	M	Omega	Ω ω	long O

ANCIENT

Greek, one of the Indo-European languages, was spoken in one or other of its forms (dialects) in the Balkan peninsula, on the west coast of Asia Minor, in south Italy and Sicily, and in the islands of the Ionian and Aegean seas. By the fourth century B.C. the political supremacy of Athens and the greatness of Attic literature had caused the Attic dialect to become the basis of a lingua *franca* for all Greeks, which in the long run superseded the other dialects. The conquests of Alexander the Great caused Greek (in the form of this *lingua franca* or *κοίνη* to become the speech of the whole Near East (Asia Minor, Syria, Mesopotamia, Egypt). Under the Romans these regions continued to use Greek, and at the present day Russians and Serbians use a modified form of the Greek alphabet.

Authenticity of Our Texts.—Documents written in Greek have reached us, some in the originals, others in copies. The originals are: (a) inscriptions, decrees, treaties, temple inventories, dedications, etc., engraved on stone and found in Greece and all over the Near East; the earliest may date from the eighth century B.C. and they become numerous in the fifth and later centuries; (b) documents (letters, contracts, petitions, accounts, etc.) written on papyrus between the late fourth century B.C. and the eighth century A.D., and preserved by the dry sands of Egypt, from which the excavations, mainly of the end of the 19th and beginning of the 20th century, have brought them to light in large numbers (see PAPYROLOGY). Papyri have not been recovered from other parts of the Greek-speaking norld (except at Herculaneum, where they were buried by the eruption of Vesuvius in AD. 79), but legal documents written on vellum in the second and first centuries B C. have been found at Sâlihîyeh (the ancient Dura-Europos, in Mesopotamia), and at Avroman (Parthia).

The copies, on which we rely for our knowledge of almost all Greek literary works, are written at first on papyrus, and later on vellum or paper. For long the oldest known Greek mss. were those containing the Greek Bible, written on vellum and dating from the 4th and 5th centuries A.D., and the texts of other Greek works rested on vellum (later paper) mss. which were (in general) not older than the 9th and 10th centuries A.D. These remain the broadest basis of our knowledge, but recent excavations have brought to light papyrus mss., some mere scraps, others very substantial rolls or books, of Homer and other classical texts, a few of them written in the 3rd, and and 1st centuries B.C., and many of them in the earliest centuries of the Christian era. In a number of cases we have recovered papyrus copies of works which had perished, no copies having reached us in mediaeval mss. (see GREEK LITERATURE).

Important accessions to our knowledge of the language, its pronunciation, spelling and vocabulary, have resulted from the recovery of so many well-authenticated texts. So long as the mediaeval copies were the only source of our knowledge it was impossible to have much confidence in the spelling which they offered, and certain variations which they exhibited, *e.g.* the variation between ει and ι (τειμή-τιμή; ἀποτεῖσαι-ἀποτῖσαι, etc.) presented a little understood problem. Moreover, the grammatical treatises of Herodian (2nd century A.D.), Choeroboscus (6th century A D.) and others, show that these problems presented themselves already in the early centuries of the Christian era; these grammarians drew up lists of words recommending particular spellings in doubtful cases. It remained doubtful, hon ever, how far the grammarians could be regarded as knowing the truth or as providing a trustworthy criterion for the correction of the mss.

The inscriptions and papyri often provide evidence which settles once and for all a disputed question of spelling. They often carry us back to a time when speech-sounds which later became identical were still distinct from one another. For instance, the inscriptions and papyri of any date earlier than about 150 B.C. are almost wholly free from the hesitation between ει and ι. They have ει without exception in certain words (*e.g.* ἀποτεῖσαι "to pay") and ι without exception in certain others (e g., τιμή). Before 150 B.C. (approximately) the two spellings represented distinct sounds; after 150 B C. the sounds were identical; and the spellings ει and ι were interchangeable. Again the Greek of the 3rd century B.C. possessed the long diphthongs αι ηι ωι (the spelling ᾳ ῃ ῳ is not older than the 12th century A.D.). From the end of the 2nd century B C they are written α η ω nithout the iota. The uniformity nith nhich this happens, and the appearance of the iota in the wrong place (spellings like ἄνωι for ἄνω are frequent) shows that the iota, which must have been pronounced in the 3rd century B C., had ceased to be pronounced in the 1st century B.C., and was sometimes added in writing by persons who thought (rightly or mrongly) that they knew the older spelling. At least one erroneous restoration of iota has been perpetuated. Where our mediaeval mss. (even the most accurate of them) and late inscriptions give us ῥαιθυμεῖν, the papyri of the 3rd century B C. have ῥαθῦμεῖν (without iota), which must be the original and only correct spelling. Unlike ῥᾴδιος, the word can never have been pronounced with an iota. Many of the inscriptions and still more of the papyri are written by persons of little education, whose spelling tends to be phonetic; their very errors throw light on the pronunciation. One instance must suffice: the word ἑαυτοῦ in inscriptions and papyri of the 1st century B C. is often written ἑατοῦ, whereas αὐτοῦ is not written ἀτοῦ. The reason is that ἑαυτοῦ was pronounced at first ἑᾱυτοῦ (being derived by contraction from ἕο αὐτοῦ like the Ionic ἑωυτοῦ which has a different type of contraction) later ἑᾶτοῦ. By the study of such spelling-variations the chief changes in the pronunciation of Greek can be dated with considerable accuracy. Many of the changes which mark the passage from ancient to modern Greek took place in the three or four centuries preceding and the three or four centuries following the Christian era. The language of the period (2nd century A.D.) in which Herodian spoke and wrote was already so different from Attic that his spelling-rules must be assumed to be based not on observation of contemporary pronunciation (it was in fact the divergence between this and the traditional spelling which made spelling-rules a necessity) but on antiquarian research, and in this field the modern investigator has the advantage over him.

Nature of the Tradition of the Accents.—Greek texts, whether on stone, papyrus, vellum or paper, are usually written without spaces between the words. and the continuous use of breathings and accents is found only in mediaeval mss. from the 9th century onwards. Inscriptions (with rare exceptions) and non-literary papyri are entirely without breathings and accents. The same is often true of literary papyri, but these are sometimes more or less sporadically marked with breathings and accents, especially if epic, dramatic or lyric texts. The accentuated literary papyri are in the main not older than the opening centuries of our era. On the other hand, the features of pronunciation of which breathings and accents are the written signs are more ancient than the use of the signs. From numerous references in Greek authors, and especially from Apollonius Dyscolus and his son Herodian, who wrote in the 2nd century A D., we learn many details of the accentuation of Greek, which was a variation of pitch; the syllable marked with the acute accent was high-pitched, the others, those which in the printed books are marked with the grave accent or with no mark at all, nere spoken on the low pitch, while circumflexed syllables, were spoken on a descending pitch, the first part of the syllable being higher than the second. Such is the most probable inference from the statements of grammarians and certain other evidence (*e.g.* the marks found in accented papyri, and the scanty remains of Greek music), though several points are still disputed.

The general accuracy, and at the same time the great antiquity, of the traditional accentuation of Greek in modern printed editions may be proved by means of a comparison between it and the accentuation of Vedic Sanskrit; the tno exhibit a number of striking coincidences which point to an unbroken oral tradition in both cases from the hypothetical parent "Indo-European." In 1876 Karl Verner demonstrated that certain consonant changes in Germanic could be explained if the position of the accent thus observed in Greek and Sanskrit were admitted to have existed at one time in Germanic also. The antiquity of the distinction between the acute and the circumflex has been demonstrated by a comparison with the accentuation of modern Lithuanian, in mhich a corresponding distinction has been observed.

The breathings and accentual marks found in our text of a classical author, such as Plato, cannot have been copied, even at many removes, from his autograph: Plato cannot have written more than the bare series of letters forming the words. It is, however, clear that he pronounced an h or a high pitch even when he did not put it down in writing, and that those who, in transmitting his text to us, inserted the breathings and accentual marks (in the main Byzantine scholars of the 9th century) were guided by contemporary living speech (the position of the accent is in general still the same in Modern Greek), and by antiquarian knowledge to a very large measure of success.

Varieties of Early Greek.—The language of the inscriptions from the 7th to the 4th century B.C. presents varieties of two kinds, varieties of alphabet and spelling, and varieties of dialect.

(1) Varieties of alphabet and spelling. The Greek alphabet is an adaptation of the Semitic alphabet, and differs according

to locality and date. One of these differences throws much light on the language, viz., the varying mode of representing ε sounds and o sounds.

The contraction of ε+ε (ĕ+ĕ) must obviously have resulted, to begin with, in a long ē, and similarly the contraction of o+o must have given ō. Hence EL in the 4th century Attic (and later Greek) form ἐπεστάτει (from ἐπεστάτε-ε) must have been pronounced from the beginning not as a diphthong, but as a long ē, and similarly the ου of μισθοῦμεν (from μισθόομεν) must have been from the first pronounced 6, not as a diphthong ου. In the oldest inscriptions these sounds are in fact written E and O (επεστατε, μισθομεν). When EL and ου are thus demonstrably monophthongs, they are called "spurious diphthongs."

In the local Attic and many other alphabets there was no vowel-symbol η (H), and no ω (Ω). In such alphabets E had to represent three sounds, viz., ε (as in φέρω), ē (as in ἐπεστατε) and the other kind of ē which was written η when that letter was introduced (ανεθεκε, later ανεθηκε). Similarly o had to represent o (in φερομεν), ō (in μισθομεν) and the other ō which was later written ω (δορον later δῶρον).

But EL and ου are not always spurious diphthongs. In εἶμι ("I shall go") the EL is, in origin at least, a diphthong (Lith. *einù*, "I go," Lat. eo from ei-o through *e[y]-o*, *i-tur* from ei-tur; Gr. ἴμεν shows the i-element bereft of the e). In εἰλήλουθα the υ is the same as in ἤλυθον, so that ov is here in origin a genuine diphthong. In early inscriptions. EL and ου are in certain words fixed and not capable of alternating with E and o. Thus εἶπε, δοκεῖ (from δοκέ-ει), πρεσβεία, πειθομένοις, ἔπει (Dat. of ἔπος), ἐπεί ("when"), εἰ, ἀτέλεια, οὐκ, οὐδένος, are constant spellings, of course without accents even in an inscription (Dittenberger, Sylloge[3] 64), which has only E and o in place of the later "spurious diphthongs" (ἒναι, τρῆς, τô δέμο, 78 Διὸς, τô Ὀλυμπίο, οἰκôντες, etc.). Thus the early inscriptions sometimes yield information attainable in no other way, *e.g.* they tell us that οὐκ, οὗτος, εἶπε and φέρεις φέρει have genuine diphthongs.

The spurious diphthongs sometimes owe their origin to what is known as "compensatory lengthening." Just as the long ᾱ in πᾶς arises from a lengthening of the ᾰ in *πάνς (from *παντ-ς *cf.* Genitive παντ-ός) to compensate for the loss of the v, so the nominative *τιθέντ-ς became *τιθένς and then τιθēς, which is written τιθες on the older inscriptions, τιθείς in later Attic, and τιθής in some other dialects.

At the end of the 5th century B.C. the local Ionic alphabet, which possessed the vowel signs η and ω in addition to ε and o, began to supersede the other Greek alphabets. It was officially adopted at Athens in place of the Attic alphabet in 403 B.C., and by the end of the 4th century it was in general use throughout Greece.

The ē and ō mhich resulted from contraction and compensatory lengthening were not everywhere written in the same way in the 4th century B.C. In some dialects we find not τελεῖτε, τιθείς, διδούς, but τελῆτε, τιθής, διδώς. Within the Doric area both spellings are found (*e.g.* in some places ἦμεν, in others εἶμεν, from *es-men*, infinitive of the verb "to be"). The difference is perhaps one not of pronunciation, but only of spelling.

The distinction between genuine and spurious diphthongs shows itself even after general adoption of the Ionic alphabet in the case of contractions with a preceding vowel; *e.g.* ὁράεις ὁράει, which have the genuine EL, become ὁρᾶις ὁρᾶι (ὁρᾳς ὁρᾳ in mediaeval rnss.), but ὁράειν, which has the spurious EL, becomes ὁρᾶν. Similarly in οὐκέθ' ὁμῶς τιμῆς ἔσεαι (Il. 9, 605), τιμῆς is the contracted form of τιμήεις, which has the spurious EL (τιμη-[ϝ]εις from -ϝεντ-ς *cf.* gen. -εντ-ος, Sanskrit *-vant-*). In 11. 3, 13, where the mss. have κονίσαλος ὤρνυτ' ἀελλῆς, Buttmann's conjecture, that the last word is a contraction of ἀελλήεις "eddying," involves only a change of accent (to ἀελλῆς): it would be a mistake to write, as he proposed, ἀελλῆς.

The study of the ancient Greek language is based on written documents and the textual critic seeks to restore and interpret the actual letters of the autograph, in cases where this autograph has not reached us.

The mediaeval mss. offer texts written in the Ionic alphabet, and in a spelling which, at its most accurate, is that of the 3rd century B C., but more often shows signs of the passing of the centuries between that date and the 9th and 10th centuries A.D. The spelling of the 3rd century B.C. is clearly not appropriate to authors who wrote in the 5th century B.C. (especially the beginning of it), or earlier; in the case of Homer the composition of the poems was earlier than the knowledge of writing in Greece.

Many of the great Athenians (Sophocles, Euripides, Aristophanes, Thucydides) arote in the second half of the 5th century. They may well have used the Ionic alphabet, which inscriptions prove to have been used at Athens some decades before 403 B.C. Aeschylus, who wrote in the first half of the 5th century, is more likely to have used the Attic alphabet, employed in fragments of the earlier lyrics which are painted on Attic vases of the 6th and 5th centuries. The old spellings may well have survived longest in the case of the oldest books (Homer, Hesiod, Theognis, Alcman, etc.).

The study of the Homeric poems from this point of view has led to tangible results. In the older alphabets of Greece, ε and o, as already mentioned, can stand for ē and ō ("spurious" EL and ου), and a single consonant is written where the later practice is to write it double (ἀλογλωσος = ἀλλογλώσσους). Both features are to be seen in τειχιοσης (= Τειχιούσσης) in a Milesian inscription of the 6th century B.C. In the line καιροσέων δ'ὀθονέων ἀπολείβεται ὑγρὸν ἔλαιον (Od. 7. 107) καιροσέων is the archaic spelling of καιρουσσέων, a word which was so rare that the rhapsodes of the 6th century did not understand what they found in their written texts of Homer. In this way the spelling escaped modernization. The word ἀνηρείψαντο which is given by our mss. of Il. 20, 234 is a mistake for ἀνηρέψαντο as we now know from the forms ἀ[να]ρέψατο in a Paean of Pindar and ἀναρεψαμένη in mss. of Hesiod (Theog. 990). In Il. 7, 434 ἔγρετο means "gathered, assembled," and is the archaic spelling of the aor. of ἀγείρω (later written ἤγρετο). It was mistaken for the aor. of ἐγείρω (ἔγρετο "arose") and to this mistake it owes its preservation. In Il. 5, 293: αἰχμὴ 6' ἐξελύθη ("came out") παρὰ νείατον ἀνθερεῶνα the poet clearly meant ἐξέλυθε, the unaugmented form corresponding to the augmented ἐξήλυθε; because it resembled the aorist passive of ἐκλύω and because the metre demanded a long vowel in the last place, it became ἐξελύθη.

The two instances just given (ἔγρετο, ἐξελύθη) show us a Homer written in an alphabet which possessed no H, but used E instead.

Certain other indications point to a time when the poems existed only in oral transmission and had not yet been written down. Bentley showed that many irregularities in the metre vanished when once it was admitted that at the time of the composition of the poems the language possessed the sound w (written ϝ in dialect-inscriptions, but nowhere written in our mss. of Homer).

The traces of this sound consist of lengthenings of a preceding vowel (*e.g.*, κᾱλός is really καλϝός—this form occurs in a Boeotian inscription of the 7th century B.C.), and of cases of hiatus (*e.g.*, ὄπα ἀρνῶν Il. 4, 43j—the dialect inscriptions have ϝαρήν, ϝαρνός).

Bentley's observations were true, but more recently it has been recognized that some lines in the poems may have been composed nhen the w-sound was already lost from the language. It is probable that the composing of the poems extended over a long period, within which the w ceased to be pronounced.

In Il. 24, 154 ὃς ἄξει is defective both metrically and in point of sense; the parallel ὅς a' ἄξει (line 183) shows that the poet meant in 154 8s ϝh' ἄξει, where ϝhε is the older form of the Attic ἑ (Doric ϝε and Pamphylian ϝhε are found in inscriptions). Such cases (there are several of them) bring out clearly the reality of the sound w in Homer. In a number of other respects the spelling which we find in our mss. of Homer can be shown to be unoriginal. The first person plur. subj. of ἔστην is written στείομεν (Il. 1j, 297), instead of στήομεν as the analysis requires (the root is στᾱ, *cf.* Lat. *stāre*, which gives Ionic στη-, and the sign of the subjunctive in unthematic verbs is a short -ο- or -ε-). The later Ionic form στέωμεν (which arose by a regular change of -ηο- to -εω- cf. βασιλῆος: βασιλέως) occurs in Il. 11. 348. The reciters found στεομεν in their written texts of Il. 15. 297, and lengthened the ε to ē (which they wrote EI, as we have seen), because, as the living form nas στέωμεν, it did not occur to them that στεομεν was the old way of writing στήομεν. The group -ηο- thus came to be written -ειο- in many other words as well.

The word εἰνάτερες was believed by Herodian to be the plural of εἰνάτηρ. Inscriptions have proved however that the nominative sing. was ἐνάτηρ, and εἰνάτερες is the poet's arbitrary way of modifying the word ἐνάτερες in order to fit it into a hexameter. Here again, the lengthening of ε is expressed by the spurious diphthong, the introduction of nhich into the text can hardly be much older than the 4th century B.C. Other examples of EI and ov resulting from metrical lengthening are εἰν ἀγορῇ, Πειρίθοος, δουλιχόδειρος (for δολυχόδερϝος) οὐλόμενος, Οὐλύμποιο, and many others. The numerous forms of which ὁρόωντες, ὁράασθαι are specimens, in which the older ᾰο, ᾰε seem to have become ow and αᾱ, have no parallel in dialect inscriptions. The poets (whether in writing or in oral composition) must have used the forms ὁράοντες, ὁράεσθαι. In the course of the transmission the later contracted forms ὁρῶντες, ὁρᾶσθαι tended to be substituted, but the metre compelled the reciters to "pull out" the contracted forms into ὁρόωντες and ὁράασθαι, by prefixing in each case to the long vowel (which resulted from the contraction) its short form (ο, a). Forms, such as ναιετάει, which did not survive (there was no ναιετᾷ in later Greek), were not exposed to this modernizing tendency, and were left untouched.

Distinct from differences of alphabet and spelling are differences between the spoken forms of the language in different places, *i.e.*, differences of dialect. Our knowledge of the dialects is derived mainly from inscriptions of the 6th, 5th, 4th and 3rd centuries B.c.; from the time of the Athenian supremacy the Attic dialect begins to supersede the others, so that many documents show a mixture of non-Attic and Attic elements. In later centuries there were revivals of the use of dialects in inscriptions, but their artificial character is proved by the presence in them of forms which earlier inscriptions show to have been long obsolete, *e.g.* ῥαψάϝυδος (=ῥαψῳδός) in a late Boeotian inscription, whereas earlier Boeotian inscriptions indicate that ϝ between vowels had long been lost. The literary documents written in dialect are often of larger compass than the inscriptions, and therefore in some ways more instructive, especially for the vocabulary; but the variations in the manuscript tradition (*e.g.*, of Hippocrates and Herodotus) constitute a difficulty which only the inscriptions can help us to overcome. The inscriptions have in fact enabled us to pick our way with greater certainty among the variants, and to detect (for instance) the fact that the consistent absence of the so-called v ἐφελκυστικόν from our mss. of Herodotus is not a feature of the Ionic dialect, but is the result of unintelligent editing by some unknown ancient critic; the Ionic inscriptions have this v in even greater profusion than the Attic (Ion. ἐποίειν where Att. has ἐποίει).

The main dialect divisions are: (1) Ionic, of which Attic is a sub-dialect; (2) Aeolic; (3) Arcadian and Cyprian; (4) Doric. In the 6th and jth centuries B.C. the local distribution was as follows: Ionic was spoken in the central part of the coast of Asia Minor, in many of the Aegean islands, in Euboea and the Chalcidian peninsula, and (in its Attic form) in Attica. Aeolic is the collective name of the dialects spoken in the northern part of the Asiatic coast (Aeolis) including Lesbos, and (with a Doric admixture) in Thessaly and Boeotia. Arcadian and Cyprian are named from the places in which they were spoken; the recognition of their close resemblance in spite of the great distance between them was one of the surprises which resulted from the discovery of Arcadian and Cyprian inscriptions and of the deciphering of the Cyprian syllabary in the '70s and '80s of the 19th century. Lastly Doric in many varieties was spoken in the Peloponnese (except Arcadia) in north-west Greece (Locris, Phocis, Epirus) in the more southerly Aegean islands, especially Thera, Crete, Cos, Rhodes, and on the neighbouring part of the Asiatic coast.

Colonists took with them the dialect of the mother-city; we find Ionic spoken in several Milesian settlements on the Black sea coast, and Doric in Syracuse and other Doric foundations in Sicily and south Italy.

Such, in outline, is the geographical distribution of the Greek dialects at the period when they become known to us. For an earlier period we have to rely mainly on the evidence of Greek historians (especially Herodotus and Thucydides). From them we learn that there was in early times a migration from Epirus into the Aeolic land of Thessaly, which drove before it another migration from Thessaly into Boeotia. At the time of the Trojan War, according to Thucydides, the later Boeotians were not yet in Boeotia. From Herodotus, Strabo and Pausanias, we learn of the former presence of Ionians in Cynuria, and on the shores of the Saronic gulf. The resemblance between the land-enclosed Arcadian dialect and the distant Cyprian is less surprising when we find that Arcadian mas at one time spoken as far south as the promontory of Taenarum. This is proved by the name of the festival to Poseidon which was celebrated there, viz., Π*oh*οιδαια. The dialect of Taenarum in historical times was Laconian (Doric), in which σ between vowels had become *h*. Accordingly Π*oh*οιδαια is the Laconized form of Ποσοιδαια, and an Arcadian inscription proves that Ποσοιδαν was the Arcadian name of the god. It may be inferred that Arcadian was once spoken throughout the Peloponnese and perhaps over a still wider area, before it was overwhelmed and shut in by the Dorian migration.

Greek and the Other Indo-European Languages.—The dialects show considerable differences from one another in respect of sounds, inflexions, syntax and vocabulary, and the comparison of the dialects with one another often throws light on the past, enabling us to reconstruct an earlier condition of the Greek language. In this reconstruction use is made at the same time of a comparison with the other Indo-European languages. In what follows an attempt will be made to indicate briefly some of the more important sound-changes to which Greek owes its differences from the other languages.

Of the consonants which the parent speech had, Greek has lost inter-vocalic y and s; Sanskrit *tráyas* "three" and Greek (Cretan) τρέες are both descended from Indo-Eur. *trĕyĕs;* Sanskrit tras-ati "trembles" and Greek τρέ-ω come from tres-. At the beginning of a word both y and *s* became h: ὅς (rel. pron.) corresponds to Sanskrit yas (Indo-Eur. yos), and the article 6 to Sanskrit sa (Indo-Eur. so). Sometimes *y* became ζ (Sanskrit *yugdm*, Gr. ζυγόν). The earliest records of many dialects show a complete loss of the sound *w* (*e.g.*, ὄϊς [οἶς] from Indo-Eur. *owis*, cf. Lat. *ovis*) but other dialects retain this sound (which is written ϝ [digamma]), *e.g.*, ὄϝινς (accus. plur.) is found in an Argive inscription of the 5th century B.C.

The loss of these three sounds often left two vowels standing next one another in a word; this was at first tolerated, but later led to contraction into a single vowel. These contractions occurred in the main after the composition of the Homeric poems, and the method of contraction differs in different dialects. Hence forms like ναιετάει in Homer, and the contrast between (*e.g.*) Att. τιμῶ, τιμᾷ and Dor. τιμῶ, τιμῇ or between Att. φιλῶ and Ion. φιλέω.

In combination with liquids and nasals y, *s* and w often caused a lengthening of the preceding vowel before disappearing; ἔτεινα (pronounce ἔτēνα) arose from ἔ-τεν-s-α, τείνω (pron. τēνω) from τεν-yω, Ion. ξεῖνος (pron. ξēνος) from ξένϝος (πρόξενϝος occurs in an inscription). Here too, the dialects diverge; the details are too complex to be enumerated here.

A y following a guttural, dental or labial stop combined with it into a single sound: φυλακ-yω became φυλάσσω, μεθ-yος (*cf.* Lat. *medius*, Sanskrit *madhyas*) became μέσσος and then μέσος, μεγ-yων became μέζων (Ion.), χαλεπ-yω became χαλέπτω.

A nasal before σ (which generally arose, as in yiaos, from a dental +*y*, sometimes from a dental +*s*) disappeared in most dialects (*e.g.*, Att. πᾶσα from πάνσα, τιθεῖσα from τιθένσα) leaving behind it a lengthened vowel. Some dialects, however, *retained the -νσ- combination (Arc. πάνσα).*

When the numerous long vowels which arose from contraction and from compensatory lengthening are left out of account, the remainder of the Greek vowels are found to be, in the main, survivals from the parent speech: e.g., μάτηρ (Dor. etc.), Lat. miter; δῶρον, Lat. dō-num; (ϝ)ίς, Lat. vis; μῦς, Lat. mūs; πλῆ-το, Lat. plē-nus; ἄγω, Lat. ago; ὄ(ϝ)ις, Lat. ovis; φέρω, Lat. *fero; sometimes when most of the languages agree in ᾰ (πατήρ, pater, etc.) Sanskrit has ĭ (pitar-); in such cases the parent-form is believed to have had an indistinct vowel like the first o in potato.*

Indo-Eur. t, p, d, b have survived unchanged in Greek (some instances will be found among the words already quoted). Sanskrit has the sounds dh, bh; these go back to Indo-Eur. dh, bh, which have yielded Greek θ, φ (pronounced like t, p, in the Irish pronunciation of English), e.g., Sanskrit bhar-, Lat. fero, Greek φέρω, Sanskrit dadhāmi, Lith. dd-ti (infin. "to *lay"), Greek τίθημι.*

The Indo-Eur. gutturals are of two kinds, technically called palatals and labio-velars.

The palatals appear in Greek as κ, γ, χ, in Latin as c, g. h, and as gutturals in Celtic and Germanic: e.g., κύων, Lat. canis; ἄγω, Lat. ego; χιών, Lat. hiems. In the Eastern group of Indo-Eur. languages (Indo-Iranian, Armenian, Slavonic and Baltic) they appear as sibilants, e.g., Sanskrit śvā (stem Sun)"dog," ajati "he drives," himàs "frost, snow," Lith. Sun-"dog," žiemà and Slav. zima "winter."

The labio-velars were sounds of the **qu** *'or k^w type, They survive more or less clearly in Latin quis, ni-n-guit. In some languages they drop the u or w element, and become k, g* and *gh (so in Sanskrit). Sometimes they appear as p, b; e.g., Oscan* **pis** *corresponding to Latin quis, Old Irish ben "woman" corresponding to English queen. In the Greek dialects they tend to appear before a and o* vowels *as labials (π, β, φ) e.g., ποινή, Avestan kadna* "punishment," *Lith. kaina "price" (all from Indo-Eur. kwoind);* **-βόρος**, Lat.*-vorus, Sankr. -garó̄s* "swallowing"; **φόνος**, *Sanskrit ghands (from Indo-Eur. gwhonos). Before e and i vowels they tend to appear as dentals, e.g., τίνω, τεῖσαι (from kwĭ-, k^wei-, forms of* the *same root as in ποινή), τις,* Lat. *quis, θείνω, Sanskrit hanti "he kills," Hittite kuenzi "he kills" (Indo-Eur. g^when-ti, from the same root as φόνος, ἔπεφνε, πέφαται).* In Aeolic *the labials appear even before e*-vowels, *e.g., πήλοι* "far," Att. τῆλε; Boeot. *πέτταρες*, Att. *τέτταρες*, Dor. *τέτορες* (*cf.* Lat. *quatuor*). Occasionally *a* labio-velar develops into a Greek guttural, *often* owing *to the* neighbourhood of *u*, e.g., **βου-κόλος** with the same *ending* as *αἰ(γ)-πόλος, cf.* Lat. *colo, in-quiz-inus;* **κύκλος**, Lith. *kāklas "neck,"* Eng. *wheel; γυνή*, Boeot. *βανά*, Eng. *queen.* The *pronoun τις appears in* Thessalian as *κις*; for *πότερος, πῶς Herodotus has κότερος, κῶς.*

The Greek *πατράσι* (dat. pl. of *πατήρ*) corresponds very closely *(even in respect* of *the accent)* to *the Sanskrit Locative pitṛṣu. In this, as in many Sanskrit words, r functions as a vowel. This* "sonant" *r as it is called, is descended from the same sound in the parent-speech. In the other langages the result is r preceded or* followed by a short vowel: *Greek ρᾰ or ᾰρ, Lat. or, Lith. ir, Ger. ur, etc. The variation in the quality of the vowel is a sign that* it has been separately developed in each language. The same *phenomenon is observed in the case of l, m and n. So-nant m, for* example, is observed in the word for 100, Indo-Eur. *kṃtom, Lat. centum, Lith. šimtas, Ger. hund; Greek ἑ-κατόν and Sanskrit śatám indicate that* sonant *m became a in these languages. The same ᾰ from ṃ or ṇ (to use the technical notation of these sounds) is found in πόδ-α from ποδ-m* (which *has the same ending as the o-stem ἔργο-ν* [from *-o-m*], *Lat. illu-m), and in γεγράφαται (from γεγράφηται) which has the same ending as λέλυ-νται.*

The Aeolic *dialect has po and not pa in place* of *the* sonant, *e.g. στρότος and not στρατός from stṛtos.*

Bibliography.—*Texts. A* list *of editions of Greek authors,* inscriptions and papyri will be found in Pt. I (Oxford, *1925*) of the 9th ed. *of* Liddell *and Scott's Greek-English Lexicon (see below).* For *Facsimiles see* Palaeography. *Grammars.* The fullest reference work (it **is** not *always* **up** *to date)* is *R. Kuhner's* ***Ausführliche Grammatik** der griechischen Sprache, 3rd ed. by F.* Blass *and B. Gerth,* 1890–1904. *For details of the spelling of Greek inscriptions and papyri the best works are K. Meisterhans, Grammatik der attischen Inschriften (3rd ed. by E. Schwyzer,* 1900); *W. Cronert, Memoria Graeca Herculanensis, Leipzig* (1903) *(compares the Herculaneum papyri with the other papyri, inscriptions and* mss.); *E. Mayser, Grammatik der griechischen Papyri aus der Ptolemäerzeit (esp. vol. I [Leipzig,* 1906]; vol. *2* [1926] *contains the syntax); H. St. J. Thackeray, Grammar of the Old Testament in Greek, I, Cambridge,* 1909; *J. H.* Moulton, *Grammar of New Testament Greek,* vol. *I* (3rd *ed.), Edinburgh,* 1908; *vol. 2, pts.* i. *and* ii. *revised by W. F. Howard,* 1919, *1920; F.* Blass, *Grammatik des Neutestamentlichen Griechisch,* 5th *ed. by A. Debrunner, Gottingen, 1921. The language of* Homer *is treated in D. B. Monro, Homeric Grammar,* 2nd ed. *Oxford, 1891; J.* Wackernagel, *Sprachliche Untersuchungen zu Homer, Gottinpen,* 1916; *K. Meister, Die Homerische Kunstsprache, Leipzig, 1921. The dialects are treated by C. D. Buck, Introduction to the Greek Dialects (grammar, texts, vocabulary, rev. ed.* 1928) *and by F. Bechtel, Die Griechischen Dialekte,* 1921–24 *(grammar only). A convenient collection of* dialect-*inscriptions is E. Schwyzer, Dialectorum graecarum exempla epigraphic~potiora, Leipzig,* 1923 *(with index). The relation of Greek to the other Indo-Eur. languages is studied in K. Brugmann, Griechische Grammatik, 4th ed. revised by A. Thumb, Munich,* 1913, *and in Brugmann and* Delbrück's *large Grundriss der vergleichenden Grammatik der Indogermanischen Sprachen,* 2nd *ed.. Strassburg* 1897–1916; *more briefly in A. Meillet, Introduction à l'étude comparative des langues indo-européennes,* 1908 *(and later eds.). Lexicons. The Thesaurus Linguae Graecae of H. Stephanus (Henri Etienne), first* published *in* 1572, *was greatly enlarged by K. B. Hase and the brothers W. and L. Dindorf (Paris,* 1831–65) *and remains valuable, but does not cover the inscriptions and papyri. The vocabulary of the non-literary papyri is covered by F. Preisigke, Worterbuch der griechischen Papyrusurkunden, which* was *rapidly published at Berlin in* 1924 *and the following years. The papyri and inscriptions are included in the new* (9th) *ed. of* Liddell *and Scott's Greek-English Lexicon, revised and enlarged by H. Stuart Jones* with *the assistance of R.* McKenzie *and with the co-operation* of *many scholars, which is in course of publication. The New Testament vocabulary is treated in J. H.* Moulton *and G. Milligan's Vocabulary of the Greek Testament illustrated from the papyri and other non-literary sources (Pt. VI. carrying the work down to ῥώννυμι appeared in 1926). The best etymological dictionary is E. Boisacq, Dictionnaire e'tymologique de la langue grecque, Heidelberg-Paris,* 1916. *For the numerous special lexicons, see H. Schone, Repertorium griechischer Wörterverzeichnisse* und *Speziallexika,* Leipzig, 1907. *(R.*McK.)

MODERN

Apart from numerous differences in *dialect, there are* two *broad* types of language used in modern Greece, viz., the "pure," or *καθαρεύουσα* and the "popular," or *δημοτική*, *to use the most dig*nified of the terms employed *to* distinguish *them. The former* is a conscious and artificial *return to Ancient Greek,* and is taught in schools, and used for official *purposes* and generally *by news*papers; the latter is the natural language of *the* people, *and em*bodies a good many foreign words which have crept into the language in the course of later Greek history. The "popular" is primarily a spoken language, that of the Greek *songs* and bal*lads, and as such has not a fixed orthography, but it possesses the force* of a living language, and is largely employed by modern writers of poetry and fiction. Tendencies towards compromise may be observed between the "purist" and "popular" schools.

Phonetics.—One broad distinction between Ancient Greek and *the modern language is that the ancient accent was a "pitch"* or "musical" accent, the modern is a "stress" accent, so that if a line of ancient Greek poetry, say of Homer, is read aloud with the modern stress value *assigned to the accented syllables, the rhythm is destroyed, and the modern Greek can only regain its* effect by arbitrarily shifting the stress accent in such a way that *the values of the ancient quantities are approximately reproduced.*

This change in the effect, though not in the position, of the accent in Modern Greek has resulted in a levelling out of vowel values, although the ancient vowel forms are retained in writing, a is pronounced, continental fashion, as ah (father); ϵ as eh (led); η, ι, υ have all the same value -ee (see); o and ω oh (cope). Of the diphthongs, αι is pronounced as ϵ; ει, οι, υι as η, etc.; *ου as oo (brood); αυ as ahv, except before the hard consonants* (κ, π, τ, χ, φ, θ, σ), when it is pronounced *ahf. Similarly ευ* is pronounced as *ev* and *ef* respectively. *ηυ* as *eev* and *eef*. The consonants *approximate to the sounds* of *the corresponding* English *consonants, with these exceptions: β* is pronounced *as v; γ as hard* gh, except before e, η, ι, υ, αι, ευ, οι, υι, when it has the value of y; when doubled or before κ, it has the value of ng; δ is sounded as th (the), φ as f; χ as ch in Scotch loch, but before the vowels and diphthongs mentioned under γ it is soft, as in German ich; ψ has the value of ps. To express the equivalents of English b, d and hard g, Modern Greek uses μπ, ντ and γκ respectively. In the middle of words, π after μ has a b sound, e.g., ἔμπορος=émboros; τ after ν a d sound, e.g., ἐντροπή=endropée. The final ν of the article and the initial π or τ of the following word also undergo a change of sound. Thus τὸν πατέρα tom batéra, τὴν τέχνην teem dechneen. The above are the main rules for pronunciation, though some refinements of minor importance for the English student are omitted. The accented syllable is strongly stressed, so much so that the beginner seems only to catch the accented syllable. The distinction between acute, grave and circumflex is immaterial for speaking, but is generally retained in writing after the manner of Ancient Greek. There is no aspirate in pronunciation, though the signs for rough and smooth breathing are retained in writing.

Grammar.— The "popular" language diverges from Ancient Greek far more than the "purist," both as regards forms and the shifting of accent. Full information can be obtained from some of the works mentioned in the Bibliography.

Declension.— Modern Greek has lost the dual. Except in the very "purist" style and in a few stereotyped phrases, it has also lost the dative case; in place of this, εἰς or πρός with the accusative, the accusative alone, or the genitive is substituted. For the genitive, ἀπό with the accusative is often used, or the simple accusative. As regards substantives in general, though the "purist" language practically follows the classical, the following features of the "popular" should be noted: words of the first declension ending in -α, -η, -ας or -ης, have plural in -ες. In the second declension there is a tendency to favour neuters, e.g., τὸ χερί for ἡ χείρ. In the third, Popular Greek adopts accusative singular of feminine nouns as nominative, e.g. μητέρα, τρίχα, etc., and the accusative plural of masculine nouns, e.g., πατέρας, γέροντας, etc. Often masculine forms in this declension are shifted to the second, e.g., γέρων to γέρος, γόνυ to γόνατον, etc. Note also that the plural of nouns of the third declension are often augmented by a syllable, e.g. παπᾶς, priest, plural παπάδες; παπουτζῆς, shoemaker; plural, παπουτζῆδες.

Adjectives.— "Popular" usage retains -η in the feminine after ρ and in words compounded with α-negative, e.g., ἄσπρη, ἄμορφη, and prefers uncontracted adjectives, e.g., χρυσός for χρυσοῦς. In forming comparatives πλέον is much used with the positive form. To express "than" after comparatives the following are used: genitive case, ἤ or παρά with nominative, or ἀπό with accusative. To express superlatives, the definite article is used with the comparative form, e.g., ὁ καλύτερος.

Pronouns.—In case of ἐγώ and σύ note accusative singular ἐμένα, ἐσένα and genitive plural μᾶς, σᾶς; in αὐτός genitive singular τοῦ, τῆς and genitive plural τῶ(ν), τούς. The curious indeclinable expression τοῦ λόγου μου, σου, του, της for *myself*, etc. is worth remarking; in possessive pronouns ἰδικός, e.g. ὁ ἰδικός μου υἱός my own son; in relative pronouns, ὁ ὁποῖος and ὁποῦ (indeclinable)=who; in indefinite pronouns, κάτι, something; τίποτε anything, nothing; κανείς anyone, no one; καθείς, any, every, and expressions like κάθε ἄνθρωπος, *everyman*; κάποιος, *a certain*; κάμποσος, several. Of interrogatives, note τί invariable, e.g., τί ὥρα εἶνε; what's the *time*? τί λογῆς; *of what* sort?

Numerals.— The general usage follows the classical, but "popular" Greek has many divergent forms, such as ἕξη (6), τριάντα (30), σαράντα (40), πενῆντα (50), ἑξῆντα (60), etc. The following miscellaneous expressions may be noted: ἑκατομμύριον (*million*), δωδεκάς (dozen), δύο φοραίς (twice), τρία τέταρτα (3/4), δύο ἀπὸ τὰ πέντε (2/5), δύο στὸ πέντε (2/5), ἕξε τοῖς ἑκατόν (6%), μισὴ ὥρα (*half-hour*), εἰς τὰς πέντε (5 o'clock), τρεῖς καὶ τέταρτο (3.15), ἕξε παρὰ εἴκοσι (5.40), εἴκοσι Φεβρουαρίου εἰς τὰ χίλια ἐννακόσια εἰκοσιοκτώ (20th Feb., 1928).

Conjugation.— The Modern Greek verb has no dual, optative or infinitive. The optative is expressed by εἴθε νά e.g., εἴθε νὰ ἦτο would that it had been, the infinitive by νά followed by the subjunctive, e.g., θέλω νὰ γράφω, I want to write. There is a tendency to substitute the -ω ending for μι, e.g., δεικνύω, and to abandon contracted verbs, e.g., χρυσόνω takes the place of χρυσόω. The auxiliary verbs ἔχω and θέλω have largely taken the place of the old tense forms; θέλω is generally used in its abbreviated form θά thus θὰ εἶμαι, I shall be; ἔχω λάβει, I have *received*; θὰ εἶχον λάβει, I should have received. In these examples λάβει is an invariable form, corresponding (according to some) to an infinitive without ν, according to others, to the 3rd singular aorist subjunctive and as such sometimes written λάβῃ. The corresponding passive form is ληφθῆ—ἔχω ληφθῆ, I *have* been received. For the imperative, ἄς with the subjunctive is largely used, e.g., ἄς γράφῃ, let *him* write. It should be observed that for the forms described as subjunctive, the corresponding indicative forms, γράφει, etc., are freely used. The invariable present participle form ending in -οντας should be noted, e.g., ὄντας, *being*, γράφοντας, *writing*. As to the principles of the Modern Greek verb with regard to time, the most important distinction is between the continuous (present) and the momentary (aorist), e.g., θὰ γράφω I shall be *writing*, and θὰ γράψω, I shall write. In conditionals, classical refinements have been largely obliterated: ἐάν or ἄν is commonly used with the indicative, e.g., ἐὰν εἶχε γράψει, ἤθελον μάθει, If he had written, I *should* have learned; thus θέλω has ousted ancient ἄν in the apodosis.

Vocabulary.— The "purists" go to Ancient Greek for their vocabulary, and are anxious to oust all foreign words. To meet modern conditions, they introduce many neologisms, coined on analogy with the ancient language; e.g., ἀσύρματος τηλεγραφία, wireless telegraphy; ῥαδιοτηλεγράφημα, wireless *telegram*; δακτυλογραφία, typewriting; συνάλλαγμα, bill *of* exchange; ὑπάλληλος, employee; καρβουνότουβλα, *briquettes*; ταχυδρομεῖον, *post-office*; ἁμαξοστοιχία, railway *train*; ἀτμόπλοιον, steamer; ὑποβρύχιον, submarine; θωρηκτόν, *warship*; εὔελπις, cadet; συνταγματάρχης, colonel; ἀεροπλάνον, aeroplane; πολυβόλον, *machine-gun*; περίστροφον, *revolver*, etc.

The foreign words still surviving in "popular" language mirror the vicissitudes of post-classical Greece; they are naturally far more common in the literature of mediaeval Greece than they are to-day. The principal languages from which such words are drawn are Latin, Italian and Romance languages (reminiscent of the settlements of the crusading Latins in Greece), Slav, Walachian, Albanian, and above all Turkish (in which may be included some earlier Arabic survivals). Examples:

Latin.—ἀκκουμβῶ, *lean*; ἄρματα, *arms*; βάρκα, boat; βέργα, rod; βοῦλλα, seal; κάμπος, *field*; κουρσεύω, be pirate; παλάτιον, *palace*; πλουμίζω, adorn; σπίτι, house; στράτα, street; ταβέρνα, tavern.

Italian and **Romance.**—ἁρμάδα, *fleet*; βελοῦδο, velvet; γάτα, cat; κάλτσα, stocking; καπέλλο, hat; καπετάνιος, captain; κουμπάρος, best-man; λεβάντες, E. *Wind*; λίστα, list; μοῦτσος, *cabin-boy*; ντάμα, lady; πέννα, pen; πονέντες, W. *Wind*; πόρτον, *harbour*; ῥιμάρω, rhyme; σαλόνι, *saloon*; τιμόνι, tiller; φορτοῦνα, storm. It is sometimes difficult to distinguish between borrowings from Latin and Italian and Romance languages.

Slav.—βάλτος, marsh; γοῦνα, *fur*; κουνέλι, rabbit; ῥοῦχα, clothes.

Walachian.—βλάχος, rustic; κατσίβελος, *gypsy*.

Albanian.—κοπέλα, girl; λουλούδι, *flower*.

Turkish and Arabic.—ἀμπᾶς, *serge*; γάιδαρος, ass; δραγουμάνος, *interpreter*; ζαγάρι, hunting-dog; (Ar.); καδῆς, judge; καζάνι, cauldron; καΐκι, *boat*; καλαφατίζω, caulk (Ar.); κέφι, good *humour*; κιόσκι, kiosk; λουφές, pay; μαιμοῦ, monkey; μουσαφίρης, *guest*; μπαρούτι, gunpowder; ντουλάπι, *cupboard*; ὀντᾶς, *room*; παζάρι, *bazaar*; παπούτσι, shoe; παράδες, *money*; ῥακί, spirits; ῥαχάτι, ease; σαράγι, palace; σαράφης, *money-changer* (Ar.); σεφέρι, war; τζάμι, glass; τζαμί, *mosque*; τεμπέλης, lazy; τουμπεκί, tobacco; φλιτζάνι, *cup*; χαμπάρι, *news*; χάνι, inn; χαράτσι, tribute; χαρτζιλίκι, *pocket-money*; χατίρι, *favour*.

Select Bibliography.—*Dictionaries:* A. N. Jannaris, *A concise dictionary of the English and Modern Greek Languages* (1895); A. Kyriakides, *Modern Greek-English dictionary* (2nd ed., 1909); A. T. Hepites, *Dictionnaire grec-français* (1908–10); *français-grec* (1911–12); E. Brighenti, *Dizionario Greco Moderno-Italiano and Italiano-Greco Moderno* (1912). Mention should also be made of the Λεξικογραφικὸν Ἀρχεῖον τῆς Μέσης καὶ Νέας Ἑλληνικῆς, now in course of

publication at Athens in connection with the forthcoming *Great Dictionary of the Greek Language.*

GREEK LAW. The basis for the development of Greek law was laid by the rise in Greece of city-states (*poleis*). Primitively all Greeks were tribal; or, to use their own term, ethnic. But between 1200 and 800 B.C. among those of them who had entered the area of the Aegean civilization tribes were replaced by city-states. Of Greek tribal law little need be said. Its source was twofold. For the most part it issued from kindred-groups—families and brotherhoods (*phratries*)—by which also in this event it was enforced. But it likewise sprang from the tribal government—kings, elders and assemblies; and tribal, and even intertribal, pressure operated to produce or maintain a general sameness in the rules and regulations of the lesser groups. Tribal law, and the law of the early city-states as well, consisted of customary rules preserved by popular memory. So long as they were thus intangible they could be changed only unconsciously by the slow processes of social growth. Thus, they seemed unchangeable. Nor did the gods withhold their hands after they had laid down the fundamental ordinances. From Zeus there came to every king, so Homer tells us, the dooms *(themistes)* according to which he settled disputes (*Il.* ix. 99).

Tribal justice had as its mainspring self-help. Its course may be illustrated in cases of homicide. Fear of vengeance at the hands of the kindred of the slain man drove his slayer, whether guilty or innocent, to seek exile, sanctuary or the protection of his blood-brothers. But to avoid the feuds, to which acts of violence and reprisals gave rise, recourse was had to commutation, and if this proved inefficacious, to arbitration. The oldest Greek trial of which we have record was one arising out of a dispute between a slayer and avenger as to the receipt or non-receipt of blood-money. The hearing was held publicly, in the place of assembly, and was attended by partisans of both contestants, who were restrained by public officers (heralds). The "daysman" (ἵστωρ) was supported by the elders. They sat on "polished stones in the sacred circle," and in their midst lay two pieces of gold to be awarded either to the disputant who made good his contention or to the elder who declared most righteously the rule of law (δίκη) governing the case (*Il.* xviii. 497–508).

The scope of self-help was wider than the scope of kinsmen-help. The adulterer, no less than the homicide, could be dealt with directly by the party aggrieved; but since unmitigated self-help was socially suicidal, even if he were caught *in flagrante delicto* he might be ransomed if a bondsman went surety for him (Od. viii. 344–599). Where death or violence were not its normal accompaniments the practice of affirming rights solely by self-help lasted longer. Until a late date a creditor might seize the person of his debtor for nonfulfillment of contract. Long after the rights of talio and "distress" had been subordinated to state law they continued to he legitimate remedies of international law.

The *Iliad* and *Odyssey* of Homer are the sole contemporary source for early Greek law. They reflect its condition in the period of transition from the tribe to the city-state. Between Homer and the 7th century revolutionary changes in constitutional law occurred. They affected comparatively little the rules applicable within the family sphere; but the autonomy of the kinsmen-groups in pursuing private vengeance was radically affected by the coming to prevalence of an attitude toward homicide that lifted murder out of the category of ordinary acts of violence; the slayer was thought to pollute the entire community. So the state could no longer remain neutral.

The defects of unwritten laws were not so much their vagueness as their failure to cover new situations. They might coerce facts and outlaw novelties, like those of the ancient Spartans and the modern Albanians. But where new situations developed in spite of them, a frontier region of uncertainty arose in which the magistrates were unguided and unrestrained. Such was the characteristic aspect of justice in the "iron age" in which Hesiod wrote (700 B.C.). An obvious remedy was to separate the determining of law from the passing on facts and to leave one function only to magistrates. The function Rome left them was the one Athens took from them. In *c.* 683 B.C. it created a body of six "determiners of customs" *(thesmothetai:* cf. the Persian *databara*), to whom, it may be assumed, the chief magistrates (archon, *q.v.* polemarch, king) were bound to refer for an authoritative definition of the "law" that bore on disputes brought before them.

In the 7th century the Greek city-states began putting their laws into writing. The method used was to entrust the task of determining all the laws and issuing them in the form of a code to a single individual described as a "law-determiner" (*nomothetes).* The early codes have all perished except for a few isolated passages; so that our direct knowledge of them is slight. But we may say that laws were, on the one hand, instructions issued for the guidance of boards and officials in the performance of their public duties, and, on the other hand, rules of general application containing prohibitions with their attendant penalties, and specifications as to what should be done in certain contemplated acts or situations. Since the rules were linked up for enforcement with definite organs of government, the entire code was arranged under the heads of the competent public authorities.

Greek law-codes were accordingly a blend of public law, including the forms to be observed by priests in public worship, and private law. A pre-condition for their publication was the spread of literacy. Since they were demanded because of the inadequacy of traditions, they naturally appeared first in the colonies and in progressive states. The earliest *nomothetes* is said to have been Zaleucus of Locri in Magna Graecia. Charondas of Catana was perhaps a younger contemporary. Other famous law-givers were Dracon of Athens (*c.* 621 B.C.), Pittacus of Mitylene and Philolaus of Corinth. The historical reality of Lycurgus of Sparta, Theseus of Attica, and even Minos of Cnossus has been sustained by some recent writers, and the divinity of Zaleucus, Charondas, and even Draco has been affirmed by others; unwisely in both instances.

Since each city-state had its own law it is apparent that strictly there was no such thing as Greek law, but only hundreds of local codes. And indeed in the sense in which England developed a common law and France "received" another, there was no possibility for a common law to arise in Greece, unless it be in the area of the short-lived Athenian empire (477–405 B.C.). The common law which Greece possessed was simply the law that was common to all its numerous codes. This need not have been inconsiderable. The law given by Zaleucus to Locri was adopted by Sybaris; that given by Charondas to Catana was shared by the other Chalcidian cities in Sicily and Italy, and what is even more remarkable, it was not only drawn on by Thurii, but also used in Mazaca in Cappadocia. None the less cases of migratory codes were exceptional. The unity of Greek law, such as it was, depended rather upon the possession by all Greeks of a common stock of legal principles. This was partly an inheritance from a distant past. The rules governing marriage, right of succession (*anchisteia*), the disposition of heiresses, adoption-family life in general—were everywhere similar because they were derived from ancient Hellenic ideas. But it was also the outcome of reciprocal borrowing. Commerce in Greece was at all times international in part and largely in the hands of metics. The ideas of commercial right and wrong were established in the international ports and on the high seas by a kind of mental and moral barter. They were brought to greater precision by the negotiation of commercial treaties (σύμβολα); and finally they became so consolidated that Demosthenes jxxxv. 45) could affirm that the laws governing commercial cases "were everywhere identical."

Between the 7th and 4th centuries codes tended to converge. The movement of law had to conform to the general movement in Greece, which was towards greater and greater uniformity. But there was an inevitable relation between laws and the character of states; and since for a long time noble or class-states, which had existed generally at the time laws were first codified, persisted in certain parts of Greece, the convergence was at first on two types of law rather than on one—an aristocratic type and a democratic type. The former is well illustrated in the laws of Gortyn in Crete.

As these have reached us, they consist of earlier and later portions, the latter a supplement made at c. 450 B.C. In this collection, especially in its earlier portions, the rules of a class-state predominated. A magistrate, unassisted by jurors, judged cases, and there was a special judge for the privileged class. The right to make a will was not recognized Women inherited as well as men. The penalties for offences varied with personal status. For private seizure of an alleged wrong-doer in advance of trial a fine of 10 staters was imposed if he was a freeman, one of j if he was a slave. Rape of a free man or woman was penalized by roo staters, rape of an apetairos by 10, and of a serf by 5; but if the violator was a slave the penalty was doubled. The number of witnesses required to prove an allegation varied similarly; five, for example, to convict a free man. three to convict an apetairos, one to convict a serf. In the event of conflict the law defined which witnesses "were nearer," that is, should prevail.

The other type of code emphasized by contrast what the Greeks called *isonomia.* This meant. in terms of public law, the admission of all free-born native adult males to equal share in the assemblies in which sovereign action was taken, and, in terms of private law, the cancelling of all class distinctions. Athens is the classic example of this type; and the influence, power and policy of Athens helped greatly to spread throughout Greece the principles of law for which it itself stood. Historically there was a connection between political and legal equality, and in Athens both were realized finally on a basis of self-government in 507 B.c., after the expulsion of the Peisistratids. But they were not inseparable. In Boeotia, for example, a way was found to reserve participation on equal terms in the sovereign assemblies to citizens of the middle and upper classes without giving them any rights under private law which all free-born native adults did not also have. Those owning a certain amount of property simply became "councillors"; and councillors alone were organized for the transaction of public business. For a brief time after the fall of the Four Hundred in 411 B.C. Athens itself adopted this form of *isonomia.* There the experiment failed politically and was not repeated.

Growth **of** Law in Athens.—In the centre of Greek law, as we know it, stands the law of Athens. It was first codified by Dracon. The thought then, uppermost in the minds of the Athenians was to fix once for all existing customs. Stability, presumed for the law while it was unwritten, was naturally presumed for the written law also. But, owing, as it seemed, to the rapacity of the rich and the extravagant hopes of the poor, the situation became so acute within a generation that Solon, archon for the year 594 B.C., on being given the full power of the state to reconcile the warring factions, took the extreme step of issuing a new code of laws. The only part of Dracon's code which he retained unchanged was the law of homicide. The constitutional provisions, including those regulating judicial procedure, were profoundly altered, notably by a rule, pregnant with history, authorizing appeal from judicial decisions of magistrates to a popular assembly organized as a court (heliaia). All free-born adult males native in Attica were given the public-law rights of isonomia—membership on equal terms in Assembly and heliaia. For classes based on birth Solon substituted classes based on property. These new classes were recognized in the distribution of public offices and services. Were they also recognized in the assessment of legal penalties? There is no conclusive evidence on the point. The spirit of the Solonian constitution was hostile to their maintenance. It struck at the roots of privilege by including wrongs done to citizens individually in the category of wrongs done to the state. In all cases (excepting homicide), which involved more than business settlements, Solon established the right of any citizen whatsoever to appear as public prosecutor.

Solon regarded law-making as an abnormal function of government and he bound the Athenians by oath not to resort to it again for 100 years. This attitude toward it persisted under the Peisistratids, who preserved Solon's laws while administering them to serve their own ends. Cleisthenes, too, was an extra-constitutional law-maker. But at some point, not precisely determinable, between the time of Cleisthenes and the downfall of the Four Hundred in 411 B.C., the method of legislating through suspension of the constitution in favour of an autocratic nomothetes was abandoned for the more democratic method of vesting the law-giving power in a board of nomothetai; and it was according to the more modern method that the *régime* of the Five Thousand was inaugurated in August 411 B.C. and the democratic laws re-enacted on the overthrow of the Thirty and the Ten in 403 B.C. On the latter occasion it proved necessary both to make a general revision of the laws and to issue a new code. The legislative work was entrusted to a corps of 1,000 representatives taken from the demes, half by lot and half by popular vote (the *nomothetai*). This body issued the laws, old and new, in the form of drafts (συγγραφαί) and put them in the hands of a commission of "publishers" (*anagrapheis*) for editing. This body had them cut on stone slabs in the King's Porch, where also the old code had been inscribed.

Thus far legislation was an occasional and not a regular function of government. But this view of it was now abandoned. Athens had henceforth a process by which the laws might be changed annually. It was initiated at the first meeting each year of the Assembly. Votes were then taken on the laws, section by section, to determine whether or not they seemed adequate; first on the laws concerning the Councils; secondly, on those classified as general (κοινοί); thirdly, on those relating to the nine archons, and finally on those relating to the other magistrates. For the defence of laws judged inadequate five attorneys were elected; and during the succeeding three weeks anyone who chose might bring forward substitutes for laws under indictment and have them posted on the state bulletin boards. Then, at its third meeting the Assembly ordered nomothetai to be chosen. The nomothetai—on one occasion 1,001 in number (Dem. xxiv. 27)—were selected from the jurors (dicasts) empanelled for the year. In this particular they resembled a court. Their proceedings, too, were in the form of a trial with pleas by the proponents of changes and counter-pleas by the attorneys for the defendant laws. But since their presiding officers consisted of the identical type of presidency used in the Assembly, they also resembled the sovereign political body. Their decisions, too, were reached as in an Assembly and not in a court—by open vote. Unlike a decree a law could be enacted only after due notice had been given and the public interests had been defended by counsel. It emanated from a body carefully selected to ensure the representation of every section of the population, not, like a decree, from the group of citizens who chanced to be present at a particular meeting of the Assembly. The nomothetai were dicasts; but they rendered a political not a judicial verdict. Hence unlike the action of a court, it was subject to suspension. like the action of the Assembly, if indicted for illegality, and became definitely binding only when reaffirmed by a regular tribunal.

The code was a thing of many complex interrelations. An alteration at one point might produce unsuspected trouble at others. The officials who had most to do with law-enforcement were the *thesmothetai.* It was therefore made incumbent upon them to examine the code carefully in the course of their administration, and, if they found in it obsolete articles not so designated, or articles which contradicted or duplicated one another, to put on the bulletin boards the editorial revisions they deemed necessary. For the validation of these clerical corrections an ordinary meeting of the Assembly was competent, but it was held constructively to have been a session of *nomothetai.* A much less innocuous participation of the Assembly in legislation is demonstrated by documents for the period following c. 360 B.C. Impeded in action it wished to take by lack of legal authority, the Assembly passed votes requiring the chairmen and president who should preside at the first session of *nomothetai* to present for consideration the additions to the laws it desired. This may have led to an over-weakening of constitutional law (Dem. xx. 89 sqq.); but so long as this was fused with private law there was no alternative. The magistrates' courts, being incompetent to render judicial decisions except in trifles, were incapable of developing a *ius honorarium.* Neither could law in Athens be court-made, since every verdict of the dicasts was independent of every other verdict.

Until the age of Pericles, the Athenians entrusted the function of acting as "guardian of the laws" to the Areopagus. Then they did away with it as being derogatory to popular sovereignty. Yet the laws had to be safeguarded, not perhaps against the demos itself—for like the king the dentos could do no wrong—but against individuals in Council and Assembly who should mislead it. The remedy applied was to hold all makers of motions at meetings of these bodies liable to public actions for illegality (γραφαὶ παρανόμων), thus placing the protection of the laws in the large category of public interests for the vindication of which each and every citizen in good standing might assume the rôle of state prosecutor. The test of illegality was that the motion should seek to accomplish something prohibited by the laws. There was, however, nothing illegal in persuading the Assembly to use decrees (*psephismata*) to fill gaps in the laws; and in the 5th century, when legislation was still a quasi-revolutionary activity, this course was frequently followed. It was by means of decrees primarily that law was built up for the empire. The constitution of the council itself was extended by decree. New magistracies were created in this way. Decrees were therefore often indistinguishable from laws in subject matter, and since the courts were required to take account of them both, they might have precisely the same force as laws. Yet there was a fundamental difference between the two. A decree could be abrogated by a new decree without ceremony, whereas a law stood until annulled by further legislation. The revisions of 411–10 and 403 B.C. must have conferred the superior status of laws on many rules which theretofore had rested on decrees alone; and thenceforth the Athenians lessened the need for decrees to trespass on the province of laws by providing for annual legislation. Naturally they made the proposers of new laws liable to the same form of public action as the proposers of new decrees. And indeed they went even farther than this; they made them liable to public prosecution if the laws originated by them were found within a year to be inexpedient. After the twelve months had expired, laws, like decrees, alone were indictable, not their authors.

Official transcripts of the laws were ordered to be made on stone tablets in 410–04 B.C.; and to this measure we owe the preservation, though in a very fragmentary condition, of Dracon's law on involuntary homicide (I.G. I. 115), Cleisthenes' law on the Council of the Five Hundred (I G. I. 114), and a law of uncertain date governing grants of maintenance in the *prutaneion* (I.G. I. 77). On the occasion of the revision made in 403 B.C. a new text was issued in the Ionic alphabet then officially adopted. The new laws passed during the following 80 years were attached to the code in the form of the minutes of the sessions of *nomo*thetai in which they originated, and like the laws of Rome they were regularly cited by the names of their proposers. A small number of these novellae has come into our possession textually, three in inscriptions (I.G. II. 140, 333, 244). Most of the laws that have reached us, whether in whole or in part or in paraphrase, were entered by ancient grammarians at points where they seemed to be called for in the speeches of the Attic orators. These and others, culled from lexicographers and scholiasts and elsewhere, are collected in Telfy's Corpus *Juris Attici* (Pest and Leipzig, 1868). The descriptive portion of Aristotle's *Constitution* of Athens (§§42–70), composed between 329 and 322 B.C. was based directly on the code of that epoch. Though it is confined to an exposition of public law and has reached us without its final portions, it is by far the most extensive abstract of the Athenian laws that we possess.

So far as we can judge from the specimens preserved, the laws of Athens were drafted in simple language. Some ancient phrases survived in their older portions. In style they resembled the laws of the Twelve Tables rather than the matured legislation of republican Rome. No attempt was made in them completely, to define parties or objects concerned by the use of synonymous terms and to adhere rigorously thereafter to the definitions once made—a defect that opened the way to subterfuge in litigation (Lysias, x. 1;), but was less troublesome in the equitable processes of the dicastic courts than it would have been in courts guided by strict law. The laws dealt with concrete situations that had arisen in actual experience. Hence they were adequate through being numerous and detailed rather than through embodying principles that were capable of wide application. The distinctions between the hundred and more actions open to suitors were drawn with acuteness, if not with over-subtlety. The rules of procedure were "at times casual and incomplete (set practice being taken for granted), at times minutely specific." Penalties for "criminal" offences were remarkable for their severity—a reflex doubtless of the passion and intensity of their political life; they included death (with circumstances of atrocious cruelty in the case of common malefactors) ; fines that were often confiscatory; total or partial disfranchisement; and detention, but not imprisonment. The code was thought not to measure up to the standards of contemporary jurisprudence; but when it was refashioned by Demetrius of Phalerum to give effect to the Peripatetic theory of society (317 B.C.), the Athenians would have none of it. On the expulsion of the unpopular *nomothetes*—his office was an anachronism, no less than many of his laws—they revived the "laws of Solon," revised them to suit the altered circumstances and republished them (307–304 B.C.).

The task of abstracting the law of Athens (or of Greece) from the instructions of magistrates, and setting it out under appropriate headings for comparison with Roman and other systems of law, has been undertaken by modern scholars, notably lawyers. But from the nature of the materials, which also precludes any attempt to summarize the laws under their original headings. we must content ourselves here with citing the works by Beauchet, Partsch, Mitteis, Vinogradoff and Weiss mentioned in the bibliography.

Judicial System **of** Athens in **the 4th** Century.—Except for (1) a special group of public actions, itself divisible into subgroups, suits fell into two general categories: (2) dikai, or private suits, and (3) *graphai,* or public suits.

1. The special actions may be thought of as a residuum of the means in use before Solon for dealing with crimes against the state. The small fines (ἐπιβολαί) imposable by administrative officials upon citizens who disputed their authority represented another such residuum. Their common characteristic is that the council and assembly or the magistrates were competent to punish, if they chose, without observing the regular forms of judicial procedure. The most striking example of executive justice is apagoge (with its variants endeixis and *hyphegesis*), the arrest and detention of malefactors (κακοῦργοι, *e.g.,* thieves) caught in the act or of persons (exiles, state debtors and the like) caught exercising rights of which they had been legally deprived. If the prisoners admitted their guilt the "eleven" were authorized to inflict summarily the penalties prescribed, ordinarily death; otherwise, they, or exceptionally the thesmothetai, had to conduct the case as a public action.

By far the most important of these special forms was impeachment (εἰσαγγελία). Typically it may be described as the process designed to cover acts that may be loosely defined as treason. The offences were at first left indeterminate, but eventually a law *was elaborated including among them, specifically, treason and conspiracy to commit treason; betrayal of a city, ship, army or fleet; unauthorized traffic with an enemy, residence in his country or service in his army; the acceptance by a public man of bribes as a consideration for misleading the demos. From actions of this type many causes célèbres arose, notably the trial of the eight generals who commanded in the battle of Arginusae. The denunciation might be presented to either the council or the assembly and accepted or rejected by them. If accepted, the defendant was arrested and if the matter was grave he was kept in prison pending trial,. The council drew up the definite proposal for action, in the one instance on its own initiative, in the other at the request of the assembly. If the penalty deemed sufficient was a fine of 500 drachmae or less, the council was fully competent to impose it. Otherwise it transmitted its proposal, through the agency of the thesmothetai, to the Assembly, which had thereupon to decide either to try the case itself, which it did by the process used in enacting a decree, or, as was more usual, to hand it over to a dicastery. The penalty was ordinarily death with confiscation of property. The dead bodies of traitors were cast beyond the boundaries of Attica. "Presentment" (προβολή) was somewhat similar to impeachment. Actions regarding contraband (φάσις) and wrongful possession of public property (ἀπογραφή) were also special in that those who prosecuted them paid court fees, as in civil suits, but received half or three-fourths of the penalty. This was the prime source of sycophancy (the trade of informing).*

2. **Dikai**—The *characteristic feature of dikai was that the right to bring them rested upon the possession by the plaintiff of a private interest. But they fall into two altogether different classes: (a) actions for homicide, and (b) civil suits.*

(a.) Because of its antiquity the law of homicide contained a relic of the primitive practice of self-help. It placed the obligation of seeking redress for homicide upon the kinsmen of the slain man — upon his father, brothers and sons as prosecutors, and upon his cousins, sons of cousins, male relatives by marriage and blood-brothers (phratores) as co-prosecutors. A man belonging to the inner group alone had the right to bring action; or, more probably, his was the prior right, since in cases where it was permissible to arrange a settlement (αἴδεσις), even the blood-brothers were competent to act if none of the nearer relatives existed. Dracon had recognized the essential difference that exists between wilful murder and other kinds of homicide; but it was a distinction that did not permit any discrimination in the religious ritual of the occasion; the king-archon presided and voted at all trials, the courts sat in holy places in the open air, and pending trial the accused was excluded from the agora and all shrines and religious ceremonies, but not imprisoned. When the offence charged was wilful murder, or wounding or poisoning or arson with intent to kill, and the victim was an Athenian, the Areopagus as a whole formed the court, it sat on Ares' Hill, and the penalty, when life was taken, was death; otherwise exile. Other kinds of homicide were regarded as of lesser seriousness, and a board of judges called Ephetai—originally a commission, perhaps, of 51 Areopagites, later a panel of dicasts — constituted the tribunal. The place in which the trial was held varied with the nature of the defence. To the Palladium belonged cases of involuntary homicide and instigation thereto, the penalty being temporary exile; also suits for killing non-citizens—slaves, metics, and foreigners. To the Delphinium belonged cases of justifiable killing, and to the Phreatto, accusations against citizens already in exile. The defendant pleaded from a boat anchored off the shore so as not to pollute the country by setting foot on it. In the Prytaneum the king-archon had the phulobasileis, instead of the Areopagus or the Ephetai, associated with him as judges, and to it belonged trials which were purely ceremonial in character — where the "doer" was unknown or an animal or, as in the obsolete English law of "deodands," something inanimate. The objects found guilty were cast beyond the frontiers.

(b.) Civil suits could be brought only by the parties interested or their legal representatives. Their entry was governed by the general principle of Athenian law that magistrates should accept cases arising in the sphere of their own administration; but the principle was inapplicable to magistrates whose duties were mainly or wholly judicial. Of these the thesmothetai were comparatively unimportant in civil suits. The other t o — the Introducers and the Forty — received civil suits only. The competence of the Introducers was limited to suits which by reason of their special urgency had to be brought to trial within a month of the filing of the cornplaint (δικαὶ ἔμμηνοι); but not all such suits came to them. Those that they received were actions arising from non-restitution of dowry, from loans that were in the nature of an accommodation — where the rate of interest was low (12% or less) or the security poor — from transactions with business associates, partners, or bankers, and from trierarchies. Also actions for assault. For each pair of phulae there was one Introducer.

Of the Forty, four acted for each phule. If the object of litigation was worth 10 drachmae or less they settled it with full authority. Otherwise they referred it to a public arbitrator (διαιτητής), whose business was first of all to reconcile the parties. Failing in this he heard the case. If his decision was accepted by both parties it was final. But if the loser chose to appeal from it, the arbitrator sealed up in caskets all the papers submitted at the hearing, those of each litigant separately, and referred the case back to the section of the Forty uhence it came. This had then to take it to a public court, where the usual course was followed.

It was characteristic of civil-suits that the winner had himself to obtain the rights awarded; but if he encountered resistance he could bring a suit of ejectment. The feature of this class of actions that calls for special notice was the provision for compulsory arbitration. It applied to all civil suits that came before the Forty either directly, or indirectly from other magistrates. Excepting the monthly suits, which would not brook delay, most disputes about property, sales, leases, contracts, debts, etc., implicating either citizens (office-holders and non-office-holders alike) or metics and other privileged aliens had to be submitred to arbitration. The task of arbitrating was reserved exclusively to the last class of citizens on the roll of those liable for military service; in other words, the Athenians in their 60th year. The appointment of the arbitrator for each case was made by lot and the arbitrator on whom the lot fell could not decline to serve, unless he were holding office or absent from the country, without incurring the penalty of disfranchisement, to which he was also liable, on complaint to the whole body of arbitrators, if he abused his position. The state had more confidence in the average capacity of its sexagenarians than it had in their public spirit and integrity. But what of the litigants? That they would respect the findings of an obviously incompetent arbitrator, however unbiassed he might be, was not to be expected. The essence of the system was "that in a large number of disputes the constitution did not compel two quiet citizens to face the ordeal of a trial in court, but provided a cheap and simple and reasonable means of getting justice" (Wyse).

3. **Graphai.**—The *judicial vindication of a public interest was the object of these suits. They could be entered by any citizen in good standing. He might be himself the aggrieved party, but in that event, even if the award was pecuniary, it fell to the state, which in all cases exacted the penalty. As in private suits, so in public, the magistrates were confined to a passive rôle: before taking action they had to wait till private individuals filed complaints with them. The principle that executive competence determined judicial competence also prevailed.*

Accordingly the generals and the other army officers were alone competent to receive suits for infractions of military duty. To the archon and the polemarch came suits (private or public as the case demanded) concerning matters of family — the rights of widows, orphans, minors and heiresses, the management and division of family prooerty, the appointment of guardians or patrons, etc.—to the a-chon, if they involved citizens; to the polemarch, if they involved metics and other privileged aliens. The king-archon received suits concerning religious marters — impiety, hereditary priesthoods, the share of genê and priests in sacrificial offerings and the like. Since over 100 species of suits are known, divided about equally between dikai and graphai, it is impossible here to give a complete classification of suits and magistrates. But the rôle of the *thesmothetai* calls for special comment. The six men constituting this board had duties to perform in connection both with making and administering the law which make it almost unintelligible that they should have been elected by lot (after 487 B.C.) and changed every year. They acted as intermediaries of the Council and the Assembly in cases which went to the courts from either of these bodies; and they were alone competent to receive indictments of decrees and laws and their authors, as well as of officials who presided at sessions of the deliberative and legislative assemblies They also received actions against the generals. Besides offences against the state many offences against society were within their competence—theft, adultery, bribery and corruption of officials, councillors, and dicasts; usurpation of rights of citizenship, sycophancy, falsification or suppression of records, etc. Their civil suits were incidental.

The correct entry of suits required no small acquaintance with law on the part of average citizens, but so did the entire judicial system. The magistrates who accepted .entries, with unimportant exceptions, were always new to their office and possessed neither more nor less legal training than litigants. All litigants had to be their own attorneys. The state depended wholly upon private initiative to set the judicial processes in motion. What was everybody's business proved to be the business of a low rather than a high type of citizen; so that the community was harassed by blackmailing and sycophants. Suits were as thick in Athens as leaves in Vallombrosa. Instead of employing fisticuffs or duelling or lawyers the Athenians went to law It has been said that they were a nation of lawyers; but it has been also said that they were a nation without lawyers. And both statements are true.

The duty of assessing the evidence dnd rendering the verdict devolved upon tribunals on which sat jurors (Areopagites, *ephetai*, dicasts) ranging in number from 201 to 2,500 and exceptionally to 6,000. The Areopagus was a fixed body of about 220 members made up of ex-archons; and cases of wilful murder came to it automatically. Seeing that the archons were elected by lot with regard to local distribution, the Areopagites were simply typical Athenians; but they entered the tribunal fresh from an exceptional experience with the whole judicial system, and as the years passed they acquired a close knowledge of the law and physiognomy of murder. Hence their judgments enjoyed in marked degree general respect.

The king-archon was the only magistrate for whom the tribunal was fixed in advance The rest had to apply to the *thesmothetai*, who assigned panels of dicasts to them by lot, 201 or 401 for ordinary civil cases, 501 or 1,001 for ordinary public cases The *thesmothetai* determined on which one of the days fixed by them for sessions each magistrate should have his case tried and in which court-house the trial should be held. The selection of the panel of dicasts for each court-house was made on the day of the trial by a most intricate process of lot (Aristotle, *Constitution of Athens, $63 sqq.)*. Its objects were fivefold; to ensure (1) that each individual in each of the ten sections into which the *heliaia* was divided should have a like chance to serve; (2) that every panel, containing, as it must, a like number of dicasts from each *phule,* should reproduce in miniature the whole people for which constructively it was to act; (3) that no one whatsoever should know in advance of the entrance of the dicasts into the court-house who was to judge any particular case; (4) that no one should impersonate the dicasts selected; (5) that dicasts who failed to turn up in the court-house should not receive their daily stipend of 3 obols. There was no mistaking the intention of the Athenians: they desired every panel to speak with the voice of all Athens, uninfluenced by bribery, intimidation, or collusion. And they got their wish.

The sorting of the evidence was made at a preliminary hearing *(anakrisis)*. There the elements of the proof and disproof were assembled—the statements under oath of the parties, the depositions of witnesses, laws, decrees, contracts, and the like. The testimony of slaves was admissible only when elicited by torture; that of women and minors was admissible only in murder cases, and that of the parties to the suit was not admissible at all. Hearsay evidence was excluded. The cross-examination of witnesses was not permitted. Till 403 B.C. the pleadings were oral, but written pleadings, found necessary in cases appealed under the system of public arbitration, were adopted generally early in the 4th century. There were permissible ways of barring suits by contesting their admissibility. A civil suit might be dropped at any time. The prosecutor, however, must proceed with a public suit once it was instituted or pay a fine of 1,000 drachmae and forfeit the right to bring further actions, and he incurred the same penalty if he failed to secure one-fifth of the dicasts' votes. Court fees were collected in civil suits. Public suits more than paid for themselves by fines and confiscations. There were careful rules to govern default.

The presidency of the tribunal belonged either to the *thesmothetai* or ordinarily, to the magistrate who was connected with the suit in its earlier stages. The president had to see that the trial followed the course laid down by law, and, since his legal training was no greater than that of the litigants and dicasts, he had no claim or right to intervene further. Precedents having no legal standing, no one was needed to assess their bearing. The dicasts were in fact under oath to disregard them and to make decisions solely on the evidence and arguments presented, giving effect to laws and decrees where these sufficed, otherwise to their own sense of right. The proceedings in court consisted essentially of arguments addressed to the dicasts by the plaintiff and the defendant personally and by friends (not paid professional advocates) who appeared to support either party with their reputation and court experience. At the proper places the statements and depositions contained in the *dossier* of the preliminary hearing were read by the clerk of the court and acknowledged under oath by the litigants and the witnesses. The law authorized actions to compel the appearance of witnesses and the production by third parties of relevant documents, which, too, were read from the *dossier* by the clerk. A time, greater in public than in private suits, was set for the entire argument. Half of it was given to each party, and the water-clock *(klepsudra),* by which it was apportioned, was stopped during the reading. An inarticulate litigant would normally leave the burden of the argument to his supporters, and the practice was general for the main speeches to be prepared by professional speech-writers *(logographoi),* whose art consisted in no small degree in concealing their handiwork. If we except the disreputable tribe of sycophants, from whom speakers took special pains to distinguish themselves, this was the only professional class produced by the administration of law in Athens. They were accomplished pleaders, versed in the intricacies and pitfalls of the law, adepts in appealing to the prejudices of the dicasts; and since some of them were active in instituting public suits, they might come very near to being lawyers.

Once the arguments were concluded the dicasts voted, without discussion, either to acquit or to condemn. The utmost care was taken to preserve secrecy and honesty in the balloting. If the vote was against the defendant, but the bare decision did not suffice to dispose of the case, an argument upon the penalty ensued, at the end of which the dicasts balloted to decide whose estimate, the winner's or the loser's, should be accepted. The court was powerless to substitute an estimate of its own. but a compromise could be reached if the litigants chose to meet each other half way in their estimates. An appeal from the verdict was possible only in cases of non-culpable default; or on the ground of perjury, and then only if notice to contest the verdict on this score were given before the dicasts voted.

We do not possess the *dossier* of a single trial. The opposing arguments have seldom reached us. The speeches of the Attic orators were published as masterpieces of eloquence. They do not form a case-book of Athenian law. What they reveal is the sort of argument to which the dicasts were thought to be responsive. In public cases appeals were made to their ignorance, prejudices and cupidity, which, if successful, must have made their verdicts travesties of justice; and we know that in times of great political excitement they succeeded all too frequently But the courts were a political as well as a judicial body They were there to give the *coup de grâce* to discredited politicians; they were the heirs of ostracism. In private cases the speeches were often such as might be addressed to modern juries; and we have little reason to impugn the verdicts. The vicious tendencies of the judicial system are obvious; the contamination of justice by politics; the weakening of responsibility through its diffusion among so many jurors; the rendering of unlike decisions in like cases. But the correctives were also present; the unexampled familiarity of common man with law and legal practice; and their unique experience in taking collective action in large bodies. History contains no other instance of justice so thoroughly organized to accord with the principles of radical democracy. The Athenians were so situated that they did not feel the need either of delegating their government to picked representatives or of entrusting their justice to experts specialized in lam. The Romans enshrined their justice in their great system and profession of the law, and. thus safeguarded in their private rights, left their government to autocrats.

GREEK LITERATURE has a continuous history extending from the 1st millennium B C. to the present day. From the beginning its writers were Greeks living not only in Greece proper but also in Asia Minor, the Aegean islands and Magna Graecia (Sicily and southern Italy); later, after the conquests of Alexander the Great. as Greek became the common language of the eastern Mediterranean lands and then of the Byzantine empire, Greek literature was produced over a much wider area and also by those whose mother tongue was not Greek. Even before the Turkish conquest (1453) the area had begun to shrink again, and now it is chiefly confined to the territory of the kingdom of Greece.

The main divisions of this article are as follows:

I. ANCIENT (TO THE 4TH CENTURY A.D.)

Of the literature of ancient Greece only a relatively small proportion survives. Yet it remains important, not only because much of it is of supreme quality but also because until the mid-19th century the greater part of the literature of the western world was produced by men who were familiar with the Greek tradition, either directly or through the medium of Latin. who were conscious that the forms they used were mostly of Greek invention and who took for granted in their readers some familiarity with classical literature.

A. CLASSICAL POETRY

Tno things are likely to appear strange to anyone unfamiliar with Greek literature. First, Greek poetry was intended to be sung or recited publicly, not to be read in private; the audience might be a large part of the population of a city. as for a play or a small private party, but poetry before the Hellenistic period (beginning c. 300 B.C.) was part of social activity. Secondly. the subject of Greek poetry was myth, that is to say the great mass of traditional material which was one of the peculiar riches of the Greek spirit; this was part legend, sometimes based on the dim memory of historical events like the fall of Troy or Thebes. part folk tale, part primitive religious speculation (*see* GREEK RELIGION). The myths of the Greeks, unlike those of most peoples, nere not closely associated for the most part with religious ritual. Accordingly, although they told of gods and of half-divine, heroic men. and often suggest the forms under which the gods were visualized. they had no particular authority and could be varied and developed as the poet wished. Indeed in the early stages Greek thought advanced largely by the half-conscious refashioning of the myths to give expression to new conceptions. The poet enjoyed the immense advantage of using material familiar to his audience, who would be sensitive to every new emphasis or fresh interpretation of the ideal of heroic life which the myth contained.

1. The Epic Tradition.— At the beginning of Greek literature stand the two great epics, the *Iliad* and the *Odyssey (see* HOMER). in their existing form not earlier than the 8th century but with roots reaching far into the Mycenaean age *(see* AEGEAN CIVILIZATION). perhaps to 1500 B C. The *Iliad* is the tragic story of the wrath of Achilles, the splendid hero, son of a goddess and richly endowed with all the qualities that make men admirable who destroys himself by his own love of honour. Being slighted by Agamemnon, the Greek leader, he refuses to take any further part in the nar against Troy; when the Greeks are hard pressed and Agamemnon offers amends. he persists in his refusal; the plight of the Greeks worsens and Achilles is so far moved by pity that he sends his friend Patroclus in his own armour to their aid; Patroclus saves the Greeks but is killed himself; Achilles in a frenzy of grief returns to the war and kills Hector. the slayer of Patroclus. and outrages his dead body. Finally he brings himself to restore the body to Priam, Hector's father, and the poem ends in reconciliation. Achilles' end is outside the poem, but right from the beginning the brilliant hero is shadowed by the knowledge of earlv death With his readiness to sacrifice all to honour. Achilles embodies the Greek heroic ideal, and the contrast between his superb qualities and his short and troubled life reflects the sense of tragedy which was alnays a part of the sad wisdom of the Greeks, though in Homer. more than in later literature, the vitality is such that it is easy to forget the strain of melancholy. Whereas the *Iliad*, though earlier than the invention of drama, is tragedy as the Greeks themselves allowed, the *Odyssey* is tragicomedy. It is an enriched version of the old folk tale of the wanderer's return and of his triumph over those who were usurping his rights and persecuting his wife at home. Odysseus too represents a Greek ideal. Though by no means inadequate in battle, he works mainly by craft and guile; only so can he defeat the superior strength of the Cyclops and the superior numbers of the suitors who have taken possession of his palace. During his ten-year journey home from Troy he loses first his fleet, then his own ship and crew, and back in Ithaca he moves disguised as a beggar in his own palace. Through all these hazards it is by mental superiority that he survives and prevails.

Both poems are based on plots which grip the reader, and the story is told in language which 'is simple and direct, yet full of natural eloquence and nobility. In the course of previous generations the epic storytellers had fashioned a linguistic instrument of extraordinary beauty and flexibility, even though, since it resembled no language ever spoken by Greeks, it was highly artificial. The *Iliad* and the *Odyssey,* though the oldest European poetry, are by no means primitive. They mark the fulfillment rather than the beginning of the literary form to which they belong. Whether or not the poems in their present form were composed with the aid of writing, they are in essence and in origin oral poetry. Nameless poets over a period of centuries had recited, or rather performed. the traditional stories, developing and modifying them in the process. Comparison with oral poetry as it has survived elsenhere suggests that the poet did not learn by heart a traditional work but was free to re-create his poems within a given framework with fresh detail. The conventional epic style was sufficiently rich in phrase and formula for it to be possible for a professional bard to perform the difficult feat of improvisation in a strict metre for comparatively long periods. If this is how the Homeric poems developed, it need cause no surprise thal the world they reflect is full of so-called inconsistencies; weapons belong to both the Bronze and Iron Ages; objects like those found in Mycenaean excavations jostle others from the Geometric period five centuries later; the fabulous wealth of Egyptian Thebes in the 15th century B.C. is referred to along with the activities of Phoenician traders in the 9th. But certain mysteries remain. What was the date of the great poet or poets nho gave structure and shape to the two epics which survive? What was the social function of poems which take several days to recite? By what process and at what stage did these poems come to be recorded in writing? These are among the Homeric questions of today.

In the ancient world the *Iliad* and *Odyssey* stood in a class apart among epic poems. Of these there were a large number known later as the epic cycle, sometimes referred to as the work of Homer, sometimes associated with various shadowy figures of whom the latest in time was Eugammon of Cyrene (*c.* 600). They covered the whole story of the wars of Thebes and Troy as well as other famous myths. A number of shorter poems in epic style, the Homeric Hymns, include three addressed to Demeter, Apollo and Xphrodite which are of considerable beauty.

Didactic poetry was not regarded by the Greeks as a form distinct from epic, since it used the same metre and the same composite dialect. Yet Hesiod belongs to an altogether different world from Homer. He liver! in Boeotia about 800 B.C. In his *Works and Days,* under pretense of advising his idle brother Perses, he describes the ways of peasant life and incidentally gives an unforgettable description of the dreary Boeotian plain afflicted by heat, cold and the oppression of a "gift-devouring" aristocracy. He believed passionately what is rarely hinted at in Homer, that Zeus cares about right and wrong and that Justice is his daughter. His other surviving poem, the *Theogony,* tells of the generations of the gods and attempts in mythical terms to supply a cosmogony and to reduce to a coherent system the mass of legends about the gods and their parentage. Near eastern influence is clearly to be seen, especially in some of the cruder speculation about the origin of the universe. Similar attempts at systemization were made by the Hesiodic school of poets, writers of "catalogues" which were often attributed to Hesiod himself. They tried to reduce to order the stories of gods and heroes and of the many aristocratic families who claimed descent from them.

By the end of the 6th century the epic tradition was a spent force until its revival in the Hellenistic period, and the few composers of epic narrative left little but their names. One of the last of them was Panyassis, the uncle of Herodotus, who wrote an epic on Heracles.

2. Lyric Poetry.—Hesiod, unlike Homer, tells us something of himself. and the same is true of the lyric poets. who were responsible for most of the poetry written in Greece between the decline of epic and the rise of drama. Except for Pindar and Bacchylides at the end of the period, only fragments of the works of these poets survive, but like Homer they show no signs of immaturity. There had always been lyric poetry in Greece, and in Homer there are occasional references to vintage songs, funeral dirges and the like. All the great events of life as well as many occupations had their proper songs, and here too the way was open to advance from the anonymous to the individual poet.

The word "lyric" is inadequate for describing the various categories of poetry which the Greeks distinguished. On the one hand, lyrics in the narrow sense, poems sung by individuals or chorus to lyre or sometimes to the flute, were called melic; elegiacs. in which the epic hexameter alternated with a shorter line, the pentameter, were traditionally associated with lamentation and a flute accompaniment, but they were used for many kinds of poem, often with a more personal tone than was appropriate to the hexameter, and were spoken as well as sung. Iambics were the verse form of the lampoon and usually of an abusive or satyrical character. Like the trochaic verse, which was used in much the same way. iambics were not normally sung. While the melic poets confined themselves for the most part to the numerous varieties of their own medium, iambics, elegiacs and trochaics were often written by the same poet, so that the main division comes between melic and nonmelic writers. (*See* PROSODY, CLASSICAL.)

If Archilochus, from the Aegean island of Paros, was really writing as early as 700 B C., he was the first of the post-epic poets, but there is some reason for dating him 50 years later. The not very numerous fragments suggest a trenchant personality to which he gave uninhibited expression. They reflect the turbulent life of an embittered adventurer and soldier of fortune, son of an aristocratic father and a slave mother. Scorn both of men and convention is the emotion which seems uppermost, and the story that he hounded to his death Lycambes, who had withdrawn his daughter from a promised marriage, is. true or not, a fair tribute to Archilochus' powers of invective. Though much of his poetry was unedifying, he was regarded throughout antiquity as a major poet.

Somewhat younger than Archilochus, Simonides or Semonides of Amorgos is represented by a long and rather laboured fragment in which women are compared to animals, and nearly a century later the iambics of Hipponax of Ephesus showed something of the savagery of Archilochus without his genius, but his vivid pictures of low life were much imitated by writers of the Hellenistic age.

Like the iambic writers, the elegiac poets came mostly from the islands and the Ionian regions of Asia Minor. Callinus of Ephesus, a little after 700, called on his countrymen to defend their city against the barbarians, but a more characteristic use of the elegiac was made by Mimnermus of the neighbouring city of Colophon, who sang in tuneful but low-spirited verse of the sweetness of love and the horrors of old age; since he exchanged verses on the latter theme with the Athenian Solon (b. *c.* 638 B.C.), he must have lived well into the 6th century. On the mainland of Greece Tyrtaeus roused the spirit of the Spartans in their desperate struggle with the Messenian rebels in the years after 650. His martial poems were among the few that Spartans were encouraged to be familiar with; today they are perhaps valued more for their historical than for their literary interest. The same is to some extent true of the poems in elegaic. iambic and trochaic metres by Solon. He was no professional poet, but at a time when books did not exist a poem was the best medium for propaganda, and he used verse to rouse the Athenians for the reconquest of Salamis *c.* 600 B C., to express his views about the source of their political troubles and, after he had carried out his great reforms, to explain and to defend them, as well as to assert his faith that in the long run the gods see that justice prevails. Xenophanes (b. *c.* 560). rather in the same may, used his poems, both elegiac and hexameter, to propagate his revolutionary religious and ethical ideas. The collection of elegiacs which has come down under the name of Theognis seems to be composed of poems of various dates suitable for use at drinking parties. Many of them are from the hand of Theognis himself (c. 580–530?). Some give uninhibited expression to his hatred of the lower-class rulers who had ousted the aristocracy of Megara; others are love poems, sometimes passionately reproachful, to the boy Cyrnus; others again are gnomic, neat statements of the commonplaces of Greek wisdom and morality (see GNOME AND GNOMIC POETRY).

About the beginning of the 6th century a new kind of poetry made its appearance in the island of Lesbos off the coast of Asia Minor. It was composed in the local Aeolic dialect by members of the turbulent and faction-ridden aristocracy. Alcaeus (b. *c.* 620) and Sappho, a few years younger, both spent part of their lives in exile. Alcaeus, absorbed in political feuds and in civil war, expresses with striking directness searing hate and blind exultation. With the same directness and infinite grace, Sappho, who seems to have enjoyed a freedom unknown to the women of mainland Greece, tells of her loves and, hardly less frequently, of her hates. Of the milieu in which she moved and of her relations with the girls who are named in her poems much has been guessed but nothing can be regarded as known. The remains of their successor in personal lyric, the Ionian Anacreon of Teos, a generation later, suggests a more convivial amorousness. His reputation has suffered from the ascription to him of a number of feeble poems of late date, the *Anacreontea* (see ANACREONTICS).

The Greeks did not themselves distinguish choral lyric as a separate category. but it was associated with the Dorian parts of the Greek mainland and the settlements in Sicily and south Italy as opposed to the poetry for solo performance of the Ionian coast and the Aegean islands, and for this reason it was composed in a dialect with a Doric flavour even when, as often, the poets were themselves of Ionian birth.

Choral lyric, quite apart from the music, of which little is known except that both lyre and flute had their appropriate uses. was highly complicated in structure. It aid not use traditional lines or stanzas, but the metre was formed afresh for each poem and never used again in exactly the same form, though the metrical units from which the stanzas, or strophes, were built up were drawn from a common stock. The strophes, either single or in systems of three, were repeated through the poem, and in many cases their form was related to the accompanying dance. This elaborate art form with its need for a trained choir and skilled musicians was connected mainly with the cult of the gods or, as in the case of Pindar, the celebration of the victors in the great Hellenic games.

The earliest poet of choral lyrics of whose work anything survives was Alcman, whose choirs performed in Sparta in the late 7th century before the Spartans put aside the graces of life. His original home may have been Lydian Sardis. In the next century Stesichorus worked in Sicily, an area to which Homeric poems may not yet have penetrated, and his lyric versions of the great myths mark an important stage in the development of these stories. Simonides of Ceos in Ionia, whose long life extended far into the 5th century, mas among the most versatile of Greek poets. He traveled far and wide in Greece, celebrating in Thessaly. in Athens and in Sicily the princely houses whose patronage he enjoyed. He was famed for his pathos, which is admirably revealed in his lines describing Danae set adrift with her child on the open sea. But today he is best known by his elegiac epitaphs, especially those on the Greeks who fell in the struggle against Persia, the epitome of the grace, restraint and sincerity to be found in the greatest Greek art.

But the supreme poet of choral lyric mas Pindar from Thebes in Boeotia, a part of the Greek world otherwise undistinguished in the annals of poetry except for Hesiod and for Pindar's contemporary, if contemporary she mas, the lyric poetess Corinna. Pindar (*c.* 520–440), though he composed many varieties of choral lyric, is known mainly by his epinician odes, poems in honour of the victors at the great games held at Olympia, Delphi, the isthmus of Corinth and Nemea. They were usually performed as part of the festivities which greeted the triumphant athlete on his return to his city. Among Pindar's patrons were many of the most aristocratic houses of Greece, but they were patrons whom Pindar, intensely conscious of his own divine gift of inspiration, treated as equals. In honouring athletes in the hour of glory, when they were exalted almost to the level of the heroes of old from whom they claimed descent, Pindar felt he was making no unworthy use of his gift. Even in Pindar's day the athletic ideal was growing obsolete and it is hard to recapture in imagination, hut the glowing magnificence of his tributes and the splendid passages of lyric narrative embedded in them still represent one of the extremes of poetic grandeur.

The last of the lyric poets was Bacchylides (b. *c.* 510), a nephew of Simonides. whose work, though often exquisite, is empty. The myth was losing its significance and becoming merely ornamental, and Bacchylides' treatment of it is a foretaste of the antiquarian prettiness of Hellenistic poetry.

3. Tragedy.— Before the 5th century Athens was celebrated rather for the visual arts than for poetry. But under the patronage of the tyrants, poets gathered at Athens and poetry had its part in the festivals with which the tyrants tried to popularize their rule. The decisive moment was when, in or about 534 B.C., tragedy became an official part of the spring festival of the Dionysia. Tragedy is generally believed to have developed from the dithyramb, the choral cult song of Dionysus (see DRAMA: Greek *Drama:* Origins). Arion of Lesbos. who worked at Corinth *c.* 600, was the first to write serious poetry in this medium. Lasus of Hermione, the teacher of Pindar. produced dithyrambs at Athens; and Thespis; 6th century B.C., possibly combining with them something of the Attic ritual of Dionysus of Eleutherae, invented tragedy by introducing an actor who conversed with the leader of the chorus and gave its songs a quasi-dramatic point of reference; but nothing approaching true drama was possible until Aeschylus (525?–456), the creator of the tragedy, introduced a second actor. However, his drama is still centred in the chorus, to whom, rather than to each other, his actors direct themselves.

It was customary at the tragic contests at the Dionysia for each of the three competing poets to produce three tragedies and a satyr play. the last being of a burlesque character with a chorus of satyrs who were part men. part horse or goat. Aeschylus, unlike later poets. usually made of his three tragedies a dramatic whole, treating a single story which might extend over a considerable period of time. His main concern was not dramatic structure and the portrayal of character but rather the presentation of human action in relation to the overriding purpose of the gods, though at times the accumulation of tension through long passages of lyric leads to scenes of tremendous emotional force. And the un-Greek opulence of his language and his richness of metaphor make him to most modern readers the most obviously exciting of Greek poets after Homer.

The successor of Aeschylus was Sophocles (495?–406), who abandoned for the most part the practice of writing in trilogies, reduced the importance of the chorus and introduced a third actor. The myth as the expression of an aristocratic and heroic ideal remained for him a satisfying theme and his heroes are still the heroes of Homer somewhat modified by contact with the standards of 5th-century Athens. But whereas Aeschyius tried to make more intelligible the workings of the divine purpose in its effects on man's life, Sophocles was readier to accept the gods as given and to reveal the values of life as it can be lived within the traditional framework of moral standards. He believed that in the fullness of time the wicked are punished, but not that all human suffering is punishment for wickedness. His earliest surviving plays, the *Ajax* and the *Antigone,* are the closest to Aeschylus both in stiffness of movement and in the awareness that the divine will is being fulfilled. Thereafter the actors become more detached from the background. and Sophocles' supreme skill in control of dramatic movement and his mastery of speech are devoted to the presentation of the decisive, usually tragic, hours in the lives of men and women at once "heroic" and human, such as Oedipus.

Euripides (c. 485–407), the last of the three great tragic poets, was only about ten years younger than Sophocles. but he belonged to a different world. When he came to manhood the Sophistic movement was in full swing (see SOPHISTS). Traditional beliefs were scrutinized in the light of what claimed, not always unjustifiably. to be reason, and this was a test to which much of Greek religion was highly vulnerable. The whole structure of society and its values was called in question. It is rarely possible to tell precisely what a dramatist thinks. but this movement of largely destructive criticism n-as clearly not uncongenial to Euripides. as it was to Sophocles. But as a dramatic poet Euripides found himself in an unfortunate position. He was bound to draw his material from myths, which for him had to a great extent lost their meaning. He strained and twisted them to make room for contemporary problems which were his real interest, and the divine presuppositions of the myth are accepted or rejected from moment to moment as the plot requires. In consequence, many of his plays suffer from a certain internal disharmony. On the other hand, his sensibilities and his moments of psychological insight bring him far closer than most Greek writers to modern taste. There are studies, wonderfully sympathetic, of wholly unsympathetic actions in the *Medea* and *Hippolytus,* a vivid presentation of the beauty and horror of religious ecstasy in the *Bacchae,* in the *Electra* a *reductio ad absurdum* of the values of a myth that justifies matricide, in the *Helen* and *Iphigeneia in Tauris* melodrama with a faint flavour of romance.

4. Comedy.—Like tragedy, comedy arose from a ritual in honour of Dionysus, a riotous ritual full of abuse and obscenity which was inspired not only by high spirits but by hopes of averting the attentions of evil demons and of encouraging fertility *(see* DRAMA: *Greek Drama: Origins).* The parabasis, the part of the play in which the chorus broke off the action and commented in their own persons on characters and events of the day, was probably a direct descendant of such revels. The dramatic element may have been derived from the secular Dorian comedy without chorus which is said to have arisen at Megara and was developed at Syracuse by Epicharmus *(c.* 530–*c.* 440). Hardly anything survives of his farces or of the mimes. short scenes of everyday life, of which Sophron of Syracuse was the most celebrated writer. At Athens comedy did not become an official part of the celebrations of Dionysus till 50 years later than tragedy, and the early years of its growth are correspondingly more obscure. The earliest comic poef of n-hom it is possible to form an impression was Cratinus. About 50 years later Aristophanes and Eupolis, who together with Cratinus make up the great trio of comic poets, refined somewhat the wild robustness of the older poet. But even so, for boldness of fantasy, for merciless invective, for unabashed indecency and, in the earlier plays, for freedom of political criticism, there is nothing like the Old Comedy of Aristophanes. whose work alone has survived. Cleon the politician, Socrates the philosopher, Euripides the poet are alike the victims of his masterly unfairness. the first in *The Knights,* the second in *The Clouds,* the third in the *Thesmophoriazusae* and *The Frogs,* while in *The Birds* the Athenian democracy itself is held up to a kindlier ridicule. As the war situation grew grimmer, direct political criticism became more dangerous and may have been the subject of legal restrictions. Aristophanes survived the fall of Athens in 404. but the Old Comedy had no place in the revived democracy. Except for short episodes the two plays of his of 4th-century date which have come down lack the sparkle and the poetic brilliance of his best work.

The gradual change from Old to Middle Comedy took place in the early years of the 4th century; the *Ecclesiazusae* and *Plutus* of Xristophanes belong to the transition. Of Middle Comedy no fully developed specimen has survived. It seems to have been distinguished by the disappearance of the chorus and of outspoken political criticism and by the growth of social satire and of parody; Xntiphanes and Alexis were the two most distinguished writers. Some plays appear to have had intricate plots treated in a comparatively realistic spirit. and it was these which led on to the New Comedy of Diphilus. Philemon. and. most important. Menander. one of the most admired poets in the ancient world. The transition took place around *320.* One complete play, the *Dyscolus*, and appreciable fragments of four others, out of Menander's 105 plays are extant on papyrus. New Comedy, as ancient critics were aware. was derived in part from Euripidean tragedy; its characteristic plot was a translation into terms of city life of the story of the maiden wronged by a god who bears her child in secret, exposes it and recognizes it years after by means of the trinkets she had put in its cradle. The god becomes a young man about town, the child a courtesan with whom a young man about town of the next generation is involved and whom he joyfully marries when she is revealed as the daughter of free parents. However great the delicacy of the language and the subtlety of the portrayal of the recurring types, it is hard to believe that such essentially barren themes of amiable virtue and petty vice could ever again arouse an enthusiasm such as possessed the ancient world for several centuries after Menander's death.

B. Early and Attic Prose

By the end of the 7th century the first written codes of law were appearing and knowledge of reading and writing was becoming more widespread. This encouraged the development of a prose literature. When writing replaced verse as an aid to memory, it was natural that the poetry of the Hesiodic school, dealing with the origin of the world and with the ordering of the generations of gods and heroes, should continue in prose form and supply the beginnings both for philosophy and history. There is no positive evidence that fables associated with the name of Aesop and traditional stories like those that appear in Herodotus' history were written down in the course of the 6th century. No prose writer is known earlier than Pherecydes *(c.* 550 B.C.) of Syros, who wrote about the beginnings of the world, but the earliest extant author among many otherwise unknown names is Hecataeus of Miletus, who played the part of elder statesman at the time of the Ionian revolt (499–494) ; he wrote both about the mythical past and about the geography of the Mediterranean and surrounding lands.

Prose came late to Athens. The oldest extant piece of Attic prose is an antidemocratic essay on the constitution of Athens (preserved as a result of a false attribution to Xenophon), the sole example of a considerable pamphlet literature. It was probably written c. *430* B.C., just after the outbreak of the Peloponnesian War, and it is an example of effective rather than elegant expression. But since Athens had risen after the Persian Wars to be the capital of a great confederacy, distinguished foreigners had been frequent visitors or residents, among them Anaxagoras from Clazomenae near Ephesus, author of one of the earliest philosophic essays in prose, and sophists like Protagoras who contributed both to originating the study of language and to developing the theory of its use as a means of persuasion through rhetoric. All these. as well as the medical writers of the Hippocratean corpus, used the traditional language of prose, Ionic.

1. History.—By far the most important of the writers of history was Herodotus, who was born at Halicarnassus and, after travels which took him as far as the First cataract on the Nile. Babylonia and southern Russia, spent some time in Athens in the years after 450 before settling in the Athenian colony of Thurii in south Italy. The theme of his history, written in large part for Athenian readers, is the clash between Europe and Asia culminating in the Persian War, but it is likely that he began by writing an account of the countries on the fringe of the Greek world in the manner of Hecataeus of Miletus, and that the idea of writing history, a thing which so far existed only in the form of local, largely mythical, chronicles, occurred to him as his work progressed. The account of the war itself. which occupies roughly the second half of the work. must have been composed by means of laborious inquiry from those whose memories were long enough to recall events which happened when Herodotus was a child or earlier. The whole history, though in places badly put together, is magnificent in its compass and unified by the consciousness of an overriding power which keeps the balance of the universe even and humbles the ambition of those who aspire too high. Though his notion of historical causation is rather naïve—the impulse which leads men to action is usually simple and purely personal, most often the desire to avenge a wrong—he has served mankind better as the faithful recorder of what he sa and what he was told than he could ever have done had he subordinated his narrative to more sophisticated notions. The style is equable. conversational, yet capable of quiet solemnity, rarely self-conscious or artificial, and the earlier books

in particular abound in enchanting digressions.

Of prose writers who were Herodotus' contemporaries the most important was Hellanicus of Lesbos, who wrote, among a large number of historical works and works on mythology, the first *Atthis,* a chronicle of the local legends and traditions of Attica.

Thucydides (c. 460–c. 400) was perhaps the first person to apply a first-class mind to a prolonged examination of the nature of political power and the factors by which policies of states are determined. At the outbreak of the Peloponnesian War (431–404) he recognized its momentousness and decided to record its history. As a member of the board of generals he acquired inside knowledge of the way policy Is shaped. After his failure to save Amphipolis in 424 he spent 20 years in exile, which he used as an opportunity for getting at the truth from both sides. The result is a history of the war narrowly military and political, but of the most penetrating quality. It was Thucydides' belief not that history repeats itself but that the forces which go to make history are unchanging: the judgment and insight of statesmen and their necessary limitations, the psychological pressures of success and failure exerted both on peoples and individuals and the incalculable element of chance. His own interpretation of the workings of these forces are given mainly in the numerous speeches, often in balancing pairs, in which he reveals the essentials of the situation as it presented itself to the leading participants at decisive moments in the war. Scholars have found some difficulty in believing that these speeches reproduce as much of the substance of what was actually said as Thucydides appears to claim. And though the war is described throughout with an appearance of utter detachment, the author reveals much about his own ideals in his admiration for the sagacity of Themistocles and the authority of Pericles, who represents the spirit of that Athens which the war destroyed, and in his detestation of Cleon's demagogic opportunism.

The Greek of Thucydides, especially in the speeches, is of great difficulty. As he wrote he was forging the instrument to express the most complicated thought yet conveyed in writing. Though harsh and austere in the opinion of Greek critics, he was not uninfluenced by contemporary fashion, but he owes less to the euphuism of Gorgias (see below) than is often supposed. In using the new methods of grouping ideas in a balanced and antithetical pattern he sometimes failed to fit his subject matter to the pattern which he imposed upon it; this, together with an occasional overconcentration of thought, is the main source of the obscurity which has troubled ancient as well as modern readers.

Just as Thucydides had linked his work by means of a digression in his first book to the point at which Herodotus had stopped, so Xenophon (c. 430–c. 354) began his *Hellenica* where Thucydides' unfinished history breaks off in 411, as did Theopompus and Cratippus after him. He carried it down to the end of the war and later wrote a continuation down to 362. His work is superficial by comparison with that of Thucydides, but he writes with authority of military affairs and accordingly appears at his best in the *Anabasis,* an account of his participation in the enterprise of the Greek mercenary army with which the Persian prince Cyrus tried to expel his brother from the throne, and of the adventurous march of the Greeks after the murder of their leaders by the Persians, from near Babylon to the Black sea coast. Xenophon also wrote three books, *Memorabilia, Symposium* and Apologia, in praise of Socrates, whom he seems to have admired rather than to have understood. His other major work, the *Cyropaedia,* was a piece of acknowledged fiction, perhaps the first of its kind, an imaginary account of the education of the great Cyrus, the founder of the Persian empire. He wrote also a number of short essays of which those on hunting and horsemanship are the best. His personality is engaging, but his moralizing is rather prosy, and the survival of a possibly disproportionate bulk of his work is due to the high esteem in which his style was held in antiquity.

No other historical writing of the 4th century has survived except for a substantial papyrus fragment containing a record of events of the years 396–395. The two leading historians who are known to have covered this period are Ephorus (c. 405–330) of Cyme in Asia Minor who n-rote the first universal history of Greece beginning in the heroic age with the coming of the Dorians c. 1000 B.C. and continuing to his own time, a highly influential work much used as a source by later writers; and Theopompus of Chios. Both were closer in spirit to Xenophon than to Thucydides, lavish with moral judgments and rhetorical embellishment. They mark the beginning of the decline of history toward the position of a mere province of rhetoric, the composition of a narrative which will at once edify and divert a reader, so that it was possible, four centuries later, for Dionysius of Halicarnassus to censure Thucydides for choosing a historical subject so little to the credit of his countrymen as the Peloponnesian War.

More scientific work was done by the successors of Hellanicus in the field of regional histories, especially of Attica. Androtion and Cleidemus in the 4th century and Philochorus continuing into the 3rd century did valuable work in an unpretentious way, basing their conclusions to a considerable extent on the study of the Athenian archives. In the west Philistus (c. 430–*c.* 360) of Syracuse, himself a man of action, wrote a history of Sicily which was highly esteemed. The same cannot be said of Ctesias who at the other end of the Greek world served as physician at the Persian court of Artaxerxes II (404–358) and wrote histories of Persia and India which were a byword for mendacity.

2. Rhetoric and Oratory. — In few societies has the power of fluent and persuasive speech been more highly valued than it was in Greece, and even in Homer there are speeches which are pieces of finished rhetoric. But it was the rise of democratic forms of government that provided the great incentive to study and instruction in the arts of persuasion, which were equally necessary for political debate in the assembly and for attack and defense in the law courts. Litigants mere not represented by advocates and the only professional help available to the private individual was that of the speech writer who could use his skill and knowledge to provide a speech to be learned and delivered before the jury (see RHETORIC).

The formal study of rhetoric seems to have originated in the democracy of Syracuse *c.* 460 B.C. with Corax and with his pupils Tisias and Gorgias (d. 376 B.C.); they also gave instruction in Athens. Corax is reputed to have been the first to write a *techne* or handbook on the art of rhetoric dealing with such topics as arguments from probability and the parts into which speeches should be divided; soon a number of such works were in circulation. Most of the Sophists had pretensions as teachers of the art of speaking, especially Protagoras with his doctrine that on each subject there is a stronger and a weaker (not a better and a worse) argument and that by art the weaker can be made to prevail, and Prodicus (c. 465–after 399 B.C.) of Ceos with his studies in the use of words.

Antiphon (c. 480–411), the first professional speech writer, was an opponent of democracy and influential behind the scenes politically. Three speeches of his have been preserved, all dealing with homicide cases, and three "tetralogies," sets of two pairs of speeches containing the arguments to be used on both sides in imaginary cases of homicide. Their authenticity has been doubled, but they are undoubtedly early, and they are of great interest because of the primitive ideas concerning bloodguilt and the duty of vengeance which they contain. The style of Antiphon is bare and closely knit and the structure sometimes rather crudely antithetical; he was little influenced by the technical advances of the late 5th century. Gorgias from Sicily! who paid a memorable visit to Athens in 427, introduced an elaborate balance and symmetry emphasized by rhyme and assonance by which the Athenians were for a short time much attracted: and Thrasymachus of Chalcedon, best known for his appearance in Plato's *Republic,* made a more solid contribution to the evolution of a periodic and rhythmical style.

Andocides (*c.* 440–*c.* 390) was involved in the scandal of the profanation of the Eleusinian mysteries in 415 (see ALCIBIADES) and spent much of his life in exile. His three speeches contain vivid narrative: but as an orator he was admittedly amateurish. Of the earlier generation of orators the most important was Lysias (*c.* 455–c. 380), who lived at Athens for many years as a resident alien and supported himself by writing speeches when he lost his wealth and all but his life in the troubled times which followed the fall of the city. Of all the Attic orators he is the one most likely to be read with pleasure today. His simple, lucid style has obvious charm, though those who preferred him to Plato carried their devotion to Attic purity rather far. His speeches, some of them written for litigants of humble station, show dexterous adaptation to the character of the speaker, though the most interesting of all is his own attack on Eratosthenes, one of the "Thirty Tyrants" imposed on Athens by the Spartans in 404 B.C., which contains a brilliant account of their reign of terror.

The 12 extant speeches of Isaeus, who was active in the first half of the 4th century B.C., all deal with testamentary cases, and are of interest mainly for the light they throw on Athenian law. But Isocrates, who was influential in Athens for half a century before his death at the age of 98 in 338, exerted an influence out of proportion to his talents. He perfected a periodic prose style which through the medium of Latin was widely accepted as a pattern, and he helped to give to rhetoric its predominance in the educational system of the ancient world. Because of the weakness of his voice and the diffidence of his temperament he did not himself speak in public, but after a short career as a writer of forensic speeches he set up a school of rhetoric and political science at Athens which was attended by many of the most distinguished figures of the period. His own writings were in the form of speeches, but were never intended to be delivered. He shows some insight into the political troubles of the Greek world with its endless bickerings between cities incapable of co-operation, and he dreamed of unity expressing itself in common action against Persia under the leadership of Athens or, when that became impossible, of blacedon. But he thought and wrote in generalities and drew his examples from bogus history; he may have done something to prepare Greek opinion for what was to come, but his appeal was to the emotions. Never has a political pamphleteer been so utterly devoid of incisiveness, and this defect in his mind was reflected in his style. He avoided the exuberant excess of his master Gorgias while retaining much of his balance and symmetry. He was the first master of the long periodic sentence in which the clauses are so grouped and subordinated to the sense of the whole that the reader is never in danger of losing the thread of the argument. This was a great achievement, but Isocrates had insufficient mental vigour and technical finesse to avoid monotony.

The greatest of the orators was by general consent Demosthenes (384/3–322), supreme in vehemence and power though lacking in some of the more delicate shades of rhetorical skill. In his case a number of deliberative speeches have survived, the actual words —or something very like them—spoken before the assembly, in addition to forensic speeches of which many are of a political character. He made efforts to rouse the Athenians to an awareness of the growing menace of Macedon, and in the series of three great speeches culminating in *On the Crown* his bitter feud with the opposing orator Aeschines lives again, the more vividly because the speeches which he answers are the only three of Aeschines that survive.

After Demosthenes, oratory faded together with the political setting to which it owed its pre-eminence. Of Hyperides (*c.* 390–322), an able all-round speaker, a good deal has been recovered on papyrus; of the statesman and financier Lycurgus (*c.* 396–325) a single speech survives, and of the undistinguished Dinarchus (c. 361–c. 290), probably three.

3. Philosophy.—Philosophic prose, the greatest literary achievement of the 4th century, derives from Socrates (who himself wrote nothing) and his characteristic method of teaching by question and answer, which leads naturally to the dialogue. Socratic dialogues were first composed by Alexamenus of Teos and the dialogue form was used also by Antisthenes, both disciples of Socrates. But by far the greatest of these writers was Plato (428/7–348/7), uho came of a distinguished Athenian family. Shortly after Socrates' death in 399 he wrote some dialogues, mostly short, which probably owed a good deal to the prose mimes of Sophron of Syracuse; to this group of works belongs the *Apology*, an idealized version of Socrates' defense at his trial, and probably two profounder dialogues, *Protagoras* and *Gorgias* In the decade after 385 he wrote the series of brilliant works, *Phaedo*, *Phaedrus*, *Symposium*, culminating in the *Republic*. His Socrates is the most carefully drawn character in Greek literature. The personal touches, the mannerisms and turns of phrase which the dramatic poets had excluded from their art are here used with wonderful effect. Subsequent dialogues became more austerely philosophical; Socrates tends increasingly to be a mere spokesman for Plato's thought, and in the last of his works, the *Laws*, he is replaced by a colourless "stranger."

Plato's style is a thing of matchless beauty, though ancient critics, who were apt to entangle themselves in the rules they had invented, found it too poetical. All human experience is within its range; it fits itself to every nuance of a developing argument, rises to the heights of earnest eloquence in discourse on man's destiny, and reflects with equal faithfulness the wit and gaiety of a drinking party and the grandeur of Socrates in the condemned cell.

Plato's pupil Aristotle (384–322) was admired in antiquity for his style, but those of his works which have survived are all of the "esoteric" sort, intended for use in connection with his philosophical and scientific school, the Lyceum. They are without literary grace and approximate at times to lecture notes, the only exception being the *Constitution of Athens*. His works on literary subjects, the *Rhetoric* and, above all, the *Poetics*, had an immense effect on literary theory in the centuries after the Renaissance, which was not less potent because they were generally misunderstood. But in the ancient world Aristotelian doctrine was known mainly through the works of his successor Theophrastus (371/0–288/7), which are lost except for two books on plants and the famous collection of 30 *Characters*, sketches of human types much imitated by English writers of the 17th century.

With Theophrastus Attic prose dies out until the artificial revival in the 2nd century A.D. In the meantime a vast amount of prose was written, much of it of a very technical nature. but with few literary pretensions. Rhetoric, become a mere literary exercise in a world in which rhetoric was divorced from political influence, developed an ornate and flowery manner associated with the Asian school of Hegesias of Magnesia (fl. *c.* 300 B.C.).

C. Hellenistic and Greco-Roman Periods

Alexander the Great's conquest of Asia between 334 and 323 transformed Greek life. Macedonians and Greeks composed the new governing class over the whole of the eastern Mediterranean and much of the continent beyond, and Greek became the language of administration, a new composite dialect based to some extent on Attic and spoken with little variation over wide areas, the so-called koine or common language. At the same time the cities of Greece and Asia Minor, even when they preserved their independence, lost most of their significance. The city ceased to be the universal frame within which the life of the people was conducted. More than ever before the individual was becoming aware of his isolation and seeking consolation and satisfaction outside corporate society. Henceforward the impulse to artistic creation and its reward came from the individual patron and not from a city, and the poet's audience, except at Athens. where comedy was still a living form during the first third of the 3rd century, consisted of a body of highly cultivated readers scattered over the Greek world. The things which appealed to this audience were finished workmanship and aealth of learned allusion. Their self-consciousness led them to appreciate psychological subtlety, above all in the treatment of love, and since many lived in the great cities whose growth was a feature of the period they began to develop the townsman's sensibility to values which are taken for granted when all human life is within reach of the country. Nature began to take a new place in poetry.

An event of great importance for the development of the new tendencies was the founding of the Museum, the shrine of the Muses, at Alexandria, the most famous of Alexander's new cities. Ptolemy I, Alexander's general. to whom fell the kingdom of Egypt when the empire was divided up in the civil wars which followed Alexander's death, was inspired by Demetrius Phalereus. both a man of action and a member of the Peripatetic school of philosophers founded by Aristotle, to establish this institution with its enormous library and facilities for pursuing the life of scholarship. The chief librarian was a sort of regius professor and sometimes a poet, as well as tutor of the heir apparent. The task of accumulating and preserving knowledge was for the first time properly endowed; the Sophists had begun it, Aristotle. who attached more importance than did most philosophers to knowledge for its own sake, had continued it, his Peripatetic followers developed this rather than the philosophic side of their master's activity, and finally the scholars of Alexandria pursued with zeal numerous branches of research. To them are owed not only the texts of ancient authors but a great deal of the learning required for their elucidation. More often than not the scholars were the poets of the Hellenistic age, and their scholarship influenced their poetry more perhaps than their poetry their scholarship.

The Hellenistic period lasted from the establishment of the kingdoms into which Alexander's empire was resolved to the end of the 1st century B.C., when Roman supremacy had been extended over the near east and a new Greco-Roman culture began to develop. For the next three centuries, until Constantinople became the capital of the later Roman or Byzantine empire, Greek writers were conscious of belonging to a world of which Rome was the centre, even though by a convention rarely disregarded they ignored the existence of Latin literature.

1. Poetry. — The creative period of Hellenism was practically contained within the span of the 3rd century. To this period belong the outstanding poets, Theocritus, Callimachus and Apollonius of Rhodes, to whom ancient critics would have added Xratus. Theocritus (c. 310–250), born at Syracuse, was associated with Phiietas of Cos, earliest of Hellenistic poets, and enjoyed the patronage of Ptolemy II at Alexandria. He was essentially a writer of mimes, short dramatic scenes of everyday life. and he is best known as the inventor of bucolic mime or pastoral poetry, in which he presented with varying degrees of realism scenes from the lives of shepherds and goatherds in Sicily and southern Italy; whether he adopted the device of later pastoral poetry and presented in the guise of rustics persons from higher walks of life is uncertain. He also dramatized mith brilliant realism scenes from middle-class life, and in his second idyll Simaetha. who tries by incantations to recover the love of the man who has deserted her, touches the fringe of tragedy. He used also another Hellenistic form, the epyllion, which is the modern name for the short scene of heroic narrative poetry in which heroic stature is often reduced by playful realism and delicate psychology. It may seem strange that one who touches so rarely on serious things should rank so high among poets, but in his hands the hexameter attained a lyric purity and sweetness unrivaled elsewhere, and in it he expressed the awakening delight in the charms of nature. His followers in bucolic were Moschus and Bion; not all the few poems ascribed to them are genuine and some are as late as the 1st century B.C.

Callimachus (fl. *c.* 260 B.C.) was a scholar as well as a poet. and his great catalogue of the Alexandrian library was of enduring importance. His most famous work, of which substantial fragments survive, was the *Aitia,* an elegiac poem describing the origins of various rites and customs; it was heavy with learning but diversified by passages of entertaining narrative. His six hymns show immense poetic expertise; solemnity, playful charm, downright humour, antiquarian sentiment — everything is there except religious feeling. which the obsolete gods of Olympus could no longer be expected to awaken unless used symbolically, as by the Stoic Cleanthes in his *Hymn* to *Zeus.*

Callimachus also wrote epigrams, and fragments survive of *Iambi,* a revival in milder terms of Hipponax. The form was used by a number of writers of the 3rd century, many of them under the influence of Cynic philosophy, to denounce the vanities of the world; their work, sometimes in mixed prose and verse. had connections with both satire and the popular sermon. Bion the Borysthenite. Menippus of Gadara. Cercidas and Phoenix of Colophon, the last two represented by appreciable fragments, were the chief writers in this field in the 3rd century B.C.

Callimachus seems to have advanced a poetic theory strongly hostile to the full-scale epic and favouring the high intensity possible only in shorter works. His epyllion *Hecale,* telling the story of Theseus and the boar of Marathon, was something of a manifesto in opposition to Apollonius of Rhodes (b. c. 295 B.C.), scholar, tutor to Ptolemy III and author of the only extant classical Creek epic apart from the *Iliad* and the *Odyssey.* Apollonius' epic on the voyage of the Argonauts is so full of local legend, connected with the places touched at by the voyagers, that the coherence of the poem is lost, but Medea's wild passion for Jason is marked by a new sort of romantic awareness of which there are only hints in Euripides and which is fully realized in the Dido episode of Virgil's *Aeneid.* Though Callimachus is usually counted the immediate victor in the controversy with Apollonius, who nonetheless achieved the office of head librarian, epics continued to be written in large numbers; Rhianus (275–195) wrote an epic on the war between Sparta and Messenia.

The desire to combine learning mith poetry led to the revival of didactic verse; a form which had lost its *raison d'être* when prose came into general use. The *Phainomena* of Aratus (c. 315–c. 240), a work which enjoyed a strange celebrity and was several times translated into Latin, is a versification of a treatise on the stars by Eudoxus of Cnidus (c. 400–c.347); its appeal. not obvious to the modern reader. must have lain in the skill with which an intractable theme was handled in verse. Chance has preserved the poems of Nicander (probably 2nd century B.c.) on the unlikely subjects of cures for bites and antidotes to poisons. An even more repulsive example of versified erudition is the *Alexandra* attributed to Lycophron (fl. c. 285 B.c.), a riddling prophecy of 1,500 iambics spoken by Cassandra.

The mimes of Herodas (3rd century B.c.), short realistic sketches of low life in iambic verse, have affinities both with the nonpastoral mimes of Theocritus and with the satire of the 6th-century Hipponax. They perhaps give a hint as to the character of the literature of popular entertainment, now lost except for a few scraps such as the moving complaint of a deserted maiden. the *Fragmentum Grenfellianum (c.* 2nd century B.C.). Much of the theatrical entertainment of the early empire consisted of mimes, though the pantomime in which the dancer expressed himself entirely by gesture was even more popular.

After the middle of the 3rd century poetic activity largely died away, though the great period of scholarship at Alexandria and at Pergamum was still to come. A few names of poets are known only because of their influence on Latin writers: Euphorion (b. c. 275 B.C.) of Chalcis and Parthenius (fl. 1st century B.c.), the teacher of Virgil. Thereafter Greek poetry practically ceases apart from a sporadic revival in the 4th century A.D. There is one exception; epigrams, usually in elegiac couplets, a form which goes back at least to Archilochus, continued to be written far into the Byzantine period. They have survived mainly in the two great compilations, the Planudean and Palatine Anthologies *(see* ANTHOLOGY'). based on several earlier collections of which the first of importance was the *Garland* of the Syrian poet Meleager of Gadara. made c. 100 B.C. This diminutive form was well suited to the exquisiteness of Hellenistic technique, and many of these little poems are of special interest because they seem to provide an outlet for the purely personal emotion so rarely expressed by Greek poets. Apart from poets otherwise known the chief epigrammatists were Asclepiades (fl. 270 B.C.j. Leonidas (3rd century B.c.) of Tarentum and Philodemus (d. 40 B.c.).

2. Prose. — Of the great mass of Hellenistic and later prose, historical, scholarly and scientific, almost all has perished, unconsciously condemned to destruction by the readers and schoolmasters of the later Roman and Byzantine empires. What they selected for reading was copied from papyrus onto parchment and had some chance of survival till the age of printing: the rest was left to crumble away and only relatively few scraps on papyrus have been rescued from the rubbish heaps of Egypt. In a world addicted to rhetoric and indifferent to science, the businesslike but rarely elegant prose of the koine aroused no interest.

History.—Among historians Polybius (c. 200–*c.* 118), the most outstanding. has survived in a fragmentary condition. Himself a leader of the Achaean league! then for many years a hostage in Italy where he won the friendship of Roman Hellenists, he was in a good position to appreciate the great historical phenomenon of the time, the rise of Rome. He wrote mainly of events of which he had direct experience, often with great insight; his work. in 40 books of which 5 are extant, covered the period from 264 to 146. The surviving books of the universal history of Diodorus Siculus (1st century B.C) are important to historians for the information derived from better writers which they contain. Considerable excerpts remain of the immense work of Nicolaus of Damascus (1st century B.c.), who was secretary to Herod and tutor to the children of Antony and Cleopatra, but they contain as much fable as history. The most considerable of lost historians was Timaeus (c. 350–c. 250), whose history of the Greeks in the west down to 264 provided Polybius with his starting point. Later historians were Dionysius of Halicarnassus (fl. c. 20 B.C.), the literary critic, about half of whose Roman Antiquities are extant, Appian of Alexandria, who lived at Rome at the time of Hadrian and wrote on Rome and its conquests, and Arrian (c. 96–c. 180 A.D.) from Bithynia, who is the most valuable source for the life of Alexander the Great.

Criticism.—The modest treatise On Style by an unknown Demetrius, sometimes identified with Demetrius Phalereus, is a piece of work in the Peripatetic tradition, perhaps as late as the 1st century A.D. It is generally believed that the treatise On the Sublime was written c. A.D. 40 by an otherwise unknown author (usually known as Longinus). Alone among ancient critics he does justice to creative literature as "the echo of a great soul," and he is exceptional for a Greek in that he mentions both Cicero and the Book of Genesis. On a lower plane Dionysius of Halicarnassus discussed with great subtlety the stylistic techniques of various writers. The so-called Bibliotheca of Apollodorus, long attributed to Apollodorus of Athens (c. 180 B.c.) but probably belonging to the Greco-Roman period, is a handy compendium of mythology, and in a sense a work of learning. The rest of the vast literary learning of the age is lost except for the little that mas preserved by later commentators and a few papyrus fragments like Satyrus' chapters on Euripides.

Science and Topography.—Scientific work such as the astronomy and geography of Eratosthenes (c. 276–c. 192) of Alexandria, also a poet of some distinction, is known mainly from later summaries, but considerable quantities of the mathematicians, especially of Euclid (fl. 300 B.C.) and of Archimedes (c. 287–212), have been preserved.

The great medical writer Galen (c. 130–c. 200) was physician to both Marcus Aurelius and Commodus; an enormous voluine of his work has survived. The medical writings of his contemporary Sextus Empiricus are lost, but his philosophical writings are an important source for the history of Greek philosophy. The survey of the Mediterranean by Strabo in the time of Augustus preserves much valuable information and so, in a more limited field. does the description of Greece by Pausanias, which is rich in local legend and useful to the archaeologist for its account of the monuments and works of art to be seen in the later part of the 2nd century A.D. The Greek achievement in astronomy and geography was summed up in the work of Ptolemy of Alexandria in the 2nd century A.D.

Judaeo-Christian Writings.—Prose of a different kind has come down from the eastern end of the Mediterranean. Greek became the language of the large settlement of Jews at Alexandria; Hebrew and Aramaic were forgotten by many, and the Septuagint, the Greek version of the Old Testament for Greek-speaking Jews, was completed by about the end of the 2nd century. Most of the Apocrypha is extant in Greek, and much of it was originally composed in that language. A surprising work, fragments of which are preserved in Eusebius of Caesarea, is the Exagoge of Ezekiel, a play in more or less Euripidean iambics on the exodus of the Jews from Egypt. In Alexandria the change from Macedonian to Roman rule made little difference. Philo in the early years of the Roman empire commented on the Jewish scriptures in the light of Greek thought. Josephus (c. 37–c. 98) fought on both sides in Roman-Jewish wars and wrote important works on Jewish history. The New Testament was written in popular Greek (koine), though in some parts the influence of Aramaic is to be suspected. Clement of Rome and Ignatius of Antioch were the most famous of the Apostolic Fathers. Justin Martyr (c. 100–c. 165) was the first in the line of Christian apologists which culminated in Clement of Alexandria (c. 150–c. 215) and Origen (c. 185–C. 254).

Plutarch.—The Parallel Lives of famous Greeks and Romans by Plutarch (c. 45–c. 120) of Chaeronea in Boeotia was for centuries one of the formative books for educated Europeans. Great figures from an idealized past are presented for the edification of the lesser men of his own day, and the anecdotes with which the Lives abound are of various degrees of credibility. They belong to biography rather than to history, though they are an important source for historians. A number of shorter works on a wide variety of subjects have come down under the title of Moralia. Plutarch's rambling curiosity and uncritical piety show the intellectual tide of Greece as being well on the ebb.

Second Sophistic Movement.—There was much concern over a question which had been argued ever since the days when Athens had ceased to be a free city: to what extent was Attic prose a norm which writers and especially orators were bound to follow? Those who preferred the more full-blooded Asiatic style could claim that they were escaping from an unprofitable bondage to the past, but hardly anything is left to show its quality. Many prose writers, notably Dionysius, had given their language an Attic flavour, but it was not until near the end of the 1st century A.D. that, with the movement which is flattered by the name of the Second Sophistic. the task of reviving a dead dialect was pursued with full vigour. These writers were orators in the sense that they gave displays of their virtuosity in a society which was still greedy for the spoken word and they published their speeches to be read in a wider circle; some of them also wrote essays and dialogues. Dio Chrysostom (c. 40–after 114) of Prusa in Bithynia exemplified in exile under Domitian the virtues of Stoic and Cynic philosophy, and was too intent on his message to be a mere stylist. His experiences as a wanderer in remote provinces gave his speeches an extraneous interest! but they have also many of the qualities of the sermon. A more thoroughgoing Atticist was Aelius Aristides (c. 117–189), a writer of undeniable brilliance, interesting mainly for his account of his prolonged search for an escape from ill-health. But the only writer of real consequence from this period was Lucian (c. 125–after 180) of Samosata in Syria. His works are mainly slight and satirical, but his gift of humour, even though it is repetitive, cannot be denied. His talent was for revealing the ridiculous side of things, and in an increasingly credulous world of astrologers, charlatans and miracle mongers he found much to ridicule. but an undue proportion of his effort was devoted to making easy fun of the moribund deities of Olympus. Yet he is the last Greek to show confidence in the validity of human reason as a test of the possible and the credible. The defect of this quality can be illustrated from the fascinating Life of *Apollonius* of Tyana, philosopher and mystic, by Philostratus (*c.* 170–c. 245 A.D.), who also wrote the Lives of the *Sophists.* A more valuable though less accomplished work is the Lives and Opinions of Famous Philosophers by an otherwise unknown Diogenes Laertius probably of the 3rd century A.D. Other examples of learned miscellanies, often frivolous and always undiscriminating, are the compilations of Aelian and of Athenaeus, both of the same period as Philostratus.

Philosophy.—Philosophical activity in the early empire was almost confined to moralizings based on Stoicism. Epictetus (b. *c.* A.D. 50) has had a wide appeal to the seriods-minded of all periods, and he influenced especially the philosophic emperor Marcus Aurelius (121–180), whose *Meditations* have taken their place beside works of Christian devotion. Many of Plutarch's *Moralia* are Platonic with vaguely mystical tendencies, but Plotinus (205–270) is the last major thinker in the classical world. He gave a new direction to Platonic and Pythagorean mysticism expressed in a style usually obscure but rising at times to real grandeur (see NEOPLATONISM).

The Novel.—The latest creation of the Greek genius was the novel. or erotic romance. It now seems likely that the first developments were as early as the 1st century B.C., and the origins reach back to such plays of love triumphant as the lost Andromeda of Euripides and the New Comedy, to Xenophon's daydreams about the education of Cyrus and to the largely fictitious narratives which were one extreme of what passed for history from the 3rd century B.C. onward. Of these last the best-known examples are the Alexander Romances. a mildly distorted and embroidered version of the exploits of Alexander the Great which supplied some of the favourite reading of the middle ages. Erotic elegy and epigram may have contributed something and so may the lost "Milesian Tales" of Aristides of Miletus (c. 100 B.C.), though these last appear to have depended on a pornographic interest which is almost completely absent from the Greek romances. Of the Sinus romance (dealing with the love of Ninus, founder of Nineveh), which was probably of the 1st century B.C., only fragments survive. but full-length works survive by Chariton (2nd century A.D.). Heliodorus (3rd century A.D.). Xenophon (2nd or 3rd century A.D.) of Ephesus and Achilles Tatius (2nd century A.D.); all deal with true lovers separated by innumerable obstacles of human wickedness and natural catastrophe and finally united. *Daphnis and Chloe* by Longus (probably 3rd century A.D.) stands apart from the others because of its pastoral rather than quasi-historical setting. The works of Dictys Cretensis and Dares Phrygius belong to the same period. They claim to give a pre-Homeric account of the Trojan War. The Greek originals are almost wholly lost. but the Latin version was for the middle ages the main source for the story of Troy. (D. W. Ls.)

II. BYZANTINE (4TH CENTURY A.D.–1453)

1. Characteristics. — By Byzantine literature is meant the literature written in Greek during the so-called Byzantine period (*c.* 300–1453). After Byzantine art it is the most genuine and direct expression of Byzantine civilization — that is to say, of that self-contained medieval Christian culture of which the Byzantine empire was the vehicle. If it is to be rightly judged it is of no use either to apply to it the standards of value of modern literary criticism. or to bring to it a mind attuned by the classics to an overrating of Greek antiquity. Instead, an attempt must be made to understand the particular religious, political and social worlds from which it derives.

Byzantine literature was a constituent part of a civilization whose character was determined by the centralized structure of politics in the Byzantine empire, particularly by court life in Constantinople (Byzantium). Byzantine culture was the direct and organic continuation of Greco-Roman culture in Christian dress. In the 3rd century A.D. the spiritual foundations of literature and art were a mixture of religious and philosophical tendencies—a union of Neoplatonic emanation doctrine, Gnosis. heliolatry, emperor cult and magic. To this Christianity, strengthened and organized by three centuries of persecution, brought a new note which in the course of a further three centuries succeeded in becoming the dominant in all literary activity in the empire. This came about after Constantine the Great christianized Augustus' idea of a Roman world empire and made the Christian church the guardian of the Greco-Roman cultural tradition. It came about in the tough fight against the ancient powers of civilization—against paganism, Seoplatonism, Gnosticism and against the Christian heresies; and in the course of that fight there flowed from these into the new Christian orthodoxy an abundance of ideas and beliefs. In the process Constantinople, the "New Rome" on the Bosporus, raised by Constantine to be the new capital, drew all the significant powers of the empire to itself. allowing the old cities of learning and literature — Rome. Alexandria, Antioch, Athens — gradually to decay. Byzantine literature thus acquired a metropolitan. court and exclusively aristocratic character. This development explains many of its peculiarities, for instance the number and the solemnity of the laudatory speeches to the emperor and his family and the preponderance of poems on the emperor's glorious deeds. which become intelligible in view of the unique position which the Byzantine emperor held as Christ's substitute on earth: the praise won from his subjects is therefore paid primarily to Christ himself.

In the light of the same development Byzantine conservatism in the use of outward literary forms, particularly language, becomes understandable. This language had to preserve the forms of the speech of the New Testament and the Fathers and, on the other hand, those of the Attic models from the great literary past. For it was the pride of the Byzantines that God had given mankind his revelation (beyond which no advance in human knowledge seemed possible) in the Greek tongue; and that the classical poetry and learned writings of the pagan forefathers, who had cultivated the most varied sorts of literature, was also clothed in this language; and that in addition the "Attic" language was up to that time the speech of the cultured in all the schools of the known world. Thus they would not permit this language to display in literature the leveling and simplifying influences which it suffered in daily use in the mouths of the people. This Byzantine pride in being the chosen people of the New Covenant and the heir of an unsurpassable spiritual culture is also the basic explanation of the principle of excluding all fertilization and invigoration by the ideas and literature of other nations. While the language of daily life developed according to its own intrinsic laws into modern Greek (a process practically complete by the middle of the 15th century), in the literary field Byzantium clung to speech forms artificially frozen at the Hellenistic Greek stage, falling into what was at times misunderstood Atticism. Mimesis (imitation of the ancients) became the principle behind all literary forms and scarcely allowed the genuine note of feeling and passion, springing straight from the heart, to appear in poetry or preaching. The undue value placed on form soon began to smother the sense for originality of content and invention; virtuosity in the mastery of verse technique or of the rules of rhetoric became an end in itself, so that metrical forms were even used, for example, in astronomical or legal treatises. On the other hand the consciousness of being in sole possession of the treasures of knowledge inherited from the ancients led to an overrating of erudition — hence the pedantic, obtrusively didactic form of many Byzantine writers or the gloss mania of philologists like John Tzetzes (d. 1185), who thought it necessary to annotate the copious literary conceits of his own letters.

In addition there is the all-pervading Byzantine rationalism, which forms a curious polarity to the religious tendency toward mysticism and which at times assumes that the secrets of nature and of the divine are to be stormed by a naïve prosiness. Further, there is the deeply rooted individualism, still to be seen in the Greek people, which caused a peculiar tension with regard to the confining bonds of ecclesiastical and political orthodoxy. These contrasts explain the discords which are to be felt in much Byzantine literature: the direct juxtaposition of devout Christian faith and an occasional flippant atheism; the lack of humour and the pleasure in malicious ridicule which appears from time to time; the tendency toward a bigoted asceticism shot through by fear of eternal retribution. All this explains why love lyrics form a very small part of early Byzantine literature and inner experience takes refuge in religious lyrics, though these are sometimes magnificent of their type.

The failings of Byzantine literature stem, therefore, largely from the religious and political tendencies of the time, though the psychological make-up of the Byzantine world also plays a part. The failings are balanced by certain merits. Thus, belief in the divine vocation of the Christian "Roman empire of the Greek nation!' meant that Byzantine historical writing preserved the best traditions of the Roman *historia* right through the centuries until the end of the empire with only short interruptions, and accompanied Byzantine history to the end with a long series of highly finished accounts of events; it was the 12th century before western Europe had anything comparable to set beside this achievement. In these works Byzantine rationalism provides to a large extent not only a good descriptive survey of the fate of the empire but in addition information about the many neighbouring European and non-European peoples against whom the empire had perpetually to assert itself; in many cases Byzantine historical writing provides the only available information about the period. Then, the traditionalism of the Byzantines, their ambition to match the ancient models, saved for posterity the best of ancient Greek literature, which served them as a pattern; even so, much was allowed to perish on the principle enunciated by the emperor Constantine VII Porphyrogenitus (d. 959) in the preface to his great series of excerpts: that it is better for mankind to possess a careful selection of a whole literature than an endless abundance of inferior work. As a result of the Byzantine tendency toward pedantry. many early scholia (explanatory notes) were preserved and added to by such Byzantine scholars as Eustathius of Thessalonica (d. 1194) or Maximus Planudes (early 14th century); without these scholia, begun by the Alexandrine scholars of the 4th century B.C., many passages in ancient literature would remain obscure. The comparative purity in which the ancient texts have come down to us is also largely due to the pedantry of Byzantine scholars. An especially important result of the speculative propensity of the Byzantines was the shaping of early Christian theology by the philosophically trained Fathers of the Church, particularly by the 4th-century Basil of Caesarea, Gregory of Nazianzus, Gregory of Nyssa; Christianity, at a critical stage in its history, was thus equipped to win its way against the philosophically supported religions and ideologies (Gnosticism, Neoplatonism) and to become the religion also of the educated and the upper classes. Further, one result of Byzantine melancholia was the mysticism embodied in its purest form in the Pseudo-Dionysius the Areopagite. This was important not only for theologians in the Christian east, such as Symeon the New Theologian (d. 1022) and Nicholas Cabasilas (14th century); after the 9th century it became influential in the west also and may be viewed as the root of one of the basic ideals of piety in European spiritual history. The rich garland of ecclesiastical Byzantine poetry, at once deeply felt and varied in form, sprang from the same piety, which penetrated all sections of life.

The Byzantine achievement in the sphere of popular poetry perhaps appeals most to modern taste. It is composed in the language of the people, that is to say in the language evolved from the idiom of daily life, and in the also popular pentadecasyllabic (15-foot) metre. The higher officials and clerics, the class which dominated literary criticism, did not therefore regard this folk poetry as "literature" at all and it consequently survived only in relatively late manuscripts (15th–17th century; *i.e.*, partly from the post-Byzantine period). Besides the extensive, imaginative epic of Digenes Akritas, whose origins go back to the 10th century, this poetry, filled with the spirit of the common people, includes a quantity of fairy tale and historical material clothed in epic form: the animal fables particularly show an overflowing power of invention and great epic talent.

In spite of the unquestioned superiority of Byzantine literature over western literature of the same period, which was written in Latin, and in spite of the admiration which the west entertained for Byzantine culture, the effect of the one on the other was comparatively small. On the one hand, the Byzantines, as has been mentioned, excluded on principle western literary forms and, up to the 12th century, western material and subjects; in the west, on the other hand, the Germanic conquests made a break in cultural tradition which meant that the knowledge of Greek was soon lost. Jerome and Rufinus translated a relatively small amount into Latin in the 4th and 5th centuries, but even Augustine could scarcely read the Greek authors in the original. The important influence of the 5th–6th century Pseudo-Dionysius the Areopagite was only transmitted to the west after his work had been translated into Latin in the 9th century by Abbot Hildwin of St. Denis and by Duns Scotus Erigena. A Latin translation of the Pege gnoseos ("Fountain of Knowledge") by John of Damascus also exercised a certain influence on Thomas Aquinas (d. 1274); on the other hand. it was not until c. 1400 that parts of Aquinas' writings were knonn in the Byzantine world and then they had no noticeable effect. Give and take in the realm of popular literature is more frequent and more noticeable, being an accompaniment of the contact of the lower classes through the crusades. especially in the 12th century; saga and story, much of which had come to Byzantium from the middle east, was at that time freely exchanged In general. however, literary contact between the Byzantine empire and its western neighbours suffered from the mistrust which was increased by religious schism and the political rivalries aroused by the crusades.

Even in Egypt and Asia Minor, both of which were centres of theological literature in the 4th and 5th centuries, the influence of Greek literature could not withstand the revival of the vernaculars (Coptic, Syriac), and after the provinces were conquered by the Arabs (641) it was completely lost.

On the other hand, Byzantine literature exercised a relatively strong influence on the peoples of eastern Europe, especially on the Slavs. There, to Bulgaria, to Serbia and, after Prince Vladimir's conversion to Christianity (c. 988), to Russia, Byzantine missionaries brought not only the Bible and liturgical texts but also the sermons of their best preachers and the "chronicles" (history books; see below) which were saturated with the spirit of Byzantine theocracy; and through their tenure of the most important missionary bishoprics they saw to it that the education and political and ecclesiastical life of the newly won converts remained Byzantine. It was by these means that Byzantine literature acquired its most important and, for world history, its most significant success.

2. Theology. — The great period of Greek theological literature, in the 4th and early 5th centuries, was largely the product of two factors: the establishment of Christianity as a permitted and then as the official religion of the state, and the stimulus afforded by heretical teachers such as Arius, Apollinaris, Nestorius and Eutyches (see also ARIANISM; MONOPHYSITES). The main theologians of the 4th–5th centuries were Athanasius (c. 295–373), the chief opponent of Arius and creator of the pattern for Byzantine hagiography in his life of St. Anthony of Egypt; Eusebius (c. 260–c. 340), who wrote the first ecclesiastical history as well as apologetic and antiheretical works and biblical commentaries; the three Cappadocian Fathers, Basil of Caesarea (St. Basil the Great; *c.* 330–379), who organized eastern monasticism, his brother Gregory of Nyssa (c. 330–c. 395), the earliest Greek ascetical author, and their friend Gregory of Nazianzus (c. 329–c. 389), known as Gregory the Theologian, who was also a poet; John Chrysostom (c. 347–407), bishop of Constantinople, the great preacher; Cyril (376–444) of Alexandria, untiring opponent of Nestorius, who represented the Alexandrian school; Theodoret (c. 386–*c.* 457) of Cyrrhus, who represented the school of Antioch.

After the middle of the 5th century theological literature was largely concerned with combating heresy. Leontius of Byzantium (d. *c.* 545), the first to introduce Aristotelian definitions into theology, wrote against Monophysites as did Anastasius of Sinai (d. c. 700) and Maximus the Confessor, the 7th-century mystic. Iconoclasm was opposed by John of Damascus whose Pege gnoseos was the first comprehensive exposition of Christian dogma, and who was one of the chief composers of the kanons (see Religious Poetry, below). The works of Theodore Studites (759–826), who also attacked iconoclasm, include kanons and homilies which give much information about monastic life. The great bibliographer Photius (d. 895), patriarch of Constantinople, was the first to crystallize the differences between the Latin and the Eastern churches into rigid formulas. The emperor Leo VI the Wise (c. 866–911) wrote liturgical poems and homilies for a number of festivals. In the early 12th century Euthymius Zigabenus compiled his *Panoplia dogmatica,* an armoury of theology against all heresies.

At this time (11th to 12th century) there arose a tendency to introduce a kind of dialectic into theology in place of the accumulated citations from the Fathers, which had hitherto been the cherished and the only recognized method of supporting a dogmatic thesis. But, instead of developing into something like western scholasticism, this tendency, represented by Michael Psellus, John Italus (both 11th century) and Eustratius of Nicaea (d. c. 1120), soon fell under the reproach of heresy and disappeared. Anti-Latin writings increased in number; their authors include the emperor Theodore II Lascaris (1222–58). Gregory Palamas and Nilus Cabasilas (both 14th century). In the last century of the empire theological writing was almost wholly concerned with the Latin question and nith hesychasm, the doctrine of the uncreated light on Mt. Tabor, of which Gregory Palamas was the defender.

3. Hagiography. — The literature consisting of the acts of the martyrs and the lives of the saints forms an independent group which is comparatively unaffected by theological issues. Its main interest centres in the personalities of the martyrs and saints themselves. Apart from Athanasius' life of St. Anthony, Palladius' Lausiac history (5th century), Cyril of Scythopolis' lives of St. Saba and six other Palestinian abbots (6th century) and the life of John the Merciful, bishop of Alexandria, by Leontius of Neapolis in Cyprus (7th century), the authors are mostly anonymous. Most of the acts of the martyrs date from the great persecutions before the Byzantine period; together with the later lives of the saints, they were revised in the 10th century by Simeon Metaphrastes on the rhetorical and linguistic principles of his own day. His new collection, in several volumes, largely superseded the older original texts (see also HAGIOLOGY; BOLLANDISTS). From the popular lives of the saints, which for the reading public of the Byzantine empire formed the chief substitute for modern belles-lettres, it is easy to trace the transition to the religious novel, of which the best-known example is the story of Barlaam and Josaphat.

4. Religious Poetry. — The oldest surviving religious poetry was composed in the ancient Greek metres and was for use in private devotions, not public services; belonging to this group are the so-called "maiden's song" in the *Symposium* of Methodius of Philippi (not "of Olympus" as he is mistakenly called; *c.* 311) and the religious poems of Gregory of Nazianzus (written between 381 and 389; the few poems extant under his name which are not in ancient metres are not by him). The heretic Apollinaris of Laodicea (4th century) turned the Psalms into hexameters, perhaps with the intention of evading the emperor Julian's interdict on Christian education. Synesius, bishop of Cyrene (early 5th century). who was also the valiant defender of his city against its barbarian attackers, showed himself in the Christian hymns which he composed in classical metres to be saturated with the Neoplatonic spirit; the poems are a Christian counterpart to the pagan hymns of his contemporary Proclus.

More important than this private religious poetry are the Byzantine liturgical hymns. From comparatively modest beginnings the need for congregational hymns developed under the influence of the propagandist success which the Gnostics and above all the heretic Arius (d. *c.* 335) had with their religious poetry set to folk music. The model for the poetical development may well have been the Syrian church hymns. The earliest evidence which has been preserved, short poems (tropes) clinging closely to the language of the Scriptures, dates from the end of the 5th century. The verses are arranged in lines all with the same number of syllables, the accent (which here regulates the rhythm) coinciding with the emphasis. The principle behind ancient Greek prosody of regulating the rhythm by long and short syllables ceased to function; from about the 2nd century A.D. all syllables became the same length in Greek, so that accent took over the function of regulating rhythm. On this principle there grew up from the 5th–6th century the kontakion of several strophes, each having the same refrain, preceded by a strophe of irregular rhythmical form (the kukulion). The most prolific and successful writer of kontakia was the Syrian Romanos (6th century); besides the 85 kontakia which have survived under his name he probably wrote the famous Aknthistos hymn to the Virgin Mary. The dramatic construction of some of the kontakia shows that this literary form was a substitute to the Byzantines for the religious and secular drama which they did not possess.

In the 7th century church poetry entered upon a new stage, characterized by an increase in artistic finish and a falling-off in poetical vigour, with the composition of the kanon, a poem built up out of eight or nine lyrics, all differently constructed. Andrew of Crete (c. 650–720) is regarded as the inventor of this new class of song. The most celebrated writers of kanons are John of Damascus and Cosmas of Jerusalem (both first half of the 8th century). Later. the composition of kanons was more particularly cultivated in the monastery of Studiu in Constantinople by its abbot, Theodore Studites, and others.

5. History. — Byzantine historical accounts fall into two groups: historical works, describing a period of history in which the authors had lived and moved or one which only immediately preceded their own times, and chronicles, briefly recapitulating the history of the world. This second class has no exact counterpart in ancient literature.

Byzantine histories of contemporary events do not differ substantially in nature from ancient historical works, except in their Christian colouring. Yet even this is often very faint and blurred because of the close adherence to ancient methods. Apart from this, neither a new style nor a new critical method nor any radically new views appreciably altered the main character of Byzantine historiography.

The outstripping of the Latin west by the Greek east, which after the close of the 4th century was a self-evident fact, is reflected in historiography also. After Constantine the Great (d. 337), the history of the empire, although its Latin character was maintained until the 6th century, was mostly written by Greeks; *e.g.*, Eunapius (d. *c.* 347), Olympiodorus (5th century), Priscus, Malchus (c. 490) and Zosimus, the last pagan historian (c. 500), all of whom, with the exception of Zosimus, are preserved only in fragments.

To this period also belong the 5th-century continuations of Eusebius' ecclesiastical history made by Gelasius of Caesarea (d. *c.* 394), by Philip of Side (fl. early 5th century) and by Philostorgius (d. *c.* 439), who shows Arian sympathies. These survive only in fragments and extracts. A complete church history for the years 305–439 was written by the lawyer Socrates (fl. early 5th century); the work of Sozomen (d. 443) provides a source partly independent of Socrates. Historiography received a great impulse in the 6th century. Procopius and Agathias described the stirring and eventful times of Justinian I; and Theophanes of Byzantium. Menander Protector, John of Epiphaneia, of whose works only fragments survive, and Theophylact Simocattes described the second half of the 6th century. The last independent ecclesiastical historian, Evagrius Scholasticus, who wrote the history of the church from 431 to 593, lived in the latter part of the 6th century. After his time there was little historical writing, beyond the compilation of a few chronicles, until a fresh impetus was provided by the revival of classical studies in the 10th century.

Several historical works are associated with the name of the emperor Constantine VII Porphyrogenitus (10th century). To his learned circle belonged also Joseph Genesius, who at the emperor's instance compiled the history of the period from 813 to 886. The priest John Cameniata wrote an eyewitness account of the taking of Thessalonica by the Cretan corsairs in 904, which is interesting from the point of view of historical and ethnographical science. Leo Diaconus left a graphic account of the period 959–975 which covered the wars of the Byzantines with the Arabs in Crete and with the Bulgarians. A continuation of this was undertaken by the philosopher Michael Psellus in work covering the period from 976 to 1077, a valuable supplement to which (describing the period from 1034 to 1079) was supplied by the jurist Michael Attaliates. The history of the empire during the first four crusades was written by Nicephorus Bryennius, his wife Anna Comnena and John Cinnamus; an exhaustive work by Nicetas Choniates (d. *c.* 1215) is authoritative for the history of the fourth crusade. The unhappy conditions and decay of the empire under the Palaeologi (13th–15th centuries) are described in a similar lofty style, though with a still closer following of classical models. The events which took place between the taking of Constantinople by the Latins and the restoration of Byzantine rule (1203–61) are recounted by George Acropolites, who emphasized his own share in them. The history of the succeeding period was written by George Pachymeres (d. c. 1310), Nicephorus Gregoras and the emperor John VI Cantacuzenus. Lastly, the death struggle between the Byzantine empire and the rising power of the Ottoman Turks was narrated by three historians, all differing in culture and in style, Laonicus Chalcocondyles, Ducas and George Sphrantzes. With them may be classed a fourth (though he lived outside the Byzantine period), Critobulus, a highborn Greek of Imbros, who wrote, in the style of the age of Pericles, the history of the times of the sultan Mohammed II (1451–67).

The essential importance of the Byzantine chronicles consists in the fact that they in part replace older lost aorks, and thus fill up many gaps (*e.g.*, for the period from about 600 to 800, of which few records remain). They lay no claim to literary merit, but are often interesting from the linguistic point of view. The authors of the chronicles were mostly monks, which explains the strong clerical and popular tendency of these works. And it is due to these two qualities that the chronicles obtained a circulation abroad, both in the west and also among the peoples christianized from Byzantium, *e.g.*, the Slavs, and in all of them sowed the seeds of an indigenous historical literature. Thus the chronicles, despite their jejune style and uncritical treatment of material, were of far greater importance for the general culture of the middle ages than the erudite contemporary histories designed only for the highly educated circles in Byzantium. The oldest extant Byzantine chronicle of universal history is that of John Malalas (6th century), which is also the purest type of this class of literature. In the 7th century the Paschal Chronicle (Chronicon *Paschale*) was completed. About the end of the 8th or the beginning of the 9th century George the Syncellus compiled a concise chronicle, which began with the creation and was continued down to the year A.D. 284. At the request of the author the continuation of this work was undertaken by Theophanes Confessor, who brought down the account from 284 to his own times (813).

Besides Theophanes there is for the years 602–769 the short history of the patriarch Nicephorus (d. c. 529) which was largely drawn from the same sources. Theophanes' chronicle was also extended to cover the period 813–886 by the so-called *Theophanes Continuatus* commissioned by Constantine VII Porphyrogenitus; this consists of five biographies of the emperors reigning during the period, Constantine VII Porphyrogenitus, who commissioned the work, himself contributing the life of his grandfather Basil. A further continuation for the period 886–961 was made by Theodorus Daphnopates. George the Monk compiled an influential chronicle of the world's history (from Adam until the year 842, the end of the Iconoclast movement), far more theological and monastic in character than the work of Theophanes. Among later chroniclers John Scylitzes stands out conspicuously. His work (covering the period from 811 to 1057), as regards the range of its subject matter, is something between a universal and a contemporary history. In the 11th century Georgius Cedrenus embodied the whole of Scylitzes' work, almost unaltered, in his universal chronicle. In the 12th century the general increase in literary production was also reflected in the number of chronicles produced. From this period dates, for instance, the most distinguished and learned work of this class, the great universal chronicle of John Zonaras. Lastly, in the 12th century, Constantine Manasses wrote a universal chronicle in "political" verse (see below).

6. Geography. — Two works dealing with geography and topography deserve mention, the 6th-century Topographia Christiana of Cosmas Indicopleustes, which contains important information as to Byzantine trade, and the 10th-century history and description of Constantinople entitled *Patria.* Besides these there were handbooks of navigation, guides for pilgrims and catalogues of provinces. cities, metropolitan sees and bishoprics.

7. Philosophy. — Ancient Greek philosophy under the empire sent forth two new shoots — Neopythagoreanism and Neoplatonism. It was the latter with which moribund paganism essayed to stem the advancing tide of Christianity. The last great exponent of this philosophy was Proclus (410–485) in Athens. The dissolution, by order of Justinian I, of the school of philosophy at Athens in 529 was a fatal blow to this nebulous system, which had long outlived the conditions that made it a living force. Nevertheless, it had contributed many ideas to the world of early Christian thought, and contributed essentially to its philosophical framework. In the succeeding period philosophical activity was of two main kinds: on the one hand, the old philosophy. *e.g.*, that of Aristotle, was employed to systematize Christian doctrine; on the other, the old works were furnished with copious commentaries and paraphrases. Leontius of Byzantium introduced Aristotelian definitions into Christology; but the real founder of medieval ecclesiastical philosophy was John of Damascus. As a result, however, of his having early attained to canonical authority, the independent progress of ecclesiastical philosophy was arrested; and to this it is due that in this respect the later Byzantine period is far poorer than the corresponding era in the west. In the 11th century there was a revival of philosophical studies, mainly because of Michael Psellus, who again laid more emphasis on Platonic ideas, as against Aristotelian, and John Italus, who attempted in vain to introduce into Byzantium a philosophy free from the tutelage of theology. The attempt of Gemistus Pletho, about the middle of the 15th century, to introduce, in conjunction with plans for a political restoration, the old pagan religion and the old Platonism also came to nothing.

Ethics mas represented in Byzantium by the numerous "mirrors for princes"; in these the prince was exhorted to all the virtues, the prototype being that by the deacon Agapetus (6th century).

8. Rhetoric. — Ancient rhetoric was cultivated in the Eyzantine period with greater ardour than scientific philosophy, being regarded as an indispensable aid to education. Among the almost tedious rhetorical productions of the time are to be found a few interesting pieces, such as the short dialogue entitled *Philopatris*, in the style of Lucian, which gives a remarkable picture of the times of Nicephorus Phocas (10th century). Lucian's Nekyomantia was also the prototype for the satirical *Mazaris' Journey* to Hades (composed c. 1414–15). An important branch of rhetoric for the Byzantines was the public speech, usually a state speech addressed to the emperor on feast days, particularly at Epiphany. In this field considerable fame was won by the pagan Libanius (d. 393), head of a school of rhetoric at Antioch, who numbered among his pupils John Chrysostom and Basil (afterward bishop of Caesarea) and whose thought profoundly influenced the emperor Julian. Of his writings there survive imperial eulogies, funeral speeches and more than 1,500 declamations and letters. Rhetorically elaborate letters were also considered by the Byzantines as a considerable artistic achievement; collections of them were made so as to preserve them for posterity. There are collected letters also of Photius, Psellus, Eustathius and Michael Choniates, archbishop of Athens, and many other important figures of Byzantine literature. The great number of treatises written on rhetoric also shows the high regard of the Byzantines for this literary form.

9. Scholarship.—Byzantium was dominated to an extravagant extent by the rules of what in modern times is termed classical scholarship. The numerous works which belong to this category, such as grammars, dictionaries, encyclopaedias, commentaries on ancient authors, extracts from ancient literature and metrical and musical treatises, are of little general interest, although of great value for special branches of literary study, *e.g.*, for tracing the influences through which surviving ancient works have passed, as well as for their interpretation and emendation; for information about ancient authors now lost; for the history of education; and for the underlying principles of intellectual life in Byzantium. The most important monument of Byzantine scholarship is perhaps the Bibliotheca or Myriobiblon of the patriarch Photius, which consists of 280 essays summarizing all he had read. Much literature now lost is thus preserved in epitome. Rather more than a century later appeared the Suda Lexicon (sometimes erroneously attributed to "Suidas"), an encyclopaedia including valuable biographical information on classical and Byzantine authors. Eustathius (d. c. 1194), archbishop of Thessalonica, was a commentator on classical texts; various scholia on the Iliad and the Odyssey and fragments of other lost writings survive in his works.

10. Military Science. — The Byzantines had shown an interest in military science since the time of Arrian (d. c. 180), who wrote an account of the campaigns of Alexander the Great. The *Strategikon*, a book attributed to the emperor Maurice (582–602), shows the changes made in Byzantine tactics in order to meet the attacks of contemporary invaders, the Avars, Persians and Turks. This treatise was several times brought up to date under the names, among others, of the emperors Leo VI and Constantine VII. The emperor Nicephorus Phocas (d. 969) is credited with an original manual on guerrilla warfare.

11. Law. — The emperors Leo VI the Wise and Constantine VII Porphyrogenitus issued the Basilica, the Greek translation of the emperor Justinian I's Institutes and Digest, which had been published in Latin; they were newly arranged and enlarged by the addition of the imperial constitutions of Justinian's Codex and its *Novels,* which had been in Greek from the first. The Peira is one of the collections of high court judgments which the chief justice Eustathius (11th century) caused to be compiled. The canon law was an important contribution of the Byzantines to jurisprudence.

12. Secular Poetry. — The metre of secular poetry is, for the most part, either the Byzantine regular 12-syllable verse which took the place of the ancient trimeter or the 15-syllable ("political") verse; more rarely the heroic and Anacreontic measures.

Epic popular poetry, in the ancient sense, begins only with the vernacular Greek literature (see below); but among the literary works of the period there are several which can be compared with the epics of the Alexandrian age. Nonnus (fl. *c.* 400) wrote. while still a pagan, an epic on the triumphal progress of the god Dionysus to India. and, as a Christian, a lengthy versification of St. John's Gospel. Paulus Silentiarius (6th century) wrote in perfectly correct Nonnian hexameters a description (*Ekphrasis*) of Hagia Sophia. built by Justinian I; the Church of the Apostles, also a splendid erection of Justinian I, had to wait until 940 to find a less gifted poet in Constantine of Rhodes. The historic epic was also carefully preserved by the Byzantines. In the 7th century George the Pisidian described in several iambic poems the wars of the emperor Heraclius. Later the deacon Theodosius (10th century) immortalized in extravagant language the capture of Crete by the emperor Nicephorus Phocas.

In the 12th-century revival of culture under the Commeni several long poems were composed in imitation of the ancient Greek romances. Two of these are written in the duodecasyllable metre: the story of Rodanthe and Dosicles by Theodore Prodromus, and an imitation of it, the story of Drosilla and Charicles by Nicetas Eugenianus; one in political verse, the love story of Aristander and Callithea by Constantine Manasses, which has only been preserved in fragments; and one in prose, the story of Hysmine and Hysminias by Eustathius Macrembolites. These Byzantine romances are of interest chiefly by way of contrast to the romances in the vernacular produced in the 13th and 14th centuries.

The detached and ascetic point of view which dominated the whole Byzantine period was fatal to the development of secular lyrical poetry. A few poems by John Geometres and Christopher (11th century) of Mytilene and others, in which personal experiences are recorded with some show of feeling, may be placed in this category. The dominant form for all subjective poetry was the epigram, which was employed in all its variations from playful trifles to long elegiac and narrative poems. George the Pisidian treated the most diverse themes epigrammatically. In the 9th century Theodore Studites immortalized monastic life in a series of epigrams. The same century produced the only Byzantine poetess, Casia, who wrote several epigrammatic productions and church hymns. Epigrammatic poetry reached its highest development in the 10th and 11th centuries, in the productions of John Geometres, Christopher of Mytilene and John Mauropus. Less happy are Theodore Prodromus (12th century) and Manuel Philes (14th century). From the beginning of the 10th century also dates the most valuable collection of ancient and of Byzantine epigrammatic poems, the Anthologia Palatina (see ANTHOLOGY).

The didactic poem was a much loved form among the Byzantines; this predilection was in line with their tendency, noted above, to instruct their fellow men rather intrusively and to display the fullness of their own knowledge. John Tzetzes wrote metrical commentaries on Homer, Hesiod, Pindar, Aeschylus, Euripides and Aristophanes. Constantine Manasses also composed a verse chronicle of the world of this kind.

Dramatic poetry, in the strict sense of the term, was as completely lacking among the Byzantine Greeks as was the condition necessary for its existence, namely, public performance. Apart from some moralizing allegorical dialogues (by Theodore Prodromus. Manuel Philes and others), the only work of the Byzantine period which resembles a drama, at least in external form is the *Christos paschon.* This cento on the passion, erroneously included among the works of Gregory of Nazianzus but written probably in the 12th century, is largely composed of lines taken from ancient playwrights, *e.g.,* Aeschylus, Euripides and Lycophron; it was certainly not written for dramatic production.

13. Vernacular Literature. — The vernacular literature stands alone, both in form and in content. It shows remarkable originality of conception and probably also entirely new and typically medieval matter. While in the courtly literature prose is preeminent, in the vernacular literature poetry both in quantity and quality takes the first place. Though a few preliminary attempts were known (proverbs. acclamations addressed by the people to the emperor, etc.), longer Greek vernacular works were written donn only from the 12th century onward; at first poems. most of nhich were cast in political verse. Toward the close of the 15th century rhyme came into use. The subjects treated in this vernacular poetry are exceedingly diverse. In Constantinople a mixture of the learned and the popular language was first used in poems of admonition, praise and supplication. To this oldest class (12th century) of vernacular works belongs the Spaneas, an admonitory poem in imitation of the letter of Pseudo-Isocrates addressed to Demonicus; a supplicatory poem composed in prison by the chronicler Michael Glycas; and several begging poems of Theodore Prodromus (Ptochoprodromus). In the succeeding period erotic poems began to be written, such as the so-called Rhodian love songs and the story of Ptocholeon. the wise old man who saved his royal master from disasters by his miraculous knowledge. Long epic poems. in which are treated such subjects as the legends of Troy, of Achilles and of Alexander. form a separate group. To these may be added romances in verse after the manner of the romances written in the artificial classical language, e g., *Callimachus* and Chrysorrhoe, *Belthandrus* and Chrysantsa, *Lybistrus* and Rhodamne, also romances in verse after the western pattern such as *Phlorius* and *Platziaphlora* (the old French story of *Flore* et *Blanchefleur*), *Imberius* and *Margarona* and *Apollonius* of Tyre. The well-known stories from the *Physiologus* (see BESTIARY) about animals. plants and stones were put into political verse in this period. and other animal tales in political verse were also popular: *Pulologus* (a book of birds), a history of animals, both satirical in intent, and a version of Reynard the Fox which relates the adventures of an ass, a wolf and a fox. Other satirical poems are the *Sachlikis,* which originated in 15th-century Crete. and its imitation by Markus Depharanas, also Cretan in origin. There are also several legendary and historical poems in which famous heroes and historical events are celebrated; for instance. poems on the exploits of Belisarius (Justinian I's general), the fall of Constantinople (1453), the taking of Athens (1458), the devastating campaign of Timur, the Chronicle of the Morea (the history of the Frankish government of the Peloponnese. 1204–92). the battle of Varna (1444) and the plague in Rhodes in 1498. The chief of these is the great heroic epic of Digenes Akritas, preserved in several versions, the oldest of which, a linguistic mixture of popular and literary language, dates from the 10th century. There is no doubt, however, that this epic originated among the people and was spread by folk singers before it was written down; large parts of it can still be recited by aged and illiterate people. Digenes Akritas represents the bold frontier warrior (akrites) on the Euphrates frontier in the 8th–10th centuries. The conversion of the emir indeed betrays Byzantine piety. and there are numerous oriental touches. But the emir's son. Digenes Akritas, in his feeling for nature and strong family affections has much in common with the Greek palikar of the klephtic ballads (see below). In these respects the poem may be regarded as the forerunner of such works as the great Cretan national romance, the Erotokritos (see below) and as forecasting much that is best in modern Greek popular poetry. (K. K.; F. Do.)

III. MODERN (AFTER 1453)

1. Language. — After the capture of Constantinople by the Turks in 1453, the destruction of Greek national life and the almost complete effacement of Byzantine civilization naturally involved a more or less complete cessation of Greek literary production in the subjected regions. Learned Greeks found refuge away from their native land; they spoke the languages of foreign peoples and, when they wrote books, they often used the languages of those peoples. though most of them also wrote in Greek.

It is, however. a mistake to regard 13-53 as a sharp dividing line betn-een Byzantine and modern Greek literature. As shown above, the germs of modern Greek popular poetry can be detected as early as the 10th century in the epic cycle of Digenes Akritas. and still more in the Greek verse romances of the 13th and 14th centuries. More directly a result of the conquest by the Franks is the chronicle of Leontios Makhairas, which deals with Cyprus in the 15th century. Here again the Greek vernacular language is employed. Italian influence had a predominating share in the production of the flourishing Cretan literature of the 16th and 17th centuries described below. The literary debt of modern Greece to the crusaders should not be overlooked. Among other things, they were responsible for the introduction of rhyming verse.

Modern Greece has inherited two literary styles—the consciously classical. known as the *katharevousa*, and the really living popular, known as the *demotiki*. Both have been greatly promoted by the invigorating influence of Italian and French literature. In the progress of these two literary streams the demotic movement of the 1880s reached a turning point when a group of young and gifted writers, the most important of whom was Kostis Palamas (1859–1943), founded the so-called "new school of Athens." This school was a reaction against the dead and conventional classical language and the flabby exuberance of the Greek romantics. In 1888 Ioannes Psycharis (1854–1929) became the leader of the movement with the publication of his famous book *To taxidi mou* (ostensibly a series of traveling impressions, but really intended to awaken the linguistic coriscience of the Greeks). The battle flared up, and a number of distinguished critics, scholars and writers joined the struggle, which broadened into a reaction against the dead weight of the whole classical tradition, and advocated a return of Greek art and literature to contemporary life. This was greatly helped by the study of modern Greek folklore. then promoted by Nikolaos Politis (1852–1942), and by the researches of Konstantinos Paparrhigopoulos (1815–91) into medieval and modern Greek history. The battle ended with the decisive victory of the popular language, the *demotiki*, for all writings of an imaginative character. Even in works of science and in official documents its influence became increasingly felt.

The classical language was unsuited for the production of a really living drama. Hence, although numerous plays were written in the 19th century both in verse and in prose, only two names of older dramatists need be mentioned. Dimetrios Vernardakis (1834–1907) and Spyridon Vasiliadis (1844–74). The employment of the demotic and the choice of themes relating to contemporary life gave plays fresh vitality and did much toward the foundation of a national drama. G. Xenopoulos was the inaugurator of this. Together with him mention should be made of I. Kambysis (1872–1902), S. Melas (1883–), T. Moraitinis (1875–), N. Laskaris (1868–1945), P. Horn (1881–1941), D. Bogris (1890–), T. Synadinos. A. Terzakis (1906–) and G. Theotokas. A number of distinguished Greek poets like K. Palamas, A. Sikelianos and N. Kazantzakis have also written for the theatre, but their plays are more notable for their lyrical than for their dramatic qualities.

It is convenient to treat poetry and prose in two different sections, since few writers have distinguished themselves in both.

2. Poetry.—From the fall of Constantinople till the War of Greek Independence (1821–29) the most developed and personal, though not the most arresting, poetry appeared in Greek lands occupied by the Franks. The beginnings of modern Greek lyric poetry can be traced to Rhodes and Cyprus, then under the rule of the Knights Templar and the Lusignans.

Cretan Literature.—It was in Crete. however, that the most vigorous and remarkable literature flourished in the 16th and 17th centuries. when the island was under Venetian occupation; this was brought to a premature close by the Turkish capture of Candia in 1659. The progress made in versification can be traced from the unpolished, rhymed 15-syllable political lines of Georgios Choumis in his paraphrase of Genesis arid Exodus,' written early in the 16th century, to the finished handling of the same metre by Vikentios Kornaros in his great romantic poem *Erotokritos*, which probably dates from the middle of the 17th century and describes the trials and sorrows of two lovers, Erotokritos and Aretousa, whose love story is finally crowned with a happy ending. Though based on a French work, *Paris et Vienne*, which Kornaros probably knew through an Italian version, the *Erotokritos* has many purely Greek and local Cretan elements and can be fairly called "the national poem of Crete." In connection with this should be mentioned an interesting series of Cretan dramas. The best known, though not the best, of these is the *Erophili* of Georgios Chortatzis, inspired by G. B. Giraldi's *Orbecche* and written *c.* 1600. It describes the tragic history of the love of Panaretos, adopted at an early age into the court of King Philogonos of Egypt, for the princess Erophili, which results in the violent death of all three principal characters. These Cretan plays also include comedies, such as the *Stathis* and *Fortounatos* (17th century) which, though in the main borrowed from Italian and ultimately going back to Plautine and Terentian comedy, are interesting for the introduction of local characters and colouring. But the real gems of the Cretan drama are the pastoral comedy *Gypat-is* and the mystery play *Thysia tou Abraam*, on the sacrifice of Abraham, also based on an Italian model, the *Isach* (1586) by L. Groto. Both are anonymous. though Kornaros has been supposed by some modern scholars to be the author of the mystery play. The *Gyparis* dates from *c.* 1600 and describes in a masterly and humorous manner the conversion to love of two shepherdesses, who had previously scorned it. In many respects it is extraordinarily modern. The *Thysia tou Abraam*, though in form a mystery play, is really a highly sympathetic study of family life. It is said to have been printed as early as 1535, but this may well be a mistake for 1635.

Crete possesses an interesting series of popular songs, and in connection with these a charming pastoral poem. *I oraia voskopoula.* It is usually coupled with the name of Nikolaos Drymitinos. who published the version he selected in 1627. The language of this attractive Cretan literature has naturally incorporated a good many Venetian words, but its general character is that of a vigorous native tongue with a number of peculiar Cretan forms and idioms. Had Crete not been captured by the Turks in 1660, the course of the whole of modern Greek literature would probably have been quite different.

Folk Songs and Klephtic Ballads.—In those parts of the Greek world under Turkish domination. the only noteworthy poetry is to be found in the folk songs and the klephtic ballads (the klepht was an armed Greek living as a free man and an outlaw). The roots and subject of many of these go back to the Byzantine era and one, the *Chelidonisma*, has even been traced as far back as Greek antiquity. Greek folk songs fall into three main divisions: (1) The historical folk songs, treating of historical events as they caught the imagination of the people. The Akritic ballads. as sung in Asia Minor, the Aegean islands and Cyprus. the laments on the fall of Constantinople and certain klephtic ballads are among the most notable of this group. (2) The songs of everyday life, *i.e.*, love songs, lullabies, marriage songs, working songs, dirges and carols. Here strong family feeling predominates. Death is personified in the form of Charos who struggles with his victim, is sometimes worsted, but as a rule triumphs in the conflict. (3) The *paralogis*, short narratives of a swift epic character, often almost summaries of folk traditions or folk tales. Some of the most beautiful and vivid verse written in Greek is to be found in the folk songs and the klephtic ballads. Most of the latter date from the 18th century and are excellent examples of an entirely spontaneous poetry composed in popular language and in the 15-syllable verse, rhymed and unrhymed. They are pervaded with the spirit of the forests and the mountains and, like so much of Greek popular poetry, personify trees. rocks and rivers. Even the mountains sing the prowess of the klephts, bewail their death and comfort the disconsolate wife or mother. Klephtic ballads have been a source of constant inspiration and rejuvenation to modern Greek poetry.

The Phanariotes.—The 18th century witnessed: side by side with the folk songs, the development of a different type of literature in the urban and cultivated society of the Phanariotes (the Greeks who gathered round the ecumenical patriarch in Constantinople). This can be seen as an endeavour to continue the classical Byzantine tradition and to link it with the great literatures of the west, notably that of France. Until the 1830s very little poetry of any value was produced from this source. But mention should be made of Kaisarios Dapontis (1714–74), whose long works of a moralizing and religious character, especially *Kathreptis* ton gynaikon ("Mirror of Ladies") and Kipos *Chariton* ("The Garden of Graces"), were praised and imitated by his contemporaries; of Rhigas (1757–98), whose patriotic poetry enjoyed widespread popularity; and also of Athanasios Christopoulos (1772–1849) and Ioannis Vilaras (1771–1823). in whose writings the influence of the Anacreontics and the 18th-century French drawing-room bucolics can be clearly seen. Vilaras is of particular interest, because the application to his verse of the extreme linguistic ideas expressed in his book Romeiki glossa led him to link personal lyric poetry with the folk-song tradition.

The Greek Romantics.—The liberation of Greece from the Turks (1828) made the capital of the new kingdom the centre of all Greek political and intellectual life. The Phanariotes moved first to Nauplia and then to Athens, mingling with the Greeks who came from the west to their newly freed country, and with the leading families that had fought and distinguished themselves during the War of Independence. In this mixed and unsettled society the romantic school of Athens flourished; its founder and leading spirit was Alexandros Soutsos (1803–63). He studied in Paris, where he came under the influence of the French romantics, but his exuberant and patriotic writings never succeeded in capturing the spirit of his models. As a satirist, however, he is often terse and vigorous. The influence he exercised upon Greek poetry was felt for many years. The other main representatives of the earlier days of the romantic school of Athens, his brother Panagiotis boutsos (1806–68), Alexandros Rizos Rangavis (1809–92), Georgios Zalokostas (1805–58), Theodoros Orphanidis (1817–86), Elias Tantalidis (1818–76) and Ioannis Karasoutsas (1824–73), though their poetry varies in quality and character, are all slaves of a boundless romanticism, use mainly the *katharevousa* as their language and are painstakingly patriotic. Among them Rangavis is perhaps the most striking figure. A man of extraordinary fertility of mind. he achieved considerable charm in the classical style. His works include odes, hymns. ballads, narrative poems, tragedies and comedies and several prose works. Achilles Paraschos (1838–95) is the leading figure in the last period of the school. Alfred de Musset, Victor Hugo and Lord Byron were his idols, but the rhetorical profuseness and mock-heroic patriotism of his verses prevent him from ever rising to their level, though a spark of true poetry is often evident. His brother Georgios Paraschos (1822–86) and his contemporaries Angelos Vlachos (1838–1920), Alexandros Vyzantios (1841–98), Dimitrios Paparrigopoulos (1843–73) and Georgios Vizyiinos (1849–96) were all overshadowed by his reputation, in spite of the greater sincerity and more delicate technique evident in many of their writings.

The School oj the Ionian Islands.—.Another school of poetry, parallel to the romantics of Athens, flourished in the Ionian islands, which were under British rule till 1864. Its founder and greatest representative was Dionysios Solomos (1798–1857), a native of Zante. Like others of the Ionian aristocracy of his day he was practically bilingual, and, having received his education in Italy, wrote his first poems in Italian. He soon, however, developed a preference for Greek. His early works in Greek were short lyrics, but the War of Independence stirred him to more ambitious projects. As the years passed, his philosophic approach to art and life deepened and expressed itself in verses of great delicacy and balance, unsurpassed in modern Greek. From the hymn of liberty (the first stanzas of which became the Greek national anthem) to Hoi elevtheroi *poliorkimenoi* ("Free Besieged"), which sings of the heroic resistance and sally at Missolonghi, the development of a highly spiritual nature can be traced. Unfortunately most of his mature work is known only from fragments, since his temperamental instability seems to have prevented him from finishing any of his major works. In the struggle that continued from Byzantine days between the katharevousa and the demotiki as the language of literature, Solomos marks a turning point. For, by choosing the latter, he pointed the way which Greek poetry was to follow after the demotic movement of the 1880s. Moreover, he introduced a number of western metrical forms (the sestina, the ottava rima, the *terza rima*, etc.), thus freeing Greek poetry from the monotony of the 15-syllable political verse mainly in use previously. Of the other poets of the Ionian school, Georgios Tertsetis (1800–74), Ioulios Typaldos (1814–83), Gerasimos Markoras (1826–1911) and Lorentzos Mavilis (1860–1912) must be mentioned, but undoubtedly Andreas Kalvos (1792–1869) and Aristotelis Valaoritis (1824–79) are the most distinguished. Kalvos drew his inspiration from the Greek classics and indulged in an austere and moralizing poetry and in a classicizing form of language, without exercising any notable influence on subsequent literature. Valaoritis. on the other hand, though deeply romantic and often too grandiloquent, was greatly admired by his contemporaries and is one of the authors who influenced Kostis Palamas in adopting the spoken tongue as the language of poetry. Thus Valaoritis became the link that connects the Ionian school with the new school of Athens.

The *New* School of Athens.—The feeling that Greek poetry, by employing the stilted *katharevousa* and by indulging in the weaker side of the romantic movement, was heading for utter sterility stirred a group of young poets to form about 1880 the new school of Athens. They aspired to become Greek Parnassians, masters of a restrained and objective art, but at the same time drawing their inspiration from contemporary Greece and using the living idiom. The central figure of this new school was Kostis Palamas (1859–1943), a man of versatile talent and wide reading. His many important poetic works portray modern Greek life, the continuity of Greek history and the social and spiritual convulsions of the late 19th and early 20th centuries. The long philosophic poem Dodecalogos tou Gyftou, perhaps his greatest achievement, shows the gypsy musician, symbol of freedom and art, gradually deepening into the patriot, the Greek and, finally, into the "Hellene," citizen and teacher of the world. His powerful epico-lyric work I *flogera* tou Vasilia and his collection of lyrics have established his reputation throughout the western world, and his influence upon all subsequent Greek literature has been profound. In poetry his distinguished contemporaries Georgios Drosinis (1859–1952), Ioannis Polemis (1862–1922) and Kostas Krystallis (1868–94), as well as his immediate successors Ioannis Gryparis (1871–1942), Kostas Chatzopoulos (1871–1920), Miltiadis Malakasis (1870–1943), Lambros Porfyras (1879–1932), Sotiris Skipis (1881–1951) and Z. Papandoniou (1877–1940), all acknowledged their debt to the leader of the school. It is the poets of this school who have explored the expressive and metrical possibilities of the spoken idiom and who introduced symbolism and free verse into Greek poetry, which has greatly enriched and enlivened it in the course of the 20th century. Of the women writers of the new school of Athens, Myrtiotissa (Theoni Dracopoulos; b. 1883), Aimilia S. Dafni (Aimilia T. Zoiopoulos; 1887–1941) and Maria Polydouri (1905–30) are noteworthy for the elegance and passion of their verses.

After Palamas, the most important figure in modern Greek poetry is undoubtedly Angelos Sikelianos. His vigorous verse has its roots in the new school of Athens, but his thought followed a different and often more obscure course. Greek nature and history are seen in the light of a Dionysiac mysticism. His rich incisive diction brings landscape and human form in clear-cut relief before the eyes.

The one great Greek poet who remained untouched by the influence of Palamas and the new school of Athens was Konstantinos Kavafis. An Alexandrian both by birth and by spiritual inclination, his main theme was the tragic glory of Hellenistic Greece and its decadence. But in his work historical memories and personal experiences were inextricably blended. In no other Greek poet is the tragedy of life so sensually expressed or sensuality felt more tragically, although the tragic outlook is relieved by exquisitely lyrical and often ironical passages. His writings, because of their reflection of modern tendencies in western culture, have been universally acknowledged.

Of the many other poets who wrote in Greece after the end of World War I, four only can be mentioned here: Kostas Karyotakis (1897–1928), whose pessimistic and often sarcastic poems are most arresting; George Seferis (1900–), a genuine symbolist, who records with true poetic touch the fate of modern man; the "surrealist" Odysseus Elytis (b. 1911), whose lines are full of the light and colour of the Aegean islands; and Nikos Kazantzakis, better known as a novelist, who is also the author of a formidable "epic" poem 33,333 lines long, *Odyssey.* Its hero, a modern Odysseus, wandering in the world of thought, seems to be haunted by the idea of nihilism. The size and style of the work are overwhelming, but there are long passages of great beauty and a use of language of extreme wealth and vigour.
